[3]The Babraham Institute, Bioinformatics Group, Babraham, United Kingdom

Study question: How extensive are the gene expression changes in preimplantation embryos derived from Assisted Reproductive Technologies and how can we decrease them?

Summary answer: Blastocysts produced by in-vitro fertilization (IVF) with reproductive fluids (Natur-IVF) in the culture media showed fewer differentially expressed genes than embryos obtained by conventional-IVF (C-IVF).

What is known already: In mouse and human, accumulating evidence indicates that the embryo is sensitive to its early environment, and culture media used in ART may have long-lasting consequences. Abnormal phenotypes related to culture system include fetal overgrowth in cattle and sheep, and imprinting syndromes or growth restriction in humans and pigs. Epidemiologic studies in humans suggest that ART-associated procedures can perturb gene expression during early development, although such alterations could also be a consequence of parental characteristics, gamete quality or technique-derived effects. An animal model such as swine, with boars of proven fertility, could allow informative modelling of ART-related disorders in human.

Study design, size, duration: To investigate the basis of increased *birth defects* among *ART*-derived offspring, we analyzed whole transcriptome from individual day 7.5 blastocysts (3 embryos per group) produced *in vivo*, or *in vitro* using a new IVF system (Natur-IVF) or a conventional IVF system (C-IVF).

Participants/materials, setting, methods: A swim-up protocol for selection of porcine spermatozoa and reproductive secretions (follicular, oviductal and uterine fluids) as additives in the culture media were used for embryo production. RNA from single blastocysts was extracted and libraries were generated, further amplified and sequenced 100 bp single end. Raw sequence reads were trimmed to remove adapter contamination and reads with poor quality. Mapping was performed (Tophat software) and data were visualised and quantified (Seqmonk) (Canovas et al., 2017; *eLife*).

Main results and the role of chance: Blastocysts shared 334 genes aberrantly expressed Natur-IVF and C-IVF *vs. In-vivo*. However, 440 genes showed aberrant expression in C-IVF *vs. In-vivo*, but not in Natur-IVF, which could be considered as restored using Natur-IVF system. Amongst these genes were factors related to epigenetic reprogramming (*DNMT3B, DNMT1, HDAC5, KDM5A*), embryo development (*CTGF, ING2, KIT, EZH2, BMP4, TLN1, ADAR*), cell growth (*CDCA5, SMC1A, RB1, SMARCA2*), and imprinting (*IGF2BP2, GNAS, DIRAS3*). Ingenuity Pathway Analysis showed 5 networks (score > 30, > 20 factors /network) between these 440 genes. Associated networks functions were: i) RNA post-transcriptional modification/molecular transport/RNA trafficking; ii) Cell morphology, function and maintenance, organ morphology; iii) Cellular development, growth and proliferation, carbohydrate metabolism; iv) Cell-to-cell signalling and interaction, digestive system development and function, embryonic development; v) Cell signalling, post-translational modification, cellular development. Upstream regulators with 10 or more target molecules were HNF4A (53), TP53 (47), ESR1 (32), MYC (28), NR3C1 (27), NUPR1 (15), TCF7L2 (13) and EZH2 (10). Top canonical pathways were Superpathway of cholesterol biosynthesis, NAD Phosphorylation and dephosphorylation, AMPK signalling, tRNA splicing, tRNA charging. Top molecular and cellular functions were Cellular Development (144 factors), Movement (94), Growth and Proliferation (151), Function and Maintenance (122) and Morphology (116).

Limitations, reasons for caution: A limited number of single embryos were analyzed and individual variation between samples from the same group could mask some additional differences between groups.

Wider implications of the findings: Results showed that Natur-ART blastocysts are closer in their gene expression profile to *In-vivo* blastocysts than C-IVF blastocysts, with a number of functionally significant gene expression changes detected only in C-IVF embryos.

Trial registration number: Not applicable.

P-230 Zona thinning and classic assisted hatching preformed with systematic multipulse laser settings result in significant improvements of clinical outcomes in frozen embryo transfer cycles

N. Costa-Borges[1], E. Nikitos[2], K. Agapitou[2], S. Kallergi[2], D. Botzaki[2], C. Makri[2], G. Vassilopoulos[2], N. Vlachos[2], G. Zervomanolakis[2], P. Polyzos[2], K. Dimitropoulos[2], K. Kostaras[2], P. Psathas[2], K. Rink[1], G. Calderon[1]

[1]Embryotools, R&D center, Barcelona, Spain
[2]Institute of Life IoLife, IVF Center, Athens, Greece

Study question: What is the impact of zona pellucida thinning (ZPT) or classic assisted hatching (AH) techniques in the clinical outcomes of a frozen embryo transfer program?

Summary answer: Both ZPT and AH techniques performed with systematic laser settings on Day3 and Day5/6 embryos can significantly increase clinical outcomes in frozen transfer cycles

What is known already: Improvement of implantation rates is a main goal in human IVF. Intrinsic abnormalities in the blastocyst or ZP can result in implantation failure. The effects of ZP hardening on embryo hatching as a consequence of embryos vitrification/warming may impair their following implantation. Theoretically, ZPT or AH with laser may facilitate this process and subsequently increase implantation rates. However, conflicting reports on the beneficial effects of both techniques have been published possibly due to the lack of consistency on the size of the AH hole or ZP thinned area or on the systematic application of laser settings in the different studies

Study design, size, duration: This study was performed between March 2016 and January 2017. Patients (n = 361) were transferred with vitrified/warmed embryos (from own or donor oocytes) at the cleavage (Day 3) or blastocyst (Day 5/6) stage. Patients were randomized at the time of warming the embryos and assigned to the study or control (non-manipulated) groups. The study groups included: ZPT for Day3 embryos, and either ZPT or AH for Day5/6 blastocysts. In total, 719 warmed embryos were transferred.

Participants/materials, setting, methods: Warmed embryos were treated according to the assigned group. Half of ZP thickness was reduced in a quarter of its perimeter using systematic multipulse laser (NavilaseTM, Octax) settings in all Day3 or Day5/6 embryos included in ZPT groups. In the AH group, a ZP hole (size = 60 μm) was made in the warmed blastocysts. Control embryos were not subjected to laser pulses. Embryo transfers were performed 2–4 h post-warming. Results were compared by X2 or Student's t-test.

Main results and the role of chance: A total of 149 patients were transferred with own Day3 embryos (n = 312) after warming. No differences were found between the control (n = 146) and ZPT group (n = 166) with regards to pregnancy (50.0% vs 45.5%, respectively) or implantation (28.1% vs 22.9%, respectively) rates. However, patients in ZPT group (37.2 y/o) were significantly older (p = 0.004) than those in control (35.7 y/o) group, which may indicate a beneficial effect of ZPT in this patients' group. This tendency was further confirmed in 70 recipients (age factor excluded) transferred with Day3 (n = 143) warmed embryos (donor oocytes). Pregnancy and implantation rates were significantly higher (p < 0.05) in the ZPT (71.9% and 44.6, respectively) group compared to control (44.7% and 25.6, respectively). Interestingly, clinical pregnancy and implantation rates were equivalent between control (51.5% and 47.5%) and ZPT (48.5% and 30.2%) or AH (58.1% and 40.7%) groups when Day5/6 blastocysts (own oocytes) were transferred into 109 patients (average age was 35.8; 37.8 and 36.4 y/o for the three groups, respectively). In the oocyte donation program, pregnancy and implantation rates with Day5/6 warmed blastocysts were significantly higher (p < 0.05) in the AH (84.6% and 52.0%) compared to the control (69.2% and 47.8%) or ZPT (57.1% and 45.5%) group.

Limitations, reasons for caution: Different publications have shown that the size of the AH hole or ZP thinned area may have an impact in the clinical outcomes of frozen cycles. Laser settings used here were firstly optimized in the mouse model. The study shall continue to increase the statistical power of the data analysis.

Wider implications of the findings: The new generation of lasers developed for ART ensure that multipulse laser settings can be applied in a systematic way in all embryos subjected to ZPT or AH. This allows for more technical reproducibility and consistency in the results in further studies, which should confirm the benefits of both techniques.

Trial registration number: Not applicable for non-clinical trials

P-231 Altered morphokinetics in sequential and single step culture media: a randomized prospective sibling oocyte study

H. Yin[1], Q.I. Zhan[2], Z.H. Ye[2], C.A. Cook[2], R. Clarke[2], Z.E. Rosenwaks[3], N.I. Zaninovic[2]

[1]New York, U.S.A.,
[2]Center for Reproductive Medicine, IVF Lab, New York, U.S.A.
[3]Center for Reproductive Medicine, IVF, New York, U.S.A.

Study question: Does timing and embryo development differ in sequential vs. single step culture media?

Summary answer: Embryos grown in sequential or single step media have a similar embryological developmental profile but exhibit altered morphokinetics.

What is known already: Various culture conditions, as well as culture media, can influence embryo development and clinical outcome. Before introducing new media and different culture conditions, it is imperative to carry out in-house comparative analyses, ideally on sibling oocytes. It has been shown that embryo morphokinetics are greatly altered between different culture media (sequential vs. single step) and different oxygen concentrations. Moreover, no studies have categorically proven that single step media is better than or equal to sequential media.

Study design, size, duration: A prospective randomize study on sibling oocytes at an academic medical center. Each patient's oocytes were randomly allocated amongst sequential or single step media. All embryos were cultured in time-lapse incubator (Embryoscope, Vitrolife, Sweden) under the same conditions. Embryos were cultured until D6 and ETs were executed on D3 either D5. The best grade embryos were transferred regardless of the culture media used.

Participants/materials, setting, methods: Sequential in-house media C1/C2 and commercial G1/G2 and single step in-house media (C3) and commercial G-TL were used. The study included: Group 1: C1/C2 vs. C3 (n = 123 patients, n = 1579 embryos); Group 2: C1/C2 vs. G1/G2 (n = 20 patients, 298 embryos) and Group 3: C1/C2 vs. G-TL (n = 48 patients, 635 embryos). 2PN; D3 embryo; D3 ET and D5 ET and cryo; blastocyst (BL) rates, and morphokinetic were analyzed. X^2 and Wilcox/Kruskal-Wallis tests were used.

Main results and the role of chance: Fertilization rates between culture media did not differ. Embryos in C1/C2 media had a higher percentage of high grade embryos on D3 compared to C3 or GTL media (p = NS). Embryos selected for D3-ET did not vary among groups and many patients had mix media transfers. On D5, significantly more BL were transferred from C1/C2 vs. C3 (p < 0.05). However, the overall percentage of embryos used (D5-ET + cryo) and having achieved high grade BL did not differ among media. The rate of abnormal division (DUCs) and preliminary ploidy analysis revealed no differences between media.

Embryo kinetic analysis: Group 1. Embryos grew more rapidly in C3 vs. C1/C2 media for the first three divisions and equalized until BL stage (t9 to tEB). Group 2. Embryos in C1/C2 media grew slightly faster during the first two divisions (t2-t4) when compared to G1/G2, without differences in later stages. Group 3. Embryos grown in C1/C2 media had a tendency of growing faster until the morula stage (tM), whereas GTL embryos caught up at morula and early BL stages. No differences were observed in the expanded BL stage. Kinetic studies performed equally if DUCs were removed from the data.

Limitations, reasons for caution: Although this is a randomized sibling oocyte study, retrospective data were used for analysis. Implantation and ploidy couldn't be evaluated due to the mixed media transfers and a small sample of PGS cycles. Additional commercial media and a higher number of sibling oocyte cycles are needed to confirm this finding.

Wider implications of the findings: The timing of embryo development is influenced by culture media composition. This should be taken into account when creating embryo selection models. Sibling oocyte studies represent an optimal approach to evaluate different media. Media specific morphokinetics should be applied when creating embryo selection models for D3 or D5 ET.

Trial registration number: N/A.

P-232 Blastocysts from abnormally-fertilized zygotes can be euploid/diploid and are reproductively competent: live-births from preimplantation genetic diagnosis of aneuploidy/polyploidy in embryos with abnormal pronuclear morphology

A. Capalbo[1], N. Treff[2], D. Cimadomo[3], X. Tao[2], S. Ferrero[3], A. Vaiarelli[3], S. Colamaria[3], M. Giuliani[3], F. Sapienza[3], F.M. Ubaldi[3], R. Scott[2], L. Rienzi[3]

[1]Genetyx, Molecular Genetics laboratory, Marostica VI, Italy
[2]Reproductive Medicine Associates of New Jersey, RMA NJ, Basking Ridge- NJ, U.S.A.
[3]Clinica valle giulia, Genera- Reproductive Medicine Center, Roma, Italy

Study question: Is it possible to rescue abnormally fertilized zygote (AFZs) if the risk of polyploidy is evaluated by a novel combined protocol for simultaneous aneuploidy/polyploidy assessment?

Summary answer: Polyploidy assessment in AFZ-derived blastocysts is an effective approach to rescue diploid embryos from monopronuclear/tripronuclear-derived blastocysts and may improve the live-birth rate in IVF cycles.

What is known already: Approximately 10% of inseminated oocytes fertilized abnormally and the embryos derived from them are discarded all over the world in the absence of a reliable approach for the monitoring of the genetic risk for polyploidy. Here, we report the development and application of an improved comprehensive chromosomal diagnosis protocol for the detection of 24-chromosome aneuploidy and parallel polyploidy assessment. The combined test was implemented clinically, with the aim of rescuing AFZs in poor prognosis patients to maximize live-birth rate per IVF cycle.

Study design, size, duration: Longitudinal cohort study performed between January2015-September2016 involving 553 patients (39.2 ± 3.2 yr) and 719 consecutive PGD-A cycles. Blastocyst PGD-A was offered to patients of advanced female age (> 35 years), a history of unsuccessful IVF (> two failed IVF cycles) or previous miscarriages (> two). The combined genetic analysis was performed when a blastocyst from monopronuclear(1PN) or tripronuclear(3.1PN) zygote was obtained. Euploid-diploid embryos obtained from AFZs were considered suitable for replacement if others from normally-fertilized zygotes (NFZs) were not available.

Participants/materials, setting, methods: Injected oocytes were individually cultured and fertilization was assessed between 16–18 hours. 1PN zygotes were defined when a single pronucleus was present. Zygotes showing one extra smaller pronucleus on the top of two evenly sized pronuclei were defined as 3.1PN. Blinded ploidy assessment using single nucleotide polymorphism allele ratios was conducted on trophectoderm biopsies from AFZ-derived blastocysts by targeted-NGS (1:1 = diploid; 2:1 = triploid; loss of heterozygosity = haploid). Samples of known ploidy were included as controls

Main results and the role of chance: For validation, a blinded analysis of previously-established triploid and diploid cells was performed. The allele ratio was 2.12 ± 0.12(1.97–2.31) and 1.29 ± 0.15(1.18–1.50) for triploidy and diploidy, respectively(p < 0.01). Furthermore, the DNA products from one triploid miscarried blastocyst and two sibling unknown-ploidy vitrified euploid blastocysts were blindly submitted to ploidy assessment. The results correctly identified the triploid blastocyst.

In the clinical phase, 3785 zygotes (200 1PN-AFZs;27 3.1PN-AFZs;3558 2PN-NFZs) from 719 PGD-A cycles were assessed. In 25.2% (n = 181/719) and 3.6% (n = 26/719) of the cycles AFZs and AFZ-derived blastocysts were observed, respectively. Significantly less blastocysts were obtained from 1PN-AFZs (n = 13/200, 6.5%) with respect to both 3.1PN-AFZs and 2PN-NFZs (n = 14/27, 51.9%; n = 1667/3558, 46.9%; p < 0.05), mainly due to a lower cleavage rate at the first cell division after fertilization.

Ploidy analysis identified 23.1% (n = 3/13), 69.2%(n = 9/13) and 7.7% (n = 1/13) of the 1PN-AFZ-derived blastocysts as haploid, diploid and triploid, respectively. A normal diploid constitution was observed in 85.7% (n = 12/14) of the 3.1PN-AFZ-derived blastocysts, while 2 (3%) were triploid.

In 0.8% of the cycles (n = 6/719) AFZ-derived euploid/diploid blastocysts were identified. Four of them were transferred and resulted in 2 healthy pregnancies (one from a 1PN-AFZ and one from a 3.1PN-AFZ).

Limitations, reasons for caution: Gestational and neonatal outcomes of AFZ-derived pregnancies still need to be investigated in a larger sample size. Only 1/3 of the pronuclei check on day1 was performed in a time lapse system. However,AFZs were re-evaluated within 4 hours from the first check by an independent embryologist to confirm the pronuclear abnormality

Wider implications of the findings: Overall, AFZs account for ~10% of the zygotes in IVF and are generally discarded. Here, we report the development and validation of a reliable protocol for simultaneous aneuploidy and ploidy assessment from a single trophectoderm biopsy and the first clinical experience that resulted in two healthy pregnancies from AFZs.

Trial registration number: none.

P-233 Impact of endometrial decidualization on human blastocyst growth and cytokine secretion

A. Aberkane[1], Y.H. Lee[2], K. Sermon[3], H. Tournaye[4], J. Brosens[5], H. Van de Velde[1]

[1]Vrije Universiteit Brussel, Research Group Reproductive Immunology and Implantation, Brussels, Belgium
[2]KK Women's and Children's Hospital, KK Research Centre, Singapore, Singapore Rep. of
[3]Vrije Universiteit Brussel, Research Group Reproduction and Genetics, Brussels, Belgium
[4]UZ Brussel, Centre for Reproductive Medicine, Brussels, Belgium
[5]University of Warwick, Tommy's National Miscarriage Research Centre, Warwick, United Kingdom

Study question: We hypothesize that the decidualization status of the endometrium has a positive impact on human blastocyst development.

Summary answer: Exposure of human blastocysts to secretome/conditioned media (CM) of decidual cells does not compromise the blastocyst growth and results in a blastocyst-specific secretion of CXCL8/IL8.

What is known already: Human endometrial decidualization is the transformation of endometrial stromal cells (EnSC) into decidual cells (DEC). It is a sequential process characterized initially by a transient pro-inflammatory response, which spans the window of implantation. This is followed by an anti-inflammatory response and acquisition of a mature decidual phenotype. Exposure of murine uterus to the pro-inflammatory secretome of human DEC promotes implantation of transferred murine embryos. However, exposure to secreted factors from EnSC or DEC of anti-inflammatory phase leads to embryonic demise prior or soon after implantation.

Study design, size, duration: Endometrial biopsies were obtained from ten patients undergoing infertility treatment. EnSC were isolated and pooled into one *in vitro* cell culture. Forty-one high quality blastocysts (thirty patients) that became available for research after a legally determined storage period were warmed. Thirty-one of the warmed blastocysts had good survival and were included in the experiment. Both biopsies and embryos were used with informed consent of the patients and following approval of the relevant ethical committees.

Participants/materials, setting, methods: Isolated EnSC were decidualized *in vitro* to DEC in the pro- and anti-inflammatory phase (4 and 10 days *in vitro* decidualization, respectively). CM of DEC (Day 4 and 10) and CM of their EnSC-controls were collected. Next, six to eight day 5 human blastocysts were cultured individually for 24 h in microdroplets of the different CM. Blastocyst growth was scored and 45 cytokines in microdroplets were quantified by multiplex suspension bead immunoassay (controls = empty CM microdroplets).

Main results and the role of chance: Analysis of the blastocyst growth rates demonstrated that the CM of EnSC compromised blastocyst development, exemplified by a growth score 0 (indicative of poor development) in 8/17 (47%) embryos. By contrast, the growth rates were not compromised when blastocysts were incubated in CM of DEC [growth score 0 in 1/14 (7.1%) embryos (Chi-square test: P = 0.02)], irrespective of the phase of decidualization. In addition, cytokine analysis revealed a blastocyst-specific response following culture in DEC versus EnSC CM, which was most pronounced in DEC CM of the pro-inflammatory phase. Taking into account the cytokine concentration in the control droplets, two cytokines were identified as potentially important mediators of the blastocyst response. CXCL8/IL8 was secreted by the blastocysts in response to signals from DEC and not EnSC (Two-way ANOVA test: P < 0.0001). On the contrary, CCL2/MCP-1 was only secreted to signals from Day 4 EnSC (Two-way ANOVA test: P < 0.0001).

Limitations, reasons for caution: This study is limited by the use of endometrial biopsies from patients undergoing infertility treatment. Culture of blastocyst with their autologous EnSC was not possible. Nevertheless, EnSC from the ten patient biopsies were pooled together into one *in vitro* cell culture to reduce the patient-to-patient variability across the experiments.

Wider implications of the findings: Understanding the endometrium-embryo crosstalk during human embryo implantation will advance the development of new strategies to improve the IVF outcome, for example optimized embryo culture medium and timing of embryo transfer.

Further experiments on the effect of the blastocyst-secreted cytokines on endometrial cells are ongoing.

Trial registration number: None.

P-234 Culturing human embryos in benchtop/topload incubators improves clinical outcomes compared with large-box conventional incubation systems

N. Sermondade[1], C. Herbemont[2], J. Boujenah[2], C. Sonigo[2], I. Cedrin-Durnerin[3], M. Grynberg[4], C. Sifer[2]

[1]Hôpital Jean Verdier, Histologie-Embryologie-Biologie de la Reproduction-CECOS, Bondy, France
[2]Hôpital Jean Verdier, Histologie-Embryologie-Cytogénétique-CECOS, Bondy, France
[3]Hôpital jean Verdier, Médecine de la reproduction, Bondy, France
[4]Hôpital jean verdier, Medecine de la Reproduction, Bondy, France

Study question: Does culture in individual small incubator chambers improve good quality embryo (GQE) rates and clinical in vitro fertilization-embryo transfer (IVF-ET) outcomes in comparison with culture in a conventional system?

Summary answer: Despite similar GQE rates at early cleavage stages on days 2/3, culturing embryos in benchtop/topload incubators increases good quality blastocyst, implantation and clinical pregnancy rates.

What is known already: New generation of benchtop/topload incubators with individual small chambers, aiming to ensure continuous and reliable temperatures and gas mix while providing optimal environment for the embryos, have rapidly emerged in laboratories of reproductive biology worldwide. However, despite expected improvement in terms of embryo development and pregnancy rates, objective data is still lacking.

Study design, size, duration: This single-center study included retrospectively 1424 IVF-ET cycles from September 2013 to December 2015. After transvaginal ultrasound-guided retrival, oocytes were allocated for culture either in conventional large-box (n = 732) or benchtop/topload incubators (n = 692). In both groups, top (TQE) or good (GQE) quality embryo rates at early cleavage stages, implantation (IR) and clinical pregnancy (CPR) rates were analyzed. In case of extended culture, blastulation and good quality blastocyst (GQB) rates were also compared.

Participants/materials, setting, methods: Overall, 1424 cycles, with at least one mature oocyte recovered, were enrolled in the present investigation. Oocytes were fertilized either using standard IVF or ICSI procedures. Embryos were cultured using appropriate media at 37°C under 6% CO_2, 21% O_2 atmosphere, for 2, 3, or 5 days either in conventional large-box incubator or in benchtop/topload incubators

Main results and the role of chance: Overall, mean day 2 or 3 TQE (38.4 ± 30.6 *vs.* 39.1 ± 30.2%; 23.3 ± 22.0 *vs.* 24.1 ± 22.7%, respectively) and GQE (53.0 ± 31.0 *vs.* 53.7 ± 31.0%; 47.3 ± 28.7 *vs.* 49.9 ± 28.0%, respectively) rates did not differ between conventional and benchtop/topload incubators groups. However, IR (21.6 *vs.* 16.7%; p = 0.01) and CPR per embryo transferred (32.7 *vs.* 26.3%, p = 0.04) were significantly increased after embryo culture in individual small incubator chambers. When extended culture was decided, both blastulation (89.1 ± 25.2 *vs.* 82.0 ± 30.0%, p = 0.03) and GQB (37.7 ± 34.0 *vs.* 29.7 ± 28.5%, p = 0.04) rates were significantly higher in benchtop/topload incubators (n = 197 cycles) when compared with a large-box conventional system (n = 103 cycles)

Limitations, reasons for caution: The major limitation of the present investigation is the lack of randomization.

Wider implications of the findings: The present study, based on the analysis of embryo morphology, constitutes the first demonstration of the superiority of small individual incubator chambers over conventional large-box incubators for optimizing embryo viability, blastulation and GQB rates following culture. As a result, these benchtop/topload incubators should be preferred to others in ART laboratories

Trial registration number: Not applicable.

P-235 Comparison of vitrified-warmed blastocyst transfer in natural and artificially prepared menstrual cycle

M. Reljic, J. Knez, V. Kovač, V. Gavrić Lovrec, L. Mlakar, P. Kores Testen, B. Kovačič

University Medical Centre Maribor, Dpt. for Reproductive Medicine & Gynecological Endocrinology, Maribor, Slovenia

Study question: Is the reproductive outcome of vitrified-warmed blastocyst transfer in natural cycle comparable to artificial cycle protocol?

Summary answer: The clinical pregnancy rate is comparable in both protocols for endometrium preparation. The live-birth rate was higher in natural cycle due to lower miscarriage rate.

What is known already: In recent years, frozen embryo transfer (FET) has become a very important part of in vitro fertilization program. Still, it is not clear what is the optimal method of endometrium preparation. To date, meta-analyses comparing artificial cycle (prepared by oestrogen and progesterone) and natural cycle showed no difference in terms of clinical pregnancy rate (CPR) and live-birth rate (LBR). Nevertheless, some investigators have reported higher CPR and lower miscarriage rates in natural cycles. Excessive oestrogen environment or suboptimal ratio between progesterone and oestradiol has been suggested as a possible cause of less favourable reproductive outcome in artificial cycles.

Study design, size, duration: All vitrified-warmed blastocyst transfers (n = 1,865) performed during a period of 3 years (2013–2015) at the Department for reproductive medicine, University Medical Centre Maribor were included in this retrospective study. In women with regular ovulatory cycles, vitrified-warmed blastocyst transfer was performed in natural cycle without hCG triggering (NC). Endometrium preparation by oestrogen and progesterone without GnRH agonist suppression (AC) was used in women with unpredictable or irregular cycles.

Participants/materials, setting, methods: Patients' characteristics and clinical data were collected from our software database. Reproductive outcomes between AC and NC were compared using Pearson's Chi-squared test. Univariate and multivariate logistic regression models were constructed to identify the factors that were significantly associated with the LBR and clinical pregnancy loss.

Main results and the role of chance: In the study period, there were 1,317 vitrified-warmed blastocyst transfers performed using NC and 528 using AC. The clinical pregnancy rate was comparable in both groups (37.0% vs. 36.6%), but there was statistically significant higher live-birth rate (32.8% vs. 26.7%, p = 0.01) and lower clinical miscarriage rate (13.7% vs. 27.3%, p < 0.001) in NC compared to AC group. In the multivariate logistic regression model, women's age (OR: 0.94, 95% CI: 0.91–0.98), transfer of morphologically optimal blastocysts (OR: 1.72, 95% CI: 1.28–2.31) and the type of endometrium preparation (OR: 0.63, 95% CI: 0.45–0.88) were important independent prognostic factors for live birth. The only independent factors that were significantly associated with pregnancy loss were women's age (OR: 1.07, 95% CI: 1.02–1.13) and the type of endometrium preparation (OR: 2.26, 95% CI: 1.39–3.68). Endometrial thickness, number of blastocysts transferred, cause of infertility, cycle irregularity, assisted hatching and prior birth after fresh transfer were not found to be associated with reproductive outcome.

Limitations, reasons for caution: This is a single-centre retrospective analysis and despite robust methodological approach, the presence of potential bias cannot be excluded.

Wider implications of the findings: Results of our study suggest that in women with regular cycles FET in natural cycle should be recommended. Larger prospective randomized multicentric studies are needed to confirm these findings. There is a need for further basic studies to optimise endometrial preparation with hormone supplementation.

Trial registration number: None.

P-236 Analysis of embryo morphokinetics as a probable predictive variable of euploid embryos by time-lapse monitoring technique

M. Duran Retamal[1], X. Vinals[2], X. Brunetti[2], J. Ben Nagi[3], A. Alchami[3], W. Saab[3], P. Serhal[3], S. Seshadri[3]

[1]The Centre for Reproductive and Genetic Health, Reproducive Medicine, London, United Kingdom
[2]The Centre for Reproductive and Genetic Health, Embriology, London, United Kingdom
[3]The Centre for Reproductive and Genetic Health, Reproductive Medicine, London, United Kingdom

Study question: Does time-lapse monitoring (TLM) analysis of blastocysts has a predictive value in depicting aneuploid embryos?

Summary answer: There is a different morphokinetic behavior observed on TLM between euploid and aneuploid embryos after next generation sequencing (NGS) testing.

What is known already: Embryo morphokinetics have been observed to be different between euploid and aneuploid embryos. In 2014, Basile et al introduced a proposed algorithm as a predictive tool to classify embryos in order to increase the probability of noninvasively selecting chromosomally normal embryos after arrayCGH. Although the safety of trophectoderm biopsy on embryo survival has been validated, the request for a non-invasive method for aneuploidy prediction is required. There has been an ongoing debate on the reduced implantation potential of biopsied embryos and therefore development of a model based on morphokinetics is valuable.

Study design, size, duration: 161 blastocysts generated after intracytoplasmic sperm injection (ICSI) from 46 patients were included in this study. The time period of this retrospective observational cohort study is between January 2016 to January of 2017. The patient data was divided into different age groups ($\leq$35, 36–39 and $\geq$40 years old). The blastocysts were divided into two groups: euploid and aneuploid embryos after performing NGS.

Participants/materials, setting, methods: Patients for preimplantation genetic screening (PGS) were included. The conditions for PGS were recurrent implantation failure, recurrent pregnancy loss and advanced maternal age. The embryo development was retrospectively analyzed using a time-lapse imaging system (Embryoscope, Unisense Fertilitech). Different kinetic parameters were considered in this study calculated in hours post-insemination (t2, t3, t4, t5, tM, tsB, tB, cc2, cc3 and s2). The Student's t-test was used for the statistical analysis of the data.

Main results and the role of chance: We observed that the time from insemination to blastocyst formation (tB) was statistically significant in all age groups when comparing euploid and aneuploid embryos. In the $\leq$ 35 year-old group, the tB was 97.1 ± 9.6 hours for euploid embryos versus 106.9 ± 8.9 hours for aneuploid embryos (p value: 0.017); in the 36–39 year-old group, tB was 103.5 ± 7.8 hours versus 108.7 ± 9.9 hours respectively (p value: 0.015) and in the $\geq$40 year-old group, tB was 97.1 ± 6.7 hours versus 107.1 ± 9.9 hours (p value: 0.005). The delay in blastocyst formation in aneuploid embryos is particularly noted in the advanced maternal age group and the role of chance is that in $\geq$ 40 year-old patients, we require more blastocysts (ratio 1:8) to detect one euploid embryo. This is the first study that has observed this morphokinetic difference in comparison to aneuploidy rates using NGS technique.

Limitations, reasons for caution: Larger studies with an increased number of blastocysts are needed to confirm our findings.

Wider implications of the findings: The morphokinetic analysis of the embryo can be used as a non invasive tool for selecting euploid embryos.

Trial registration number: Not applicable.

P-237 The influence of clinical and laboratory factors on the formation of monopronucleated zygotes after intracytoplasmic sperm injection (ICSI)

M.G. Amendola, G. Fabozzi, E. Rega, M.F. Starita, M. Majoli, P. Giannini, A. Colicchia, C. Piscitelli

Casa di Cura Villa Margherita, Ferticlinic, Rome, Italy

Study question: Do clinical or laboratory factors affect the development of monopronucleated zygotes (1PN-2PB) after ICSI?

Summary answer: 1PN-2PB zygote formation is associated with impaired sperm motility, higher number of oocytes retrieved, higher number of MII and longer time to injection.

What is known already: The formation of 1PN-2PN zygotes is an unexpected complication of ICSI. It has been suggested that they can be the product of asynchrony during pronuclear formation, result of syngamy or of oocyte parthenogenetic activation. However, recent data from time-laps monitoring have not confirmed any of these theories: recent reports show that 1PN-2PB ICSI are zygotes with maternal and paternal genomes combined together and surrounded by an irregular membrane, most of which are chromosomally abnormal even if they develop up to the blastocyst stage. However, none of these reports investigate any possible relation between clinical or laboratory factors and 1PN formation.

Study design, size, duration: This was a retrospective comparative study. ICSI cycles were reviewed and analyzed according to the occurrence of 1PN-2PB zygotes at fertilization after ICSI and divided into two groups: cycles with no 1PN-2PB (control group, A) and cycles with one or more 1PN-2PB (study group, B). Adjusted odds ratios were calculated by multivariable logistic regression.

Participants/materials, setting, methods: A total of 341 ICSI cycles performed at FertiClinic -Villa Margherita from January 2012 to December 2016 were enrolled in the study. Group A included 240 cycles with no 1PN-2PB while the Group B included 101 cycles with 1 or more 1PN-2PB. Age, stimulation protocol, infertility factor, amount of gonadotrophin administered, peak estradiol levels, number of follicles, oocytes retrieved and mature oocytes, time between retrieval and injection and sperm characteristics were compared between groups.

Main results and the role of chance: Compared to patients in group A, those in group B showed a higher number of astenozoospermic male patients, 28.7% (68/237) vs. 45.3% (43/95) respectively, ($p = 0.004$). The two groups differed also in the median(Q1-Q3) number of oocytes retrieved at pick-up, 5(3–8) for group A vs. 11(7–15) for group B ($p < 0.001$) and in the median number of MII, 4(2–7) for group A vs. 9(6–12) for group B, ($p < 0.001$). A statistically significant difference was observed also in the length of time interval between hCG administration and ICSI, specifically, group B showed a longer time interval 39 h(39-40 h) with respect to group A, 38 h(38-39 h), $p < 0.001$. The final logistic multivariable model confirmed all the associations: group B showed a higher incidence of astenozoospermia (OR 2.15, 95% CI = 1.20–3.86, $p < 0.010$), a higher number of oocytes retrieved (OR 1.12, 95% CI = 1.07–1.17, $p < 0.001$), higher number of mature oocytes (OR 1.18, 95% CI = 1.11–1.25, $p < 0.001$) and longer time to injection (OR 2.13, 95% CI = 1.50–3.03 $p < 0.001$) compared to group A.

Limitations, reasons for caution: This was a retrospective observational study. A prospective study where the influence of 1PN-2PB zygotes on clinical outcomes is examined should be conducted also to understand if their occurrence has a prognostic value to predict the fate of the remaining cohort of zygotes and the final outcome of the cycle.

Wider implications of the findings: This study demonstrate that 1PN occurrence can be associated also with clinical or laboratory factors, thus, clinicians and embryologists should be respectively aware that enhancing ovarian stimulation in order to increase the number of CCOCs retrieved or delaying the time of injection can raise the probability of 1PN formation.

Trial registration number: none.

P-238 When should cleavage stage embryos be biopsied?

S. Tisser, Y. Kalma, L. Bar-El, T. Cohen, A. Carmon, A. Shpiz, M. Malcov, A. Reches, F. Azem, D. Ben-Yosef

Sourasky Medical Center, Racine IVF Unit- Lis Maternity Hospital, Tel Aviv, Israel

Study question: To evaluate the precise biopsy timing during the 8 cell stage on day 3 for which the embryos will have the best implantation potential.

Summary answer: Our results demonstrate that biopsying fast-cleaving embryos during 15–20 h post t8, has the least effect on their further development.

What is known already: Blastomere biopsy at the cleavage stage is routinely used for women with a genetic indication who undergo PGD. Embryo biopsy is

usually performed on the morning of day 3 when the embryos are at the 6- to 8-cell stage. Human embryos usually remain at the 8-cell stage for a relatively long "arrest phase" in which cells grow, duplicate their DNA and synthesize various proteins in preparation for the subsequent division.

Study design, size, duration: We studied 195 embryos that underwent blastomere biopsy for PGD between 9/2012–6/2014 and were cultured in the EmbryoScope[TM]. The control group included 115 embryos from ICSI cycles (not biopsied) performed during the same period and cultured until day 5, resulting in good-quality blastocysts (3AA, 3AB, 3BA 4AA, 4AB, and 4BA). Time points of key embryonic events were annotated and analyzed with an EmbryoViewer.

Participants/materials, setting, methods: Biopsy during the 8-cell stage was divided into 4 quarters: during the first 5 h post-t8 (Q1), at 5–10 h post-t8 (Q2), at 10–15 h post-t8 (Q3) and at 15–20 h post-t8 (Q4). The non-biopsied control embryos were divided into 4 equivalent quarters. The study embryos were evaluated for timing of developmental events following biopsy, and those were compared between PGD and control embryos as well as with 56 PGD implanted embryos with known implantation data (KID positive).

Main results and the role of chance: Embryos that were biopsied during Q3 were delayed in all 3 subsequent developmental events, including first cleavage after biopsy, compaction (tM) and start of blastulation (tSB). In contrast, these events in embryos that were biopsied during Q1, Q2 or Q4 of the 8-cell stage occurred exactly at the same time as in the control group.

The results also show that embryos that were biopsied during Q1, Q2 or Q3 of the 8-cell stage demonstrated a significant delay compared to the biopsied implanted embryos already in t8 as well as in tM and tSB. However, embryos that were biopsied during Q4 demonstrated dynamics similar to those of the biopsied implanted embryos in t8 and tM, with only a delay observed in tSB.

Limitations, reasons for caution: This is a retrospective study that is limited to the timing of biopsy routinely performed in IVF. A prospective study in which biopsies are performed at a desired timing is needed in order to differentiate between the effect of the biopsy per-se and the effect of its natural cleavage rate.

Wider implications of the findings: When selecting biopsied embryos for transfer, it may be preferable to choose the fast-cleaving embryos that were biopsied during Q4 of the 8-cell stage. Those embryos are probably less affected by the biopsy procedure, and their implantation potential is better than that of embryos biopsied earlier during the 8-cell stage.

Trial registration number: not applicable.

P-239 Embryological outcomes in patients with previous developmental problems: a sibling study using Ca2+ ionophore

H.K. Yelke, C. Pirkevi, Y. Kumtepe Colakoglu, S. Kahraman

Istanbul Memorial Hospital, ART&Reproductive Genetics Center, Istanbul, Turkey

Study question: Can Ca2+ ionophore improve embryological outcomes in patients with previous developmental problems?

Summary answer: Although statistically not significant, the rate of usable embryos was higher in the group of oocytes treated with Ca2+ ionophore.

What is known already: The use of calcium ionophore in IVF was initially recommended for couples with severe male infertility, previous history of fertilization failure or major morphological sperm defects like globozoospermia. Recently, a prospective multicenter study including patients with complete embryo developmental arrest in a previous cycle, complete developmental delay or reduced blastocyst formation on day 5 showed that application of Ca2 + ionophore leads to increased rates of cleavage to 2-cell stage, blastocyst formation and clinical pregnancy/live birth (Ebner et al., 2015). In this study, preceding cycles of the same patients constituted the control group.

Study design, size, duration: This retrospective study comprised a two-year period (2015-2016). Patients with previous poor embryo development (n = 73) and without severe male factor were included in the study. In the treatment cycles, half of the metaphase II (MII) oocytes were exposed to a commercially available ready-to-use ionophore for 15 min immediately after ICSI. After a three-step washing procedure, in vitro culture was performed in low oxygen tension using a single-step culture medium as for the control sibling oocytes.

Participants/materials, setting, methods: The mean age of patients was 31.2. The mean number of cumulus oocyte complexes was 14.2. A total of 5.1 MII oocytes were allocated for treatment with Ca2+ ionophore. The mean number of control sibling oocytes was 6.6.

Main results and the role of chance: The fertilization rate was 68.9% and 66.8% for the oocytes with and without ionophore treatment, respectively. The rate of day 3 grade 1 embryo rate was higher in the absence of treatment (30.4% and 25.2%), although not reaching statistical significance (p = 0.19). On day 4, the grade 1 embryo rate was 24.4% and 22.9% for the oocytes with and without ionophore treatment, respectively. Similarly, the rate of blastocyst formation was slightly higher for the group subjected to Ca2+ ionophore (43.7% vs. 42.2%; p = 0.6). The good quality blastocyst rate was of 21.7% and of 20.1% for the oocytes with and without ionophore treatment, respectively (p = 0.68). Finally, the usable embryo rate (including transferred and frozen embryos) was superior when Ca2+ ionophore was used (34.9% vs. 29.2%).

Limitations, reasons for caution: Although the sibling approach allowed a realistic comparison of embryo development, statistical significance could not be reached.

Wider implications of the findings: Ionophore treatment can benefit to patients with compromised embryo development. However, the effect on pregnancy outcomes needs to be addressed in prospective randomized trials.

Trial registration number: Not applicable.

P-240 What is the effect of follicle flushing on oocyte yield and quality in ART cycles of poor responders?

Y. Aydin[1], F. Taplamacioglu[2], S. Gokce[3]

[1]Eskisehir Osmangazi University, Eskehr, Turkey
[2]Eskisehir Osmangazi University, Obstetricsand Gynecology Department- IVF Unit, Eskisehir, Turkey
[3]Eskisehir Osmangazi University, Obstetrics and Gynecology Department- IVF Unit, Eskisehir, Turkey

Study question: Is there any role of sequential follicle flushing on oocyte number and quality in poor responders?

Summary answer: By sequential flushing, number of retrieved oocytes were increased additional to no detrimental effect on quality.

What is known already: Although previous studies have shown no beneficial effect of follicular flushing in normal responders, it may result in lower implantation and clinical pregnancy rates in poor responders. However, no study have demonstrated the net effect of sequential aspiration-flushing on oocyte quality. Due to the limited number of studies in poor responder patients, it is still not so clear whether flushing may increase the oocyte retrieval or not.

Study design, size, duration: This preliminary prospective cohort study was aimed to determine whether sequential follicular aspiration-flushing increases oocyte number and to evaluate the effect of follicle flushing on oocyte quality, in 45 poor responder patient according to Bolognia criterias who underwent standard Antagonist protocol. 17-gauge double lumen needle was used to aspirate the follicles. After each aspiration if cumulus-oocyte-corona complexes (COC) was not obtained, 2-3 ml aspiration medium was reinjected and aspirated three times maximally.

Participants/materials, setting, methods: Each oocyte was investigated according to 6 criteria for quality: morphology, cytoplasm, perivitelline space, zona pellucida, polar body and oocyte size, so establishing an average total oocyte score (TOS) as offered by Lazzaroni-Tealdi-et al. 2015. Average TOS values for oocytes obtained by directly/non-flushing group (group 0) compared with oocytes obtained by flushing 1 (group 1), flushing 2 (group 2), flushing 3 (group 3).

Main results and the role of chance: Average age for all patients was 37.5 ± 5.3 years and mean oocyte yield was 3.27 ± 2.29. 50 (35.2%), 34 (23.9%), 38 (26.8%) and 20 (14.1%) oocytes were aspirated in group 0, 1, 2, and 3. There was no significant difference between Median TOS values of group 0: 3 (range -2 to 5) compared to group 1: 2.5 (range -1 to 5); group 2: 3

(range -2 to 6); group 3: 3 (range -2 to 5) and average value for all oocytes obtained by flushing: 3 (range -2 to 6).

Limitations, reasons for caution: According to this preliminary study, we reported the results of 142 separately evaluated oocytes. Implantation rates should also be evaluated after the investigation of more oocytes.

Wider implications of the findings: This was the first preliminary study in literature that evaluated the effect of aspiration-flushing on oocyte yield and quality follicle by follicle. We demonstrated an increase in the number of oocytes retrieved by sequential flushing. Additionally, serial flushing had no negative impact on the oocyte quality.

Trial registration number: -.

P-241   Single or group embryo culture in an oocyte donation programme: a prospective, randomized sibling-oocyte study

T. Pavlidou[1], Y. Panagiotidis[1], A. Papatheodorou[1], S. Petousis[1], M. Goudakou[1], A. Gkountis[1], P. Vanderzwalmen[2], K. Ravanos[1], N. Prapas[1], Y. Prapas[1,3]

[1]Iakentro Fertility Centre, IVF Laboratory, Thessaloniki, Greece
[2]Centers Prof. Zech, IVF, Bregenz, Austria
[3]Institut Médical de Champel, IVF, Geneve, Switzerland

Study question: Is there a difference in embryo development between single and group embryo culture by terms of blastocyst rate and top quality blastocyst rate?

Summary answer: Group culture embryos are characterized by a trend for higher, not statistically significant, top-quality blastocyst formation rate.

What is known already: Obtaining the optimal culture conditions that improve embryo development and IVF outcomes, is still an issue of great importance. Studies in mice and bovine models suggested that group culture ameliorates blastocyst formation. However, even though group culture of human embryos has not been reported to be detrimental, it is controversial if it has an impact on embryo development in reference to blastocyst formation, overall blastocyst quality and pregnancy rate. Embryo density and droplet volume are determining variables for the secretion of autocrine factors/accumulation of paracrine byproducts but few studies have evaluated them.

Study design, size, duration: A prospective, randomized, comparative study was performed from May 2016 to December 2016. All cases were participating in oocyte donation program of Iakentro IVF Center and followed ICSI. For each case, the injected oocytes were randomly allocated in Control Group and Study Group and cultured individually and in group, respectively.

Participants/materials, setting, methods: A total of 1915 sibling oocytes were used for the study, 1008 in the Control Group and 907 in the Study Group. The Control Group droplet was 30 μl while for the Study Group were used two different volume droplets, a 30 μl droplet or a 60 μl droplet. Blastocyst formation rate and top quality blastocyst rate were the main outcomes.

Main results and the role of chance: On day-5, no statistically significant difference was observed in the blastocyst formation rate between Control and Study Group, in both 30 μl (58.6% vs. 61.1% respectively, p = 0.29) and 60 μl (57.8% vs. 58.5% respectively, p = 0.3) Study Group droplets. However, a tendency for top quality blastocysts was observed in both 30 μl (28.5% in Control Group vs. 32.5% in Study Group) and 60 μl (30.5% in Control Group vs. 35% in Study Group) Study Group droplet even though no statistical significant difference was detected (p = 0.08 and p = 0.09 respectively). As it refers to pregnancy rates, the opposite trends were observed. In the oocytes of the 30 μl Study Group droplet we observed a reduction in pregnancy rate (68% in Control Group vs. 53% in Study Group, p = 0.3) which is the opposite from what observed in the oocytes of the 60 μl Study Group droplet (66% in Control Group vs. 75% in Study Group, p = 0.7).

Limitations, reasons for caution: Being a study with oocytes from a donation program, the results may not be reproducible in cases of older patients. Moreover, the number of cases should be increased in order to confirm the above data and extend the clinical outcomes.

Wider implications of the findings: We speculate that the decrease in pregnancy rate that is observed in the 30 μl Study Group droplet is due to the restricted amount of nutrients per embryo and the higher accumulation of embryo byproducts when many embryos are cultured together in small volume of media.

Trial registration number: None.

P-242   Efficiency of a closed vitrification system for the cryopreservation of human oocytes: a case series study

E. Kasapi, A. Zisopoulou, C. Karakosta, E. Kachpani, A. Stamkopoulou, A. Pantelis, D. Dovas

Newlife IVF unit, IVF Lab, Thessaloniki, Greece

Study question: Can a closed-aseptic vitrification system be compared in efficiency to the widely adopted but under criticism, open systems for the cryopreservation of oocytes?

Summary answer: The closed vitrification system applied can be as efficient as widely adopted open ones in terms of survival, fertilization, blastocyst formation, pregnancy and implantation rates.

What is known already: Many vitrification procedures have been described that differ from each other in many parameters and most fundamentally, in the type of cooling and storage device. These either permit or not the direct contact of the biological material with the liquid nitrogen and are characterized as open and closed vitrification systems, respectively. Nevertheless, a controversy about the potential risk of the sample from its direct contact with the liquid nitrogen still exists. For this purpose, closed vitrification systems have been proposed and validated as equally effective but yet not widely adopted.

Study design, size, duration: A case series study was performed, including a total of 300 oocytes, retrieved from 6 stimulated cycles of patients undergoing IVF treatment and of 24 donors participating in our Unit's (Newlife IVF-Greece) oocyte donation program, between December 2015 and November 2016.

Participants/materials, setting, methods: All retrieved oocytes after denudation underwent vitrification using FertiPro Vitrification kit (FertiVit Cooling kit). After their exposure to the equilibration and vitrification solutions, they were loaded on the gutter of the vitrification carrier (VitriSafe), inserted into a 0.3 ml straw (CBS), thermo sealed and submerged in liquid nitrogen. Warming was performed using Fertipro warming Kit (FertiVit Warming kit). All survived oocytes were fertilized by ICSI.

Main results and the role of chance: Regarding the homologous cycles, a total of 48 oocytes underwent vitrification. The survival rate after warming was 87,5 % (42/48) and the fertilization rate after ICSI was 85,7 % (36/42). The blastocyst formation rate was 33,3 %. Four out of 6 had a positive βHCG (clinical pregnancy rate 66,6 %). Regarding the donor cycles, a total of 252 oocytes underwent vitrification. The survival rate after warming was 92,8 % (234/252) and the fertilization rate was 68,3 % (160/234). The blastocyst formation rate was 40% (64/160). Eighteen out of 24 cases had a positive βHCG (clinical pregnancy rate 75%). In 6 of these cases a severe male factor was detected and sperm from a testicular biopsy was used. Four out of 6 had a positive βHCG. In total, from these pregnancies, 14 are still ongoing while 8 had led to full term delivery giving birth to 10 healthy babies.

Limitations, reasons for caution: Small sample size of the study participants is due to the rarity of such cases. Larger prospective trials with an increased number of patients are needed to confirm our findings.

Wider implications of the findings: Closed vitrification system could be efficiently applied for oocyte cryopreservation in cases of urgent fertility preservation or due to male incapability to produce semen on the day of oocyte retrieval. Furthermore, could be applied as a standard procedure in oocyte banks cryopreservation programs increasing the total safety conditions.

Trial registration number: n/a.

P-243   Autologous Endometrial Cell Co-culture (AECC) significantly improves human embryo quality

J. Kadoch[1], C. Le Saint[2], A. Bourdiec[1], K. Crespo[1], S. Phillips[3], S. Bisotto[1], J. Sampalis[4], M. Stutz[4], J.N. Gouze[5], S. Hamamah[6], F. Bissonnette[3]

[1]clinique ovo, ovo r&d, Montréal, Canada
[2]clinique ovo, ovo labo, Montréal, Canada
[3]clinique ovo, ovo fertilité, Montréal, Canada
[4]JSS Medical Research, Scientific affairs, Montréal, Canada
[5]Genbiotech, Genbiotech, Sophia-Antipolis, France
[6]CHRU- Montpellier Hopital Arnaud de Villeneuve, ART-PGD, Montpellier, France

Study question: Does Autologous Endometrial Cell Co-culture (AECC) clinically improve IVF treatment outcomes?

Summary answer: AECC increases the number and quality of blastocysts, as well as their survival post vitrification, compared to conventional culture medium.

What is known already: Studies have demonstrated the benefits of AECC in terms of embryo maturation and pregnancy outcome. However, the majority of these studies were conducted in specific clinical cases of infertility, such as poor ovarian reserve and repeated implantation failure. Our group focused on demonstrating the potential beneficial effects of AECC in patients predicted to be good responders to IVF treatments.

Study design, size, duration: This interventional study took place at **clinique ovo** from April 2013 to March 2015, as a monocentric, randomized, double-blind controlled trial. A total of 1398 mature ovocytes from 136 couples undergoing IVF were analysed: 326 embryos from 63 patients were cultured on an autologous co-culture system of endometrial cells (EC) (study group) and 573 embryos from 73 patients in conventional culture medium (control group); 475 ovocytes, unsuccessfully fertilized, were excluded from the current analysis.

Participants/materials, setting, methods: A biopsy of the endometrium was performed during the luteal phase of the cycle before IVF treatment. EC isolated from biopsies were put in culture the day following ovulation triggering. According to randomization group, embryos were either placed at day 2 (D2) on AECC, or in conventional culture medium. All IVF cycles were then pursued following clinic standards.

Main results and the role of chance: Our results demonstrate that the use of a co-culture system for embryo development increases the number of available top quality blastocysts (TQB) per cycle.

Growth on AECC was found to significantly increase the number of useful embryos compared to conventional culture medium (46% vs. 35%, respectfully; p < 0.05), as well as significantly improved blastulation rate (42.6% vs. 28.8%; p < 0.001). Predictors of blastulation [OR(95%CI)], identified using logistic regression models, were AECC cohort [4.819(3.599, 6.452); p < 0.001], and higher number of mature oocytes [1.046 (1.022, 1.071); p < 0.001].

In addition, blastocyst survival rates showed improvement after AECC, with a rate of 85.4% in the AECC group, compared to 73.8% in the control group. Following frozen embryo transfers, pregnancy outcomes, assessed using live birth rate, were higher after AECC (34.1%) than following conventional medium culture (25.6%), for all stages of embryo growth. Although not found to be statistically significant, these improvements in survival and live birth rates are nonetheless of clinical relevance in the context of IVF.

Limitations, reasons for caution: N/A

Wider implications of the findings: AECC utilisation increases the number of available embryos per cycle, thus improving IVF treatments, Moreover, the quality blastocysts obtained from AECC show improved survival and pregnancy rates after frozen embryo transfer.

Trial registration number: NCT01886118.

P-244 Differential human blastocyst vitrification: A randomized comparative trial assessing solution and device treatments under varying laboratory conditions

M.C. Schiewe[1], C. Gibbs[2], R. VanTol[1], K. Waggoner[1], K. Howard[2], J. Howard[2], M. Freeman[2], A. Jones[2], S. Zozula[1]

[1]Ovation Fertility, ART Lab, Newport Beach- CA, U.S.A.
[2]Ovation Fertility, ART Lab, Nashville- TN, U.S.A.

Study question: How is human blastocyst vitrification influenced by different solutions in an open or closed device system using a crossover re-vitrification (rVTF) experimental model?

Summary answer: Human blastocysts rVTF success proved vulnerable to a technicians' device and solution familiarity and may be adversely influenced by total exposure to different cryoprotective agents.

What is known already: Human blastocysts vitrification has evolved into a highly reliable and efficient process within most laboratories. Slower cooling, closed aseptic vitrification devices have proven to be equally effective to ultra-rapid cooling open methods. Yet, variation between laboratories in the type of cryoprotective agent or device system used has created some concerns. Less toxic, potentially unstable vitrification solutions (e.g., 30%EG/DMSO) are used

widely in open device systems, while a more concentrated, metastable solution (e.g., Glycerol/EG) may be more appropriate with a closed device. There have been no comparative trials contrasting the potential advantages or disadvantages of these commonly used clinical systems.

Study design, size, duration: Research consented, discard blastocysts at 2 laboratories (A/B; n = 40 and 41 embryos, respectively; 4 technicians/lab) were randomly assigned to a 2×2 factorial design: comparing open-Cryolock (CL) devices to a closed-microSecure (μS) vitrification system using either a EG/DMSO (15/15% solution) or a Glycerol/EG (G/EG;≥7.9 M) vitrification solution. Differences in recovery rate, %survival and %24hr development were statistically compared by Chi-square analysis (p < 0.05). Additionally, a series of objective survey questions pertaining to potential device usage differences were contrast.

Participants/materials, setting, methods: Vitrified blastocysts (AA to BB quality) were obtained from patients consenting to research discard usage. Standard rapid warming/sucrose dilution protocols were applied consistent with the device-solution treatment combinations. Embryos were allowed to equilibrate in culture before being randomly selected for rVTF treatment, and subsequently warmed, re-equilibrated and cultured in a humidified, tri-gas atmosphere (37°C). Embryo survival assessments, including photo documentation, was performed at 0-2hr and +24hr (i.e.,continued development) post-warming across control and crossover treatments.

Main results and the role of chance: Laboratory A has previously shown that human blastocysts are highly cryotolerant to rVTF (up to 5 times) in their control μS-VTF/G-EG system. However, in this study Lab B (a control CL-EG/DMSO user) experienced decreased post-warming survival/development in μS-G/EG treated blastocysts (64% vs their 89%control) and a further decrease in the crossover treatments (30–36%). In contrast, Lab A showed no difference between control groups (100% survival and development) and only a 10–20% developmental decline in the CL-G/EG or μS-EG/DMSO groups. Overall, mean survival/ development in the CL-EG/DMSO control (100%/94.7%) was higher (p < 0.05) than CL-G/EG (81%/66.7%) or μS-EG/DMSO (75%/65%), but not different than μS-G/EG controls (81%/81%). Interestingly, survey responses reflected a laboratory bias toward their control treatments, however all technicians agree that μS-VTF was safer than open-blade devices (e.g.,CL) in terms of LN$_2$ handling procedures or potential embryo-pathogen interaction risk factors. As an aseptic closed device, μS-VTF offers greater long-term security and tamperproof labeling, as well as an appreciable annual cost-savings as a non-commercialized VTF system. In summary, technician familiarity and experience to vitrification devices and solutions had a greater effect than anticipated, revealing that a learning curve for the μS device and G/EG solution treatments is needed to optimize post-warming viability.

Limitations, reasons for caution: Additional trials, increased sample sizes and an additional collaborating laboratory are needed to fully discern the treatment effects of differential cryoprotective agent exposures causing damaging osmotic stress to vulnerable blastocysts. It is also possible that differences in blastocyst quality/cryo-stress vulnerability between laboratories may have contributed to rVTF survivability.

Wider implications of the findings: To reduce inter-laboratory variability and make continued improvements in global human blastocyst vitrification success, we must continue asking questions and challenge existing methodologies to fully understand the complexity of outcome data. This study has demonstrated the value and importance of implementing continuing education/quality control studies, even among well-trained Embryologists.

Trial registration number: None.

P-245 The association between vitamin A, E, D and B6 concentrations in follicular fluid with embryomorphokinetics, embryo quality and pregnancy rates in assisted reproductive techniques

A.Z. Isik, F. Gode, S. Akarsu

Izmir Medicalpark Hospital, In Vitro Fertilization Unit, Izmir, Turkey

Study question: Is there any association between vitamin A, E, D and B6 levels in follicular fluid with embryomorphokinetics, embryo quality and clinical pregnancy rates?

Summary answer: High follicular fluid vitamin A and B6 levels were significantly associated with high embryo quality and optimal embryo morphokinetics.

What is known already: There is a paucity of information regarding the roles of antioxidant vitamins (vitamin A, E, D and B6) in early embryogenesis, embryomorphokinetics and clinical pregnancy rates.

Study design, size, duration: Fifty eight patients with unexplained infertility who were admitted to the IVF center of Izmir University Medical Park Hospital between March 2016 and June 2016 were included in this prospective clinical study.

Participants/materials, setting, methods: For each patient vitamin A, E, D and B6 levels of follicular fluid was assayed by high performance liquid chromatography system. After ICSI of each oocyte the relation between level of vitamin A, E, D and B6 content of each follicular fluid and subsequent embryo quality, embryo morphokinetics and clinical pregnancy rates were investigated. Embryos were classified as grade 1,2,3,4 according to morphokinetic parameters using t5-t2 and t5-t3 (cc3)

Main results and the role of chance: Follicular fluid vitamin A and B6 levels were significantly higher in Grade 1-2 embryos than grade3, 4 embryos (p < 0.05). There were no significant relation between follicular fluid vit E and D levels and embryo quality. There were no significant relation between vitamin A, E, D and B6 levels in follicular fluid and clinical pregnancy rates.

Limitations, reasons for caution: Relatively small sample size might be a limitation of our study.

Wider implications of the findings: Our results support the role of vitamin A and B6 in early embryogenesis and embryomorphokinetics. Vitamin A and B6 supplementation might be beneficial to improve embryo quality. Further research is necessary to find out the clinical effects of these vitamins in in vitro fertilization outcomes.

Trial registration number: none.

P-246   Embryo selection: are we looking at the full picture?

I. Dimitriadis[1], G. Christou[2], K. Dickinson[2], C. Veiga[2], M. Brock[2], I. Souter[1], C. Bormann[1]

[1]Harvard Medical School-Massachusetts General Hospital, Obstetrics and Gynecology/Reproductive Endocrinology and Infertility, Boston- MA, U.S.A.
[2]Massachusetts General Hospital Fertility Center, Obstetrics and Gynecology/ Reproductive Endocrinology and Infertility, Boston- MA, U.S.A.

Study question: Is day-3 (D3) embryo selection improved by examining all embryos simultaneously in a cohort compared to individually evaluating and selecting them based on morphology measurements and/or morphokinetic parameters?

Summary answer: D3 embryo cohort selection improves identification of embryos most likely to develop into high-quality blastocysts when compared to using standard morphology and morphokinetic selection methods.

What is known already: Recent attention has been focused on the ability of non-invasive computer-automated morphokinetic measurements to predict blastocyst formation with the ultimate goal of successful single cleavage-stage embryo transfer. Studies have shown that adjunctive use of standard morphology scoring plus morphokinetic parameters improves embryo selection by enabling the deduction of embryos unlikely to develop to the blastocysts. In traditional methods of embryo grading, embryos have always been evaluated individually and ranked accordingly for transfer. However, simultaneous evaluation of patients' entire embryo cohort at a single time-point to predict high-quality blastocysts has never been looked at.

Study design, size, duration: Study Design: Retrospective case-control study.

Size: 50 infertile women with their entire cohort of embryos imaged in the EmbryoScope from Day 1 to Day 5 and who had at least one blastocyst on day-5 of development.

Duration: September 2014 - December 2015.

Participants/materials, setting, methods: Top quality embryos from each patient cohort were selected based on: 1) D3 morphology (D3M), 2) D3M and validated morphokinetic parameters (P2 and P3 time-lapse scoring) (TLM), 3) D3 embryo cohort selection performed individually by 3 embryologists, blinded

to D3M and TLM results, who selected the top quality embryo from a single image taken at 68hrs of all embryos in the cohort (CM).

Statistics: Chi-square test. P < 0.05 was considered statistically significant.

Main results and the role of chance: The overall blastocyst formation prediction rate was higher with the CM when compared to D3M and TLM (95% vs 86% and 89%; p = 0.06 and p = 0.21, respectively). Similarly, predicting high quality blastocyst formation (expanded blastocysts with good ICM and trophectoderm) was higher with the CM when compared to both D3M and TLM (75% vs 66% and 67%; p = 0.21 and 0.33, respectively). The prediction rate for overall and high quality blastocyst formation between D3M and TLM was similar.

Limitations, reasons for caution: Limitations include:

- retrospective design
- the completion at a single academic center with higher blastocyst prediction rates using D3M than that reported in the literature, indicating the need for larger numbers to prove potential statistical significance in the differences seen
- only one time point (D3) was evaluated, potentially masking other important time-points

Wider implications of the findings: This improved method of identifying embryos with the highest potential to form a blastocyst, may not only improve success of cleavage-stage transfers in a cost-effective manner but also aid in the development of deep learning models designed to identify top quality embryos from a patient's entire embryo cohort.

Trial registration number: Not applicable.

P-247   Impact of morphological parameters at high magnification, nuclear structure and ultrastructure of spermatozoa on ART outcomes

S. Ghazali[1], A.R. Talebi[2], M.A. Khalili[3], A. Aflatoonian[4]

[1]Islamic Azad University- Sanandaj Branch, Midwifery, Sanandaj, Iran
[2]Shahid Sadoughi University of Medical Sciences- Research and Clinical Center for Infertility, Andrology, Yazd, Iran
[3]Shahid Sadoughi University of Medical Sciences- Research and Clinical Center for Infertility, Embryology, Yazd, Iran
[4]Shahid Sadoughi University of Medical Sciences- Research and Clinical Center for Infertility, Obstetrics and Gynecology, Yazd, Iran

Study question: Whether morphological parameters at high magnification, nuclear structure and ultra-structure of spermatozoa can effect on ART outcome in patients with male infertility.

Summary answer: Head size of Spermatozoa and large nuclear vacuoles are significant relation with ART outcome. TEM assessments revealed that origin of vacuoles are mainly nuclear.

What is known already: Sperm morphology is one of the important characteristics in semen analysis for evaluation of male fertility. Emerging high magnification evaluation of sperm morphology has improved some aspects of the infertility treatment in assisted reproductive technology such as repeated implantation failure.

Study design, size, duration: This study was performed as a prospective observational study. 113 men diagnosed with male infertility were randomly selected for the study from March 2013 to July 2015 at Yazd Research and Clinical Center for Infertility.

Participants/materials, setting, methods: Men undergone ICSI treatment were randomly selected, of whom 99 cases met inclusion criteria. Smears of CMA3 were prepared and examined after density gradient sperm washing and preparation. Suspended spermatozoa introduced 3 µl of PVP micro-droplets were then evaluated at high magnification (> 6000x), upon MSOME parameters including: Cassuto-Barak criterion, presence of vacuoles, size and number of vacuoles, measurement of the head length, head shape, presence of cytoplasmic droplet and shape of acrosome.

Main results and the role of chance: In terms of vacuole presence, only 8% of spermatozoa had no vacuoles and mix vacuoles allocated the highest rate. Moreover, around 40% of spermatozoa had normal size, 8% showed normal shape, 51% illustrated normal acrosome and 40% with cytoplasmic droplets. There were no correlation between different types of vacuole and embryo

quality and pregnancy rate; while, spermatozoa having large vacuole revealed an inverse correlation with fertilization rate (p = 0.05). On the other hand, pregnancy rate showed a direct relationship with normal size of spermatozoa (p = 0.045), though no significant correlations were found with other MSOME parameters such as shape of head, presence of cytoplasmic droplet and shape of acrosome. There was no relevance between these parameters and quality of embryo. In addition, there was a significant correlation between spermatozoa having no vacuole and parameters of normal head size, normal shape and normal acrosome rates (p = 0.012, p < 0001 and p < 000, respectively).Regarding chromatin packaging, $CMA3^+$ showed a direct significant relationship with parameters of mix vacuole and sperm count (p = 0.007 and p = 0.012, respectively) and an inverse correlation with small vacuole and presence of cytoplasmic droplet (p = 0.027 and p = 0.012, respectively).

Limitations, reasons for caution: Quality of high magnification microscope still is not enough good and need to be better.

Wider implications of the findings: Our data showed, there were no significant correlation between Cassuto-Barak classes of spermatozoa with fertilization and quality of embryos rates.Similarly, there were no correlation between different types of vacuole and embryo quality and pregnancy rate. Some nuclear vacuoles appears to be a membranous folding of sperm head at TEM assessments.

Trial registration number: not applicable.

P-248 Antioxidants in IVF medium significantly improve embryo development

D.K. Gardner, T.T. Truong

University of Melbourne, School of BioSciences, Melbourne, Australia

Study question: What is the effect combined antioxidants Acetyl-L-Carnitine (ALC), N-Acetyl-L-Cysteine (NAC) and α-Lipoic Acid (ALA) on embryo development, when present in the IVF medium?

Summary answer: Combined antioxidants resulted in a significant increase in blastocyst cell number and faster developmental times from 5- cell stage through to expanded blastocyst stage.

What is known already: The combination of the antioxidants ALC, NAC and ALA in IVF media and/or culture media has a significant beneficial effect on embryo development.

Study design, size, duration: Morphokinetics of mouse embryos were quantitated using time-lapse imaging. Blastocysts underwent differential nuclear staining for inner cell mass (ICM) and trophectoderm (TE).

Participants/materials, setting, methods: IVF was conducted in atmospheric oxygen in the presence or absence of antioxidants (10 μM ALC /10 μM NAC /5 μM ALA). Gamete collection and fertilisation was conducted in IVF medium with and without antioxidants and subsequent embryos cultured in 20% oxygen. Embryo development was analysed through time-lapse microscopy followed by differential nuclear staining to determine cell allocation in the blastocyst. Controls were gametes and embryos that were not exposed to antioxidants in the medium.

Main results and the role of chance: IVF was conducted with antioxidants present or absent in oocyte and/or sperm IVF medium and subsequent embryos cultured in medium without antioxidants. Embryos with antioxidants in both oocyte and sperm IVF medium developed faster to 2 cell cleavage stage (14.8 ± 0.1 h vs. 15.2 ± 0.1 h; $P < 0.05$) which continued to hatching blastocysts (85.9 ± 0.9 h vs. 89.1 ± 0.8 h; $P < 0.05$), and had higher TE cell numbers (49.8 ± 2.1 vs. 36.6 ± 2.0; P < 0.01) and total blastocyst cell numbers (61.9 ± 2.6 vs. 47.2 ± 2.4; P < 0.001), when compared to controls that had no antioxidants in oocyte and sperm IVF medium. Embryos with antioxidants solely in oocyte IVF medium had faster times to 2 cell cleavage stage (14.8 ± 0.1 h; $P < 0.01$) which continued to expanded blastocysts (81.2 ± 0.6 h; $P < 0.01$) and had increased TE cell numbers (46.5 ± 2.1; P < 0.01) and total blastocyst cell numbers (58.5 ± 2.5; P < 0.05) when compared to controls. Embryos with antioxidants only in the sperm IVF medium had no differences in developmental times and blastocyst total cell numbers (51.3 ± 2.2) compared to controls. There were no differences in fertilisation or blastocyst development rates between all groups.

Limitations, reasons for caution: Embryo development was only examined in the mouse.

Wider implications of the findings: The presence of antioxidants during IVF imparts significant benefits on embryo development rate and cell numbers. This indicates that supplementation of antioxidants to the IVF medium, especially during oocyte collection and fertilisation will further assist in maintaining the viability of human embryos in ART, through the reduction of oxidative stress.

Trial registration number: not applicable

POSTER VIEWING SESSION
ENDOMETRIOSIS AND ENDOMETRIAL DISORDERS

P-249 Endometriosis and adverse pregnancy outcomes: Systematic review and meta-analysis

H. Minebois, R. Callec, A. De Souza, O. Morel

University Hospital of NANCY, Obstetric department, NANCY, France

Study question: Are adverse pregnancy outcomes higher for spontaneous pregnancy in endometriosis-affected patients compared to general population?

Summary answer: In spontaneous pregnancies, endometriosis appears to be a risk factor of adverse pregnancy outcomes and especially of miscarriages, small-for-gestational-age fetuses and preterm births.

What is known already: The association between endometriosis and adverse pregnancy outcomes in spontaneous pregnancy has long been debated without reaching a consensus.

Study design, size, duration: We searched the Cochrane Library, MEDLINE and reference lists of eligible studies from inception to December 2015, without any restriction. We selected studies that compared endometriosis-affected pregnant women to disease-free pregnant women. To ensure the quality of the methodology, the PRISMA criteria have been met at all stages of the development of this meta-analysis.

Participants/materials, setting, methods: The primary adverse pregnancy outcomes studied were placenta-mediated outcomes, which include: pre-eclampsia, gestational hypertension, intra uterine growth restriction (IUGR), miscarriage, stillbirth, and placenta praevia. The secondary outcomes we considered were others adverse pregnancy outcomes including small-for-gestational-age new born (SGA), gestational diabetes, antenatal bleeding incidence, preterm birth and caesarian birth. Two reviewers independently extracted the studies' characteristics and outcome data. Finally, estimates were assessed using random effects models and sensitivity analyses.

Main results and the role of chance: Of 424 identified abstracts, 9 primary studies (8 cohorts, 1 case control) met our inclusion criteria by comparing spontaneous pregnant patients with endometriosis to disease-free women. Compared to the general population, endometriosis pregnant women experienced a higher incidence of SGA age new born (OR 1,39 [CI 95%; 1.07–1.80]). The risk of preterm birth was higher in the OSIS group (OR 1.40 [CI 95%; 1.22–1.62]), along with caesarian section (OR 1.75 [IC 95%; 1,58–1.95]) and antenatal bleeding (OR 1,95 [IC 95%; 1,07– 3,54]). Fetal loss was also increased in the OSIS group due to a higher miscarriage rate (OR 1,77 [CI 95% 1.13 – 2,78]). The hypertensive outcomes, gestational diabetes, IUGR and placenta praevia risks did not show a significant statistical difference between the two groups.

Limitations, reasons for caution: The main criticism of the analysis of available evidence is the heterogeneity in exposure categorizations, disease phenotypes and criteria for endometriosis diagnosis in studies included.

Wider implications of the findings: Further prospective studies or an individual patient-level meta-analysis are needed to confirm these results and to establish the exact link between endometriosis and adverse pregnancy outcomes in spontaneous pregnancy.

Trial registration number: No trial registration number.

P-250   The efficacy of medroxyprogesterone acetate (MPA) in women with endometriosis undergoing controlled ovarian hyperstimulation for in vitro fertilization

H. Guo

Shanghai 9th People's Hospital, Assisted Reproductive Department, Shanghai, China

Study question: This study investigated using MPA for patients with advanced endometriosis and tubal infertility during COH and to compare cycle characteristics and pregnancy outcomes.

Summary answer: MPA is effective for women with endometriosis and normal ovarian function undergoing controlled ovary hyperstimulation.

What is known already: Progestins, synthetic progestational agents, have been used in endometriosis therapy for more than 40 years, and it is believed that they act as progesterone receptor agonists. Our previous work has shown that progesterone can prevent moderate/severe ovarian hyperstimulation syndrome (OHSS) in controlled ovarian stimulation. Subsequently, we have further found that MPA is an effective oral alternative for the prevention of a premature LH surge in woman undergoing COH, and the pregnancy outcomes from frozen-thawed embryo transfer (FET) indicated that the embryos originating from MPA co-treatment with human menopausal gonadotrophin (hMG) regimen had similar developmental potential as the short protocol.

Study design, size, duration: A retrospective case control study of 147 advanced endometriosis patients and 147 age-matched tubal infertility patients from November 2015 to October 2016. Patients were allocated to three groups: the surgery group (62 patients) were diagnosed with ovarian endometriomas by laparoscopy or laparotomy underwent 71 IVF/ICSI; the aspiration group (85 patients) had ovarian "chocolate" cysts (> 3 cm) that were aspirated underwent 90 IVF/ICSI; the control group (147 patients) with tubal infertility underwent 168 IVF/ICSI.

Participants/materials, setting, methods: This study investigated using MPA for patients with advanced endometriosis who have normal ovarian function and tubal infertility during controlled ovarian hyperstimulation and to compare cycle characteristics and pregnancy outcomes in subsequent frozen-thawed ET (FET) cycles. Human menopausal gonadotropin (hMG) and MPA were administered simultaneously beginning on cycle day 3 in tertiary-care academic medical center. Response to gonadotropins, fertilization, cleavage, implantation, and clinical pregnancy outcomes were recorded.

Main results and the role of chance: The mature oocyte rate and the fertilization rate were not significantly different between the two endometriosis groups and the control group. The cleavage rate was higher in the surgery group compared with the control group, but there was no significant difference between the aspiration and control groups. This might be because: 1) the endometriosis itself is unlikely to affect the quality of oocytes; 2) it is associated with a small sample size; 3) the application of progesterone may improve the egg or embryo quality of women with endometriosis. Viable embryo rate referred to number of high-quality embryos and blastocysts that were finally frozen, which did not show difference compared with the number of high-quality embryos frozen on D3. This may be because that P can improve the abdominal and ovarian microenvironment in patients with endometriosis, so as to improve the inflammatory reaction, thereby improving quality of oocytes and embryos. At the same time, in terms of pregnancy outcome, there were no significant differences in implantation rate and clinical pregnancy among the three groups. This again proved that for endometriosis patients with normal ovarian function, a high-P ovulation regimen is a very appropriate choice.

Limitations, reasons for caution: A major limitation is that it is a retrospective analysis; a well-designed, prospective, randomized study in severe advanced endometriosis patients undergoing FET and embryos derived from long-term pituitary downregulation should be performed. Another probable bias was the effect of granulosa cells and various immune factors during the MPA protocol.

Wider implications of the findings: The new treatment provides a novel insight into an alternative to the ultra-GnRH agonist regimen. Progestogens are generally well-tolerated, and may be used repeatedly. The role of MPA appears to be promising although many questions remain to be answered, the possible influence on embryo development potential and the hormonal milieu.

Trial registration number: none.

P-251   Intrafollicular inflammatory cytokines but not steroid hormone concentrations are increased in naturally matured follicles of women with proven endometriosis

G. Wu[1], N.A. Bersinger[2], M.D. Mueller[2], M. Von Wolff[2]

[1]*Renmin Hospital of Wuhan University, Reproductive Medicine Center, Wuhan-Hubei, China*
[2]*University of Women's Hospital-University of Berne, Division of Gynaecological Endocrinology and Reproductive Medicine, Bern, Switzerland*

Study question: To assess whether the intrafollicular cytokine profile in naturally developed follicles is different in women with endometriosis, possibly explaining the lower reproductive outcome in endometriosis patients.

Summary answer: Intrafollicular inflammatory cytokines are increased in naturally matured follicles of women with proven endometriosis, which may contribute to the reproductive dysfunction in endometriosis.

What is known already: Altered levels of inflammatory cytokines have been found in the follicular fluid (FF) of endometriosis patients undergoing conventional, gonadotropin stimulated IVF (cIVF) and the hormonal milieu was altered in the FF of patients with endometriosis. A dysregulated intrafollicular hormone milieu and an abnormal intrafollicular cytokine profile might be a cause of reduced fertility in endometriosis patients. However, these findings were mostly obtained from cIVF in which the exogenous gonadotropins considerably affect the intrafollicular immune system and hormonal milieu. Natural cycle-IVF (NC-IVF) seems to be an adequate model for a physiological follicle and closely represent natural follicles.

Study design, size, duration: A matched case-control study was conducted at a University based infertility and endometriosis centre. The study population included 17 patients with laparoscopically and histologically confirmed endometriosis (rAFS II-IV), each undergoing one Natural cycle IVF (NC-IVF) treatment cycle between 2013 and 2015, and 17 age matched NC-IVF women without diagnosed endometriosis (control group).

Participants/materials, setting, methods: Follicular fluid and serum was collected at the time of follicle aspiration. The concentrations of inflammatory cytokines (IL-1β, IL-6, IL-8, IL-15, IL-18, TNF-α) and hormones (testosterone, estradiol, AMH) were determined in follicular fluid and serum by single or multiplexed immunoassay and compared between both groups.

Main results and the role of chance: In the FF, IL-1β and IL-6 showed significantly higher median concentrations in the endometriosis than in the control group (P < 0.001 and 0.010 respectively, N = 17). IL-8 and IL-18 were not significantly different. Moreover, IL-1β and IL-6 showed a tendency towards a dependence on the severity of the disease (rAFS stage) while no such trend was observed for the FF concentrations of IL-8 and IL-18. IL-15 and TNF-α could not be detected in the FF.

The four cytokines which were measurable in FF were also investigated in the serum. IL-1β and IL-6 could not be detected in the matching serum samples collected on the day of oocyte recovery, except for one result for IL-1β. The concentrations of all four interleukins were significantly higher (p < 0.01) in FF than in serum over the entire study population.

Regarding the hormones in FF, E$_2$ concentrations were lower in severe than in mild cases of endometriosis (without statistical significance) and in control women (P = 0.036). Median follicular AMH concentration was slightly increased with severe endometriosis (without reaching statistical significance), while testosterone did not differ between groups. In FF, hormone and cytokine concentrations did not correlate with the different endometriosis stages.

Limitations, reasons for caution: We did not prove that women of the control group were free of endometriosis as laparoscopy without any signs of endometriosis is not indicated and therefore ethically not acceptable.

Wider implications of the findings: In women with moderate and severe endometriosis some intrafollicular inflammatory cytokines are upregulated and not correlated with intrafollicular hormone concentrations. This might be due to the inflammatory microenvironment in endometriosis women, affecting follicular function and thereby possibly contributing to the reproductive dysfunction in endometriosis.

Trial registration number: No trial registration number.

P-252 Clinical outcomes of infertility treatment for women with adenomyosis

H. Tamura, M. Okada, H. Asada, N. Sugino

Yamaguchi University School of Medicine, Obstetrics and Gynecology, Ube, Japan

Study question: Does adenomyosis have negative impact on female fertility? Dose pre-treatment including medication and conservative surgery improve reproductive outcome?

Summary answer: The pregnancy rate of women with adenomyosis is about 40%. There was no data suggesting that medication or surgery increased the pregnancy rate.

What is known already: The relationship between adenomyosis and female fertility is still unclear. Adenomyosis can be classified into two categories, focal type and diffuse type. The involvement of the type of adenomyosis in female fertility is also obscure. Although successful pregnancies after prolonged down-regulation with GnRH-agonist and conservative surgery have been reported, there is no agreement on the most appropriate therapeutic methods for managing infertile patients with adenomyosis. Since available data on the relationship between adenomyosis and infertility is still scant and limited to small-scale cases, it is difficult to evaluate the accurate impact of adenomyosis on female fertility.

Study design, size, duration: We conducted a nationwide survey to evaluate the effect of adenomyosis on infertility treatment and pregnancy outcomes as an official project of the Japan Society of Obstetrics and Gynecology (JSOG). A retrospective survey was performed using questionnaires sent to 1149 Japanese medical facilities, including 725 institutes authorized as a training facilities by the JSOG and 582 institutes registered to the JSOG for assisted reproductive technology (ART).

Participants/materials, setting, methods: Questionnaire 1 (Q1): management policy of infertile women with adenomyosis, Questionnaire 2 (Q2): outcomes of infertility treatment in women with adenomyosis. Q2 involved methods of the diagnosis, size, type, localization, infertility treatment, outcome of infertility treatments, and any pre-treatments for adenomyosis before infertility treatment. Patients with leiomyoma and endometriosis were excluded to eliminate the influence of these diseases on fertility. This survey was approved by the Ethical Committee of Yamaguchi University Graduate School of Medicine.

Main results and the role of chance: Q1: Out of the 155 facilities providing the management policy, infertility treatment was performed without any pre-treatment for adenomyosis in 26 facilities (16.8%), after medication 9 facilities (5.8%), after operation in 4 facilities (2.6%). Management policies were not established in 105 facilities (67.1%). Q2 was obtained from 190 facilities with data on 535 infertile women with adenomyosis. The total pregnancy rate was 41.7% and the miscarriage rate was 29.8%. The pregnancy rate and miscarriage rate by the usual infertility treatment without ART were 37.5% (90/240) and 21.1% (20/90), whereas the rate was 44.4% (131/295) and 34.3% (54/157) by ART. Eighty-five patients received medications (GnRH agonist 67, LEP 12, Danazol 7, Dienogest 4) and 89 patients underwent surgery (laparoscopic operation 24, laparotomy 65) as pre-treatment before infertility treatment, while 361 patients had no pre-treatment. Pregnancy rate (no treatment: 41.3%, medication: 43.5%, operation: 41.5%) and miscarriage rate (no treatment: 30.3%, medication: 31.7%, operation: 26.1%) were not affected by pre-treatment for adenomyosis. Of 535 patients, 162 patients represented the focal type and 336 patients diffuse type. The pregnancy rate and miscarriage rate in focal type (43.2% and 24.7%) and in diffuse type (42.9% and 33.1%) was not affected by the type of adenomyosis.

Limitations, reasons for caution: The study was nationwide questionnaire survey to investigate the current clinical status of adenomyosis without control. The survey was a retrospective analysis based on the clinical records of each facility, the diagnosis of adenomyosis was made by the gynecologist of each facility.

Wider implications of the findings: There were no data suggesting that medication or surgery as a pre-treatment for adenomyosis improved the reproductive outcome, and the type of adenomyosis showed any association with the reproductive outcomes. However, a prospective and well-conducted randomized study is required to evaluate the true effect of adenomyosis on fertility outcomes.

Trial registration number: NO.

P-253 Oocytes retrieval difficulties in women with ovarian endometriomas

L. Benaglia[1], A. Busnelli[2], R. Biancardi[3], A.E. Nicolosi[4], F. Filippi[4], E. Somigliana[5]

[1]*Fondazione Ospedale Maggiore Policlinico U.O. Centro Sterilita, Centro Sterilità, Milano, Italy*
[2]*Fondazione IRCSS Ca' Granda Ospedale Maggiore Policlinico, Fertility Unit, MILANO, Italy*
[3]*Fondazione IRCSS Ca' Granda Ospedale Maggiore Policlinico, Infertity Unit, MILANO, Italy*
[4]*Fondazione IRCSS Ca' Granda Ospedale Maggiore Policlinico, Infertility Unit, MILANO, Italy*
[5]*Fondazione IRCSS Ca' Granda Ospedale Maggiore Policlinico - University of Milan, Infertility Unit, MILANO, Italy*

Study question: What is the impact of the presence of ovarian endometriomas on the technique of oocytes retrieval?

Summary answer: The presence of ovarian endometriomas is associated with increased technical difficulties during oocytes retrieval.

What is known already: Considering that ovarian reserve may be injured following surgery for ovarian endometriomas, conservative management has grown in recent years. There is now an increasing conformity that endometriomas, in particular those with a mean diameter below 4 cm, should not be systematically removed before IVF. However, conservative management is not without potential drawbacks and risks. A neglected issue here is the possibility that the presence of these cysts may interfere with oocytes retrieval. In particular, one may hypothesize that the procedure may be more difficult and dangerous.

Study design, size, duration: Prospective cross-sectional study. All women undergoing oocytes retrieval between January and December 2015 in a single institution were recruited. Cases were women with an ultrasound diagnosis of one or more endometriomas. Controls were women without a diagnosis of endometriosis. Women could be included only for their first treatment cycle.

Participants/materials, setting, methods: We recruited 56 women with endometriomas and 227 unaffected controls. Each clinician was requested to complete a questionnaire regarding the technical difficulties encountered during the oocytes retrieval. Moreover, patients were interviewed two weeks after the procedure to assess complications occurring after they were discharged. A binomial distribution model was used to calculate the 95% Confidence Interval (95%CI) of the most relevant proportions.

Main results and the role of chance: The endometrioma had to be transfixed during oocytes retrieval in 8 cases (14%, 95%CI: 7–25%). Follicular fluid contamination with the endometrioma content occurred in 9 cases (16%, 95% CI: 8–27%). The number of retrieved oocytes was significantly inferior in cases compared to controls (5.6 ± 4.4 and 7.2 ± 5.2, respectively), (p = 003). However, the proportion of retrieved oocytes per aspired follicles did not differ. The median (interquartile range) was 61% (40–80%) and 67% (50–87%), respectively (p = 0.31). The procedure of oocytes retrieval was scored as difficult or very difficult in 5 (9%) cases and 8 (4%) controls (p = 0.14). The aspiration of follicles was not complete (some follicles were not punctured because of technical difficulties) in 8 cases (14%) and 10 controls (4%) (p = 0.01). The corresponding Odds Ratio (OR) was 3.6 (95%CI: 1.4–9.6). Finally, four women with endometriomas (7%) and four controls (2%) referred to the hospital during the two weeks period after oocytes retrieval because of pain (p = 0.05), corresponding to an OR of 4.3 (95%CI: 1.0–17.8). None of these cases was diagnosed with clinically relevant complications and all recovered with pain killers. No ovarian abscess occurred (0%, 95%CI: 0–5%).

Limitations, reasons for caution: Personnel was aware of the condition of the patients and study purposes. It cannot thus be totally excluded that differences could have been inflated for some of the outcomes. Type II errors cannot be fully excluded in some outcomes due to the relatively small samples size.

Wider implications of the findings: The presence of ovarian endometriomas exposes women to higher risks. However, the magnitude of the observed differences is modest and we did not observe any clinically demanding complication. Advocating systematic surgery before IVF based on this evidence is thus not justified.

Trial registration number: Not applicable.

P-254 Freeze-all strategy in endometriosis patients – a new indication?

M. Cerrillo Martínez[1], M. Cruz Palomino[2], R. Ferrando[3], J.A. García Velasco[4]

[1]IVI Madrid, Madrid, Spain
[2]IVI Madrid, IVF Lab, Madrid, Spain
[3]Equipo IVI, Equipo IVI, Valencia, Spain
[4]IVI Madrid- Universidad Rey Juan Carlos, Proffesor, Madrid, Spain

Study question: To compare IVF outcome in women with moderate/severe endometriosis undergoing fresh versus subsequent embryo transfer after elective freezing of oocytes/embryos.

Summary answer: A freeze-all strategy does not improve IVF outcome in women with moderate/severe endometriosis.

What is known already: The strategy of freeze-all is gaining popularity among physicians and patients due to the concept of a more natural environment and its implication on endometrial receptivity if embryos are transferred in an unstimulated cycle. This could be of particular interest in women with endometriosis, whose endometrial receptivity is still poorly understood as there is a pro-inflammatory status that could be enhanced by ovarian stimulation. Data of freeze-all strategy in this particular groups of patients is scarce and not clear.

Study design, size, duration: Retrospective analysis conducted in a University-affiliated IVF unit – infertile women undergoing IVF/ICSI between January 2014 and December 2015. Endometriosis was diagnosed either by histologically proven biopsy in those patients who had previous surgery or by published imaging criteria using transvaginal ultrasound.

Participants/materials, setting, methods: Infertile women diagnosed with moderate or severe endometriosis –early stages were not considered- underwent ovarian stimulation for IVF/ICSI. One group of patients underwent fresh embryo transfer in the stimulated cycle whereas the other group opted for elective freezing of oocytes/embryos and embryo transfer was deferred in a subsequent cycle, under hormonal replacement therapy.

Main results and the role of chance: 1674 women were included in the study. Patients received similar doses of gonadotropins (UI), 1805 ± 64 vs. 1745 ± 99, $p = 0.336$ of recombinant FSH and 1310 ± 62 vs, 1158 ± 100, $p = 0.013$ of HP-hMG for fresh and frozen embryo transfer respectively.

Patients who underwent elective freezing showed significant higher estradiol levels compared with the fresh group at the time of triggering (1591 ± 90 vs. 2858 ± 287 pg/mL, $p < 0.001$), higher progesterone levels (0.7 ± 0.1 vs. 1.9 ± 0.5 ng/ml, $p = 0.048$), and more metaphase II oocytes (8.5 ± 0.2 vs 11.4 ± 0.8, $p < 0.001$). Finally, clinical results were significant better with fresh embryo transfer compared with elective freezing for implantation rate (41.7% vs. 34.5%, $p = 0.016$), miscarriage rate (15.8% vs. 20.7%, $p = 0.040$) and ongoing pregnancy rate (38.0% vs. 32.1%, $p = 0.046$).

When we analyzed the data based on whether or not patients had operated on endometriosis prior to initiating the reproductive treatment, we did not find statistical differences in ovarian response parameters or clinical outcomes, although patients with previous ovarian surgery showed lower estradiol levels but differences were non-significant (1800 ± 186 vs. 2081 ± 88 pg/ml, $p = 0.052$).

Limitations, reasons for caution: Since it is a retrospective study, not all pertinent risk factors are likely to have been identified and subsequently recorded. So only association, and not causation, can be inferred from the results. The study design could be improved in a prospective, randomized controlled trial.

Wider implications of the findings: From our study, it does not seem that women with endometriosis may benefit from a freeze-all strategy, as it may not only increase time to pregnancy but also add unnecessary interventions such as oocyte/embryo freezing.

Trial registration number: 1701-MAD-005-JG

P-255 Increased interleukin-6 and interleukin-8 expression via hypoxia-mediated down-regulation of dual specificity phosphatase-2 in endometriosis

M.H. Wu[1], N. Chang[2], K.Y. Hsiao[3], S.C. Lin[3], S.J. Tsai[3]

[1]College of Medicine and Hospital- National Cheng Kung University, Obstetrics and Gynecology, Tainan City, Taiwan R.O.C.
[2]College of Medicine- National Cheng Kung University, Obstetrics and Gynecology, Tainan City, Taiwan R.O.C.
[3]College of Medicine- National Cheng Kung University, Physiology, Tainan City, Taiwan R.O.C.

Study question: How does hypoxia-mediated down-regulation of dual specificity phosphatase-2 (DUSP2) affect the development of endometriosis?

Summary answer: It demonstrated the angiogenic role of interleukin-8 (IL-8) and the anti-apoptosis function of interleukin-6 (IL-6) in loss-of-DUSP2 endometriotic stromal cells.

What is known already: DUSP2 is down-regulated in endometriotic stromal cells in a hypoxia-dependent manner. Down-regulation of DUSP2 may contribute to the pathological process of endometriosis.

Study design, size, duration: This study recruited 20 patients of reproductive age with endometriosis treated with laparoscopy at the University Hospital. In addition, a transplant-induced mouse model of endometriosis using 13 mice in a 28-day treatment was also included.

Participants/materials, setting, methods: Eutopic endometrial and ectopic endometriotic stromal cells from patients with endometriosis were isolated for primary culture and for various experimental treatments. The microarray analysis in DUSP2-overexpressed cells was aimed to identify genes regulated by DUSP2 in endometriosis. Molecular and cellular techniques were employed to assess effects of hypoxia-mediated DUSP2 downregulation, including quantitative RT-PCR, promoter activity assay, Western blot, tube formation assay, proliferation assay. The transplant-induced mouse model was used to elucidate the angiogenic function.

Main results and the role of chance: Quantitative RT-PCR results showed that levels of IL-6 and IL-8 were elevated in endometriotic stromal cells than that in eutopic stromal cells, which is inversely correlated with the expression of DUSP2. The increased levels of IL-6 and IL-8 were recapitulated by hypoxic treatment or knockdown of DUSP2 in eutopic stromal cells. Treatment with IL-8 receptor inhibitor significantly blocked the tube formation of human umbilical vein endothelial cells induced by conditioned medium collected from hypoxia-treated stromal cells, demonstrating the critical role of IL-8 in angiogenesis. Nevertheless, DUSP2-induced IL-6 induced the phosphorylation of signal transducer and activator of transcription 3 (STAT3) in eutopic stromal cells, which promoted cell proliferation and protected eutopic stromal cells from apoptosis.

Limitations, reasons for caution: This study was conducted in primary human cell cultures and a mouse model, which may not fully reflect the in vivo situation.

Wider implications of the findings: Results from this study demonstrate that loss-of-DUSP2 in endometriotic stromal cells causes the upregulation of IL-6 and IL-8, which ultimately results in increased angiogenic capacity, cell survival and cell proliferation.

It suggests an alternative mechanism via hypoxia which may enhance the development of endometriosis.

Trial registration number: nil.

P-256 Vitamin D and endometriosis: facts or fancies

L. Buggio, E. Somigliana, G. Barbara, P. Vercellini

Fondazione Istituto di Ricovero e Cura a Carattere Scientifico Ca' Granda Ospedale Maggiore Policlinico- Via Commenda- 12— 20122 Milan- Italy, Department of Clinical Sciences and Community Health- Università degli Studi- Milan, Milan, Italy

Study question: Is there any difference in serum 25-hydroxyvitamin-D_3 [25(OH)D] between women with and without endometriosis?

Summary answer: Serum levels of 25(OH)D do not differ between women with and without endometriosis.

What is known already: A growing amount of evidence suggests a potential role of vitamin D in the pathogenesis and progression of numerous diseases, including gynecological ones, due to its immune-modulatory, anti-proliferative and anti-inflammatory properties. In addition, vitamin D receptor is expressed in ovarian tissue, endometrium and fallopian epithelial cells. In the last decade, both molecular and animal studies supported a possible role of vitamin D in the pathogenesis of endometriosis. However, studies investigating serum 25(OH)D (the form of the vitamin D reflecting human body reserve) in affected women are scanty and inconsistent.

Study design, size, duration: Case-control study recruiting Caucasian Italian women with endometriosis between 2014–2016. Controls were asymptomatic

women referring for periodical gynecological care and without a previous diagnosis of endometriosis. They were matched to cases for age, parity and study period. Exclusion criteria were a recent significant sun exposure, assumption of supplementary vitamin D, a diagnosis of uterine fibroids, unexplained infertility or multiple sclerosis and a history of cancer. Recruitment was limited to the autumn and winter seasons.

Participants/materials, setting, methods: 282 women with endometriosis ($n = 113$ with deep endometriosis (DIE), and $n = 169$ with ovarian endometriomas) and 282 controls were enrolled. The diagnosis of endometriosis was based on standard histologic criteria and, in case of rectovaginal forms, on vaginal and rectal examination, presence of visible endometriotic lesions, transvaginal and transrectal ultrasonography, and biopsy of the posterior fornix. Vitamin D insufficiency and deficiency corresponded to serum levels of 25(OH)D < 20 and < 10 ng/ml, respectively.

Main results and the role of chance: The mean $\pm$ SD serum 25(OH)D in women with and without endometriosis was 18.9 ± 7.1 and 18.1 ± 7.3 ng/ml, respectively ($p = 0.18$). The number (%) of women with vitamin D insufficiency was 170 (60%) and 185 (66%), respectively ($p = 0.22$). The number (%) of women with vitamin D deficiency was 34 (12%) and 38 (13%), respectively ($p = 0.70$). Moreover, no statistical difference was identified when comparing the two endometriosis sub-groups: the mean $\pm$ SD serum 25(OH)D was 19.0 ± 7.0 ng/ml in women with DIE and 18.8 ± 7.2 ng/ml in those with ovarian endometriosis ($p = 0.20$). The number (%) of women with vitamin D insufficiency was 68 (60%) in DIE and 103 (61%) in ovarian endometriosis group ($p = 0.90$). The number (%) of women with vitamin D deficiency was 13 (12%) in DIE and 21 (12%) in ovarian endometriosis group ($p = 0.85$).

Limitations, reasons for caution: Vitamin D status is fluctuating and can be influenced by several external factors such as seasonality, sun exposure, age, parity, diet and BMI. Restriction of the study period to autumn-winter and the strict selection criteria adopted should have reduced the possible impact of confounders but could not completely eliminate them.

Wider implications of the findings: Our findings do not support a crucial role of vitamin D deficiency in the pathogenesis of endometriosis. Systematic testing and supplementation with vitamin D products with the objective of preventing and treating endometriosis seems unsubstantiated.

Trial registration number: not applicable.

P-257 Comparison of oocyte quality in IVF/ICSI cycles between patients with histologically proven endometriosis and patients where endometriosis has been excluded by laparoscopy

R. Dittrich, I. Hoffmann, M.W. Beckmann, L. Lotz

Erlangen University Hospital- Friedrich-Alexander University of Erlangen-Nuremberg, Obstetrics and Gynecology, Erlangen, Germany

Study question: Does endometriosis affect oocyte quality? Are oocytes of endometrioses patients different in quality and appearance compared to oocytes of patients without endometriosis?

Summary answer: In operated patients with histologically proven endometriosis, lower-quality oocytes are present. Endometrioma surgically treated before IVF/ICSI has no impact on number and quality of oocytes.

What is known already: Endometriosis, a highly prevalent gynecological disease is often associated with infertility. However, no consensus has been established about this interrelation, and the possible mechanisms involved have not been completely elucidated. Controversial studies have suggested that impaired oocyte quality may be involved in the pathogenesis of endometriosis-related infertility. Oxidative stress events associated with alterations in the peritoneal, serum or follicular microenvironments might result in poor oocyte quality and compromise the reproductive potential. Up to now, no study has evaluated the effect of oocyte quality with a zygote score from infertile women with endometriosis in comparison to women excluded endometriosis.

Study design, size, duration: In this experimental study, 413 zygotes from 39 women with histologically proven endometriosis were examined. 22 of them had mild and 17 severe endometrioses graded according to the revised American Society for Reproductive Medicine guidelines of 1997. 13 had additional surgery of endometrioma. Controls were 309 zygotes from 37 women,

where endometriosis has been excluded by laparoscopy and who were matched to cases by age and type of cycle.

Participants/materials, setting, methods: IVF and ICSI procedures were carried out using standard protocols. The morphology of the zygotes was rated on using an inverted microscope at magnification of ×400 including size, number and alignment of pronuclei and nucleoli, cytoplasmic halo effect, the presence of vacuoles and granularity of ooplasm. This established PN-scoring system allows selection of those zygotes with favourable developmental potential for further embryo culture. Serum total protein and albumin were measured out of the follicular fluids.

Main results and the role of chance: There were no significant differences in the number of retrieved oocytes between patients with endometriosis and the control group (8.4 ± 5.0 vs. 10.4 ± 9.9). However patients with endometriosis had a lower quality of zygote, showing significantly higher mean zygote scores (18.1 ± 2.3 vs. 16.8 ± 1.8, $p = 0,002$) with often strong cytoplasmic vacuolization and an extreme or no halo effect. Comparison between severe endometriosis and mild endometriosis revealed a significantly lower rate of the mean number of mature oocytes in patients with severe endometriosis (12.9 ± 11.7 vs. 6.5 ± 5.4, $p = 0,019$). No difference was observed with regard to the mean zygote number. Ovarian responsiveness and oocyte quality did not significantly differ between patients with a history of laparoscopic excision of endometriom and patients without. Moreover, there was no difference in the serum total protein and albumin in the follicular fluid between patients with endometriosis and endometrioma and the control group.

Limitations, reasons for caution: This study had a small sample size and thus further properly designed studies using a large cohort of patients are needed to confirm these results. Also, we cannot exclude that our group of infertile women present associated other causes of infertility.

Wider implications of the findings: Endometriosis patients, in particular those with severe endometriosis, present a lower ovarian responsiveness and quality of oocytes. Further studies are necessary to understand mechanisms of endometriosis-associated infertility to improve the chances of a successful IVF/ICSI in endometriosis patients.

Trial registration number: None.

P-258 The incidence of polycystic ovarian syndrome is not decreased in women suffering from endometriosis

C. Tran[1], M. Bourdon[2], P. Santulli[2], C. Maignien[2], V. Gayet[2], L. Marcellin[2], J. Gonnot[2], C. Cervantes[2], V. Blanchet[2], C. Chapron[2], D. De Ziegler[2]

[1]*Cochin University Hospital- Faculty of Medicine- Paris- France, Gynecology and Obstetrics II and Reproductive Medicine Professor Chapron, paris, France*
[2]*Cochin University Hospital- Faculty of Medicine- Paris- France., Gynecology and Obstetrics II and Reproductive Medicine Professor Chapron, paris, France*

Study question: To determine whether there is a reduced incidence of polycystic ovarian syndrome (PCOS) in endometriosis – an ovulation associated disorder.

Summary answer: The incidence of PCOS is comparable in women with endometriosis and non-affected controls. In addition, no differences were observed according to the endometriosis phenotype.

What is known already: Endometriosis is an enigmatic disorder of unknown origin affecting up to 10% of women of reproductive age and 40–50% of infertile women. PCOS is the most common ovulatory disorder encountered in young women, affecting 5–10% of women. No information currently exists on the incidence of PCOS in endometriosis women. Because endometriosis appears fueled by ovulation, we queried whether due to its oligo-anovulation feature, PCOS might be rarer in endometriosis.

Study design, size, duration: This cross-sectional study, carried out in a tertiary care university-based clinic, used data prospectively collected in non-pregnant < 42-year-old patients who were surgically explored for a benign gynecological condition between 2004 and 2016. For each patient, a structured questionnaire was completed by the surgeon before surgery and AMH levels were measured in serum samples during the previous month.

Participants/materials, setting, methods: Two groups were compared: a group made up of women with histologically proven endometriosis and no prior

endometriosis surgery (Endometriosis group) and a control group having no endometriosis.

Endometriosis women were phenotyped according to the surgical classification of endometriosis in superficial endometriosis (SUP), endometrioma (OMA) and deep endometriosis (DIE). PCOS in this study was arbitrarily defined as AMH > 4.9 ng/ml (surrogate for multi-cystic ovaries) associated with oligo-anovulation.

Main results and the role of chance: During the study period, 2607 women had surgery of whom 2465 signed the informed consent. Serum AMH was available in 991 of them. After thorough surgical examination of the abdomino-pelvic cavity, 354 women were allocated to the endometriosis group (superficial endometriosis (n = 66), endometrioma (n = 113) and deep endometriosis (n = 175)) and 474 non-affected women constituted the controls.

Mean serum AMH was not different in endometriosis and controls, at 3.83 ± 3.12 and 4.10 ± 3.49 ng/mL, p = 0.506, respectively. Likewise, the frequency of oligo-anovulation was not different with 53 cases (15%) in endometriosis and 53 (11.2%) in controls (p = 0.106).

The incidence of PCOS defined as AMH > 4.9 ng/mL associated with oligo-anovulation was not different in endometriosis and controls, with 26(7.3%) and 31(6.5%), p = 0.651, respectively. In endometriosis women, the incidence of PCOS was comparable in all 3 endometriosis phenotypes with 7(10.6%), 6 (5.3%) and 17 (7.4%) cases (p = 0.566), for SUP, OMA, DIE, respectively.

Additional analyses also showed no differences between endometriosis and controls when different AMH cuts-off of 4.2 ng/mL and 5.6 ng/mL are taken.

Limitations, reasons for caution: PCOS defined by the Rotterdam consensus takes the antral follicle count (AFC) as one of the diagnostic criteria. For our study, we used an AMH cut-off as surrogate for AFC in the diagnosis of PCOS. Moreover, androgen excess (clinical or biological) was not taken into account.

Wider implications of the findings: This study indicates that the presence of PCOS should not lessen our efforts to diagnose endometriosis on the wrongful assumption that this association might be rare.

Trial registration number: NA.

P-259   Endometrioma Related Reduced Ovarian Reserve: Preliminary Results of the ERROR Study

I. Kasapoglu, A. Orhan, O. Uyanıklar, G. Uncu

Uludag University, Obstetrics and Gynecology, Bursa, Turkey

Study question: Do the existence of endometriomas are related with diminished ovarian reserve and naturally induce ovarian damage as evaluated by consecutive serum anti-Müllerian hormone (AMH) levels?

Summary answer: Endometriomas cause a significant reduction in consecutive serum AMH levels, assessed in 6 to 8 months interval. Decline was even more highlighted for bilateral endometriomas.

What is known already: It is controversial whether existence of endometrioma itself affects ovarian reserve. There has been no prior data evalauting followed-up ovarian reserve markes in a cohort of endometrioma patients. Previous studies indirectly evaluated ovarian reserve in endometrioma patients by response to ovarian stimulation in IVF cycles. Due to lack of sufficient knowledge, we aimed to determine effect of endometriomas on ovarian reserve by consecutive serum AMH levels, in the same patient cohort with endometriomas.

Study design, size, duration: A prospective cohort study including 60 women of reproductive age who had an ultrasonographic diagnosis of endometrioma and age matched women, without diagnosis of ovarian pathology as the healthy control group.

Participants/materials, setting, methods: Women who had diagnosis of endometrioma ≥3 cm and who followed up for 6–8 months period, without surgical or medical intervention which could affect ovarian reserve. Serum samples for AMH levels were examined at the first visit. After follow up period, control AMH levels were examined for comparison. Same assessments done for the healthy control group. Statistical analyses were performed as correlation analyses to detect factors of endometrioma related alteration in ovarian reserve.

Main results and the role of chance: From 60 women with endometrioma, 39 (65 %) had unilateral and 21 (35 %) had bilateral endometriomas, with a median diameter of 6 cm (3 – 8). Overall serum AMH values were significantly decreased after 6–8 months follow up period, compared to initial, in endometrioma patients (3.6 ± 3.2 ng/ml versus 3.08 ± 2.6 ng/ml, p = 0.004). Acording to laterality; decline in serum AMH levels was more remarkable for bilateral endometrioma patients (4.1 ± 3.4 versus 2.9 ± 2.1, p = 0.016) than unilateral endometrioma patients.

Limitations, reasons for caution: As preliminary results of our study, because of ongoing patient recruitment, the absence of control groups' (defined as non-endometiroma group) consecutive AMH levels results prevents precision of the comment for the endometrioma related decline in ovarian reserve.

Wider implications of the findings: Our findings suggest that existence of endometrioma can be related with diminished ovarian reserve. The present study is the first to show that endometriomas themself induces ovarian damage in naturally. However, it should also be acknowledged that additional studies are required to conclude definitive results for the prominent issue.

Trial registration number: NCT02438735.

P-260   Metabolomics analysis of follicular fluid in women with ovarian endometriosis undergoing in vitro fertilization

A. Karaer[1], G. Tuncay[1], A. Mumcu[2], B. Dogan[3]

[1]*Inonu University- School of Medicine, Division of Reproductive Endocrinology and Infertility- Department of Obstetrics and Gynecology, Malatya, Turkey*
[2]*Scientific and Technological Research Center- Inonu University, Laboratory of NMR, Malatya, Turkey*
[3]*Inonu University- School of Engineering, Department of Biomedical Engineering, Malatya, Turkey*

Study question: Is there any difference between the follicular fluid metabolomics profile of women with ovarian endometriosis and controls when undergoing in vitro fertilization

Summary answer: Follicular fluid metabolomics profile has altered in infertile women with ovarian endometriosis

What is known already: Previous studies have shown alterations in the content of follicular fluid from women with endometriosis. However, to date no study has investigated the metabolomics of follicular fluid from infertile women with endometriosis.

Study design, size, duration: This study was conducted between January 2015- May 2016. Twelve (12) women with ovarian endometriosis (age < 40 and BMI < 30 kg/m^2) and 12 age-BMI matched controls (women with infertility as a result of pure male factor) who underwent ovarian stimulation for intracytoplasmic sperm injection enrolled in this study.

Participants/materials, setting, methods: Follicular fluid samples were collected from both of the groups at the time of oocyte retrieval for ICSI. Next, ^{1}H NMR spectroscopy of the collected follicular fluids was performed. Metabolic compositions of follicular fluids were then compared with the help of univariate and multivariate statistical analysis of NMR data.

Main results and the role of chance: Univariate and multivariate statistical analysis of NMR data showed that, metabolomics profiles of follicular fluids obtained from the women with ovarian endometriosis were distinctly different from the control group.

With the univariate statistical analysis, it is found that follicular fluid of women with endometrioma contain higher levels of lactate (2.75 mM vs. 1.6 mM, p = 0.05, respectively); β-glucose (1.25 mM vs 0.83 mM, p = 0.03, respectively); pyruvate (0.19 mM vs. 0.14 mM, p = 0.03, respectively) and valine (0.17 mM vs. 0.12 mM, p = 0.02 respectively) than controls.

Limitations, reasons for caution: This study has a small sample size. An investigation with a larger group of patients would certainly enhance the study.

Wider implications of the findings: This study provides a new perspective on the etiopathogenic mechanism of infertility related to ovarian endometrioma. Identifying and understanding the underlying molecular mechanism responsible for endometrioma-associated infertility provide novel diagnostic and therapeutic approaches for endometriosis related infertility.

Trial registration number: None.

P-261 Prognostic markers in women with primary idiopathic infertility

R. Rizzo[1], G. Lo Monte[2], D. Bortolotti[3], V. Gentili[3], R. Capucci[4], P. Greco[5], D. Di Luca[3], R. Marci[6]

[1]University Of Ferrara, Ferrara, Italy
[2]Hospital of Bruneck, Center of Reproductive Medicine and Cryoconservation of Gametes, Bruneck, Italy
[3]University of Ferrara, Department of Medical Sciences- Section of Microbiology and Medical Genetics, Ferrara, Italy
[4]University of Ferrara, Department of Morphology- Surgery and Experimental Medicine - Section of Obstetrics and Gynecology, Ferrara, Italy
[5]University of Ferrara, Department of Morphology- Surgery and Experimental Medicine - Section of Obstetrics and Gynecology, Ferrara, Italy
[6]University of Geneve, School of Medicine, Geneve, Switzerland

Study question: Endometrial Natural killer cells and soluble molecules in the uterine flushing of idiopathic primary infertile women can be considred as potential "co- factors"of female infertility?

Summary answer: Endometrial NK cells, molecular components (HLA-G, HLA-E, cytokines) and viral infections create an unfavorable condition for the embryo implantation in primary idiopathic infertile women.

What is known already: A coordinated complex of biochemical and structural events is responsible for the so-called "window of uterine receptivity", during the mid-luteal phase of each menstrual cycle. It is believed that the impairment of endometrial receptivity can be a major cause of primary idiopathic infertility, a phenomenon that occurs with the failure of implantation. The reduction of endometrial Natural killer cell frequency, the presence of a herpesvirus concurrent viremia and changes in the expression of Human leukocyte antigen (HLA)-G and HLA-E molecules,Th17Th2/Th17 cytokines and leukemia inhibitory factor (LIF) have been associated by some authors to the "sterility" condition.

Study design, size, duration: The project has enrolled 103 women sudivided into 67 primary infertile and 36 secondary infertile women, during two years recruitment. Forty control women with proven fertility were also enrolled. Uterine flushing samples were collected and stored as required by the study protocol.

Participants/materials, setting, methods: This is a prospective observational case-control study. The samples were collected by the OU Gynecology (University of Ferrara) and the Center of Reproductive Medicine (Hospital of Bruneck) and were analyzed as follow: Analysis of NK cells: flow cytometry with anti-CD56, CD16, CD9, CD49a, KIRs, CD94, CD107a

Herpesvirus (HSV-1,-2, EBV, CMV, HHV-6, HHV-7, VZV, HHV-8) DNA detection: PCR

Analysis sHLA-G: ELISA (MEM-G9 and anti-beta2-microglobulin HRP)

Analysis sHLA-E: ELISA (anti-HLA-E (3D12) and anti-beta2-microglobulin HRP)

Main results and the role of chance: The analysis of NK cells as a prognostic marker for primary idiopathic infertility has led to the identification of an endometrial NK phenotype (CD56bright CD16-) which has lower frequencies in patients with primary infertility (2.8% vs 12%, p < 0.0001). These results suggest a possible implication of eNK cells in primary idiopathic infertile condition. The infection with HHV-6 A was detected in 40% of women with primary infertility and correlated with a decreased percentage of eNK CD56posCD16neg cells (6.3% vs 18.9%; p = 0.001), suggesting a role of this infection in the endometrial immunological status. We observed average levels of sHLA-G and sHLA-E significantly lower (p = 0.001) in uterine flushings of women with primary idiopathic infertility, who also have higher levels of IFN-gamma, IL-1b and IL-6 (p = 0.001).

Limitations, reasons for caution: The main limitation of this project is the number of enrolled subjects. To confim these data it will be necessary to validate them in a new cohort of subjects.

Wider implications of the findings: Although our data do not lead to a definitive solution to the idiopathic infertile condition, they sustain the implication of immunological and microbiological mechanisms, suggesting that this is probably the correct way to go to reach the solution of these healthcare problem.

Trial registration number: NA.

P-262 EFI or r-AFS: the non-IVF-ET pregnancy in endometriosis-associated infertility

W. Zhili, M. Tang

Women's Hospital Zhejiang University of Medicine, division of reproductive endocrinology andinfertility, Hangzhou, China

Study question: To discuss the predictive value of endometriosis fertility index and r-AFS score to the pregnancy outcome in endometriosis-associated infertility after laparoscopic surgery.

Summary answer: The EFI has clinical guiding significance for the pregnancy outcome of endometriosis-associated infertility after laparoscopic surgery while r-AFS score doesn't have.

What is known already: Endometriosis (EMT) is a disease associated with infertility. The current EMT staging criteria is revised American Fertility Society (r-AFS) in 1996.The r-AFS have large predictive value of postoperative recurrence, but the predictive value of postoperative pregnancy outcome is insufficient. In 2010, Adamson and Pasta proposed endometriosis fertility index (EFI) as a new stage standard of endometriosis. The standard is based on total historical factors and total surgical factors, including age, years infertile, prior pregnancy, AFS endometriosis score, AFS total score, and puts forward the least function score (LF) to predict postoperative pregnancy rate.

Study design, size, duration: A retrospective cohort study including 516 patients with infertility and diagnosed endometriosis after laparoscopic surgery from January 1st 2010 to June 30th 2014. And 87.40% of the patients got followed up.

Participants/materials, setting, methods: We followed-up all patients through outpatient medical records and telephone after the operation, collected the condition about postoperative pregnancy including natural pregnancy and artificial insemination pregnancy from after operation, till the longest to 3 years after operation. Then the non IVF-ET pregnancy rate were compared among 9-10 EFI points, 7-8 points, 4–6 points and 0–3 points patients, and between mild group with stage I-II and severe group with stage III-IV according to r-AFS staging.

Main results and the role of chance: The non-IVF-ET pregnancy rate showed a downward trend with EFI (P < 0.05) in 6months, 12months, 18months, 24months, 36months after laparoscopic surgery (P < 0.05); and compared in pairs, the non-IVF-ET pregnancy rate showed significant difference between 4–6 score group and 9-10 score group or 7-8 score group (P < 0.05), but no significant difference between 9-10 score group and 7-8 score group (P > 0.05) in each period. What's more, the non-IVF-ET pregnancy rate had no significant difference between I-II and III-IV r-AFS score (P > 0.05).

Limitations, reasons for caution: The couples who suffered endometriosis-associated infertility might not try to get pregnant actively, and turned to get IVF in three years, even though they would succeed if they kept trying.That may infect the non-IVF-ET pregnancy rate.

Wider implications of the findings: Our reach verified previous literature in larger number of subjects and different periods of time from 6months, 12months, 18months, 24months till 36months after surgery.

Trial registration number: none.

P-263 Evaluation of an experimental mouse model of endometriosis, Role of Estrus cycle and transplantation period

K. Kiani[1], M. Movahedin[2], H. Malekafzali[3], S.N. Sadati[4], A. Moini[5], R. Aflatoonian[6], S.N. Ostad[7]

[6]Royan Institute for Reproductive Biomedicine- ACECR, Department of Endocrinology and Female Infertility- Reproductive Biomedicine Research Center-, Teharn, Iran
[7]Tehran University of Medical Sciences-, Department of Toxicology & Pharmacology- Faculty of Pharmacy-, Teharn, Iran

Study question: influence of transplantation period and estrus cycle of uterine tissue samples sutured to the abdominal wall on the establishment and maintenance of endometriotic lesions in an autologous endometriosis mouse model.

Summary answer: the endometriotic lesions at metestrus/diestrus phase after six to eight weeks of implantation are more likely to develop relative to other cycles or periods.

What is known already: In the majority of previous animal studies, either the endometrium or uterine tissues are implanted at proestrus phase and in some other studies authors have not mentioned the estrus cycle. Furthermore, there are different methods for inducing the endometriosis in rodents, including homologous or heterologous methods. These models have different limitations such as the lack of consistency with respect to estrogen supplementation, different types of tissue used for implantation, low and variable (30–50%) or unreported peritoneal implant take rates as well as model take rate.

Study design, size, duration: experimental design

Participants/materials, setting, methods: An autologous endometriosis mouse model was induced in 52 female *NMRI* mice by suturing the uterine tissue samples of the left uterine horn to the right and left sides of the peritoneum in the abdominal wall. To induce the endometriosis model, some mice were transplanted at proestrus or estrus cycles and others at metestrus or diestrus cycles. The mice were also randomly divided into four groups based on transplantation duration

Main results and the role of chance: The mice were also randomly divided into four groups based on transplantation duration and were sacrificed as follows: group 1 (two weeks, n = 13), group 2 (four weeks, n = 13), group 3 (six weeks, n = 13), and group 4 (eight weeks, n = 13). Six and eight weeks after transplantation, the incidence rate was 100% at metestrus or diestrus mice. However, in proestrus/estrus mice, the highest model take rate was observed after four and six weeks of transplantation (71.4%) and decreased to (42.9%) after eight weeks of transplantation. The expression of Caspase3, ki67, and CD31 proteins was different among four time transplantation periods. These results show that the endometriotic lesions best develop at the metestrus/diestrus phase and after six to eight weeks of transplantation.

Limitations, reasons for caution: The NMRI strain was chosen because of its low price and easily handling. Only female mice were suitable for inducing of endometriosis model.

Wider implications of the findings: In conclusion, these results show that the estrous cycle and implantation period affect the change of ectopic endometriosis. It seems that the endometriotic lesions at metestrus/diestrus phase after six to eight weeks of implantation are more likely to develop relative to other cycles or periods.

Trial registration number: —.

P-264   Long term pretreatment with GnRH agonist before standard GnRH agonist protocol for adenomyosis in IVF/ICSI fresh embryo transfer cycles

M.H. Chen, L. Luo, X. Zhang, J. Gao, W. Qiong, C. Zhou

The First Affiliated Hospital of Sun Yat-sen University, Reproductive medicine center, Guangzhou, China

Study question: Can long term pretreatment with GnRH agonist before standard GnRH agonist protocol improve pregnancy outcome of IVF/ICSI fresh embryo transfer cycles in adenomyosis?

Summary answer: Uterine size on hCG day, but not control ovarian stimulation protocol is associated with live birth rate of IVF/ICSI fresh embryo transfer cycles in adenomyosis.

What is known already: Although adverse effect of adenomyosis on implantation in IVF is controversial, present evidences indicate that adenomyosis is associated with higher miscarriage rate in IVF. GnRH agonist can cause hypoestrogenism therefore reduce uterine size. Long term use of GnRH agonist is shown to improve pregnancy outcomes in women with adenomyosis in frozen embryo transfer cycle. Standard GnRH agonist protocol can cause supra-physical elevation of estrogen level and enlargement of uterus, therefore may counteract with shrinkage effect of long term pretreatment with GnRH agonist on uterus in IVF/ICSI fresh embryo transfer cycles.

Study design, size, duration: This is a retrospective cohort study; patients were categorized into two groups (standard GnRH agonist protocol with or without long term pretreatment with GnRH agonist); Fresh embryo transfer live birth rate (LBR) were evaluated by group. Binary logistic regression was used to assess the association between control ovarian stimulation (COH) protocol and LBR after adjusting for confounding factors that were identified as significant in the univariate analysis.

Participants/materials, setting, methods: A total of 95 women diagnosed as adenomyosis who underwent standard GnRH agonist protocol with or without long term pretreatment with GnRH agonist in IVF/ICSI fresh embryo transfer cycles at our hospital from 2012 to 2015 were identified and reviewed. Associations between COH protocol and LBR were analyzed.

Main results and the role of chance: There was no significant difference in the clinical pregnancy rate and live birth rate in two groups as well as the other baseline characteristics as female age, insemination method, basal FSH, progesterone level and uterine anteroposterior diameter on hCG day, number and type of transferred embryo, et al. The LBR is associated with uterine anteroposterior diameter on hCG day (OR 0.565, 95% CI 0.329–0.970, P = 0.038), but not COH protocol (long term pretreatment group OR 2.707, 95% CI 0.662–11.069, P = 0.166)after adjusted for female age, basal FSH, complication with endometriosis, progesterone level on hCG day, number of retrieved oocytes, metaphase II oocytes, normally fertilized oocytes, transferrable embryo, transferred embryo, high quality embryo and type of embryo.

Limitations, reasons for caution: As a retrospective study, our analysis depends on previously recorded data; therefore, certain variables such as serum CA125 level could not be collected.

Wider implications of the findings: COH with long term pretreatment with GnRH agonist may benefit pregnancy outcome of IVF/ICSI fresh embryo transfer in adenomyosis when uterine size on hCG day is controlled and suitable for embryo transfer. However, suitable uterine size for embryo transfer is still to be explored.

Trial registration number: none.

P-265   Pain activations in patients with Dysmenorrhea – An fMRI Study

B. Boettcher[1], C. Siedentopf[2,7], R. Steiger[2,7], M. Verius[3], D. Riedl[4], A. Ischebeck[5], J. Schmid[6], S. Elsenbruch[6], L. Wildt[1], B. Toth[1]

[1]Department of Gynecological Endocrinology and Reproductive Medicine, Innsbruck Medical University, Innsbruck, Austria
[2]Department of Neuroradiology, Innsbruck Medical University, Innsbruck, Austria
[3]Department of Radiology, Innsbruck Medical University, Innsbruck, Österreich
[4]Department of Psychological Medicine, Medical University Innsbruck, Innsbruck, Österreich
[5]Institut of Psychology, Karl- Franzens- University Graz, Graz, Österreich
[6]Institute of Medical Psychology & Behavioral Immunobiology, University Hospital Essen, Essen, Germany
[7]Neuroimaging Research Core Facility, Medizinische Universität Innsbruck, Innsbruck, Österreich

Study question: Patients with dysmenorrhea/ endometriosis have an altered neural processing of interoceptive pain.

Summary answer: Patients with dysmenorrhea/ endometriosis did not show altered cerebral processing of interoceptive pain stimuli compared to healthy controls.

What is known already: Brain imaging studies have shown certain characteristics in dysmenorrhea patients such as structural alterations in gray matter volume or an abnormal cerebral metabolism. Former studies especially in patients with irritable bowel syndrome- another chronic pelvic pain condition- revealed altered cerebral processing of interoceptive pain stimuli. In dysmenorrhea patients no studies with visceral pain stimuli in combination with fMRI (functional magnetic resonance imaging) exist.

Study design, size, duration: This case-control study was designed with female patients suffering from dysmenorrhea/ endometriosis in comparison to a healthy control group. On the first visit informed consent was given and inclusion and exclusion criteria were analyzed. On the second visit within day 1–5 of the menstrual cycle the fMRI measurement with an interoceptive pain stimulus was performed. The aim was to include 20 subjects in each group over a period of two years.

Participants/materials, setting, methods: 23 female patients with primary/secondary dysmenorrhea and 23 healthy women underwent fMRI measurements in a 3 T scanner (Verio, Siemens) at a university hospital. A visceral pain stimulus was applied by rectal distensions using a MRI-compatible BAROSTAT device. Sub- and suprathreshold pain stimuli (distensions) were applied in a pseudo-randomized paradigm. FMRI data analysis was performed with SPM12 in the framework of the general linear model.

Main results and the role of chance: After excluding 7 patients with motion artefacts and handling errors 19 dysmenorrhea patients and 20 healthy controls were analysed. The contrast of pain vs. baseline and pain vs. no-pain in both groups revealed typical areas involved in pain processing with activations in the insular cortex, prefrontal, orbitofrontal and somatosensory cortices and cingulate cortex (p < 0.05 FEW-corrected). Nevertheless, no significant differences between the groups were found.

Limitations, reasons for caution: Study limitations are the small sample size and a single measurement only. Therefore no comparison between different cycle phases and in the patient group under spontaneous pain and no pain within one person is possible. Possibly other interventional stimuli than rectal are applicable in this patient group.

Wider implications of the findings: As chronic pelvic pain leads to an altered central pain processing cyclic chronic pain might induce other mechanisms of adaption to the pain.

Dysmenorrhea and endometriosis deserve attention as a chronic pain condition as they have an enormous impact on the patients´ daily quality of life.

Trial registration number: AN 4940 321/ 4.16 at Innsbruck Medical University.

P-266   Gene expression of human endometrial L-selectin ligand (LSL) in relation to the phases of the natural menstrual cycle

T.H. Lai[1], F.W. Chang[2], J.J. Lin[3], Q.D. Ling[4]

[1]Cathay General Hospital, REI division- OBGYN, Taipei, Taiwan R.O.C.
[2]Tri-Service General Hospital- National Defense Medical Center, Department of Obstetrics and Gynecology-, Taipei, Taiwan R.O.C.
[3]Cathay General Hospital, Cathay Medical Research Institute, New Taipei City, Taiwan R.O.C.
[4]National Central University, Institute of Systems Biology and Bioinformatics, Taoyuan, Taiwan R.O.C.

Study question: Little information is available on the types of LSL components and gene expression patterns at different phases of the natural cycle in human endometrium.

Summary answer: Five peptide components of LSL were detected: podocalyxin, endomucin, nepmucin, GlyCAM-1, and CD34. Their gene expressions showed differential patterns throughout the natural cycle.

What is known already: LSLs in high endothelial venules of lymph nodes are glycoproteins that serve as addressin for homing and support of lymphocyte extravasation. The ligands include CD34, podocalyxin, GlyCAM-1, endomucin, and nepmucin in mouse. All have mucin-like polypeptide structures with sulfated O-linked glycans. In human, the expression of LSLs is associated with endometrial receptivity. However, there are no studies exploring the gene expression patterns of LSLs in human endometrium throughout the menstrual cycle. It is unclear whether the types of LSL components in human endometrium are the same as that in mouse lymph nodes.

Study design, size, duration: This is a prospective, cross sectional study. We recruited 41 endometrial samples from reproductive-aged women with leiomyoma undergoing hysterectomy from Aug 2008 to July 2009. Eleven from the proliferative phase (days 7 to 14), 9 from the early-secretory phase (days 15 to 19), 10 from the mid-secretory phase (days 20 to 24), and 11 from the late-secretory phase (days ≥ 25). Eleven samples were obtained as controls from menopausal women undergoing vaginal hysterectomy.

Participants/materials, setting, methods: The inclusion criteria of the participants were: (1) age ranging from 35 to 50 years; (2) regular menstrual cycle; (3) body mass index < 28; (4) no hormone therapy at least 2 months before surgery; (5) no known gynecological diseases; (6) no sexually transmitted diseases. Immunohistochemistry and RT-PCR were performed in the study. Nonparametric Kruskal-Wallis one-way analysis of variance with multiple comparisons was performed to examine differences between the phases of the menstrual cycle.

Main results and the role of chance: The mean age and BMI of the patients were not significantly different between phases (P > 0.05). Immunohistochemistry showed that L-selectin ligands were expressed in the luminal and glandular epithelium of the endometrium in all four phases. The MECA-79 intensity of L-selectin ligands varied between phases and was strongly expressed at the early and mid-secretory phases. Interestingly, weak expression of L-selectin ligands was also found in menopausal endometrium.

Five types of L-selectin ligand components were detected in the reproductive and menopausal endometrium by RT-PCR: podocalyxin, endomucin, nepmucin, GlyCAM-1, and CD34. The expression patterns of L-selectin ligand genes revealed variation among the four phases. The relative fold changes of endomucin, nepmucin, and CD34 are higher in the proliferative phase. The relative fold changes in endomucin are significantly different between the proliferative and early-secretory phases (P < 0.05).

The gene expressions of CHST2 and CHST4, which are the key enzymes for the generation of L-selectin ligand epitopes, were steady among the four phases. Estrogen receptor α expression was also relatively stable without significant differences among the four phases. However, the gene expression of progesterone receptor showed a significant, gradual decrease from the proliferative to the late-secretory phase (P < 0.05).

Limitations, reasons for caution: The small number of samples could limit the power of the study. The heterogeneity of the samples could impact the results. Finally, because of ethical considerations, we used the endometrial samples of uteruses with leiomyoma instead of normal uteruses, which could not completely represent the actual natural cycle.

Wider implications of the findings: Five types of L-selectin ligand components were detected in human endometrium: podocalyxin, endomucin, nepmucin, GlyCAM-1, and CD34. The expression patterns of L-selectin ligand genes revealed variation among the four phases. The significant gene expression of endomucin between the proliferative and early-secretory phases might highlight its potential role in endometrial receptivity.

Trial registration number: none.

P-267   In vitro and in vivo synergistic effects of MK2206 and chloroquine combination therapy on endometriosis

S. Matsuzaki[1], C. Darcha[2], M. Canis[1], J.L. Pouly[1]

[1]CHU Clermont-Ferrand, Department of Gynecology, Clermont-Ferrand, France
[2]CHU Clermont-Ferrand, Department of Pathology, Clermont-Ferrand, France

Study question: Is MK2206 (an AKT inhibitor) and chloroquine (anti-malarial, autophagy inhibitor) combination therapy effective treatment in endometriosis?

Summary answer: MK2206 and chloroquine combination therapy significantly decreased the size of endometriotic implants in a xenograft model of endometriosis compared with treatment with either drug alone.

What is known already: We previously showed that the combined treatment with U0126 (a MEK inhibitor) and MK2206 synergistically inhibited cell proliferation of deep endometriotic stromal cells (DES) in vitro. However, cell proliferation of DES after drug discontinuation was high. Our previous findings suggest that MK2206 treatment may induce autophagy, which may inhibit cell death, resulting in cell survival from combined treatment with U0126 and MK2206 and subsequent cell proliferation. A recent study showed that hydroxychloroquine, an autophagy inhibitor, could decrease lesion numbers and disrupt lesion histopathology in a mouse model of endometriosis.

Study design, size, duration: A laboratory study. Forty patients (20 with and 20 without endometriosis) of reproductive age with normal menstrual cycles were recruited. A total of 40 nude mice received a single injection of

proliferative endometrial fragments on day 0. Then, mice were randomized into four experimental groups. Each group of mice was given vehicle, chloroquine, MK2206 or chloroquine with MK2206 for 6 days. Treatment was started on day 15 and mice were sacrificed on day 21.

Participants/materials, setting, methods: We evaluated the effects of MK2206 and autophagy inhibition on cell proliferation of DES in vitro. Autophagy was inhibited by knockdown of the Beclin 1 gene, and/or pharmacologic agents (chloroquine, bafilomycin A1 and/or 3-methyalanine) treatment. Clonogenic assay was performed to evaluate the effects of MK2206 and chloroquine on long-term survival of DES. Additionally, the effects of MK2206 and chloroquine treatment on endometriotic implants were evaluated in a xenograft model of endometriosis in immunodeficient nude mice.

Main results and the role of chance: MK2206 and chloroquine synergistically inhibit proliferation of DES in vitro. A combination of MK2206 (9 μM) and chloroquine (50 μM) significantly more inhibited cell proliferation of DES (83.0 % ± 11.0, mean ± SD, p < 0.01) compared with those treated with either drug alone (chloroquine: 17.5 % ± 12.0, MK2206: 26.1 % ± 8.3). Clonogenic assay confirmed that this combined treatment dramatically suppressed long-term cell survival of DES. In a xenograft mouse model, combined treatment with MK2206 and chloroquine significantly decreased the size of endometriotic implants (median size reduction –79.5%, range -51 to -87.1, p < 0.01) compared with those treated with either drug alone. However, treatment with either drug alone did not significantly affect the size of endometriotic implants compared with those treated with vehicle alone. The TUNEL assay demonstrated that endometriotic implants treated with a combination of MK2206 and chloroquine, exhibited a significant increase in apoptotic cells (48.2% ± 12.6, p < 0.0001) when compared with those treated with either drug alone (chloroquine: 4.3 % ± 2.8, MK2206:7.5 % ± 5.8).

Limitations, reasons for caution: The present mouse model of endometriosis does not mimic human endometriosis. In the present mouse model, it is not possible to evaluate whether re-growth of endometriotic implants could occur after drug discontinuation.

Wider implications of the findings: The combination therapy of MK2206 and chloroquine may be effective for treatment in patients with endometriosis.

Trial registration number: N.A.

P-268   Differential epithelial-mesenchymal transition status between types of endometriosis and adenomyosis

H. Masuda[1], M. Furuya[1], T. Maruyama[1], H. Asada[2], H. Katabuchi[3], H. Saya[4], T. Mamoru[1]

[1]Keio University School of Medicine, Obstetrics and Gynecology, Tokyo, Japan
[2]Shin-yurigaoka General Hospital, Department of Obstetrics- Gynecology and Gynecologic Minimally invasive Surgery, Tokyo, Japan
[3]Faculty of Life Sciences- Kumamoto University, Obstetrics and Gynecology, Kumamoto, Japan
[4]Keio University School of Medicine, Division of Gene Regulation- Institute for Advanced Medical Research, Tokyo, Japan

Study question: Is there any difference in epithelial-mesenchymal transition (EMT) status between endometriosis, adenomyosis and normal endometrium?

Summary answer: The results suggested the differential EMT status in each endometriotic lesion and the potential of ZEB1 as an indicator of invasiveness or severity of endometriosis.

What is known already: Although endometriosis is a benign disease, it shares some features with cancers, such as invasiveness and the potential to metastasize. It has been reported that EMT plays a critical role in invasion and subsequent metastasis of cancers. In recent years, several reports suggested that EMT might be involved in the pathogenesis of endometriosis and adenomyosis. However, there is no report about ZEB1 (Zinc finger E-box-binding homeobox 1, an EMT-associated transcriptional factor) expression on endometriosis and adenomyosis, and EMT status have not yet been investigated on each type of endometriosis and adenomyosis.

Study design, size, duration: Ten endometriosis patients and nine adenomyosis patients undergoing laparoscopic excision of lesions were recruited. Twelve control women without endometriosis undergoing surgery for other

benign diseases were also recruited. Excised lesions of endometriosis, adenomyosis and normal endometria were subjected to immunohistochemistry.

Participants/materials, setting, methods: We evaluated the expression of E-cadherin, N-cadherin, vimentin and EMT-related transcriptional factors (Snail and ZEB1) in epithelial cells of various endometriotic lesions, adenomyosis and normal endometria by immunohistochemical analysis on the paraffin sections prepared from all excised lesions. The relationship between ZEB1 expression and serum level of CA125 was also investigated.

Main results and the role of chance: Immunohistochemical scoring revealed that E-cadherin, N-cadherin, Snail, and vimentin were expressed in epithelia of all types of endometriosis and adenomyosis as well as normal endometria. However, most markers were differently expressed between the types of samples. Notably, ZEB1 expression was only expressed in epithelia of endometriosis and adenomyosis, not in normal endometira. Additionally, ZEB1 was more frequently observed in epithelial cells of deep infiltrating endometriosis and adenomyosis than the other types of endometriosis. Furthermore, the patients with high serum CA125 level were more likely to have ZEB1-positive lesions.

Limitations, reasons for caution: The sample size of this study is relatively small.

Wider implications of the findings: We here for the first time demonstrate the differential EMT status, especially ZEB1 expression, in each endometriotic lesion and adenomyosis. The preferential expression of ZEB1 in deep infiltrating endometriosis and adenomyosis raises a possibility that ZEB1 might be a switch to endow endometriosis with invasive properties through EMT.

Trial registration number: Not applicable.

P-269   P450-aromatase pathway is altered in granulosa cells from women with endometriosis

A.M. Sanchez Garcia[1], E. Giacomini[1], A. Alteri[2], E. Papaleo[2], F. De Stefano[2], M. Candiani[2], P. Vigano'[1]

[1]IRCCS San Raffaele Scientific Institute, Reproductive Sciences Laboratory- Division of Genetics and Cell Biology, Milano, Italy
[2]IRCCS San Raffaele Scientific Institute, Obstetrics and Gynecology Unit, Milano, Italy

Study question: To evaluate the molecular mechanisms by which endometriosis can negatively influence growth, steroidogenesis and function of granulosa cells (GCs).

Summary answer: GCs from women with endometriosis show a dysregulation of the steroidogenesis pathway involving P450-aromatase and ERK1/2 signaling pathway potentially affecting oocyte development

What is known already: Main functions of GCs are nurture the oocyte and, via hormonal influence, guide it through the series of events necessary for achieving cytoplasmic and nuclear competence. Previous evidence would indicate that P450-aromatase mRNA expression is lower in GCs from women with endometriosis. This could influence estradiol production and could be the cause of some of the detrimental effects found in the local intrafollicular environment of endometriosis patients. The molecular mechanisms by which endometriosis can negatively influence growth, steroidogenesis and function of GCs are still lacking.

Study design, size, duration: Human GCs were obtained by ultrasound-guided follicle aspiration from women receiving assisted reproduction treatment at Centro Scienze Natalità of San Raffaele Hospital (Milan, Italy). Patients with a laparoscopic diagnosis of endometriosis with stage III-IV endometriosis (n = 28) and women undergoing assisted reproduction procedures for male infertility (control group n = 41) were studied

Participants/materials, setting, methods: GCs were isolated from the follicular fluids after density gradient centrifugation on Ficoll-Paque and removal of contaminating adherent macrophages. The P450-aromatase and 3β-hydroxysteroid dehydrogenase mRNA expression levels of GCs were determined by qPCR. Furthermore, protein levels of phosphorylated ERK1/2 were assessed using *Western Blotting* analysis.

Main results and the role of chance: GCs from women with endometriosis patients had significantly lower transcripts of 3β-hydroxysteroid dehydrogenase and P450-aromatase compared to controls (0.37 ± 0.07 vs 0.76 ± 0.14 relative

units; p = 0.04 and 0.03 ± 0.009 *vs* 0.27 ± 0.06 relative units p = 0.01, respectively); both key enzymes are involved in the estradiol production. Indeed, we found a higher estradiol content in the culture media from GCs of control women compared with those from GCs of women with endometriosis. We focused our study on the P450-aromatase enzyme and found for the first time that not only the enzyme transcript but also the protein content were reduced in GCs from women with endometriosis. Since it has been shown that a sustained activation of ERK1/2 signaling cascade may have an inhibitory effect to the steroidogenesis pathway, we decided to test the activation of this pathway through the analysis of the phosphorylation levels of ERK1/2 in these cells. Phosphorylation levels of ERK1/2 were higher in GCs from women with endometriosis compared to those from controls. In order to analyze whether the up-regulation of phospho-ERK1/2 signaling correlated with the lower expression of P450-aromatase in GCs cells, we *in vitro* treated GCs with the ERK1/2 inhibitor U0126 resulting in an increase of aromatase protein.

Limitations, reasons for caution: Future analyses need to be performed in order to correlate these data with oocyte quality and IVF outcomes. Furthermore, the analysis should be extended to a higher number of cases and controls

Wider implications of the findings: These data suggest a dysregulation of the steroidogenesis pathway in GCs from patients with endometriosis. This alteration may negatively alter the follicular environment underlying an adequate development of the oocyte and may be one of the cause of the worse performance of assisted reproduction procedures in this population.

Trial registration number: n.a.

P-270   IVF in patients with recurrent endometrioma and low ovarian reserve: original treatment technology improves outcomes

I. Gyulmamedova[1], T. Tatarchuk[2], O. Nosenko[3], G. Strelko[4], O. Giulmamedova[5], V. Kucharchuk[6], V. Klymova[7], I. Mogilevkina[7]

[1]Institute of Pediatrics- Obstetrics and Gynecology, Department of Endocrine Gynecology, Kyiv, Ukraine
[2]Institute of Pediatrics- Obstetrics and Gynecology, Department of the Endocrine Gynecology, Kyiv, Ukraine
[3]Odessa National Medical University, Department of Obstetrics and Gynecology N 1, Odessa, Ukraine
[4]"IVMED" clinic, Reproductive department, Kyiv, Ukraine
[5]Institute of Pediatrics- Obstetrics and Gynecology, Department of Endocrine Gynecology, Kyiv, Ukraine
[6]Institute for planning family, Reproductive department, Kyiv, Ukraine
[7]The International Academy of Ecology and Medicine, Reproductive department, Kyiv, Ukraine

Study question: If the original treatment technology of recurrent ovarian endometrioma prior to treatment with ART affects IVF-ICSI outcome in low ovarian reserve patients?

Summary answer: Original treatment technology do not reduce ovarian reserve (OR), increases number of eggs, embryos quantity and quality, IVF-ICSI pregnancy rate with own oocytes.

What is known already: Endometriosis is considered one of the main challenges in the ART. Evidence drawn from studies on oocyte recipient cycles demonstrated worse reproductive outcomes in those who received oocytes from women with endometriosis, suggested that the oocyte quality of women with endometriosis is compromised. Ovarian endometrioma is another challenge. On the one hand, there is no evidence that cystectomy prior to treatment with ART improves pregnancy rates. Moreover, surgery prior to treatment with ART can reduce ovarian reserve especially in the women with previous ovarian surgery. On the other hand, surgery can be needed to improve the accessibility of follicles.

Study design, size, duration: During 2010–2016 thirty eight infertile women with endometriosis and low ovarian reserve due to previous ovarian surgery were admitted to the Reproductive Health Institution for ART treatment with recurrent endometrioma (> 3 cm). Among them, in 17 women laparoscopic cystectomy was done prior to admission for ART (the Control). After informed consent 21 women were enrolled in the study aimed to test effect of original technology for recurrent ovarian endometrioma treatment on ART outcome (the Case).

Participants/materials, setting, methods: There was no difference in mean age (33.11 ± 0.90 vs 33.2 ± 1.07 years old), infertility duration (6.34 ± 0.61 vs 7.41 ± 0.87 years), endometriosis history (6.76 ± 0.58 vs 6.18 ± 0.76 years) between the groups. Original technology included Dienogest for two months prescription with aspiration of endometrioma after desensitization by GnRH agonists. Ovarian reserve tests: AMH, antral follicle count (AFC), tumor markers (CA125; HE4) were studied before and after either laparoscopic surgery or transvaginal echo guide endometrioma

Main results and the role of chance: There were no difference in AFC (4.57 ± 0.32 vs 4.06 ± 0.5) between the Groups before enrolment. No difference was in AMH among the Cases before and after aspiration of the endometrioma (0,63 ± 0.07 vs 0.7 ± 0.13 ng/ml), whereas in the Controls decline was significant (0.74 ± 0.08 vs 0,35 ± 0.07 ng/ml, p < 0.05). Both Groups demonstrated decrease in CA 125 (55.73 ± 4.45 to 36.53 ± 3.47 in the Case and 50.61 ± 3.93 to 29.35 ± 3.8 U/ml in the Control, p < 0.05) after intervention.

Controlled ovarian stimulation was done in long agonists GnRH (0,1) protocol. Duration of stimulation was 12.72 ± 0.3 and 13.18 ± 0.36 days, respectively. Cancelled cycle: 1 in the Case and 6 in the Control. Embryological data: oocytes 4.24 ± 0.87 in the Case and 2.18 ± 0.49 in the Control (p < 0.05); oocytes M2 – 3.32 ± 0,71 and 1.53 ± 0,34 (p < 0,05); zygotes 2PN - 2.68 ± 0.55 and 1.18 ± 0.27 respectively, p < 0,05. Embryos transferred (ET) were 1.87 ± 0.11 and 1.82 ± 0.15. Embryo criopreservation were done to 13 women in the Case and 1 – in the Control. There were 14 pregnancies (66.67%) in the Case and 3 (17.65%) in the Control. Subsequent Cryo ET increased total pregnancy rate in the Case to 71.43% and in Control group 23,53% (p < 0,05).

Limitations, reasons for caution: Because there is no difference in the basic characteristics of the patients, results obtained can be associated with original treatment technology proposed for recurrent ovarian endometrioma. These results are to be treated carefully because patients were not randomly assigned for the treatment.

Wider implications of the findings: Original treatment technology can be considered as the only option for those needed in ART with recurrent ovarian endometrioma and low ovarian reserve to improve the accessibility of follicles and not affect ovarian reserve. Clinical trial is needed to prove our findings.

Trial registration number: Not trial. This study was approved by Ethics Committee of the Reproductive Health Institution.

P-271   Untargeted metabolomics reveals altered metabolite profile in tissue and serum of women with endometriosis

S. Ghosh[1], M. Dutta[2], C. Dutta Ray[3], R. Chattoapdhyay[1], H.S. Sarkar[1], K. Chaudhury[2], B. Chakravarty[1]

[1]Institute of Reproductive Medicine, ART, Calcutta, India
[2]Indian Institute of Technology- Kharagpur, School of Medical Science and Technology, Kharagpur, India
[3]Institute of Post-Graduate Medical Education and Research, Obstetrics and Gynaecology, Kolkata, India

Study question: Does any correlation exist between serum and eutopic endometrial tissue metabolic profile of women with endometriosis?

Summary answer: Our study indicates that there is correlation between the tissue and serum metabolic profile of endometriosis women.

What is known already: Preliminary studies suggest that the serum metabolic profile in endometriosis patients is altered compared to controls.

Study design, size, duration:
[1] H NMR was performed on tissue and serum samples collected from endometriosis and controls over a period of three years.

Participants/materials, setting, methods: Eutopic endometrial tissue and serum samples were collected from two tertiary referral hospitals, Institute of Reproductive Medicine and Institute of Post-Graduate Medical Education and Research, Kolkata, India. The experiments, data analysis and interpretation were performed in the School of Medical Science and Technology, IIT Kharagpur, India. Endometriosis cases (n = 126) with Stage I (n = 20), Stage II

(n = 16), Stage III (n = 45) and Stage IV (n = 45) were recruited. Fifty seven cases undergoing interval tubectomy were used as controls.

Main results and the role of chance: Several metabolites such as proline, alanine, leucine, lysine, glucose, phenylalanine, glutamine, glutamate, acetate, tyrosine, formate, taurine, myo-inositol and glycine were found to be characteristic for different stages of endometriosis. While alanine ($p < 0.0001$), lysine ($p = 0.0017$), phenylalanine ($p = 0.005$) and leucine ($p = 0.01$) showed negative correlation, proline (0.001) showed positive correlation between serum and tissue levels of early stage endometriosis patients.

Limitations, reasons for caution: The present study focuses only on the secretary phase. For robust assessment of these markers, the candidate metabolites' expression in the proliferative phase also needs investigation.

Wider implications of the findings: Since the current gold standard for diagnosis of endometriosis is a surgical procedure, laparoscopy, identification of a panel of metabolite markers is expected to be useful in early prediction of the disease in a minimally invasive manner.

Trial registration number: Not applicable.

P-272   DNA microarray analysis of gene expression in eutopic endometrium from patients with endometriosis

K.R. Hwang[1], Y.M. Choi[2], S.H. Yoon[3], Y.J. Kim[4]

[1]SNU-SMG Boramae Medical Center, Obstetrics and Gynecology, Seoul, Korea-South
[2]Seoul National University College of Medicine, Obsterics and Gynecology, Seoul, Korea- South
[3]Graduate School of Medicine- Dongguk University, Obstetrics and Gynaecology, Seoul, Korea- South
[4]College of Medicine- Korea University, Obstetrics and Gynaecology, Seoul, Korea-South

Study question: Does endometrial gene expression in late secretory phase endometrium differ between patients with and without endometriosis?

Summary answer: The eutopic endometrium from patients with advanced-stage endometriosis has distinct gene expression profile from eutopic endometrium of control without endometriosis.

What is known already: Endometriosis, a condition in which the uterus lining tissue appears and flourishes outside the uterus, is a progressive disease that causes diverse symptoms such as pelvic pain, menstrual pain, and infertility. However, the exact molecular mechanism of the development of endometriosis has not been elucidated. It has recently been proposed that there are differences between the endometrial tissues of women with endometriosis and those of normal women, and these may be the cause of infertility in these patients.

Study design, size, duration: This was prospective laboratory study. Five patients with laparoscopically proven advanced-stage endometriosis and 5 controls underwent endometrial biopsy in the late secretory phase.

Participants/materials, setting, methods: Analysis of eutopic endometrial gene expression was performed using Affymetrix gene arrays and differentially expressed genes were assigned to gene ontology groups based on overrepresented analysis using DAVID software. Microarray data were obtained for 5 control samples and 3 samples from the patients with endometriosis. However, during Affymetrix GeneChip® analysis, the array data of two patients that may be biological outliers were excluded. Expression patterns of selected five genes were validated by quantitative RT-PCR.

Main results and the role of chance: Four hundred sixty two genes were identified as up-regulated such as matrix metalloproteinase 10 (MMP10), cytochrome P450 family 24 subfamily A polypeptide 1 (CYP24A1), matrix metalloproteinase 3 (MMP3), chemokine (C-C motif) ligand 20 (CCL20), Rho family GTPase 1 (RND1), interleukin 1-beta (IL1B), and insulin-like growth factor binding protein 1 (IGFBP1), while 643 genes were down-regulated in all endometriotic samples. A lot of genes related with metabolic process, cellular ketone metabolic process and ncRNA metabolic processing were included.

Limitations, reasons for caution: The question still remains whether the interactions or differences between genes that show increased or decreased expression is the cause or result of endometriosis, and so studies are required

to compare the genetic expression in each subdivided phase of menstrual cycle and which use more diverse bioinformatics.

Wider implications of the findings: The confirmation of the existence of pathophysiologically meaningful genes in patients with endometriosis through microarray analysis both broadens our understanding of the pathogenesis of endometriosis and assists the development of noninvasive diagnosis techniques and new approaches to therapy.

Trial registration number: N/A.

P-273   Gamma secretase inhibition reveals a possible crosstalk of LIFR, SOX2 and PODXL with the Notch-Msi1 signaling pathway in primary endometriotic cells

M. Götte[1], L. Kettler[1], M. Hubert[1], A. Starzinski-Powitz[2], L. Kiesel[1], A. Schüring[1], B. Greve[3], S. Schäfer[1]

[1]Universitätsklinik Münster, Dept. of Gynaecology, Münster/Westf., Germany
[2]University of Frankfurt, Department of Biology, Frankfurt/Main, Germany
[3]Universitätsklinik Münster, Department of Radiotherapy-Radiooncology, Münster/Westf., Germany

Study question: Which functional properties and stemness-associated molecular pathways are influenced by inhibition of notch signaling in primary endometriotic cells?

Summary answer: Gamma secretase inhibition of primary and immortalised endometriotic cells induces apoptosis and results in downregulation of SOX2, LIFR, IFITM1 and PODXL.

What is known already: Expression of Msi1, a modulator of the stemness-associated notch signaling pathway, is upregulated in endometriosis and endometrial carcinoma. Interference with Msi1 function leads to a downregulation of notch-1 and to an induction of apoptosis in endometrial carcinoma cells.

Study design, size, duration: In vitro cell culture study (control vs gamma secretase inhibitor treatment) on the imortalized endometriotic cell line 12Z and primary stroma cells derived from endometriotic lesions of 7 patients.

Participants/materials, setting, methods: Stroma cells were isolated from biopsies of endometriotic lesions of 7 patients and cultured in vitro. The immortalied endometriotic epithelial cell line 12Z and primary endometriotic stroma cells were subjected to gamma secretase inhibitor treatment for 24 h and analyzed for changes in gene expression by TaqMan low density arrrays and qPCR. The impact on stem cell properties was investigated by flow cytometric aldehyde dehydrogenase activity assays, cell cycle analysis and annexin V apoptosis assay.

Main results and the role of chance: qPCR analysis demonstrated expression of the notch pathway components notch 1–4, Msi1-2, numb, DLL1,3,4, Hes1, Hey1 and the presence of an ALDH+ cell pool, a surrogate marker of stem cell activity in 12Z cells. GSI treatment lead to a reduction of ALDH+ cells ($p < 0.05$), reduced cell viability in MTT assays ($p < 0.05$), and increased apoptosis ($p < 0.05$). In 12Z cells, the cell cycle shifted from the S- to the G2 phase after GSI-treatment. TaqMan Low density array analysis followed by qPCR confirmation in 12Z and primary cells revealed a significant downregulation of the pluripotency-associated transcription factor SOX2, previously shown to be associated with endometriosis, of the LIF receptor (confirmed by flow cytometry), IFITM1, a regulator of primordial germ cell function, and the stemness-associated factor PODXL (all $p < 0.05$). Expression of Msi1 and the notch antagonist numb was upregulated by GSI, while treatment of 12Z cells with recombinant notch-1 induced transcriptional downregulation of Msi1, numb, and the notch ligands DLL1 and DLL4 (all $p < 0.05$).

Limitations, reasons for caution: This in vitro study needs to be confirmed in more complex in vivo assays to assess possible side effects. The study relies on one pharmacological inhibitor and should be confirmed using other modes of notch pathway inhibition.

Wider implications of the findings: Our data suggest that pharmacological interference with the notch signaling pathway may be a worthwhile approach in the treatment of endometriosis that warrants further investigation. Inhibition of stemness-associated functions in endometriosis may reduce pathogenesis-associated parameters such as unlimited proliferative potential and developmental plasticity, thus reducing lesion persistence.

Trial registration number: not applicable.

P-274 IL-10 secreted by plasmacytoid dendritic cell contributing to the pathogenesis of endometriosis by triggering angiogenic growth factors

E.M. Tsai[1,2], Y. Change[3], J.L. Suen[2], T.C. Hour[2]

[1]Department of Obstetrics and Gynecology, Kaohsiung Medical University Hospital-Kaohsiung Medical University, Kaohsiung, Taiwan R.O.C.
[2]Graduate Institute of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan R.O.C.
[3]Department of Obstetrics and Gynecology, E-Da Hospital, Kaohsiung, Taiwan R.O.C.

Study question: We propose that altered IL-10 expression may contribute to the immune suppression as well as angiogenesis in the development of endometriosis

Summary answer: The plasmacytoid dendritic cells can regulate the angiogenic activity of IL-10, which was mediated by VEGF in vitro and contributes to endometriosis development.

What is known already: Accumulating evidence suggest that angiogenesis and immune dysregulation may play crucial roles in the pathogenesis and development of endometriosis. Our previous study has shown that anti-inflammatory cytokine IL-10 over-expression may enhance the growth of endometrial tissue through suppressing the anti-endometrial immunity.

Study design, size, duration: After treating cytokine IL-10 and anti-IL10R in HUVEC cells and ectopic endometrial cells, the regulated angiogenic and migratory activity were investigated. Whether IL-10 expressing stimulated by pDCs promote endometriosis development was investigated in a surgery-induced mice model. The dermal biopsy punches of uterine horns were sutured to the peritoneal walls in female C57BL/6 mice

Participants/materials, setting, methods: HUVEC cells and ectopic endometrial cells were used to determine the angiogenic activity of IL-10 using tube formation assay and transwell migratory assay. Purified pDCs (2×10^4) from C57BL/6 mice or PBS as control were intravenously transferred into syngeneic female mice. Purified pDCs from IL-10 +/+ and IL-10 -/- mice were adoptively transferred into C57BL/6 mice

Main results and the role of chance: We found that IL-10 promote the tube formation and migratory activity of HUVEC cells, while anti-IL-10 R blocking antibody significantly suppress these two angiogenic activities of HUVEC cells. Furthermore, the soluble factor(s) released by IL-10-treated ectopic stromal cells also enhanced the tube formation and migratory activity of HUVEC cells using transwell assay. We showed that the angiogenic activity of IL-10, at least in part, was mediated by VEGF in vitro, and plasmoid dendrite cell secretes IL-10 can promote endometriosis in vivo.

Limitations, reasons for caution: The main limitation of this study was that it was limited to cell and animal experiment, further validation should be investigated in clinical patients.

Wider implications of the findings: The final goal of this research is to ultimately define the mechanistic link between immune suppression and angiogenesis, and to provide a rational basis for the development of novel therapeutic approaches that will have the direct and significant impact on endometriosis and endometriosis-associated cancers.

Trial registration number: Not applicable.

P-275 Novel endometrial receptivity markers detected in large-scale RNA-sequencing study combining samples from different populations

T. Laisk[1,2], M. Suhorutshenko[1,2], V. Kukushkina[3,4], A. Velthut-Meikas[2], R. Mägi[4], M. Peters[1,2], S. Altmäe[2], K. Krjutškov[2], J.F. Martinez-Blanch[9], F.M. Codoñer[9], F. Vilella[5,6], C. Simon[5,6,7], A. Salumets[1,2,8]

[1]Institute of Clinical Medicine- University of Tartu, Department of Obstetrics and Gynecology, Tartu, Estonia
[2]Competence Centre on Health Technologies, Tartu, Estonia
[3]Institute of Molecular and Cell Biology- University of Tartu, Tartu, Estonia
[4]Estonian Genome Center, Tartu, Estonia
[5]Instituto Universitario IVI/INCLIVA, Valencia, Spain
[6]Igenomix SL, Valencia, Spain
[7]Fundación Instituto Valenciano de Infertilidad, Department of Obstetrics and Gynecology- School of Medicine- Valencia University, Valencia, Spain
[8]Institute of Bio- and Translational Medicine, University of Tartu, Tartu, Estonia
[9]Lifesequencing SL, Valencia, Spain

Study question: Can we find novel, robust and reproducible endometrial receptivity markers using RNA-sequencing and comprehensive analytical design in a study group combining different populations?

Summary answer: In healthy women, 3,591 potential transcriptome-based endometrial receptivity biomarkers were identified. Comparison with recurrent IVF failure patients proposed novel mechanisms for endometrial-origin implantation failure.

What is known already: Endometrial transcriptome studies have reported numerous differentially expressed genes during the transition from pre-receptive to receptive state. Additionally, transcriptome dysregulation leading to problems with endometrial receptivity has been proposed as a potential mechanism behind repeated IVF failure in some patients. However, due to small between-study overlap, we still have only a handful of robust clinical biomarkers for diagnosing problems with endometrial receptivity or selecting the optimal receptivity window for embryo transfer in IVF.

Study design, size, duration: Cohort study; paired samples from pre-receptive (n = 35) and receptive (n = 35) endometrium in healthy fertile women (aged 23–36) and receptive phase samples (n = 39) from women with repeated IVF failure (aged 26–49) were collected in Estonia and Spain.

Participants/materials, setting, methods: Endometrial biopsies were analysed using Illumina paired-end RNA-sequencing. In each cohort, paired pre-receptive phase samples were compared to receptive phase samples from the same healthy women, while receptive phase samples from women with repeated IVF failure were compared to those of healthy women. For cohort-level differential expression analyses, edgeR software was used, and meta-analysis was performed using METAL software. g:profiler was used for enrichment analyses. Results were selectively validated using qPCR.

Main results and the role of chance: A total of 17,490 mRNA transcripts were evaluated. After Bonferroni multiple testing correction, 3,591 differentially expressed transcripts (1,799 up-regulated, 1,791 down-regulated) were identified in the pre-receptive vs receptive endometrium analysis of healthy women, with consistent effects in all studied groups. Up-regulated transcripts were enriched for immune system and cellular adhesion terms, while cell-cycle and DNA repair-related processes were down-regulated. In addition, differentially expressed genes were enriched for E2F, ETF, ZF5 and Sp1 transcription factor binding sites ($p < 5 \times 10^{-45}$), proposing their central role in regulating endometrial function. Comparison of receptive phase samples from healthy women and repeated IVF failure patients resulted in 49 transcripts with significantly different expression levels after multiple testing correction, and similar effects in both Estonian and Spanish datasets. These transcripts were clearly enriched for cellular adhesion and immune response, including several HLA molecules.

Limitations, reasons for caution: Rigorous analytical design can result in the loss of some potentially relevant markers. Not all differentially expressed transcripts have been assessed for their suitability as biomarkers.

Wider implications of the findings: Differentially expressed transcripts identified in our study have consistent effects in different populations and therefore have the potential for being evaluated as robust and efficient markers for endometrial receptivity in the clinical setting. Comparison between healthy women and IVF patients provides novel information on potential causes of repeated IVF failure.

Trial registration number: NA.

P-276 History of surgery for endometriosis and Assisted-Reproductive Technology outcomes in women with deep infiltrating endometriosis

C. Maignien[1], P. Santulli[1], M. Bourdon[1], D. Korb[1], L. Marcellin[1], V. Gayet[1], A.E. Millischer[2], K. Pocate-Cheriet[3], D. De Ziegler[1], C. Chapron[1]

[1]Assistance Publique-Hôpitaux de Paris AP-HP- Hôpital Universitaire Paris Centre-Centre Hospitalier Universitaire CHU Cochin- Université Paris Descartes- Sorbonne Paris Cité, Department of Gynaecology Obstetrics II and Reproductive Medicine, Paris, Fra

[2]Centre de Radiologie Bachaumont IMPC-Paris, Radiology, Paris, France
[3]Assistance Publique-Hôpitaux de Paris AP-HP- Hôpital Universitaire Paris Centre-Centre Hospitalier Universitaire CHU Cochin- Université Paris Descartes- Sorbonne Paris Cité, Department of Histology- Embryology and Reproductive Biology, Paris, France

Study question: To evaluate assisted reproductive technology (ART) outcomes in a series of 222 deep infiltrating endometriosis (DIE) patients and to assess the impact of previous surgery for endometriosis

Summary answer: In a population of DIE patients, a history of previous surgery for endometriosis is associated with poor assisted-reproductive technology outcomes.

What is known already: Surgical removal of endometriosis (OSIS) lesions is one of the options to manage OSIS-related infertility. However, surgery results remain controversial, with some authors showing that excision of endometriosis lesions improves in vitro fertilization (IVF) outcomes and others describing a negative impact on ART pregnancy rate. Surgery may also result in severe complications particularly in DIE, requiring significant expertise. Conversely, reverting to IVF may expose women to some risks, as the ovarian stimulation may accelerate the growth and progression of the lesions. In this context of discordant ART results after surgery, there is still no consensus about managing infertile-DIE patients.

Study design, size, duration: Retrospective observational cohort study, including 222 consecutive DIE patients undergoing in vitro fertilization or intracytoplasmic sperm injection, between June 2005 and February 2013 at a University Hospital. The diagnosis of DIE was based on imaging criteria (transvaginal ultrasound (TVS), magnetic resonance imaging (MRI)); histological proof confirmed the diagnosis in women with a history of surgery for endometriosis.

Participants/materials, setting, methods: ART outcomes were studied in the whole population, and then compared between patients with a history of surgery and those without. Main outcome measures were clinical pregnancy rates and live birth rates per cycle and per embryo transfer. Cumulative pregnancy rates were also calculated. Prognostic factors were identified by comparing women who became pregnant and those who did not, using univariate and adjusted multiple logistic regression models.

Main results and the role of chance: Two hundred and twenty-two DIE patients underwent 440 assisted reproductive technology cycles. Ninety (40.5%) patients became pregnant, and 70 (31.5%) had a live birth. The clinical pregnancy rate and the live birth rate per embryo transfer was 27.6% and 20.1% respectively. Patients with a history of previous surgery for endometriosis had significantly lower implantation rates (p < 0.001), clinical pregnancy rates (p < 0.001) and live birth rates per embryo transfer (p = 0.002), than patients who never had endometriosis surgery. They also had lower cumulative live birth rates compared to non-operated women (26% versus 51.3% after 4 cycles, p < 0.001). After multivariate analysis, previous history of surgery for endometriosis (p = 0.001) or past surgery for endometrioma (p = 0.005) were independent factors associated with lower pregnancy rates. Age > 35 years (p = 0.018), AMH levels < 2 ng/mL (p = 0.018), antral follicle count < 10 (p = 0.005) and multifocality of DIE lesions (p = 0.002) were also associated with negative assisted reproductive technology outcomes.

Limitations, reasons for caution: In 30.2% of patients there was no histological proof of endometriosis. However, endometriosis was diagnosed using previously published imaging criteria using TVS and MRI. This limitation – lack of surgical/histological confirmation of diagnosis – is one that affects most studies on OSIS and ART and is therefore not entirely avoidable.

Wider implications of the findings: These findings need to be confirmed by further prospective studies taking into account the type of surgery. Yet, it brings a new insight in the complex task of dealing with infertile DIE patients and might help the physicians to choose between reverting to ART or surgery.

Trial registration number: NA.

P-277 Influence of ovarian endometriosis on ovarian-responsiveness to hyperstimulation: An AMH-matched controlled study

J. Raad[1], M. Bourdon[1], P. Santulli[1], M. Even[1], C. Maignien[1], V. Gayet[1], K. Pocate-Cheriet[2], L. Marcellin[1], J. Gonnot[1], C. Cervantes[1], V. Blanchet[1], C. Chapron[1]

[1]Université Paris Descartes- Faculté de Médecine- Assistance Publique—Hôpitaux de Paris AP- HP, Service de Gynécologie Obstétrique II and Reproductive Médicine Professor Chapron, Paris, France

[2]Université Paris Descartes- Faculté de Médecine- Assistance Publique – Hôpitaux de Paris AP- HP, Service d'Histologie-Embryologie-Biologie de la Reproduction, Paris, France

Study question: To evaluate ovarian responsiveness to hyperstimulation and assisted reproductive technology (ART) outcomes in women suffering from ovarian endometriosis (OMA), as compared to disease-free controls.

Summary answer: Presence of OMA decrease ovarian responsiveness to hyperstimulation but not pregnancy chances. Previous history of OMA surgery is a main risk-factor of poor ovarian response.

What is known already: Reverting to ART is a therapeutic option for many endometriosis-affected infertile women. However, the influence of ovarian endometriosis (OMA) on ovarian responsiveness to hyperstimulation is a matter of debate.

Study design, size, duration: We conducted a large retrospective observational cohort study in a tertiary care university hospital between 01/10/2010 and 31/12/2015. After matching by age and AMH level, 201 infertile women suffering from OMA (OMA group) and 402 disease-free women (control group) undertaking ART procedure were included in the study. Study endpoints were number of oocytes retrieved and live birth rate.

Participants/materials, setting, methods: All endometriosis-affected women have undergone a pre-ART work-up, in order to precise diagnosis and staging of endometriosis. OMA Diagnosis was based on published imaging criteria (transvaginal sonography or magnetic resonance imaging) or on histology for patients with a previous history of endometriosis surgery. Poor ovarian response to hyperstimulation was defined as a reduced number of retrieved oocytes (≤3 oocytes retrieved). Statistical analyses were conducted using univariate and multivariate logistic regression models.

Main results and the role of chance: The number of oocytes retrieved (7.5 ± 5.4 in OMA group versus 9.4 ± 6.1 in control group; p < 0.01) and the number of mature oocytes (6.4 ± 4.8 in OMA group versus 7.6 ± 5.0 in control group; p < 0.01) were significantly lower in OMA group as compared to control group. An embryo transfer was performed in 151/201 (75.12%) and 324/402 (80.59%) women in OMA and control group respectively. No significant differences were found between OMA and control groups in term of clinical pregnancy rate [53/151 (35%) versus 134/324(41.3%) respectively; p = 0.23] and live birth rate [39/151 (25.8%) versus 99/324(30.5%) respectively; p = 0.33]. After a multivariate logistic regression analysis, independent risk factors for poor ovarian response to hyperstimulation are the following: Previous history of OMA surgery [OR = 2.21; 95% CI:1.141-4.260], women's age (> 35y.o) [OR = 1.73; 95% CI: 1.161-2.575] and pre-operative AMH serum level (< 2 ng/ml) [OR = 3.49; 95% CI: 2.346-5.193].

Limitations, reasons for caution: The fact that all women did not have an endoscopic exploration to phenotype or exclude the endometriosis status could constitute a possible bias. However, all included women underwent an appropriate pre-ART evaluation with a careful clinical examination and pelvic imaging to determine the endometriosis status.

Wider implications of the findings: Our results suggest that previous history of OMA surgery is linked to poor ovarian response to hyperstimulation. In some case where surgery appears essential, a primary fertility preservation could be proposed.

Trial registration number: NA.

P-278 Decreased autophagy of human endometrial stromal cells (HESCs) impairs decidualization via PI3K-Akt-mTOR pathway in adenomyosis

X. Cheng, X. Huang, L. Chen, B. Yao

Nanjing Jinling Hospital affiliated to Nanjing University, Reproductive Medicine Center, Nanjing, China

Study question: To explore whether maladjusted autophagy impacts the regulation of human endometrial decidualization for patients with adenomyosis.

Summary answer: The lower decidualization response of eutopic HESCs from patients with adenomyosis is associated with its reduced autophagy induced by mTOR pathway.

What is known already: A defective decidualization response has been associated with reproductive disorders such as adenomyosis, endometriosis and

recurrent pregnancy loss. Common benign gynecological disorder as adeno-myosis is, studies revealed its blunted decidualization, even in eutopic stromal cells, which has a negative effect on implantation rates and increase the miscar-riage risk. Autophagy is the natural, regulated, destructive mechanism of the cell that disassembles unnecessary or dysfunctional components. It was reported that some autophagy-related genes was abnormally expressed in eutopic endo-metria, which was supposed to affect the proliferation and migration of endo-metrial cells. Whether autophagy defect is envloved in decidualization process is still unkown.

Study design, size, duration: Immortal human endometrial stromal cell line T-HESCs and primary secretory phase HESCs are applied in *in vitro* experi-ments. Medroxyprogesterone acetate (MPA) and 8-Br-cAMP are uesd to induce decidualization, with PRL and IGFBP-1 as markers of decidualization. Rapamycin and M3-methyladenine are uesd to inhibit or activate mTOR or autophagy.

Participants/materials, setting, methods: Primary HESCs are isolated from eutopic endometrial biopsy of infertile patients with simple fallopian tube problems (n = 7) and patients with adenomyosis (n = 5) by diagnostic uterine curettage during secretory phase. Decidual samples (n = 7) are obtain though abortion operation of early pregancy. The expression of LC3A/B, Beclin-1, ATG5 and ATG12 are analyzed by western blot. QPCR and ELFA was per-formed to measure secretion of PRL and IGFBP-1.

Main results and the role of chance: LC3A/B, Beclin-1, ATG5 and ATG12 are up-regulated in a time-dependent manner in HESCs when stimulated with both 8-Br-cAMP and MPA for 24 h. Correspondingly, decidua (n = 7) of early pregnant women demonstrated higher expression of LC3A/B (P < 0.01), Beclin-1 (P < 0.01), ATG5 (P < 0.05) and ATG12 (P < 0.05) compared with secretory phase endometria (n = 7) from women with normal menstrual cycle. M3-methyladenine, the inhibitor of PI3K, significantly decreased PRL and IGFBP-1 (P < 0.001) secretion from decidual T-HESCs. LC3A/B(P < 0.001), Beclin-1(P < 0.01), ATG5(P < 0.05) and ATG12(P < 0.01) are all decreased expressed in edometria from patients with adenomyosis (n = 5) compared with the control groups (n = 7). The lower secretion of PRL and IGFBP-1 of decidual HESCS from adenomyosis patients endometria was recovered by mTOR inhibi-tor Rapamycin to a relatively normal level.

Limitations, reasons for caution: This study was only performed *in vitro*, animal experiments and autophagy relevant mechanism exploration are demanded in the further study.

Wider implications of the findings: We provide convinced evidences that autophagy is induced druing decidualization and the inhibitor of PI3K impairs T-HESCs decidualization. Except for adenomyosis, endometrial autophay disorder has been discovered in endometriosis, PCOS, and obesity, which are all impres-sionable for decidualization defect, indicating that autophay may be a new target for endometrium diseases.

Trial registration number: None.

P-279   Dysregulated immune genes and pathways likely contribute to endometriosis-associated infertility

K.D. Nayar, M. Saxena, R. Ahuja, M. Singh, G. Kant, N. Sharma, K. Nayar

Akanksha IVF Centre, Mata Chanan Devi Hospital, New Delhi, India

Study question: Are immune genes and pathways dysregulated in the eutopic endometrium of women with endometriosis?

Summary answer: In the eutopic endometrium of women with endometri-osis, immune genes and pathways are upregulated contributing to infertility in women with endometriosis.

What is known already: Endometriosis is a pro-inflammatory disease leading to infertility in women with endometriosis. In endometriosis, impaired immune surveillance contributes to increased inflammation as well as ectopic invasion of tissue. Alteration in the immune response may lead to infertility.

Study design, size, duration: A prospective case-control study was con-ducted on 16 women with endometriosis and 13 without the disease between 1 April 2015 and 30 March 2016.

Participants/materials, setting, methods: Eutopic endometrial biopsies were obtained by Pipelle curette. Paralleled gene expression profiling using high density oligonucleotide microarrays was applied to investigate dysregulation of genes and pathways in eutopic endometrium of women with endometriosis and compared to that of women without the disease. Data analysis was conducted by GeneSpring version 4.0.4. T-test using P value < 0.05 and a fold-change expression > 1.5 was applied to assess statistical significance. Dysregulated genes were randomly chosen and validated by RT-PCR.

Main results and the role of chance: In the eutopic endometrium of women with endometriosis, genes involved in regulating immune response as well as the pathways involved in maintaining immune surveillance were signifi-cantly upregulated when compared to that from women without endometriosis.

Limitations, reasons for caution: The limitation of the study may be the sample size.

Wider implications of the findings: Upregulation of genes and pathways involved in regulating immune response likely contributes to increased inflam-mation by promoting production of cytokines, growth factors and oxidative stress. These may further contribute to impaired embryo attachment and apop-tosis during the window of implantation leading to decreased pregnancy rates in women with endometriosis.

Trial registration number: Nil.

P-280   Identification of markers of endometrial epithelial cells (EEC's) contributes to the characterisation of EEC subtypes

A. Maclean[1], J. Drury[2], D. Hapangama[1]

[1]*Institute of Translational Medicine- University of Liverpool, Centre for Women's Health Research, Liverpool, United Kingdom*
[2]*Institute of Translational Medicine- University of Liverpool, Centre of Women's Health Research, Liverpool, United Kingdom*

Study question: Are there specific markers to define human endometrial epi-thelial cell (EEC) subtypes?

Summary answer: The expression pattern of specific markers in the 3 differ-ent anatomical areas of the endometrium suggests that different EEC subtypes exist.

What is known already: The EECs reside in three different anatomical loca-tions in the endometrium: the luminal epithelium, the functionalis glands, and the basalis glands. These three areas respond differentially to the same circulat-ing steroid hormones, suggesting the presence of functionally distinct EEC's. There is detailed understanding of the epithelial cell subtypes in other organs with similar regenerative capacity to the endometrium, such as the intestine and fallopian tube. This has facilitated cell specific research, which has improved the understanding of epithelial associated disease. This detailed knowledge is still lacking in the endometrium.

Study design, size, duration: This is a prospective observational study, ana-lysing full-thickness, healthy human endometrial samples from a total of 21 women (n = 16 pre-menopausal and n = 5 post-menopausal).

Participants/materials, setting, methods: Endometrium was obtained from women undergoing hysterectomy for benign conditions. The premeno-pausal samples were from proliferative (n = 7), secretory (n = 6) and menstrual (n = 3) phases of the menstrual cycle. The expression of AKR1C3, CD133, CK5/6, PODXL, MUC-1, Sialylated-SSEA-1, SSEA-1, and proliferative marker, Ki-67, was examined with immunohistochemistry. We also examined the differ-ential expression of the genes coding these proteins by interrogating the pub-lished microarray datasets using a system biology approach.

Main results and the role of chance: The epithelial-specific marker CK5/6 was expressed in all 3 EEC subtypes, with greatest expression in the secretory phase luminal epithelium (P < 0.05). The hormone-metabolising enzyme AKR1C3 was highly expressed in the functionalis EEC's during the proliferative phase (P < 0.01). The transmembrane protein PODXL was found to express strong immunoreactivity in the cytoplasm, most notably in the basalis, and in post-menopausal endometrium. This pattern was distinct from the expected apical expression seen in the majority of EEC's, and provides evidence that basalis EEC's could be functionally different. The surface marker sialylated-SSEA-1 was highly expressed almost exclusively on the basalis EEC's. The embryonic stem cell surface marker, SSEA-1, marked the basalis EEC's, where expression was significantly greater than in the proliferative phase functionalis

($P = < 0.05$). CD133 expression was weakest in luminal epithelium throughout the menstrual cycle, and strongest in the basalis, specifically in the postmenopausal endometrium. The microarray data generally confirmed the expression pattern specific to the functionalis of the genes coding for the proteins studied, highlighting the difficulties when all EEC's are considered together. This has provided a snapshot of differences in protein expression in EECs across the endometrium, suggesting functional dissimilarities, and the presence of EEC subtypes.

Limitations, reasons for caution: This is a descriptive study with a small sample size, and only protein expression of possible EEC markers analysed.

Wider implications of the findings: The differential expression of these EEC markers has provided preliminary evidence of the presence of different EEC subtypes. This warrants further investigation; with the aim of identifying the EEC subtypes that predispose to conditions such as endometriosis and endometrial carcinogenesis, and developing methods of isolation.

Trial registration number: Not applicable.

P-281 Usefulness of hematological parameters for differential diagnosis of endometriomas in younger and older women

B. Seckin[1], M.C. Ates[2], A. Kirbas[3], H. Yesilyurt[4]

[1]Zekai Tahir Burak Women's Health Research And Education Hospital, Department of Reproductive Endocrinology, Ankara, Turkey
[2]Zekai Tahir Burak Women's Health Research and Education Hospital, Department of Reproductive Endocrinology, Ankara, Turkey
[3]Zekai Tahir Burak Women's Health Research and Education Hospital, Department of Reproductive Endocrinolog, Ankara, Turkey
[4]Zekai Tahir Burak Women's Health Research and Education Hospital, Department of Reproductive Endocrinology, Ankara, Turkey

Study question: Does evaluation of hematological parameters has clinical significance in the differential diagnosis of endometriomas from other benign adnexal cysts in younger and older women?

Summary answer: Hematological markers have poor diagnostic value for distinguishing endometriomas from other benign adnexal cysts in both younger and older reproductive age women.

What is known already: Numerous biochemical markers have been evaluated to confirm the presence of the endometriosis. The most extensively used marker is CA-125, but it has limited diagnostic performance in detecting endometriosis. The available evidence suggests that inflammatory responses are involved in the etiopathogenesis of endometriosis. Previous studies have investigated the use of inflammatory markers including white blood cell (WBC) count, neutrophil- to- lymphocyte ratio (NLR), platelet indices, and platelet- to -lymphocyte ratio (PLR) for determining endometriosis. But, controversy remains regarding the clinical value of these complete blood count parameters in the differential diagnosis of endometriomas.

Study design, size, duration: This was a retrospective chart review study included five hundred and two patients during the period between January 2013 and December 2016.

Participants/materials, setting, methods: The study comprised a total of 502 patients who underwent laparoscopic surgery at Zekai Tahir BurakWomen's Health Research and Education Hospital. Of these, 267 had histologically proven endometriomas (endometrioma group) and 235 had other benign adnexal cysts (control group). Hematological parameters including WBC count, NLR, platelet indices, PLR, and serum CA-125 levels were compared between the groups. Furthermore, subgroup analysis was undertaken based on age (younger (< 25 years) and older (≥25 years) women).

Main results and the role of chance: There were no statistically significant differences in total and differential WBC counts, NLR, mean platelet volume (MPV) and platelet distribution width (PDW) levels among the endometrioma and control groups, The mean levels of hemoglobin,platelet count, PLR, plateletcrit (PCT) and CA-125 levels were significantly higher in the endometrioma group than the control group (p = 0.001). In subgroup analysis, these results were also not differ significantly in both younger and older women. The area under the curve (AUC) value for CA-125 was 0.854 (95% CI, 0.820-0.887) at the optimal cut-off value of 24.8 IU/mL with 78.7% sensitivity and 82.1%

specificity (p = 0.001) for detecting endometriomas. But, platelet count, PLR and PCT showed poor discriminative ability.

Limitations, reasons for caution: The main limitation of our study is that the subgroup analysis based on age was done with limited number of women. Futher larger studies are needed to investigate the clinical usefulness of hematological parameters as simple and inexpensive markers for differential diagnosis of endometriomas.

Wider implications of the findings: Hematological markers are not sufficient for distinguishing endometriomas from other benign cysts in both younger and older women. It seems that, CA-125 remains more accurate biomarker for the differential diagnosis of endometriomas.

Trial registration number: NA.

P-282 In Vitro study of two natural compounds for Endometriosis treatment: Ellagic and Retinoic acid

B.A. Mc Cormack[1], D. Madanes[1], L. Ferella[2], M.A. Bilotas[1], A.G. Ricci[1], R.I. Barañao[1]

[1]Instituto de Biología y Medicina experimental IBYME, Inmunología de la Reproducción, Buenos Aires, Argentina
[2]Instituto de Biología y Medicina Experimental IBYME, Fisiopatología Endometrial, Buenos Aires, Argentina

Study question: In this work we propose to assess the in vitro effect of two natural compounds: ellagic acid (EA) and retinoic acid (RA), on human endometrial cell adhesion.

Summary answer: EA and RA significantly reduced cell adhesion of human endometrial stromal cell line (T-HESC) and endometrial epithelial carcinoma cell line (ECC-1).

What is known already: EA is a natural poliphenol, which has been widely demonstrated to have properties as antioxidant and anti-tumoral in-vitro and in-vivo. RA is the active metabolite of vitamin A (retinol). It is known that retinoids have many biological effects, including a variety of immunomodulatory and anti-inflammatory activities, and have already shown satisfactory results in cancer research. In our previous work was demonstrated that 10 µM RA significantly inhibited T-HESC and ECC-1 proliferation, while 100 µM EA inhibited ECC-1 proliferation and no interfere with T-HESC viability. In the same way, we observed a significant tendency towards T-HESC cycle arrest after RA and EA treatment.

Study design, size, duration: Both cell lines, T-HESCs and ECC-1, were incubated with EA or RA for 24 h, and subsequent evaluated for plastic adhesion.

Participants/materials, setting, methods: Cell adhesion was evaluated by plastic adhesion assay in ECC-1 and T-HESC cultures. Briefly, cells were treated with 50-100 µM EA and 5-10 µM RA. After 24 h cells were trypsinized and allowed to recover for 40 min in fresh serum-free medium. Then were sowed and 60 min later adhered cells were washed, trypsinized and counted.

Main results and the role of chance: We observed that 24 h treatment reduced plastic adhesion of both cell lines under study. ECC-1 treated with 50 and 100 µM EA significantly reduced their plastic adhesion ability (p < 0.01 and p<0.001 respectively). In the same way, ECC-1 treated with 5 and 10 µM RA, showed a significant reduced adhesion (p<0.01 and p<0.001 respectively). As well as ECC-1, T-HESC treated with both assayed doses of EA and RA showed reduced plastic adhesion (p<0.05 and p<0.01 respectively).

Limitations, reasons for caution: Further studies should be aimed at fully understanding the mechanism behind the obtained results, as well as in vivo trials to subsequently assess these compounds safety for patients with endometriosis.

Wider implications of the findings: Current treatments for endometriosis consist on laparoscopic-surgery and continuous hormonal treatments. As their efficiency is under discussion, non-adverse effect long-term therapies remain a field of strong research. From these results, and taken together with the background, we highlight the idea to investigate natural compounds as novel and promising therapeutic treatment.

Trial registration number: not applicable.

P-283 Active biomolecules present in Scutellaria baicalensis and Rosmarinus officinalis induce cell cycle arrest in in-vitro model of endometriosis

L. Ferella[1], J.I. Bastón[2], M. Bilotas[3], B. Mc Cormack[3], J.J. Singla[4], A. Gonzalez[5], C. Olivares[2], G. Meresman[2]

[1]Instituto de Bilogía y Medicina Experimental- CONICET, Laboratorio de Fisiopatología Endometrial, Buenos Aires, Argentina
[2]Instituto de Biología y Medicina Experimental- CONICET, Laboratorio de Fisiopatología Endometrial, Buenos Aires, Argentina
[3]Instituto de Biología y Medicina Experimental- CONICET, Laboratorio de Inmunología de la Reproducción, Buenos Aires, Argentina
[4]Universidad de Buenos Aires, Hospital de Clínicas José de San Martín, Buenos Aires, Argentina
[5]Hospital Naval de Buenos Aires "Cirujano Mayor Dr. Pedro Mallo", Endoscopía Ginecológica, Buenos Aires, Argentina

Study question: The objective was to evaluate the effect of Wogonin (WG), Carnosic Acid (CA) and Rosmarinic Acid (RA) on human endometrial stromal cell line (t-HESC) growth.

Summary answer: Results suggest that inhibition of t-HESC proliferation by CA and WG might be associated to cell cycle arrest induction in G2/M phase.

What is known already: Current medical therapies available for endometriosis result inefficient due to their long term side effects and high levels of recurrence. Natural compounds are being investigated because of their beneficial properties. WG, a flavonoid isolated from *Scutellaria baicalensis* root, is the most active constituent of Chinese Herbal Medicine. CA and RA are two of the main antioxidant compounds found in *Rosmarinus officinallis* leaves. Anti-tumoral effects of these polyphenols have already been reported in several types of tumor cell lines. Previous studies developed in our laboratory demonstrated that these compounds inhibit endometrial stromal cell proliferation in both *in-vitro* and *in-vivo* endometriosis model.

Study design, size, duration: T-HESC cell line was incubated with WG, CA or RA for 24 hours or 48 hours for apoptosis assay or cell cycle analysis respectively. After incubation, cells were harvested and fixed, and TUNEL technique or propidium iodine staining was performed. Apoptosis and cell cycle analysis were measured by flow cytometry.

Participants/materials, setting, methods: After 24-h incubation with CA (5 and 7.5 μg/ml), RA (50 and 100 μg/ml) and WG (40 and 80 μM), cells were fixed to assess the percentage of apoptosis by the TUNEL technique. After 48-h incubation with CA (2.5 and 5 μg/ml), RA (50 and 100 μg/ml) and WG (40 and 80 μM), cells were fixed and DNA was stained with propidium iodine. Subsequently, apoptosis and cell cycle were measured in t-HESC by flow cytometry.

Main results and the role of chance: Pro-apoptotic effect of WG, CA and RA has not been evidenced by TUNEL technique in t-HESC cell line after 24-h incubation with each compound. WG 40 and 80 μM significantly decreased the percentage of cells in the G0/G1 phase and complementarily increased the percentage of cells in G2/M phase (p<0.001 vs. basal). In the same way, CA 5 μg/ml decreased G0/G1 percentage with an increase of G2/M phase percent (p<0.01 vs. basal). Cell cycle deregulation has not been observed after RA incubation. These results suggest that inhibition of endometrial stromal cell proliferation induced by WG and CA might be associated to cell cycle arrest induction at G2/M stage.

Limitations, reasons for caution: More studies should be addressed to fully understand the mechanism behind the results obtained.

Wider implications of the findings: Previous results demonstrated that WG, RA and CA exerted inhibitory effect on *in-vitro* cell proliferation and *in-vivo* endometriosis-like lesions development. New results indicate that this antiproliferative effect could be associated to cell cycle arrest. Our studies support further investigation of novel, safe and well-tolerated botanical products as future endometriosis treatments.

Trial registration number: not applicable.

P-284 Searching for endometriosis biomarkers with proteomics

S. Irungu[1], D. Mavrelos[2], J. Worthington[1], O. Blyuss[1], E. Saridogan[2], J. Timms[1]

[1]University College London, Institute of Women's Health, London, United Kingdom
[2]University College London Hospital, Reproductive Medicine Unit, London, United Kingdom

Study question: We aimed to identify novel biomarkers of endometriosis in eutopic and ectopic endometrium and verify these biomarkers in serum.

Summary answer: We did not identify any biomarkers that performed better than CA - 125 alone.

What is known already: Endometriosis is a common gynaecological disorder affecting 5-10% of women of reproductive age and occurs when endometrial cells implant on surfaces in the abdomen and pelvis. There they form lesions that respond to hormones of the cycle and stimulate inflammation. Women with endometriosis experience painful periods, pain on intercourse and defecation and may have difficulties conceiving. Definitive diagnosis is surgical, requiring laparoscopy under general anaesthetic, exposing patients to potentially serious complications.

Study design, size, duration: Prospective observational cross sectional study of women presenting to a tertiary referral centre with a history of pelvic pain or for prophylactic surgery (control) recruited between March 2013 and March 2016.

Participants/materials, setting, methods: We collected eutopic and ectopic endometrial tissue from 28 patients with endometriosis and 18 controls. We used quantitative 2D difference gel electrophoresis and multiplex mass tagging of peptides linked to 3D liquid chromatography-based separation and tandem mass spectrometry to select candidates (LUM, CPM, TNC, TPM2, PAEP/glycodelin). We verified these by ELISA in 109 serum samples from the same and additional women. Reported biomarkers (CA125, sICAM1, FST, VEGF, MCP1, MIF and IL1R2) were also tested.

Main results and the role of chance: Cycle phase and endometriosis-associated changes were identified in the eutopic tissue expression profiles from over 1,400 identified gene products. Bioinformatics analysis revealed enrichment of adhesion/extracellular matrix proteins and progesterone signalling. The best single marker for discriminating endometriosis from controls remained CA125 (AUC = 0.72). The best cross-validated multi-marker model (CA125, sICAM1, FST) gave an AUC of 0.75 for discriminating endometriosis from both control groups.

Limitations, reasons for caution: We have performed a comprehensive proteomic analysis of eutopic tissue samples from patients with endometriosis, relevant pain controls and healthy women identifying candidate biomarkers. These and previously reported markers were tested in a larger set of serum samples taking cycle stage into account.

Wider implications of the findings: The best models gave only marginal improvement on using CA125 alone, and would thus be unsuitable as standalone diagnostic tests or for use in triaging for surgery.

Trial registration number: N/A.

P-285 Protein expression and cellular localization of Estrogen Receptors alpha and beta in endometriosis-associated epithelial ovarian cancer cell lines

J.I. Bastón[1], L. Ferella[1], J.J. Singla[2], A.M. Gonzalez[3], G.F. Meresman[1]

[1]Institute of Biology and Experimental Medicine- National Council of Scientific and Technical Research, Laboratory of Endometrial Pathophysiology, Buenos Aires, Argentina
[2]Buenos Aires University, Clinic Hospital "José de San Martín"-, Buenos Aires, Argentina
[3]Navy Hospital "Dr. Pedro Mallo", Gynaecology Endoscopic Section, Buenos Aires, Argentina

Study question: To evaluate the protein expression and the cellular localization of Estrogen Receptor alpha (ERα) and beta (ERβ) in cell lines derived from human endometrioid and clear-cell Epithelial Ovarian Cancer (EOC).

Summary answer: Both endometriosis-associated cell lines expressed these steroid receptor proteins. ERα was mainly localized into the cellular nucleus, whereas ERβ was mostly localized into cytoplasm.

What is known already: The pathophysiological mechanisms involved in the etiology of the endometriosis-associated EOC, such as endometrioid and clear-cell ovarian tumors, are not entirely known yet. However it is well-known that the local hormonal environment that promotes the development of these ovarian carcinomas is similar to the peritoneal hormonal environment found in patients with endometriosis, where the steroid hormones levels, mainly

estradiol, are particularly high. Therefore, it is crucial the development of suitable experimental models in order to allow an accurate characterization of the potential role exerted by the endometriotic lesions-released estrogens on the occurrence and progression of endometriosis-associated EOC.

Study design, size, duration: Human epithelial ovarian cancer cell lines were cultured under standard conditions until confluence to further analysis of ERα and ERβ protein expression and cellular localization.

Participants/materials, setting, methods: TOV-112D cell line (ATCC CRL-11731) derived from a human endometrioid-type ovarian carcinoma and TOV-21 G cell line (ATCC CRL-11730) derived from a human clear-cell ovarian carcinoma were purchased from the American Type Culture Collection (ATCC). The protein expression and cellular localization of ERα and ERβ in each cell line was analyzed by Western blot and indirect immunofluorescence (IFI) respectively, in 4 independent experiments.

Main results and the role of chance: We found that both EOC cell lines expressed ERα and ERβ proteins, being the ERα expression qualitatively stronger than ERβ in both cell lines. These results suggest that these endometriosis-associated EOC cell lines have the necessary molecular machinery to respond to steroid hormones stimuli. In addition, we found that in both cell lines ERα was mostly located into the nucleus, indicating that this receptor had been activated by its canonical ligand, dimerized and translocated to the cellular nucleus, where it regulates the transcription of its target genes. ERβ was mainly found in the cytoplasm, where it is mostly inactive.

Limitations, reasons for caution: This is an initial descriptive study, so it is very important to make it clear that functional studies will be addressed to fully understand the role of the estradiol secreted by endometriotic lesion on the pathophysiological mechanisms underlying the etiology of endometriosis-associated EOC.

Wider implications of the findings: These cell lines are endowed with the necessary molecular machinery (i.e. ERα and ERβ) to respond to estradiol released by endometriotic lesions, thus becoming a suitable *in vitro* model to study the potential role of steroid hormones on the onset and development of endometriosis-associated EOC.

Trial registration number: not applicable.

P-286　A comparison of IVF cycles in women with endometriomas pre-treated with either depolurpolide acetate or depoluprolide acetate and letrozole

T. Litvin[1], S. Tan[2], M.H. Dahan[1]

[1]McGill University, Obstetrics and Gynecology, Montreal, Canada
[2]McGill University, Obstetrics and Gyencology, Montreal, Canada

Study question: Does the addition of an aromataze inhibitor improve IVF outcomes when pre-treating women with gonadotropin releasing hormone agonists with endometriomas?

Summary answer: The combination of depoluprolide-acetate 3.75 mg monthly for 60 days combined with letrozole 5 mg daily orally, has better clinical outcomes at IVF than depoluprolide-acetate alone.

What is known already: At meta-analysis and in five randomized studies, three to six months of depolurprolide pre-IVF improves clinical outcomes, as compared to placebo. Most clinicians give depoluprolide for two months to prevent extended delays in care. Depoluprolide causes a pseudo-menopausal state decreasing estradiol, through which it diminishes endometriosis. Aromatase inhibitors affect the endogenous aromatase in the endometriosis lesions. Combining both can results in decreasing diameter or resolutions of the cysts. Comparison of both protocols have not been previously tried in IVF patients with endometriosis.

Study design, size, duration: A prospective cohort study was performed from 2011 until 2016. 62 women with endometriomas were offered depolupron and 52 completed care. 64 women with endometriomas were prescribed depoluprolide and letrozole and 50 completed care.

Participants/materials, setting, methods: Patients with a failed previous IVF cycle and all subsequent frozen embryo transfers, ground glass appearance persistent cysts consistent with endometriomas on ultrasound, treated at a University IVF center were non-randomly assigned to one or the other

treatment pre-fresh IVF. Statistics were evaluated with t tests and chi-square tests. Data is presented as Mean ± SD.

Main results and the role of chance: Among letrozole (negative vs. positive) treated subjects respectively, demographics did not differ for: female age (34.2 ± 3.2 vs. 34.6 ± 3.4 years, p = 0.54), antral follicle count pre-luprolide (6.7 ± 2.4 vs. 6.2 ± 1.9, p = 0.25), serum basal FSH level pre-luprolide (10.6 ± 2.6 vs. 11.3 ± 2.3 IU/L, p = 0.15), mean largest endometrioma diameter pre-luprolide (3.4 ± 0.7 vs. 3.5 ± 0.7 cm, p = 0.47) or number of failed embryo transfers (1.4 ± 0.2 vs. 1.4 ± 0.2, p = 1.0). Post luprolide the AFC differed between the letrozole (negative vs. positive) treated groups (6.4 ± 2.5 vs. 10.3 ± 2.0, p = 0.0001), as did the mean endometrioma maximum diameter (3.2 ± 0.8 vs. 1.8 ± 0.4 cm, p = 0.0001). At IVF, the gonadotropin dose used was less in the letrozole treated subjects (3716 ± 1314 vs. 2079 ± 1119 IU, p = 0.0001), the number of mature oocytes collected was greater (4.0 ± 1.7vs. 9.1 ± 2.4, p = 0.0001), the number of 2 PN embryos was greater (1.3 ± 1.0 vs. 7.3 ± 2.9, p = 0.0001), the number of blastocysts was greater (0.6 ± 0.2 vs. 3.1 ± 1.1, p = 0.0001). The number of transferred embryos were similar. The clinical pregnancy rates was higher in the letrozole treated group (12/52 vs. 25/50, p = 0.0047) as was the ongoing pregnancy rate (9/52 vs. 20/50. p = 0.01).Note non-of the subjects had complete resolution of the endometriomas with letrozole as seen in non-fertility studies.

Limitations, reasons for caution: This preliminary study was performed to gather evidence for the development of a prospective randomized trial. The non-randomized allocation of subjects may mask a hidden bias.

Wider implications of the findings: Data suggests that among women with endometriomas ovarian reserve tests and clinical outcomes can be improved with pretreatment of several months of gonadotropin releasing hormone agonist combined with an aromatase inhibitor. Data from the prospective trial will be needed to confirm these results.

Trial registration number: Not aplicable.

P-287　Pharmacokinetics, pharmacodynamics, and safety of relugolix, a potent oral once-daily gonadotropin-releasing hormone (GnRH) receptor antagonist, as monotherapy and in combination with estradiol/norethindrone acetate add-back therapy

A. Lukes[1], B. Johnson[2], L. Jones[2], J. Berg[3], R. Williams[4], B. Bock[5], K. Morton[6], A. Langenberg[7], P. Mudd Jr[8]

[1]Carolina Women's Research and Wellness Center, GYN, Durham, U.S.A.
[2]Roivant Sciences, Clinical Pharmacology, Durham, U.S.A.
[3]DaVita Clinical Research, Minneapolis, U.S.A.
[4]DaVita Clinical Research, Denver, U.S.A.
[5]WCCT Global, Costa Mesa, U.S.A.
[6]QPS, Springfield, U.S.A.
[7]Independent Consultant, Ross, U.S.A.
[8]Roivant Sciences, Clinical Research, Durham, U.S.A.

Study question: To evaluate pharmacokinetics/pharmacodynamics (PK/PD) and safety/tolerability during 6 weeks of treatment with relugolix or relugolix plus low-dose estradiol/norethindrone acetate add-back therapy in healthy premenopausal women.

Summary answer: Relugolix plus estradiol/norethindrone acetate hormonal add-back therapy resulted in estradiol plasma concentrations that mitigated bone turnover and vasomotor symptoms associated with administration of relugolix alone.

What is known already: Relugolix, an oral GnRH receptor antagonist, has demonstrated clinical benefit in the symptomatic treatment of women with uterine fibroids or endometriosis in phase 2 clinical studies when used at doses resulting in a high degree of estradiol suppression. However, these doses are associated with time-dependent loss of bone mineral density and burdensome hot flashes. Low-dose hormonal add-back therapy, comprised of an estrogen and progestogen, has been shown in prior studies with other agents to mitigate these adverse effects with minimal impact on symptom control. This is the first study evaluating the PK/PD and safety of relugolix combined with add-back therapy.

Study design, size, duration: This was a phase 1, open-label, parallel-group, PK/PD study. Forty-eight women were randomized to receive relugolix 40 mg

or relugolix 40 mg plus estradiol/norethindrone acetate (1 mg/0.5 mg) once daily for 6 weeks. The first day of dosing occurred on Day 1 to 6 of the menstrual cycle. PK/PD samples were collected throughout the study, and 24-hour PK profiles were obtained at Week 3 and 6. Subjects returned for a follow-up visit at Week 8.

Participants/materials, setting, methods: Healthy premenopausal women were enrolled at 4 clinical sites in the United States. In addition to laboratory safety assessments, serum was sampled for follicle-stimulating hormone, luteinizing hormone, estradiol, and progesterone concentrations. Relugolix, estradiol, estrone, norethindrone, and ethinyl estradiol PK concentrations and PK parameters were determined. Bone resorption markers N- and C-telopeptide were also determined at baseline, Week 3, and Week 6. Vasomotor symptoms and menstrual bleeding were captured using a daily diary.

Main results and the role of chance: Relugolix PK were not impacted by estradiol/norethindrone acetate.

After treatment with relugolix alone, Week 6 median C_{trough} and C_{max} estradiol concentrations were 5.77 and 7.22 pg/mL, respectively. With estradiol/norethindrone, the median values increased to 21.4 and 49.2 pg/mL, respectively.

After 6 weeks, the % change from baseline in N-telopeptide and C-telopeptide were significantly elevated after treatment with relugolix, but not after treatment with relugolix plus estradiol/norethindrone acetate, indicating reduced bone resorption.

The proportions of women reporting no menstrual bleeding other than min- or spotting over the last 28 days of treatment were 88.0% and 47.8% after treatment with relugolix alone or relugolix plus estradiol/norethindrone acetate, respectively. The proportion of women reporting hot flashes (any grade) was significantly mitigated by the addition of estradiol/norethindrone acetate (60.0% for relugolix alone vs 17.4% with estradiol/norethindrone during Week 6).

The most commonly (≥10%) reported adverse events in the study were hot flash, headache, nausea, and events of uterine bleeding, consistent with GnRH antagonist pharmacology. With the exception of severe hot flash, adverse events were mild or moderate in intensity. One subject experienced 2 serious adverse events (syncope and chest pain) unrelated to study drug. There were no deaths, withdrawals due to AE, or reported pregnancies.

Limitations, reasons for caution: In this study, treatment with relugolix plus estradiol/norethindrone acetate was limited to 6 weeks in healthy premenopausal women. The impact of relugolix co-administered with add-back therapy in patients with endometriosis or uterine fibroids requires further evaluation in longer duration phase 3 studies.

Wider implications of the findings: This study characterized the effects of relugolix co-administered with hormonal add-back therapy and provides a rationale to evaluate this combination in women with symptoms associated with uterine fibroids or endometriosis. The data suggest add-back therapy may mitigate bone mineral density loss and vasomotor symptoms associated with estradiol-suppressive doses of relugolix.

Trial registration number: NA.

P-288   Anatomical visualization of inferior hypogastric nerves during uterosacral ligamentectomy for deep infiltrating endometriosis contributes to the prevention of postoperative dysuria

K. Watanabe, M. Ichikawa, T. Shiraishi, N. Terada, Y. Shirai, H. Kaseki, M. Yonezawa, S. Ono, T. Ichikawa, Y. Kuwabara, S. Akira, T. Takeshita

Nippon Medical School, OB/GYN, Tokyo, Japan

Study question: This study was performed to establish the optimal surgical strategy for deep infiltrating endometriosis to prevent postoperative dysuria.

Summary answer: Anatomical visualization of inferior hypogastric nerves during uterosacral ligamentectomy for deep infiltrating endometriosis is suggested to contribute to the prevention of postoperative dysuria.

What is known already: Uterosacral ligamentectomy is an established surgical method to improve pain related to deeply infiltrating endometriosis, including menstrual, sexual, bowel, and chronic pelvic pain. Owing to the closed

anatomical location of the ureter, hypogastric nerve, and pelvic plexus to the uterosacral ligament, dysuria can be caused by the damage to these tissues. Approximately 30% of patients who underwent extensive ligamentectomy without attention to tissue injury were reported to have urinary disorders that required transient or permanent self-catheter urination. However, the surgical strategy to prevent these postoperative complications has not been elucidated.

Study design, size, duration: In this study, 48 patients who underwent surgery for endometriosis in our institute between August 2013 and December 2015 without uterosacral ligamentectomy (group A, n = 14), with bilateral uterosacral ligamentectomy (group B, n = 24), and with unilateral uterosacral ligamentectomy (group C, n = 10) were enrolled. Postoperative dysuria in each group was retrospectively assessed based on the Core Lower Urinary Tract Symptom Score (CLSS) and statistically evaluated.

Participants/materials, setting, methods: In this study, we introduced a procedure to prevent tissue injury by anatomically visualizing the hypogastric nerve during uterosacral ligamentectomy. From among the CLSS evaluation items, 'Slow urinary stream," 'Need to strain when urinating," and 'Feeling of incomplete emptying of the bladder after urination" were evaluated and rated in four stages as follows: no, 0; rare, 1; sometimes, 2; and often, 3. The total scores were compared between the groups and statistically analyzed.

Main results and the role of chance: In contrast to the previous report, none of the patients in either group showed severe postoperative dysuria that required catheter urination. The scores of the urinary disorders were not significantly different among the groups (A: 1.14 ± 0.48, B: 0.92 ± 0.31, C: 0.60 ± 0.40), indicating that postoperative dysuria after deep endometriosis can be prevented by visualizing the hypogastric nerve anatomically and selectively resecting only the sacral uterine ligament itself without damaging surrounding tissues.

Limitations, reasons for caution: Owing to the small sample size of this study, further investigation with more patients is necessary to confirm our preliminary findings.

Wider implications of the findings: Not only pursuing the improvement of the symptoms of the original disease but also developing a surgical strategy by paying attention to the prevention of complication will contribute to the improvement of the true postoperative quality of life of patients with deep endometriosis.

Trial registration number: not applicable.

P-289   Is pregnancy the panacea for pain symptoms associated with endometriosis?

D. Alberico[1], G. Barbara[2], F. Facchin[3], P. Mosconi[4], A. Roberto[4], D. Dridi[2], E. Somigliana[5], P. Vercellini[5]

[1]*Fondazione IRCCS"Ca'Granda"-Ospedale Maggiore Policlinico, Clinica Ostetrico-Ginecologica "L. Mangiagalli", Milan, Italy*
[2]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Obstetrics and Gynecology, Milan, Italy*
[3]*Catholic University, Department of Psychology, Milan, Italy*
[4]*IRCCS Istituto di Ricerche Farmacologiche Mario Negri, Department of Public Health, Milan, Italy*
[5]*Università degli Studi di Milano, Department of Clinical Sciences and Community Health, Milan, Italy*

Study question: What is the long- term impact of pregnancy on endometriosis-related pain?

Summary answer: Women with endometriosis experience symptoms relief during and immediately after pregnancy. However, as for hormonal therapy, symptoms rapidly recur in the vast majority of cases.

What is known already: Albeit based on scanty evidence, pregnancy is commonly believed to confer symptomatic benefit to women with endometriosis. In fact, the supposed beneficial effects of pregnancy have inspired modern therapy of endometriosis. The idea of curing the disease with progestins, thus mimicking pregnancy, has guided investigators for decades. However, while pregnancy is claimed to determine long-term benefits that can definitely cure endometriosis or at least determine a long-term protection from recurrences, the benefits of progestins are well-known to rapidly vanish once treatment is

discontinued. This inconsistency is intriguing and merits more in-depth investigation.

Study design, size, duration: Retrospective cohort study performed at a tertiary care center for the treatment of endometriosis. We included women who had a live birth after at least one surgery for endometriosis and who reported pre-pregnancy moderate to severe pelvic pain symptoms. The study period lasted from 2008 to 2013.

Participants/materials, setting, methods: 144 women were identified, aged between 18 and 45 years. Data were primarily extracted from patients' charts. They referred to the last pre-pregnancy clinical evaluation and to the assessment made at two years after delivery. Comparisons were made for pain symptoms, quality of life (using the SF-12 questionnaire), psychological status (using the Hospital Anxiety and Depression scale) and sexual functioning (using the Female Sexual Function Index).

Main results and the role of chance: Pre-pregnancy moderate to severe dysmenorrhea, deep dyspareunia, non-menstrual pelvic pain and dyschezia were reported in 137 (95%), 91 (63%), 71 (49%) and 60 (42%) cases, respectively. Sixty women (42%) initiated medical therapy during the follow-up period. Specifically, 29 (20%) started because of pain complaints, 10 (7%) for prevention purposes, 3 (2%) for contraception and the remaining 18 (12%) because of both pain recurrence and need for contraception. Four women (5%) required a surgical intervention for endometriosis. Overall, 49 women had a clinically relevant recurrence requiring treatment, corresponding to 34% (95%CI: 27-42%). This proportion rose to 54% (95% CI 39-68%) when restricting the analysis to women who were already assuming medical therapy because of pain before pregnancy seeking. Two years after delivery, 84% of women (95% CI 77-90%) reported at least one moderate-severe pain symptom. A statistically significant improvement was observed for SF-12 and HADS scores but not for FSFI scores. For SF-12, improvements were observed for both physical and mental health scales. Similarly, the HADS scores showed improvements for both anxiety and depression scales.

Limitations, reasons for caution: The retrospective design potentially implicates inaccuracies even if in our center information is systematically collected at every visit. Moreover, pre-post pregnancy comparisons were complicated by the heterogeneous therapeutic trajectories of the population, and a selection bias cannot be ruled out, as women who did not refer after pregnancy were excluded.

Wider implications of the findings: The pregnancy-related hormonal milieu and the psychological benefits of parenthood may benefit women. However, as for hormonal therapy, symptoms rapidly relapse in the vast majority of cases. Pregnancy represents a period of substantial but only transient symptoms relief, and cannot be viewed as a definitive cure of the disease.

Trial registration number: Not applicable.

P-290   Epigenetic alteration of Thymic Stromal Lymphopoietin, TSLP, in endometriosis

S. Habibi[1,2], E. Amirchaghmaghi[3,4], F. Ramezanali[4], R. Aflatoonian[4], P. Afsharian[1], M. Shahhoseini[1]

[1]Department of Genetics- Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine- ACECR, Tehran, Iran
[2]Faculty of Basic Sciences and Technologies, University of Science and Culture- ACECR, Tehran, Iran
[3]Department of Regenerative Biomedicine- Cell Science Research Center, Royan Institute for Stem Cell Biology and Technology- ACECR, Tehran, Iran
[4]Department of Endocrinology and Female Infertility- Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine- ACECR, Tehran, Iran

Study question: Is there any changes in expression and epigenetic profiles of Thymic Stromal Lymphopoietin and its receptor in endometrium of women with endometriosis?

Summary answer: TSLP is up-regulated in ectopic endometrial tissues of women with endometriosis through hyper-acetylation and hypo-methylation of histone H_3 region in its promoter.

What is known already: Endometriosis which is defined as the presence of endometrium like tissue outside of uterine is an estrogen dependent and inflammatory disease. It has been suggested that immunological factors play important roles in the pathogenesis of endometriosis. TSLP is an interleukin 7–like cytokine that triggers dendritic cell–mediated T helper2 inflammatory responses. TSLP receptor, also known as cytokine receptor- like factor 2 (CRLF2), forms a functional heterodimeric complex with IL-7 R to bind with TSLP. On the other hand, epigenetic aberrations such as DNA methylation and histone modifications appear to be involved in various diseases such as endometriosis.

Study design, size, duration: In this case-control study, ectopic and eutopic endometrial samples were obtained through laparoscopic procedure from 15 women with endometriosis. As control group, endometrial tissue biopsies were collected by pipelle from 16 healthy fertile women. Women with any other uterine abnormalities were excluded. Informed written consent was obtained from all women according to local ethical approval.

Participants/materials, setting, methods: The relative mRNA expressions of TSLP and TSLPR were studied by the use of quantitative-PCR technique. Chromatin Immunoprecipitation (ChIP) coupled with real-time PCR was used to monitor histone modifications (methylation/acetylation) on lysine 9 of histone 3 (H3K9me/ ac) in the regulatory region of TSLP gene.

Main results and the role of chance: Expression profile of TSLP and TSLPR genes revealed significant increase (p < 0.05) in ectopic lesion of patients with endometriosis in comparison to endometrium of eutopic samples and control group.

In ectopic tissues of endometriosis patients, a significant H_3K_9 hyper acetylation parallel to hypo methylation was detected in regulatory region of TSLP gene compared to eutopic and control groups (p < 0.05). These epigenetic changes were aligned with its expression changes.

Limitations, reasons for caution: For getting more information, we need to investigate TSLP genes in a large number of endometriosis patients and control group and also to evaluate expression of other related genes. Other Epigenetic studies such as DNA methylation of TSLP promoter region are recommended.

Wider implications of the findings: These data collectively identify TSLP and TSLPR as a candidate gene critically involved in development of endometriosis beyond its role in promoting Th_2 immune responses.

Trial registration number: -.

P-291   Targets for improvement in endometriosis care in a secondary and tertiary clinic

W. Nelen[1], A. Schreurs[2], W. Kuchenbecker[3], L. Van der Houwen[2], E. Dancet[4], S. Apers[4], C. Lambalk[2], V. Mijatovic[2]

[1]Radboud university medical center, gynecology, Nijmegen, The Netherlands
[2]VU University Medical center, gynecology, Amsterdam, The Netherlands
[3]Isala, gynecology, Zwolle, The Netherlands
[4]University Hospitals Leuven, gynecology, Leuven, Belgium

Study question: What are, according to patients, differences in strengths and targets of improvement regarding endometriosis care in a tertiary and a secondary clinic in the Netherlands?

Summary answer: We found 3 corresponding strengths and 9 targets for improvements. Patients experienced 9 aspects variously as strength or as targets for improvement between the clinics.

What is known already: Endometriosis is a chronic disease with high impact. Therefore, it is important to optimize the quality of endometriosis care. One of the cornerstones for high quality of care is patient-centeredness, which can be assessed with the Endocare questionnaire (ECQ). Patients' quality of life (QoL) differ between a secondary and tertiary clinic, which might mean that the patient-centeredness of care also differs between tertiary and secondary clinics. To date, the ECQ has solely been used in two tertiary care facilities.

Study design, size, duration: A cross sectional study was conducted in surgically diagnosed patients with endometriosis. A total of 401 of them received the ECQ between 2015 and 2016. Two reminders were sent.

Participants/materials, setting, methods: All patients were selected from a Dutch tertiary and a Dutch secondary clinic. Patients underwent endometriosis surgery in 2013 or 2014.

The ECQ asks patients to score performance in different care aspects and asks patients how important those aspects are, combining these results in the patient-centeredness scores (PCS). Patient-centeredness was deducted from

the ECQ's using the previous published scoring system. Strengths and targets for improvement were identified using an importance-performance matrix.

Main results and the role of chance: The overall response rate was 56.9%. In total, data from 209 patients could be analyzed (133 and 76 respectively for the tertiary and secondary clinic).

In both clinics 'shared decision making', 'managing expectations' and 'kindness of caregivers' were experienced as strengths. Targets for improvement were 'advise on self-care and recovery after surgery', 'receiving consistent information from different caregivers', 'ability to discuss daily complaints', 'having one regular caregiver', 'accessibility of caregiver in urgencies', 'waiting periods', 'indicated limits of competences' and 'pro-activity of doctors'.

Care aspects that were strengths in the tertiary clinic, but were targets for improvement in the secondary clinic were 'being taken seriously', 'information on pain medication' and 'short diagnostic delay'. Conversely, strengths in the secondary clinic were 'treated as a person instead of a number', 'clarifying information', 'understanding and caring caregivers', 'being reassured', 'known head practitioner', and 'trust in the experience of caregivers', whereas in the tertiary clinic these items were targets for improvement.

Limitations, reasons for caution: The differences in strengths and targets for improvement between secondary and tertiary clinics might be due to a difference in what patients value or what they experience between type of clinics.

Wider implications of the findings: The two investigated clinics could learn from another how to improve the patient-centeredness, and thereby quality of care, since the strengths from one clinic are the targets for improvement in the other. Improvement projects need to be set-up and evaluated.

Trial registration number: not applicable.

P-292   Effect of cabergoline and letrozole on subcutaneous experimental model of endometriosis

S. Jouhari[1], M. Naderi[2], A. Mohammadzade[3], S. Khazali[4], H. Soltanghoraee[5], Z. Mohammadi[6], F. Fatemi[7], S. Zafardoust[7]

[1]Avicenna Research Institute- ACECR, Avicenna infertility Clinic, Tehran, Iran
[2]Avicenna Research Institute-ACECR, Reproductive Biotechnology Research Center, Tehran, Iran
[3]Avicenna Research Institute-ACECR, Avicenna Infertility Clinic, Tehran, Iran
[4]Ashford and St. Peter's Hospital NHS Foundation Trust- Chertsey- Surrey, Centre for Endometriosis and Minimally Invasive Gynaecology CEMIG, London, United Kingdom
[5]Avicenna Research Institute-ACECR, Pathology, Tehran, Iran
[6]Avicenna Research Institute, Nanobiotechnology Research Center, Tehran, Iran
[7]Avicenna Research Institute, Avicenna Infertility Clinic, Tehran, Iran

Study question: What is the effects of cabergoline and letrozole on induced subcutaneous endometrial lesion in experimental endometriosis model of rat?

Summary answer: cabergoline and letrozole administration resulted in decreased size of the induced subcutaneous endometrial lesions in experimental endometriosis model of rat.

What is known already: A great number of medications were examined in preclinical models of endometriosis and suggest that letrozole (non-steroid third generation aromatase enzyme inhibitor) is effective in treatment of patients with endometriosis (reducing size and symptoms), But there is less information regarding the effects of cabergoline (dopamine agonist) on endometriosis.

Study design, size, duration: Twenty four female Sprague-Dawley mature rats were used for an experimental study in the Avicenna Research Institute.

Participants/materials, setting, methods: Endometriosis was surgically induced in 24 rats by transplanting of autografted endometrial tissue subcutaneously. After 3 weeks (for establishment of implants), animals were randomized into three groups and treated with cabergoline (0.5 mg/kg/day) (group I),letrozole (0.18 mg/kg/day) (Group II) and vehicle solution (Group III,control), subcutaneously. Three weeks later, the rats were euthanized and the implants were assessed for volume and histopathological grade of implants.

Main results and the role of chance: All the animals had comparable baseline characteristics. We found that the volume of endometrial lesions decreased significantly in cabergolin and letrozole groups ($p < 0.001$) compared to the control group. The histopathology grade of implants had significant difference between groups with $\alpha = 0.1$ (p:0.078).

Limitations, reasons for caution: The study was done on animal subjects. Assessment of effect of drugs in human is difficult because it needs surgery.

Wider implications of the findings: cabergoline resulted in decreased size of the induced endometrial lesions in rat.cabergoline appear to be a virtual therapeutic agent for treatment of endometriosis probably due to its potent antiangiogenic properties.Also The model of subcutaneous endometriosis is a considerable,low-cost,easy to perform, and proper for the study of the effects of drugs.

Trial registration number: Not applicable.

P-293   Evaluation of coagulation variables in endometriosis

V. Sarais[1], J. Ottolina[1], L. Privitera[1], G. Rebonato[1], L. Pagliardini[2], E. Somigliana[3], P. Viganò[2]

[1]IRCCS San Raffaele Scientific Institute, Obstetrics and Gynaecology Department, Milano, Italy
[2]IRCCS San Raffaele Scientific Institute, Division of Genetics and Cell Biology- Reproductive Sciences Laboratory, Milano, Italy
[3]Fondazione Ca' Granda - Ospedale Maggiore Policlinico, Infertility Unit, milano, Italy

Study question: Is there a strong relation between endometriosis and clotting abnormalities and inflammation blood parameters?

Summary answer: We confirm the presence of a shorter, but still in the normal range, APTT in women with ovarian endometriomas compared to a control population.

What is known already: Subtle alterations of coagulation and fibrinolysis parameters have been recently reported in endometriosis patients supporting a potential hypercoagulable status associated with this disease.

Study design, size, duration: This cross-sectional study was carried out retrospectively querying our prospective surgical database at San Raffaele Scientific Institute in MIilan. A total of 314 Patients who underwent surgery between January 2013 and December 2015 were considered. The case group (n = 169) included

The case group (n = 169) included patients with a surgical diagnosis of endometriosis, at any stage of disease.The control group (n = 145) included women with a surgical diagnosis of benign gynecologic pathology.

Participants/materials, setting, methods: Both the surgical and the histopathological examinations confirmed that no stage of endometriosis was present in the control group.

The routine preoperative included complete blood count parameters, NLR, platelet-lymphocyte ratio (PLR), TT ratio, APTT ratio and INR.

A univariate linear regression analysis was conducted in order evaluate the association of each variable with different phenotypes of endometriosis, that were included in the regression analysis as n-1 dummy variables.

Main results and the role of chance: No difference were found for thrombin time, INR, platelet count, and platelet-to-lymphocyte ratio between women with endometriosis and controls. Conversely, patients with endometriosis had significantly shortened activated partial thromboplastin time (APTT) as compared with controls (1.08 + 0.06 and 1.12 + 0.19, respectively; P < 0.01). In the subgroup analysis, women with ovarian endometriosis had significantly shortened APTT values in comparison with women without this form (controls and women with peritoneal and deep endometriosis). In multivariate logistic regression analysis, after controlling for potential confounders, a shortened APTT remained associated to the disease.

Limitations, reasons for caution: Limits included the retrospective querying and the presence of only one type of controls, the surgical population. All the subjects considered had a laparoscopic diagnosis, were not on oral contraceptives and we could include a large sample size with a great variety of forms and manifestations of the disease.

Wider implications of the findings: The evidence is insufficient to claim a crucial role of a systemic hypercoagulable state in the origin of the disease. Our evidence does not exclude a role of the local coagulation system in the pathogenesis of endometriosis.

Trial registration number: not applicable.

P-294 Reduced ovarian sensitivity but similar chance of cumulative live birth after IVF/ICSI and high frequency SET in women with endometriosis-associated infertility

M. Feichtinger[1], E. Nordenhök[2], J.I. Olofsson[2], K.A. Rodriguez-Wallberg[2]

[1]Medical University Vienna, Obstetrics and Gyneology, Vienna, Austria
[2]Karolinska University Hospital, Reproductive Medicine- Obstetrics and Gynecology, Stockholm, Sweden

Study question: Does endometriosis associate with a reduced ovarian sensitivity and worse IVF/ICSI outcome estimated as cumulative live-birth rates per ovum pickup (OPU) than other infertility causes?

Summary answer: Endometriosis patients had significantly reduced ovarian sensitivity compared to infertile women without endometriosis; however, IVF/ICSI with predominantly SET resulted in similar cumulative live-birth per OPU.

What is known already: Single-embryo transfer (SET) with subsequent frozen-embryo transfer (FET) was shown to result in similar cumulative live-birth rates compared to double-embryo transfer in infertile patients < 36 years. Several studies reported a negative effect of endometriosis on the ovarian reserve and on IVF/ICSI outcome, suggesting negative effects in both oocyte yields and the endometrial environment resulting in implantation failure. If endometriosis would predominately affect endometrial factors, fresh and FETs should be affected in such patients while ovarian factors might negatively affect cumulative live-birth rates.

Study design, size, duration: Retrospective cohort study of 2757 consecutive patients undergoing IVF/ICSI at a single center from January 2009 until December 2013 with reported data on live birth. A total of 2757 patients underwent 8236 treatment cycles (4598 fresh and 3638 frozen). Infertile women with symptomatic and demonstrated endometriosis during their infertility work-up undergoing IVF/ICSI (cases N = 172) were compared to infertile women without endometriosis (controls N = 2585).

Participants/materials, setting, methods: Approximately 2/3 of the women with endometriosis had previous adnexal surgery and nearly 40% had endometriomas. Patients underwent IVF/ICSI followed by SET in most cases and single FET in consecutive cycles. Statistical analysis was done using a generalized estimated equation (GEE) model accounting for dependences between consecutive treatments. Primary outcome measures: Ovarian sensitivity index and cumulative live-birth per OPU.

Main results and the role of chance: Women with endometriosis were similar to controls as regards to age (33.56 vs. 33.59 years, p = 0.82) or BMI (p = 0.60). Patients with endometriosis required significantly longer stimulation (p = 0.0008) and higher FSH doses (p = 0.0001). There was no difference in cycle cancellations (p = 0.76) or miscarriages (p = 0.83) between the two groups. In both groups, over 70% of the patients received SET and about 80% received frozen-thawed SET in consecutive cycles (p = 0.49). In fresh cycles, live-birth rates per OPU were similar between endometriosis vs. controls, (26.41% vs. 25.52%, respectively, p = 0.71) and per ET (29.18% vs. 28.39%, respectively, p = 0.78). Live birth rate was also similar after FET in both groups (22.22% vs. 26.16%, respectively, p = 0.43) and the cumulative live-birth per OPU did not differ between the groups (35.56% vs. 34.67%, respectively, p = 0.73). The results did not change after adjusting for age, and they were also similar irrespective of presence of ovarian endometriomas.

Limitations, reasons for caution: Retrospective character of the study that allows to examine associations but not causality. A minor proportion of the study population received DET (< 20%).

Wider implications of the findings: SET and consecutive FET conclusively can be encouraged in patients with endometriosis. Endometriosis patients had a reduced ovarian sensitivity with lower oocyte yields but similar live-birth rates per ET compared to controls, suggesting that the effect of endometriosis is more pronounced on ovarian factors rather than on the endometrial environment.

Trial registration number: not applicable.

P-295 Cell migration, apoptosis and myofibroblastic metaplasia are differentially regulated by seminal plasma in regard to endometriosis pathogenesis

M.G. Ibrahim[1], S. Schäfer[2], S. Kliesch[3], L. Kiesel[2], B. Greve[4], M. Götte[2], A. Schüring[1]

[1]University Hospital of Muenster, UKM Fertility Center - Department of Gynecology and Obstetrics, Muenster, Germany
[2]University Hospital of Muenster, Department of Gynecology and Obstetrics, Muenster, Germany
[3]University Hospital of Muenster, Center of Reproductive Medicine and Andrology CeRA, Muenster, Germany
[4]University Hospital of Muenster, Department of Radiotherapy-Radiooncology, Muenster, Germany

Study question: Can seminal plasma (SP) induce metaplasia-associated pathogenic properties in endometriosis (EM)?

Summary answer: While SP induces changes in metaplasia marker expression, it inhibits endometriotic cell migration and apoptosis, suggesting a possible effect on endometriotic cell behavior.

What is known already: EM pathogenesis involves different biological steps; detachment of the endometrium, retrograde transit, prolonged cell survival, implantation on the peritoneum, metaplasia and angiogenesis. SP comes in contact with the endometrium following intercourse, delivering many growth factors (especially TGFβ1) to endometrial cells as a possible mechanism to contribute to EM. In our previous study (presented on ESHRE annual meeting 2016, O-024), SP (1:10) induced an early myofibroblastic metaplasia observed 6 h after incubation with endometrial cells. In this study we investigated a longer incubation time using a more diluted SP to study cell migration, apoptosis and metaplasia on endometrial cells.

Study design, size, duration: SP collected from semen samples of normozoospermic men (n = 23) were centrifuged after liquefaction, pooled and used for in-vitro experiments in 1:10 and 1:100 dilutions. Peritoneal fluid (PF) (n = 14) was collected during laparoscopy from EM patients. Premenopausal women (n = 4) underwent transcervical endometrial biopsy. In-vitro studies were carried out in 5 groups; controls, SP1%, SP1%+TGFβ1 Activin receptor-Like Kinase Inhibitor (ALK-I) to block TGFβ1 receptor signaling pathway, ALK-I and TGFβ1.

Participants/materials, setting, methods: TGFβ1 level in SP and PF was assessed using ELISA. 12Z (endometriotic epithelial), St-T1b (endometrial stromal) cell lines as well as endometrial biopsies were used for the in-vitro studies. Flow cytometry analysis to assess **apoptosis** using the Annexin V/PI method. To assess cell **migration** a scratch wound assay was done. A quantitative real-time PCR assessed the mRNA expression of a **metaplasia** marker (alpha smooth muscle actin 'ASMA", a marker of myofibroblasts).

Main results and the role of chance: TGFß1 concentrations. TGFß1 in SP (average= 92.88 ng/ml) as well as in SP-pool (88.17 ng/ml) was significantly higher than in PF (average= 6.79 pg/ml) (p < 0.001).

Cell Migration. SP 1% inhibited cell migration of endometrial epithelial cells which were not reversed by blocking TGFβ1 in SP. Nevertheless, TGFβ1 alone stimulated cell migration, which could be partially blocked by adding TGFβ1-inhibitor.

Apoptosis. SP 1% forced endometriotic cells into apoptosis; the latter was partially reversed by blocking TGFβ1 in SP. Notably, cell cycle analysis revealed that more cells shifted into the G1 phase in 12Z, whereas a shift to the G2 phase occurred in St T1b. SP10 % massively induced apoptosis and reduced cell viability after prolonged incubation times (24 h), resulting in cell detachment from culture plates.

Myofibroblastic metaplasia. While SP 10% robustly up-regulated the ASMA-expression in both endometrial tissue as well as cell lines, the effect of SP 1% was yet more variable.

Limitations, reasons for caution: All experiments are in-vitro and they need to be reconfirmed in in-vivo studies, before translation into clinical practice can be accomplished.

Wider implications of the findings: These findings together with our previous results propose a possible role of SP on the different biological steps of EM

pathogenesis. They necessitate yet a study on a possible role of SP on immuno-modulation and angiogenesis as further crucial steps of the disease.

Trial registration number: Irrelevant.

P-296   Regression rates of symptomatic and asymptomatic endometrial polyps after 3-month of subcutaneous progesterone administration in premenopausal woman: a preliminary retrospective analysis

R. Venturella[1], G.M. Miele[1], K. Cefalì[1], D. Lico[1], A. Di Cello[1], P. D'Alessandro[1], F. Zullo[1], A. Vaiarelli[2]

[1]University Magna Graecia, Chair of Obstetrics and Gynecology, Catanzaro, Italy
[2]Valle Giulia Clinic- GENERA Centers for Reproductive Medicine, GENERA, Rome, Italy

Study question: Can medical therapy through the administration of 3 cycles of luteal progesterone improve the regression rate of symptomatic and asymptomatic endometrial polyps in premenopausal woman?

Summary answer: Three cycles of luteal phase subcutaneous progesterone administration were associated with a regression rate four times greater than that seen with watch-and-wait approach.

What is known already: In premenopause, 25% of endometrial polyps regresses spontaneously in 1 year. According to guidelines, given that most premenopausal polyps are not malignant, there is an option for expectant approach with no surgical intervention. Studies on the efficacy of medical treatments for endometrial polyps are also recommended by gynaecologic societies, with the aim of finding cost-saving not invasive strategies to manage this common pathology. Up to now nobody has investigated the effect of progestin administration on polyps, but molecular and clinical data suggest that the antiestrogenic effect of this hormone can be exploited to increase and speed-up their regression rate.

Study design, size, duration: A retrospective analysis of the data of all the premenopausal women with endometrial polyps managed in our unit from January to December 2016 was conducted. The regression rates of women managed with watch-and-wait approach and of those treated with 3 cycles of luteal progesterone were compared. Ninety-three out of 127 women completed the follow-up and were included in this study. Sixty-one accepted the therapy while 32 chose to wait for the spontaneous regression of polyp.

Participants/materials, setting, methods: Polyps were diagnosed through vaginal ultrasonography performed in follicular (94%) or luteal (6%) phase. Doppler examination was performed to confirm the diagnosis by visualization of the polyp feeding vessel. Treatment consisted of 7 days of 25 mg subcutaneous progesterone administered from 18° to 25° day of the menstrual cycle and repeated for 3 cycles. Patients refusing therapy were re-evaluated after 3 menstrual cycles, as per our standard protocol. Persistent polyps were treated by hysteroscopic resection.

Main results and the role of chance: Mean age of the study population was $37.2+3.7$ years. Among 93 women included, 32% consulted our Unit for infertility, 58% had abnormal uterine bleeding (AUB), 10% were diagnosed with asymptomatic polyps during a routine check-up. Asymptomatic women were less inclined to undergo therapy for their polyps, whereas infertility and AUB were factors positively related with the choice of the patients to undergo to progesterone. Thirty-two out of 61 and 28 out of 32 polyps persisted in the progesterone treatment and watch-and-wait groups, respectively, with a regression rate of 47.5% and 12.5% in patients managed by medical therapy and in those who refused progesterone, respectively. Persistent endometrial polyps had a longer diameter significantly greater at inclusion ($13.2+3.89$ mm) compared with polyps that regressed spontaneously or after therapy ($8.27 +1,85$ mm) ($p < 0,001$). Although not disappeared, polyps persisting after progesterone administration significantly reduced in size after therapy ($14.93 +2.98$ mm vs. $10.87 + 3.32$ mm $p<0,001$), with a mean reduction of 4.06 ± 2.81 mm. In the watch-and-wait group, persistent endometrial polyps had a longer diameter at inclusion greater than those spontaneously regressed ($11.46+3.54$ mm vs $7.5+0.57$ mm in progesterone and watch-and-wait groups, respectively; $p<0,001$). The histological diagnosis of all polyps persisting at 3-months re-evaluation was "endometrial polyp".

Limitations, reasons for caution: The retrospective design of the study currently limits the exploitation of our results in the general population but it

gave us useful data to calculate the sample size required for an adequate prospective randomized trial on the topic.

Wider implications of the findings: Although hysteroscopy is recognized as a safe and effective treatment for endometrial polyps, medical management could become a fascinating alternative because of its lower cost and invasiveness. Among infertile population, progesterone administration can increase the regression rate of polyps, allowing faster conception through natural and Assisted Reproductive Technology attempts.

Trial registration number: Not applicable.

P-297   Sensibility and specificity of the molecular vs classical diagnosis of chronic endometritis

I. Garcia-Grau[1], E. Cicinelli[2], M. Gonzalez-Monfort[3], F. Vilella[4], D. Valbuena[5], C. Simon[6], I. Moreno[5]

[1]Igenomix Foundation - University of Valencia, Research Department, Valencia, Spain
[2]University of Bari, Department of Obstetrics & Gynecology, Bari, Italy
[3]Igenomix, Research Department, Valencia, Spain
[4]Igenomix Foundation - University of Valencia - INCLIVA-, Research Department, Valencia, Spain
[5]Igenomix Foundation - Igenomix, Research Department, Valencia, Spain
[6]Igenomix Foundation - University of Valencia - INCLIVA - Igenomix, Research Department, Valencia, Spain

Study question: Is the molecular diagnosis of chronic endometritis (CE) comparable to classical hysteroscopic, histological and/ or microbial diagnosis?

Summary answer: Compared to the classical diagnosis, the molecular detection showed a sensitivity and specificity of 0.73 and 1, respectively, and allowed the identification of non-cultivable bacteria.

What is known already: CE is a persistent inflammation of the endometrial lining with 40% prevalence in infertile patients, causing recurrent implantation failure and clinical miscarriage. The most common bacteria causing CE are: Enterobacteria, Gardnerella vaginalis, Enterococcus faecalis, Streptococcus, Staphylococcus, Mycoplasma, and Ureaplasma spp.

Current diagnosis of CE is based on hysteroscopy of the uterine cavity with endometrial biopsy in which plasmatic cells are identified, while specific treatment can be only set out based on microbial culture to identify pathogens causing CE. However, bacterial culture is not routinely performed because is expensive, with turnaround time of one week and not all microorganisms are culturable.

Study design, size, duration: Endometrial biopsies from 28 patients, previously diagnosed for CE using at least one (hysteroscopy) or several classical methods (histology and/or microbial culture) in an independent center were blindly processed and analyzed by quantitative PCR (qPCR) using specific primers for the variable regions of the 16 S rRNA gene of the most common bacteria causing CE. The results of our molecular analysis were compared with their prior diagnosis by the indicated classic methods in an independent center.

Participants/materials, setting, methods: Twenty-eight endometrial biopsies from clinically diagnosed patients for CE were used in this study. Total DNA was isolated upon enzymatic digestion for difficult-to-lyse bacteria and subjected to qPCR to detect the presence of the most prevalent infectious agents of CE. The organisms tested were: Enterobacteria, Enterococcus faecalis, Streptococcus and Staphylococcus spp., Gardnerella vaginalis and Mycoplasma spp. Known amounts of total DNA from these bacteria were used as positive controls.

Main results and the role of chance: In 14 patients diagnosed of CE by microbial culture, hysteroscopy and histology, we identified bacterial pathogens in 12 out of 14 cases.

In 12 patients diagnosed of CE by hysteroscopy or histology without, or with negative, culture, molecular detection of pathogens was confirmed in 7 out of 12 cases. From the 5 remaining in which no bacterial DNA was detected by PCR, 4 samples were diagnosed only based on hysteroscopy, but were negative for histology.

In the 2 women diagnosed as negative for CE by all classical methods, our molecular test confirmed the negative results in both cases.

Overall, the sensitivity and specificity of the molecular diagnosis versus at least one classical method was 0.73 and 1.00, respectively. The positive

predictive value and the negative predictive value of the molecular method were 100% and 22%, respectively. The false positive rate and false negative rates of PCR compared to the current diagnosis with at least one of the classical methods were 26% and 0%, respectively.

Limitations, reasons for caution: The main limitation of the method is the establishment of the minimum amount of bacterial DNA that causes the disease, as the copy numbers for the interrogated gene could be variable between different bacterial species and this effect could cause a slight deviation on the number of bacteria estimated.

Wider implications of the findings: The proposed molecular method represents an objective, fast and cheap diagnostic tool that allows us to detect culturable and non-culturable bacteria improving the diagnostic and treatment of this ghost endometrial pathology.

Trial registration number: This study has been approved by the local Ethical Committee at the University of Bary, where it has been registered with the number 4880.

P-298 Toxicogenomic profiling and chemical-gene interaction reveal the potentiation of environmental toxins risk on endometriosis

H.W. Chen[1], C.R. Tzeng[2]

[1]National Taiwan University, Graduate Ins. Toxicology, Taipei, Taiwan R.O.C.
[2]Taipei Medical University, Center of Reproductive Medicine, Taipei, Taiwan R.O.C.

Study question: How can we study and evaluate the synergistic risks or mechanisms of multiple environmental chemicals on pathogenesis of endometriosis?

Summary answer: By integrating the endometriosis-related genes and chemical-gene interactome, the combinatory and potentiated risks of environmental chemicals co-exposure in endometriosis was investigated.

What is known already: Several transcriptomic analysis of endometriosis-related genes have been profiled; whereas, we have already identified 52 endometriosis-related genes (52 Endo-genes). Although, the genes related chemical exposures are also discovered as well; the synergistic effects of the environmental toxins, such as dioxins, polychlorinated biphenyls (PCB), benzo (a)pyrene, alfatoxins, arsenic, and phthalates, on endometriosis via the integrated databases of toxicogenomcis and protein-protein interaction/conectome has not been described.

Study design, size, duration: According to our database and literature survey, the gene expression profile of endometriosis has been established. The toxicogenomic database and putative signaling analysis were performed and analyzed via the comparative toxicogenomic database (CTD), TOXNET, AltTox, and STRING to study the chemical-gene interaction and protein-protein intercatome.

Participants/materials, setting, methods: For the intersection of the environmental chemicals and the 52 Endo-genes, ten common environmental toxins were selected for the analysis, including tetrachlorodibenzodioxin, benzo (a)pyrene, alfatoxin A1, arsenic, and dibutyl phthalate. For the individual of the intersect genes, the combinatory analysis of the synergistic effects of the target Endo-genes of the environmental chemicals were evaluated and confirmed via Q-PCR.

Main results and the role of chance: Here, we have identified 52 endometriosis-related genes (52 Endo-genes), including FRZB, MGP, PDLIM5, TNS1, SPEG, and MEF2C signaling which may controlling the cell migration, immune regulation and cell survival on endometriosis; also, we try to identify the intersection of the endometriosis-related and the environmental chemical-induced genes or hubs. Interestingly, several important genes in endometriosis could be synergistically regulated via different environmental chemicals, such as dioxins and polychlorinated biphenyls (PCBs), which have been suggested to play a significant role in the development of endometriosis. We found that tetrachlorodibenzodioxin could induce 42 of the 52 Endo-genes; whereas, benzo (a)pyrene could up-regulate 38 Endo-genes. Most importantly, there are 34 Endo-genes could be regulated via both tetrachlorodibenzodioxin and benzo(a) pyrene. Furthermore, we can found that TNS1, the regulator to promote cell migration, could be regulated via not only dioxins and benzo(a)pyrene, but also dibutyl phthalate, bisphenol A and alfatoxin B1. Whereas, clustering (CLU) and

FGL2 could be regulated via estrogen, dioxins, bisphenol A, indicating the transcriptional signaling of MEF2C, CTGF, ER and AHR may co-contribute on these pathological pathways. These results indicate the combinatory risks as co-exposure to the environmental chemicals; also discover the potential signaling pathway for the prevention or therapeutic interventions for endometriosis.

Limitations, reasons for caution: Thousands of environmental chemicals might need to be analyzed and should be further validated in vitro or even in vivo study to exam the potency and power of the analysis of the chemical-gene interactome approach. Furthermore, the methodology also needs optimization in different or certain types of the response cells.

Wider implications of the findings: Such approach could be helpful for evaluate the potential interactions or potentiation of multiple environmental chemicals on diseases, such as endometriosis. Under the risk of the complicated environmental hazards, we should learn how to make the risk assessment via the integration of the genomic databases and the big data analysis.

Trial registration number: Not applicable.

P-299 How do endometriosis and adenomyosis and their subtypes affect women's reproductive life-course from the quality of oocyte to birth?

Y. Cheong[4], J. Horton[1], M. Hamdan[2], T.C. Li[3]

[1]University of Southampton, Human Development and Health, Southampton, United Kingdom
[2]University of Malaya, Obstetrics and Gynaecology, Kuala Lumpur, Malaysia
[3]Chinese University of Hong Kong, Reproductive Medicine and Surgery, Shatin, Hong Kong
[4]University of Southampton, Reproductive Medicine, Southampton, United Kingdom

Study question: How do endometriosis and adenomyosis affect reproduction from oocyte development to neonatal outcomes and how do these outcomes relate to the various disease subtypes individually?

Summary answer: Endometriosis and adenomyosis negatively impact on fertility. Subtypes of the disease present specific complications relating to either the oocyte quality and/or the endometrium.

What is known already: Endometriosis is known to cause hormonal, cellular and immunological alterations within the endometrium as well as DNA damage to oocytes, resulting in subfertility. Severe endometriosis is associated with a worse reproductive outcome in those undergoing assisted reproduction. Aberrant decidualisation and placentation within a disturbed uterine environment is known to influence the developmental programming of health and disease (Barker's hypothesis). It is unclear if and how such early aberrant reproductive developments relate to later pregnancy outcomes in endometriosis and adenomyosis and if these are subtype or severity specific.

Study design, size, duration: A systematic literature review of various databases was performed and screened by two reviewers independently from which a meta-analysis was conducted.

Participants/materials, setting, methods: A systematic literature review identified all comparative and observational studies published between 1980 and 2016 in any language on endometriosis and adenomyosis (all severity, stages and subtypes) and fertility, obstetric and neonatal outcomes (23 search terms). A proforma was used to extract data for meta-analysis. 1493 papers were reviewed by title and abstract. 118 full texts were reviewed, 60 papers were finally selected for data extraction. A standardised checklist was used to evaluate study quality.

Main results and the role of chance: The majority of studies have examined reproductive outcomes of in-vitro fertilisation and intra-cytoplasmic sperm injection treatment. Some population based studies included spontaneous conception. Stage I-II endometriosis specifically was associated with reduced fertilisation rate per oocyte (stage I-II: OR 0.82; 0.75-0.90 95% CI) whereas stage III-IV endometriosis was associated with reduced implantation rate per embryo transfer (OR 0.72; 0.58-0.90 95% CI) and reduced clinical pregnancy rate per cycle (OR 0.71; 0.53-0.95 95% CI). The live birth rate, however was unaffected by endometriosis regardless of severity. Patients with adenomyosis were found to have lower implantation rate (OR 0.51; 0.49-0.88 95%CI), pregnancy rate (OR 0.51; 0.38-0.69 95% CI) and live birth rate (OR 0.54; 0.36-0.80 95% CI) with an increased risk of miscarriage (OR 3.62; 2.01-6.51 95% CI). The

presence of endometriosis and/or adenomyosis is associated with increased obstetrics complications including preterm birth and placenta praevia but more studies are required to draw meaningful statistical conclusions.

Limitations, reasons for caution: The Downs and Black checklist revealed weaknesses mainly in internal validity and confounding and selection bias in many of the included studies. Meta-analysis demonstrated that quantitative and qualitative heterogeneity between studies varied considerably but I^2 is <50% in the majority of studies.

Wider implications of the findings: Endometriosis may have subtype-specific impacts across the entire reproductive process. In seeking diagnostic and therapeutic strategies, a reproductive life course systems approach is necessary in order to achieve useful long-term reproductive health impact.

Trial registration number: Not applicable.

P-300 Downregulation tensin 1 following GnRHa treatment in tissues and serum women with endometriosis

E. Rahmawati[1], W.C.V. Yang[2], P.K. Maurya[3], H.W. Chen[4], C.R. Tzeng[5]

[1]Taipei Medical University, Graduate Institute of Clinical Medicine, Taipei City, Taiwan R.O.C.
[2]Taipei Medical University, The PhD Program for Translational Medicine- College of Medical Science and Technology, Taipei, Taiwan R.O.C.
[3]Amity University Uttar Pradesh, Amity Institute of Biotechnology, Noida, India
[4]National Taiwan University, Graduate Institute of Toxicology- College of Medicine, Taipei, Taiwan R.O.C.
[5]Taipei Medical University Hospital, Center for Reproductive Medicine- Department of Obstetrics and Gynecology, Taipei, Taiwan R.O.C.

Study question: Is tensin 1 associated with gonadotropin-releasing hormone agonist (GnRHa) treatment in the patient with endometriosis?

Summary answer: Treatment with GnRHa on the women with endometriosis down regulates the expression of tensin 1 in mRNA and protein level both in tissues and serum.

What is known already: The underlying pathogenesis of endometriosis is still poorly understood, many cell migration and invasion-related molecules have been reported to be associated with endometriosis disease progression. Tensin 1 is focal adhesion phosophoprotein molecule localized in cytoplasm, which play a role in cel migration as the transmembrane junctions between the extracellular matrix, and the cytoskeleton. Currently, one of the most widely used agents for the medical treatment of endometriosis is gonadotropin-releasing-hormone agonist (GnRHa). To date, there is no report related with expression of tensin 1 in women with endometriosis following GnRHa treatment.

Study design, size, duration: Tissues and serum were collected from the endometriosis patients with (n = 48) and without (n = 41) GnRHa treatment. Serum from patients with non-endometriosis (adenomyosis and myoma, n = 16) were used as comparasion for investigating serum level of tensin 1 in women with endometriosis

Participants/materials, setting, methods: Messenger RNA and protein level of tensin 1 from patients with and without GnRHa treatment were examined by qPCR and western blot respectively. Immunolocalization was examined by IHC. Serum level of tensin 1 was examined by ELISA in the patients before and after GnRHa treatment and also compared with non-endometriosis patients. We also investigated expression of tensin 1 in tissues and serum based on the menstrual cycle and also duration of GnRHa treatment.

Main results and the role of chance: Tensin 1 mRNA in endometriotic tissues showed significantly lower expression in the GnRHa treatment group than in controls (P = 0.0064). The level of tensin 1 protein was consistent with the level of mRNA (P = 0.0024). From IHC experiment we observed cytoplasmic tensin 1 protein expression in both epithelial and stromal cells and tensin 1 expression in endometriosis tissue from controls was higher than in the treated group. Follow up study showed after GnRHa treatment, the average concentration of tensin 1 was significantly decreased by 27.27% from pretreatment levels (from 2732 ± 710.3 to 1987 ± 620.9 pg/ml). There was significant difference serum level of tensin 1 between women with adenomyoma and women with moderate-severe endometriosis (676.7 ± 27754.99 VS 1016 ± 45.55 pg/ml, P = 0.04) but no difference between women with myoma and endometriosis at any stage. Based on the different stage of endometriosis there was no significant

difference in serum levels of tensin 1 between patients with minimal-mild and moderate-severe (993.4 ± 142 vs. 1016 ± 45.55 pg/ml). There was no difference in tensin 1 expression in the proliferative and secretory phases of the menstrual cycle in both tissues and serum.

Limitations, reasons for caution: Our results should be further confirmed in a larger cohort of patients and functional assay is needed for further investigation related to involvement of tensin 1 in the pathogenesis of endometriosis.

Wider implications of the findings: Down regulated expression of tensin 1 by GnRHa may contribute to the inhibition of cell motility of endometriotic cells. The results emphasise the importance of migration-related factor of tensin 1 in the pathogenesis of endometriosis. Tensin 1 may be target for therapeutic intervention by GnRHa treatment in women endometriosis

Trial registration number: not applicable.

P-301 Uterine Natural Killer Cell Phenotype: Predicting ART (Assisted Reproductive Technology) success in endometriosis-associated infertility

L. Glover[1], D. Crosby[1], U. Thiruchelvam[2], C. Ni Chorcora[2], C. O'Farrelly[2], M. Wingfield[1,3]

[1]Merrion Fertility Clinic, National Maternity Hospital, Dublin, Ireland
[2]Trinity Biomedical Sciences Institute- Trinity College Dublin, Medicine, Dublin, Ireland
[3]University College Dublin, Obstetrics and Gynaecology, Dublin, Ireland

Study question: Do women with endometriosis-related infertility display differences in blood or uterine NK cell profiles that may be predictive of ART outcomes?

Summary answer: Uterine, but not blood, NK cell phenotype was found to differ between endometriosis patients with successful and unsuccessful implantation following ART.

What is known already: Uterine natural killer (uNK) cells are the dominant mucosal immune cell in the uterus, are abundant early in gestation and contribute to placentation. Their role in implantation is currently unclear. We have previously shown maturation of lymphoid progenitors in human endometrium and increased uterine haematopoetic precursors in women with infertility. We also found increased proportions of uNK progenitor cells in women with endometriosis and infertility compared to fertile controls. The aim of this study was to examine mature NK cells and their progenitors in the endometrium and blood of women with endometriosis who underwent ART.

Study design, size, duration: Patients were prospectively recruited to a cohort study between March 2013 and June 2015. Endometrial tissue from proliferative or secretory phase endometrium was obtained by aspiration biopsy from thirty-one women with a diagnosis of endometriosis-associated infertility (21 stage 1-2, 10 stage 3-4). Matched peripheral blood samples were also collected. Ethical approval was granted by the National Maternity Hospital. Patients underwent ART treatment (IVF, ICSI or IUI) within a mean interval of 9.5 months of surgery.

Participants/materials, setting, methods: Study participants were similar with regard to age, BMI, parity, AMH levels and duration of infertility at endometrial biopsy. Endometrial tissue was processed and peripheral blood mononuclear cells were isolated using established protocols. NK cells were analyzed by flow cytometry using antibodies to CD45, CD56, CD1, CD34, CD117 and CD94. Successful implantation was defined as evidence of a clinical pregnancy. Data were analyzed using Mann-Whitney or Kruskal–Wallis test, with Dunn's multiple comparison test.

Main results and the role of chance: Of thirty-one patients with a confirmed surgical diagnosis of endometriosis who underwent ART in a nonconsecutive cycle, twenty-one women (68%) had successful implantation and ten (32%) were unsuccessful. No difference in age, number of treatment cycles or stage of endometriosis was noted between patients with a positive outcome and those without. CD34+ haematopoietic progenitor cells were increased in the endometrium of women with successful implantation (4.9% vs 1.2% P < 0.05). This difference was more pronounced in proliferative endometrium. While there was considerable heterogeneity in NK phenotypes and numbers, women with successful implantation had fewer mature CD94[+] uNK cells (22.6% vs 38.2% P = 0.07) and higher levels of immature CD10[+]CD117[+] uNK

cells (5.2% vs 1.0% P = 0.02) than women with failed implantation. Furthermore, uNK expression of the NK cell receptor NKp46 was markedly lower in women who progressed to clinical pregnancy. In contrast, levels of mature peripheral blood NK cells were higher in women with successful implantation while levels of blood NK progenitors were similar in both groups.

Limitations, reasons for caution: The study cohort was limited in size and interval between endometrial biopsy and ART intervention ranged between four and twenty-one months (mean of 9.5 months, standard deviation 4.5).

Wider implications of the findings: This work demonstrates the marked differences in NK repertoires and developmental pathways in blood and uterine compartments. Moreover, these findings emphasise the limitations of focusing on blood NK cells for diagnostic or therapeutic interventions in female infertility.

Trial registration number: not applicable.

P-302   Differential transcript profile of cumulus cells of infertile women with and without advanced endometriosis who underwent ovarian stimulation

C.M. Luz[1], J. Meola[1], M.G. Da Broi[1], L.F.I. Silva[1], J.R. Plaça[2], W.A. Silva Jr[2], R.A. Ferriani[1], P.A. Navarro[1]

[1]Human Reproduction Division- Ribeirao Preto School of Medicine- University of São Paulo, Obstetrics and Gynecology, Ribeirão Preto, Brazil
[2]Ribeirao Preto School of Medicine- University of São Paulo, Laboratory of Molecular Genetics and Bioinformatics, Ribeirão Preto, Brazil

Study question: Are the cumulus cells (CC) of infertile women with advanced endometriosis molecularly different from the CC of infertile women without endometriosis?

Summary answer: CC of infertile women with advanced endometriosis seems to be molecularly different from those of infertile women without endometriosis.

What is known already: Several researches report a deleterious effect of endometriosis on oocyte quality. Since CC play a crucial role in oocyte competence acquisition, studies suggest that gene expression analysis of these cells can be used as indirect biomarkers of oocyte quality. Our group was pioneer in this theme demonstrating altered genes potentially related to compromised oocyte competence. However, the study of individual genes in CC restricts the exploration of deregulated metabolic pathways, whose investigation is essential to understand the mechanisms of infertility related to endometriosis. Until now no research evaluate the complete transcriptome of CC from infertile women with endometriosis.

Study design, size, duration: This prospective case-control study, was conducted between August of 2014 and February of 2016 at the Human Reproduction Division of the University Hospital, FMRP-USP. The study size was established based on previous researches that used the global transcripts profile screening methodology. Therefore, we used 9 patients per group, grouped in 3 pools/samples of 3 women each.

Participants/materials, setting, methods: CC were collected after controlled ovarian stimulation (COS) for intracytoplasmic sperm injection (ICSI). RNA next generation sequencing (RNA-Seq) was performed in 3 infertile women groups (controls without endometriosis, with endometriosis III/IV without endometrioma, and with endometriosis III/IV with endometrioma) by the Illumina platform HiSeq2500, High Output, pair-end. Data normalization and differential expression analyses were performed using the R statistical environment and STAR package.

Main results and the role of chance: The comparison between endometriosis III/IV with and without endometrioma to control group revealed 461 and 66 altered genes, respectively. No difference was achieved between endometriosis groups. Further, analysis of the top deregulated genes among groups of advanced endometriosis and control patients evidenced genes associated with oxidative phosphorylation pathway, acetylation, ubiquitination processes, and genes related to cholesterol and estradiol regulation. These data suggest that CC of infertile woman with advanced endometriosis carry essential molecular alterations linked with follicular and gametic development. Through enrichment of the top deregulated genes, we can point out the potential pathways altered in this process toward oocyte impairment and infertility.

Limitations, reasons for caution: The main limitation was the small sample size evaluated owing to restrictive eligibility criteria adopted and the difficulty in obtaining adequate samples for RNA-Seq, which compromises the generalizability of the study. On the other hand, the strict eligibility criteria increase the internal validity of this study.

Wider implications of the findings: The evidenced differentially expressed transcripts suggest molecular alterations in CC of infertile women with advanced endometriosis with and without endometrioma undergoing COS. As the identified top deregulated genes are related to pathways potentially involved with oocyte quality, these findings open new perspectives on the mechanisms involved in advanced endometriosis-related infertility.

Trial registration number: Not applicable.

P-303   Specific biopsychosocial variables affect sexual function in endometriosis patients

N. Pluchino, S. Shabanov, R. Marci, J.M. Wenger

Hopital Universitaire de Genève, Ob/Gyn, Geneva, Switzerland

Study question: Is sexual function in endometriosis affected only by disease severity or additional biological and psychosocial variables are also associated with sexual dysfunction?

Summary answer: Dyspareunia, length of pain and specific psychobiological variables affect sexuality. Hormonal treatment and previous surgeries were also associated with increased risk of sexual dysfunction.

What is known already: Sexual function is an important aspect of health and quality of life and is influenced by both medical conditions and health-care interventions, especially when gynecologic disorders are involved. Coital pain is among the main factors that affect sexual functioning, and this symptom is reported by almost half of women suffering from endometriosis. However, sexuality is a complex phenomenon driven by social, psychological and biological/hormonal factors and the presence of endometriosis might further affect domains of sexual function and the quality of a sexual relationship.

Study design, size, duration: Cross-sectional design. All participants were recruited among consecutive inpatients scheduled for laparoscopic surgery at the Geneva University Hospital based on signs and symptoms suggestive of endometriosis (ie, dysmenorrhea, nonmenstrual pelvic pain, ovarian cysts, and infertility) between January 2014 and September 2015. The study was reviewed and approved by the institution's Ethics Committee.

Participants/materials, setting, methods: A total of 198 women with histologically confirmed endometriosis were enrolled in this study. Before laparoscopy, a semi-structured questionnaire was used to collect demographic data, medical history (including infertility status, hormonal treatment and pain) and disease characteristics. Female Sexual Function Index was used to assess sexual function and Endometriosis Health Profile 30 (EHP30) questionnaire was utilized to investigate measures of quality of life. All sub-scores of FSFI and EHP30 (core questionnaire 5 scales) were analyzed.

Main results and the role of chance: 171 with histological proven endometriosis completed questionnaires. Crude prevalence of sexual dysfunction according to FSFI score was 71%. Low FSFI score was correlated with higher EHP30 values. Dyspareunia and dyschesia scoring, the presence of deep lesions in the pouch of Douglas and advance staged were associated to sexual dysfunction. Length of pain symptoms, intensity of pain, current use of hormonal treatment and previous surgery were likely associated sexual dysfunction. After multiple backward logistic regression analysis including also demographic variables, only the length of pain symptoms (any type of pelvic pain), dyspareunia scoring, current use of hormonal treatment and previous surgery were significantly associated with female sexual dysfunction. Compared to women with no history of surgery for endometriosis, those who received one or more surgeries are at higher risk of having sexual dysfunction after adjustment for confounding factors.

Limitations, reasons for caution: This study analyzed patients with a surgical indication for endometriosis treatment (pain or infertility) and it couldn't be representative of the entire population of women affected by endometriosis.

Wider implications of the findings: Endometriosis negatively affects different domains of sexual function. Specific quality of life measures of endometriosis patients, disease charactestics and medical interventions may further affect quality of sexual function in endometriosis

Trial registration number: 09-193 R.

P-304   Efficacy of preimplantation genetic screening (PGS) for successful pregnancy in infertile, endometrioma patients

S.J. Chon, Y.J. Lee

Gil hospital, Obstetrics and Gynecology, Incheon-si, Korea- South

Study question: Wound PGS be effective on infertile women having endometrioma?

Summary answer: Endometrioma may result the poorer quality of embryos, but PGS may not be recommended routinely for women having endometrioma

What is known already: Although there have been improvements in process of in vitro fertilization-embryo transfer (IVF-ET), implantation rates are reported to be approximately 30% in women less than 35 years old and less than 10% in women more than 40 years old. Approximately 50-75% of spontaneous miscarriages are due to numeric chromosomal abnormalities of embryos. Endometriosis is known to have detrimental effects on oocyte and embryo qualities. Recently, preimplantation genetic screening (PGS) seems to be one of the methods in screening chromosomally abnormal embryos. Therefore, in this study, we are to study on effectiveness of PGS on quality of embryos in endometrioma patients.

Study design, size, duration: Retrospective cross sectional study

Total 100 cases of infertile women having endometrioma

From August 2014 to January 2016

Participants/materials, setting, methods: Fifty cases of infertile women who had endometrioma and 50 who did not have endometrioma underwent IVF and agreed to do PGS at Gil hospital were enrolled. Data were collected retrospectively. From a good quality embryo (grade I, II), embryo biopsy was done on day 3 and WGA with CMA were done on the same day. Percentages of euploidy status were calculated and analyzed according to the presence of endometrioma.

Main results and the role of chance: Total 234 embryos were sent for PGS. One hundred thirty embryos were from women with endometrioma, and 104 embryos were from women without endometrioma. The total retrieved numbers of embryos were similar, but the proportion of good quality embryos (Grade I, II) was statistically higher in non-endometrioma patients (49 % vs. 67 %, p-value = 0.02). However, the the results of euploidy proportions from PGS were statistically similar (57 % vs. 54 %, p-value = 0.79).

Limitations, reasons for caution: Single centered study

Infertile reasons were not all excluded

Wider implications of the findings: Although PGS has becoming the new issue for higher pregnancy rate, it should not be routinely recommended to endometrioma infertile couples.

Trial registration number: not applicable.

P-305   The cytokines analysis suggest the immune system activity in endometriosis

A. Turienzo Diez[1], A. Fabregat Reolid[2], B. Moliner Renau[3], B. Lledó Bosch[2], J. Llácer Aparicio[3], R. Bernabeu Perez[3]

[1]Instituto Bernabeu, IB Biotech, Alicante, Spain
[2]Instituto Bernabeu, Biotech, Alicante, Spain
[3]Instituto Bernabeu, Clinical, Alicante, Spain

Study question: To compare cytokines profile between endometriosis grade I-II patients and recurrent implantation failure (RIF) patients

Summary answer: Despite of fact that endometriosis is considered an inflammatory disease, RIF patients are comparable in this immunological response.

What is known already: Cytokines can help in the diagnosis of endometriosis through its inflammation response. Their paper in Recurrent Implantation Failure is still unknown, althouth the association with different cytokines together with T Helper Lymphocytes families are being investigated.

Study design, size, duration: Peripheral blood samples were obtained from sixty five women who attended Instituto Bernabeu between February and September 2016. Fifty five of them with a previous history of recurrent embryos implantation failure (RIF) and ten with unilateral mild endometriosis. We considered recurrent failed implantation when at least four good quality embryos were transferred in three transfers. Blood was centrifugated and serum frozen at -20 °C until its determination.

Participants/materials, setting, methods: A prospective study was carried out to achieve our objective. After serum thawing, we determined immune profile

that included biomarkers as IL-2, IL-4, IL-6, IL-8, IL-10, VEGF, IFN-δ, TNF-α, IL-1-α, IL-1β, MCP-1, EGF. For the analysis, we used "Cytokine and Growth Factors High Sensitivity" Randox Biochip. This technique consists of a sandwich chemiluminescent immunoassay. For the statistical analysis we used T Student analysis

Main results and the role of chance: All of the results of the levels of cytokines between groups (Endometriosis vs RIF) were comparable with the exception found in IL-1-α levels in which differences statistically significant were found (Endometriosis group: 0,14 vs RIF group: 0,39; p = 0.0069)

Limitations, reasons for caution: The main limitation is the sample size.In order to evaluate the effect of cytokines in implantation clinical data would be added. Patients with different indications

Wider implications of the findings: RIF patients could have associated an special immunological response. The fact that IL-1-α levels are lower in women with unilateral mild endometriosis could be interpreted as these patients have a different immunologic profile. So, IL-1-α levels could represent an early biomarker before endometriosis diagnosis.

Trial registration number: No trial

POSTER VIEWING SESSION
ETHICS AND LAW

P-306   Indications of the global prevalence of inheritable mitochondrial modifications

T. Ishii[1], Y. Hibino[2]

[1]Hokkaido University, Office of Health and Safety, Sapporo, Japan
[2]Kanazawa University, Graduate School of Medical Science, Kanazawa, Japan

Study question: At present, how widely are inheritable mitochondrial modifications (IMMs) permitted and provided in countries with different reproductive policies?

Summary answer: IMMs are currently permitted and provided at fertility clinics in at least 12 countries.

What is known already: Various types of IMMs have been developed to treat unexplained female infertility or prevent the inheritance of mitochondrial disease by offspring. Most IMMs require oocyte donation, but some do not. Clinical uses of ooplasmic (cytoplasmic) transfer and pronuclear transfer for infertility treatment led to regulatory responses in the US and China, respectively. Recently, MII spindle transfer for preventing mitochondrial disease has been implemented in Mexico. Furthermore, pronuclear transfer in Ukraine and AUGMENT in Canada, Japan and Spain are ongoing as an infertility treatment. However, the current state of the global clinical provisions and the regulations of IMMs remain unclear.

Study design, size, duration: First, in addition to relevant medical reports and clinical trial data, the uses indicated in the IFFS 2016 report as well as relevant information in the websites of reproductive tourism and clinics were investigated. Those results were then compared, and several countries were selected for further legal analyses regarding oocyte donation and germline genetic modifications for reproduction. Finally, the wider implications of the findings were discussed from regulatory and ethical standpoints.

Participants/materials, setting, methods: The surveyed reports include works published until December 2016 in English, Chinese or Japanese that were available through PubMed. Relevant trials were surveyed using ClinicalTrials.gov. The internet survey was based on the information available at the end of December 2016.

Main results and the role of chance: An analysis of document records and clinical trial data identified eight countries where IMMs had been clinically practiced or were being practiced. Further investigations of IFFS reports and tourism websites and clinics added 28 countries. Among the total 36 countries, 16 countries satisfying least 1 of our 4 criteria were selected for a legal analysis. Oocyte donation was allowed or permissible with some limitations in all 16 countries. In conclusion, cytoplasmic transfer or other IMMs are permitted and provided in at least 12 countries (Canada, Czech Rep., India, Israel, Japan, Mexico, Northern Cyprus, Panama, Russian Fed., Spain, UK and Ukraine). However, the regulatory positions differ among such countries; some simply do not regulate IMMs, other implicitly or explicitly regulate IMMs. Pronuclear transfer is or may be prohibited in Canada,

Czech Rep. and Japan. Currently, there is no evidence that IMMs are provided in China, Italy, Taiwan and the US. China largely prohibits IMMs except for AUGMENT and granular cell mitochondrial transfer. Italy implicitly prohibits IMMs. Taiwan and the US regulate IMMs by reviewing relevant clinical trials.

Limitations, reasons for caution: This study does not intend to encourage reproductive tourism. The results in part depend on the accuracy of information available on the internet. Furthermore, the accessibility and interpretation of legal documents might influence the regulatory analysis. We ask physicians to consult regulators in their own countries.

Wider implications of the findings: IMMs may prove attractive to female patients who value genetic relatedness. However, their unregulated use might globally cause social problems such as health problems in offspring and increasing oocyte transactions. The technical definitions and medical purposes should be contemplated t in their regulations, or the trials should be carefully reviewed.

Trial registration number: Not applicable.

P-307 Zika Virus Outbreak - Assisted reproduction patients should avoid pregnancy?

E. Ono[1], D.P.A.F. Braga[2], A.S. Setti[3], A. Iaconelli Jr.[2], E. Borges Jr.[4]

[1]Instituto Sapientiae - Centro de Estudos e Pesquisa em Reprodução Assistida, Scientific research, Sao Paulo/SP, Brazil
[2]Fertility Medical Group, Scientific Research, São Paulo, Brazil
[3]Instituto Sapientiae - Centro de Estudos e Pesquisa em Reprodução Assitida, Scientific Research, São Paulo, Brazil
[4]Fertility Medical Group, Clinical Departament, São Paulo, Brazil

Study question: Women should avoid pregnancy, because of the current Zika virus (ZIKV) outbreak, as recommended by public health authorities and government leaders of some countries?

Summary answer: ZIKV infection risk deserves special attention; however infection with ZIKV during pregnancy does not lead to increased risks than any other previously known pathogens.

What is known already: Zika virus (ZIKV) is predominantly spread via the *Aedes* species of mosquitos. An outbreak is currently spreading throughout South America, resulting in a large number of cases of microcephaly, Guillain–Barre syndrome, and meningoencephalitis. The World Health Organization (WHO) declared the ZIKV epidemic a Public Health Emergency of International Concern, and the CDC Emergency Operations Center elevated their response to ZIKV to level 1, the highest level of activation, for only the fourth time in the history of the organization. Moreover, public health authorities and government leaders in multiple countries have issued first-ever recommendations for women to simply avoid pregnancy.

Study design, size, duration: This study was performed in a university-affiliated *In vitro* fertilization center in Brazil, in which the issue concerning the ZIKV infection in pregnant women is an extremely real problem, with drastic consequences for the reproductive population and assisted reproduction centers. Considering the fast spread of ZIKV worldwide, a critical discussion on the risk of microcephaly due to ZIKV infection, and incidence rate (IR) of others harmful pathogens to vulnerable pregnant women and infants was conducted.

Participants/materials, setting, methods: Brazil has experienced over 1.5 million cases of ZIKV, and WHO estimates that potentially 4 million people in the Americas may become infected in 2016. The Brazilian health officials warned women to avoid pregnancy until the ZIKV outbreak passes. Governments in Colombia and Ecuador made similar recommendations. Recommendations in El Salvador are even more extreme, and women there have been advised to avoid pregnancy until 2018. This study discusses whether such recommendations are justified.

Main results and the role of chance: Pregnant women are exposed to many infectious agents that are potentially harmful. Intrauterine bacterial infection, such as: *Chlamydia trachomatis* (IR=3.8%); *Neisseria gonorrhea* (IR=1.9%); and *Treponema pallidum* (Syphilis, IR=0.15-1.5%), viruses infection, such as: Parvovirus B19 (IR= 1-5%); Cytomegalovirus (IR=1-3%); Varicella Zoster (chickenpox) (IR=0.02%); Herpes Simplex Virus (IR=2%);; and parasites infection, such as: *Trypanosoma cruzi* (Chagas disease, IR= 0.5-10%); *Toxoplasma gondii* (IR=0.4%); and *Plasmodium sp* (Malaria, IR= 2.9% in endemic regions), may represent major risks for pregnant women and fetus. Investigators studying the 2013–2014 ZIKV outbreak in French Polynesia estimated that the risk of microcephaly due to ZIKV infection in the first trimester of pregnancy was 0.95% and recently, the magnitude of the risk of

microcephaly in Brazil (IR) is estimated to be approximately 0.88%. However, patients who face infertility and the fact that their ovarian reserve is declining, specially older patients, when receiving adequate orientation, did not postpone their IVF cycles, in Brazil. In fact, in the present assisted reproduction center, despite the recommendation of health authorities and government leaders in 2015, 844 cycles were performed, in which 34.0% of the patients were >38 y-old, while in 2016, 769 cycles were performed and 36.8% of the patients were >38 y-old.

Limitations, reasons for caution: This is a literature review and authors opinion.

Wider implications of the findings: The ZIKV infection risk is extremely high, especially in endemic regions. However the microcephaly risk due to ZIKV is not higher than the risk of miscarriage and birth defects due to other recognized pathogens. Therefore, it is prudent to take precautions to avoid ZIKV as any other infection during pregnancy

Trial registration number: None.

P-308 What legal aspects worry ART professionals?

M. Boada[1,2], F. Abellán[3,4]

[1]ASEBIR, Association for the Study of Reproductive Biology, Barcelona, Spain
[2]Women's Health Dexeus, Barcelona, Spain
[3]ASEBIR, Legal Consultancy, Madrid, Spain
[4]Derecho Sanitario Asesores, Madrid, Spain

Study question: Which aspects generate most legal doubts among ART professionals in order to establish adequate mechanisms to solve these concerns?

Summary answer: During 2016, questions addressed to the Scientific Society's Legal Consultancy were mainly focused on aspects related to Donation (35.4%) and gametes and embryos Cryopreservation (21.2%).

What is known already: European Tissues and Cells Directive (EUTCD) applies to all member states. Moreover, each country has its own legislation according to its idiosyncrasy and specific context. Despite this, many legal questions arise in ART practice that are difficult for users to understand or that are not specified in the legal texts.

Scientific societies play an important role publishing position papers and articles about those aspects of ART that need to be treated more extensively. Having a Legal Consultancy service available to all members of the society is another way to contribute to it.

Study design, size, duration: Longitudinal descriptive study.

The use of the Society's Legal Consultancy has been quantified from the beginning of the service in 2006 to 2016. A total of 1290 legal questions was received. Those received during the last year (n = 226) have been analysed and classified according to their subjects.

Participants/materials, setting, methods: Legal questions from members were addressed to the Legal Consultancy on line through the society's Website. All questions were recorded and transferred to the lawyer specialist in ART legislation who advises the society and handles members' queries. The reply to each question according to Spanish legislation and the EUTCD was sent to the member in a maximum of 2 days. Questions were classified in 10 different groups according to their topic.

Main results and the role of chance: The implementation of the Legal Consultancy in our society was in 2006 coinciding with publication of the new law on ART in our country and two EU Commission Directives implementing the EUTCD. Since its incorporation as a free service for all the membership of the society, the number of questions received has shown a great increase not only due to the higher number of members but also to the growing interest in legal questions related to ART. While in the first 5 years (2006-2010) the annual number of questions was <100 (2-54) with a mean rate of <0.1 questions/member, in the next 2 years (2011-2012) it exceeded 100 questions (0-1-0.2 questions/member) and in the last 4 years (2013-2016) it was >200 queries/year (>0.2 questions/member). A peak was observed in 2014 coinciding with the publication of new national rules. The most frequent questions received during the last year were related to gamete and embryo donation (35.4%; 80/226), cryopreservation (21.2%; 48/226), shipping and distribution of reproductive samples (5.7%; 13/226), preimplantation genetic diagnosis (4.9%; 11/226), posthumous reproduction (3.5%; 8/226); surrogacy (3.1%; 7/226), consent forms (8%; 18/226), status of the embryologists (4%; 9/226), ART centres (4.9%; 11/226) and others (9.3%; 21/226).

Limitations, reasons for caution: Descriptive analysis that includes only questions addressed to one specific scientific society that mainly consists of embryologists. Questions like medical concerns might not be sufficiently reflected in the sample analysed.

Wider implications of the findings: Our scientific society will offer different specific actions and events focused on the topics that have been detected as the most conflictive in order to give its members necessary tools for better knowledge and understanding of the current legislation on ART.

Trial registration number: None.

P-309 What raises ethical concerns on oocyte cryopreservation for social indications in lay people? Results from a factorial survey in Germany

A. Forke[1], P. Siegers[2]

[1]Institute of Sociology, Research Group Social Stratification, Mainz, Germany
[2]GESIS Leibniz-Institute for Social Sciences, Research Data Center German General Social Survey, Cologne, Germany

Study question: Which factors of oocyte cryopreservation for non-medical reasons raise ethical concerns in the general population?

Summary answer: They evaluate the specific social implications and consequences of cryopreservation in order to avoid harm and stick to social norms of a mother's age.

What is known already: Very few studies on lay peoples' attitudes towards cryopreservation have been published. They report high levels of support, also for social indications. However, participants for these studies where recruited at reproductive care centres or on dedicated websites. Results on factors that raise ethical concerns in lay people have not been published yet. We assume that support for cryopreservation is based on its benefit to avoid suffering from involuntary childlessness. Likely this benefit is balanced by potential harm for the (unborn) children resulting from cryopreservation. There is no study on situational and individual factors influencing acceptance of cryopreservation for non-medical reason.

Study design, size, duration: We collected data of 749 German speaking people from an online access panel. Every participant rated 12 short descriptions (vignettes) of different women using cryopreservation for non-medical reasons. The vignettes contain controlled variation with respect to the factors expected to influence acceptance. The different categories of the factors represent the treatments and controls as in experimental designs. Therefore, effects are unbiased and causal interpretation is valid (Auspug/Hinz 2015:9; Dülmer 2014a: 721 f.).

Participants/materials, setting, methods: We identified 5 factors from ethical discussions about cryopreservation expected to influence lay peoples' acceptance: age at cryopreservation (28 or 33 years), maximum age for using preserved oocytes (40 or 55 years), strength of wish for a child (weak or strong), number of oocytes for preservation (4, 12 or 30) and motives (financial security, career or self- realization). We performed a multilevel analysis that simultaneously accounts for the variation between respondents and within each respondent.

Main results and the role of chance: Cryopreservation for social indications is highly controversial in the sample: The mean rating is 6.14 (sd=3.40) on the 11 point scale (0 "not justifiable at all" 10 "completely justifiable"). The woman's age at the time of oocyte preservation does not influence acceptance (p>0.1). All other factors significantly influence acceptance of cryopreservation (p<0.01): The strongest effect yields the maximum age until which the women plan to use the preserved oocytes for IVF (-2.094). Compared to a woman that plans to become pregnant up to age 40, acceptance is two scale points lower for woman that plan IVF up to age 55. As expected, acceptance is higher for women who have a strong wish for a child (0.124). Supporting arguments from pro-life critiques of cryopreservation, a greater number of preserved oocytes decreases acceptance. The difference is 0.211 scale points for 12 oocytes compared to 30 and 0.247 scale point for 4 oocytes compared to 30. Egoistic motivations (career, self-realization) also decrease the acceptance. The effect size for the pursuing a career before parenthood (0.218) is smaller than for self-realization (0.251). This difference is not significant, indicating that respondents do not differentiate between economic and other egoistic motives.

Limitations, reasons for caution: The online access panel we drew the sample from is not representative for the German population. Although factorial surveys are quasi-experimental designs allowing for causal interpretation of the results, we have to be careful with generalizing the results to the general population.

Wider implications of the findings: To address ethical concerns regarding cryopreservation for social indications more information on potential harm and benefit of late parenthood for child development should be provided to potential users and the general public.

Trial registration number: This study is not a clinical trial.

P-310 Ethical issues raised by offering ovarian tissue cryopreservation to girls with Turner syndrome

M. Schleedoorn[1], K. Fleischer[1], W. Nelen[2], D. Braat[1], I. Beerendonk[3], R. Peek[1], J. Van Alfen - van der Velden[4], E. Van Leeuwen[5]

[1]Radboud University Medical Center, Obstetrics and Gynaecology, Nijmegen, The Netherlands
[2]Radboud University Medical Center, Radboud University Medical Center, Nijmegen, The Netherlands
[3]Obstetrics and Gynaecology, Obstetrics and Gynaecology, Nijmegen, The Netherlands
[4]Radboud University Medical Center, Pediatric Endocrinology, Nijmegen, The Netherlands
[5]Radboud University Medical Center, Medical Ethics, Nijmegen, The Netherlands

Study question: What are the ethical issues raised by offering ovarian tissue cryopreservation (OTC) to girls with Turner syndrome (TS)?

Summary answer: An overview of ethical issues raised by offering OTC to girls with TS with focus on four basic ethical principles: autonomy, beneficence, non-maleficence and justice.

What is known already: OTC has been well described in girls undergoing gonadotoxic cancer treatments. Auto transplantation of cryopreserved-thawed ovarian tissue in cancer survivors has resulted in restoration of ovarian function and pregnancy, with a life birth rate of 25% per transplantation. This has led to a new debate to expand OTC as a fertility preservation option to girls with TS. Due to an accelerated loss of oocytes, most girls with TS undergo ovarian failure before reaching adulthood. Although OTC has been experimentally performed in these patients, the promise of fertility preservation is at present hypothetical according to what we know.

Study design, size, duration: A two-round ethical Delphi method including a questionnaire survey and a consensus meeting.

Participants/materials, setting, methods: A literature search was undertaken to identify the ethical issues associated with OTC in girls with TS. All arguments identified were divided into four subcategories based on basic ethical principles (autonomy, beneficence, non-maleficence, and justice). A multidisciplinary expert panel (including patients and parents) rated and prioritized all arguments extracted from the literature during the questionnaire round. Key arguments were selected by using a strict consensus methodology. Group consensus was reached during a consensus meeting.

Main results and the role of chance: OTC in girls with TS raises a number of ethical considerations. The primary objective of OTC remains to promote the autonomy of patients by giving them the hope of having genetic concordant children in the future, and thus improve their psychosocial well-being. However, patients younger than 16 do not have the legal capacity to make their own decision, requiring an approved consent from both parents. Furthermore, besides the potential risks associated with the surgical retrieval it is important to be aware that, at present, the promise of fertility preservation in girls with TS is still hypothetical and may produce false hope. Still, we think that it is defensible to offer OTC to patients with TS who are demanding this fertility preservation option, provided that these girls (and their parents) are well-informed about all aspects of the experimental procedure.

Limitations, reasons for caution: Since all arguments were retrieved from published data only, potential publication bias with an underrepresentation of negative study results may have occurred.

Wider implications of the findings: This ethical analysis forms a basis for further debates and may be helpful for the development of research protocols to collect more data on the possible benefits and harms of OTC in girls with TS.

Trial registration number: not applicable.

P-311 Banned for 10 years, ART gametes donation cycles now allowed in Italy: first national data collection

G. Scaravelli, R. De Luca, R. Spoletini, V. Vigiliano, S. Bolli, S. Fiaccavento, L. Speaziale

National Health Institute, National Centre for Disease Prevention and Health Promotion, Rome, Italy

Study question: Analyze the number and type of gametes donation cycles collected by the Italian Assisted Reproductive Technology Register (IARTR). After the change of the law that banned these procedures for 10 years

Summary answer: IARTR collected aggregate data on 3,046 gametes donation cycles performed from May 2014 till December 2015 by 76 clinics

What is known already: The postponement of childbearing age in Italy determine a large number of older women wanting a baby. In these cases and in many others gametes donation could represent the only option in infertility treatments. Recent change of the Law in Italy, allows gamete donations, but not any form of compensation for donors. In the absence of Italian donors especially for oocytes, almost all the gametes utilized in Italy comes from abroad (80.9%)

Study design, size, duration: In this study IARTR analyzed retrospectively data on 3,046 gametes donation cycles performed on 2,699 patients. 205 ART clinics and 172 IUI clinics sent data to the National Italian Register and participating in the study with 73 out of 205 (35.6%) and 3 out of 172 (1.7%) performed donation cycles

Participants/materials, setting, methods: All ART centres which has performed at least one cycle with gametes donation, that have sent data during the study period. Parameters regarding number of patients, number of cycles, treatment indications, age classes, pregnancies and live births rates were analysed. Data were statistically analysed using SPSS statistic 22.0

Main results and the role of chance: IARTR collected 2,496 gametes donation from ART cycles and 550 from IUI, by 76 clinics. Among the clinics only 8 were public. Most of cycles were oocyte donation cycles (47.3%), while semen donation were 1,151 Cycles (37.8%) and 454 cycles were done with cryopreserved embryos obtained from gametes donation (14.9%). The principal cause for oocyte donation was the advanced maternal age in 41.6% of cases, while for semen donation 95.2% of cases were pathologies affecting sperm viability. Almost all the gametes utilized for treatments (85.7 % of oocytes and 72.9 % of semen) comes from abroad. Pregnancy rate per transfer was 41.7% for fresh donor eggs, 32.1% for frozen donor eggs cycles and 33.9% for cryopreserved embryos. Pregnancy rate per cycle in sperm donations was 24.8%. Multiple delivery rates were 20.7%, 39.3%, 18% and 17.1% respectively. During the study period 663 infants were born

Limitations, reasons for caution: With the limitation of donors due to the impossibility to give any form of compensation or benefit to these persons, the picture of the situation in Italy on gametes donation is far from exhaustive. Few public clinics have had the possibility to apply those procedures, due to lack of resources

Wider implications of the findings: the Italian situation regarding gametes donation policy, arise the question of equity in access to these procedures. The impossibility to compensate the donor determine the difficulties of public services to perform these procedures due to the lack of resources to import gametes

Trial registration number: not applicable.

P-312   Legally Enforceable IVF Surrogacy in the U.K as an Exclusive Treatment Option for Recurrent Miscarriage of Unknown Aetiology- Time for Debate

C. Miti, S. Keay

University Hospital Coventry & Warwickshire, Obstetrics & Gynaecology, Coventry, United Kingdom

Study question: Can a legally enforceable and regulated system of IVF surrogacy be a treatment option offered by the UK National Health Service to couples facing recurrent miscarriage of unknown aetiology?

Summary answer: It is ethically unacceptable to allow gestational surrogacy without legal enforcement while permitting medical intervention and therapies of unproven efficacy in managing recurrent miscarriage

What is known already: Traditional and gestational forms of surrogacy are either commercialised or altruistic and the U.K law permits the latter arrangement. Furthermore, in the U.K although IVF surrogacy is fully regulated in HFEA centres, it remains unenforceable.

Optimal management of recurrent miscarriages of unknown aetiology remains elusive and current therapies offered to emotive couples often lack therapeutic efficacy.

Study design, size, duration: Literature Review

Participants/materials, setting, methods: A literature search of surrogacy and management of recurrent miscarriages of unknown aetiology was made in Pub Med & COCHRANE databases using search terms [recurrent pregnancy loss and IVF surrogacy] or [recurrent miscarriage and IVF surrogacy] and relevant studies reviewed

Main results and the role of chance: The current legal position in the UK of fully regulating gestational surrogacy in licensed HFEA centres still does not provide legal enforcement for the arrangement. The ethics of failing to offer a couple an intervention with proven efficacy as is that of carefully selected and screened altruistic surrogates has to be debated

IVF performance and conception rates in gestational surrogacy are comparable to standard IVF including the perinatal outcomes of the children that result. Current therapies of recurrent miscarriage of unknown aetiology include hCG, Progesterone, anticoagulation, immunotherapy and all but psychological care do not have the evidence to support their efficacy.

Awareness and campaign for legislation to enforce IVF surrogacy in a contained pathway as a treatment option exclusively for couples with recurrent miscarriages is long overdue but lacking. For this purpose we have coined the term 'therapeutic gestational surrogacy' to encapsulate the exclusive nature of this proposed arrangement.

Limitations, reasons for caution: Literature concerning IVF surrogacy in recurrent pregnancy loss is sparse and the topic poorly researched. The conclusions drawn here are therefore limited and further research in this area is needed.

Wider implications of the findings: The success of UK HFEA centres can be extended to include legally enforceable gestational surrogacy as an exclusive evidence based treatment option. The quest for a 'miracle cure' to recurrent pregnancy loss has denied serious debate and campaign for enforcement of IVF surrogacy which would be welcomed by affected couples.

Trial registration number: N/A.

P-313   Will it be possible once and for all to establish the single Embryo Transfer (sET) as gold (and unique) standard in IVF procedures?

G. Barrenetxea Ziarrusta[1], E. Martínez[2], M. De Las Heras[2], J.I. Arambarri[3], M.C. Garcia[3], J. Barrenetxea[3]

[1]Universidad del País Vasco/Euskal Herriko Unibertsitatea, Gynecology, Bilbao, Spain
[2]Reproduccion Bilbao, Embriology, Bilbao, Spain
[3]Reproduccion Bilbao, Gynecology, BILBAO, Spain

Study question: Despite the general agreement that multiple pregnancy represents a serious (and avoidable) complication of assisted reproduction, in most procedures, 2 (even 3) embryos are transferred.

Summary answer: The implementation of a strict sET policy does not represent a limitation in IVF success and multiple pregnancy rates (and their complications) are reduced dramatically.

What is known already: Spanish legislation allows the transfer of up 3 embryos in each IVF procedure. Although some limitations are advised and there is a general agreement that among good prognosis patients a sET should be the preferred choice, in more than 70% of treatments 2 or even 3 embryos are transferred in Spain. The complications of multiple pregnancies (MP) are (should be) well known by assisted reproduction specialists and include both maternal and perinatal events. Unfortunately, the lack of legal limitation constitutes a "pathway" to keep on with this inappropriate and sometimes hazardous policy.

Study design, size, duration: A retrospective cohort analysis with a study group of IVF cycles undertaken between June, 2015 and May, 2016 at an University associated ART center were assessed and the results were compared to those published by Spanish Fertility Society (SEF) (www.registrosef.com) corresponding to the activity of Spanish centers in 2014 (last reported year). Participation in such registry is mandatory in Spain. A total of 225 centers (91,80% of the officially accredited) reported their results in 2014.

Participants/materials, setting, methods: A total of 397 IVF cycles (203 fresh and 194 vitrified-embryos cycles) (study group) were compared to the

72598 IVF cycles reported in the SEF 2014-Report (51591 fresh and 21007 frozen-embryos cycles). Cycles in which donor eggs were used were not included.

The frequencies of single, double and triple embryo transfer were compared. Pregnancy rates per transfer and differences in multiple pregnancy rates were also assessed. Pearson's Chi-squared test was used to analyze the differences.

Main results and the role of chance: A sET was performed in 184 out of 203 fresh embryo transfers (ET) (90,64%). Regarding vitrified-thawed ET, in 184 out of 194 cases, a decision was taken to transfer one single embryo (94,85%). Overall in 368 out of 397 (92,70%) a sET was performed. No triple embryo transfer was undertaken. The clinical and ongoing pregnancy rates were 37,19% and 29,65% per transfer respectively.

Among the 51591 ET performed in the control group, in a 25,43%, 68,20% and 6,37%, one, two and three embryos were transferred respectively. The clinical and ongoing pregnancy rates per transfer were 37,16% and 29,31% respectively.

The transfer of more than one embryo was not associated to a higher chance of pregnancy. Furthermore, the multiple pregnancy rate in our study group was 3,69% whereas a 20,87% and 0,43% of the pregnancies achieved in the control group were twins and triplets respectively (p = 0,000). The delivery of the double pregnancies of the control group was premature in 50,47% of gestations (9,81% <32 weeks of amenorrhea) and in 100% of triplet gestations (58,52% <32 weeks of amenorrhea).

Limitations, reasons for caution: The retrospective nature of the study constitutes a limitation. Furthermore, we have to be cautious because 2 different groups are being compared in terms of size. Moreover, two different periods of time are being compared (2014 vs. 2015). Nevertheless, the evolution in embryo transfer policy has not changed so dramatically.

Wider implications of the findings: The availability of both, embryos and gamete effective preservation procedures, such as vitrification and the huge improvement in laboratory conditions including video-time-lapse systems and genetic screening procedures should become mandatory a change in some countries' legislation, by banning the achievement of high risk pregnancies (including MP, specially among aged women).

Trial registration number: Not applicable

POSTER VIEWING SESSION
FEMALE (IN)FERTILITY

P-314   Impact of vitamin D deficiency on ICSI outcomes

S. Mnallah[1], K. Kacem Berjeb[1], M. Khrouf[2], S. Chtourou[1], H. Elloumi[1], O. Bahri[3], M. Braham[2], M. Ben Mefteh[2], F. Zhioua[2], A. Zhioua[1]

[1]Aziza Othmana Hospital, IVF Departement, Tunis, Tunisia
[2]Aziza Othmana Hospital, Gynecology obstetrics, Tunis, Tunisia
[3]Aziza Othmana Hospital, Medical biology laboratory, Tunis, Tunisia

Study question: Is there an association between the vitamin D levels and ICSI (Intracytoplasmic Sperm Injection) outcomes in a large population of patients in a sun-rich environment?

Summary answer: Women with sufficient levels of vitamin D are significantly more likely than those with insufficient levels to achieve a pregnancy following ICSI

What is known already: Vitamin D deficiency is highly prevalent in the general population, and especially in women in reproductive age. The role of this vitamin in ovarian steroidogenesis is well established, and recent evidence has shown its effect on uterine receptivity. In addition, vitamin D has also been shown to be involved in the pathophysiology of some disorders among women of childbearing age that are most commonly encountered among infertile women undergoing IVF procedures.

Study design, size, duration: It is a prospective observational study including 92 women who underwent ICSI cycles between July 2013 and July 2014. Patients were divided into two groups according to their vitamin D plasma levels: Group A (n = 61) < 30 ng/ml, and Group B (n = 31) ≥30 ng/ml. The vitamin D level in follicular fluid was also assayed.

Participants/materials, setting, methods: Stimulation by long agonist protocol, FSH ≤10 (IU/L), age ≤38 years and first or second ART cycle were the inclusion criteria. Severe male factor, endometriosis, white puncture and cycles without transfer were the exclusion criteria. Vitamin D was assayed by *ELISA 25-OH Vitamin D total, DRG Diagnostics*. The mains parameters compared between the two groups were clinical parameters and ICSI outcomes (pregnancy and implantation rates).

Main results and the role of chance: The mean age of patients was 31,8 years, the mean level of serum vitamin D was 26,01 ng/ml and the mean level of follicular fluid vitamin D was 18,87 ng/ml with a deficiency vitamin D prevalence of 66.3%. The clinic and paraclinic characteristics, the stimulation parameters, the ovarian response, the embryo development, and the number of embryos transferred were similar in both groups. The body mass index was significantly higher in women with insufficient vitamin D levels than in those with sufficient levels (p = 0.03). The thickness of the endometrium, was significantly higher in group B in comparison to group A (p = 0.002).A Better embryo quality was found when vitamin D levels were higher (p = 0.035). In addition, the study of ICSI outcomes based on serum vitamin D showed significantly a better pregnancy rate in group B compared to group A (74.19 % vs. 14.75 %, p = 0.000) and a higher implantation rate in group B (36.3% vs 4.9 %). Finally, a positive correlation between vitamin D levels in follicular fluid and serum levels (r=0.7) has also been established.

Limitations, reasons for caution: The observational character of the study, and the reduced size of the samples studied constitute major limitations. In addition, there are several possible confounding factors such as age and BMI which are both risk factors for infertility and vitamin D deficiency.

Wider implications of the findings: We confirm prior results about the association between vitamin D levels and ICSI outcomes by improving endometrial thickness.

Assessment of vitamin D status might be used in routine before artificial reproductive treatment, especially in women with high BMI, as vitamin D supplementation may be a way to improve pregnancy rates.

Trial registration number: It is not a clinical trial.

P-315   In vitro culture of vitrified and stimulated human ovarian tissue

M. Salehnia[1], M. Ramezani[2], J. Mina[3]

[1]Tarbiat Modares University, Anatomy, Tehran, Iran
[2]Tarbiat Modares University, Dept of Anatomy, Tehran, Iran
[3]Tehran University of Medical Sciences- Tehran- Iran., Reproductive Health Research Center-, Tehran, Iran

Study question: What is the effect of vitrification procedure on the integrity, morphology, follicular development and gene expression of stimulated human ovarian tissue after warming and two weeks in vitro culture?

Summary answer: The vitrification had no adverse effects on the morphology, development of follicles and gene expression of stimulated human ovarian tissue

What is known already: It was shown that vitrification and warming can guarantee the good preservation of follicular and stromal tissue structure in non-stimulated ovarian tissue.

Study design, size, duration: The biopsies of ovarian cortexes were collected from ovarian stimulated women that are candidate for transsexual surgery during laparoscopic surgery and cut into small pieces and were divided into non-vitrified and vitrified groups. Some of the tissues fragments in both groups randomly were culture for two weeks.

Participants/materials, setting, methods: The morphology of tissues was evaluated using hematoxylin and eosin and masson's trichrome staining. The expression of genes related to folliculogenesis was evaluated using real-time RT- PCR. The 17-β estradiol (E2) and anti mullerian hormones (AMH) analysis were done in collected culture media in the beginning and end of culture period.

Main results and the role of chance: The structure of human stimulated ovarian tissue after vitrification and culture was normal. In spite of high rate of normal follicles in both non-cultured tissues, these rates were significantly

decreased after in vitro culture (P < 0.05). There was no significant difference in the percentage of normal follicles at different developmental stages between vitrified and non-vitrified groups before and after of culture period. The percent of growing follicles (secondary follicles) was increased in both cultured tissues than their non-cultured groups (P < 0.05). The expression of folliculogenesis related genes in vitrified-warmed tissues were not changed compared to non-vitrified ones. During in vitro culture the expression of GDF-9 and FSHR genes were increased and the expression of FIGLA and KL genes were decreased (P < 0.05). An increase in E2 level was observed after 14 days of culture in both vitrified and non-vitrified groups. The AMH concentration was not statistically increased during culture period.

Limitations, reasons for caution: Human sampling

Wider implications of the findings: The heterogeneity of the human ovarian sample. The distribution of follicles within the human ovarian tissue is not uniform.

Trial registration number: 52 / 883.

P-316   Is more better? Inseminated volume 0.2 ml vs. 0.5 ml in donor intrauterine insemination (dIUI) cycles: a prospective randomized controlled trial

J. Rodriguez-Purata, L. Latre, C. Gonzalez-Llagostera, M. Ballester, I. Rodriguez, F. Martinez, P.N. Barri, B. Coroleu

USP Institut Universitari Dexeus, Reproductive Medicine Service, Barcelona, Spain

Study question: What is the impact on live birth rates when dIUI is performed with a volume of 0.5 mL versus 0.2 mL?

Summary answer: Live birth (LB) rates (LBRs) after dIUI cycles are not different when performed with 0.5 mL versus 0.2 mL.

What is known already: dIUI has an important role in the treatment of severe male infertility, and is often used in same-sex female couples and single parents. Different variables have been studied as factors correlated with clinical outcomes (IUI scheduling, ovarian stimulation, sperm parameters) but little is known about the inseminated volume. The use of conical bottom test tubes could contribute substantially to the loss of inseminated spermatozoa because it precludes the total recovery of the sample. Additionally, the insemination catheter could uphold this reduction causing sperm adhesion on the inner walls of the insemination catheter, decreasing even more the total inseminated volume.

Study design, size, duration: A prospective RCT, including patients undergoing natural or stimulated dIUI was performed between March 2013-April 2015. dIUI cycles (n = 293) were randomized to undergo insemination with 0.2 mL (control) or 0.5 mL (study group), of which 24 were excluded (protocol deviation) and 269 received the allocated intervention. Study was designed with 80% power to detect a 20% difference in LBR with a reference of 20% and a two-tailed 5% significance level. The required sample size was 125/group.

Participants/materials, setting, methods: There were 143 cycles (0.2 mL group) and 126 cycles (0.5 mL group). A multivariate logistic regression model was constructed to adjust for potential predictor variables regardless of association within a univariate model. Additionally, cycles that resulted in LB were compared to those that did not (total and by group) by Mann-Whitney test. Lastly, a ROC curve was developed to determine whether LB was associated with total motile sperm (TMS, in millions) as total and by group.

Main results and the role of chance: Groups (0.2 mL group vs. 0.5 mL group, respectively) were similar in age (35.8 ± 3.9 vs. 35.4 ± 4.0), AMH (2.2 ± 1.8 vs. 2.0 ± 1.5), basal antral follicle count (13.2 ± 6.4 vs. 13.6 ± 6.0), BMI (23.5 ± 3.9 vs. 23.7 ± 4.1), follicles >17 mm (1.1 ± 0.5 vs. 1.1 ± 0.5), total GND dose (553.1 ± 366.3 vs. 494.6 ± 237.1), and TMS count (8.22 ± 7.1 vs. 7.7 ± 5.7). Similar clinical pregnancy rate (18.9% (27/143) vs. 19.8% (25/126), NS), live birth rate (15.4% (22/143) vs. 19.0% (24/126), NS) and miscarriage rate (18.5% (5/27) vs. 4.0% (1/25), NS) were observed between groups. After adjusting in a logistic regression model for variables mentioned before, the inseminated volume was not shown to be associated with LB (OR 1.1 (95% CI 0.6 – 1.9). Comparison of all patients who achieved a LB versus those that did not, no demographic differences were observed in the included variables, both as a total (LB vs. no LB) or by subgroup (LB vs. no LB in the 0.2 mL group, and LB

vs. no LB in the 0.5 mL group). Lastly, an ROC curve did not demonstrated correlation of the TMS inseminated with the probability of obtaining a LB.

Limitations, reasons for caution: Study was not powered to detect a statistical difference in miscarriage rate. Furthermore, a similar study in a larger number of women is required to confirm these results.

Wider implications of the findings: This is the first RCT showing that the inseminated volume is not correlated with LB. We speculate the lower miscarriage rate observed in the 0.5 mL group could be related to the presence of contractions similar of those generated during sexual intercourse, implicated in the inception of early biochemical embryo-endometrium communication.

Trial registration number: The trial was registered at clinicaltrials.gov (Identifier: NCT03006523).

P-317   Results of ovulation induction with pulsatile GnRH using a novel portable device (LutrePulse®)

T. Hildebrandt[1], S. Bartnitzky[2], K. Bauer[3], H. Boppert[4], J. Luckhaus[5], B. Ristau[6]

[1]University of Erlangen-Nuremberg, Gynecology and Obstetrics, Erlangen, Germany
[2]novum, Zentrum für Reproduktionsmedizin, Essen, Germany
[3]Praxisklinik City Leipzig, Kinderwunschzentrum, Leipzig, Germany
[4]Tagesklinik Oldenburg, Kinderwunschzentrum, Oldenburg, Germany
[5]Bergisches Kinderwunschzentrum Remscheid, Frauenarztpraxis, Remscheid, Germany
[6]Hormon- und Kinderwunschzentrum am Kurfürstendamm MVZ, Kinderwunschzentrum, Berlin, Germany

Study question: We investigated the practical applicability and success rates of a new one-way portable pump in the pulsatile delivery of GnRH for ovulation induction.

Summary answer: LutrePulse® proved to be an easy-to-handle and reliable system. Ovulation could dependably be induced, and live birth was achieved in 2/3 of the patients.

What is known already: Pulsatile GnRH stimulation has long been established for ovulation induction of patients with hypothalamic amenorrhea. Previously used automatized systems suffered from patients' discomfort in daily use and were cumbersome to work with for medical staff. In spite of therapeutic efficacy many physicians were reluctant to use this particular form of stimulation. In 2012 with the introduction of a new comfortable insulin pump system to pulsatile GnRH therapy handling was vastly improved.

Study design, size, duration: We performed a retrospective analysis of pulsatile GnRH therapy using LutrePulse® in all patients with hypothalamic ovarian failure from six German fertility centers. 62 patients were treated from 2013 thru 2016. After diagnosis was established, stimulation was individually designed according to the physician's judgment.189 treatment cycles could be evaluated. Duration of GnRH application as well as pregnancy rate and live-birth rate were analyzed.

Participants/materials, setting, methods: Infertility patients were selected by clinical and laboratory features qualifying them for the diagnosis of hypothalamic ovarian failure. Male factor infertility was excluded by repeated sperm analysis. Patients with suspected tubal factor infertility were also not included. Duration and dose of GnRH therapy until the day of ovulation induction were evaluated. The number of treatment cycles needed to achieve a clinical pregnancy, live-birth rates as well as drop-out rates were determined as primary outcome parameters.

Main results and the role of chance: The mean age of patients was 30.3 years. Patients were treated from 1 up to 10 cycles. Mean BMI was 21 kg/m². Doses depending on clinical features ranged from 5–40ug with a pulse interval of 90 min. The dose in 1/3 of all treatment cycles was 15ug every 90 min.

Duration of treatment until ovulation induction ranged from 8 to 53 days. In 22% of all cycles, treatment was prolonged for more than 20 days, while mean duration of therapy was 17 days.

Luteal support differed between treatment centers. In 35 patients, pulsatile GnRH was continued after ovulation induction for luteal support. During the luteal phase application interval was prolonged to 120 min in luteal phase without changes in GnRH dose. The remaining patients were treated with

progesterone and hCG for luteal support. No differences in pregnancy rate could be seen with respect to luteal phase management.

52 pregnancies and 39 live-births could be achieved. 5 abortions and 1 termination due to malformation in ultrasonographic screening were reported. Pregnancy rate was 84% and live birth resulted in 63% of treatment cycles.

As of today, 7 pregnancies are still ongoing and were obviously not included in live-birth rate.

Limitations, reasons for caution: Data were collected in 6 fertility centers in Germany. Most centers collected patients according to clinical features, while one center additionally performed a GnRH-test to evaluate patients for treatment. Although no differences in outcome could be seen, luteal support differed in treatment centers and might influence pregnancy outcome.

Wider implications of the findings: Pulsatile GnRH therapy is well established in fertility treatment of hypothalamic amenorrhea. While excellent pregnancy rates have been presented in literature, the focus of the pharmaceutical industry has shifted more towards patients' and physicians' satisfaction with practical treatment modalities. LutrePulse® combines high treatment comfort and safety with excellent pregnancy rates.

Trial registration number: none.

P-318 IUI in the stimulated cycle versus IUI in the natural cycle: a cohort study from China

S. Huang[1], R. Wang[2], R. Li[1], H.Y. Wang[1], B.W.J. Mol[2], J. Qiao[1]

[1]Peking University Third Hospital, Centre of Reproductive Medicine, Beijing, China
[2]University of Adelaide, Robinson Research Institute, Adelaide, Australia

Study question: What is the effectiveness of different ovarian stimulation protocols as compared to natural cycle treatment in an intrauterine insemination (IUI) program?

Summary answer: In an IUI program, ovarian stimulation significantly increased the clinical pregnancy rate with 3% as compared to natural cycle IUI.

What is known already: In many countries, IUI is the treatment of first choice for couples with unexplained and mild male factor infertility. While IUI can be applied in the natural cycle, in many settings ovarian stimulation aiming to establish multiple follicle growth is applied. It is however controversial whether ovarian stimulation improves fertility outcomes in an IUI program. Here, we compare the success- and twin rates of natural and stimulated IUI cycles in a large centre in Beijing, China.

Study design, size, duration: We performed a retrospective cohort study in the Reproductive Medicine Centre of Peking University Third Hospitalin. Couples with unexplained and mild male subfertility were treated with IUI with or without ovarian stimulation. Women with polycystic ovary syndrome (PCOS) were excluded. Here, we compare IUI cycles stimulated with clomiphenes citrate (CC), letrozole, and gonadotropins to IUI cycles without ovarian stimulation.

Participants/materials, setting, methods: We compared the baseline characteristics among the groups. We then compared the number of dominant follicles, clinical pregnancy, miscarriage and live birth between groups with CC, letrozole, gonadotropins stimulation and natural cycle IUI. We also report on multiple pregnancies. We calculated relative risks (RR) and 95% confidence intervals (CI) for stimulated versus natural cycles, as well as Numbers Needed to Treat (NNT). ANOVA, t-test and Chi square analysis were conducted in SPSS 19.0.

Main results and the role of chance: Between January 2015 and September 2016, we performed 5, 177 IUI cycles, including 1,003 CC, 743 letrozole, 583 gonadotropins and 2,848 natural cycles. Baseline characteristics did not differ between the groups. The mean number of follicles was higher in stimulated IUI cycles with CC (1.64 ± 0.85), letrozole (1.37 ± 0.66), and gonadotropin (1.39 ± 0.79), as compared to natural cycle IUI (1.01 ± 0.16) (all P-values < 0.001).

After stimulation with CC, letrozole, or gonadotropin, clinical pregnancy rates were 11.1%, 11.6%, and 11.5% respectively. In natural cycle group, the clinical pregnancy rate was 8.7%. Compared to natural cycle, the pregnancy rate in stimulated IUI cycles with CC (RR 1.28, 95% CI1.03 to 1.58), letrozole (RR 1.33, CI1.06 to 1.68) and gonadotropins (RR1.33, CI1.03 to 1.71) were

significantly higher compared to unstimulated IUI cycles. The NNTs to establish one additional pregnancy with IUI with ovarian stimulation as compared to natural cycle IUI were 42, 34 and 35 for CC, letrozole and and gonadotropins, respectively. Live birth rates were 10.9%, 10.6% and 6.5% in the CC, letrozole, and gonadotropins group versus 6.37% in the natural cycle group. Multiple pregnancy occurred in 3/111, 0/86, 2/67, 1/247 in the CC, letrozole, gonadotropins and natural cycle groups.

Limitations, reasons for caution: This is a retrospective study that could be biased by indication. Since we did not include cancelled cycles, results might be biased, probably in favour of ovarian stimulation. Also, we reported results per cycle and not per couple. Our data should inform a randomised controlled trial on the subject.

Wider implications of the findings: This study showed that ovarian stimulation in an IUI program improves pregnancy rate. However, as the numbers to treat for ovarian stimulation versus natural cycle were between 34 and 42, natural cycle IUI can be considered as the treatment of first choice.

P-319 Is intrauterine insemination more effective than expectant management in couples with unexplained subfertility? A secondary analysis of a prospective cohort

R. Van Eekelen[1,2], N. Van Geloven[3], M. Van Wely[1], I.M. Custers[1], P. Steures[4], F. Van der Veen[1], M.J. Eijkemans[2]

[1]Academic Medical Center, Centre for Reproductive Medicine, Amsterdam, The Netherlands
[2]University Medical Center Utrecht, Department of Biostatistics and Research Support, Utrecht, The Netherlands
[3]Leiden University Medical Center, Department of Medical Statistics and Bioinformatics, Leiden, The Netherlands
[4]Jeroen Bosch Ziekenhuis, Department of Obstetrics and Gynaecology, Den Bosch, The Netherlands

Study question: What is the benefit of intrauterine insemination (IUI) compared to a wait-and-see policy i.e. expectant management in couples diagnosed with unexplained subfertility?

Summary answer: Intrauterine insemination seems to increase the chances of ongoing pregnancy compared to expectant management in couples with unexplained subfertility.

What is known already: Intrauterine insemination with or without ovarian stimulation is often the first-line treatment for couples with unexplained subfertility although the effectiveness of IUI over expectant management has never been demonstrated.

Study design, size, duration: A prospective cohort studying the long term follow up of 1946 couples diagnosed with unexplained subfertility after expectant management and after IUI, mostly with ovarian stimulation, included in 7 centres in the Netherlands between January 1999 and October 2005. Couples with bilateral tubal occlusion, anovulation, or a total motile sperm count <1 x 10^6 were excluded.

Participants/materials, setting, methods: The primary endpoint was time until conception leading to an ongoing pregnancy. Follow up time was censored at the start of IVF treatment or at the last date of contact. We used the sequential Cox approach where we compared in each month couples who started IUI with couples on expectant management for their six month outcome. We used inverse probability weights to balance the known predictors for conception between groups.

Main results and the role of chance: Data of 1946 couples were available. Follow up was truncated at one and a half years after the fertility workup due to insufficient sample sizes for our approach thereafter. The median time of expectant management follow up was 7-8 months after the workup, median time until initiation of IUI was 6-7 months and median time spent in an IUI regimen was 4-5 months. 391 (20%) couples conceived naturally within one and half years after the fertility workup (rate: 0.30 per couple per year). 803 couples had at least one IUI cycle within one and a half years after the workup of which 140 (17%) couples conceived (rate: 0.41 per couple per year). Most treated couples (82%) used ovarian stimulation in at least one IUI cycle.

The sequential Cox approach estimated a fecundability ratio of 1.56 (95%CI: 1.20-2.03) for conceiving after starting IUI compared to expectant management. The predicted chance for a couple to conceive within one year of expectant management after the fertility workup was 27.3%. If this couple would instead opt for six months of IUI after six unsuccessful months of expectant management, their predicted chance to conceive within this year increased to 32.2%.

Limitations, reasons for caution: The effect estimates are based on a prospective cohort. Although we balanced the known predictors of pregnancy between treated and untreated couples using inverse probability weighting, these estimates do not allow for causal interpretation. The results need to be confirmed by large randomised controlled trials.

Wider implications of the findings: IUI may benefit unexplained subfertile couples as first-line treatment although the absolute difference in cumulative pregnancy chances is modest.

Trial registration number: Not applicable.

P-320   Low dosing of gonadotropins in IVF cycles for women with poor ovarian reserve: Systematic review and meta-analysis

M. Youssef[1], M. Van Wely[2], M. Mochtar[3], U. Fouad[4], -M. Abd El Ghafar[5], F. Van der Veen[6]

[1]Cairo, Egypt
[2]Academic Medical Centre- University of Amsterdam-, Centre for Reproductive Medicine-, Amsterdam, Neth. Antilles
[3]University of Amstedam, Center for Reproductive Medicine, Amsterdam, Neth. Antilles
[4]Cairo University, Obstetrics & Gynecology, Cairo, Egypt
[5]Beni Suef University, Obstetrics and Gynecology, Beni Suef, Egypt
[6]University of Amsterdam, Center for Reproductive Medicine, Amsterdam, Neth. Antilles

Study question: How does low dosing of gonadotropins and high doses of gonadotropins in ovarian stimulation regimens compare in terms of ongoing pregnancy per fresh IVF attempt in women with poor ovarian reserve?

Summary answer: We found no evidence of a difference in pregnancy outcomes between low dosing of gonadotropins and high doses of gonadotropins in ovarian stimulation.

What is known already: Ovarian stimulation regimens for women with poor ovarian reserve include high doses of gonadotropins combined with various protocols of GnRH analogues. These regimens are of long duration, expensive and burdensome. Low dosing of gonadotropins has been suggested as an alternative, either by reducing the dose of gonadotropins itself or by a combination of gonadotropins and oral compounds such as antiestrogens or aromatase inhibitors which shorten the duration of stimulation and thereby lower the dose.

Study design, size, duration: A systematic review and meta-analysis of randomized controlled studies that evaluate the effectiveness of low dosing of gonadotropins compared to high doses of gonadotropins in women with poor ovarian reserve undergoing IVF/ICSI treatment.

Participants/materials, setting, methods: We searched the PubMed, EMBASE, Web of Science, the Cochrane Library and the Clinical Trials Registry using Medical Subject Headings and free text terms up to June 2016, without language or year restrictions. We included truly randomized controlled studies (RCTs) enrolling subfertile women with poor ovarian reserve undergoing IVF/ICSI treatment and comparing low doses of gonadotropins versus high doses of gonadotropins. The primary outcome was ongoing pregnancy rate per woman randomized.

Main results and the role of chance: We retrieved 788 records. Fifteen RCTs (N = 2183 women) were included in the analysis. Six studies (N = 796 women) compared low doses of gonadotropins versus high doses of gonadotropins. There was no evidence of a difference in ongoing pregnancy rate ((3 RCTs: RR 1.05, 95% CI 0.66 to 1.65, I^2 = 0%)). This suggests that for a woman with a 13% chance of achieving an ongoing pregnancy with the use of high doses of gonadotropins, the chance of an ongoing pregnancy with the use of low doses of gonadotropins would be between 7% and 17%.

Nine studies (N = 1387 women) compared ovarian stimulation using gonadotropins combined with the oral compounds letrozole (n = 6), or clomiphene

citrate (CC) (n = 3) versus the high doses of gonadotropins only. There was no evidence of a difference in ongoing pregnancy rate (3 RCTs: RR 0.90, 95% CI: 0.63 to 1.27; I^2 = 0%) This suggests that for a woman with a 13% chance of achieving ongoing pregnancy with the use of high doses of gonadotropins, the chance of an ongoing pregnancy with the use of a gonadotropins combined with oral compounds would be between 8% and 16%.

Limitations, reasons for caution: Although we used strict inclusion criteria in the conduct of the systematic review, the included studies had several methodological considerations and clinical heterogeneity that have to be taken into account when interpreting the results.

Wider implications of the findings: We found no evidence of a difference in pregnancy outcomes between low doses of gonadotropins and gonadotropins combined with oral compounds compared to high doses of gonadotropins in ovarian stimulation regimens. Whether the low doses of gonadotropins or the gonadotropins combined with oral compounds is to be preferred is unknown

Trial registration number: CRD42016041301.

P-321   A genetic test to predict recurrent implantation failure based on the association of SNPs

L.D. Vagnini[1,2], C.G. Petersen[1,2], A. Renzi[1], B. Petersen[1], A.L. Mauri[1,2], M.C. Mattila[2], V.A. Comar[2], A. Nicoletti[2], F. Dieamant[1,2], J.B.A. Oliveira[1,2], R.L.R. Baruffi[1,2], J.G. Franco Jr[1,2]

[1]Paulista Center for Diagnosis- Research and Training, Research, Ribeirao Preto, Brazil
[2]Centre for Human Reproduction Prof. Franco Jr, Research, Ribeirao Preto, Brazil

Study question: Can single-nucleotide polymorphisms (SNPs) in genes involved in the implantation process be used in a test to predict recurrent implantation failure (RIF)?

Summary answer: A genetic test (GT) to predict RIF was created from the association of several SNPs in genes involved in the implantation process.

What is known already: It is known that single genes can be associated with the regulation of invasion, angiogenesis and endometrium-embryo communication during the implantation process and that SNPs in these genes can increase susceptibility to RIF. Thus, there is a gene pattern signature of endometrial receptivity or embryo communication. The development of next-generation sequencing (NGS) technologies has allowed the identification of large sets of SNPs in several genes that can potentially be related to that phenomenon.

Study design, size, duration: A cross-sectional study was conducted with the blood samples from 49 women (35.2 ± 2.7years) representing the RIF group (RIF-G) that underwent IVF/ICSI, and from 47 fertile women constituted the control group (C-G). The RIF-G inclusion criteria: ≥2 failed IVF/ICSI attempts/≥5embryos transferred, age≤39years and normal karyotype. The exclusion criteria: uterine defects, hydrosalpinx, infections, endocrine problems, coagulation defects or thrombophilia and autoimmune defects. The C-G: volunteers with at least 2 live births without treatment and history of miscarriage.

Participants/materials, setting, methods: Genomic DNA was extracted from the peripheral blood of the RIF-G and C-G. The coding regions (exons), untranslated regions in both 3'/5' ends (UTRs) and some intronic regions of 36 selected genes were analysed by NGS using TruSeq Custom Amplicon/MiSeq-Systems. GATK's Unified Genotyper was used as a variant caller to detect SNPs on the full alignments, and logistic regression (LR) analysis was used to compare the SNP frequencies in the RIF-G and in C-G.

Main results and the role of chance: Sequencing showed 12 prevalent SNPs in the RIF-G and 10 prevalent SNPs in the C-G. LR multivariate analysis (considering RIF-G=1 and C-G=0) identified a significant association of 7 SNPs: 3 are prevalent in RIF-G(B1,B2,B3), and 4 in C-G(G1,G2,G3,G4). That association is represented by the equation $Logit(y)=1/(1+e^{-y})$, $y=0.377+1.638xB1+1.408xB2+1.348xB3-1.194xG1-1.232xG2-0.974xG3-1.548xG4$ (Table 1). Considering the result of this equation/Logit(y) between 0.99 and 0.01, the GT classified the patient as RIF if the value was closer to 0.99 and as a control if the value was closer to 0.01. This GT applied on the RIF-G/C-G patients exhibited 81.6%/sensitivity, 76.6%/specificity, and 79.1%/efficiency, and the false-positive and false-negative rates were 23.4% and 18.4%, respectively. These data support the use of this GT to predict RIF.

Table 1. Variables in the Equation.

	B	S.E.	df	Sig.	Exp(B)	95% C.I. for EXP (B)Lower	95% C.I. for EXP (B)Upper
B1(VEGFA)	1.638	.536	1	.002	5.142	1.798	14.706
B2(PGR)	1.408	.611	1	.021	4.087	1.235	13.529
B3(LIF)	1.348	.552	1	.015	3.850	1.306	11.351
G1(LEPR)	-1.194	.546	1	.029	.303	.104	.884
G2(TP63)	-1.232	.541	1	.023	.292	.101	.843
G3(ESR1)	-.974	.527	1	.050	.378	.135	1.060
G4(IGF1R)	-1.548	.598	1	.010	.213	.066	.687
Constant	.377	.331	1	.254	1.458		

Limitations, reasons for caution: Additional validation of the analysed SNPs (i.e., increasing the number of cases and/or expanding to different ethnic groups) is needed to provide more information regarding the potential use of this GT for RIF prediction.

Wider implications of the findings: The ability to predict RIF with a reliable GT can give the physician tools to analyse the risks for each patient.

Trial registration number: Not applicable. All patients provided written consent, and the local Research Ethics Committee approved the study.

P-322 The association between preconception maternal caffeinated and non-caffeinated beverage intake on IVF outcomes

R. Machtinger[1], A. Gaskins[2], A. Mansur[1], M. Adir[1], C. Racowsky[3], A. Baccarelli[4], R. Hauser[5], J. Chavarro[2]

[1]Sheba Medical Center and Sackler School of Medicine- Tel Aviv University, Obstetrics and Gynecology, Ramat Gan- Israel, Israel
[2]Harvard Chan School of Public Health, Department of Nutrition, Boston, U.S.A.
[3]Brigham and Women's Hospital and Harvard School of Medicine, Obstetrics and Gynecology, Boston, U.S.A.
[4]Columbia University- Mailman School of Public Health-, Environmental Health, New York, U.S.A.
[5]Harvard School of Public Health, Harvard T.H. Chan School of Public Health, Boston, U.S.A.

Study question: Does maternal intake of caffeinated or non-caffeinated beverages before IVF affect intermediate and clinical outcomes of IVF?

Summary answer: While total caffeine intake was unrelated to IVF outcomes, higher sugar sweetened beverages consumption may decrease the chances of pregnancy and live birth following IVF.

What is known already: Caffeine is a stimulant of the central nervous system. Increased caffeine consumption is associated with lower estrogen and progesterone levels in the luteal phase, shorter menstrual cycles (<25 days), and increased rates of spontaneous abortion. The effect of caffeinated beverages on fecundity is still controversial. Sugar sweetened beverages, both with and without caffeine, are associated with increased insulin resistance and weight gain which might lead to reduced fecundity. Moreover, soda drinkers are potentially exposed to higher levels of chemical contaminants such as bisphenol A, which is embedded in soda cans.

Study design, size, duration: A prospective study of 340 women undergoing IVF at a Tertiary, University Affiliated Hospital. Participants were enrolled from January 2014 through August 2016 during ovarian stimulation and completed a questionnaire on the first day of stimulation and/or on the day of egg retrieval. Intermediate (i.e., number of oocytes retrieved, mature oocytes, fertilization and day 3 top embryos) and clinical (i.e., positive beta-hCG, clinical pregnancy and spontaneous abortion) IVF outcomes were abstracted from medical records.

Participants/materials, setting, methods: Women reported on their usual consumption of 14 different beverages including coffee and espresso drinks, tea, hot chocolate, soda, and energy drinks. Total caffeine intake was estimated by summing the caffeine content for specific beverages multiplied by their frequency of intake. Associations between specific types of beverages and IVF outcomes were analyzed using Poisson regression models adjusting for age, BMI, smoking status and nationality, as well as other beverage intake.

Main results and the role of chance: Neither overall caffeine (range: 0-816 mg/day) nor coffee (range: 0-10 cups/day) intake was associated with intermediate or clinical IVF endpoints. A significant inverse association was observed with higher intake of caffeinated tea, sugar sweetened beverages, and energy drinks and lower total, mature, and fertilized oocyte counts following ovarian stimulation. Specifically, women who consumed energy drinks had, on average, 4.4 fewer oocytes retrieved, 2.9 fewer mature oocytes retrieved, and 1.6 fewer fertilized oocytes compared to women who did not consume energy drinks. Of these beverages, only intake of sugar sweetened beverages was significantly associated with clinical IVF outcomes. Compared to women in the lowest category of sugar sweetened beverages intake (0 cups/day), the adjusted difference in percent of cycles resulting in live birth for women consuming 0.1-1 cups/day and >1 cup/day were -9% and -13%, respectively (p-trend=0.04). A similar inverse association was observed for clinical pregnancy (p-trend=0.04). No associations were found between diet soda consumption and intermediate or clinical IVF outcomes.

Limitations, reasons for caution: Due to the observational nature of this study, we cannot rule out residual or unmeasured confounding due to other diet or lifestyle characteristics. We also had limited power to detect small differences in clinical outcomes given our sample size.

Wider implications of the findings: Among women undergoing IVF, tea, sugar sweetened beverages and energy drinks, may have adverse effects on oocyte and embryo quality. Higher intake of sugar sweetened beverages may decrease a women's chance of clinical pregnancy and live birth following IVF. These associations do not appear to be driven by caffeine intake.

Trial registration number: n/a.

P-323 Progesterone to Oocyte Index – a novel predictor for fresh IVF cycle outcome

L. Grin[1], Y. Mizrachi[2], T. Lazer[1], G. Liberty[1], S. Meltcer[1], E.Y. Anteby[1], S. Friedler[1]

[1]Barzilai Medical Centre, Infertility and IVF Unit- Barzilai University Medical Center- Ashkelon- Faculty of Health Sciences- Ben Gurion University of the Negev- Israel, Ashkelon, Israel
[2]Department of Obstetrics and Gynecology- the Edith Wolfson Medical Center- Affiliated with Sackler Faculty of Medicine- Tel Aviv University- Holon- Israel, OBGYN, tel aviv, Israel

Study question: What is the relative predictive value of Progesterone to Oocyte Index (POI) for fresh IVF-ET cycle outcome?

Summary answer: POI is inversely related to clinical pregnancy (CP) and live-birth (LB), similar to Progesterone to Follicle Index (PFI) and superior to serum Progesterone (SP).

What is known already: The possible deleterious effect of elevated serum progesterone on the day of hCG administration on implantation is controversial in the relevant literature and no consensus exists about the detrimental threshold level. PFI has been suggested as a superior parameter to predict clinical pregnancy rate, in a single study. The number of oocytes aspirated may serve as a more objective parameter than the number of follicles measured by ultrasound.

Study design, size, duration: This is a retrospective analysis of a cohort of fresh IVF/ICSI-ET cycles (n = 2493) performed in a single IVF center during the period of 2010–2015.

Participants/materials, setting, methods: Patients who underwent COH for IVF/ICSI using GnRH-antagonist protocol. PFI and POI were calculated by dividing SP level (ng/mL) by the number of follicles (≥ 15 mm) on the day of hCG or the number of oocytes retrieved, respectively. A multivariate logistic regression analysis, after adjustment for patient's age and BMI, cycle number, E2 level, and endometrial thickness was performed to evaluate the prediction value of P level, PFI, and POI for CP and LB.

Main results and the role of chance: Although the mean values for many parameters differ significantly between conception and non-conception cycles, multivariate analysis indicate that whereas P had no significant association with CP and LB, with odds ratio of 0.85 (95% CI 0.61–1.2, P = 0.37) and 0.74 (95% CI 0.49-1.10, P = 0.14) respectively, PFI and POI were inversely associated with clinical pregnancy adjusted OR 0.177 (95% CI 0.052-0.60, P = 0.006) and 0.063 (95% CI 0.016-0.249, P < 0.001) respectively and with live birth adjusted OR 0.054 (95% CI 0.011-0.272, P < 0.001) and OR 0.036 (95% CI 0.007-0.199, P < 0.001) respectively. For prediction of LB, the area under the curve (AUC) was 0.66 (95% CI 0.62-0.69, p<0.001) for the PFI model, and 0.68 (95% CI 0.64-0.71, p<0.001) for the POI model. Dividing POI to deciles, after the 9th decile - (POI of 0.360), CPR and LB decreased to 8.0% and 5.9% respectively.

Limitations, reasons for caution: This is a retrospective analysis of data collected during a 3-year period, and although the effect of the most important confounders was controlled for in the multivariable analysis, the presence of residual bias cannot be excluded.

Wider implications of the findings: This study offers a new and simple index for prediction of fresh ET outcome, emphasizing the need for a multivariable approach.

Trial registration number: 88-15-BRZ (this is aregistration number in our hospital)

P-324 Centromere protein C(CENP-C) antibody causes spindle defects and chromosome misalignment during meiosis of mouse oocyte

J. Fan[1], Y. Zhong[2]

[1]GuangZhou, China
[2]The first affiliated hospital of Sun Yat-sen University, Reproductive medicine center, Guangzhou, China

Study question: Whether centromere protein C(CENP-C) antibody developed by active immunized method could impact oocyte meiosis.

Summary answer: oocyte meiosis was severely impaired by CENP-C antibody.

What is known already: Anticentromere antibodies were associated with lower oocyte maturation rate, fertilization rate, cleavage rate, pregnancy rate and implantation rate and higher abortion rate. CENP-C linked the centromeric chromatin with the outer kinetochore and was more closer to cell division than other centromere proteins.

Study design, size, duration: Mice were divided into two groups, one was experimental group immunized with human centromere protein C in Freund's adjuvant (CFA), the other was control group injected with CFA only.

Participants/materials, setting, methods: Serum and oocytes of BALB/c mice immunized with human centromere protein C(CENP-C) in complete Freund's adjuvant (CFA) or injected with CFA only were studied for the development of CENP-C antibody. Rates of germinal vesicle breakdown (GVBD), first polar body (Pb1) extrusion, abnormal spindle morphology, chromosome misalignment and aneuploidy were compared between experimental group and control mice.

Main results and the role of chance: Following immunization, CENP-C antibody was observed in serum and oocytes of mice immunized with centreomere protein C antigen, compared with mice injected with CFA only. Decreased first polar body (Pb1) extrusion rate was found among the centromere-immunized mice compared with the CFA-injected mice (P < 0.01). Higher percentage of spindle defects, chromosome congression failure and aneuploidy were detected in immunized mice oocytes, (spindle defects:64.67 ± 1.16% vs 9.27 ± 2.28% control; chromosome misalignment:50.80 ± 2.40% vs 8.30 ± 1.16% control; aneuploidy:55.83 ± 3.63% vs 9.60 ± 1.86% control; p < 0.01 for both).

Limitations, reasons for caution: The impacts of CENP-C antibody on oocyte meiosis were only examined in mice.

Wider implications of the findings: This study revealed immunologic factors could affect oocyte meiosis and cause oocyte aneuploidy, which could

provide some new thoughts and clues for improving reproductive outcomes of anticentromere antibody positive women.

Trial registration number: not applied.

P-325 Obese women have a different polunsaturated fatty acid pattern in their oocytes

R. Matorras[1], A. Exposito[1], Z. Larreategui[2], L. Lainz[1], F. Quintana[2], R. Mendoza[1], M. Ferrando[2], L. Aranburu[3], M.B. Ruiz Larrea[4], J.I. Ruiz Sanz[4]

[1]Cruces University Hospital. Biocruces.Basque Country University, Human Reproduction Unit, Vizcaya, Spain
[2]Instituto Valenciano de Infertilidad-, IVI Bilbao, Vizcaya, Spain
[3]Department of Mathematics, Basque Country University, Vizcaya, Spain
[4]Department of Human Physiology-, University of the Basque Country., Vizcaya., Spain

Study question: Is the fatty acid oocyte composition related with maternal weight?

Summary answer: Obese women and also overweight women had a different fatty acid profile when compared with normal weight women.

What is known already: Obesity complications are well known in medicine, gynecology and reproductive medicine. The siblings of obese women have higher weights when newborn infants and have an increased rate of infant obesity. Polyunsaturated FA are of paramount importance in a healthy diet. Current western diets have an excess of n6 FA and a relative lack of n3 FA. This disbalance has been associated with obesity. We have previously shown that a number of FA can be detected in human oocytes (Matorras et al, 1998), and that their n6/n3 ratio was inside the ranges of the recommended dietary allowances.

Study design, size, duration: During a 18 month period, 922 oocytes (381 germinal vesicle, 208 metaphase I, 333 unfertilized metaphase II), corresponding to 237 women performing IVF/ICSI in two different centers were recruited. Three groups were established: normal weight (BMI 20-25), overweight (BMI 25-30), obesity (BMI > 30).

Participants/materials, setting, methods: The obtained oocytes were grouped according BMI and maturation status (germinal vesicle, metaphase I or II). They were thawed and later were subjected to chromatography analysis in groups of 15-20 oocytes (since a lower number precluded the FA analysis). Analysis was performed using capillary gas chromatography. Results were expressed in percentages of total FA amount.

Statistical analysis was performed by means of non-parametric analysis (Willcoxon, Mann Withney)

Main results and the role of chance: A different FA profile was observed in the majority of FA in the three body groups considered.

The "classical" n3 FA, Docosahexaenoic acid (DHA) was significantly lower in normal weight (0.58) than in overweight (0.81) than in obesity (1.01). On the other hand eicosapentaenoic acid (also a n3 FA) was much higher in normal weight (0.74) than in obesity (0.07). Thus, when analysed togheter, total n3 FA were significantly different in women with normal weight (1.82) than in overweight women (1.64) than in obese women (1.55). n6 fatt acids were significantly increased in obese women (11.59) vs 12.31 in normal weight (12.31) and overweight (12.54).

A number of quotients were significantly different among the three aforementioned populations: the arachidonic acid/DHA was higher in normal weight and lower in overweight whereas the opposite occurred with arachidonic/linoleic acid and the Docosahexaenoic acid (DHA)/α linolenic acid were lower in normal weight and higher in obese.

When the analysis was restricted to the same oocyte maturation status, the aforementioned differences persisted.

Limitations, reasons for caution: Our MII population was restricted to unfertilized MII oocytes, thus the results may not be extrapolated to MII oocytes which do fertilize.

Wider implications of the findings:

(1) The well-known poor outcome in obese women may be also related to an unfavourable FA pattern

(2) It could be speculated that an unfavorable oocyte FA pattern could be an early determinant of obesity in the infant and the adult

Trial registration number: None.

P-326   Impact of zinc, selenium and malondialdehyde acid levels in follicular fluid on the IVF outcome

H. Mustapha[1], F. Atig[1], M. Harzallah[1], K. Asma[2], A. Saad[3], M. Ajina[1]

[1]University Farhat Hached Hospital, Reproductive Medecine Unit, Sousse, Tunisia
[2]Faculty of Medecine- University of Monastir, Research Laboratory of "Trace elements- free radicals and antioxidants"- Biophysical Department, Monastir, Tunisia
[3]University Farhat Hached Hospital, laboratory of Cytogenetic- Reproductive Biology and Molecular Biology, Sousse, Tunisia

Study question: Have zinc, selenium and malondialdehyde acid (MDA) follicular concentrations any impact on the early embryonic development?

Summary answer: Zinc concentration in the follicular fluid (FF) is positively correlated to the oocyte maturity, fertilization, cleavage and Top quality embryos rates.

What is known already: It has been shown that there are detectable levels of zinc and selenium in human follicular fluid and it is already known that these trace elements exert an important antioxidant activity.

Study design, size, duration: Prospective study, including 190 women of infertile couples undergoing IVF cycles from January to June 2016.

Participants/materials, setting, methods: FF samples were obtained form 190 female of infertile couples undergoing IVF cycles. Patients were divided into four groups based on IVF indications: Group I (n = 35) idiopathic infertility, group II (n = 50) tubal diseases, group III (n = 50) endometriosis and group IV (n = 55) male infertility. After oocyte retrieval, FF were collected and centrifuged (400 g, 15 minutes). The supernatants were frozen at -80°c until analysis. Flame and furnace atomic absorption spectrophotometry were respectively adopted for zinc and selenium dosage.

Main results and the role of chance: In comparison with group I, zinc follicular concentration in groups III and IV showed significant decrease (respectively 17,5 and 39,79 mg/l vs 67,64 mg/l; p<0.001). Selenium concentrations were significantly higher (P < 0.001) in group I compared to patients with tubal disease, endometriosis and male factor of infertility. Concerning MDA, we noted elevated rates in all patient groups (GII= 56,20 μmol/l, GIII=17,5 μmol/l and G IV=39,79 μmol/l) compared to the control group (GI=0,006 μmol/l). Regarding the early embryonic development, all patient groups demonstrated a significantly decrease in comparison with control group. Follicular zinc concentration was highly correlated to the oocyte maturity (r= 0.384**, P < 0.01), the fertilization rate (r=0.338**, P < 0.001), the cleavage rate (r=0.347**, P < 0.001) and Top quality embryos rate (r=0.269**, P < 0.001). No correlation was found between selenium and MDA concentrations and IVF outcomes.

Limitations, reasons for caution: Much larger sample size is requested, all data are limited to the power provided by the number of test subjects included.

Wider implications of the findings: It is proved that the non-enzymatic antioxidant statue and the lipid peroxidation in the follicular microenvironment may play a role in the gamatogenesis and fertilization process and they would be the best predictors of IVF outcome.

Trial registration number: It is not a clinical trial.

P-327   endometrial thickness: impact on live birth outcomes of FET from freeze-all cycles

H. Bulut[1], K. Ozgur[1], M. Berkkanoglu[1], K. Coetzee[2]

[1]Antalya IVF, Clinical, Antalya, Turkey
[2]Antalya IVF, Laboratory, Antalya, Turkey

Study question: The objective of this study was to examine the independent effect of endometrial thickness on FET outcomes of blastocyst freeze-all cycles.

Summary answer: Endometrial thickness as an independent variable in art-FET does not significantly affect reproductive outcomes, even for endometrial thickness of ≤6 mm.

What is known already: Sonographic assessment of endometrial thickness as a measure of endometrial receptivity remains part of the diagnostic work-up and follow-up of IVF patients, because of it being a relatively accurate non-invasive assessment. Its value in the prediction of IVF success, however, has been controversial. In general, a thin endometrium, defined as a thickness of ≤7 mm, has been regarded to be associated with lower implantation. Investigating the value of endometrial thickness in patients undergoing frozen embryo transfer (FET), because of the absence of adverse effects of controlled ovarian stimulation (COS), may be more revealing in terms of pregnancy prediction.

Study design, size, duration: This is a retrospective of analysis of the first artificial frozen embryo transfer (art-FET), subsequent to 1338 freeze-all cycles in a segmented-IVF program performed between February 2015 and January 2016.

Participants/materials, setting, methods: The impact of endometrial thickness on pregnancy, live birth, and pregnancy loss was assessed. Of the 1338 freeze-all cycles 1182 first FET outcomes were analysed, excluding cycles with no FET (i.e., due to patient choice, pre-implantation genetic diagnosis, blastocyst degeneration) and cycles with incomplete data. The same artificial endometrial preparation was used for all FET, with sonographic endometrial measurements performed on day 14. All blastocysts were vitrified and were transferred on the day of warming.

Main results and the role of chance: The incidence of thin endometrium (≤7 mm) in this population of infertile patients was 8.8%. The non-significantly different pregnancy, live birth (LB), and pregnancy loss rates were 63.5%, 47.1%, and 25.8%, and 74.5%, 58.0%, 22.2% for cycles with endometrial thickness of ≤7 mm and >7 mm cycles, respectively. Although numerically reduced, the pregnancy and LB rates for the group with ≤6 mm endometrial thickness were also non-significantly different at 53.9% and 46.2%, respectively. In a sub-group analysis, with endometrial thickness sub-groups increasing in increments of 1 mm, ≤7, 7.1-8, 8.1-9, 9.1-10, 10.1-11, 11.1-12, and >12 mm, and female age, number of oocytes retrieved, and number of blastocysts transferred non-significantly different the pregnancy and LB rates were non-significantly different across the sub-groups. The sub-group 9.1-10 mm, however, had the lowest numerical pregnancy loss rate compared to the other groups (16.3 vs ≥21.5%).

Limitations, reasons for caution: This was a retrospective study; only analyzing patients 1st FET cycles, restricted to patients under 43 years of age and including pre-implantation genetic diagnosis cycles.

Wider implications of the findings: Endometrial thickness may not be an independent variable of significance in the prediction of live birth in FET, as the live birth was non-significantly different across all categories of endometrial thickness.

Trial registration number: N/A.

P-328   The lncRNA landscape of human oocytes changes with age and ovarian reserve

D. Cornet[1], M. Barragán[1], A. Ferrer-Vaquer[1], A. Rodríguez[1], D. Grinberg[2], R. Vassena[1]

[1]Clínica EUGIN, EUGIN, Barcelona, Spain
[2]Universidad de Barcelona, Barcelona, Spain

Study question: Do long non-coding RNA (lncRNA) expression levels change with age and ovarian reserve in human MII oocytes?

Summary answer: The expression levels of several lncRNA changes according to a woman's age and ovarian reserve.

What is known already: Age and ovarian reserve both affect oocyte developmental competence, i.e. its ability to sustain early embryonic development. Ovarian reserve decreases with age, and oocyte competence decreases with it. The molecular mechanisms underlying a diminished ovarian reserve are poorly characterized. Long non-coding RNA (lncRNA) are involved in controlling gene expression, and have been associated with important cellular processes such as proliferation, lineage commitment and development, suggesting a role of lncRNA in early human embryonic development. The present study on lncRNA differential expression aims to dissect the effect of age and ovarian reserve on the lncRNA oocyte landscape.

Study design, size, duration: 27 in vivo matured MII oocytes from 22 fertile women were divided into 3 experimental groups n = 9 each) according to age and ovarian reserve measured by antral follicular count (AFC): Young with Low AFC (YL; 24 ± 2 y.o. and 8 ± 1 AFC); Young with High AFC (YH; 21 ± 1 y.o. and 24 ± 3 AFC) and Old with Low AFC (OL; 34 ± 2 y.o. and 7 ± 1 AFC). Oocytes were individually processed and analyzed for expression of 31 lncRNA.

Participants/materials, setting, methods: Thirty-one lncRNA were selected as candidates from a preliminary internal study. MII oocytes were dezoned and individually lysed. Total RNA extraction, single-cell whole transcriptome amplification, and quantitative PCRs (qPCR) were performed. Student's t and two-way between-subject ANOVA (p<0.1) tests were performed to analyze qPCR results.

Main results and the role of chance: There was high variability in the expression of the 31 lncRNA candidates analyzed within and among groups. Overall, we did not find any lncRNA more expressed in the YL compared to the other groups and the OL group tends to express higher amounts of lncRNA transcripts than YL and YH. Nevertheless, 8 out of 31 lncRNA showed differential expression (p<0.1) among specific two-way group comparisons. When comparing YL with OL, 5 lncRNA showed higher expression in the OL group, 3 of them (lincCCDC140, lincSLC5A12 and lincCOL1A2-2) at intergenic locations and 2 overlapping to coding genes (lincADCYAP1R1 and lincCC2D1B). The comparison between the YL and YH groups showed 2 intergenic lncRNA (lincARRDC4 and C9Orf3) with higher expression in the YH group. Finally, lincCOL1A2-1 was expressed at higher levels in OL and YH groups compared to the YL group. Among the 8 lncRNA candidates, ENCODE analysis revealed DNAse I hypersensitive genomic regions at lincCOL1A2-1, indicating the presence of a distal enhancer for the COL1A2 gene, and suggesting a regulatory role for this gene in human oocytes. Moreover, lincADCYAP1R1 could regulate the expression of an oocyte-specific receptor for Pituitary adenylate cyclase-activating polypeptide (PACAP), which controls final oocyte maturation and oocyte developmental competence.

Limitations, reasons for caution: The women included in the study were fertile and up to 35 years old, thus our results cannot readily be extrapolated to older or infertile women.

Wider implications of the findings: The relationship between diminished ovarian reserve and age on oocyte developmental competence is still poorly understood. The present study of lncRNA in the oocyte indicates that lncRNAs are differentially expressed in relation to both factors, and might serve as biomarkers of oocyte fitness.

Trial registration number: NA.

P-329   Does pituitary suppression lead to low antral follicle count during IVF Cycles in north Indian females?

P. Singh

MORADABAD, India,

Study question: To study the effect of short term pituitary suppression on antral follicle count (AFC).

Summary answer: Short-term pituitary suppression has a negative impact on AFC, suggesting the suppressive impact of exogenous hormones on the ovary during stimulation.

What is known already: To control the hypothalamic–pituitary–ovarian axis through the induction of pituitary 'down-regulation' using a continuous and supraphysiological dose of gonadotrophin-releasing hormone (GnRH) agonist (Marcus and Ledger, 2001), prevents a premature surge in luteinizing hormone (LH), which occurs in up to 23% of cycles when gonadotrophins alone are used and facilitates the timing of oocyte retrieval therefore (Janssens et al., 2000). The use of GnRH agonists in assisted reproduction treatment (ART) has been shown to increase the number of oocytes retrieved, to improve pregnancy rates and to significantly reduce the chance of cancellation (Hughes et al., 1992).

Study design, size, duration: Retrospective study.

Study was done on 407 infertile females attending the Sparsh IVF clinic, Teerthankar Mahaveer Medical College & RC, Moradabad in north India (2013 to 2016).

Participants/materials, setting, methods: Study was done on 407 infertile females attending the Sparsh IVF clinic, Teerthankar Mahaveer Medical College & RC, Moradabad in north India (2013 to 2016). Base line AFC was noted, when no medications known to cause pituitary suppression were used.Follow up AFC (suppressed AFC) while on E2, GnRH agonist (GnRH-a) or oral contraceptive (OC) pills in preparation for ovarian stimulation, performed within 6 months of initial baseline AFC.

Main results and the role of chance: There was an average decline of 0.2, 1.1, 2.8, in AFC while patients were on E2, GnRH-a, OC pills, respectively. Decline in AFC is also influenced by increasing age.

Limitations, reasons for caution: Small size of population.

Wider implications of the findings: The study shows that exogenous e2 may cause least suression of antal follicle count as compared to other agents. Futur studies with large no of subjects is needed for confirmation of findings.

Trial registration number: Trial is approved by instituitional ETICAL committee.

P-330   Differential patterns of miRNA expression in granulosa cells (GC) media and ovine follicular fluid (FF)

R. Alhamdan, J. Salter, P. Marsters

The University of Nottingham, Child Health and Obstetric and Gynaecology, Nottingham, United Kingdom

Study question: Can miRNA detected in extracellular fluids such as FF or cell culture media be used as a growth progress marker for GC and follicles.

Summary answer: Specific miRNAs were differentially expressed in ovine FF relative to follicle size and GC and their media were relative to plating cell density.

What is known already: GC growth in culture from sparsely seeded to dense clustering has been shown to parallel changing patterns of gene and protein expression. This study aimed to determine the miRNA expression profiles and assess its value as a marker of GC growth in culture. It is also aimed to compare the determined profiles to that found in the FF of antral follicle. Research to date has shown that antral FF contained a wide range of miRNA but it is not known what contribution if any is made by GC. This present study aimed to provide some insight into this important question.

Study design, size, duration: Study was 2×4 factorial with hypoxic and normoxic culture conditions and the FF was collected from different size follicles. The expression of three miRNAs in the collected FF and in the GC lysate and their media at 16-96 hours of culture was the main endpoint. Outcomes were determined from at least three experiments done in duplicates.

Participants/materials, setting, methods: Sheep tissue was utilised as a physiological model species for the human. GC cultured under conditions to inducing either hypoxic or nomoxic growth and maintained for 16, 24, 48, and 96 hours, from which cells and media were analysed for three specific miRNAs. The same miRNAs were determined in FF from large (≥4 mm) and small (≤4 mm) size follicles.

Main results and the role of chance: A small sub-set of three miRNAs (miR-30c, miR-373p, miR-548p) were normalised against an endogenous control (miR-106b-3p). These were found to differentially express in the FF of different size follicles. Both miR-30c and miR-373p showed a statistically higher expression ($P < 0.05$) in the FF of larger size follicles compared to smaller ones. Variations in the levels of expression of these miRNAs were also found in GC cultured over time in hypoxia-inducing and normoxic conditions.

Limitations, reasons for caution: Part of the results have been derived from cell culture studies which, although designed to mimic the normal differentiative processes that occur in selected follicles in response to gonadotrophin-stimulation, may not fully reflect the complex physiological miRNA expression in a growing follicle.

Wider implications of the findings: This work suggests that miRNAs can be used as non-invasive markers of GC growth in cultures and in a clinical settings during follicular development.

Trial registration number: not applicable

P-331   vascular endothelial growth factor A, VEGF receptors and interleukin 8 concentration in the blood serum after the final oocyte maturation with gonadotropin-releasing hormone agonist

Study question: Does the administration of gonadotropin-releasing hormone agonist (aGnRH) reduce angiogenic cytokines concentration and prevent the ovarian hyperstimulation syndrome (OHSS)?

Summary answer: aGnRH triggering reduces VEGF concentration on the day of oocyte retrieval (OR) and VEGFR2 during OR and OR+5, which leads to the prevention of OHSS.

What is known already: The pathophysiologic mechanism that fully explains OHSS is still unknown. But it is mainly associated with the administration of human chorionic gonadotropin (hCG), because of an increase of angiogenic cytokines (VEGF, EGF-like growth factor, IL-8, bFGF, TNF-a etc.). Administration of aGnRH for oocyte maturation became a strategy for avoiding this complication of ovarian stimulation. However, the mechanism of aGnRH action in prevention of OHSS has not yet been identified.

Study design, size, duration: This prospective randomized study included 51 high-responder patients with tubal infertility. All patients underwent IVF program in GnRH antagonist cycles. Group 1 (n = 15) consisted of patients who received the aGnRH trigger plus 1500 IU hCG support on OR day. Group 2 (n = 18) included women who received the dual trigger (aGnRH+1500 UI hCG). Group 3 (n = 15) included patients who received the hCG trigger. Plasma samples were obtained on the OR and embryo transfer days (ET).

Participants/materials, setting, methods: Inclusion criteria: age <39 years; AMH > 2,5 ng/ml; AFC>14; 18 follicles measuring >11 mm on the day of the trigger. Exclusion criteria: uterine fibroids, endometriosis, embryo transfer cancellation. Concentrations of VEGFA, VEGFR1, VEGFR2, interleukin 8 (IL-8) in serum were evaluated with ELISA kit.

Main results and the role of chance: Only 2 cytokines showed significantly different expression levels in all groups (VEGFA, VEGFR2). Specifically, concentration VEGFA levels in Group 1 (M ± s: 432.39 ± 264.39) were almost 1.5-fold lower than in Group 3 (M±s: 664.36 ± 309.05) (p = 0.0029), VEGFR2 levels in Group 1 (M ± s: 17527.50 ± 6605.67) and in Group 2 (M±s: 15755.83 ± 6565.26) were significantly lower than in Group 3 (M±s: 23699.0 ± 9602.37) (p* = 0.0456; p**=0.0122) on the OR day. But only VEGFR2 concentration levels were significantly lower in Group 1 (M ± s: 4143.61 ± 4773.53) and in Group 2 (M±s: 16931.94 ± 5962.87) than in Group 3 (M±s: 24237.67 ± 814.48) (p* = 0.0004, p**=0.0082) on the OR+5 day. There were no significant differences in VEGFR1 and IL-8 levels on the OR and ET days between the groups. According to ROC-analysis, high level of VEGFA concentration on the OR day was associated with OHSS. For the baseline level of expression set at 736 pg/ml, the area under curve was estimated to be 0.768. The model sensitivity and specificity at the baseline level were 77.1% and 87.5%, respectively. No OHSS cases were seen in Group 1 and 2, whereas two cases of moderate late-onset OHSS occurred in Group 3 (13.3%).

Limitations, reasons for caution: Our study was carried out in a relatively small subset of high-risk patients for OHSS with tubal infertility. Therefore, the results obtained cannot be readily extrapolated on other groups of patients and need to be confirmed in larger trials.

Wider implications of the findings: This study opens new possibilities for understanding the mechanism of OHSS prevention after aGnRH triggering.

Trial registration number: N/A.

P-332   Cytokine profile in follicular fluid during ovarian ageing

T. Boueilh[1], J.M. Chao de la Barca[2], S. Blanchard[3], P.E. Bouet[4], P. Jeannin[3], P. Reynier[2], P. May-Panloup[1]

[1]CHU d'Angers, Laboratoire Biologie de la Reproduction, Angers, France
[2]CHU d'Angers, Département de Biochimie et Génétique, Angers, France
[3]CHU d'Angers, Laboratoire d'Immunologie et d'Allergologie, Angers, France
[4]CHU d'Angers, Service de Gynécologie-Obstétrique, Angers, France

Study question: Does the follicular fluid of patients with diminished ovarian reserve express a specific cytokine profile, different from that of patients with a normal ovarian reserve?

Summary answer: The follicular fluid concentration of the platelet-derived growth factor BB (PDGF-BB) is significantly lower in patients with DOR as compared to the control group.

What is known already: Ovarian ageing is related to the gradual quantitative and qualitative decrease of the ovarian reserve (DOR). A large individual variability exists in the age at which this reproductive event occurs, and although early reproductive aging is relatively common, the pathogenesis of this disorder is still unclear. The follicular fluid (FF) constitutes an important microenvironment for oocyte development, and its composition is directly correlated with oocyte quality. Furthermore, both folliculogenesis and ovulation are regulated by intrafollicular cytokines, chemokines, and protein growth factors. To our knowledge, only a few cytokines have so far been evaluated in the context of ovarian ageing.

Study design, size, duration: This is a prospective, descriptive, cross-sectional, monocentric study, carried out at the Angers University Hospital between November 2015 and March 2016. Seventy-one women (aged 23-42 years), undergoing in vitro fertilization with or without intracytoplasmic sperm injection in our ART center, were included. Patients were classified according to the results of tests of their ovarian reserve and their response to ovarian stimulation.

Participants/materials, setting, methods: Oocytes were isolated for evaluation and culture from the FF of 34 patients with DOR and 37 patients with a normal reserve undergoing controlled ovarian stimulation. The remaining FF samples collected from the same patient were pooled and centrifuged to remove residual cells and the supernatants were stored until further analysis. The FF levels of 27 cytokines and growth factors were determined using the Bio-Plex Pro Human Cytokine 27-plex Assay panel.

Main results and the role of chance: Thirteen patients with uncertain ovarian profiles were excluded from the analysis. Univariate analysis and log transformation showed significant differences in the FF levels of 4 cytokines between the two groups using. The concentration of the platelet-derived growth factor BB (PDGF-BB) (p = 0.005), CCL5/regulated on activation, normal T-cell expressed and secreted (RANTES) (p = 0.023]), CCL2/monocyte chemoattractant protein-1 (MCP-1) (p = 0.030) and interleukin-1 receptor antagonist (IL-1RA) (p = 0.041) were significantly lower in the DOR group compared with normal reserve. After correction of the α-risk, using the Benjamini-Hochberg procedure, the PDGF-BB level was the only cytokine concentration significantly lower in the DOR group (7.34 ± 16.11 pg/mL) compared with controls (24.39 ± 41.38 pg/mL). No significant differences were found in the FF levels of the other 23 cytokines.

Limitations, reasons for caution: This observational study in a single ART center can only indicate possible associations between ovarian aging and the concentration of cytokines. Further studies will be needed to confirm the results reported and establish a link between ovarian ageing and PDGF-BB concentrations in the FF.

Wider implications of the findings: PDGF-BB promotes the activation of the primordial follicle via the KIT-KIT ligand system while increasing the growth of the secondary follicle and the proliferation of theca cells. The alteration of these processes in DOR patients may help to elucidate the mechanisms underlying ovarian ageing and ameliorate its management.

Trial registration number: Not applicable.

P-333 Two LH β-subunit polymorphisms are equally correlated with ovarian response in oocyte donors

Study question: To establish points of association between gene polymorphisms of gonadotropins and their receptors and ovarian response to stimulation protocols

Summary answer: A genetic variant of LH β-subunit determines a suboptimal ovarian response following a controlled ovarian stimulation protocol.

What is known already: The unpredictable variability in the response to gonadotropins represents one of the most intractable problems of an assisted reproductive treatment, with response ranging from poor to high, leading to cycle cancellation or undesired complications like ovarian hyperstimulation syndrome. Gonadotropin's and their receptors' gene carry several single-nucleotide polymorphisms (SNPs) resulting in endocrine genotypes modulating reproductive parameters leading to important implications for reproductive success. The study of SNPs is an interesting field of research that provide us with new information about the way each woman respond to exogenous gonadotropin administration during ovulation induction

Study design, size, duration: 158 oocyte donors were subjected to ovarian stimulation protocol. After oocyte recovery, they were classified into three groups depending on the number of oocytes obtained: suboptimal response ($\leq$ 6 oocytes), normal-response (7-15 oocytes) and high response (> 15 oocytes). Then we identified genetic polymorphisms associated with FSH receptor gene, the β-LH subunit, estrogen receptor, GDF-9 and BMP-15 for describing a suitable genetic profile that helps predict most effective way ovarian response

Participants/materials, setting, methods: Subjects were assigned to receive daily doses of 150 UI rFSH; from day 6 of stimulation onwards, 0.25 mg GnRH antagonist were administered and a single dose of GnRH agonist (0.2 mg) was administered for triggering final oocyte maturation. Oocyte pick-up was programmed 36 hours after inducing ovulation. Oral epithelial cells were taken using FTA cards; the further analysis of genetic polymorphisms was performed by PCR with Taqman probes on a device StepOne Plus

Main results and the role of chance: After oocyte pick-up, 12.2% of oocyte donors were classified as suboptimal responders, 35.8% had a normal ovarian response, and 51.0% were considered to have a high-ovarian response. Data showed no differences among the three groups for the female ages; according estradiol levels, we found statistical differences between suboptimal (1122 $\pm$ 1450 pg/nl) normal (2021 $\pm$ 1214 pg/ml) and high-responders (2600 $\pm$ 1443 pg/ml), p<0.001.

Genotype frequencies were in the Hardy-Weinberg equilibrium. Univariate analysis revealed that any polymorphism but LH β-subunit was associated with ovarian response. Data were as follows; FSHR T307A (p = 0,191); FSHR N680S (p = 0.189); LHB W8R (p = 0.019); LHB I15T (p = 0,019); ESR1 Pvu T/C (p = 0.840); ESR1 Xba A/G (p = 0.870); GDF9 546 G/A (p = 0,375); BMP15 -9 C/G (p = 0,498).

Finally, we observed that LH β-subunit polymorphisms, LHB W8R and LHB I15T, were segregated together since the percentage of women carrying the wild genotype, the heterozygous genotype and the homozygous variant of the polymorphism were identical in each category of ovarian response for both genetic variants.

Limitations, reasons for caution: This study has been performed in oocyte donors, which form a homogeneous group in terms of age and ovarian response, so these results may not be extrapolated to other groups of women undergoing an assisted reproductive treatment

Wider implications of the findings: Donors with these LH variants seem to be less efficient in order to sustain multiple follicle growth and oocyte maturation. This genetic condition may be related with the endogenous LH-surge generated after GnRH agonist administrations and should be evaluated in further studies

Trial registration number: Does not apply.

P-334 Does retrieved oocytes quantity correlate with quality in advanced maternal age?

E. Zohav[1], R. Almog[2], B. Almog[2], Y. Kalma[2], J. Hasson[2]

[1]IVF Unit- Tel-Aviv Sourasky Medical Center- Sackler Faculty of Medicine- Tel-Aviv University- Tel-Aviv- Israel., Department Obstetrics and Gynecology, TEL AVIV, Israel
[2]IVF Unit- Tel-Aviv Sourasky Medical Center- Sackler Faculty of Medicine- Tel-Aviv University- Tel-Aviv- Israel., Department of Obstetrics and Gynecology, Tel Aviv, Israel

Study question: Does high ovarian response (>10 retrieved oocytes) in advanced maternal age (AMA) correlate with better reproductive outcome?

Summary answer: In patients of AMA (age 40-43 years) high ovarian response does not predict higher clinical pregnancy and live birth rates

What is known already: The association between the number of retrieved oocytes and better reproductive outcome is well recognised, although most studies which demonstrated this association were performed on younger patients. It is yet to be established whether high response to ovarian stimulation and the retrieval of a high number of oocytes in patients of AMA is also associated with better reproductive outcome.

Study design, size, duration: A retrospective cohort study performed at a single academic reproductive center between January 2012 and December 2016. All fresh ovarian stimulation cycles in AMA patients were included (n = 1657). Oocyte donation and fertility preservation cycles were excluded (n = 110, 6.6%). Oocytes collection was cancelled or no oocytes were retrieved in 81 cycles (4.8%). No embryos were available for transfer in 184 cycles (11%).

Participants/materials, setting, methods: There were 1284 fresh IVF-ET cycles in patients of AMA available for analysis. Cycles were defined as high ovarian response (HOR) if more than 10 oocytes were retrieved. Normal ovarian response (NOR) was defined as cycles in which less than 10 oocytes were retrieved.

Main results and the role of chance: There were 227 (17.6%) fresh IVF-ET cycles in which more than 10 oocytes were retrieved, and 1057 (82.4%) cycles with less than 10 retrieved oocytes. Mean patients age was comparable in both groups) 41.5 vs. 41.6 years, p = 0.1). The mean number of retrieved oocytes was significantly higher in the HOR group (13.5 vs. 4.2, p<0.01), as was the number of transferred embryos (2.7 vs. 2.1, p<0.01). Clinical pregnancy rate (CPR) was comparable between study groups (17.6% in HOR vs. 13.5% in NOR, p = 0.07). Live birth rate (LBR) was also comparable (8.4% vs. 7.4%, p = 0.34). In order to adjust for repeated failures, sub group analysis of patient's first fresh IVF-ET cycle was performed. Outcome of these cycles also revealed comparable CPR and LBR in HOR group and NOR group (16.2% vs. 15.1%, p = 0.45, and 9.1% vs. 7.6%, p = 0.37; respectively).

When vitrified-warmed ET cycles were included in the analysis, the cumulative CPR was significantly higher in the HOR group (17.9% vs. 13.7%, p = 0.03). However, LBR were comparable (9.1% vs. 7.4%, p = 0.18).

Limitations, reasons for caution: The main limitation of our study is its retrospective nature.

Wider implications of the findings: In patients of AMA high oocytes yield is not associated with better oocytes quality and improved cycle outcome. These patients' age may be the predominant factor in success rates. However, high ovarian response enables vitrification of surplus embryos which may increase the cumulative pregnancy and live birth rates.

Trial registration number: N/A.

P-335 Oral dydrogesterone vs. micronized vaginal progesterone as luteal phase support in IVF: a systematic review and meta-analysis

G. Griesinger[1], H. Tournaye[2]

[1]University Hospital of Schleswig-Holstein- Campus Lübeck, Department of Gynecological Endocrinology and Reproductive Medicine, Lübeck, Germany
[2]University Hospital of the Free University Brussels, Centre for Reproductive Medicine, Brussels, Belgium

Study question: In IVF patients undergoing fresh embryo-transfer, is the probability of clinical pregnancy and live birth associated with the use of oral dydrogesterone vs. micronized vaginal progesterone (MVP)?

Summary answer: Oral dydrogesterone is associated with an improvement in live birth rate as compared to micronized vaginal progesterone as luteal phase support in IVF.

What is known already: Dydrogesterone is an established oral retroprogesterone approved for the treatment of miscarriage and luteal phase insufficiency and has been used for luteal phase support (LPS) in IVF. A recent Cochrane analysis on LPS (van der Linden et al., 2015) indicated no significant differences in live birth and ongoing pregnancy rates of oral dydrogesterone as compared to MVP. Recently, a large phase III trial (LOTUS I; NCT01850030) has been completed, proving non-inferiority of oral dydrogesterone 30 mg daily to micronized vaginal progesterone (MVP) 600 mg daily for LPS in IVF.

Study design, size, duration: Multiple databases (Allied & Complementary Medicine™, Analytical Abstracts, BIOSIS Previews®, Embase®, Embase® Alert, EMCare®, International Pharmaceutical Abstracts, MEDLINE®, ToxFile®, CENTRAL, ICTRP, ISRCTN, PQD, SCOPUS and ClinicalTrial.gov) were searched for randomized, fully published studies comparing dydrogesterone with MVP for LPS in patients undergoing controlled ovarian stimulation and IVF with fresh embryo transfer (up to 31-Dec-2016). Meta-analyses were performed using standard procedures in the software program RevMan v.5.3. All analyses were done per randomized patient.

Participants/materials, setting, methods: Six randomized controlled trials could be included. The comparisons were 600 mg MVP vs. 20 mg dydrogesterone (two studies), 600 mg MVP vs. 30 mg dydrogesterone (two studies), 400 mg MVP vs. 40 mg dydrogesterone and 800 mg MVP vs. 40 mg dydrogesterone (one study each). Primary outcome is the live birth rate. When live birth was not reported in a study, clinical pregnancy rate was converted to live birth using the abortion rate estimate from the LOTUS I trial.

Main results and the role of chance: Clinical pregnancy rate per randomized patient was significantly higher in patients receiving dydrogesterone (relative risk [RR] 1.16, 95% confidence interval [CI]: 1.05 to 1.29; $p = 0.005$; $I^2 = 39\%$; six RCTs, n = 3,211 subjects; fixed-effects model). In those studies reporting live birth, the RR for live birth was 1.17 (95% CI: 0.98 to 1.38; $p = 0.08$; $I^2 = 0\%$; two RCTs; n = 1,461; fixed-effects model). In those studies reporting clinical pregnancy rates and live birth rates, the abortion rate beyond achievement of clinical pregnancy was highly similar between treatments and between studies. After estimating live birth rate from clinical pregnancy rate in four of the six studies, the estimated RR for live birth per randomized patient with dydrogesterone as LPS was 1.19 (95% CI: 1.06 to 1.33; p = 0.004; $I^2 = 34\%$; six RCTs, n = 3,211 subjects; fixed-effects model). An analysis per-protocol yielded similar results. The number-needed-to-treat to achieve one additional live birth is estimated as 20 (95% CI: 13 to 50). No differences in side-effects or adverse events were found.

Limitations, reasons for caution: There was heterogeneity in dosing of drugs. 5/6 studies were of only moderate methodological rigor with only 1/6 studies being double-dummy and placebo controlled. 4/6 studies reported side effects or adverse events, but only one study reported comprehensively. Only one study reported child health indicating no differences between treatments.

Wider implications of the findings: There is evidence of a small improvement of the chance of success with the use of dydrogesterone. Since oral intake is preferred over vaginal administration by most IVF patients, and since dydrogesterone is a comparatively cheap drug, it may replace MVP as the standard of care for luteal phase support.

Trial registration number: NA.

P-336   PREPARE trial: A randomised double blinded controlled trial of a preconception Omega 3 and Vitamin D rich dietary supplement in couples undergoing assisted reproduction treatment

A.J. Kermack[1,2,3], P.K. Lowen[4], S.J. Wellstead[5], H.L. Fisk[3], M. Montag[6], F.D. Houghton[3], P.C. Calder[1,3], N.S. Macklon[1,2,3,4]

[1]University Hospital Southampton NHS Foundation Trust and University of Southampton, National Institute for Health Research Southampton Biomedical Research Centre, Southampton, United Kingdom
[2]University Hospital Southampton NHS Foundation Trust, Department of Obstetrics and Gynaecology, Southampton, United Kingdom
[3]University of Southampton, Human Development and Health Academic Unit-Faculty of Medicine, Southampton, United Kingdom
[4]University Hospital Southampton NHS Foundation Trust, Complete Fertility Centre, Southampton, United Kingdom
[5]University Hospital Southampton NHS Foundation Trust, PAH Reproductive Health Research Team, Southampton, United Kingdom
[6]ilabcomm GmbH, Eisenachstr, St. Augustin, Germany

Study question: Does dietary supplementation with omega 3 polyunsaturated fats (EPA and DHA) and Vitamin D for six weeks prior to IVF or IVF-ICSI improve embryo quality?

Summary answer: The dietary intervention increased blood levels of EPA, DHA and vitamin D in men and women and this correlated with markers of improved embryo quality.

What is known already: Observational cohort studies have suggested links between preconception diet and fertility treatment outcomes. A prospective observational study demonstrated an association between dietary intake of polyunsaturated fats and better embryo morphology. Data are also now emerging indicating that dietary vitamin D intake may be related to embryo and fetus development. Such observations from non-intervention studies have driven the uptake of Vitamin D and Omega 3 supplements. However, prospective randomized controlled trials demonstrating that supplementation improves outcome are lacking.

Study design, size, duration: 111 couples were recruited to this double-blinded randomised placebo controlled trial. The 6 week intervention prior to oocyte retrieval consisted of a daily drink, containing 2 g of DHA plus EPA and 10micrograms of vitamin D, and olive oil and olive oil spreads, all in unmarked containers. The control group received a placebo drink and sunflower oil and spreads, again in unmarked containers. 55 couples were randomised to the treatment group and 56 to placebo.

Participants/materials, setting, methods: Couples, in whom dietary questionnaires showed no consumption of oily fish or high dose omega 3 supplements, were eligible. Following IVF, embryos were cultured in an Embryoscope and validated morphokinetic markers of embryo quality were recorded; day 3 and 5 KIDScores (Known Implantation Data Score) were calculated for individual embryos. Mean embryo scores per couple were analysed. Blood EPA, DHA and vitamin D levels were measured before and after the intervention period.

Main results and the role of chance: 102 couples completed the study and 750 embryos were available for analysis of morphokinetic markers. There were no differences in age, BMI, background diet, caffeine and alcohol intake or AMH between the two groups. Men and women randomised to the intervention arm demonstrated statistically significant increases in the level of DHA (p<0.001) and EPA (p<0.001) in red blood cells (RBC) and in vitamin D in blood serum (p<0.001). There were no statistically significant differences between the two groups in the number of oocytes collected, the number of embryos formed or the proportion of embryos reaching the blastocyst stage. While overall, no statistically significant differences in mean embryo scores (KIDScore D3 and D5) between the two groups were observed (p = 0.074 and p = 0.178), those receiving the intervention and IVF without ICSI produced embryos with a significant increase in KIDScore on D5 (p = 0.036) and an improvement in CC4 (p = 0.003). Furthermore, embryo quality positively correlated with the women's RBC DHA and EPA: KIDScore D3 with EPA (coefficient=0.243, p = 0.018) and DHA (coefficient=0.201, p = 0.050) and KIDScore D5 with DHA (coefficient=0.258, p = 0.012). CC4 and S4 demonstrated a negative correlation with women's RBC DHA (p = 0.031 for CC4, p = 0.014 for S4) and EPA (p = 0.024 for CC4, p = 0.022 for S4).

Limitations, reasons for caution: While the intervention was shown to alter blood levels of the target nutrients, indicating compliance, the period of intervention may have been too short to impact significantly on gamete quality. The study was powered to investigate current morphokinetic markers and not pregnancy rates.

Wider implications of the findings: This study demonstrates that blood levels of omega 3 fats and vitamin D are increased by a six week dietary intervention and that this can have a significant impact on embryo quality, possibly by improving sperm quality and function. Further studies are required to clarify the mechanisms of action.

Trial registration number: ISRCTN50956936.

P-337   Is selective reduction necessary for twin pregnancies in women with a unicornuate uterus after in vitro fertilization-embryo transfer

Y. Wen[1], X. Li[2], Y. Ouyang[2], B. Yin[2], F. Gong[3], G. Lu[3]

[1]Reproductive & Genetic Hospital of CITIC-Xiangya, Image Division, Changsha-Hunan, China
[2]Reproductive and Genetic Hospital of CITIC-Xiangya, imaging department, changsha, China
[3]Reproductive and Genetic Hospital of CITIC-Xiangya, reproductive center, changsha, China

Study question: Is selective reduction necessary for twin pregnancies in women with a unicornuate uterus after in vitro fertilization-embryo transfer (IVF-ET)

Summary answer: Twin pregnancies in women with a unicornuate uterus conferred worse perinatal outcomes and selective reduction to singleton could obtain similar pregnancy outcomes with singleton pregnancy.

What is known already: Unicornuate uteri account for 5.0-13.0% of all Müllerian anomalies and are caused by non-development of one Müllerian duct. This condition has been related to miscarriage, premature delivery, low birth weight, perinatal mortality and other complications. Little research has been conducted on the correlations between the unicornuate uterine anomaly and the perinatal outcomes as well as the outcomes of selective reduction of twins after IVF-ET till now. To the best of our knowledge, this study is the largest series to describe unicornuate uteri following IVF treatment at a single reproductive center to date.

Study design, size, duration: A retrospective, single-center cohort study was conducted with 206 women with a unicornuate uterus who delivered greater than or equal to 20 weeks' gestation from January 2012 to December 2015 after IVF-ET treatment. In order to avoid selection bias, only the first pregnancy of each patient were considered. Miscarriage, spontaneous reduction of twins to singleton and triple pregnancy were excluded from analysis.

Participants/materials, setting, methods: This study was approved by the ethics committee of the Reproductive and Genetic Hospital of CITIC-Xiangya (Changsha, China). Written informed consent was obtained from all participants. The included 206 women were divided into singleton (n = 139), selective reduction of twins to singleton (n = 21) and twin (n = 46) groups. The perinatal outcomes were compared among these 3 groups and the main outcome measures included preterm delivery, perinatal mortality, live birth rate, gestational weeks at delivery and birth weight.

Main results and the role of chance: Compared with the singleton group, the twin group showed significantly higher rates of premature delivery (67.4% vs. 18.0%, OR 3.07; P < 0.001) and perinatal mortality (21.7% vs. 0.7%, OR 38.33; p < 0.001), significantly lower live birth rate (80.4% vs. 99.3%, OR 0.03; p < 0.001), gestational weeks at delivery (33.7 ± 4.7 vs. 38.2 ± 2.0, p < 0.001) and birth weight (2071.7 ± 766.9 vs. 3082.1 ± 556.0 kg, p < 0.001); however, selective reduction group had obtained similar rates of preterm delivery (9.5% vs. 18.0%), perinatal mortality (0 vs. 0.7%) and live birth (100% vs. 99.3%), similar gestational weeks at delivery (38.3 ± 2.3 vs. 38.2 ± 2.0) and birth weight (2989.1 ± 484.3 vs. 3082.1 ± 556.0) (p > 0.05). Additionally, compared with the twin group, the selective reduction group showed markedly lower rates of preterm delivery (9.5 % vs. 67.4%, OR 19.63; p < 0.001) and perinatal mortality (0 vs. 21.7%, p = 0.022), significantly higher live birth rate (100% vs. 80.4%, p = 0.048), gestational week at delivery (38.3 ± 2.3 vs. 33.7 ± 4.7, p < 0.001) and birth weight (2989.1 ± 484.3 vs. 2071.7 ± 766.9, p < 0.001).

Limitations, reasons for caution: All pregnancy outcomes were obtained via telephone calls or faxes, thus, some detailed obstetric complications, such as an abnormal fetal position or placenta previa, were not studied. Secondly, the results were confined to pregnancies greater than 20 gestational weeks and pregnancies with lower gestational weeks were not analyzed.

Wider implications of the findings: Our findings can be used to counsel women whose twin pregnancies are complicated by a unicornuate anomaly and help guide appropriate selective reduction, antenatal treatment and surveillance.

Trial registration number: None.

P-338   anti-adhesive effects of the newly developed two-layered gelatin sheet in dogs

M. Matoba[1,2], H. Torii[2], H. Miyamoto[2], A. Hagiwara[2], A. Fukuda[1], Y. Morimoto[1]

[1]IVF Osaka Clinic, Department of Obstetrics and Gynecology, Higashi-Osaka, Japan
[2]Doshisha University, Department of Life and Medical Science, Kyotanabe, Japan

Study question: Does the two-layered gelatin sheet which we newly developed prevent the cauterized uterus adhesion more effectively than the conventional anti-adhesive materials?

Summary answer: The two-layered gelatin sheet had significantly superior anti-adhesive effects to the conventional anti-adhesive materials

What is known already: Hyaluronic acid carboxymethyl cellulose membrane (HA/CMC) is frequently used as a conventional anti-adhesive material clinically but the anti-adhesive effect of HA/CMC is controversial, concretely speaking it has reported to decrease severity of adhesion but not incidence in human and to have no effects to prevent pelvic adhesion in woman. Oxidized regenerated cellulose (TC7) is also a conventional material, however TC7 is only available to the non-bleeding site and provoke a large leucocyte response, which result in inducing adhesion.

Study design, size, duration: We have developed the two-layered gelatin sheet composed of gelatin film and gelatin sponge. Human fibroblasts and mesothelial cells were cultured on the materials for a week and the cell growth was evaluated. The dogs were randomly assigned to 4 groups: 1) control group, 2) two-layered gelatin sheet group, 3) HA/CMC group, and 4) TC7 group. The macroscopic and microscopic findings were evaluated on 3 and 6 weeks postoperatively.

Participants/materials, setting, methods: The viable cell number in each well was counted with the ATP assay. One side of the uterus horns was cauterized 40 mm long circumferentially with electric scalpel. Adhesions were scored with a grading scale macroscopically. The cauterized site of the uterus were stained with hematoxylin-eosin (HE) and investigated histologically.

Main results and the role of chance: Cell growth of human fibroblasts and mesothelial cells were proliferated significantly on the two-layered gelatin sheet compared with the HA/CMC and TC7. The score in the two-layered gelatin sheet group was significantly lower than those in the HA/CMC and TC7 groups macroscopically. The degree of lymphocyte infiltration in the two-layered gelatin sheet group was sparse compared with those in the HA/CMC and TC7 group within 6 weeks. A single-cell layer of matured mesothelium was formed in the two-layered gelatin sheet group, however peritoneal regeneration in the HA/CMC and TC7 groups were incomplete and delayed. Inflammation around the each anti-adhesive material was the weakest in the two-layered gelatin sheet group. The anti-adhesive effects of two-layered gelatin sheet is superior to the conventional materials in the canine cauterized uterus model. Early regeneration of the peritoneum, weak inflammation, and longtime remain of the material contributes these results. The two-layered gelatin sheet is considered to be a useful anti-adhesive material in deeply injured and hemorrhagic sites.

Limitations, reasons for caution: The results are not easy to apply to human, because the structure of canine uteri are different from those of human.

Wider implications of the findings: The two-layered gelatin sheet is easier to use than the HA/CMC and TC7 in deeply injured and hemorrhagic sites or organ, because the sheet is able to be bent but not brittle.

Trial registration number: N/A.

P-339   Short term intervention with liraglutide and metformin increased fertility potential in a subset of obese PCOS proceeding IVF

V. Salamun[1], M. Jensterle[2], A. Janez[3], E. Vrtacnik Bokal[4]

[1]University Medical Centre Ljubljana, Ljubljana, Slovenia
[2]University Medical Centre Ljubljana- Ljubljana- Slovenia, Department of Endocrinology- Diabetes and Metabolic Diseases, Ljubljana, Slovenia
[3]University Medical Centre Ljubljana- Ljubljana- Slovenia, Department of Endocrinology- Diabetes and Metabolic Diseases- University Medical, Ljubljana, Slovenia

[4]University Medical Centre Ljubljana- Ljubljana- Slovenia, Department of Human Reproduction- Division of Obstetrics and Gynecology-, Ljubljana, Slovenia

Study question: Does short-term weight reduction more than 5% with metformin and liraglutide (COMBI) improve oocyte maturity and embryo quality in obese PCOS?

Summary answer: Weight loss with innovative anti-obesity therapy (COMBI) resulted in the highest percentage of mature oocytes and the highest blastocysts/patient rate.

What is known already: The maternal metabolic environment in obesity has a negative influence on oocyte development with more immature oocytes and lower fertilisation rate. Embryos reach the morula stage faster and the blastocysts contain fewer cells in the trophectoderm. A decreased blastocyst formation rate likely significantlly contributes to poorer reproductive outcome.

Few is known about the impact of weight reduction prior IVF and no information on impact of glucagon-like peptid (GLP-1) liraglutide in obese infertile PCOS. Research in rats suggested that GLP-1 plays a role in regulating the reproductive system by linking energy input to the short-term adjustment of the hypothalamic pituitary gonadal axis.

Study design, size, duration: A 12-week prospective randomized open-label study was conducted with 40 infertile obese PCOS patients. They were assigned to 3 groups: i) metformin (MET) (MET 1000 mg BID), ii) COMBI (MET 1000 mg BID and low dose liraglutide 1.2 mg s.c.) and iii) CON (control)group with no therapy. CON and patients from MET and COMBI who were good responders to treatment and lost at least 5% of the initial body weight proceeded with IVF.

Participants/materials, setting, methods: All the patients initially underwent the following evaluations: height, weight, whole-body composition with Hologic dual energy X-ray absorptiometry. At week 4, 8 and 12 measurements were repeated in MET and COMBI group. Short antagonist cetrorelix protocol (225 IU of follicle stimulating hormone QD s.c., 0.25 mg cetrorelix acetate QD s.c.≥ dominant follicle was 14 mm) was used for ovarian stimulation in all the patients.A buserelin acetate 0,6 mg s.c was used for oocyte maturation.

Main results and the role of chance: 11 women in MET, 13 in COMBI and 11 in CON group completed the study according to the protocol. Patients in MET lost on average 6,70 ± 6,70 kg (P<0.001) compared with 7,68 ± 3,74 kg loss in COMBI group (P<0.001), COMBI not being superior to MET (P = 0,103). COMBI group resulted in a significant reduction of visceral adipose tissue (VAT) area (-20,65 ± 7,40 cm2; P = 0,028). More than 5% of weight reduction was achieved in 76,9% of patients in COMBI group and 45,5% of patients in MET group. In high responders who lost more than 5% of initial body weight, numbers of blastocysts/patient were greater in both treatment arms than in controls (3,67 ± 4,82 in COMBI; 3,60 ± 6,95 in MET; vs 2,09 ± 2,07 in CON). High responders in COMBI also had the highest number of oocytes/patient 14,67 ± 9,59 and the highest percentage of mature oocytes 11,22 ± 9,27 among all three groups, although treatment differences were not statistically significant yet. Furthermore one patient in COMBI group become spontaneously pregnant before IVF and two become spontaneously pregnant after unsuccessful IVF. There were no spontaneous pregnancies in MET and CON groups

Limitations, reasons for caution: The most important limitation is in the size of the study with small number of participants.

Wider implications of the findings: This is the first study of anti-obesity treatment with GLP-1analog in specific infertile obese PCOS population. It shows promising results in weight loss and suggests the possible effect of weight loss on oocyte and embryo development. It should be tested also for improvement of ovulation frequencies and eventual spontaneous pregnancies.

Trial registration number: Clinical Trial: NCT03034941.

P-340　prognostic factors for the success of oocyte thawing

E. Capitanio[1], I. Candeloro[2], A. Galimberti[2], L. Zanga[2], F. Paternostro[2], S. Melis[2], F. Fusi[2]

[1]Azienda Ospedaliera Papa Giovanni XXIII, Centro pma, Bergamo, Italy
[2]ASST PAPA GIOVANNI XXIII, CENTRO PMA, BERGAMO, Italy

Study question: What biological and biochemical factors can be considered predictive for oocyte survival, fertilization and for obtaining a pregnancy after oocyte thawing cycles?

Summary answer: None of the considered factors in fresh cycles is able to predict the trend of the oocyte thawing cycle.

What is known already: Currently the morphological selection of oocyte before cryopreservation is important to ensure a good survival rate, a development of good quality embryos and to achieve pregnancy in thawing cycles. There are several factors that affect oocyte quality, including the physiological and psychophysical state of the patient and the hormonal stimulation protocol to which she is subjected. Nowadays there are no data about what could predict whether a patient who undergoes In Vitro Fertilization (IVF) cycles can be considered a good candidate for oocyte freezing.

Study design, size, duration: This study was conducted on a total of 237 patients aged between 22 and 42 years scheduled for an IVF cycle at the Centro PMA of ASST Ospedale Papa Giovanni XXII between January 2012 and December 2015. Patients that cryopreserved supernumerary oocytes and subsequently were subjected to the oocyte thaw cycles were included in the study.

Participants/materials, setting, methods: Oocytes were cryopreserved using vitrification. For each patient we collected: age, Antimüllerian Hormone (AMH) level, Body Mass Index (BMI), Androstenedione, Testosterone, estrogen, stimulation protocol, ratio between estrogen and number of recovered oocytes. After oocytes thawing we evaluated these possible confounding factors: thawing embryologist, progressive spermatozoa motility, number of spermatozoa after capacitation, embryo quality and number of transferred embryos. All parameters have been compared with oocyte survival, fertilization, total and on-going pregnancy in oocytes thawing cycle.

Main results and the role of chance: None of the considered factors can be predictive of oocyte survival after thawing.

About fertilization rate we observed that a BMI >30 kg/m[2] has a negative affect: only 20% of patients had a fertilization rate more than 80%. Moreover, the number of patients that had a fertilization rate higher than 80% was superior in the group of tubal infertility. These results are influenced by progressive sperm motility and concentration, and the thawing operator. The subsequence multivariate analysis of these data shows that none of these factors influence the fertilization rate.

Considering the pregnancy rate after oocytes thawing, it was not influenced by any of the factors in fresh cycles but it was higher when we transferred more than one embryo and at least one top quality embryo. In the subsequent multivariate analysis we included the data showing a P < 0.1: stimolation with GnRH antagonist, BMI 18-25 kg/m[2] and BMI< 18 kg/m[2] to obtain positive βhCG; stimolation with GnRH antagonist and BMI 18-25 kg/m[2] to obtain of an evolutionary pregnancy.

This analysis demonstrates that none of the pre-freezing factors has a statistically significant impact on the pregnancy rate. Only the transfer of at least one grade 1 embryo influenced the outcome.

Limitations, reasons for caution: Patients having cryopreserved oocytes for fertility preservation or that didn't accept the cryopreservation of supernumerary embryos have been excluded from this study.

Wider implications of the findings: Further studies and a wider group of patient would be necessary to establish if the considered factors can influence the negative outcome of the thawing cycles in terms of failed oocytes survival, fertilization and embryo cleavage.

Trial registration number: Not applicable.

P-341　Vitamin D can inhibit proliferation of uterine fibroid cells in vitro through the Wnt/β-Catenin signalling pathway

A. Corachán[1], H. Ferrero[1], A. Aguilar[2], N. García[2], J. Monleón[2], A. Faus[1], D. Galiano[1,3], I. Cervelló[1], A. Pellicer[1,3]

[1]Fundacion Instituto Valenciano de Infertilidad FIVI, Department of Obstetrics & Gynecology- School of Medicine- Valencia University and Instituto Universitario IVI/INCLIVA, Paterna Valencia, Spain
[2]Hospital Universitario y Politécnico La Fe, Servicio de Ginecología, Valencia, Spain
[3]Instituto Valenciano de Infertilidad IVI, Instituto Valenciano de Infertilidad IVI- Rome, Rome, Italy

Study question: Does Vitamin D act to inhibit uterine fibroid growth in vitro through the Wnt/β-Catenin signalling pathway?

Summary answer: Vitamin D inhibits in vitro proliferation rates in uterine fibroid cells that express vitamin D receptor through Wnt/β-Catenin signalling pathway.

What is known already: Uterine fibroids (UF) are the most common benign tumour in women during the reproductive years. Several studies demonstrated that gonadotropin-releasing hormone (GnRH) activates the Wnt/β-catenin signaling pathway promoting the proliferation and differentiation of UF. Although the main treatment for UF is surgery, inhibition of estrogen and progesterone by GnRH agonists (GnRHa) is also widely used. However, GnRHa administration cannot be continued more than 6 months due to adverse effects. As an alternative, Vitamin D (VitD), with its well-described role inhibiting Wnt/β-catenin signalling in cancer cells, has been proposed as a long-term treatment option for UF.

Study design, size, duration: This study was approved by the Clinical Research Ethics Committee at the Hospital Univeritario y Politécnico La Fe de Valencia (Spain) (2014/0691). Our pilot study was carried out in the Hospital Univeritario y Politécnico La Fe de Valencia and Fundación Instituto Valenciano de Infertilidad (FIVI). Intramural UF were collected from patients undergoing surgery due to UF pathology (n = 14) without any previous treatment. All participants provided written informed consent.

Participants/materials, setting, methods: UF tissue (n = 14) was analysed by Western blot to determine the presence of Vitamin D receptor (VDR) and WISP1 (Wnt1 inducible signalling pathway protein 1) as well as proliferation (PCNA; proliferating cell nuclear antigen) at protein level. UF was disaggregated with collagenase-II and cells were cultured with and without 1,25-dihydroxyvitamin D3 (VitD, 100 mM) treatment. Subsequently, in vitro UF cell proliferation was measured by flow cytometry using propidium iodide.

Main results and the role of chance: We observed that 92.8% of UF tissue showed greater proliferation than its corresponding myometrium. In addition, not all UF tissues presented the VDR. Interestingly, however, the 80% of UF with VDR also overexpressed WISP1, suggesting a correlation between the Wnt/β-Catenin signalling pathway and VDR in this pathology. In addition, following in vitro treatment with VitD, 75% of UF cells with VDR had inhibited proliferation. These findings suggest that VitD could inhibit UF proliferation through its receptor and via the Wnt/β-Catenin signalling pathway.

Limitations, reasons for caution: Limitations of this pilot study include the small sample size.

Wider implications of the findings: UF tissues show greater proliferation in comparison with myometrium. However, not all UF have altered Wnt/β-Catenin pathway. This study demonstrated that UF expressing VDR have upregulated Wnt/β-Catenin signalling. Moreover, treatment with VitD in UF cells expressing VDR decreases cell proliferation, indicating the potential role of this receptor in UF pathology.

Trial registration number: No clinical trial.

P-342 Do not discard! Significant live birth rates from immature, denuded, non-GV oocytes collected after conventional controlled ovarian stimulation

N. Martin-Palomino Olid[1], D. García[2], A. Rodríguez[1], R. Vassena[1]

[1]Clínica EUGIN, EUGIN, Barcelona, Spain
[2]Fundación EUGIN, EUGIN, Barcelona, Spain

Study question: Do denuded, immature oocytes (non-GV) collected after conventional ovarian stimulation give rise to live births after maturing in vitro?

Summary answer: Denuded immature oocytes (non-GV) that completed meiosis in vitro (IVMC) gave rise to 5% of live birth in transfers where all embryos proceed from IVMC

What is known already: On average, 15% of all oocytes collected in conventional IVF cycles do not reach the MII stage at the time of the ovum pick up (OPU). Having undergone the LH surge, however, their cumulus is most often expanded, and cumulus-oocyte connections irremediably severed. These immature, non-GV oocytes are therefore often discarded, especially when a sufficient number of MII oocytes are also retrieved. There is scarce information available in the literature on either the most appropriate maturation protocol for immature oocytes, or the reproductive potential of embryo generated from IVMC oocytes.

Study design, size, duration: Retrospective study including 4,022 IVF cycles from 3779 patients between January 2011 and December 2015; 4450 immature non-GV oocytes were collected from 1440 of these cycles and matured in vitro; 2365 reached the MII stage (IVMC) and were inseminated. Overall, 3,933 ETs were performed: 3,579 included embryos from MII oocytes; 264 included embryos derived from MII + IVMC oocytes, and 90 with embryos from IVMC only; 399 IVMC embryos in total were transferred fresh.

Participants/materials, setting, methods: Immature, non-GV oocytes retrieved at OPU strictly 36 h after the ovulation trigger were matured in vitro during 2-8 h, in either medium IVF[TM]PLUS (n = 671 cycles; 2421 oocytes) or G-2[TM]PLUS (n = 769 cycles; 2029 oocytes). Maturations were all confirmed visually by the extrusion of the first PB. A strict control of laboratory times was guaranteed by an automated electromagnetic tracking system (RI Witness® System). Mature oocytes were inseminated with either partner or donor sperm.

Main results and the role of chance: Overall, the maturation rate for immature, non-GV oocytes was 53.1%; importantly, significantly higher maturation rate was registered when using G-2[TM]PLUS (1304/2029; 64.7%) rather than G-IVF[TM]PLUS (1061/2421; 43.8%; p<0.001). Fertilization rate of the IVMC group was 64.3% (71% in MII group, p<0.001). Transferred embryos from IVMC oocytes had an average score of 6.8 out of 10 (7.7 for MII group; p<0.001). Regarding reproductive outcomes, the IVMC group gave overall 11.1%, 10.0%, 7.8% and 5.6% biochemical, clinical, ongoing pregnancy and live birth rates, respectively, versus 31.8%, 24.6%, 18.6% and 15.3% in the MII +IVMC group and 36.9%, 30.1%, 24.4%, 18.9% in the MII group. Importantly, single embryo transfer was the mostly transfer within IVMC only group (72.2%), while transfer of 2 embryos was more common among the MII group (61.0%). Interestingly, IVMC matured in G2 medium seemed to give a higher clinical pregnancy rates when transferred (12.1% vs. 6.3%, p>0.05).

Limitations, reasons for caution: Most embryo transfers that included IVMC derived embryos were mixed transfers, making it difficult to identify the full capacity of IVMC oocytes to give live births. Nevertheless, data from 90 transfers with embryos strictly derived from IVMC oocytes are encouraging, and might even underestimate the developmental potential of these embryos.

Wider implications of the findings: The maturation in vitro of denuded, non-GV immature oocytes should be performed at the very least when few MII are collected, and likely in all patients, as there is an acceptable maturation rate and a significant potential to give rise to live birth from these oocytes.

Trial registration number: NA.

P-343 Transcriptomic signatures in follicular cells associated with failure of in vitro fertilization in humans

C. Fortin[1], N. Mahutte[2], A. Leader[3], M. Gysler[4], M. Villeneuve[5], M.A. Sirard[1]

[1]Laval University, Centre de recherche en reproduction- développement et santé intergénérationnelle CRDSI, Quebec, Canada
[2]Montreal Fertility Centre, Montreal Fertility Centre, Montreal, Canada
[3]Ottawa fertility Centre, Ottawa Fertility Centre, Ottawa, Canada
[4]The Reproductive Care Centre, RCC Mississauga, Mississauga, Canada
[5]Procrea Fertility, Procrea Fertility, Quebec, Canada

Study question: Can transcriptomic analysis of human follicular cells from failed in vitro fertilization (IVF) cycles reveal potential reasons for failure?

Summary answer: These findings provide potential biomarkers to identify the profile of different types of failure where proper control of inflammation appears to be a key element.

What is known already: Hormonal stimulation prior to IVF influences the ovarian environment and therefore impacts oocytes and subsequent embryo quality. The response to hormonal stimulation is highly variable among patients, but there is currently no way to characterize the patient's response and to know in which way its oocytes were affected by the treatment. Few studies have analysed what went wrong in failed IVF cycles. Having such information would allow clinicians to adapt and personalize the treatment, which would potentially improve success rate.

Study design, size, duration: Follicular cells principally composed of granulosa cells were obtained from a total of 200 consenting patients undergoing IVF

treatment in 4 Canadian fertility clinics. Samples were analyzed according to the outcome of the IVF cycle. Positive group refers to patients for which pregnancy (heart beat) was confirmed and negative group refers to the failed IVF cycles (no pregnancy after the used of all embryos from the stimulation cycle).

Participants/materials, setting, methods: Using microarray, 32 samples (16 negative group vs 16 positive group) were compared to determine how gene expression is affected in follicles from failed cycles. Functional analysis of the differentially expressed genes was performed using ingenuity pathway analysis. In a larger cohort of patients (n = 97), quantitative RT-PCR was used to validate the microarray results and to analyze potential markers of failure. Hierarchical clustering was then used to segregate the negative patients based on gene expression.

Main results and the role of chance: A total of 165 genes were differently expressed (P <0.05, fold change >1.5) in the negative group compared to the pregnancy group, including many pro-inflammatory cytokines or other factors related to inflammation. Several factors, some of which act upstream from vascular endothelial growth factor (VEGF), were also overexpressed in the non-pregnant group. The functional analysis highlighted the importance of the immune system and inflammatory reactions and showed an imbalance between pro-inflammatory and anti-inflammatory mediators which may account for the failure to conceive following ovarian stimulation. In addition, other differentially expressed genes appear related to abnormal differentiation and increased apoptosis. After hierarchical clustering, 3 distinct subgroups were identified and characterized according to the genes changes associated with these groups. This analysis resulted in a panel of 3 different diagnostic outcomes: 1) Follicles still in the growing mode; 2) hyper inflammation response; 3) follicular heterogeneity including overgrown follicles.

Limitations, reasons for caution: These analyses were performed in a single cohort of patients coming from 4 Canadian IVF clinics. Further analyses are needed to select the best biomarkers which will require further validation in a larger set of patients to ensure their global applicability.

Wider implications of the findings: Our results suggest that failure to conceive following ovarian stimulation could be associated with an imbalance between pro-inflammatory and anti-inflammatory mediators or by the abnormal differentiation profile of the pool of follicles. The findings point to potential biomarkers of failure causes and thereby suggest means of adapting subsequent stimulation protocols.

Trial registration number: This project was approved by Université Laval REB (2014-102/08-09-2014) for the collection and use of human tissues.

P-344   Andrographolide disrupts meiotic maturation by blocking cytoskeletal reorganization and decreases the fertilization potential of mouse oocytes

Z. Yan[1], H. Liang[2], S. Lu[2], Q. Lyu[1]

[1]Shanghai 9th People's Hospital, Department of Assisted Reproduction, Shanghai, China
[2]College of Animal Science and Technology- Guangxi University, Guangxi High Education Key Laboratory for Animal Reproduction and Biotechnology, Nanning, China

Study question: The study aimed to explore the potential mechanism by which Andrographolide may cause infertility in females.

Summary answer: Andrographolide disrupts mouse oocyte meiotic maturation by blocking cytoskeletal reorganization and decreases the fertilization potential, which has an adverse effect on female fertility.

What is known already: Andrographolide(AG), a natural diterpenoid lactone isolated from Andrographis paniculata, has been widely used in Asian countries like China, India, and Thailand for its anti-inflammatory, antibacterial, antiviral, and immunostimulatory properties. Several animal studies have reported a negative effect of AG on male fertility. However, evidence regarding the effects of AG on female fertility is limited and inconsistent. Although an early study found no change in fertility in female mice fed a diet supplemented with AG, others reported poor pregnancy outcome of mice received AG. The mechanisms underlying the effects of AG on female reproduction have not been investigated to date.

Study design, size, duration: Germinal vesicle stage mouse oocytes were matured in vitro in the presence or absence of AG at various concentrations and for different periods, after which germinal vesicle breakdown (GVBD) and metaphase II (MII) rates were assessed. Furthermore, the effects on spindle formation and actin polarization of the AG-treated oocytes were analyzed by immunostaining. Finally, we examined the apoptosis rates and fertilization potential of the oocytes treated with AG.

Participants/materials, setting, methods: Immature germinal vesicle stage oocytes from female Kun Ming Bai mice were incubated in KSOM medium containing 0, 5, 10 or 20 μM AG and assessed the oocytes maturation at 6, 14, or 24 h of incubatuion. The spindle morphology and actin formation were examined by Immunofluorescence staining of β-tubulin and phalloidin. Apoptosis was detect by TUNEL assay. intracytoplasmic injection of sperm was performed to analyze the fertilization rate.

Main results and the role of chance: Immature oocytes incubated for 6, 14, or 24 h in medium containing 5, 10, or 20 μM AG showed time- and dose-dependent decreases in maturation rates as compared to the control group. Immunostaining revealed that AG exposure disrupted spindle organization and migration as well as actin cap formation and cytokinesis. Furthermore, most oocytes exposed to 20 μM AG underwent apoptosis when compared to control group, and the few oocytes exposed to 5 or 10 μM AG reaching metaphase II exhibited lower fertilization rates than that of control group after intracytoplasmic sperm injection. Our results suggest that AG may disrupt mouse oocyte meiotic maturation by blocking cytoskeletal reorganization and decreases the fertilization potential, which may thus have an adverse effect on female fertility.

Limitations, reasons for caution: The effects of AG on oocyte during in vivo maturation were not assessed. Only mouse oocytes were analyzed. Further studies using in vivo mouse experiments as well as clinical trials in humans to examine the drug safety are required.

Wider implications of the findings: This study firstly presented an important and uninvestigated aspect of the potential adverse effects of AG on oocyte maturation, providing a plausible explanation for the reported negative effects of AG on female fertility in mice. Based upon our findings, AG should be prudently consumed by women attempting to achieve conception.

Trial registration number: The trial registration number is not required for this study.

P-345   New trial of dydrogesterone regimen as an effective oral alternative for suppression of premature luteinizing hormone surges during controlled ovarian stimulation of assisted reproductive therapy

N. Iwami, N. Hirayama, Y. Kobayashi, M. Kanaya, A. Yagi, T. Saito, J. Ozawa, T. Yamamoto, E. Watanabe, O. Moriwaka, H. Kamiya

Kamiya Ladies Clinic, Center of reproductive medicine, Sapporo, Japan

Study question: Can a dydrogesteron with human menopausal gonadotropin (HMG) protocol suppress premature LH surges in women undergoing controlled ovarian stimulation (COS) for IVF/ICSI?

Summary answer: The dydrogesterone with HMG protocol can be effective for suppression of premature LH surges and this protocol is not inferior to GnRH antagonist protocol.

What is known already: It is widely known that GnRH antagonist is effective for rapid and reversible LH suppression to prevent premature LH surge during COS. However, the GnRH antagonist protocol is expensive and some patients experience premature LH surges. Previous studies demonstrated that medroxyprogesterone acetate suppressed premature LH surges during COS, and ovarian stimulation during luteal-phase with high progesterone level doesn't have a negative impact on oocyte/ embryo quality. Dydrogesterone, which has been widely used for luteal insufficiency, is structurally and pharmacologically similar to natural progesterone and lacks androgenic activity. It has good oral bioavailability and few side effects, compared with other progestins.

Study design, size, duration: This was a prospective observation study in 271 women (aged <41, AMH level >1.0) undergoing COS for IVF/ICSI at our private infertility clinic between July 2016 and December 2016. The patients

were allocated alternately into two groups, one with the dydrogesterone and HMG protocol (study group, n = 145) and the other with the GnRH antagonist protocol (control group, n = 126).

Participants/materials, setting, methods: In the study group, dydrogesterone (20 mg/day) with HMG (150-225IU) was administered simultaneously beginning on day 2 or 3. In the control group, a GnRH antagonist protocol was given. In both groups, ovulation was triggered with GnRH agonist and HCG (1000-2500IU), when the leading follicle matured. All high quality embryos were cryopreserved for later transfer. Statistical analysis of the outcomes of cycles was performed using the unpaired t-test, Mann-Whitney U test and Chi-square test.

Main results and the role of chance: Patient characteristics: the age, body mass index, basal hormone profile, duration of infertility, and AMH level were similar in two groups. No statistically difference was found between the study group and the control group for the number of oocytes retrieved (10.23 ± 6.94 vs. 10.13 ± 6.03), the number of mature oocytes (8.1 ± 5.8 vs. 7.8 ± 4.8), the rate of fertilization (76.7% vs. 77.7%) and the viable embryos rate (66.0% vs. 66.8%). The study group received slightly higher HMG doze than the control group (2039.7 ± 833.6 IU vs. 1591.3 ± 695.2 IU, P < 0.001), but the duration of COS is statistically similar between the study group and the control group (14.9 ± 2.5 vs. 14.3 ± 1.9, P = 0.064). Premature LH surge occurred in each one patient of both groups, but they continued to perform luteal-phase ovarian stimulation and several follicles were retrieved from these patients. During the following up of frozen embryo transfer (FET), total 166 FET cycles were completed and no significant difference was seen between the study group and the control group for the clinical pregnancy rate (50.8% vs. 49.5%), implantation rate (50.7% vs. 48.6%), and on going pregnancy rate (43.1% vs. 42.6%) and early pregnancy loss rate (15.2% vs. 14.0%).

Limitations, reasons for caution: This study was not a randomized control study and was performed using women with normal ovarian reserves. For further research, live-birth outcomes following this protocol are needed.

Wider implications of the findings: Dydrogesterone has a more tolerability profile than other progestins and the advantages of oral administration, user convenience and cost reduction. This first study showed that the dydrogesterone with HMG protocol could be a new regimen as an oral alternative for prevention of premature LH surges during COS.

Trial registration number: Not applicable.

P-346   Effect of vitamin D supplementation on preconception immune tolerance in infertile women

Y. Ikemoto[1], K. Keiji[1], N. Koji[2], O. Asako[1], J. Makoto[1], M. Keisuke[1], U. Yuki[1], M. Akemi[1], S. Rikikazu[2], T. Satoru[1]

[1]Juntendo University Faculty of Medicine, Obstetrics and gynecology, Tokyo, Japan
[2]Division of Reproductive Medicine- Sugiyama Clinic, Obstetrics and gynecology, Tokyo, Japan

Study question: What is the relationship between vitamin D (VD) level and T-helper (Th) cells in infertile women as well as the effect of VD supplementation on maternal immune tolerance?

Summary answer: Most of the infertile women were deficient of VD. VD supplementation in infertile women with VD deficiency decreased Th1 cells associated with immune rejection.

What is known already: Th1 and Th2 cells play significant roles in immune rejection and tolerance. Pregnancy is Th2 dominance, and Th1 immune response is related to embryonic rejection. VD has been reported to play an important role in the modulation of the immune system through inhibition of Th1 cell proliferation and Th2 cell promotion. VD deficiency is associated with implantation failure, recurrent miscarriage and pregnancy complications, such as preeclampsia and gestational diabetes mellitus. However, the relationship between VD level and Th cells and the effect of preconception VD supplementation on the immune tolerance of infertile women with low VD are not clearly understood.

Study design, size, duration: This study was approved by the Local Ethics Committee. 25-hydroxyvitamin D (storage form) and Th1/Th2 cell levels were measured in infertile women from 2014 to 2016. We evaluated the alteration of immune levels during 3 months of VD supplementation (1,000IU/d) in women with VD deficiency.

Participants/materials, setting, methods: Out of 585 infertile women who underwent immunological examination, we excluded 309 patients with a history of recurrent miscarriage or repeated implantation failure due to the possibility of immune abnormality. In 276 generally infertile patients, we categorised VD deficiency(< 20 ng/ml), insufficiency(21–30 ng/ml) and sufficiency (>30 ng/ml) and compared Th1(CD4$^+$/IFN-γ^+) and Th2(CD4$^+$/IL-4$^+$) cell levels and Th1/Th2 cell ratio among the 3 groups. We additionally performed a detailed immunological test pre- and post-VD supplementation in 8 patients with VD deficiency.

Main results and the role of chance: The numbers of patients with VD deficiency, insufficiency and sufficiency were 130 (47.1%), 111 (40.2%) and 35 (12.7%), respectively. The infertile women have an extremely high proportion of low VD level. In addition, the infertile women with VD deficiency, insufficiency and sufficiency had 21.0 ± 6.8%, 21.0 ± 6.7% and 19.6 ± 5.6% Th1 cell levels, 2.3 ± 0.8%, 2.4 ± 1.2% and 2.5 ± 1.2% Th2 cell levels and 10.5 ± 5.5, 10.6 ± 6.0 and 8.6 ± 4.5 Th1/Th2 cell ratios, respectively. In the VD-sufficient group, there were relatively lower Th1 cells and Th1/Th2 cell ratio, but there were no significant differences among the 3 groups. In the patients who were supplemented with VD for VD deficiency, levels of Th1 cells were significantly decreased from 21.9 ± 6.2% to 19.6 ± 5.0% post-VD supplementation (p = 0.008). However, no significant changes in levels of Th2 cells, Th1/Th2 cell ratio, regulatory T cells and Th17 cells were detected in the patients with VD deficiency. No complications or adverse effects were identified in all patients.

Limitations, reasons for caution: VD is affected by exposure to sunlight. Therefore, the limitation of this study is that VD levels may be varied according to seasonal changes.

Wider implications of the findings: Appropriate Th1/Th2 cell balance is important during implantation and maintenance of pregnancy. An aberrantly high population of Th1 cells is associated with embryonic rejection, leading to repeated reproductive failure and complications during pregnancy. Preconception VD supplementation in women with VD deficiency may sufficiently suppress maternal immune rejection against the embryo.

Trial registration number: None.

P-347   In vitro fertilization outcomes in relation to adherence to the Mediterranean diet among women from a fertility clinic

D. Karayiannis[1], M. Kontogianni[1], C. Mendorou[2], M. Mastrominas[2], N. Yiannakouris[1]

[1]Harokopio University, Department of Nutrition and Dietetics- School of Health Science and Education, Athens, Greece
[2]Embryogenesis, Assisted Conception Unit, Athens, Greece

Study question: Is adherence to the Mediterranean diet (MedDiet) associated with better in vitro fertilization (IVF) performance in women attempting fertility?

Summary answer: Higher adherence to the MedDiet was associated with higher odds of achieving clinical pregnancy and live birth among women undergoing infertility treatment.

What is known already: A-posteriori dietary pattern approaches have revealed that dietary patterns with some of the characteristics of the MedDiet (i.e. high intakes of fruits, vegetables, legumes, whole grains, fish and low intake of meat) are associated with increased chances of pregnancy in couples undergoing IVF treatments. Yet, whether adherence to the MedDiet is associated with better reproductive performance of women attempting fertility remains largely unexplored.

Study design, size, duration: The study population comprised a total of 244 women who underwent a first IVF treatment in an Assisted Conception Unit in Athens, Greece, between June 2013 and September 2016. The study was designed to evaluate the influence of habitual dietary intake and lifestyle on fertility outcomes.

Participants/materials, setting, methods: Women aged 22-41 years (24.2% overweight) with complete dietary data were analyzed. Diet was assessed before the IVF treatment via a food-frequency questionnaire and adherence to the MedDiet through the validated MedDietScore (range: 0–55;

higher scores indicating greater adherence to MedDiet). Study outcomes included oocyte yield, fertilization rates, embryo quality measures and clinical outcomes (implantation, clinical pregnancy and live birth rates). Associations were tested using multiple logistic regression controlling for various potential confounders.

Main results and the role of chance: Overall, 141 women (61.8%) had a successful implantation (elevation of b-hCG levels above 20 IU/l after embryo transfer), 104 women (45.6%) had intrauterine pregnancy confirmed by ultrasound, first performed at 6 weeks of gestation, and 98 women (43.2%) had a live birth. No association was found between MedDietScore and any of the intermediate IVF outcomes. However, a statistically significant association was observed between MedDietScore and clinical pregnancy and live birth rates (p < 0.05). Compared to women in the lowest tertile of the MedDietScore (≤30, N = 71), those in the highest tertile of the score (≥36, N = 83) exhibited higher clinical pregnancy rates (51.8 vs. 32.4%, p = 0.03) and corresponding live birth rates (49.4% vs. 29.6%, p = 0.02). In the multivariable adjusted models, women in the highest tertile of the MedDietScore had 2.2 times higher likelihood of having a clinical pregnancy (p for trend =0.03) compared to women in the lowest tertile of the score, and 2.5 times higher likelihood of achieving a live birth (p for trend =0.02), after adjusting for age, BMI, ovarian stimulation protocol, smoking, physical activity, anxiety levels, total energy intake, and cause of infertility.

Limitations, reasons for caution: The main limitation of the study stems from to its cross-sectional nature, so causal inference is limited. Moreover, results may not be extrapolated to women without a history of infertility.

Wider implications of the findings: The results suggest that diet modifications and adherence to the MedDiet may help increase the chance of achieving a clinical pregnancy and a live birth in women attempting fertility.

Trial registration number: Not applicable.

P-348 Increased peripheral blood natural killer cell fraction is associated with lower level of anti-Müllerian hormone

Y.J. Hur[1], S.A. Choe[2], T.K. Yoon[1], I.P. Kwak[1], W.S. Lee[1], Y.S. Kim[1], S.W. Lyu[1], J. Kim[1], E.M. Chang[1], J.W. Kim[1], H.J. Lee[1], I.S. Kang[1], M.K. Koong[1], M.J. Kim[1], Y. Lee[1]

[1]CHA fertility center, infertility, Seoul, Korea- South
[2]CHA University School of Medicine, Obstetrics and Gynecology, Seoul, Korea- South

Study question: Is natural killer (NK) cell fraction associated with ovarian reserve in reproductive-age women?

Summary answer: There was an inverse relationship between peripheral blood NK cell fraction and measured-to-reference anti-Müllerian hormone (AMH) ratio.

What is known already: High peripheral blood NK cell percentage is associated with adverse fertility and pregnancy outcomes such as recurrent pregnancy loss (RPL) and repeated implantation failure (RIF). Recent studies suggest a potential cytotoxic effect of NK cells on ovarian tumors. Yet, current knowledge of the effect of NK cell fraction on ovarian reserve in reproductive-age women is limited.

Study design, size, duration: This was a retrospective cohort study using data of women who were tested for NK cell activity and AMH at a university-affiliated fertility center from 2013 to 2015. Women with a history of bilateral/unilateral oophorectomy or chemotherapy and ≥ 1 year interval between NK cell and AMH tests were excluded. A total of 667 women who were tested for NK cell fraction in total lymphocytes and AMH were identified.

Participants/materials, setting, methods: Peripheral blood levels of NK cells were determined using flow cytometry and analyzed as a percentage of lymphocytes (%). To consider women's age, measured-to-(age-appropriate) reference AMH ratio ($AMH_{measured}/AMH_{age-appropriate\ reference}$) was used for the analysis. Age-appropriate reference level of AMH was calculated from a previously described quadratic model (logAMH = -1.442 + 0.225 × age - 0.004 × age^2). The association between NK cell activity and measured-to-reference AMH ratio was explored with Spearman correlation test.

Main results and the role of chance: The mean age of study population was 36.4 years. 37.2 % had histories of PRL and 59.7% experienced RIF. Mean level of peripheral blood NK cell fraction was 14.14 % (range: 2.50 - 41.60 %) and mean AMH was 3.51 ng/mL (range: 0.14 – 19.32 ng/mL). There was an inverse relationship between peripheral blood NK cell fraction and serum AMH (rho = -0.11,

P = 0.007) which does not considered women's age. There was no significant correlation between NK cell fraction and women's age. Correlation test revealed a decreasing tendency of measured-to-reference AMH ratio according to increasing level of NK cell fraction (rho = -0.09, P = 0.026).

Limitations, reasons for caution: Since the data was collected in a single center cohort, a study of large general population is warranted.

Wider implications of the findings: The finding of this study suggests higher NK cell fraction in the peripheral blood may have a harmful effect on ovarian reserve. The potential role of NK cell fraction in women with decreased ovarian reserve should be explored to improve fertility outcomes.

Trial registration number: Not applicable.

P-349 Advanced glycation end-products accumulation affects assisted reproductive technology outcomes

R. Kawabe[1], T. Nishihara[2], T. Inoue[1], Y. Morimoto[1]

[1]HORAC Grand Front Osaka Clinic, medical doctor, Osaka, Japan
[2]HORAC Grand Front Osaka Clinic, division of culture environment, Osaka, Japan

Study question: Do the accumulation of advanced glycation end-products (AGEs) affect the clinical outcomes in ART program?

Summary answer: Accumulation of AGEs has been associated with poor clinical outcomes in ART program.

What is known already: AGEs are produced endogenously in the body or exogenously by intake of diet containing high levels of AGEs. AGEs are known to play a role in the pathogenesis of several diseases, and recently female infertility by causing oxidative stress, altering enzymatic activities, affecting cytotoxic pathways, or damaging nucleic acids.

Study design, size, duration: Prospective study in a clinical-based cohort of 148 women who agreed with measurements after the new patient visit, from November 2015 until December 2016 inclusive.

Participants/materials, setting, methods: We measured skin autofluorescence non-invasively by AGE-Reader in female infertility patients (n = 148) seen between November 2015 until December 2016 at HORAC Grand Front Osaka Clinic. To evaluate the cumulative effect of AGEs, we compared cycle outcomes between patients with high-AGEs (HA) and low-AGE (LA). Primary outcome measures were infertility factors and clinical outcomes.

Main results and the role of chance: Accumulation of AGEs were higher in fertility patients than in patients whose infertility was attributed to male factors. The AMH levels of patients with HA were significantly lower than in patients with LA (2.1 vs. 3.7 ng/mL, respectively; p < 0.05). No correlation was observed between AGEs and other hormones (basal FSH, DHEA-S, testosterone and prolactin). There were no significant differences between the patients with HA and LA in the fertilization rate, rate of good quality embryos, blastocyst rates, rate of good quality blastocysts. Accumulation of AGEs were higher in patients with no pregnancy than in patients with pregnancy (195.3 vs. 175.1 AU, respectively; p < 0.05)

Limitations, reasons for caution: AGEs were measured three times at the volar side of the arm. Exposure to sunlight is a possible confounding factor in skin AGE accumulation, but the similarity between AGEs measurements taken at the volar side suggests that this effect is probably limited. Clinical outcomes included both ICSI and conventional IVF.

Wider implications of the findings: High AGEs levels are a contributing potential biomarker for diminishing ovarian reserve. AGEs accumulations correlated with a lower likelihood of pregnancy. The AGE-Reader is useful as a non-invasive clinical tool for assessment of increasing risk for infertility and may provide information for the development of more effective therapeutic strategies.

Trial registration number: Not applicable.

P-350 Vaginal microbiota and IVF outcomes - Development of a simple diagnostic tool to predict patients at risk of a poor reproductive outcome

T. Haahr[1], P. Humaidan[2], H.O. Elbaek[2], B. Alsbjerg[2], K. Rygaard[3], B. Lilje[4], P. Andersen[4], K. Ng[4], J.S. Jensen[4]

[1]The Fertility Clinic- Skive- Skive Regional Hospital, Department of Clinical medicine Aarhus University, Skive, Denmark

[2]The Fertility Clinic- Skive- Skive Regional Hospital, Department of Clinical Medicine-Aarhus University, Skive, Denmark
[3]Trianglen Fertility Clinic, N/A, Copenhagen, Denmark
[4]Statens Serum institute, Department of sexually transmitted diseases, Copenhagen, Denmark

Study question: Could 16 S rRNA gene sequencing improve the diagnosis of abnormal vaginal microbiota (AVM) to predict patients at risk of a poor reproductive outcome?

Summary answer: 16 S rRNA gene sequencing did not add substantial diagnostic value compared to a quantitative PCR (qPCR) assay targeting Gardnerella (G.) vaginalis and Atopobium (A.) vaginae.

What is known already: Female reproductive tract microbiota might have an important impact on the implantation of the embryo and subsequently, the reproductive outcome. However, only a few studies have investigated this emerging issue. Previously, a qPCR assay for AVM diagnosis that targets G. vaginalis and A. vaginae above threshold levels suggested a poorer reproductive outcome in IVF patients with AVM. In the present study, qPCR was compared to 16 S rRNA gene sequencing of the vaginal microbiota to develop a diagnostic approach that could predict a poor reproductive outcome in IVF patients.

Study design, size, duration: The present study included a cohort of 111 IVF patients. Patients were followed with the primary outcome of clinical pregnancy at 7 weeks gestation and followed-up until birth.

Participants/materials, setting, methods: Patients were assigned to IVF treatment and prospectively enrolled from two centers in Denmark. Vaginal swabs were taken during speculum examination from the posterior fornix. 16 S rRNA gene sequencing of the V4 region was performed on the specimens from the same DNA extraction as was used for qPCR.

Main results and the role of chance: 16 S rRNA gene sequencing provided further insight into the vaginal microbiota of IVF patients. In a principal component analysis comparing qPCR and 16 S rRNA, a total of 28/32 AVM positive samples were clustered together. The 16 S AVM group had an age adjusted OR 0.18 (95%CI 0.03-0.98) for clinical pregnancy which was similar to the qPCR AVM group. Furthermore, a broader panel of tentative pathogenic bacteria did not seem to predict reproductive outcomes better than the qPCR approach. The only AVM patient (1/17) gave birth in gestational week 35 and the child had a low birth weight of 2320 grams.

Limitations, reasons for caution: The results from specific qPCR analysis suggest that the species selection is valid. However, it is a limitation that only the V4 region was used for 16 S rRNA gene analysis. Furthermore, due to the small number of patients, one should be cautious when interpreting the reproductive outcome results.

Wider implications of the findings: Although the number of detected bacterial species increases with 16 S rRNA gene sequencing, the simpler and less expensive qPCR diagnostic approach seems non-inferior compared to16S sequencing in the prediction of IVF patients at risk of a poor reproductive outcome.

Trial registration number: The project was registered at clinicaltrials.gov (file number NCT02042352).

P-351　Producing a polyclonal antibody specific to embryonic poly (A)-binding protein (EPAB) and characterizing EPAB protein expression in mouse somatic tissues, oocytes and early embryos

F. Uysal-Alaoglu, S. Ozturk

Akdeniz University, Department of Histology and Embryology- Akdeniz University-School of Medicine, Antalya, Turkey

Study question: What are the spatial and temporal expression patterns of EPAB and poly(A)-binding protein, cytoplasmic 1 (PABPC1) proteins in mouse somatic tissues, oocytes and early embryos?

Summary answer: We produced a polyclonal antibody specific to EPAB. EPABP and PABPC1 exhibit different spatial and temporal expression patterns in mouse tissues, oocytes and early embryos.

What is known already: Embryonic poly(A)-binding protein (EPAB) functions in translational control of maternal mRNAs during oocyte maturation, fertilization and early embryo development in mammals. EPAB is expressed in mouse and human germ cells and early embryos as well as in the ovary and testis tissues. It is revealed that female mice lacking Epab gene are infertility. Since there is no EPAB-specific antibody, there is no study aimed to analyze spatial and temporal expression pattern of the EPAB protein in mouse somatic tissues, oocytes and early embryos. Notably, PABPC1 shows a high homology with EPAB protein and can compensate the EPAB's functions.

Study design, size, duration: The study is designed as follows: 1) Polyclonal antibody production for EPAB protein, 2) Analyzing EPAB and PABPC1 protein expression in the 5-week old Balb/C mouse (n = 5) somatic tissues including ovary, testis, stomach, kidney, small intestine, heart, spleen, brain, and lung, 3) Characterizing expression of the EPAB and PABPC1 proteins in the germinal vesicle, metaphase II oocytes and 1-cell, 2-cell and 4-cell early embryos obtained from 5-week old Balb/C female mice (n = 5) using superovulation.

Participants/materials, setting, methods: The competitive enzyme-linked immunosorbent assay (ELISA) has been used to determine the immune specificity of the produced EPAB polyclonal antibody in rabbit. To determine the EPAB and PABPC1 protein expression in the mouse somatic tissues, we have used immunohistochemistry. Also, the spatial and temporal expression the EPAB and PABPC1 proteins in the mouse germinal vesicle and metaphase II oocytes and in the 1-cell, 2-cell, and 4-cell embryos have been characterize by using immunofluorescence staining.

Main results and the role of chance: The competitive ELISA test revealed that produced EPAB polyclonal antibody is highly specific to the EPAB synthetic peptide. Then, we have observed that EPAB protein is only expressed in the mouse ovary and testis tissue samples; however it is not detected in the somatic tissues including stomach, kidney, small intestine, heart, spleen, brain, and lung. On the other hand, PABPC1 is expressed in both gonadal and somatic tissues. It is important to note that Epab mRNA expression had been characterized only in the mouse gonadal tissues. The immunostaining on the mouse oocytes and early embryos showed that EPAB protein is expressed in the nuclear and cytoplasmic regions of the GV and MII oocytes and early embryos and its expression exhibit remarkably differences during oocytes maturation and early embryo development (P < 0.05). Similarly, PABPC1 expression has been determined in the nuclear and cytoplasmic regions of the oocytes and early embryos, and its expression exhibit predominant changes during oocyte maturation and early embryo development (P < 0.05).

Limitations, reasons for caution: There is no limitation for this study.

Wider implications of the findings: We have tested firstly produced EPAB antibody and analyzed EPAB and PABPC1 protein expression in the mouse tissues, oocytes and early embryos. This is a preliminary study to determine the critical functions of EPAB protein in the translational control of the maternal mRNAs in the mouse oocytes and early embryos.

Trial registration number: As this study is a basic scientific research, there is no trial registration number.

P-352　Time to pregnancy and birth during fertility treatment – A Delphi consensus

E. Bosch[1], S. Longobardi[2], T. D'Hooghe[2], P. Humaidan[3,4]

[1]Instituto Valenciano de Infertilidad, Human Reproduction, Valencia, Spain
[2]Merck KGaA, Global Medical Affairs Fertility, Darmstadt, Germany
[3]Skive Regional Hospital, The Fertility Clinic, Skive, Denmark
[4]Aarhus University, Faculty of Health, Aarhus, Denmark

Study question: Does time to pregnancy/birth (TTP/B) play a significant role for fertility treatment and if so, how could it be shortened?

Summary answer: Overall, TTP/B was considered an important factor that should be included in any decision making related to fertility treatment.

What is known already: TTP/B has been suggested to be of importance when considering treatment choices for assisted reproductive technologies (ART). Although TTP/B is applicable to all patients, it is of particular importance for ageing women due to the decline in fertility observed with age. Until now there is no consensus as to how TTP/B could be taken into account during fertility treatment.

Study design, size, duration: This Delphi consensus process comprised three steps.

　Step 1: A panel of experts developed 12 statements.

Step 2: A larger panel of experts voted on these statements, giving motivations for their vote. Consensus was reached if ≥66% of participants agreed/disagreed with the statement(s). Any statement(s) without consensus would be revised and voting repeated until consensus was reached.

Step 3: Details on any statements reaching consensus was communicated to participants.

Participants/materials, setting, methods: The core scientific panel for Step 1 comprised 12 experts. The larger panel for Step 2 included the core scientific panel plus 15 experts recommended by the core panel (total of 27 experts). Discussions (Steps 1&3) were held by WebEx and voting for consensus was conducted by an online poll. Each statement was accompanied by references to provide a context for the statement and these were considered part of the statement that was agreed/disagreed with.

Main results and the role of chance: During Step 1, 12 statements were developed, focussing on the following topics related to TTP/B:

– Managing fertility treatment in a timely manner, avoiding over- or under-treatment is crucial;
– In all subfertile women <40 years old, IVF outcomes could be optimized by performing 3–6 embryo transfers;
– A number of procedures might reduce TTP/B, including preimplantation genetic screening, and the use of frozen replacement cycles immediately after failed fresh cycles, as clinical pregnancy rates are similar to those for frozen cycles postponed to a later time. Moreover, use of gonadotropin-releasing hormone (GnRH) antagonist protocols shorten the treatment period, and reduce OHSS cycle cancellation rates;
– The number of oocytes retrieved should be maximised to increase the cumulative live birth rate;
– Double stimulation (follicular and luteal phase) could be used in patients with reduced ovarian reserve to accumulate oocytes/embryos.

Consensus (agreement) was reached on all statements after the first round of voting; four statements reached 100% consensus. These four statements related to an increased live birth rate with a larger number of oocytes retrieved, patient age not affecting donor cycles if donors were aged 18-34 years, and the use of GnRH antagonists (two statements).

Limitations, reasons for caution: This consensus does not represent an exhaustive list of statements on TTP/B and is aimed at healthcare professionals, not patients. The views represent the collective opinion of the experts and not all statements reached 100% agreement. Some statements reached consensus even though a minority of participants absolutely disagreed with them.

Wider implications of the findings: As the population seeking ART is ageing, TTP/B is of increasing importance when selecting treatment strategies. Some approaches, e.g. GnRH antagonist co-treatment or frozen-thaw transfer immediately after a failed fresh cycle, are related to reduced treatment duration, however, more research is needed exploring the impact of treatment choices on TTP/B.

Trial registration number: N/A.

P-353 In vitro proliferation of uterine fibroids is related with vitamin D receptor and patient´s age

N. García[1], A. Aguilar[1], A. Corachán[2], J. Monleón[1], H. Ferrero[2], D. Galiano[2,3], A.T. Navarro[2], I. Cervelló[2], A. Pellicer[2,3]

[1]Hospital Universitario y Politécnico La Fe, Servicio de Ginecología, VALENCIA, Spain
[2]Fundacion Instituto Valenciano de Infertilidad FIVI, Department of Obstetrics & Gynecology- School of Medicine- Valencia University and Instituto Universitario IVI/INCLIVA, Paterna Valencia, Spain
[3]Instituto Valenciano de Infertilidad IVI, Instituto Valenciano de Infertilidad IVI- Rome, Rome, Italy

Study question: Could Vitamin D be a potential uterine fibroid treatment for women of all ages?

Summary answer: Vitamin D, acting via its receptor, is a potential treatment for uterine fibroids, which occur in women at reproductive ages.

What is known already: Uterine fibroids (UF) (also known as leiomyomas or myomas) are benign tumours occurring in an estimated 20%-40% of women during their reproductive years. UF affect a patient's quality of life, as well as her fertility and obstetrical outcomes. Recent studies have proposed Vitamin D (VitD) as an effective treatment for UF. Diverse functions for VitD have been confirmed by the presence of vitamin D receptor (VDR) in a wide range of human tissues, including the myometrium of the human uterus, but its specific role in UF remains unclear.

Study design, size, duration: This study was approved by the Clinical Research Ethics Committee at the Hospital Univeritario y Politécnico La Fe de Valencia (Spain) (2014/0691). Our pilot study was carried out in the Hospital Universitario y Politécnico La Fe de Valencia and Fundación Instituto Valenciano de Infertilidad (FIVI). Intramural UF were collected from patients undergoing surgery due to UF pathology (n = 14) without any previous treatment. All participants provided written informed consent.

Participants/materials, setting, methods: UF tissue (n = 14) was analysed by Western blot to determine the presence of Vitamin D receptor (VDR) (Cell Signaling antibody) protein. Subsequently, UF tissue was disaggregated with collagenase-II (Sigma-Aldrich) and cells were cultured in DMEM-F12 medium. In vitro cell proliferation assays were performed by flow cytometry using propidium iodide. Data were normally distributed; parametric linear regression and Student's t-test were conducted with R commander software.

Main results and the role of chance: We corroborated the statistically significant negative correlation between in vitro proliferation of UF cells and patient age (ranging from 22 to 52 years, p-value = 0.028). Additionally, cells from UF with VDR showed greater cell growth compared with cells without VDR (p = 0.008). Surprisingly, we observed a trend in which the VDR was absent in patients ranging from 44-52 years old (p = 0.07). These findings were supported by the statistically significant correlation between in vitro proliferation, presence of VDR, and patient age (p = 0.049), suggesting a strong interaction among the three.

Limitations, reasons for caution: Limitations of this pilot study include the small sample size.

Wider implications of the findings: Active uterine fibroid cells appear during the reproductive years and regress around pre-menopause. These active cells exhibit an in vitro proliferation rate that correlates with the presence of vitamin D receptor and the patient´s age. These findings provide a foundation for exploring vitamin D treatment in the clinical setting.

Trial registration number: No clinical trial.

P-354 Why do follicles rupture earlier in poor ovarian response: The role of Cyclooxygenase-2 expression in the follicular micro-environment

G. Kuspinar[1], I. Kasapoglu[2], S. Saribal[1], G. Uncu[2], B. Avcı[1]

[1]Uludag University School of Medicine, Department of Histology and Embryology, Bursa, Turkey
[2]Uludag University School of Medicine, Department of Gynecology and Obstetric IVF Center, Bursa, Turkey

Study question: Does the expression of Cyclooxygenase-2 (Cox-2) mRNA in oocytes and surrounding cumulus cells or serum and follicular fluid Cox-2 concentration has an effect on oocyte maturation and follicular rupture?

Summary answer: High follicular Cox-2 concentration could be the reason of premature follicular rupture before oocyte maturation, especially in poor responders.

What is known already: Cox-2 plays an important role via enzymatic activity on follicle rupture and cumulus expansion induced by the LH surge. Animal studies on Cox-2 inhibitor application have confirmed that Cox-2 activity is required as a key factor for ovulation, follicle rupture and oocyte competence.

Study design, size, duration: This was a prospective clinical trial of a total of 26 oocytes and 52 cumulus cells, and 52 samples of folliculer fluid retrieved from infertile patient underwent intracytoplasmic sperm injection (ICSI) cylcles at the Department of Gynecology and Obstetric ART Center, Uludag University School of Medicine, Bursa, Turkey, between September 2015 and May 2016.

Participants/materials, setting, methods: The samples were divided into three groups according to the stage of oocyte maturity and fertilization: Group1 included 16 immature oocytes with their micro-enviroments, Group2 included 10 mature-unfertilised oocytes with their micro-enviroments and Group3

consisted from 26 micro-enviroments of mature fertilized oocytes as a control group. Oocyte and cumulus cell Cox-2 mRNA expression was detected by Real Time-PCR. Serum and follicular fluid Cox-2 concentrations were measured by the ELISA assay.

Main results and the role of chance: Compared with patients baseline characteristics, serum AMH concentration and follicular Cox-2 concentration had a significant negative correlation (CF: -0.310; $p = 0.036$). When follicular Cox-2 concentration compared in terms of stimulation protocols, a significant difference was observed also. In poor ovarian response patients whom Letrozole co-administrated to gonodotropins, higher follicular concentration of Cox-2 was detected ($p = 0.026$). Follicular Cox-2 concentration and follicle diameter showed positive correlation in only Group 3 (mature and fertilized oocytes) (CF: 0.414; $p = 0.035$). The Cox-2 concentration in serum samples showed no significant difference with regard to oocyte maturation stage ($p = 0.426$, $p = 0.504$ respectively) and also relative Cox-2 mRNA expression in cumulus cells had no effect on stage of oocyte maturity ($p = 0.394$) or fertilization ($p = 0.143$).

Limitations, reasons for caution: The cumulus cells and oocytes were obtained from patient who underwent ovarian stimulation, which in comparison with natural cycles, may have affected gene and protein expression. Also due to the ethical restriction and patient rights, fertilized oocytes regarded as potential embryos and were not analyzed.

Wider implications of the findings: Our data suggest that, in patient with diminished ovarian reserve for preventing premature follicular rupture and retrieving more mature oocyte, co-administrating Cox-2 inhibitors in COH protocols could be a novel clinical approach.

Trial registration number: We do not have clinical trials registration number.

P-355   Targeted mutant mZP1 results in defective zona pellucida and reduced fecundity in female mice

C. Lv[1], H. Xiao[2], Y. Wang[2], H. Huang[2], W. Xian[2]

[1]Institute of Reproductive & Stem Cell Engineering, school of basic medical science central south university, changsha Hunan, China
[2]Institute of Reproductive & Stem Cell Engineering, school of basic medical science central south university-, changsha, China

Study question: Does a homozygous frameshift mutation in mZP1, cause a defect on zona pellucida (ZP) development and fertility in vivo same as human?

Summary answer: The mutant mZP1 exerts defects on ZP development and fertility results in a thin and looser weave ZP of most of eggs and reduced fecundity.

What is known already: The pervious reported research identified a novel 8 bp frameshift deletion (l390fs404X) in ZP1 gene in a consanguineous Chinese Han family. This deletion co-segregates with infertility and absence of ZP in the family, with an autosomal recessive inheritance mode. Importantly, the co-localization of truncated ZP1 and normal ZP3 proteins were detected throughout the cytoplasm but not at the cell surface in eggs from the affected patients, suggesting the different relationship between the ZP1 proteins and fertility. Nevertheless Zp1 knockout female mice ovulate the eggs surrounded by loosely organized and swollen zona pellucida, with reduced fecundity.

Study design, size, duration: The fertility of the mice was assessed by breeding Zp1$^{tm/wt}$, Zp1$^{tm/tm}$ and normal female mice. Each group contained 15 female mice, fixed with normal fertile male mice (1:1) after 6 weeks age, and got the live births after 3 weeks.

Participants/materials, setting, methods: We used CRISPR/Cas 9-mediated genomic editing technology to develop a mouse model carrying the homologous 8 bp deleted mutation in Zp1 gene(Zp1$^{tm/tm}$, tm: targeted mutation). In silico analysis was done for the sequence variants followed by molecular assays to examine the functional effects of the sequence variants in mouse. The sanger sequencing and western analysis were used to detect the mouse model edited result. Light microscope visualizing the oocytes, ovarian histology and immunocytochemistry of Zp1$^{tm/tm}$.

Main results and the role of chance: We determined that an 8 bp-deletion at nucleotides 1145-1152 (TCTTCTCA) of mouse ZP1 CDS (CCDS37918.1), which will result in a premature stop codon (l390fs411X) that leads to a truncated mouse ZP1 protein of 411 aa with the terminal recoding sequence of 22 aa bearing no homology to the corresponding aa sequence of normal mouse ZP1 protein. Examining all oocytes, the zona matrix was multitudinous, the most of zonae of Zp1tm/tm mice thinner with a poorly defined peripheral border compared to normal zonae, while Zp1tm/wt female did not have significant difference. Additionally, In some oocyte-cumulus complexes, cumulus cells were observed between the zona matrix and the oolemma, a phenomenon not observed in normal zonae. These inner cells had undergone mucification and a granular matrix was observed surrounding them and infiltrating the zona matrix. Eggs lacking zonae is not a rare phenomenon. The number of litters of Zp1$^{tm/tm}$ was reduced, in contrast with infertility of the patients.

In each group, the mean and arithmetic Average $\pm$ standard error(SE) were calculated. Student's t-test or chi-square test was used for statistical analysis of measurement data or enumeration data, respectively; significance was assumed for $P < 0.01$. The calculations were made using SPSS 19 software.

Limitations, reasons for caution: Although the in vitro assays demonstrated the causative effect of mutant zp1 on on zona pellucida (ZP) development and fertility.further studies need to validate its long-term effects on folliculogenesis.

Wider implications of the findings: These results will aid both researchers and clinicians in understanding the molecular pathology of mutant ZP1 causing a defect on zona pellucida (ZP) development and fertility in vivo and to develop diagnostic assays or therapeutics approaches.

Trial registration number: none.

P-356   Do the Bologna criteria assist in predicting ART outcome for women aged over 38?

R. Beck[1], H. Binyamini Raischer[2], S. Baram[3], Y. Geslevich[4], A. Weiss[5]

[1]Haemek Medical Centre, obstetric @ gynecology, Afula, Israel
[2]Rappaport Faculty of Medicine- -, Technion-Israel Institute of Technology, Haifa, Israel
[3]Emek Medical Center-, Fertility and In-Vitro Fertilization Unit- Department of Obstetrics and Gynecology, Afula, Israel
[4]Emek Medical Center, aFertility and In-Vitro Fertilization Unit- Department of Obstetrics and Gynecology-, Afula, Israel
[5]Emek Medical Center, Fertility and In-Vitro Fertilization Unit- Department of Obstetrics and Gynecology, Afula, Israel

Study question: What is the live birth rate (LBR) for advanced aged ART patients and do the Bologna criteria assist in predicting the treatment outcome?

Summary answer: A LBR of 14.1% was found in the study population. The LBR was not significantly lower for women fulfilling the Bologna criteria.

What is known already: Postponing parenthood has steadily increased during past decades. Women delay childbearing reassured by the belief that ART can compensate for age-related decline in fertility. Growing portions of ART patients are women in their late 30 s and older. Many of them present with poor ovarian response. In an attempt to standardize the definition of POR the Bologna criteria were set. The combination of advanced maternal age with additional features of poor ovarian response may be connected to minimal chance of achieving genetic parenthood. Unveiling these chances is important to patients and clinicians in making rational decisions about medical treatment.

Study design, size, duration: A database containing clinical and laboratory information on ART treatment cycles carried out at an academic hospital between December 2010 and February 2016 was analyzed. This data was collected prospectively and recorded in the database of the infertility unit. All women 38 years or older were included. Autologous fresh and frozen thawed cycles were included if the patients' age at the pickup was at least 38 years. The main outcome was the live birth rate.

Participants/materials, setting, methods: Two hundred and fifty four women had 696 ART cycles (571 fresh and 125 frozen thawed). To establish the diagnosis of poor ovarian response according to the Bologna criteria at least 2 of the following had to be present: 1. Advanced maternal age (>40 years), endometriosis, or previous chemotherapy. 2. A previous POR cycle ($\leq$3 oocytes retrieved with a conventional stimulation protocol). 3. Abnormal ovarian reserve tests: FSH > 12. Fifty-eight patients fulfilled these criteria.

Main results and the role of chance: Overall, 36 women had a live birth (14.1%). In comparison to the patients who failed, these patients were younger (40.5 vs 41.4, p = 0.004), had more oocytes aspirated (5.9 vs 4.3, p = 0.005), more embryos transferred (2.1 vs 1.5 p = 0.002) and frozen (1 vs 0.4, p = 0.03). A higher proportion of the patients who gave birth used donor sperm (28 vs 15% p = 0.05) and a lower proportion had 3 or less oocytes aspirated in a former cycle (38 vs 60%, p = 0.02). The patients who fulfilled the bologna criteria were less likely to have a previous delivery (34 vs 56%, p = 0.003), had lower maximal estradiol (738 vs 1220 pg/ml, p < 0.0001) and progesterone (0.78 vs 0.94 ng/ml, p = 0.007) levels, and a lower number of oocytes (2.3 vs 5.1, p < 0.0001) and mature oocytes (1.5 vs 3.2, p = 0.02) aspirated. They had fewer embryos transferred (1.2 vs 1.8, p = 0.007) and cryopreserved (0.007 vs 0.7, p = 0.014).Overall 6.9% from the patients with poor ovarian response according to the bologna criteria delivered as compared to 16.3% in the non-poor responders. This difference was not statistically significant (p = 0.07).

Limitations, reasons for caution: This is an observational study with a limited sample size. Although no statistically significant difference was seen in the primary outcome, the study may have been underpowered to a difference. No definite cutoff values can be drawn regarding the probability of live birth.

Wider implications of the findings: The public should be aware of the low pregnancy rates in advanced maternal age. It should be emphasized that advanced reproductive technologies can't overcome this age related decline in fertility and that there are no absolute values in predicting the prognosis.

Trial registration number: NA.

P-357   Does a rise in LH levels during artificial frozen–thawed embryo transfer (FET) cycles affect pregnancy rate?

E. Kadour-peero, Y. Gonen, J. Awad, S. Shlomi, S. Khoury

Bnai Zion Medical Center, OB-GYN, Haifa, Israel

Study question: To evaluate the association between high serum luteinized hormone (LH) levels during artificial FET cycles and positive pregnancy test

Summary answer: Increase in LH level in artificial FET cycles does not affect pregnancy rate.

What is known already: Supplementation of estrogen (E2) in the early follicular phase in FET cycles for endometrium preparation can lead to a rise in LH level, similar to that observed before ovulation. Such a rise of LH might interfere with endometrial receptivity during a FET cycle. According to previous studies, it was demonstrated that the likelihood of clinical pregnancy is not associated with absolute serum LH levels on day 14 of an artificial FET cycle. The association between a rise in LH level during artificial FET cycle compared to early follicular phase level and pregnancy rates, has not been studied.

Study design, size, duration: A retrospective cohort study. A total of 1685 FET cycles, between 01/2007 to 12/2016 were included in the analysis

Participants/materials, setting, methods: Women undergoing artificial FET cycles.

Setting-Assisted Reproductive Technology unit at Bnai-Zion medical center

Methods- we compared cycles in which LH double/triple itself from early follicular phase and further, to cycles without rise in LH. Endometrium preparation was achieved by administration of 2 mg*3\day estradiol valerate tablets. Embryo transfer (ET) was conducted after achieving endometrial thickness >7 mm and vaginal progesterone supplementation was added according to the embryo's age. A beta hCG was measured 13-14 days after ET.

Main results and the role of chance: Data from one thousand six hundred and eighty-five FET cycles were retrieved between the years of 2007 and 2016. LH values, E2, progesterone values, endometrial thickness and pregnancy outcomes were available in all patients. We calculated the LH rise between LH on early follicular phase in each cycle, to LH on the ET day. Moreover, we calculated a rise in E2 level and endometrial thickness during the cycle. 44.6% of 1685 FET cycles had doubling LH level until ET day, 27.24% had tripling LH level. Mean patient age was 30 years (range, 20–45 years), similar in cycles with and without rise in LH level. Overall pregnancy rate was 30.6%. Pregnancy rates per ET were similar between cycles with and without doubling or tripling LH level, (31.8% Vs. 29.8%, P = 0.38 and 31.2% Vs. 30.3%, P = 0.79, respectively). Multivariate logistic regression was performed with the dependent variable positive pregnancy test and independent variables including; doubling LH level with doubling E2 level, or with endometrial thickness above 7 mm, on ET day. In this model, there was no association between doubling LH values with doubling E2 values during the cycle or with endometrial thickness above 7 mm on ET day and pregnancy rates.

Limitations, reasons for caution: The main limitation of our study is its retrospective nature. Nevertheless, our study represents one of the largest series addressing the association between LH rise in FET cycles and Pregnancy rates.

Wider implications of the findings: Though the pregnancy rate was higher among cycles with doubling and tripling LH values, it was not statistically significant. Therefore, LH rise during FET cycles does not alter pregnancy rates. Apparently, hormonal monitoring of LH levels does not yield useful information in FET cycle, and should therefore not be conducted.

Trial registration number: 0101-16-bnz

P-358   FMR1 CGG-genotype influences FMR1 expression in human granulosa cells

J. Rehnitz[1], D.D. Alcoba[2], I.S. Brum[2], J. Dietrich[3], K. Hinderhofer[4], A. Freis[5], A. Germeyer[5], T. Strowitzki[5]

Study question: Does the CGG repeat-length (RL) of *FMR1 (*Fragile X Mental Retardation 1 gene) influence its expression in granulosa cells of women with different ovarian response?

Summary answer: Poor responder (POR) with a heterozygous low/norm CGG repeat demonstrate significantly elevated *FMR1* expression profiles in their granulosa cells during IVF/ICSI cycles.

What is known already: CGG RL of *FMR1* varies about 30 in general. >200 (Full Mutation) a Fragile-X-Syndrome can occur. Ranges of 54-200 are called premutation (PM) and show instable heredity. ~20% of the female PM-carriers suffer from premature-ovarian-failure (POF). *FMR1*-expression in peripheral blood cells, as well as female granulosa cells (GC) increase with increasing RL in PM-carriers. But variable *FMR1*-expression-profiles independent of PM in POF-women are also reported. The influence of aberrant *FMR1*-CGG-RL before PM on ovarian reserve and response is controversially discussed and an analysis of *FMR1*-expression and its potential dependence on ovarian response in womens´ GC has not yet been performed.

Study design, size, duration: 229 women undergoing IVF/ICSI-treatment were included and divided into three ovarian-response-subgroups: POR using "Bolognia Criteria", polycystic ovary syndrome (PCO) using "Rotterdam Criteria" and normal responder (control group) (. A CGG-RL of 26-34 was considered normal. Women were subdivided into 3 haplotypes (normal [both alleles in range], heterozygous [one allele outside range] or homozygous [both alleles outside range]) and 6 genotypes ("low" [<26 repeats], "normal" [26-34 repeats] or "high" [35-55 repeats]) according to their be-allelic CGG-RL.

Participants/materials, setting, methods: Clinical data were collected from a questionnaire and medical reports. CGG repeat length was determined using ALF express sequence automat or ABI 3100/ 3130xl sequencer.

RNA was extracted from granulosa cells after follicular aspiration. Quantitative RNA-expression was analysed using specific TaqMan gene expression assays and compared using ΔΔCT method. Statistical analyses were performed with SPSS (*Statistical Package for the Social Sciences V. 22.0*) and statistical significance was set at $P \leq 0.05$.

Main results and the role of chance: We here analyzed the *FMR1*-gene-expression in the female germline directly *in vivo* in human GC and evaluated

there a potential association with the different *FMR1* geno- and haplotypes, as well as ovarian response and reserve parameters. Women with POR with a normal/low genotype compared to either high/normal, or normal/normal genotypes in our study showed a significant higher *FMR1*-mRNA-level in their GC (p = 0.008, p = 0.027, respectively). So low allels putatively negatively affect female ovarian response or vice versa low response is caused by impaired folliculogenesis prior to stimulation due to a low-allel-effect.

Women with high/high and high/normal genotypes of all response groups demonstrated a tendency of lower AMH level, and patients of low/low and high/high genotypes presented the lowest number of total and MII oocytes.

Aberrations of the CGG repeat outside the normal range of 26-34 may be causal for elevated *FMR1*-gene-expression-levels in POR and also influence outcome after follicular aspiration in all response groups. Results may help to offer an optimized, risk adjusted treatment for future patients during IVF/ICSI-treatment depending on their *FMR1*-genotype and *FMR1*-expression-profile by for example better clarification of their expected outcome and potentially optimizing their stimulation protocol adapted to their elevated risk of limited response or outcome.

Limitations, reasons for caution: Study population especially of the subgroups was low. Further studies of *FMR1* expression in granulosa cells with bigger sample sizes are needed.

Wider implications of the findings: Norm/low genotype in poor responders is associated with elevated granulosa cellular *FMR1*-expression. Herewith the hypothesis of *FMR1* as relevant regulator of folliculogenesis gets further substantiated. A better understanding of *FMR1*-expression in GC and its regulation in future may help to elucidate pathomechanisms of different folliculogenesis disorders.

Trial registration number: not applicable.

P-359 Dipeptidyl peptidase-IV and Adenosine deaminase enzyme activity levels in Polycystic Ovary Syndrome

A.S. Gurbuz[1], B. Oztürk[2]

[1]Novafertil Tup Bebek Merkezi, Konya, Turkey
[2]Selçuk University Medical Faculty, Biochemistry, KONYA, Turkey

Study question: Is there any relationship between Dipeptidyl peptidase-IV and Adenosine deaminase enzyme activity levels in Polycystic Ovary Syndrome?

Summary answer: DPP-4 activity levels, ADA, AMH, HOMA-IR and insulin levels were found to be increased in PCOS patients when compared to control grup.

What is known already: Polycystic ovary syndrome (PCOS) is one of the most common endocrinopathies in reproductive age women around the world. Insulin resistance and hyperinsulinism play a critical role in the syndrome pathogenesis. Glucagon-like peptide-1 (GLP-1) promotes insulin secretion, inhibits glucagon secretion. GLP-1 is rapidly degraded by dipeptidyl peptidase-4 (DPP-4). DPP-4 also known as adenosine deaminase (ADA) binding protein. An increase in ADA activity in type 2 diabetic patients has been reported. Reduced levels of adenosine increase glucose uptake into cells. It was proved that Polycystic ovary syndrome is realeted with insulin resistance. Therefore, insulin resistance may have an important relationship with ADA activity.

Study design, size, duration: This study was made by prospective, among april of 2015 and september 2016.

Participants/materials, setting, methods: The subjects enrolled in this study were recruited from 44 patients with PCOS and 44 infertile controls which were revealed with USG and Anti-Müllerian Hormon (AMH) levels. Serum ADA and DPP-4 activities and AMH levels were measured by ELISA methods. Homeostasis model assessment of insulin resistance (HOMA-IR) method was used for evaluating insulin sensitivity (HOMA-IR=Fasting Insulin (μu/ml) x Fasting Glucose (mg/dl) / 405). All results were compared.

Main results and the role of chance: There was no difference between the PCOS and control groups in terms of age and BMI. ADA and DPP-4 activity levels and AMH, HOMA-IR (p<0.05) and insulin levels (p<0.01) were found to be increased in PCOS patients when compared to control. Glucose levels were similar in both groups.

Considering all study participants AMH levels positively correlated with ADA (r:0.734) and DPP-4 (r:0.449) activity levels. Also ADA was positively

correlated with DPP-4(r:0.472), insulin (r:0.216) and HOMA-IR (r:0.223) parameters.

Limitations, reasons for caution: Since small sample size. Future functional studies are essential to define relation of between insulin intolarance and PCOS.

Wider implications of the findings: Defining of insuline resistans for PCOS is essential in view of treatment of infertility. Oral DPP-4 inhibitor drugs and GLP-1 analogues may be used for the treatment of insulin resistance in PCOS.

Trial registration number: 1.

P-360 Abnormal ratio of CD57+ cells to CD56+ natural killer cells in women with recurrent implantation failure

R. Jiang, G. Yan, J. Xing, Z. Wang, J. Zhou, L. Ding, H. Sun

The Affiliated Drum Tower Hospital of Nanjing University Medical School, Reproductive Medicine Center, Nanjing, China

Study question: Are altered levels of endometrial and peripheral natural killer cells (NKs) and regulatory T cells (Tregs) present in women with recurrent implantation failure (RIF)?

Summary answer: An increased ratio of endometrial and peripheral $CD57^+$ cells to $CD56^+$ NKs and a decreased percentage of peripheral $Foxp3^+$ Tregs in women with RIF.

What is known already: NKs and Tregs perform important immune regulatory function in embryo implantation. Although the detection of $CD56^+$ uterine NKs using immunohistochemistry has been developed extensively, the debate regarding the predictive value of the measurement may reflect a lack of understanding of the subtypes of NKs and the relation between NKs and Tregs.

Study design, size, duration: A case control study was conducted on 32 women with RIF and 23 normal controls (regular menstrual cycle, no oral contraceptives) during the period between June 2015 and June 2016.

Participants/materials, setting, methods: Endometrial biopsies were obtained during the mid-luteal phase (LH+ 7–9 of the menstrual cycle) followed with immunohistochemistry, and the percentages of stromal cells positive for CD56, CD57, and Foxp3 were calculated. Blood samples were obtained on days 12–14 of the menstrual cycle to determine $CD45^+CD56^{bright}CD57^+$ NKs and $CD4^+CD25^+Foxp3^+$ Tregs using multi-color fluorescence flow cytometry.

Main results and the role of chance: In endometrium, lower percentage of $CD56^+$ NKs and $Foxp3^+$ Tregs, while higher percentage of $CD57^+$ cell were found in the women with RIF compared to normal controls (p<0.05). In peripheral blood, lower percentage of $CD45^+CD56^{bright}$ cells in $CD45^+$ cells was found in women with RIF compared to normal controls (p<0.05), while none difference was found in the percentage of $CD45^+CD56^{bright}CD57^+$ cells in $CD45^+$ cells (p = 0.29) and the percentage of $CD4^+CD25^+Foxp3^+$ cells in $CD4^+$ cells (p = 0.30) between two groups. Compared to normal controls, the ratio of $CD57^+$ cells to $CD56^+$ NKs was significantly increased in women with RIF, both in the endometrium [median (range)/ 29.8% (1.8–94.6%) vs 13.3% (1.4–88.2%), p<0.01] and peripheral blood [46.9% (24.7–77.8%) vs 34.1% (11.1–71.8%), p<0.05]. There was a negative correlation between the ratio of $CD57^+$ cells to $CD56^+$ NKs and the percentage of $Foxp3^+$ Tregs in the peripheral blood (correlation=-0.32, p<0.05), but none significant correlation between them was found in the endometrium (correlation=-0.20, p = 0.15).

Limitations, reasons for caution: We used nonparametric test to compare the CD56, CD57 and Foxp3 positive ratio of cells due to non-normal distribution and non-homogeneous variances which may result from the limited cases. Another limitation was the absence of double staining of CD56 and CD57 in endometrium limited to the existing test-bed condition.

Wider implications of the findings: Our study provides insights into evaluation of the subtypes of NKs as well as a clue for further understanding the relation between NKs and Tregs in women with RIF.

Trial registration number: Not applicable.

P-361 Maternal aging affects mechanisms regulating Ca2+ homeostasis in mammalian oocytes

A. Ajduk, K. Czajkowska

University of Warsaw, Faculty of Biology, Warsaw, Poland

Study question: We wished to examine whether mechanisms regulating Ca2+ homeostasis in mammalian oocytes change with female age, leading to age-dependent decline in female fertility.

Summary answer: Maternal aging affects Ca2+ homeostasis, including fertilization-induced Ca2+ oscillations and their association with ATP production, but not the overall developmental potential of mouse oocytes.

What is known already: Maternal aging (aging of oocytes in vivo in a female's organism) has been reported to have an adverse effect on the oocyte quality, leading to an age-dependent decline in female fertility. Changes associated with maternal aging include both malfunctions of the nuclear apparatus and imbalance of cytoplasmic processes. Among other cytoplasmic regulatory processes, homeostasis of Ca2+ ions combined with energy metabolism has crucial importance for the further embryo development.

Study design, size, duration: In our study we used mouse oocytes isolated from young (2-3 months old) and aged (12-15 month old) mouse females of different genetic backgrounds, which were equivalents to women in early and late (>35 yrs old) reproductive age.

Participants/materials, setting, methods: Oocytes recovered from young and aged mice were labelled with fluorescent Ca2+ and /or Mg2+ markers, fertilized in vitro and subjected to time-lapse fluorescence imaging in order to follow Ca2+ oscillations induced by fertilization and/or ATP production (associated with the Mg2+ level). Additionally, amounts of Ca2+ present in young and aged oocytes were compared, as well as expression of genes involved in Ca2+ homeostasis. TMRE staining was used to assess mitochondrial membrane potential in oocytes.

Main results and the role of chance: We show that maternal aging alters the pattern of fertilization-induced Ca2+ oscillations in a manner depending on the genetic background. These changes, as our results indicate, are caused likely by altered expression of genes coding proteins involved in maintaining the Ca2+ homeostasis and/or by different levels of available Ca2+ ions in the oocyte. We also find that maternal aging changes dynamics of ATP production accompanying Ca2+ oscillations. Interestingly, this does not associate with a significant modification of mitochondrial functionality, as a mitochondrial membrane potential is similar in young and aged oocytes. Importantly, although we notice differences in Ca2+ homeostasis in young and aged oocytes, the oocytes display the same ability to undergo fertilization and further pre- and post-implantation development.

Limitations, reasons for caution: Our study was performed on mouse oocytes, which although widely used as a model of human gametes, differ in some aspects from human counterparts. Therefore our results should be treated as an indicator of certain tendencies possibly present in other mammalian species, but should not be directly translated to humans.

Wider implications of the findings: Our findings implicate that genetic background alters oocyte susceptibility to maternal aging, at least on the Ca2+ homeostasis level. Moreover, even though maternal aging can significantly affect mechanisms involved in Ca2+ homeostasis, it does not necessarily diminish developmental potential of the oocyte.

Trial registration number: not applicable.

P-362   The effect of Liuwei Dihuang Granules on ovarian granulosa genomics of IVF patients with Kidney-yin deficiency

F. Lian[1], H. Wu[1], Z. Sun[1], C. Zhang[2], Y. Yu[1]

[1]The Affiliated Hospital of Shandong University of Traditional Chinese Medicine, Integrative Medicine Research Centre of Reproduction and Heredity, Jinan, China
[2]Jining first people's hospital, Reproduction Dept, Jining, China

Study question: To study the differences of granulosa cell gene expression pretherapy and post-treatment and to analyze the mechanism of Chinese herbs on the infertility patients with Kidney-yin deficiency by genomics.

Summary answer: After treating with Chinese herbs, patients' gene expression differences were detected, cell proliferation and apoptosis were affected, leading to the improvement of their pregnancy outcomes.

What is known already: The ovarian granulosa cell has a close relationship with the growth of the oocyte and embryo. In traditional Chinese medicine, Kidney Governing Reproduction Theory is a crucial element of Visceral Manifestation Theory. According to our former subject research supported by Chinese National Natural Science Fund, Chinese herbs for tonifying Kidney-yin can improve the quality of oocyte and embryo. However, the underlying mechanism is not known. In this work, we explore the scheme that how the Chinese herbs for tonifying Kidney-yin improve the quality of the oocyte and embryo, and hence improve pregnancy outcomes based on the ovarian granulosa cell genomics.

Study design, size, duration: Sixty-six infertility patients aged from 25 to 40 with Kidney-yin deficiency syndrome, were randomly assigned to either a treatment group or a control group according to a random number table, 33 cases in each group. Besides Western routine therapy, Chinese herbs Liuwei Dihuang Granule (LDG) were given 3 menstrual cycles before IVF to the treatment group, and placebo granules to the control group.

Participants/materials, setting, methods: The scores of Kidney-yin deficiency symptoms were assessed, the rates of high quality oocytes/embryos and clinical pregnancy rate were recorded, and the granular cell was collected on the day when the ovum was picked up. With high-throughput gene sequencing technology, the differential gene expression was detected by Gene Ontology (GO) enrichment analysis and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analysis.

Main results and the role of chance: The syndrome score in the treatment group decreased significantly(from 17.36 ± 2.41 to 9.06 ± 2.47)(P < 0.05), while it changed insignificantly in the control group(from 16.79 ± 2.61 to 16.55 ± 2.53) (P > 0.05). The high quality rates of oocytes and embryos and clinical pregnancy rate were all higher in the treatment group than the control group (83.76%&74.44%,77.89%&68.44%,54.55%&30.30%,all P < 0.05). After Chinese herbs' treatment, 280 differential expressed genes were detected, of which 156 up-regulating genes and 124 down-regulating genes. These differentially expressed genes were, according to GO functional, mainly related to the defense response, inflammatory response, cytokine activity, regulation of cell proliferation, and regulation of apoptosis; according to KEGG classification, involved multiple signal transduction pathways, including immune function, apoptosis, metabolism, and human cytokine receptor interaction.

Limitations, reasons for caution: The sample size was small and all cases were collected at our reproductive center. The patients with Kidney-yin deficiency syndrome were collected from those undergoing in vitro fertilization-embryo transfer (IVF-ET) and these results may not reflect patients in the general population.

Wider implications of the findings: Genes expression differences were detected after treated with Chinese herbs, providing a proof for the mechanism of action on Chinese herbs. This research looks for the targets of Chinese medicines, applying to clinical diagnosis, treatment and drug development, to seek for theoretical breakthrough in Kidney Governing Reproduction Genomics Mechanism.

Trial registration number: ChiCTR-IOR-17010516

P-363   Perinatal outcomes following stimulated versus unstimulated IVF: a systematic review and meta-analysis

M. Kamath[1], M. Mascarenhas[2], S.K. Sunkara[3]

[1]Christian Medical College and Hospital, Reproductive Medicine, Vellore, India
[2]Seacroft Hospital-, Leeds Centre for Reproductive Medicine, Leeds, United Kingdom
[3]Queen's Hospital, Assisted Conception Unit, Essex, United Kingdom

Study question: Does ovarian stimulation affect perinatal outcomes of pre-term birth (PTB) and low birthweight (LBW) following in vitro fertilisation (IVF) treatment?

Summary answer: There was a higher risk of PTB and LBW following stimulated compared to unstimulated IVF.

What is known already: Women with infertility have an increased risk of adverse perinatal outcomes. The incidence of adverse perinatal outcomes is also higher following assisted reproductive treatments (ART) compared to spontaneous conceptions. It is an on-going debate whether underlying infertility or the various procedures involved during ART contribute to these risks. It is a matter of interest if ovarian stimulation routinely used during IVF affects perinatal outcomes. We conducted a systematic review and meta-analysis of

studies comparing stimulated versus unstimulated IVF, to overcome the current inconsistencies in literature and provide an objective answer

Study design, size, duration: We conducted a systematic review to evaluate the risk of PTB, early PTB, LBW and very LBW following stimulated versus unstimulated IVF. The following electronic databases were searched from 1980 to September 2016: Medline, EMBASE and Web of Science. Study selection and data extraction were conducted independently by two reviewers. A meta-analysis was carried by pooling eligible studies.

Participants/materials, setting, methods: We included cycles involving stimulated IVF and unstimulated IVF (natural cycle IVF or modified natural cycle IVF). Only studies which reported singleton live births following a fresh IVF cycle were included. Perinatal outcomes were LBW (birth weight <2500 grams), PTB (live birth <37 weeks gestation), very LBW (birth weight <1500 grams) and early PTB (live birth <32 weeks gestation). Data synthesis and analysis was done using the Rev Man 5.3 software

Main results and the role of chance: Four studies with 97 702 participants were included in meta-analysis including one RCT and three cohort studies. The risk of PTB (risk ratio RR 1.25, 95% CI 1.01-1.56; 4 studies, I^2 0%), LBW (RR 1.95, 95% CI 1.03 -3.67; 4 studies, I^2 44.3%), early PTB (RR 4.42, 95% CI 1.61-12.13; 3 studies, I^2 0%) were significantly higher in stimulated IVF compared to unstimulated IVF. The RR for very LBW was 5.18 (95% CI 1.00-26.87; 2 studies, I^2 0%).

Limitations, reasons for caution: We were unable to perform age or BMI adjusted comparisons within the meta-analysis framework due to lack of information.

Wider implications of the findings: The increased risk of PTB and LBW following stimulated compared to unstimulated IVF could suggest a possible contributory role of ovarian stimulation. However, the effect size is likely to be small.

Trial registration number: Not applicable.

P-364   Digital-holographic-microscopy as a potential method for fertility diagnostic

C. Wenders[1], M. Muschol[1], D.F. Babcock[2], G. Wennemuth[1]

[1]University Clinic, Anatomy, Essen, Germany
[2]University of Washington, Physiology and Biophysics, Seattle, U.S.A.

Study question: Do sperm motility parameters change in the presence of oocytes with or without the cumulus cells in a four dimensional way?

Summary answer: Motility characteristics of capacitated and uncapacitated sperm close to the oocyte and related to cumulus cells was identified with digital-holographic-microscopy in a four dimensional way.

What is known already: The fusion of egg and sperm is the basis for a successful fertilization. Therefore only sperm with modifications of their swimming behavior in response to fluid flow (rheotaxis) and temperature (thermotaxis) are capable of penetrating the oocyte. Another parameter of sperm selection is the episodic rolling and transient attachments of sperm. Only motile, hyperactivated and acrosome-intact sperm are able to penetrate the cumulus oophorus and bind to the zona pellucida in special to the zona pellucida protein 2 (ZP2). In most studies the focus on the sperm movement and the oocyte is limited to a two dimensional way.

Study design, size, duration: In this trial a difference in swimming behavior and other motility parameters like curvilinear velocity (VCL), straight-line velocity (VSL) and also the averaged path velocity was analyzed. The influence of the cumulus cells on these parameters was studied. With these results sperm should be identified with all qualifications for a successful fertilization.

Participants/materials, setting, methods: For the study we analyzed mouse sperm and oocytes of NMRI mice. After superovulation via hCG-injection, oocytes were dissected and in some cases cumulus cells were removed using a hyaluronidase-containing medium. The sperm were dissected out of the ductus deference via swim-out procedure in a physiological buffer. Both, sperm and oocyte were collected to a dish and analyzed under the digital holographic microscope directly. With the use of numerical algorithm the swim trajectory was analyzed.

Main results and the role of chance: Four dimensional analysis of sperm movement on their way to the oocyte was measured with the use of digital-holographic-microscopy. Different motility parameters of capacitated and uncapacitated sperm were measured. Capacitated sperm showed a higher amplitude, asymmetrical flagellar bending, which was compared with higher rates in their curvilinear velocity (VCL). These changes lead capacitated sperm to penetrate the cumulus mass easier and faster. Also larger XY-excursions of the tracked head were detected, which seemed to qualify these sperm to overcome an obstacle like the cumulus mass. We performed a comparative study of swimming behavior in the presence of cumulus mass and without to show the importance of this specific cluster of cells.

Limitations, reasons for caution: All results were generated in-vitro, which could be different in-vivo. Until now, the results were generated only with one species (mouse).

Wider implications of the findings: This method provides conditions which lead to specific changes in the sperm movement. Digital-holographic-microscopy could become a method for selecting sperm with optimal parameters for in-vitro-fertilization.

Trial registration number: None.

P-365   GnRH agonist for final oocyte maturation trigger and hCG as exclusive luteal support in normal responders, a prospective observational study

S. Baram[1,2], A. Weiss[1], Y. Geslevich[1], R. Beck-Fruchter[1]

[1]Fertility and In-Vitro Fertilization Unit, Department of Obstetrics and Gynecology-Emek Medical Center, Afula, Israel
[2]Rappaport School of Medicine, Technion-Israel Institute of Technology, Haifa-, Israel

Study question: Does GnRH agonist trigger result in comparable oocyte maturation rates and allows good cycle results in comparison to hCG trigger in normal responders?

Summary answer: GnRHa trigger and hCG trigger result in comparable oocyte maturation rates in normal responders treated with the GnRH antagonist protocol

What is known already: GnRHa trigger induces FSH as well as LH surge. Previous studies suggest that this more physiologic surge may promote oocyte maturation. A drawback of GnRH agonist trigger is the luteolysis which follows, necessitating modification of luteal support. Clinical studies regarding cycle results thus far resulted in conflicting results.

Study design, size, duration: This prospective, observational study was conducted in a single center from January 2012 to December 2015. 168 patients were enrolled in the study, at a 2:1 ratio between the control and the study groups

Participants/materials, setting, methods: Patients were stimulated using a GnRH-antagonist protocol. Each patient in the study group (n = 56) was matched to 2 controls (n = 112) based upon age and number of previous cycles. Final oocyte maturation in the study group was achieved with 0.2 mg triptorelin followed by two doses of 1500 IU hCG on the day of oocyte retrieval and 4 days later. The control group was triggered with 250 mcg hCG followed by luteal support with progesterone suppositories.

Main results and the role of chance: Demographic parameters of the study group and control group did not differ. A maturation rate of 70% was found in both groups. No significant difference was found in the number of oocyte retrieved (8.2 ± 4.3 vs 7.3 ± 4.2), fertilization rate in IVF (60 ± 20 vs 60 ± 30) or ICSI (80 ± 20 vs 70 ± 30) and the number of available embryos (4 ± 2.7 vs 3.2 ± 2.3). Similar results were also seen in positive pregnancy test (33.9% vs 32.%), implantation rate (19.3 ± 32 vs 21.7 ± 39) and live birth rate (25 vs 21.4). Pregnant patients from the study group had significantly higher mean progesterone levels (ng/ml) compared to pregnant patients in the control group (55.37 ± 12.86 vs 42.9 ± 22.21, p = 0.02).

Limitations, reasons for caution: This study is limited by its non-randomized design and small sample size. It has insufficient power to conclude that the live birth rate in both protocols is equivalent. Future randomized controlled trails are needed to establish its results

Wider implications of the findings: GnRH triggering with hCG luteal support in normal responder may be a valid alternative to the traditional hCG triggering with progesterone luteal support. This protocol combines the potential

advantages of a physiological trigger with a simple, patient friendly, luteal support

Trial registration number: NCT01638026.

P-366 Prediction of tubal damage by using new serological markers for chronic Chlamydia trachomatis infection

T. Rantsi[1], K. Hokynar[2], P. Joki-Korpela[1], H.M. Surcel[3], J. Paavonen[1], A. Tiitinen[1], M. Puolakkainen[2]

[1]University of Helsinki and Helsinki University Hospital, The Department of Obstetrics and Gynecology, Helsinki, Finland
[2]University of Helsinki and Helsinki University Hospital, Virology and Immunology, Helsinki, Finland
[3]National Institute of Health and Welfare, THL, Oulu, Finland

Study question: Does the presence of serum antibodies against *Chlamydia trachomatis* proteins TroA and HtrA expressed in chronic chlamydial infection predict tubal damage in subfertile women?

Summary answer: Subfertile women with serum IgG antibodies against *C. trachomatis* TroA and HtrA have tubal pathology more often than seronegative women.

What is known already: The association between serum antichlamydial antibodies and tubal factor infertility (TFI) is well known. However, positive chlamydial antibody testing (CAT) is a marker of previous exposure to *C. trachomatis*, but does not reflect the persistence of infection and the extent of tubal damage. TroA (YtgA) and HtrA are proteins expressed in chronic chlamydial infection *in vitro*. In addition, patients with ascending infection are shown to generate antibodies against these proteins. To identify the subgroup with persistent *C. trachomatis* infection and the highest risk for tubal pathology, we studied the antibody response against *C. trachomatis* TroA and HtrA among subfertile women.

Study design, size, duration: This is a prospective study consisting of subfertile couples referred to Helsinki University Hospital for infertility investigations. Between July 2007 and December 2010, a total 258 women were enrolled and 213 were followed to June 2014 or until the first successful pregnancy. Clinical data and the results of infertility examinations, treatments and subsequent pregnancies were collected.

Participants/materials, setting, methods: Serum specimens of the participants were tested for immunoglobulin G (IgG) antibody response to recombinant *C. trachomatis* proteins TroA and HrtA by enzyme immune assay (EIA). IgG antibodies for *C. trachomatis* major outer membrane protein (MOMP) and chlamydial heat shock protein (CHSP60) were analyzed by commercially available EIA kits. Chi-squared test and Mann-Whitney U-test were used for statistical analysis.

Main results and the role of chance: Altogether 55 (21.3%) of 258 women had anti-TroA IgG antibodies and 39 (15.1%) had anti-HtrA IgG antibodies. 26 (10.1%) women were positive for both anti-TroA and anti-HtrA antibodies. Tubal patency was examined in 209 (81%) women either by hysterosalpingosonography (HSSG) or laparoscopy. Ten out of the 209 women were excluded because of severe endometriosis or previous abdominal surgery with pelvic adhesions. The result of tubal examination was unclear in 14 women (6.7%). Tubal pathology was found in 24 of 185 women (13.0%). One tube was occluded in 19 (10.3%) women and both tubes in 5 (2.7%). Women with tubal occlusion were more likely to have anti-TroA and anti-HtrA antibodies than women without (41.7% versus 16.8%, p = 0.011 for anti-TroA; 33.3% versus 11.8%, p = 0.011 for anti HtrA and 25.0% versus 7.5%, p = 0.016 for both antigens). In addition, the seroprevalence rate increased with the severity of tubal damage. However, live birth rate did not differ by the serological status (86.8% versus 86.8%, p = 1.000 for anti-TroA; 82.8% versus 87.4%, p = 0.553 for anti-HtrA and 84.2% versus 87.0% for both antigens).

Limitations, reasons for caution: The participants were followed only in the Helsinki University Hospital area. Thus, we did not have data on patients who moved to a different locality or were treated in private clinics. Consequently, the group sizes followed in this study were relatively small.

Wider implications of the findings: Non-invasive methods are needed to identify the patients with chronic *C. trachomatis* infection and TFI. CAT traditionally used in infertility work-up does not discriminate the clearance or persistence of a *C. trachomatis* infection, while our results are more specific in evaluating the persistence of infection with higher risk for TFI.

Trial registration number: -.

P-367 Thioredoxin and Glutaredoxin systems are differently expressed in the oocytes of low responder patients compared with donors

L. Rancan[1], R. Nuñez-Calonge[2], S. Cortés[2], L. Ortega[2], A. Rodrigo[2], E. Vara[1], P. Caballero[2], J.A.F. Tresguerres[3]

[1]Complutense University- School of Medicine, Biochemistry and Molecular Biology III, Madrid, Spain
[2]Clinica Quirurgica Tambre, Reproduction Unit, Madrid, Spain
[3]Complutense University- School of Medicine, Physiology, Madrid, Spain

Study question: Do Thioredoxin (TRX) and Glutaredoxin (GRX) systems play a role in the redox regulation of the ovary?

Summary answer: TRX-GRX system is differently expressed in granulosa cells of low responders compared with donors suggesting that it plays a role in the ovarian redox regulation.

What is known already: Excessive Reactive oxygen species (ROS) production or oxidative stress have been associated with several diseases, including infertility. Oxidative stress causes ageing and dysfunction of the ovary, which is accompanied by gradual depletion of ovarian follicles and poor quality oocytes. To prevent ROS-induced disorders, cells are equipped with effective antioxidant systems. The thioredoxin (TRX) and glutaredoxin (GRX) systems are two central systems upholding the sulfhydryl homeostasis by reducing disulfides and mixed disulfides within the cell and thereby protecting against oxidative stress. Moreover, TRX is likely to be involved in the optimal growth and maturation of ovarian follicles and responsiveness to hyperstimulation.

Study design, size, duration: The mRNA expression of Thioredoxin reductase 1 (TXNRD1), Thioredoxin reductase 2 (TXNRD2) and Glutathione-disulphide reductase (GSR) were measured in oocyte-cumulus (CCs) and oocyte-granulose (CGs) complexes retrieved from 4 healthy fertile oocyte donors (<35 y.o. with at least a previous cycle with pregnancy) and compared with 4 low responders patients (<35 y.o. who had ≤ 5 oocytes retrieved after gonadotropic stimulation) whom took part in a prospective observational study realized from July to December 2016.

Participants/materials, setting, methods: All patients were stimulated with the same protocol (FSHr and triggering with GnRH analogues). GCs and CCs were collected from each patient and immediately fresh-frozen. mRNA was extracted using commercial kits and the mRNA expression of TXNRD1, TXNRD2, GSR and endogenous controls was measured by qRT-PCR. Relative changes in gene expression were calculated using the 2-$\Delta\Delta$CT method. No parametric tests were used to identify any significant difference between groups. Statistical significance was set at p<0.05.

Main results and the role of chance: No significant differences were observed in the TXNRD1 gene expression of oocyte donors compared with low responders patients both in CGs (p = 0.79) and CCs (p = 0.87); whereas the TXNRD2 gene expression of donors was significantly higher than the one observed in the low responders patients both in CGs (p = 0.031) and CCs (p = 0.015). GSR gene expression was significantly reduced in low responders patients compared with donors, but this difference was only evident in CGs (p = 0.121) (CCs p = 0.94). TXNRD2 is predominantly localised in mitochondria, and seems to be important for the maintenance of mitochondrial function, presumably due to scavenging of mitochondrial ROS. Hence, its alteration in both CGs and CCs suggests the presence of a mitochondrial dysfunction that may contribute to oxidative stress.

Limitations, reasons for caution: The main limitation of this study was the relatively small sample size. Further studies are needed to elucidate the molecular and cellular mechanisms underlying the regulation of follicular TRX and GRX systems and their biological role in follicular function and activity.

Wider implications of the findings: To observe significant differences in the TRX system of low response patients compared with donors suggests that, in these patients, the antioxidant defenses are diminished. Consequently, oxidative damage occurs in the ovary. These findings could open up to new therapeutic strategies for the treatment of low ovarian reserve.

Trial registration number: This study received no external funding and there were no competing interests.

P-368　What has changed for the definition of poor responders since the introduction of the Bologna criteria?

A. Boza[1], S. Yildiz Oguz[2], S. Misirlioglu[2], K. Yakin[1,2], B. Urman[1,2]

[1]American Hospital, Women's Health Center Assisted Reproduction Unit, Istanbul, Turkey
[2]Koc University School of Medicine, Department of Obstetrics and Gynecology, Istanbul, Turkey

Study question: Are the Bologna criteria (Bc) to define poor ovarian responders (POR) embraced by the IVF community?

Summary answer: Researchers seem reluctant to incorporate the Bc into clinical research. Since 2011, less than half of the published studies on POR has used the Bc.

What is known already: In an effort to standardize the definition of POR, the ESHRE Working Group on poor responders defined a set of variables named as the Bc in 2011.

Study design, size, duration: Systematic review of published and unpublished/ongoing trials on POR between September 2011 and September 2016.

Participants/materials, setting, methods: By using the relevant terms including 'poor response', decreased response', diminished ovarian response' and/or 'Bc', MEDLINE, PubMed, Ovid®, Google Scholar, and Scopus® electronic databases were searched for relevant trials. Ongoing trials were searched through www.clinicaltrials.gov. The references of the included studies were cross-searched for potentially missed articles. Only clinical trials providing an evidence level ≥II were included. Extracted studies were reviewed and divided into two groups; studies in which the BC was used or not.

Main results and the role of chance: Ninety-four published clinical studies analyzing a total of 19853 women and 107 unpublished/ongoing trials were identified. The Bc was used to define poor responders in 42 (44.6%) of the published and 40 (37%) of the unpublished trials. The vast majority of the published studies on poor responders were retrospective cohort or case control studies and 55% utilized the criteria. Randomized controlled trials, 29.4% of which preferred the Bc constitute only a small fraction (18%) of all published studies. The number of retrieved oocytes after ovarian stimulation was the most commonly preferred primary outcome regardless of the Bc used or not used. Since 2011, the practice of the Bc has gradually increased from 33% to 42% by the end of 2016 (p = 0.98). The majority of the published studies on POR were reported from Asia. European researchers were more likely to use the criteria compared to Asian and American researchers (62%, 48% and 24%, respectively). Neither the design of the study nor the impact factor of the publishing journal was related with the utilization of the Bc.

Limitations, reasons for caution: Interpretation of the data should take into account the descriptive nature of the data based on a literature search.

Wider implications of the findings: The definition of POR continues to be vague. It seems that the problem has not been resolved by the Bc, since many of the recently published trials as well as the registered trials keep on employing other, somewhat arbitrary definitions.

Trial registration number: None.

P-369　Can high markers of ovarian reserve overcome the usual age-related decline in euploidy in IVF-PGS cycles in women over age 40

R. Kudesia[1], D. Gounko[2], J. Lee[2], A.B. Copperman[1]

[1]Reproductive Medicine Associates of New York, Reproductive Endocrinology, New York, U.S.A.
[2]Reproductive Medicine Associates of New York, Research, New York, U.S.A.

Study question: Are patients over 40 with average or above-average baseline markers of ovarian reserve protected against the typical age-related increase in aneuploidy?

Summary answer: Women with high markers of ovarian reserve and those with polycystic ovary syndrome (PCOS) retain a chance of obtaining a euploid embryo even at ≥44.

What is known already: Advanced reproductive age increases the likelihood of poor ovarian response and aneuploidy. Prior data suggests that there may be an age threshold beyond which above-average markers of ovarian reserve no longer increase viable pregnancy rates in in-vitro fertilization (IVF) cycles without preimplantation genetic screening (PGS).

Study design, size, duration: Retrospective cohort study of IVF-PGS cycles at an urban academic fertility center from 2013-2016.

Participants/materials, setting, methods: IVF-PGS cycles for women aged 40 and above using autologous oocytes were included. The cycle protocol was determined by the individual physician. PGS was performed using qPCR and Next Generation Sequencing of trophectoderm biopsies on expanded blastocysts. Descriptive statistics, Pearson's correlation, Mann-Whitney U and Kruskal-Wallis tests were computed as appropriate using Stata v12.1 (College Station, TX).

Main results and the role of chance: Of 990 IVF-PGS cycles included, 45.8% resulted in at least one euploid embryo; only about 5% yielded more than 2. The numbers (%) of cycles resulting in no euploid embryo were as follows: 129/330 (39.1%) for 40yo, 113/236 (47.9%) for 41yo, 118/194 (60.8%) for 42yo, 97/130 (74.6%) for 43yo, and 80/100 (80.0%) for 44yo and above. In each age category, the median anti-Müllerian hormone (AMH) level for those with at least one euploid embryo was substantially higher than age-based averages, ranging from 1.2-1.8 ng/mL; the median antral follicle count (AFC) in these women ranged from 8-10. AMH (p<0.001) and AFC (p<0.001) were higher, and day 3 follicle-stimulating hormone (FSH) (p<0.02) lower, in those women with a euploid embryo. However, AMH had the strongest correlation (ρ=0.39, p<0.001) with the number of euploid embryos and was most consistent across age groups, followed by AFC (ρ=0.31, p<0.001) and then FSH (ρ=-0.10,p = 0.003). Body mass index did not correlate with count of euploid embryos. Women with PCOS had a significantly higher median number (p = 0.01) of euploid embryos, 1 [0,2] versus 0 [0,1] for non-PCOS women.

Limitations, reasons for caution: The study was retrospective in nature, and certain confounders, such as ethnic background, may remain unaccounted for. As we move toward exclusive testing via a next-generation sequencing platform, it is possible that more embryos will be found to have some degree of aneuploidy, potentially changing the results reported here.

Wider implications of the findings: The age-related increase in aneuploidy is inevitable. However, women with ovarian reserve markers exceeding age-based averages retain a substantial chance of obtaining a euploid embryo despite advanced reproductive age. IVF-PGS in this population allows for identification and selective transfer of embryos with increased potential to develop into viable pregnancies.

Trial registration number: not applicable.

P-370　Is diagnostic hysteroscopy more useful than transvaginal ultrasound prior to IVF?

N. Rabbachin[1], V. Uvin[1], P. Drakopoulos[2], M. Camus[2], H. Tournaye[2], M. De Brucker[2]

[1]Universitair Ziekenhuis Brussel, Gynaecologie-Verloskunde-Fertiliteit, Brussel, Belgium
[2]Universitair Ziekenhuis Brussel, Centrum Reproductieve Geneeskunde, Brussel, Belgium

Study question: Is diagnostic hysteroscopy prior to in vitro fertilization (IVF) useful in infertile females?

Summary answer: Hysteroscopy (HSC) combined with endometrial biopsy is superior than transvaginal ultrasound (TVS) alone in diagnosing unsuspected intrauterine anomalies interfering with fertility.

What is known already: IVF-workup focusses on the assessment of ovulation and visualisation of the female anatomy. Uterine structural abnormalities can contribute to subfertility in 10% of all cases. Visualisation can be achieved by: transvaginal ultrasound, hysterosonography, hysterosalpingography or histerosalpingo foam sonography and diagnostic hysteroscopy with or without combination with laparoscopy. IVF success rates have been improved recently. Failure to implant is one of the biggest causes of IVF failure. Determining factors are the embryo's quality, endometrial receptivity and the uterine cavity's integrity. The latter is the most accessible for investigation and improvement. Most teams prefer HSC, without any justification for this choice.

Study design, size, duration: This retrospective cross-sectional observational monocentric study was conducted at the Centre for reproductive medicine (CRG) at the Brussels University Hospital. 3087 cases were included in the study; all were recruited from the CRG between 2003 and 2012.

Participants/materials, setting, methods: Patients between 18 and 48 years old presenting with primary or secondary infertility were included. They all underwent a transvaginal ultrasound and, independent of the results, they all received an hysteroscopical examination and an endometrial biopsy. The examinations were performed by multiple gynaecologists at the University Hospital Brussels (UZB). The hysteroscopy examinations were performed on an outpatient basis.

Main results and the role of chance: In our study, we implemented 3087 infertile patients. They all underwent a transvaginal ultrasound to detect possible uterine anomalies interfering with their fertility. Of these, we found 2740 cases with a normal TVS (88.8%) and 347 cases with an abnormal TVS (11.2%). Independently to the outcome of the TVS, all patients received a hysteroscopical examination. In 2246 cases the hysteroscopy was normal (72.8%) and 841 cases with an abnormal hysteroscopy (27.3%). In 2179 cases both TVS and HSC were normal (79.5%). Both showed abnormal results in 280 cases (80,7%). However, in 67 cases TVS showed intrauterine abnormalities in absence of abnormalities on HSC (19.3%). In contrast HSC showed abnormalities in 561 cases in absence of abnormalities on TVS (20.5%). We calculated a correlation between TVS and HSC of 79.7%. The expected agreement expected by chance alone is 67.7%. Finally, for the agreement between TVS and HSC, we became a Kappa value of 0.37. This implied a low agreement.

Limitations, reasons for caution: The weakness is our retrospective study design. A prospective and cohort or case-control study would be able to implement the effective pregnancy outcomes and support the use of HSC and endometrial biopsy prior to IVF much stronger.

Wider implications of the findings: We showed that the prevalence of certain pathologies was not as expected by the literature and that TVS as a screening tool is lesser than the HSC combined with endometrial biopsy. Diagnostics but also early therapeutic interventions could be implemented at the same time and thereby rise IVF pregnancy rates.

Trial registration number: not applicable.

P-371   Can we turn back the clock? The effect of melatonin on expression of clock genes in the endometrium of women with recurrent implantation failure (RIF)

L. Stocker[1], Y.H. Lee[2], F. Cagampang[3], Y. Cheong[4]

[1]Complete Fertility Centre Princess Anne Hospital, Faculty of medicine, Southampton, United Kingdom
[2]National University of Singapore, Research and Technology, Singapore, Singapore Rep. of
[3]University of Southampton, Institute of Developmental Sciences, Southampton, United Kingdom
[4]Complete Fertility, Faculty of medicine, Southampton, United Kingdom

Study question: Does the hormone melatonin alter the expression of clock genes in the decidualised and undifferentiated endometrium of fertile women and those with RIF?

Summary answer: The rhythmicity of clock genes is influenced by pathology within the endometrium of women with reproductive pathology. This expression may be altered with melatonin.

What is known already: Clock genes are found in stromal cells of the endometrium. Many aspects of reproductive function are strongly regulated by circadian rhythms and the expression of clock genes is different in RIF compared with healthy fertile women.

Endometrial dysfunction may occur if regulatory stimulation fails. If this dysregulation could be ameliorated, implantation might occur where it would have otherwise failed. The hormone melatonin, which regulates sleep and wakefulness, is also involved in modulating circadian rhythms and its cyclical release has pleiotropic effects. It is thought to be critical to reproductive functioning and this could also be mediated via the endometrium in humans.

Study design, size, duration: A case-control gene expression study (August 2013-2015) was performed in vitro to quantify mRNA levels of clock genes in human endometrial tissue. The level of gene expression was measured every 4 hours over a 36-hour period (in decidualised and non-decidualised endometrial stromal cells) to investigate how expression level changes over time. The affect of adding different concentrations of melatonin was compared with untreated cells in healthy endometrial tissue and in those women with RIF.

Participants/materials, setting, methods: Women between 25-45 years were recruited and baseline demographics and fertility characteristics were collected. Women were included if they suffered RIF or were fertile controls. Endometrial biopsies were taken by suction curette, the stromal cells were isolated and cultured in vitro before decidualisation was commenced by the addition of progesterone. Cells were sampled at baseline and four-hourly intervals. Total RNA extraction, cDNA synthesis and PCR (normalisation to ENOX2/PRDM4) of the 6 clock genes was performed.

Main results and the role of chance: Cyclical expression of the six clock genes (Clock, Bmal1, Per1, Per2, Cry1 and Cry2) varied with the addition of melatonin. It appears to alter the relative expression of these genes and this effect continues over time (up to 36 hours) without resynchronising the peripheral 'clock' and independently of central control.

Previous studies have shown that the endometrium from fertile women displays a different rhythmicity of these genes compared with those women who have suffered poor reproductive outcomes. This suggests that any underlying pathology in RIF women may be related to dysynchrony at the level of the gene regulation within the endometrium.

The timing of events at the embryo-endometrial interface during the reproductive cycle may be altered by Clock-controlled genes, which in turn may be modified by melatonin. Future work should be aimed at demonstrating the level of this control and the mechanism of the effect as well as investigating the downstream pathways involved. Melatonin is inexpensive and widely used for entrainment of circadian rhythms but its potential therapeutic role in reproduction needs further experimentation.

Limitations, reasons for caution: Our results may be confounded by a small sample size within a cell-culture environment; a larger scale study in this specific subgroup of women is further needed to confirm our findings.

Wider implications of the findings: The expression of clock genes within the endometrium are modulated by the addition of melatonin. It is not known whether cellular functions of clock genes might have a role in the process of embryo implantation but if proven by further studies, melatonin might have a beneficial therapeutic effect.

Trial registration number: Regional ethics committee number 12/SC/0568.

P-372   The effect of body mass index on IVF outcome within a polycystic ovarian syndrome population

H.G. Sun, K.H. Lee, I.H. Park, J.W. Kim, H.J. Chi, S.G. Kim, Y.Y. Kim, J.Y. Park, C.S. Yoo

Mamapapa&baby Obstetrics- Gynecology Clinic, OB&GY, Ulsan city, Korea- South

Study question: Does high body mass index (BMI) in patients with polycystic ovarian syndrome (PCOS) affect ART outcomes?

Summary answer: PCOS patients with low BMI had better ovarian response to COH compared to patients with higher BMI but showed no significant difference in ART outcomes.

What is known already: It has been established that 35-65% of PCOS patients are obese. Obesity, overweight and elevated BMI are clinical features of PCOS that may constitute a major impediment for successful fertility treatment in women diagnosed with PCOS. Reduction of weight could improve fertility in PCOS patients who attempted spontaneous conception. Current evidence suggests that, regardless of PCOS, pregnancy achievement and maintenance is adversely affected by obesity, overweight or elevated BMI. However, few studies have examined the relationship between BMI and IVF treatment success in women with PCOS.

Study design, size, duration: A retrospective study was conducted using existing records on a consecutive sample of PCOS women who received IVF treatment between January 2012 and December 2016. A total of 181 cycles were included in this study.

Participants/materials, setting, methods: BMI was calculated according to the standard formula: BMI = weight/height^2 (kg/m^2). All participants were stratified by BMI calculated from height and weight recorded at cycle start: group A (non-obese group: BMI < 24.9 kg/m^2) and group B (obese group: BMI > 25.0 kg/m^2). Of the total 181 cycles, 102 cycles were group A (non-obese group) and 79 cycles were group B (obese group).

Main results and the role of chance: During controlled ovarian hyperstimulation, obese group required more FSH dose than non-obese group [A:1240.2 IU vs. B:1653.8 IU, p<0.05]. Also, obese group needed more stimulation duration than non-obese group [A:9.1 days vs. B:10.5 days, p<0.05]. Non-obese group retrieved more oocytes than obese group [A:20.3 vs. B:14.9, p<0.05], but proportion of mature oocyte [A:55.1% vs. B:57.4%, p = 0.163] and fertilization rate [A:62.3% vs. B:65.5%, p = 0.264] were not different in both groups. Freeze all cycle rate was higher in non-obese group than in obese group due to large number of retrieved oocytes [A:44.1% (45/102) vs. B:20.3% (16/79), p = 0.0013]. Pregnancy rate did not differ between both groups [A:71.9% (41/57) vs. B:65.1% (41/63), p = 0.650]. Also, miscarriage rate had no significant difference between both groups [A:3.5% (2/57) vs. B:9.5% (6/63), p = 0.143]. For patients with PCOS, elevated BMI did not affect obvious poor IVF outcomes but required more FSH dose and stimulation duration.

Limitations, reasons for caution: The retrospective study design may have limited our ability to obtain accurate data on other potentially confounding factors such as pre-existing health conditions, smoking, alcohol and coffee consumption. Large prospective cohort studies are needed to confirm our study findings.

Wider implications of the findings: We did not observe a significant effect of BMI on final ART outcomes in PCOS patients. But, PCOS patients with low BMI had better ovarian response compared to patients with higher BMI. Therefore in PCOS patients with elevated BMI, weight reduction is an effective way to reduce cost and time.

Trial registration number: None.

P-373   The effect of intramural fibroids without an intracavitary component on in-vitro fertilization outcomes in single fresh blastocyst transfer cycles

S. Behbehani, J. Hasson, S. Polesello, J. Silver, W. Son, M. Dahan[1]

[1]McGill University, Obstetrics and gynecology, Montreal, Canada

Study question: Does the presence of non-cavity deforming intramural fibroids alter the clinical pregnancy rates and live birth rates in single fresh blastocyst transfer cycles?

Summary answer: The presence of intramural fibroids reduces the chances of clinical pregnancy in fresh single blastocyst transfer cycles, even after adjusting for possible confounders.

What is known already: Submucosal fibroids are associated with lower clinical pregnancy rates (CPR) and live birth rates (LBR) from IVF. However, the current evidence for the impact of other fibroids is controversial. Literature bias exists because patients with large fibroids are likely to undergo myomectomy prior to IVF, multiple embryo transfer complicates analysis of results, as does repeated sampling of individual patients. A unique situation existed in Quebec; a long wait list for myomectomy (>1year), and the government funded 3 IVF cycles, resulting in all subjects with fibroids attempting at least one IVF cycle prior to surgery.

Study design, size, duration: A retrospective cohort study performed at a single academic reproductive center between January 2012 and June 2015. All single fresh blastocyst transfer cycles in women less than 43 years of age were included. Cycles with donor oocytes, multiple embryo transfers, submucosal fibroids, cavity distortion, and genetic screening were excluded.

Participants/materials, setting, methods: 929 fresh single blastocyst transfer cycles were included; 165 with and 764 without, fibroids. Only intramural fibroids were included in the analysis. Subjects with submucosal or subserosal leiomyomas were excluded. Cleavage embryo transfers were excluded to reduce bias based on embryo quality. T and chi square tests were used for demographic data, stepwise logistic regression was used to evaluate the effect of fibroids on outcomes.

Main results and the role of chance: In patients with intramural fibroids, the mean age was 36.3 ± 3.2 vs. 34.2 ± 3.9 years in patients without fibroids (p<0.001). There were no differences in; gravity, parity, body mass index or smoking in patients with and without fibroids. Women with intramural fibroids had lower antral follicle counts (AFC) (15.3 ± 9.2 vs.18.9 ± 12.3, p = 0.007) and higher doses of gonadotropins used (2350 ± 1368 IU vs. 2653 ± 404 IU, p = 0.04) than women without fibroids. The number of mature oocytes collected and the quality of embryo transferred were comparable. 63% of cases had 2 fibroids, 25% had 3 fibroids, and 12% had 4 or more fibroids. The mean largest fibroid diameter was 2.7 ± 1.7 cm with 44% of cases having a fibroid of ≥ 3 cm. Interestingly, CPR (47% vs. 32%, p = 0.005) and LBR (37.8% vs. 25.5%, p = 0.02) were lower in patients who had intramural fibroids compared to those who did not. Miscarriage rates were similar (15.8% vs. 19.4% p = 0.83). After adjusting for the confounding effect of age, AFC, dose of gonadotropins, and the quality of embryo transferred, CPR were significantly lower in patients with intramural fibroids compared to those without (OR 0.6, CI 0.37-0.96). Live birth rates also trended lower (OR 0.67, CI 0.41-1.11).

Limitations, reasons for caution: Although fibroids may reduce pregnancy rates, it remains unclear if a myomectomy will improve outcomes. The retrospective nature of this study raises the possibility of an undetected bias, in spite of the ideal population situation with 100% of women undergoing care prior to myomectomy, due to unique circumstances.

Wider implications of the findings: Women with intramural fibroids should be made aware that their chances of pregnancy are reduced regardless of the size of the fibroid, despite having a good quality embryo to transfer. Clinical pregnancy rates are still reassuring, but surgery could be discussed at the initial visit prior to starting IVF.

Trial registration number: not applicable.

P-374   Molecular networks underlying ovarian aging for clinical applications

Y. Lee[1], Y.H. Roh[2], S. Kim[2], E. Choi[2], Y. Kim[2], H.K. Park[3], P.N. Kang[3], H.E. Ryu[2], D.J. Chung[3], N.Y. Kim[3], M.J. Kim[3], A.R. Han[3], K.R. Kim[3], C. Park[3]

[1]Mizmedi Women's Hospital, iDream Research Center, Seoul, Korea- South
[2]Mizmedi Women's Hospital, iDream Research Center, Seoul, Korea- South
[3]Mizmedi Women's Hospital, iDream Clinic, Seoul, Korea- South

Study question: Our objective is to determine molecular pathways of ovarian aging that result in pregnancy failure and other complications in women health to develop treatment strategies.

Summary answer: Candidate molecular networks and medicines (chemicals) for targeting were proposed to develop treatment strategies or delay ovarian aging.

What is known already: Due to modern trends with postponing childbearing and getting worse living environment in women, an ovarian aging increased pregnancy failure and other complications with menopause or premature ovarian failure. Although several theories have been suggested such as mitochondrial malfunction, DNA damage/repair/methylation, caloric restriction, studies regarding ovarian aging-related molecular mechanisms for development of therapeutic methods are insufficient so far.

Study design, size, duration: This is an experimental study that is consisted of two parts: in Phase I stage, we analyzed distinct gene expression profile between young and aged mouse ovaries, and in Phase II stage several preferentially expressed genes in both ovaries were selected and analyzed their physiological functions and involved molecular networks related to ovarian aging for development of diagnostic markers and therapeutic methods.

Participants/materials, setting, methods: Ovaries from 10 week and 11 month-old FVB/NJ female mice with synchronized estrus cycle were collected for this study. A half of each ovary was used for RNA preparation and the other half for histological analysis. Using the Illumina HiSeq 2000 System, preferentially expressed genes were identified. Functional annotation database-based gene-set enrichment analyses and Pathway Studio® were employed to evaluate aging-related molecular networks. These findings were confirmed through qRT-PCR and immunohistochemistry.

Main results and the role of chance: To validate RNA-Seq data, we examined expression patterns of marker genes (Amh, Bmp15 and Nobox) that were well-known to be decreased in ovarian aging process. In young or aged ovary, preferentially expressed 876 genes were identified and extracellular matrix (ECM; $p < 0.001$) and chromatin/nucleosome-related ($p<0.001$) protein-coded genes have the majority in these genes by GOTERM analysis. Among them, we selected several candidate genes and confirmed their expression profiles by qRT-PCR and immunohistochemistry followed by molecular network analysis. Expression levels of male enhanced antigen 1(Mea1), serum amyloid A3 (Saa3), peroxiredoxin 1 (Prdx1) and S100 calcium binding protein A9 (S100a9, calgranulin B) were significantly increased in aged ovary, whereas those of endothelin 1 (Edn1), seizure related gene 6 (Sez6), zinc finger protein 182 (Zfp182), a disintegrin-like and metallopeptidase with thrombospondin type 1 motif, 19 (Adamts19) and solute carrier family 18, member 2 (Slc18a2) were decreased. Regarding molecular interactions in these genes, Pathway Studio® was employed to predict aging-involved molecular networks in mouse ovary. Here we report a couple of candidate molecular networks and medicines (chemicals) for targeting these preferentially expressed genes/proteins. Further analyses are scheduled to produce transgenic animal models and with human ovarian tissues and cell lines.

Limitations, reasons for caution: This study does not include results from human materials, therefore it will be needed to verify their roles in ovarian aging using human ovarian tissues or cell lines for future clinical applications.

Wider implications of the findings: This study will provide new tools and enable formulation of new strategies to diagnose causes of ovarian aging and improve treatment options. It will be also providing new biomarkers useful to predict ovarian ages and reserve to care or rejuvenate aged ovaries.

Trial registration number: NA.

P-375   Link between cesarean section (CS) delivery and secondary infertility. Uterine cavity evaluation in women undergoing fertility treatment using three dimensional (3D) saline infusion sono-hysterogaphy (SIS)

G. Basir[1], J. Mamiso[2], M. Willimson[3], D. Imoedemhe[3]

[1]London Bridge Fertility- Gynaecology & Genetics Centre, London, United Kingdom
[2]The Bridge Centre, Fertility, London, United Kingdom
[3]The Bridge Centre, Fertility Clinic, London, United Kingdom

Study question: To determine the incidence of uterine cavity anomaly in women presenting with sub-fertility of at least two-years duration after successful pregnancy and birth by CS.

Summary answer: A high incidence of abnormal intrauterine morphology related to CS scar defect in association with intrauterine adhesion's with future fertility and obstetric implications were noted.

What is known already: Trauma to the basal layer of the endometrium from surgery or infection can lead to residual fertility impairing changes. This may occur from previous pregnancy or delivery. CS birth rate is increasing worldwide and remains the most invasive pregnancy related procedure on the uterus. It carries risk of endometrial trauma, infection and scarring resulting in intrauterine pathology associated with adverse pregnancy and obstetric outcome. There is a lack of systematic studies evaluating the incidence of uterine cavity anomalies in women presenting with sub-fertility following successful pregnancy and birth by cesarean section.

Study design, size, duration: This was a prospective observational study. Women presenting with sub-fertility (n = 510) of more than two years duration undergoing investigations prior to fertility treatment were included in the study for routine uterine cavity evaluation by 3D and SIS over a period of 18 months.

Participants/materials, setting, methods: Women seeking fertility treatment following previous CS who failed to conceive again after two years of trying or who returned for frozen embryo transfer FET (Group1, n = 108), were compared to age matched controls with no previous history of uterine surgery (Group 2, n = 402). Baseline 3D ultrasound scan followed by SIS was carried out between days 6 to 10 of the menstrual cycle using GE Voluson Logiq S8 ultrasound system.

Main results and the role of chance: In Group 1, 18/108 (16.6%) a defect of the CS scar line was demonstrated. In 6/18 (33.3%) of these, endometrial

bands of aadhesions were associated with CS scar defect. While significantly (p<0.01) less number 4/90 (3.6%) of adhesions bands were observed in women who showed intact scar line. This was comparable to the 17/402 (4.2%) bands of adhesions observed in Group 2.

Ten of the 18 women (55.5%) who had defective scars in Group 1 demonstrated intrauterine fluid collection at the baseline 3D scan. This was significantly higher (p<0.05) than the 8/402 (1.8%) in Group 2 who had adhesion bands.

Total number with adhesion bands in Group 1, 10/108 (9.2%) was higher than in Group 2, 17/402 (4.2%) the difference was significant (p<0.05).

Endometrial polyp(s) or submucosal fibroid distorting endometrial cavity alone or together were observed in 12/108 (11.1%), 5/108 (4.6%), and 17/108 (15.7%) respectively in Group 1. These were comparable to 57/402 (14.1), 21/402 (5.2%) and 78/402 (19.4%) observed in Group 2

Limitations, reasons for caution: This study demonstrates a high incidence of potential fertility impairing observations secondary to CS delivery. Delivery by CS is increasing world-wide the implications of these findings for future fertility, pregnancy and delivery in the wider population must be interpreted with caution and awaits further studies.

Wider implications of the findings: CS delivery is associated with a high incidence of abnormal intrauterine morphology. These anomalies are a precursor of impaired endometrial receptivity and a risk factor not just for future fertility but obstetric outcome. The implications of scar defect for future obstetric performance is unknown and requires further investigations

Trial registration number: none.

P-376   Effect of regular exercise on reproductive function of aged female mice

K.S. Lee[1], M.S. Jo[1], J.R. Choi[2]

[1]Pusan Nat. University School of Medicine, Dept. of Ob/Gyn, Pusan, Korea- South
[2]Eroom Women's Clinic, Busan, Korea

Study question: Can regular exercise improve the expression of ovarian anigogenic factors, oocyte quality and fertility potential in aged female mice

Summary answer: Regular exercise induced by illumination with incandescent lights in aged mice improves their reproductive outcomes by improving ovarian function and oocytes quality.

What is known already: Some studies have reported the relation between exercise and angiogenesis (Gustafsson et al., 2001; Prior et al., 2004). Previously it has been reported that a single bout of moderately intense treadmill running upregulates VEGF expression of skeletal muscle in rat (Breen EC et al., 1996) and upregulation of VEGF mRNA also occurs during exercise in humans in both normal healthy individuals (Gustafsson et al., 1999; Richardson et al., 1999) and patients with heart failure (Gustafsson et al., 2001).

Study design, size, duration: Forty female mice of 30-32 weeks were divided into the two groups. One group (n = 20) were induced to stimulate exercise (physical activity) by illuminating incandescent lights (60 Watts, 220 V), placed on the top of the cage, starting at 11:00 a.m. for 30 minutes daily. The other group (n = 20) were served as control without the induction of exercise.

Participants/materials, setting, methods: C57BL inbred mice were used and purchased from Korea Experimental Animal Center (Daegu, South Korea). Mice were maintained on a light-dark cycle, with light on at 5:00 AM and off at 7:00 PM, and with food and water available ad libitum.

Main results and the role of chance: The total number of pregnant mice was 15 (75%) in the exercise group, which was significantly higher than 5 (25%) in the control group (P < .05). The mean number of offspring was also significantly higher in the exercise group (9.2) than the control group (6.3) (P <.05). The mean number of one-cell embryos retrieved and blastocyst formation rate were 12.6 and 43.8% in the exercise group and 10.8 and 8.1% in the control group with a significant difference (P < .05). Ovarian VEGF and eNOS expression was increased, but ovarian apoptosis was decreased in the exercise group.

Limitations, reasons for caution: First, this study did not use a general exercise equipment, such as treadmill. Second, this study did not examine the effect of exercise on implantation because a lot of studies have shown that physical activity can affect implantation of endometrium

Wider implications of the findings: This study did not clearly elucidate the mechanism that exercise treatment results to improve ovarian function and oocyte quality. However, this study showed the increased ovarian VEGF and eNOS expression and decreased ovarian apoptosis.

Trial registration number: none.

P-377 Single human spermatozoon freezing technique for cryptozoospermia or non-obstructive azoospermia patients

T. Ichiyama, A. Tanaka, M. Nagayoshi, T. Yanagimachi, M. Ohno

Saint Mother Hospital, Department of Obstetrics and Gynecology, Kitakyushu, Japan

Study question: Is it possible to freeze a single spermatozoon and keep a high recovery rate to improve the clinical outcome of cryptozoospermia or non-obstructive azoospermia patients?

Summary answer: Our data indicates that it is highly possible to freeze a single spermatozoon with a high survival rate of about 80%.

What is known already: Clinical outcome of non-obstructive azoospermia or cryptozoospermia has increased after ICSI when using fresh spermatozoa. When oocyte collection cannot be performed on the same day of the Micro-TESE or in the case of cryptozoospermia, cryopreservation of collected spermatozoa becomes crucial. However, conventional freezing procedures are not appropriate for very low numbers of spermatozoa with poor motility.

Study design, size, duration: We performed a retrospective analysis of the clinical outcome of 79 ICSI cycles using our novel cryopreservation procedures for ejaculated spermatozoa from 27 cases of cryptozoospermia in 52 cycles and testicular spermatozoa from 20 cases of non-obstructive azoospermia in 27 cycles from January, 2012 to December, 2014.

Participants/materials, setting, methods: This study dealt with 27 men with cryptozoospermia and 20 men with non-obstructive azoospermia. Moving spermatozoa were carefully aspirated into a pipette one by one and put into a micro-drop of medium. About 2 µl of freezing medium was put on the tip of the CRYOTOP. 1-10 sperms were aspirated into an injection pipette and inserted into the medium and left in liquid nitrogen vapor for 2 min before being stirred in liquid nitrogen.

Main results and the role of chance: Five healthy babies (5 ongoing) from 47 patients were born following this freezing method. Clinical outcome is listed in the following table.

Clinical outcomes	cryptozoospermia	Non-obstructive azoospermia
No. of patients	27	20
No. of treatment cycles	52	27
No. of sperm frozen [per Cryotop®]	543	248
Sperm recovery rate after thawing (%)	81.03 (440/543)	78.23 (194/248)
Motile sperm rate after thawing (%)	57.27 (252/440)	40.72 (79/194)
No. of ICSI oocytes	215	98
Fertilization rate (%)	33.02 (71/215)	37.76 (37/98)
No. of embryos cultured for 5 days	42	19
Blastocyst rate (%)	45.24 (19/42)	36.84 (7/19)
No. of cycles transferred embryos	28	13
Clinical pregnancy rate (%)	28.57 (8/28)	38.46 (5/13)

Continued

Continued

Clinical outcomes	cryptozoospermia	Non-obstructive azoospermia
Miscarriage rate (%)	25.00 (2/8)	20.00 (1/5)
No. of ongoing pregnancies	2	3
No. of births	4	1

Limitations, reasons for caution: This freezing procedure needs a special apparatus (Inverted microscope equipped with a micromanipulator) and requires a high level of technique for gathering and expelling 1-10 spermatozoa correctly and swiftly. So this procedure can only be performed by specialists, precious sperm can easily die with poor technique.

Wider implications of the findings: Once this procedure is mastered, the clinical outcome of severe male infertility is definitely improved. Especially in the treatment of azoospermia, precious spermatozoa surgically collected from epididymis or testicles can be cryopreserved to avoid repeating a biopsy. This procedure can lessen the patients' physical, mental and financial burdens.

Trial registration number: None.

P-378 Water- and oil-based tubal flushing for subfertility, alone, both or none? Systematic review and network meta-analysis

R. Wang[1], J. Van Rijswijk[2], L. Mohiyiddeen[3], N. Johnson[1,4], R. Norman[1,5], K. Dreyer[2], V. Mijatovic[2], B. Mol[1]

[1]*University of Adelaide, Robinson Research Institute, Adelaide, Australia*
[2]*VU University Medical Centre, Department of Reproductive Medicine, Amsterdam, The Netherlands*
[3]*St Mary's Hospital, Department of Reproductive Medicine, Manchester, United Kingdom*
[4]*University of Auckland, Department of Obstetrics and Gynaecology, Auckland, New Zealand*
[5]*Fertility SA, Fertility SA, Adelaide, Australia*

Study question: Can tubal flushing with oil-based contrast media increase pregnancy rates in women with subfertility compared with water based media and no tubal flushing?

Summary answer: Tubal flushing with oil-based contrast media increases pregnancy rates in women with subfertility, compared to tubal flushing with water-based contrast media and no tubal flushing.

What is known already: The use of tubal flushing with either water- or oil-based contrast media as a therapeutic intervention has been controversial. In pairwise meta-analysis, the effectiveness of these two interventions cannot be compared to no treatment in a single statistical model and indirect evidence in these comparisons has not been used.

Study design, size, duration: We searched electronic databases including MEDLINE, EMBASE and Cochrane Central Register of Controlled Trials as well as reference lists to identify eligible studies. We performed a systematic review and network meta-analysis of relevant randomised controlled trials (RCTs).

Participants/materials, setting, methods: We included RCTs comparing the following interventions with each other or no treatment in women with subfertility: tubal flushing with water-, oil-based contrast media, or in combination. The primary outcome was clinical pregnancy rate. Network meta-analyses were conducted within a random effects multiple regression model in Stata 14 (StataCorp, USA).

Main results and the role of chance: We included 14 RCTs reporting on 3,680 women. Network meta-analyses showed that tubal flushing with oil-based contrast media led to significantly higher pregnancy rates, compared to tubal flushing with water-based contrast media (odds ratio [OR] 1.48, 95% confidence interval [CI] 1.12-1.96) and no tubal flushing (OR 2.46, 95% CI 1.48-4.10). Oil- and water-based contrast media combined were superior to water-based contrast media alone (OR 1.56, 95% CI 1.02-2.39), while this

combination was not better than oil-based contrast media alone (OR 1.05, 95% CI 0.66-1.68). It is not certain whether water-based tubal flushing is more effective than no flushing (OR 1.67, 95% CI 1.00-2.78) in terms of clinical pregnancy.

Limitations, reasons for caution: The overall quality of the evidence was low in comparisons other than water- versus oil-based contrast media. The heterogeneity should also be taken into consideration in decision making. The diagnostic methods of pregnancy were not specified in all included studies and live birth rates were reported in only six studies.

Wider implications of the findings: Since oil-based tubal flushing during tubal patency test improves pregnancy rates as compared no treatment, hysterosalpingography with oil-based tubal flushing should be offered to women with subfertility at an early stage of the infertility work-up.

Trial registration number: Not applicable.

P-379   Two-year continuation rates of long-acting reversible contraceptive methods: A cohort study in the French national healthcare insurance database

A. Agostini[1], C. Godard[2], C. Laurendeau[3], A. Benmahmoud-Zoubir[2], A. Lafuma[3], L. Lévy-Bachelot[2], J. Gourmelen[4], T. Linet[5]

[1]Service de Gynécologie-Obstétrique, Hôpital de la Conception, 147 Boulevard Baille
[2]Laboratoire MSD France, 34 Avenue Léonard de Vinci, 92418 Courbevoie, France
[3]Cemka-Eval, 43 Boulevard Maréchal Joffre, 92340 Bourg-la-reine, France
[4]Unité Cohortes épidémiologiques en population - UMS 011 INSERM-UVSQ, 16 avenue Paul Vaillant Couturier, 94807 Villejuif, France
[5]Service de Gynécologie Obstétrique, Centre Hospitalier Loire Vendée Océan, Boulevard Guérin

Study question: Are the Long-Acting Reversible Contraceptives (LARCs) associated with higher continuation rates than Oral Contraceptives (OCs) in real life practice?

Summary answer: This real-world study shows that the two-year continuation rates for LARCs were more than two-fold higher than OCs.

What is known already: The number of unintended pregnancies and abortions remains high despite efficient contraceptive methods. Poor continuation rates associated with contraceptive methods have been identified as a risk factor for unintended pregnancy. Long-acting reversible contraceptives (LARCs), such as contraceptive implants and copper or hormonal intrauterine devices (IUDs), are among the most effective birth control methods because they do not require users' action after insertion, but continuation rates in real life practice need to be investigated.

Study design, size, duration: This is a retrospective cohort study based on the EGB ("*Echantillon Généraliste des Bénéficiaires*") database which is a representative sample of the general population of subjects affiliated with the French health insurance system. The EGB database includes approximately 600,000 beneficiaries. Continuation rates were assessed in a cohort of women having used any reimbursed contraceptives from 2009 to 2012.

Participants/materials, setting, methods: Women aged 15 years and over and initiating contraception during the period 2009–2012 were included. The start of contraception was the date of the first dispensation for OCs and the date of the insertion for LARCs. The end of contraception was presumed if there was a removal for LARCs, a dispensation of a new type of contraception, a pregnancy, sterilization or the absence of dispensation at the end of the covered period.

Main results and the role of chance: A population of 42,635 women with a reimbursed contraceptive was identified in the EGB. Among the 42,635 women, 74.6% used oral contraceptives (OCs), 22.0% intrauterine device (IUD) and 3.5% subdermal contraceptive etonogestrel implant (Nexplanon®). The 24-month continuation rate was highly variable according to the method with 28.6% (95% confidence interval, 27.9–29.3) for 1st-2nd generation combined OCs, 34.7% (33.6–35.9) for 3rd generation combined OCs, 9.5% (8.4–10.6) for progestative-only OCs, 88.6% (87.3–89.7) for copper IUD, 91.4% (90.5–92.3) for hormonal IUD and 84.6% (82.0–86.8) for the etonogestrel implant.

Limitations, reasons for caution: For OCs, only the dispensation date was available in the database. The discontinuation date was estimated according to the number of delivered pills. For LARCs, insertion and removal were often not recorded in the database, and hypotheses were made based on recorded physician consultations.

Wider implications of the findings: This real-world study shows that among French reimbursed contraceptives, LARCs had the highest continuation rates thus indicating their good acceptability. The use of LARCs remains, however, too limited and training measures for health care professionals could help to initiate LARCs more largely.

Trial registration number: 0.

P-380   Quantitative assessment of endometrial volume and uterine vascularity and pregnancy outcome in frozen thawed embryo transfer cycles

K. Yun[1], K. Lee[1], M.S. Jo[2], J.R. Choi[2]

[1]Pusan National University School of Medicine, Obstetrics and Gynecology, Busan, Korea- South
[2]Eroom Women's Clinic, Busan, Korea

Study question: to investigate the usefulness of the endometrial volume and vascular indicies in endometrial region as an effective predictor for pregnancy outcome in frozen-thawed embryo transfer (FET).

Summary answer: This study suggest that endometrial volume and the vascular indices measured in endometrial region are a useful predictor for pregnancy outcome.

What is known already: Kim et al. measured the vascular indices at endometrial region and subendmetrial region within in 5 mm from the endometrial border. They reported the pregnant group had higher vascular indices in endometrial region, not in subendometrial region than non-pregnant group.

Study design, size, duration: We evaluated 131 embryo transfer cycles in 73 infertile women. After controlled ovarian stimulation all embryos were cultured to blastocyst stage, and the blastocysts with good quality were vitrified for elective FET.On the day of FET, endometrial thickness, endometrial volume, pulsatility index (PI), and resistance index of uterine artery and endometrial-subendometrial vessels (ESVs) with zonal discrimination were evaluated by transvaginal ultrasonography in each patient. These variables were compared between pregnant and nonpregnant cycles.

Participants/materials, setting, methods: We prospectively conducted this study from October 2013 to December 2014 in Infertility Center, Pusan National University Hospital. A total of 73 infertile women were recruited for this study and agreed with informed consent.

Main results and the role of chance: The endometrial volume was significantly higher in pregnant group (2.32 ± 0.86, 1.96 ± 0.62 mL, P = 0.007). Also, PI of endometrial-subendometrial vessels (ESV) was significantly higher in pregnant cycle (2.58 ± 1.32 and 2.05 ± 1.08, P = 0.016). The other variables were not different between two groups.

Limitations, reasons for caution: the number of FET cycles was relatively small. Second, the samples were collected over one year. It was relatively long period and the possibility of intra-observer variation was increased. Though these limitation, this study has several strong points. All cases were elective FET cycles and collected prospectively without omission.

Wider implications of the findings: this study suggest that endometrial volume measuring by 3D ultrasonography and the vascular indices measured in endometrial region are useful tools for predicting pregnancy in FET. If further studies with standard measuring technique are conducted, the useful prognostic protocol with ultrasonography could be established.

Trial registration number: none.

P-381   The effect of strict sperm morphology and activity/motility on IUI clinical outcome

C. S.K[1], L. Y.J.[1], C. M.K.[1], L. C.M.[2], J. J.N.[3], K. H.J.[3], K. M.K.[1], W. H. J.[1], C. J.H.[1]

[1]SARANGI IVF CENTER, IVF CENTER, SEOUL, Korea- South
[2]Sarangi IVF Center, IVF Center, Seou, Korea- South
[3]Sarangi IVF Center, IVF Center, Seoul-, Korea- South

Study question: This study was intended to evaluate whether the value of Kruger strict sperm morphology (SSM) and sperm motility (SM) could predict pregnancy after IUI

Summary answer: The values of SSM have affected IUI pregnancy rates. When the SSM is 1-3% then the IUI pregnancy rate may increase based on the SM.

What is known already: Sperm analysis is the primary method of evaluating the fertility potential of the male partner. Parameters include sperm concentration, motility and morphology. This retrospective chart review evaluated whether isolated abnormal sperm morphology in men with otherwise normal concentration and motility affected pregnancy rates for IUI procedure.

Study design, size, duration: The study was conducted in prospective observational manner since 2016 with 252 IUI cycles. IRB consent was obtained from each participant.

Participants/materials, setting, methods: The couples attending IUI were recruited for the study at a single fertility clinic. IUI was performed after spontaneous LH surge or hCG induced ovulation in induction cycle. IUI was prepared using swim- up method. Kruger strict sperm morphology value was calculated from 300 sperms according to 2010 WHO manual and criteria.

Main results and the role of chance: The average ages of wife and husband, number of IUI procedure, pre-washed semen volume, total sperm concentration, motility were (mean±SD): 33.6 ± 2.9, 35.9 ± 3.4, 2.9 ± 1.7 ml, 80.1 ± 52.2 ×106, 50.7 ± 24.3%, respectively.

There were 43/252 (17.1%) positive clinical pregnancy were observed among known outcomes. The pregnancy rate increased as its near to the normal SSM range. When SM is in 1~3% range and SM is 40%, the pregnancy rate has increased.

The relationship between SSM values and IUI outcomes is summarized as below:

Kruger Stric morphology value	1%↓	1%	2%	3%	4%↑
Cycle numbers	18	59	87	61	27
Clinical pregnancies	1	9	16	11	6
Clinical pregnancy rate	5.5%	15.3%	18.4%	18.0%	22.3%

	SM: 1-3%	> 20×106	> 40%
Cycle numbers	207	189	138
Clinical pregnancies	36	33	29
Clinical pregnancy rate	17.3%	17.5%	21.0%

Limitations, reasons for caution: Non-randomized, non-controlled nature of the study. Heterogenous population with various infertility factors, method of ovulation induction and treatment order.

Wider implications of the findings: The clinical outcome may be increased when SM is 1~3% with sperm count (20×106 over) motility(40% over) in IUI and consequently this criteria can be used in counselling of infertility couples to accelerate their decision for ART.

Trial registration number: Not applicable.

P-382   High risk of preterm birth and low birth weight following oocyte donation compared to autologous IVF: a systematic review and meta-analysis

B. Antonisamy[1], M. Kamath[2], M. Mascarenhas[3], S.K. Sunkara[4]

[1]CHRISTIAN MEDICAL COLLEGE, Department of Biostatistics, VELLORE, India
[2]Christian Medical College and Hospital, Reproductive Medicine Unit, Vellore, India
[3]Seacroft hospital, Leeds Centre of Reproductive Medicine, Leeds, United Kingdom
[4]Queen's Hospital, Assisted Conception Unit, Essex, United Kingdom

Study question: Is oocyte donation-recipient IVF treatment associated with a higher risk of adverse perinatal outcomes of preterm birth (PTB) and low birth weight (LBW)?

Summary answer: There is a higher risk of PTB and LBW following oocyte donation (OD) compared to autologous IVF.

What is known already: The trend towards delayed childbearing has been reflected in a steady increase in the average age of women undergoing IVF. Advances in the field of IVF have proven insufficient to compensate for the decline in fertility resulting from female reproductive ageing. Oocyte donation has been offered as a more successful alternative for these women contributing to a steady increase in the number of OD cycles worldwide. Although available studies have indicated higher incidence of poor obstetric outcomes following OD in comparison with spontaneous conceptions, evidence comparing perinatal outcomes following OD versus autologous IVF pregnancies has not been consistent.

Study design, size, duration: We conducted a systematic review to evaluate the risk of PTB, early PTB, LBW and very LBW following OD versus autologous IVF. The following electronic databases were searched from 1980 to December 2016: Medline, EMBASE and Web of Science. Study selection and data extraction were conducted independently by two reviewers. A meta-analysis was carried by pooling eligible studies.

Participants/materials, setting, methods: A total of 6 studies including 19,784 and 187,964 singleton live births following OD and autologous IVF respectively met the inclusion criteria for the various outcomes. Six studies reported data for PTB (live birth at <37 weeks gestation), three studies for early PTB (live birth at <32weeks gestation), five studies for LBW (<2500 grams) and three studies for very LBW (<1500 grams).

Main results and the role of chance: Meta-analysis of the included studies showed a significantly higher risk of PTB, early PTB, LBW and very LBW with OD pregnancies compared to autologous IVF: Relative risk (RR) 1.45; 95% CI 1.24-1.71 for PTB, RR 2.14; 95% CI 1.40 -3.25 for early PTB, RR 1.31; 95% CI 1.10-1.56 for LBW and RR 2.08; 95% CI 1.13-3.84 for very LBW.

Limitations, reasons for caution: We were unable to perform age-adjusted comparison within the meta-analysis framework, although individual studies included our meta-analysis had performed adjustment for confounding factors including.

Wider implications of the findings: These findings are useful for fertility clinicians in informing their patients and for obstetricians whilst managing OD-recipient pregnancies.

Trial registration number: Not applicable.

P-383   Clinical outcomes of frozen transferred blastocysts derived from monopronucleated (1PN) zygotes after conventional in vitro fertilization (cIVF) and intracytoplasmic sperm injection (ICSI) cycles

Y. Shimizu[1], H. Koi[2], T. Yorimitsu[1], M. Ohara[2], H. Sasaki[1], M. Hasui[1], S. Hondo[1], A. Arichi[1], H. Muramatsu[2], N. Omura[1], K. Ito[2], H. Komine[1], Y. Kudo[1], T. Kawamura[1]

[1]Denentoshi Ladies Clinic, OB/GYN, Yokohama, Japan
[2]Denentoshi Ladies Clinic Futakotamagawa, OB/GYN, Tokyo, Japan

Study question: To examine the clinical outcomes of frozen transferred blastocysts derived from monopronucleated (1PN) zygotes after conventional in vitro fertilization (cIVF) and intracytoplasmic sperm injection (ICSI) cycles.

Summary answer: Pregnancy rate was 31.4% after transfer of 1PN blastocysts in cIVF cycles. After transfer of 1PN blastocysts in ICSI cycles, pregnancy rate was 5.3%.

What is known already: The blastocyst formation rate of 1PN embryos was lower than 2PN embryos in cIVF and ICSI cycles. 1PN blastocysts in cIVF, and not from ICSI, demonstrated an adequate ongoing pregnancy rate. 1PN blastocysts in cIVF are available for clinical use and may lead to an increase in the chance of pregnancy in patients receiving assisted reproductive technology with 1PN embryos.

Study design, size, duration: This was a retrospective study at a reproductive center. To evaluate clinical outcomes, cIVF or ICSI cycles with 1PN embryos were compared with those with 2PN embryos. This study included single frozen blastocyst transfer cycles performed between January, 2007 to December, 2014 at our clinic.

Participants/materials, setting, methods: Women's age were limited between 30 to 40 years old at the time of freezing. We compared clinical outcomes between 3,576 cycles of 2PN (IVF-2PN,1,863 couples) in cIVF, 35cycles of 1PN (IVF-1PN,34 couples) in cIVF, 4,793cycles of 2PN (ICSI-2PN, 2,242 couples) in ICSI, and 19 cycles of 1PN (ICSI-1PN,18 couples) in ICSI.

Main results and the role of chance: Clinical pregnancy rate achieved with 1PN blastocysts in cIVF did not show any significant difference compared with 2PN blastocysts in cIVF (IVF-1PN;31.4% vs IVF-2PB;42.8%). Live birth rate also did not show any significant difference (IVF-1PN;25.7% vs IVF-2PB;31.8%) Miscarriage rate did not show significant difference(9.1% inIVF-1PN vs 21.6% in IVF-2PB). On the other hand, ICSI-1PN produced significantly low clinical pregnancy rate (ICSI-1PN;5.3% vs ICSI-2PN;42.8%, p<0.05), live birth rate (ICSI-1PN;5.3% vs ICSI-2PN;30.7%, p<0.05). Miscarriage rate of ICSI-2PN was 24.7%. One healthy infant was born with no newborn malformations after transfer of 1PN-ICSI cycle.

Limitations, reasons for caution: Confirmation of our preliminary data on a large population should be required.

Wider implications of the findings: 1PN-IVF blastocysts can produce adequate pregnancy rate. Although pregnancy rate after transfer of 1PN-ICSI blastocysts was very low, one healthy infant was born with no newborn malformations after transfer of 1PN-ICSI cycle.

Trial registration number: Not applicable.

P-384 Does endometrial scratching change the biological age of the endometrium? -A paired prospective study

M.S. Olesen[1]**, A. Starnawska**[2]**, I. Agerholm**[1]**, A. Forman**[3]**, M.T. Overgaard**[4]**, M. Nyegaard**[5]

[1]*Horsens Hospital, The Fertility Clinic, Horsens, Denmark*
[2]*Aarhus University, Department of Biomedicine-, Aarhus, Denmark*
[3]*Aarhus University Hospital- Skejby, Department of Obstetrics and Gynecology, Aarhus, Denmark*
[4]*Aalborg University, Department of Chemistry and Bioscience, Aalborg, Denmark*
[5]*Aarhus University, Department of Biomedicine, Aarhus, Denmark*

Study question: To determine if the epigenetically determined biological age of the human endometrium correlates with chronological age, and investigate if endometrial scratching changes endometrial biological age.

Summary answer: The biological age of timed endometrium samples correlates significantly with chronological age. However, any fertility effects of scratching is unlikely a result of epigenetic rejuvenation

What is known already: An algorithm that integrates specific DNA methylation sites in the genome can be used to predict biological age of individual tissues. Furthermore, a negative discrepancy between chronological and biological age is a predictor for adverse conditions.Several studies indicate, that endometrial scratching may enhance implantation in assisted reproductive technology. The molecular mechanisms behind this possible improvement are yet unknown. One attractive hypothesis is that scratching rejuvenates the methylation profile and thus the biological age. Although a tissue independent predictor of biological age has been developed, it was previously shown inconclusive in sex-hormone responsive tissues, including the endometrium.

Study design, size, duration: Nine female volunteers with a regular menstrual cycle (28-32 days) were included in a paired prospective study during the period of 2015. The volunteers were recruited through adverts in the municipality.

Inclusion criteria were: No prior use of intrauterine device or anticonception pills, age of 18-40 years, and a normal BMI (18-32 kg/m2). Women with uterine abnormalities, as well as women with suspected hydrosalpinges, adenomyosis and with pregnancy wish were excluded from the study.

Participants/materials, setting, methods: We obtained endometrial scratching samples in two consecutive cycles strictly timed to day 7 after the LH surge (LH+7), corresponding to the window of implantation, and a peripheral whole blood sample.

We analyzed the samples using the Illumina 450 K methylation array and Horvath's DNA methylation age algorithm, calculated as proxy for the biological age in endometrial samples and peripheral whole blood samples.

Main results and the role of chance: When using carefully timed endometrial sampling, the biological age of the endometrium was found to correlate significantly with chronological age (r = 0.73, p = 0.025) and with biological age of the peripheral blood (r = 0.81, p = 0.005). The biological age of the endometrium was determined to (mean 35.35 ± 4.74 years), two years higher than the corresponding whole blood biological age (mean 33.88 ± 5.90 years), and four years higher than the chronological age (mean 31.0 ± 6.56 years). No change was found in the biological age between the first (mean 35.35 ± 4.74 years) and second biopsies (35.55 ± 3.58 years; p = 0.85), suggesting that the biological age of the endometrium is not affected by scratching.

Limitations, reasons for caution: Despite using a paired design, low sample size (nine women) limits the ability to detect small effect sizes. Further, the study used homogenized tissue, composed of various cell types with potentially unique methylation profiles. We therefore cannot exclude that scratching affects biological age of specific cell types of the endometrium.

Wider implications of the findings: As an increasing number of women postpone their motherhood, it is important to assess biological age in terms of fertility prognosis and optimizing fertility treatment individually. The present study demonstrates that epigenetically based endometrial biological age can be determined reliably, providing an important novel tool in fertility research and treatment.

Trial registration number: NCT02219425.

P-385 Does night shift work increase the risk of urogenital defects after ART treatment?

M. Davies[1]**, R. Fernandez**[2]**, K. Willson**[3]**, A. Rumbold**[4]**, W. Scheil**[5]**, V. Moore**[6]

[4]*Robinson Institue- University of Adelaide, Lifecourse and Intergenerational Health, Adelaide, Australia*
[5]*South Australian Department of Health, Perinatal Outcomes, Adelaide, Australia*
[6]*Robinson Institute- Unviersity of Adelaide, Public Health, Adelaide, Australia*

Study question: Does infertility related to maternal exposure to night shift work increase the risk of urogenital defects after ART?

Summary answer: Maternal night shift work was associated with urogenital anomalies among ART first births (aOR = 1.89,CI 1.13-3.38, particularly for multiples (aOR = 3.11,CI 1.33-7.28), but not natural conceptions.

What is known already: Urogenital anomalies are among the most commonly diagnosed congenital anomalies, affecting up to 16 per 1,000 births per year, with significantly higher prevalence among births conceived using assisted reproductive technologies.

Infertility may also increase the risk of urogenital anomalies by various pathways.

Circadian perturbation is a potent endocrine disruptor, with higher rates of menstrual disturbance, endometriosis and miscarriage among shift workers.

Circadian disruption of melatonin secretion is implicated in reproductive function, particularly during pregnancy, and is important in regulating the fetal circadian rhythm. Through its effects on estrogen levels, circadian disruption may also have a sex-specific role in sexual development.

Study design, size, duration: Whole of population data-linkage cohort for the state of South Australia, comprising 302,811 births, from Jan 1986 to Dec 2002, with congenital anomalies detected until children reached age 5 years. Analysis was restricted to 98,359 nulliparous women who were in paid employment at the time of their first birth.

Participants/materials, setting, methods: The South Australian Birth Cohort is based on all registrations of birth and terminations of pregnancy, linked to all cycles of ART, and to all congenital anomalies notified to the 5th

birthday (ICD-9 British Paediatric Association codes). Logistic regression was used to investigate associations between night shift imputed from maternal occupation, treatment modality and the presence of urogenital defects. Occupation recorded at birth was used to calculate probability of shiftwork.

Main results and the role of chance: Nulliparous women employed in occupations involving night shift were older, more likely to be Caucasian, more likely to reside in wealthy areas and less likely to smoke. ART treatment received did not differ by night shift exposure status.

ART first births showed that the risk of urogenital anomalies was significantly higher among multiple births to night shift workers, OR = 3.11 (95% CI 1.33-7.28) compared to singletons without maternal exposure to night shift work. The risk of urogenital defects was elevated for singleton births to night shift workers (OR=1.85 (95% CI 0.96-3.59)), although this did not reach statistical significance. There was no difference in the risk of urogenital anomalies for multiple and single births conceived using ART where the mother was not exposure to night shift work. These results were adjusted for sex of the baby, maternal age, ethnicity, socioeconomic status, infertility diagnosis, ART treatment type, pregnancy induced hypertension, pre-existing diabetes and asthma.

A significant interaction indicated that the effect of ART conception on the risk of urogenital anomalies for night shift workers is 1.9 times higher than that of non-shift workers.

Limitations, reasons for caution: Shift work was based on a job exposure matrix which calculated the probability of exposure, whereas a more precise measures of exposure using detailed occupational records may yield a more robust result.

A caveat is that shift workers may have different patterns of exposure to unrelated occupational hazards.

Wider implications of the findings: The interaction between maternal shift work and use of ART suggests that individual susceptibility to circadian disruption, and the impact of this on the severity of infertility, are important factors in predicting adverse outcomes, such as urogenital anomalies.

Trial registration number: not applicable.

P-386 Progesterone ratio as a predictor in the ART Cycles with premature progesterone elevation on the day of hCG trigger

C.C. Huang[1], H.H. Chen[1], C.I. Lee[2], M.S. Maw-Sheng Lee[2]

[1]Lee's Women Hospital, Division of Infertility, Taichung, Taiwan R.O.C.
[2]Chung-Shan Medical University Hospital, Department of Obstetrics and Gynecology, Taichung, Taiwan R.O.C.

Study question: To evaluate the progesterone ratio as a predictor for implantation in women with a premature progesterone rise (>1.5 ng/ml) on the day of hCG trigger.

Summary answer: Serum progesterone ratio is a prediction and diagnosis tool for improvement of implantation in women with a premature progesterone rise on the day of hCG.

What is known already: Several studies suggested that poorer implantation rates occurred in IVF cycles with elevated progesterone at the end of follicular phase in ovarian stimulation. Much evidence supports the negative impact on endometrial receptivity of elevated progesterone concentrations on the day of hCG trigger. A suggested cause is a premature progesterone elevation which impairs endometrial receptivity. Freeze-all embryos and frozen embryo transfer (FET) in these patients is the other chose for improving clinical outcomes. Whether all of the woman with increased progesterone on the day of hCG trigger should undergo frozen embryo transfer and the diagnostic criteria remains to be explored.

Study design, size, duration: This is a retrospective study involving patients who underwent ICSI/IVF cycles in Lee's Women Hospital, Taiwan in the period from Jan. 2013 to Sep. 2016. One hundred and sixty-nine patients who fulfilled the inclusion criteria were recruited. Patients age range from 20 to 38 years with AFC more than five follicles per ovary and FSH level that is below 10 mIU/L were enrolled. Women with polycystic ovarian syndrome (PCOS) were excluded in this study.

Participants/materials, setting, methods: The progesterone levels were recorded until hCG trigger during ovarian stimulation cycles. The ratio of progesterone was calculated using the following formula: progesterone ratio=

progesterone level on the day of hCG trigger / progesterone level on 2 days before hCG trigger. The patients were divided into fresh or frozen embryo transfers (ET) after oocyte retrieval. The embryo vitrification was underwent on day 1 (pronuclear stage) and all embryo transferred on day 3.

Main results and the role of chance: Receiver operating curve (ROC) analysis was used to evaluate the cutoff value of progesterone ratio with maximal sensitivity and specificity to differentiate between viable and non-viable pregnancies in fresh ET cycles. The AUC was 0.701, (95% CI: 0.589–0.812). A cut of level is 1.445 that corresponded to a maximum sensitivity and (0.875) specificity (0.645). In fresh ET group, women with progesterone ratio ≤ 1.445 has significantly lower implantation (IR: 4.8%, 4/83) and pregnancy (PR: 15.4%, 4/26) rates than that in women with progesterone ratio ≤ 1.445 (IR: 22.5%, 46/204 and PR: 41.2, 28/68, respectively, p<0.05). The frozen ET in patients with progesterone ratio ≤ 1.445 has significantly higher implantation (21.3%, 20/94) and pregnancy (48.4%, 15/31) rates than that in fresh ET cycles with progesterone ratio ≤ 1.445 (p = 0.001 and 0.008, respectively). However, the implantation and pregnancy rates between fresh (IR: 22.5%, 46/204 and PR: 41.2%, 28/68) and frozen ET (IR: 27.9%, 36/129 and PR: 56.8%, 25/44) cycles with progesterone ratio > 1.445 were no significantly difference (p = 0.265 and 0.106, respectively). This study suggested that monitoring progesterone ratio can be a predictor of clinical outcomes for women with elevated progesterone on hCG day and further a diagnosis tool for FET.

Limitations, reasons for caution: This finding is only applied in normal responder but not in advanced age women or PCOS.

Wider implications of the findings: The fresh or frozen ET both can be choice in women with progesterone ratio higher than 1.445, although they have elevated progesterone level on hCG day.

Trial registration number: The retrospective data analysis was approved by the Institutional Review Board of Chung Shan Medical University, Taichung, Taiwan (CS-14124).

P-387 Number of follicles ≥15 mm and previous childbirth, but not ovarian reserve tests, are predictors of clinical pregnancy rates of ovarian stimulation and intra-uterine insemination cycles

S. Gunalp[1], S. Mumusoglu[1], G. Ozten[2], F. Aktoz[2], L.K. Sokmensuer[3], G. Bozdag[1]

[1]Hacettepe University School of Medicine, Reproductive Endocrinology and Infertility, Ankara, Turkey
[2]Hacettepe University School of Medicine, Obstetrics and Gynecology, Ankara, Turkey
[3]Hacettepe University School of Medicine, Histology and Embryology, Ankara, Turkey

Study question: Is there any predictor of clinical pregnancy rates (CPR) of ovarian stimulation and intra-uterine insemination (OS-IUI) cycle in couples with unexplained, chronic-anovulatory, and male factor infertility?

Summary answer: Number of follicles ≥15 mm on the day of oocyte maturation triggering and presence of previous childbirth were only significant predictors of CPR of OS-IUI cycles.

What is known already: One-third of subfertile couples with unexplained and mild male factor infertility achieving a live birth after several OS-IUI cycles and remaining requires in-vitro fertilization (IVF) cycle. Since the differences at live birth rate of per started cycle between OS-IUI and IVF (10-15% vs. 35-40%), identification of patient and OS related predictors of treatment success after OS-IUI may provide more effective counseling and treatment planning for the physician. There is inconclusive and limited data whether ovarian reserve test [antral follicle count (AFC) and anti-Müllerian hormone (AMH)] or OS cycle characteristics could predict ovarian response and pregnancy.

Study design, size, duration: In this retrospective cohort study a total of 323 consecutive couples with unexplained (n = 204), chronic anovulatory (n = 75) and mild male-factor (n = 44) infertility undergoing OS-IUI at tertiary university clinic in-between January-2015 and November-2016 were enrolled with their chronologically first cycle. Inclusion criteria were >5 million/ml total motile sperm count, and confirmation of tubal patency at least in one side with hysterosalpingography. Clinical pregnancy was defined as visualization of gestational sac/fetal-heart-beat by trans-vaginal ultrasound (TV-US).

Participants/materials, setting, methods: In all patients follicle stimulating hormone (FSH) starting dose was in-between 75 and 150IU and dose were adjusted according to TV-US on stimulation Day6. In logistic regression model female age, body mass index (BMI), previous childbirth, AFC, AMH, duration of OS, number of follicles ≥15 mm, FSH starting dose, total FSH dose, type of subfertility, concentration and percentage of total and progressive motile sperm count after preparation, and luteal-phase support (LPS-vaginal-gel) were studied as predictor.

Main results and the role of chance: Clinic pregnancy rates per inseminated cycle were comparable among the couples with unexplained, chronic anovulatory, and mild male-factor infertility (12.7%, 18.7%, and 11.4%, p = 0.774, respectively), with an overall rate 13.9%(45/323). Female age (29.2 ± 5.3 vs. 30.0 ± 4.5, p = 0.320), BMI (25.9 ± 4.6 vs. 24.6 ± 4.6, p = 0.103), AFC (18.3 ± 11.0 vs. 19.0 ± 10.8, p = 0.783), AMH (4.4 ± 4.0 vs. 4.2 ± 3.5, p = 0.885), duration of OS (13.4 ± 5.2 vs. 13.0 ± 4.7, p = 0.646), FSH starting dose [75.0IU(50-150) vs. 75.0IU(50-150), p = 0.624], total FSH dose (879.8 ± 369.3 vs. 883.0 ± 484.8, p = 0.961), number of follicles ≥15 mm (2.2 ± 1.4 vs. 1.9 ± 1.1, p = 0.187), percentage of total (67.1 ± 17.9% vs. 64.4 ± 16.7, p = 0.348) and progressive (73.1 ± 5.1% vs. 71.1 ± 15.6%, p = 0.431) motile sperm after preparation, patients with LPS (26.7%-12/45 vs. 39.9%-111/278, p = 0.121) were comparable among the CP-positive or CP-negative couples, respectively. However, in couples with CP-positive total (44.7 ± 25.5 vs. 35.0 ± 26.7, p = 0.027) and progressive (33.0 ± 21.5 vs. 23.8 ± 19.0, p = 0.011) motile sperm count and number of couples with previous childbirth (20/44.4% vs. 76/27.3%, p = 0.019) were significantly higher. In logistic regression model significant predictors of the CP were only the number of follicles ≥15 mm (b:0.412, 95%CI 1.107; 2.058, p = 0.009) and previous childbirth (b:0.412, 95%CI 1.151; 6.324, p = 0.022). When linear regression analysis was performed, to identify predictor for the number of follicles ≥15 mm, only BMI was significant (b:-0.039, 95%CI -0.073; -0.004, p = 0.029).

Limitations, reasons for caution: Retrospective design is a limitation. Cancelled cycles during this time period were not recorded and not included in the analysis. Thus may restrict the extrapolation of the results.

Wider implications of the findings: Number of follicles ≥15 mm and previous childbirth were only significant predictors of CPR of OS-IUI cycles. BMI was the only significant predictor for the number of follicles ≥15 mm, where as female age, AFC, AMH, FSH starting dose, duration of infertility, duration of OS, type of subfertility were not.

Trial registration number: None

P-388   Follicle stimulating hormone type is a risk factor for developing ovarian hyper stimulation syndrome during in vitro fertilisation as observed in vivo and in vitro

Abstract withdrawn by the author

P-389   Influence of male and female smoking habits on outcome of artificial insemination: results from a prospective cohort study

S. Huyghe[1], A. Thijssen[2], N. Dhont[3], W. Ombelet[3]

[1]ZOL Campus St. Jans, obstetrics & gynecology, Genk, Belgium
[2]Hasselt University, Faculty of Medicine and Life Sciences, Hasselt, Belgium
[3]Genk Institute for Fertility Technology- Ziekenhuis Oost-Limburg, Department of Obstetrics and Gynaecology, Genk, Belgium

Study question: Do female/male smoking habits influence the CPR (clinical pregnancy rate) after artificial insemination with donor or homologous semen?

Summary answer: Female smoking habits influence the CPR negatively after donor insemination, while male smoking and smoking of both partners significantly decreases the CPR after homologous insemination.

What is known already: The prevalence of smoking amongst women and men in their reproductive years remains high, despite the known negative influence of smoking on male and female infertility. Surprisingly, given the widespread studies of effect of smoking on outcome of IVF (in vitro fertilization), there is limited literature on influence of male and female smoking habits on outcome after intrauterine insemination (IUI). The few trials do not show a

significant effect. IUI remains a technique with a rather low success rate, insights in predictive factors could therefore be useful.

Study design, size, duration: A prospective cohort study was performed from 01-07-2011 until 30-09-2015. Data from 1401 homologous and 1264 heterologous IUI cycles were collected through a questionnaire during 20 minutes of mandatory bed rest after insemination. 19 cycles were lost to follow-up (0.7%). The primary outcome parameter was CPR, confirmed with a gestational sac and fetal heartbeat on ultrasonography at 7-8 weeks of gestation.

Participants/materials, setting, methods: The study, performed in a tertiary referral center, included all women elective for IUI with homologous or donor semen. Firstly the univariate relationship between smoking and CPR was studied. Secondly taking into account dependency (possibly different cycles for same patient) and confounding factors, an alternative logistic regression model, GEE (Generalized Estimating Equations) was used.

Main results and the role of chance: In the homologous IUI group the mean age of women was 32.1 years (range 19-47 years), of whom 85% were non-smokers, 13% smoked 1-14 cigarettes daily and 2% more than 15 cigarettes a day. The mean age of men was 34.6 years (range 22-63 years), of whom 70% were non-smokers, 19% smoked 1-14 cigarettes daily and 11% more than 15 cigarettes a day. In the donor IUI group the mean age of women was 33.4 years (range 20-46 years), of whom 89.5% were non-smokers, 7.5% smoked 1-14 cigarettes daily and 3% more than 15 cigarettes a day.

Multivariate GEE analysis revealed male smoking to be predictive for clinical pregnancy in the homologous insemination group (p = 0.0079), secondly a trend towards a decreased CPR was discovered with both partners smoking. In the donor IUI group female non-smoking or smoking less than 15 cigarettes a day turned out to be significantly associated with a higher CPR (p = 0.047) compared to in women smoking more than 15 cigarettes daily.

Limitations, reasons for caution: As smoking is an exposure, randomization is not feasible. Nevertheless the data were collected prospectively by means of a questionnaire. Subjects may have underreported their smoking habits. The series of women smoking more than 15 cigarettes daily is rather small.

Wider implications of the findings: Given the significant effect of smoking on IUI outcome, smoking cessation or at least reduction should be advised to all women and their male partners before artificial insemination is performed.

Trial registration number: not applicable.

P-390   Reduced pregnancy rates after intra-uterine insemination (IUI) in Human Papillomavirus (HPV) positive couples

C. Depuydt[1], J. Beert[2], D. Vanden Broeck[1], G. Salembier[1], E. Bosmans[1], A. Cox[3], E. Vandormael[3], W. Ombelet[3]

[1]AML- Sonic Healthcare, Clinical and Molecular Pathology, Antwerp, Belgium
[2]AML- Sonic Healthcare, Intermediate structure human body material, Antwerp, Belgium
[3]Genk Institute for fertility technology GIFT VZW, Zorgprogramma Reproductieve Geneeskunde B ZRGB, Genk, Belgium

Study question: Investigate the relationship between HPV infection in couples and pregnancy outcome after intra uterine insemination (IUI).

Summary answer: Presence of HPV virions detected in both male and female partner is associated with a negative IUI pregnancy outcome.

What is known already: Recent evidence has identified HPV virions as a possible cause of male and couple infertility. Serial measurements of type-specific HPV DNA can categorize HPV infections in two HPV-induced pathways, an infectious virion-producing and a non-infectious transforming cancer-inducing pathway. Because virions can bind two distinct sites on the spermatozoa's head, this may not only have a detrimental effect on sperm parameters but also on gamete interaction, since in vitro experiments have demonstrated that spermatozoa can not only transfer HPV virions to the oocyte, but the transferred HPV virions also induce stage-specific maturation arrest in infected embryos.

Study design, size, duration: Multi-centric non-interventional prospective study in which both partners of a couple undergoing IUI were tested for the presence of HPV types (6,11,16,18,31,33,35,39,45,51,52,53,56,58,59,66,67

and 68) using quantitative real-time PCR. For male partners different sperm rest fractions (density gradient rest fraction, sperm pellet, swim-up and seminal plasma) were tested. For the female partners the HPV status was assessed on the last 6 cm of the insemination catheter used after insemination.

Participants/materials, setting, methods: HPV positivity was correlated with IUI outcome using following categories: no pregnancy, biochemical pregnancy, miscarriage (>7weeks) and ongoing pregnancy. During the last 2 years rest fractions from capacitation and insemination from both men and women attending for IUI at the AML intermediate structure body material, Antwerp Belgium and the Department of Obstetrics and Gynaecology, Ziekenhuizen Oost-Limburg, Genk, Belgium were tested anonymously for 18 different HPV types. A total of 1000 couple/cycles will be tested.

Main results and the role of chance: For 629 IUI cycles the HPV status of both partners was measured. In couples where both partners were HPV negative (n = 483), 61 pregnancies were achieved (12.6%; 18 biochemical/miscarriages and 43 ongoing). In couples where men were HPV positive (41 cycles) only 2 pregnancies were achieved (4.9% 1 biochemical/miscarriages and 1 ongoing). When the female partner was HPV positive (73 cycles) 6 pregnancies were recorded (8.2%; 5 biochemical/miscarriages and 1 ongoing). When both partners were HPV positive (31 cycles) only 1 pregnancy that ended in miscarriage was detected (3.2%). There was an significant reduction in ongoing pregnancies when HPV was detected (no HPV in couple>HPV+ male partner >HPV+ female partner >both partners HPV+) X^2 for trend p = 0.0043. In the group of biochemical pregnancies and miscarriages 7/22 (31.8%) significantly more couples were HPV positive compared to couples with an ongoing pregnancy with only 2/45 (4.42%)(p = 0.0069). The HPV prevalence per IUI cycle was 23.2%(146HPV+/629).

Limitations, reasons for caution: Only a limited number of intermediate and low risk HPV types was tested for. This could result in an underestimation of the global HPV virion impact on the % achieved biochemical pregnancies and miscarriages.

Wider implications of the findings: IVF or ICSI might be indicated in HPV positive couples to increase successful pregnancies, considering the low IUI success rates in HPV positive couples.

Trial registration number: not applicable.

P-391   Proteomic and peptidomic analysis of human follicular fluid by mass spectrometry as a potential tool for oocyte quality differentiation

A. Lewandowska[1], K. Macur[1], P. Czaplewska[1], J. Liss[2], K. Łukaszuk[2,3], S. Ołdziej[1]

[1]University of Gdańsk, Intercollegiate Faculty of Biotechnology, Gdańsk, Poland
[2]Invicta, Reproduction and Fertility Centre, Gdańsk, Poland
[3]Medical University of Gdańsk, Department of Obstetrics and Gynecological Nursing, Gdańsk, Poland

Study question: Are there significant differences in proteome profiles of follicular fluids (hFF) from separate ovarian follicles of healthy women?

Summary answer: Statistically significant changes in concentrations of proteins between hFF samples from separate ovarian follicles of a single patient concern 19 identified proteins.

What is known already: Due to its close relation to maturing oocyte, human follicular fluid is hypothesized to carry traces of information revealing the quality of the oocyte. Multiple studies on hFF composition have been conducted, focusing on hormones, growth factors, anti-apoptotic factors, proteins, peptides, amino acids, and sugars. However, a great majority of proteomic studies of hFF did not undertake analysis of multiple samples from the same healthy patient to unambiguously identify biomarkers of oocyte quality instead of patient-related features. Moreover, no previous study has focused on both proteomic and peptidomic analysis of hFF.

Study design, size, duration: Twelve samples of hFF from separate ovarian follicles of four women undergoing IVF procedure (3 hFF samples per patient) were acquired at the INVICTA Fertility Clinic in October 2015. All samples were free of blood contamination. Follicular fluids from individual follicles were analyzed separately and the proteomic results were compared between oocytes of a single patient and between patients.

Participants/materials, setting, methods: Patients that participated in the study were undergoing the IVF procedure due to male infertility factor. HFF material was further subjected to ultrafiltration on a 10 kDa membrane in order to divide it into high molecular weight fraction (HMWF) containing proteins and low molecular weight fraction (LMWF) containing endogenous peptides. Both fractions were analyzed in a qualitative and quantitative manner by SWATH-MS technique (Sequential Window Acquisition of All Theoretical Fragment Ion Spectra) and compared statistically.

Main results and the role of chance: In the course of the study we identified 108 proteins in HMWF and 92 proteins in LMWF with a confidence score higher than 95%. 62 of identified proteins were never reported before in hFF literature. We were able to quantitatively measure 73 proteins of HMWF and 24 proteins in LMWF in respective single runs. With p < 0.05 and fold change higher or equal to 2, we obtained sets of proteins specific for differences between hFF from separate ovarian follicles of a single patient (alpha-1-antitrypsin, hemopexin, retinol-binding protein 4, apolipoprotein A-I, vitronectin, complement factor I, ceruloplasmin, apolipoprotein A-IV, apolipoprotein A-II, leucine-rich alpha-2-glycoprotein, clusterin, complement factor B, protein AMBP, hemoglobin subunit beta, apolipoprotein D, inter-alpha-trypsin inhibitor heavy chain H4, plasma protease C1 inhibitor, Ig heavy chain V-III region TUR, phospholipid phosphatase-related protein type 3) and between hFF from separate patients (18 proteins). In peptidomic fraction 21 peptides from 15 proteins were present showing statistically significant changes in concentrations between patients.

Limitations, reasons for caution: The main limitation of the study is a small number of participants. Moreover, it is necessary to compare proteomic results with medical outcomes in order to unambiguously establish biomarkers of good oocyte quality.

Wider implications of the findings: Our study established possible biomarkers of oocyte quality differentiation that need to be verified in large-scale research and compared with medical outcomes to develop diagnostic biomarkers of good oocyte quality, which would allow for fertilization of only most promising oocytes in the ART treatment.

Trial registration number: N/A.

P-392   In vitro fertilization outcomes in women with mullerian anomalies: Revisiting the controversy

M. Dviri, Y. Baruch, E. Zohav, Y. Hasson, F. Azem

Tel Aviv Sourasky Medical Center, Sara Racine IVF Unit- Department of Obstetrics and Gynecology, Tel aviv, Israel

Study question: Are uterine anomalies associated with decreased rates of embryo implantation and clinical pregnancy in in vitro fertilization (IVF)/intracytoplasmic sperm injection (ICSI) cycles?

Summary answer: When compared to women with normal uterine anatomy, women with uterine anomalies undergoing IVF/ICSI have comparable Implantation rates (IR) and clinical pregnancy rates (CPR).

What is known already: Mullerian anomalies are relatively uncommon. It is well known that uterine anomalies are associated with higher rates of obstetrical complications, such as preterm delivery and miscarriages, but only few studies have focused on IVF outcomes in these patients. In the past decades, rapid technological advance has led to diagnostic improvement in evaluating uterine anatomy and more anomalies are now identified in women undergoing assisted reproduction, making available literature data out of date. The existing studies are limited by very small sample sizes, so far showing conflicting results – reduced IR and CPR by some, and no significant differences by others.

Study design, size, duration: A retrospective cohort study performed at a single public academic reproductive center between January 2006 and December 2016. Computerized medical records of 11,415 IVF/ICSI patients during the study period were screened in order to identify patients with proven mullerian anomalies. Fertility preservation cycles, cycles using donor oocytes and frozen-thawed embryo transfers were excluded (n = 253, 2.2%).

Participants/materials, setting, methods: Anomalies diagnosis was confirmed by hysteroscopy or different imaging/surgical modality. Patients with no definitive diagnosis were excluded.

To prevent bias, only first IVF cycles with available fresh embryos to transfer were included.

Septate uterus was excluded since most patients underwent resection before IVF or there was unclear data about correction.

IR and CPR were compared between the anomalies group (n = 34) to age matched controls (n = 34) with anatomically normal uteri from cycles carried out during the same period.

Main results and the role of chance: The incidence of mullerian anomalies in the screened infertile population during elven years of study period was 0.68% (76/11,162). After exclusion (4 indefinite diagnosis, 14 no fresh embryo transfer (ET), 24 septate), 34 patients with the following types of congenital uterine malformation were included at the final statistical analysis: 7 arcuate, 12 unicornuate, 12 bicornuate, 1 uterus didelphy and 2 T-shape uteri.

Mean patients age was comparable in both groups)35.26 vs 35.21). There were no statistically significant differences in Body mass index (p = 0.27) or follicular stimulating hormone (FSH) day 3 (p = 0.19) The mean number of retrieved oocytes was comparable - 7.91 in the anomlies group vs 8.76 in control group (p = 0.321).

IR was comparable between the anomalies and the control group (18% vs 12%, p = 0.417), with comparable number of embryos transferred (1.88 vs 2.06, p = 0.394).

CPR and live birth rate were also comparable between the groups: 41.2% vs 26.5% (p = 0.15) and 23.5% vs 11.8% (p = 0.17), respectively.

Limitations, reasons for caution: The main limitations were the retrospective nature of the study and the small sample size, which may limit it's statistical power.

Wider implications of the findings: This information may be of vital importance when providing preconceptional counseling to women with uterine anomalies about their expected reproductive success chances.

Trial registration number: N/A.

P-393   Could embryo banking be used as a treatment strategy in the management of poor responders?

H. Exeter[1], V. Seshadri[2], E. Drew[1], A. Petrie[3], P. Serhal[4]

[1]The Centre for Reproductive and Genetic Health, Embryology, London, United Kingdom
[2]The Centre of Reproductive and Genetic Health, Clinical, London, United Kingdom

Study question: Does cumulative freezing day 3 embryos over two or more cycles improve the blastocyst conversion and pregnancy rates in poor responders?

Summary answer: Banking day 3 embryos improves blastocyst and pregnancy rates in poor responders. There is a positive linear relationship between cumulative embryos banked and pregnancy rate.

What is known already: Poor responders (≤ 9 oocytes collected) have been previously identified by the Bologna Criteria. These patients are also associated with increased aneuploidy in embryos. The POSEIDON group suggest that increased embryo numbers could improve chances of obtaining an euploid embryo and a subsequent successful clinical outcome. Cummulative embryo banking offers this opportunity. Recent data suggests frozen embryo transfers may improve pregnancy outcome compared to fresh embryo transfer.

Study design, size, duration: This is a retrospective analysis of 150 poor responder patients at Centre for Reproductive and Genetic Health (CRGH) who have undergone a minimum of twooocyte retrievals followed by day 3 vitrification. In a subsequent cycle, all embryos were thawed and culture to blastocyst with intention to transfer. Cycles were included between 2013 and 2015.

Participants/materials, setting, methods: Poor responder patients had at least two cycles of day 3 embryo vitrification. Embryos were required to be 6 cells or more at the time of vitrification. Slow embryos were not vitrified. We used Kitazato vitrification and warming kits and, post warming, embryos were cultured in Sage One Step Media. Outcomes reviewed were blastocyst formation (> equal to 1) and pregnancy outcome per cycle. Statistical analysis (SPSS) included logistic regression, ROC and Chi-Squared.

Main results and the role of chance: Logistic regression for the effect of total day 3 embryos on blastocyst outcome shows that the odds of blastocyst formation are 3.63 times greater as the number of day 3 embryos increases by one (OR = 3.63 (95%CI 2.17 to 5.79 p<0.001), which is significant. ROC analysis and a 2×2 Chi-squared table analysis indicate that, based on these patients, there is strong evidence of a difference between the chance of blastocyst with <equal 4 day 3 embryos (estimated by 30.4%) and > 4 day 3 embryos (estimated 97.8%), suggesting that a cohort of 4 or more day 3 embryos should result in at least one blastocyst per patient. Logistic regression for the effect of total day 3 embryos on pregnancy rate shows the odds of pregnancy increase by 15% as the total number of day 3 embryos increases by one (OR = 1.15, p = 0.017), which is also significant. Since the dataset is reasonably small the element of chance cannot be discounted and further studies will be required for validation.

Limitations, reasons for caution: Limitations of this study include the relatively small dataset, the fact that patients may have undergone different stimulation protocols and the objective nature if the term 'poor responder.'

Wider implications of the findings: We have shown that'poor responder' patients have an improved chance of blastocyst development and pregnancy by banking day 3 stageembryos and subsequently culturing the cumulative cohort during a frozen embryo replacement cycle.

Trial registration number: Not applicable.

P-394   Pituitary suppression protocol does affect clinical outcomes in egg donation cycles

V. Vergara Bravo[1], M. Cruz[2], E. Goyri[3], A. Requena[3]

[1]IVI Madrid, Madrid, Spain
[2]IVI Madrid, IVF Laboratory, Madrid, Spain
[3]IVI MAdrid, Gynecology, Madrid, Spain

Study question: To compare different pituitary suppression protocols in endometrial priming of egg donation cycles based on clinical outcomes and cancellation rates.

Summary answer: The use of depot GnRH agonist in midluteal phase in endometrial priming protocol is associated with better implantation rates in egg donation cycles.

What is known already: In patients with ovarian function, it is possible that during endometrial priming for embryo transfer, spontaneous ovulation occurs leading to desynchronization of implantation window. To avoid this phenomenon there are different pituitary suppression techniques as use of depot GnRH agonist or GnRH daily dose antagonist during first 5-7 days of estrogen supplement. Not administering any medication is considered a valid option if the initial dose of estrogen is maximum so suppression would be obtained by negative feedback.

Previously reported studies refer no difference in clinical outcomes using different protocols.

Study design, size, duration: Retrospective analysis with common database from 11 private clinics of IVI group. We included 7690 women with preserved ovarian function who underwent egg donation cycle with endometrial priming for fresh embryo transfer from Jan 1st 2014 to Dec 31st 2015. Statistical analysis was performed by ANOVA and chi-square.

Participants/materials, setting, methods: Participants received increasing dose of oral estradiol from 2 to 6 mg or transdermal estrogen 75 to 150 μg every 3 days. Subjects in the agonist group received GnRH agonist 3,75 mg in midluteal phase of previous cycle. The group with GnRH antagonist received 0,25 mg daily during the first 7 days of estrogen supplementation. The third group received oral estradiol with initial dose of 6 mg. Cycles were supplemented with vaginal progesterone 400 mg twice/day.

Main results and the role of chance: Patients were distributed as follows: 47.9% (n = 3684) were prepared with GnRH agonist; 35.2% (n = 2706) were primed with GnRH antagonist; 16.9% (n = 1300) did not receive any medication for pituitary suppression. According to analyzed clinical variables, we found statistical differences among the study groups. Data were as follows for agonist, antagonist and without suppressive therapy group respectively; age (41.1 ± 0.1; 41.3 ± 0.1; 40.8 ± 0.2, p<0.001); endometrial thickness (mm) (7.8 ± 1.5; 7.8 ± 1.3; 8.9 ± 0.3, p<0.001).

When we considered clinical outcomes, we found a significant increase in implantation rate in the agonist group (53.2%) compared with the antagonist group (50.8%) and the women without pituitary suppression (49, 2%), p = 0.014. Similar results were observed in pregnancy rate in favor of the

agonist group (64.7%) in relation with the antagonist group (62.8%) and women without GnRH analogues (58.3%), p = 0.001. Finally, miscarriage rates were comparable among groups being 10.2%, 8.8% and 9.1% (p = 0.346) for agonist, antagonist and no analogue administration.

Concerning cancellation rate due to endometrial impairment, data were identical for the three treatments (2.0%)

Limitations, reasons for caution: Despite the advantages that our data set confer the analysis, limitations still remain. One consequence of a retrospective study is that not all pertinent risk factors are likely to have been identified and subsequently recorded. So only association, and not causation, can be inferred from the results.

Wider implications of the findings: In the endometrial preparation for egg donation cycles, there is a statistically significant advantage regarding clinical outcomes with the use of depot GnRH agonist for pituitary suppression when compared with antagonist protocol or no pituitary suppressive protocol.

Trial registration number: Not applicable.

P-395   Real-life costs and effectiveness of contraceptive methods: A cohort study in the French national healthcare insurance database

T. Linet[1], C. Godard[2], C. Laurendeau[3], A. Benmahmoud-Zoubir[2], A. Lafuma[3], L. Lévy-Bachelot[2], J. Gourmelen[4], A. Agostini[5]

[1]Centre Hospitalier Loire Vendée Océan, Gynécology-Obstétrics, Challans, France
[2] MSD, Haut-de-Seine, Courbevoie, France
[3]Cemka-Eval, Haut-de-Seine, Bourg-la-Reine, France
[4]INSERM, Unité Cohortes épidémiologiques en population - UMS 011 INSERM-UVSQ, Villejuif, France
[5]Hôpital de la Conception, Gynecology Obstetrics, Marseille, France

Study question: What are the failure rates and utilization costs of French reimbursed contraceptive methods in real life practice?

Summary answer: The study shows that etonogestrel implant and intrauterine devices are associated with significantly lower unintended pregnancy rates and costs.

What is known already: With nearly 220,000 abortions per year in France and a proportion of repeat abortions increasing steadily, enhancing the use of contraceptive method allowing a better adherence and acceptability is a public health priority.

Study design, size, duration: This is a retrospective study based on the EGB ("*Echantillon Généraliste des Bénéficiaires*") database which is a representative sample of the general population of subjects affiliated with the French health insurance system. The EGB database includes approximately 600,000 beneficiaries. Women having used any reimbursed contraception in 2012 were included.

Participants/materials, setting, methods: Unintended pregnancies were identified through delivery and abortion occurring at least one month after contraceptive initiation. The start of contraception was the date of the first dispensation for OCs; the date of the insertion for LARCs. The end of contraception was assumed if there was a removal for LARCs, a dispensation of another type of contraception, a pregnancy, sterilization or an absence of dispensation at the end of the covered period. Associated costs were estimated.

Main results and the role of chance: A sample of 48,090 women with a reimbursed contraceptive method in 2012 was identified in the EGB: 67.6% used oral contraceptives (OCs), 28.1% intrauterine devices (IUD) and 4.3% implant (Nexplanon®). This distribution was highly dependent on women ages, except for the implant that was evenly distributed among age groups. Unintended pregnancies ranged from 0.8% for the implant to 4.8% for 1st and 2nd generation combined OCs. The mean direct cost associated with an unplanned pregnancy was estimated at about € 2,500, a weighted average of normal delivery, abortion, miscarriage and extra-uterine pregnancy costs. When the costs of the unintended pregnancies were taken into account, the total cost for the first year was lower for progestin-only OC (€251) and copper IUD (€257) compared to Nexplanon® (€300) and hormonal IUD (€323; Mirena®). For the next years through the intended use of the product, Nexplanon® was associated with the lowest cost (€87) per year.

Limitations, reasons for caution: For OCs, only the dispensation date was available in the database. The discontinuation date was estimated from the number of delivered pills. For LARCs, insertion and removal were often not recorded in the database; hypotheses were made based on physician consultations. The costs may vary from one country to another.

Wider implications of the findings: This real-world study shows that the contraceptive implant and IUDs should be considered for first-line use to prevent unintended pregnancies and related abortions in France both from a public health and economic perspective.

Trial registration number: 0.

P-396   Number of oocytes needed to have a healthy baby born

G. Pirastu, M.C. Magli, M. Dell'Aquila, C. Tabanelli, A.P. Ferraretti, A. Pomante, L. Gianaroli

S.I.S.Me.R., Reproductive Medicine Unit, Bologna, Italy

Study question: Which is the ideal number of oocytes needed to have a healthy baby born after preimplantation genetic testing?

Summary answer: In women 40 years and older, significantly more oocytes are needed to have a baby born compared to the younger categories.

What is known already: In conventional IVF, the total number of retrieved oocytes decreases significantly with maternal age. Accordingly, there is a significantly positive correlation with the number of usable embryos and the cumulative pregnancy rate. When adding chromosome analysis as an additional selection factor, these differences among the age categories are even higher confirming the association between euploidy and maternal age. It has been estimated that, although aneuploidy increases with age but not with the cohort size, the chances of having at least an euploid embryos depends on the number of oocytes and maternal age.

Study design, size, duration: Retrospective cohort study including 263 IVF cycles undergoing preimplantation genetic testing for aneuploidy (PGT) during the last 5 years. The cycles were arbitrarily divided in 5 groups according to the female age. The proportion of euploid embryos and the clinical outcome were related to the number of oocytes retrieved in each group of patients.

Participants/materials, setting, methods: Participants were divided in 5 groups: Group 1: ≤35 years old (n = 36), Group 2: 35-38 (n = 39), Group 3: age 38-40 (n = 51), Group 4: 40-43 (n = 106), Group 5: age > 43 (n = 31). For every group, the number of euploid embryos obtained after PGT was related to the number of oocytes retrieved. The number of oocytes needed to have a baby born was also calculated.

Main results and the role of chance: The mean number of retrieved oocytes decreased proportionally to maternal age (10.8, 10.3, 9.2, 8.7, and 8.2 respectively). The same trend was detected for the euploidy rate (20, 16, 16.6, 9.5 and 4.7% respectively), meaning that the number of oocytes needed to have a euploid embryo was 5 in Group 1, 6.25 in Group 2, 6 in Group 3, 10.5 in Group 4 and 21.3 in Group 5. Embryo transfer was performed in 176 cycles (89% of cycles in Group 1, 95% in Group 2, 88% in Group 3, 51% in Group 4 and 26% in Group 5) resulting in 66 term pregnancies. In all, the number of oocytes needed for a baby born was 33.3, 16, 29.4, 100 and 83 respectively. When restricting the analysis to the fertilized oocytes, for a birth to occur 20 were needed in Group 1, 11.2 in Group 2, 20.8 in Group 3, 66 in Group 4 and 66.6 in Group 5.

Limitations, reasons for caution: In the youngest group, the indication to PGT was primarily due to repeated IVF failures, while for the other groups age was the main indication.

Wider implications of the findings: In women 40 years and older, significantly more oocytes were needed to have a euploid embryo compared to the younger categories. The same trend was observed when calculating the number of oocytes required for a birth. These data can assist to assess couples' odds at producing a viable pregnancy.

Trial registration number: None.

P-397   BMI and outcome after artificial intrauterine insemination: results from a prospective cohort study

A. Verest[1], S. Huyghe[1], A. Thijssen[2], N. Dhont[2], W. Ombelet[2]

[1]ZOL Hospital Genk, Obstetrics and gynecology, Genk, Belgium
[2]Institute of fertility technology Genk, Obstetrics and Gynecology, Genk, Belgium

Study question: Does BMI influence the CPR (clinical pregnancy rate) after artificial intrauterine insemination with donor or homologous semen?

Summary answer: Female BMI does not significantly influence CPR in the donor semen group nor in homologous insemination group, even in a higher range (BMI $\geq$30 kg/m^2).

What is known already: Extreme weight and fat storage is known to be correlated with ovulation disorders and compromised fecundity. The value of obesity as a predictor of infertility treatment outcome is controversial.

Study design, size, duration: A prospective cohort study was performed from 01-07-2011 until 30-09-2015. Data from 1401 homologous and 1264 heterologous IUI cycles were collected through a questionnaire during 20 minutes of mandatory bed rest after insemination. 19 cycles were lost to follow-up (0.7%). The primary outcome parameter was CPR, confirmed with a gestational sac and fetal heartbeat on ultrasonography at 7-8 weeks of gestation.

Participants/materials, setting, methods: The study, performed in a tertiary referral center, included all women elective for IUI with homologous semen or with donor semen. Firstly the univariate relationship between smoking and CPR was studied. Secondly taking into account dependency (possibly different cycles for same patient) and confounding factors, an alternative logistic regression model, GEE (Generalized Estimating Equations) was used.

Main results and the role of chance: Mean age of patients was 33.5 years (range 20-46 years). 17.7% of women had a BMI $\leq$20 kg/m^2, BMI was 20-24.99 kg/m^2 in 52.5% of cases, in 19% of cycles BMI was situated between 25-29.99 kg/m^2 and in 10.8% of cycles BMI was 30 kg/m^2 or more. Univariate statistical analysis revealed female BMI in the homologous IUI group as a covariate significantly influencing CPR per cycle (p = 0,0319). Multivariate GEE analysis could not with hold this significant influence. Partner BMI did not significantly influence CPR per cycle (p = 0.4184). In the donor IUI group BMI was not found to be a significant factor influencing CPR in our study, although a slight decrease in CPR could be observed in women with a BMI of less than 20 kg/m^2 and 30 kg/m^2 or more.

Limitations, reasons for caution: BMI is an objective measurement; a randomized controlled trial to investigate the influence of BMI on IUI outcome is not possible. We noted that the series of women with extreme BMI ($\leq$20 kg/m^2 or $\geq$30 kg/m^2) are rather small which makes it difficult to draw strong conclusions.

Wider implications of the findings: Our results indicate that a high BMI doesn´t affect the success rate in an IUI programme, neither after homologous or donor insemination. On the other hand it is generally known that extreme high BMI ($\geq$35 kg/m^2) does affect obstetrical and perinatal outcomes.

Trial registration number: not applicable.

P-398   Should patients be advised to have treatments with Gonadotropins and Intra Uterine Insemination (IUI) before switching to IVF?

G. Peer, Z. Wiener-Megnazi, S. Doron, D. Ishai, T. Sokal-Arnon, S. Lahav-Baratz, I. Bleis, M. Koifman, M. Dirnfeld

Carmel Medical Center, IVF, Haifa, Israel

Study question: To compare pregnancy rates in IUI and IVF in women aged over 30 using either partners or donor sperm.

Summary answer: In women aged >30,with unexplained infertility or male factor the chances to conceive by IVF treatment is 5.34 times higher than with IUI.

What is known already: Gonadotropins(GT) and IUI is a common fertility treatment, in patients with unexplained infertility or mild male factor before switching to In-Vitro Fertilization (IVF). The advantage of IUI treatments prior to switching to IVF in women aged >39 has been reported low and women are advised to go directly to IVF treatments. Although the practice of GT+IUI has been the standard of care, the UK NICE guidelines state that IUI is not beneficial in couples with unexplained infertility a low sperm count or poor-quality sperm.

Study design, size, duration: A retrospective study, IRB approved in women aged 30 and above, who underwent 307 IUI with either partners or donor sperm due to unexplained infertility or male factor and 589 IVF treatments at the IVF unit in Carmel medical center during the years 2011-2013. IVF cycles included patients with an indication for IVF as the primary treatment and patients who had IVF after 3 failed IUI cycles. All groups were compared.

Participants/materials, setting, methods: Data collected included: age, number of past pregnancies, indication for IUI, IVF treatment protocol, source of sperm concentration and Motility, number of oocytes collected and their maturity, fertilization rates number of embryos transferred.Clinical Pregnancy rates were calculated per IUI treatment with partners sperm and donor sperm and compared with pregnancy rates per embryo transfer of each IVF treatment. A SPSS 22 version software was used for Statistical analysis.

Main results and the role of chance: The data included 176 women who underwent 589 IVF cycles, which resulted in 104 clinical pregnancies and 307 IUI cycles performed prior to IVF yielding 12 pregnancies.

In any age above 30, outcomes with IVF were significantly higher than with IUI (P < 0.0001). The chances to conceive by IVF was 5.34 times higher compared with IUI.

No significant difference in pregnancy rates was found between fertility treatments using partner sperm in Unexplained or Male factor infertility compared to donor sperm.

Limitations, reasons for caution: Pregnancy rates per one cycle of IUI were low during the study period probably due to low cutoff of sperm used as indication for IUI.

Results may change if better selection of patients for IUI due to male factor infertility will be implemented.

Wider implications of the findings: Although treatment with GT+IUI prior to switching to IVF is a routine in fertility centers, our results are in line with the UK NICE guidelines demonstrating that IUI is not beneficial in couples with unexplained or mild-moderate male factor at any age above 30 using either partners' or donor sperm.

Trial registration number: not aplicable.

P-399   Characterization of age-related transcriptomic changes within the follicular unit: clues to the mechanisms underlying female reproductive ageing

A. Alageel[1], E. Repapi[2], N. Gray[2], D. Wells[1], S. Williams[1]

[1]*University of Oxford, Nuffield Department of Obstetrics and Gynaecology, Oxford, United Kingdom*
[2]*university of Oxford, Weatherall Institute of Molecular Medicine, Oxford, United Kingdom*

Study question: Age is arguably the most important factor influencing female fertility. Can new technologies reveal how molecular pathways in oocytes and cumulus cells alter with age?

Summary answer: Single cell RNA sequencing (scRNA-seq) provides a unique view of alterations in transcriptional activity in oocytes and their companion cumulus cells with advancing age.

What is known already: The well-recognized decline in female fertility with age is principally attributed to reduced oocyte quality. Oocyte growth and maturation is coordinated by bidirectional communication involving the surrounding somatic cells (cumulus cells - CCs). It is possible that deterioration in the function of these critical cells with age might play a role in declining oocyte competence. Despite the importance of oocytes and cumulus cells, characterization of changes to the transcriptome, related to age, has seldom been undertaken using modern molecular genetic methods. Additionally, most studies have involved pooled oocytes or CCs, which are likely heterogeneous in terms of competence.

Study design, size, duration: 24 individual oocyte cumulus complex (COC) were recovered from three different ages of female C57 mice (8 COC from each group). Mice were stimulated with PMSG 48 hours prior to the collection of ovaries. The ages were chosen based on timing points in the mouse reproductive life span: 1-year-old (similar to premenopausal women), 9 weeks old (prime reproductive age) and at 3 weeks (prepubertal).

Participants/materials, setting, methods: Polyadenylated RNA from single oocytes and their matching CCs (recovered from the same individual follicle) was separately prepared. cDNA was synthesized and sequencing libraries were generated using Nextera (Illumina), and processed for massive parallel sequencing. RNA sequencing data was assessed statistically using R package, revealing

alterations in gene activity in the different age groups. Genes were considered differentially expressed if they had an adjusted p-value (false discovery rate - FDR) of less than 0.05.

Main results and the role of chance: 1642 genes were found to be differentially expressed in 1-year-old oocytes compared to those at 9 weeks. A diversity of pathways was affected, suggesting that aged oocytes may be compromised on multiple levels. Interestingly, significantly altered activity was seen for multiple genes associated with apoptosis and cell cycle control, DNA damage repair and nuclear stability, chromatin remodelling, lipid metabolism, and fatty acid and steroid hormone synthesis. Dysregulation of such important cellular processes could conceivably contribute to a deterioration in oocyte competence with age. 2713 genes were differentially expressed at 3 weeks of age compared to 9 weeks. These included a variety of genes encoding proteins involved in reproduction and FSH beta signalling pathways, as well as key molecules with roles in cell adhesion, all of which have essential functions in oocyte development. As for the CCs transcriptome, gene activity at 3 weeks and 9 weeks were found to be similar, suggesting relatively few changes in these vital somatic cells during early life. However, 20 genes were differentially expressed in CCs from 1-year-olds compared to 9 weeks of age, all showing downregulation. Genes displaying altered expression in CCs of older females were involved in organ senescence, cell adhesion and gap junctions.

Limitations, reasons for caution: The study was conducted in mice. While murine follicle biology closely resembles that of humans, it is possible that some differences may exist, reducing the extent to which the results can be extrapolated to our species.

Wider implications of the findings: Whole transcriptome analysis of single oocytes revealed age-related changes in pathways relevant to oocyte viability. Supporting these pathways in-vivo or in-vitro might conceivably mitigate the impact of age on oocyte competence. Altered CCs gene activity suggests that the follicular microenvironment may also contribute to age-associated changes in oocyte competence.

Trial registration number: Not applicable.

P-400 AMH at advanced reproductive age can identify a subset of patients who have comparable IUI and IVF outcomes

K. Shlush[1], **L. Eryuzlu**[2], **C. Librach**[2], **P. Sharma**[2]

[1]Rambam Healthcare Campus, Department of obsterics and gynecology, Haifa, Israel
[2]CReATe Fertility Centre, Department of obsterics and gynecology University of Toronto, toronto, Canada

Study question: Does AMH levels can predict IUI and IVF outcomes among women of advanced reproductive age?

Summary answer: IUI and IVF have similar outcomes among women above 40 years old with higher AMH levels. Women with lower AMH should be referred to IVF.

What is known already: Advanced reproductive age (ARA) is associated with decreased probability of pregnancy after intra uterine insemination (IUI), in vitro fertilization (IVF) and with a reduction in the ovarian reserve. Anti-Müllerian hormone (AMH) is a good indicator of ovarian reserve. However, there is a considerable variation in ovarian reserve among women of ARA. AMH represent ovary biological age however it was suggested that chronological age is more important. Studies reported that women above the age of 40 and low AMH levels have poor outcome from IVF. However it is unclear whether high AMH at ARA is correlated with better pregnancy outcomes.

Study design, size, duration: Retrospective case series analysis of patients with ARA (35 years old and above) from a single center over 6 years (2009-2014).

Participants/materials, setting, methods: AMH and pregnancy outcomes were available for 384 patients. 281 patients underwent 1163 IUI cycles and 93 patients underwent 145 IVF cycles. Clinical pregnancy rates were compared among different age groups and between different AMH levels among the age groups. Male and mechanical factors were excluded.

Main results and the role of chance: Women over the age of 40 with a serum AMH level above 15 pmol/L had 10.2% chance of achieving clinical pregnancy after IUI and 14.3% after IVF (p = 0.54). In the same age group women

with AMH level 8 to 15 pmol/L had 4.76% for clinical pregnancy by IUI and 13.6% by IVF (p = 0.042). Women over the age of 35 with AMH levels greater than 15 pmol/L had 17.36% chance for clinical pregnancy after IUI and 31.94% after IVF (p = 0.006). In the same age group women with AMH level 8 to 15 pmol/L had 8.48% for clinical pregnancy by IUI and 23.3% by IVF (p = 0.001).

Limitations, reasons for caution: Prospective studies are needed to confirm these results.

Wider implications of the findings: Pregnancy outcomes among women 40 years old and above with AMH level greater than 15 pmol/L are similar between IUI and IVF. Therefore, for women in this group it might reasonable to recommend IUI treatment as a first choice. However for other groups IVF should be first treatment choice.

Trial registration number: not applicable.

P-401 Evaluation the clinical and oocyte morphology parameters which may predict the fertilization failure in young poor responder patients

G. Oner, Y. Sahin, C. Pirkevi, S. Kahraman

Istanbul Memorial Hospital, ART and Reproductive Genetics Unit, Istanbul, Turkey

Study question: Are there any predictive clinical and oocyte morphology parameters for the determination of the fertilization failure in young poor responder (POR) patients?

Summary answer: The number of oocyte–cumulus complex (COC) and Metaphase-II (MII) oocyte, and oocyte morphology may predict the fertilization failure in young POR patients.

What is known already: The ESHRE consensus criteria define a poor ovarian response (POR) as less than four oocytes retrieved. Advanced female age and severe sperm disorder were associated fertilization failure after intracytoplasmic sperm injection (ICSI). Also, oocyte quality is pivotal to determine the fertilization of the oocyte. Hence there is no study to evaluate the factors that affects fertilization after ICSI in young poor responder patients where advanced female age and severe male infertility are excluded.

Study design, size, duration: In this retrospective case-control study, we analyzed poor responder patients younger than 38 years old, including 87 patients with total fertilization failure (group 1) and 132 controls with normal fertilization (group 2) in 2-year period (2015-2016). Patients who have the POR criteria according to MII oocytes lower than 4 were included in the analysis.

Participants/materials, setting, methods: Mean age, body mass index (BMI), AMH levels, day-2 FSH and E2, duration of infertility, LH and E2 levels on hCG administration day, duration of stimulation, total dose of gonadotropins used, number of previous trials, COCs, and MII oocytes were examined and compared between the groups. Sperm concentration under 5 x 10^6 mL was not included to exclude severe male factor. Oocyte morphological evaluation were performed for each patient.

Main results and the role of chance: Characteristics of the groups were similar. Number of COC and MII oocytes, and E2 levels on hCG day were lower in fertilization failure group (Table 1). Smooth endoplasmic reticulum (SER) clusters were significantly higher in fertilization failure group (Table 2).

Table 1. Characteristics of the groups.

	Fertilization failure group	Controls with fertilization	P
Number of patients	85	132	
Age	33,2 ± 3,4	32,8 ± 3,4	0,32
BMI	24,6 ± 3,9	23,6 ± 4,4	0,08
Duration of infertility	4,8 ± 4,2	4,0 ± 3,0	0,13
D2 FSH	10,4 ± 4,1	9,4 ± 3,0	0,09
D2 E2	46,6 ± 32,1	51,6 ± 32,2	0,34

Continued

Continued

	Fertilization failure group	Controls with fertilization	P
AMH	$0,78 \pm 0,9$	$0,99 \pm 1,2$	0,34
LH level on HCG day	$4,6 \pm 4,0$	$3,8 \pm 3,1$	0,15
E2 level on HCG day	$\mathbf{631 \pm 582,6}$	$\mathbf{798,9 \pm 535,3}$	**0,03**
No of COCs	$\mathbf{2,1 \pm 2,1}$	$\mathbf{3,5 \pm 2,1}$	**0,0001**
No of MII Oocytes	$\mathbf{1,2 \pm 0,5}$	$\mathbf{2,3 \pm 0,7}$	**0,0001**
Total dose of gonadotropins used (IU)	$2027,9 \pm 1573,4$	$1852,8 \pm 1180,5$	0,35
Duration of Stimulation (days)	$7,3 \pm 2,9$	$7,5 \pm 2,1$	0,58

Table 2.

	Fertilization failure group	Controls with fertilization	P
Dark cytoplasm or severe cytoplasmic granulation	111/407 % 27	33/187 % 17	0.16
Smooth endoplasmic reticulum clusters	**32/407 % 8**	**6/187 % 3**	**0.03**
Oval shape oocytes	12/407 %3	2/187 % 1	0.23
Large polar body shape	7/347 % 2	1/186 % 1	0.59
Increased perivitellin space	161/347 % 46	104/186 % 55	0.051

Limitations, reasons for caution: The study is limited by its retrospective nature. A higher sample size or a prospective randomized design might be used in the future studies to corroborate the current findings.

Wider implications of the findings: Our results showed that the number of COCs, MII oocytes and E2 levels on hCG day were lower in fertilization failure patients. In addition to the clinical parameters, the presence of the smooth endoplasmic reticulum clusters might be the useful parameters for prediction of fertilization failure in young POR patients.

Trial registration number: not applicable.

P-402   Inhibition of CXCL5-CXCR2 signaling improves the implantation of aging embryos for pregnancy

Y. Kawagoe[1], I. Kawashima[2], Y. Sato[2], N. Okamoto[2], K. Matsubara[3], K. Kawamura[2]

[1]St. Marianna University School of Medicine, Reproduction and infertility center, Kawasaki- Kanagawa, Japan
[2]St-Marianna University School of Medicine, Obstetrics and Gynecology, Kanagawa, Japan
[3]Iwate University, The United Graduate School of Agricultural Science, Iwate, Japan

Study question: Is defective cell signaling involved in the decline of embryo quality during aging?

Summary answer: Inhibition of CXCL5-CXCR2 signaling during culture of preimplantation embryos improves implantation of aging embryos, leading to successful pregnancies.

What is known already: Embryo quality declines with age due to dysfunction of mitochondria and intracellular organelles and increases in DNA damage induced by accumulation of oxidative stress and chronic inflammation. Such embryos have a low potential to implant and exhibit high proportion of miscarriage, even if the embryos showed good morphology. Despite many attempts, there is no established method to improve pregnancy rates in aging women.

Study design, size, duration: This laboratory-based observational study sampled surplus human blastocysts with same morphological grading from IVF patients in two different age groups: young: 25-27 years of age (n = 3) and aging: 39-45 years of age (n = 5), together with preimplantation embryos and serum samples from young (3-6 weeks of age) and aging (43-50 weeks of age) mice. We investigated differential cell signaling related to aging-associated decline of embryo quality.

Participants/materials, setting, methods: Human blastocysts were subjected to DNA microarray analyses to identify cell signaling factors associated with aging-induced decline in embryo implantation success. Mouse zygote cultures following blastocyst transfer were performed to assess the roles of candidate factors following treatment with candidate ligands, neutralizing antibodies to the ligand, and specific receptor antagonists. The expression of candidate factors and their cognate receptors were measured using real-time RT-qPCR. Serum levels of candidate factors were determined by ELISA.

Main results and the role of chance: In aging human blastocysts, 3,789 genes showed >5-fold increases as compared with young group. Among these genes, C-X-C motif chemokine 5 (CXCL5) showed 203-fold increases in aging embryos. In mouse embryos, the expression of CXCL5 was also increased during aging, whereas the expression of its cognate receptor, CXCR2 showed no change. Although IL8 and CXCL1 also bind CXCR2, their expressions were low and not increased by age. The expressions of both CXCL5 and CXCR2 were low in aging oviducts and uterus. However, CXCL5 expression was increased in aging lung, liver, spleen, and ovary, resulting in 1.7-fold increase in serum CXCL5 levels in aging mice, suggesting that CXCL5 could act on embryos via autocrine and paracrine manner in vivo. Although treatment of aging mouse two-cell stage embryos with CXCL5 neutralizing antibodies and CXCR2 antagonists up to the blastocyst stage did not affect embryo development judged by morphological evaluation, it significantly improved pregnancy success (control: $40.0 \pm 14.1\%$, treatment: $82.1 \pm 10.8\%$, P < 0.01). Conversely, treatment of young mouse zygotic stage embryos with CXCL5 peptide significantly decreased pregnancy success (control: $83.9 \pm 4.5\%$, treatment: $34.4 \pm 9.7\%$, P < 0.01), together with increases in aging markers (p21, p53, IL-6, and PAI-1) in CXCL5 treated blastocysts.

Limitations, reasons for caution: Due to difficulty to obtain sufficient number of human embryos, we investigated biological actions of CXCL5-CXCR2 signaling using mouse embryos and elucidated cellular and molecular changes. Clinical significance of these findings awaits further analyses.

Wider implications of the findings: Results presented here are consistent with chronic inflammation as one of the major causes of embryo aging and support a role of CXCL5-CXCR2 signaling in preimplantation embryos, providing new clues for pharmacological manipulation of aging embryos during culture and assessing embryo quality based on CXCL5 as an aging biomarker.

Trial registration number: Not applicable.

P-403   Clinical evaluation, birth rate and time to conception in women with unexplained recurrent miscarriages

C. Lindén[1], T. Lind[2,3]

[1]Kvinnokliniken, Department of Obstetrics and Gynecology Södersjukhuset, Stockholm, Sweden
[2]Karolinska Institutet, Department of Clinical Science and Education Södersjukhuset, Stockholm, Sweden
[3]Kvinnokliniken, Department Obstetrics and Gynecology Södersjukhuset, Stockholm, Sweden

Study question: What is the live birth rate (LBR) and time to conception in a cohort of women with unexplained recurrent miscarriages?

Summary answer: Half of the women had a child one year after their investigation for unexplained recurrent miscarriage.

What is known already: Recurrent miscarriage (RM), defined as three or more consecutive miscarriages, occur in 1 % of all pregnancies. Age is independently the greatest risk factor for miscarriage. The risk increases from 9% at 20-24 years of age to 50% at 42 years. Previous studies have shown a live birth rate in unexplained RM of 50-80 % Median time to live birth in the subsequent

pregnancy has been 113 weeks. No difference in LBR in subsequent pregnancy between primary, nullipara women, and secondary, women who have child/children before, their unexplained RM has been demonstrated.

Study design, size, duration: A retrospective cohort study of all women (N = 138) who underwent clinical evaluation for recurrent miscarriage at Södersjukhuset, Sweden between January 2012 and December 2014. All women had three or more consecutive miscarriages. Clinical examination were performed but also thyroid function, antiphospholipid syndrome, thrombophilia and chromosomal analyse were analyzed. Data, including time to pregnancy and pregnancy outcome, were collected until January 2017 from our own records and from five other hospitals in Stockholm.

Participants/materials, setting, methods: One hundred women (mean age 34.4 yr, SD 5.4) with unexplained RM were included in the study. 53 women (53%) were defined as primary recurrent miscarriage and 47% as secondary RM. 26 women (26%) received medical treatment. Four per cent of the women became pregnant with ART, the rest conceived naturally. Time to pregnancy was defined as the time between diagnoses of RM until the first day in the menstrual cycle in which conception took place.

Main results and the role of chance: In this study a pregnancy was successfully achieved by 87 women (87 %) and the cumulative live birth was 76 % (n = 76). Eleven women had two children during the study. The median time to pregnancy (TTP) resulting in a live birth was 19 weeks (0-113) and the median time to live birth 57 weeks (24-152). There was no significant difference in life birth rate if you received medical treatment for your unexplained RM or not (p = 0.144). The mean age was higher in the group of women (N = 13) who did not become pregnant (37.5yrs SD 5.6) compared to women who did (33.9yrs SD 5.2) (p = 0.009). No statistical significant difference in pregnancy rate, live birth rate, TTP or time to live birth, were found between women with primary or secondary recurrent miscarriage even though there were a significant age difference between the two groups; 32.9yrs and 36.1yrs (p = 0.001). The included women had a high premature rate of 10%. Time to pregnancy was significantly longer in women who had a premature birth; 44wks (0-98wks) compared to 13wks (0-113wks) (p = 0.002).

Limitations, reasons for caution: There is always a risk of information bias in a retrospective design that include detailed information about the women's ability to become pregnant during the study period. Another limitation is the limited access to information from patient's records.

Wider implications of the findings: Our results demonstrate a high live birth rate after unexplained RM and a short time to pregnancy and live birth. We should be able to counsel women that they have a high chance of child/children in a near future even if they have had unexplained RM.

Trial registration number: not applicable.

P-404   The impact of reproductive age on metabolism and gene expression indices of oocyte quality in germinal staged oocytes

C. Topipat, J. Lu, P. McKeegan, E. Collado Fernandez, J.D. Huntriss, H.M. Picton

Division of Reproduction and Early Development, LICAMM- University of Leeds, Leeds, United Kingdom

Study question: How does reproductive age alter oocyte energy metabolism and the molecular mechanism(s) regulating oocyte maturation and subsequent developmental competence or quality?

Summary answer: Pyruvate and glucose metabolism were significantly (P < 0.05) different in prepubertal vs. adult oocytes. Metabolic differences were associated with altered expression patterns of glycolytic pathway genes.

What is known already: The reproductive ageing process is associated with a deterioration of oocyte quality, which has been confirmed in both natural conception and assisted reproduction treatment. Several studies have linked the non-invasive and invasive measurement of embryo amino acid metabolism to embryo developmental potential and to be predictive of successful treatment. Furthermore, measurement of the embryo and metaphase II oocyte glucose, pyruvate and lactate metabolism have been proposed as determinants of embryo quality. The relevance of energy metabolism to the subsequent developmental competence of immature GV-staged oocytes has yet addressed.

Study design, size, duration: Prepubertal and adult GV sheep oocytes were used as a model to study the impact of reproductive ageing on metabolic and

molecular markers of oocyte quality. Glucose, pyruvate, and lactate metabolism were quantified for 126 prepubertal and 144 adult GV oocytes. Gene expression was evaluated in 6 oocytes/group in relation to the functional assessment of oocyte metabolism using a quantitative real-time PCR array.

Participants/materials, setting, methods: Cumulus enclosed oocytes (CEOs) were harvested from abattoir-derived ovarian tissue from prepubertal and adult animals. CEOs were immediately stripped and the denuded oocytes were individually incubated in microdrops of defined media for 6 hours. Spent culture media were frozen for later carbohydrate metabolism analysis using an established enzyme-linked ultramicrofluorescent assays. For genetic study, individual GV oocytes were snap frozen in RNAGEM buffer before RNA extraction and SMART amplification for analysis by real-time PCR.

Main results and the role of chance: The data demonstrated that carbohydrate metabolism can be used to evaluate quality of GV-staged oocytes. Both glucose and pyruvate utilization showed significant differences between the 2 age groups studied (P = 0.014 and P < 0.0001, respectively) while no significant different was found in lactate production between ages (P = 0.889). Adult GV oocytes consumed more pyruvate and less glucose when compared to prepubertal GV oocytes. The data confirmed that oocytes utilize pyruvate rather than glucose as a major substrate for energy production. Molecular genetic analysis revealed that there were significant differences (P < 0.05) in expression of key genes including those involved in the glycolytic pathway. Increased mRNA expression of SLC2A3, SLC16A1, IGF1R, GSK3B, and PRDX2 was detected in prepubertal GV oocytes when compared to adult oocytes. This data served to both highlight the close link between molecular control mechanisms and the metabolic function of oocytes and shows how these relationships change with reproductive age.

Limitations, reasons for caution: Denudation of CEOs was necessary to facilitate measurement of glucose, pyruvate and lactate metabolism by individual oocytes as the multiple cells in the cumulus compartment would have a major impact on CEO metabolic assessment. Further, the oocyte denudation procedure per se might have impacted on oocyte metabolism and/or gene expression.

Wider implications of the findings: Assessment of energy metabolism is a non-invasive method of determining oocyte and embryo quality. Calibration of oocyte energy metabolism against other more invasive molecular genetic indices of oocyte health may be a useful means to fully characterize the developmental competence of oocytes.

Trial registration number: NA.

P-405   A prospective study comparing the simplified Walking Egg IVF culture system and ICSI in a selected group of patients

W. Ombelet, M. Janssen, I. Van der Auwera, K. Vandenborne, N. Dhont, G. Mestdagh, R. Campo

Genk Institute for Fertility Technology, Department of Obstetrics and Gynaecology, Genk, Belgium

Study question: What are the actual results when using the new simplified IVF procedure, the so-called Walking Egg IVF culture system?

Summary answer: Our results indicate an excellent fertilization rate and ongoing pregnancy rate when using the Walking Egg IVF culture system.

What is known already: The Walking Egg simplified IVF culture system (TWE) was originally developed for resource-poor countries in order to make IVF accessible and affordable for a larger part of the world population. In a previously published pilot clinical trial on a small series of patients it was shown that this method does not compromise fertilisation, embryo development and pregnancy outcome when compared to ICSI or regular IVF.

Study design, size, duration: From January until December 2016 we performed a prospective non-inferiority study comparing ICSI with TWE in a selected group of patients with a least 6 oocytes recovered at oocyte retrieval and an inseminating motile count of more than 0.3 million. Patients eligible for this study were couples requiring IVF as assessed by our standard protocol of infertility evaluation. ICSI was performed on 50 % of eggs; the remaining 50 % were inseminated in TWE.

Participants/materials, setting, methods: 170 ART cycles were started, in 163 an oocyte retrieval was performed. Half of the eggs were treated with ICSI or TWE. The best embryo (s) for transfer were chosen by an independent person who followed the Istanbul criteria. The main outcome result was the

clinical pregnancy rate confirmed with a gestational sac and foetal heartbeat on ultrasonography at 8 weeks of gestation. Secondary outcome measures were the fertilisation rate (FR) and HCG positive cases.

Main results and the role of chance: Out of the 163 cycles no embryo transfer was performed in 18 cases (11 %) due to the absence of a good quality embryo (2 cases) or because of an increased risk for OHSS (16 cases) in which all embryos were cryopreserved. No fertilisation occurred in 8 (4.9 %) TWE cases and in 2 ICSI cases (1.2 %). An embryo transfer took place in all 165 cycles.

The fertilisation rate was 64 % for TWE, excluding the cases with no fertilisation the FR was 70.8 %. The FR of metaphase II oocytes by ICSI was 71.2 %.

In 56.5 % of cases (82/145) the transferred embryo(s) were the result of TWE, in 43.5 % the ICSI embryo(s) were transferred. Singe embryo transfer was performed in 60/82 (73.2 %) TWE cycles and in 44/63 (69.8 %) ICSI cycles. In the remaining cases a double embryo transfer took place.

HCG positive cases were noted in 46.3 % and 39.6 % of TWE and ICSI cases respectively. The CPR was 32.9 % (27/82) for TWE and 31.7 % (20/63) for ICSI, the difference was statistically not significant.

Limitations, reasons for caution: Our study results should be confirmed in other infertility centres. We have to consider that it was a selected group of patients with at least 6 eggs at oocyte retrieval. The value of TWE has to be confirmed in poor responder cases, and by using mild ovarian stimulation protocols.

Wider implications of the findings: According to our results the Walking Egg simplified culture system is equally effective compared to ICSI in a selected group of patients, even in moderate to severe male infertility cases. TWE can be used as a high quality but less expensive ART method when compared to regular IVF or ICSI.

Trial registration number: Not applicable.

P-406   Trends and reproductive outcomes of double gamete embryo donations: An analysis of a national data registry

N. Massiah[1], K. Pearce[2], M. Choudhary[1]

[1]Newcastle Fertility Centre at Life, Newcastle Fertility Centre, Newcastle upon Tyne, United Kingdom
[2]Newcastle University, Institute of Cellular Medicine, Newcastle Upon Tyne, United Kingdom

Study question: What are the trends and reproductive outcomes of fresh and frozen double gamete embryo donation cycles in UK?

Summary answer: Double gamete embryo donations have risen 13 fold with fresh donations resulting in higher live birth rate than frozen donations but with poorer reproductive outcomes.

What is known already: Reproductive options using double gamete donations are increasingly considered for single women, infertile couples needing both donor gametes and same sex couples. There is a shortage of egg and sperm donors in UK. Frozen embryos donated for the treatment of others, can be a useful resource but little is known about their utilisation in the UK. There is limited research on the reproductive outcomes of double gamete donations. Human Fertilisation Embryology authority (HFEA) regulates assisted conception treatments in UK and maintains an online anonymised data registry that is a helpful resource to analyse national data.

Study design, size, duration: This is a retrospective cohort study analysing all double gamete embryo donation cycles on the UK's anonymised national HFEA register between 1991 and 2012. There were 4486 double gamete embryo donation cycles of which 2058 (45.9%) were fresh and 2428 (54.1%) were frozen.

Participants/materials, setting, methods: Data was extracted from HFEA's registry for all women who underwent fresh or frozen double gamete donation cycles in UK over two decades. The reproductive outcome measures were live birth rate, miscarriage rate, multiple pregnancy, low birth weight and preterm birth in singleton pregnancies. Descriptive statistics and chi square statistic were used for statistical analysis with SPSS statistical software version 24. Statistical significance was p<0.05.

Main results and the role of chance: The fresh to frozen double gamete embryo donations ratio was 1:1 with a 13 fold increase seen over two decades

(16-fold for fresh and 9-fold for frozen). The mean ($\pm$ SD) number of embryos transferred was similar in both groups (fresh 0.955 $\pm$ 0.83 vs frozen 0.958 $\pm$ 0.83). Most recipients (56.9%) were 40-50 years old with fresh embryo donations more likely in women aged >42 years whilst frozen embryo donations were more likely in women $\leq$ 42 years (p<0.001). Fresh embryo donations resulted in higher live birth rate (fresh 31.8%, frozen 19.1%; p 0.027) and lower miscarriage rate (fresh 0.0%, frozen 2.8%; p <0.001) than frozen embryo donations. However, fresh embryo donations were associated with a higher risk of low birth weight (fresh 11.4%, frozen 5.5%; p 0.002) and prematurity (fresh 32.3%, frozen 27.3%; p 0.01) in singleton pregnancies. Multiple pregnancies were also significantly higher amongst fresh embryo donations (fresh 11.3%, frozen 3.5%; p 0.033). Congenital abnormalities were higher among fresh than frozen transfers but this was not significant (fresh 1.7%, frozen 0.7%; p 0.431). Removal of donor anonymity in 2005 did not affect the number of fresh embryo donations (p 0.056) or frozen embryo donations (p 0.094).

Limitations, reasons for caution: Potential confounders such as smoking that affect live birth rate could not be accounted for because that information was not recorded on the HFEA database. It was not possible to report cumulative live birth rate per woman because of the anonymised nature of the data.

Wider implications of the findings: This study showcases the rising need for double gamete donation as a reproductive option. Acute shortage of gamete donors in UK may warrant looking at alternative strategies such as the use of embryo donation. Creating awareness and appropriate information provision may help donors and recipients to make an informed decision.

Trial registration number: Not applicable.

P-407   Role of latent female genital tuberculosis in unexplained infertility in the Indian subcontinent

K. Pasricha[1], S. Pasricha[2], S. Pasricha[2]

[1]Shivam Fertility & IVF Centre, Jalandhar City, India
[2]Shivam Fertility & IVF Centre, Obstetrics & Gynaecology, Jalandhar City, India

Study question: To assess the outcome of cases of unexplained female infertility or recurrent implantation failure following anti-tubercular treatment

Summary answer: Early Institution of anti-tubercular therapy restores fertility in a major proportion of cases.

What is known already: Infertility is the commonest symptom associated with genital tuberculosis and it seems to be an important under-diagnosed factor in infertility. Clinical presentation of this disease in the female reproductive tract is protean in nature and a vast majority of patients could be completely silent. There is no consensus in giving anti-tubercular treatment based on clinical suspicion, in absence of clear diagnostic criteria. With advent and acceptance of Tuberculosis-Polymerase Chain Reaction (TB-PCR), a large number of infertile patients are being detected with latent or sub-clinical infection.

Study design, size, duration: It was a longitudinal observational study conducted at an infertility centre in India over seven years (2010-2016). After detailed history and investigations, patients with unexplained infertility were included in the study. Those with other known causes of infertility were excluded. Enrolled cases were tested by multiplex polymerase chain reaction for confirming evidence of latent genital tuberculosis. The patients with positive TB-PCR received standard anti-tubercular therapy after reconfirming the test results.

Participants/materials, setting, methods: The participants in the study with positive TB-PCR test received standard nine months anti-tubercular treatment. The patients who completed the treatment were followed up for conception following treatment completion. The overall conception rate and conception rate within 6 months of completion of anti-tubercular treatment was studied.

Main results and the role of chance: A total of 757 patients were enrolled over the study duration. Of these, 576 (76.09%) were found to be positive for latent genital tuberculosis with multiplex TB-PCR test. After giving anti-tubercular therapy for 9 months, 224 (38.89%) of these 576 patients conceived. Of the 224 patients who conceived, 150 (66.96%) conceived within 6 months of completion of treatment.

Limitations, reasons for caution: False positive results with TB-PCR do occur and the result has to be correlated clinically. Any doubt in the interpretation of result warrants a repeat test.

Wider implications of the findings: The results of this study can have a bearing on many patients of unexplained infertility who have been extensively investigated without a good outcome. A treatable infection, tuberculosis, if diagnosed and treated early can result in restoration of fertility and pregnancy with relatively less economic burden.

Trial registration number: not applicable.

P-408 Is it the ratio of exogenous LH and FSH administered for in vitro reproduction important for the treatment outcome?

D. Albu[1], A. Albu[2]

[1]Medlife Hospital- UMF Carol Davila, Maternalfetal and Reproductive medicine, Bucharest, Romania
[2]UMF Carol Davila- Elias Emergency Hospital- Medlife, Endocrinology, Bucharest, Romania

Study question: Is it the ratio of the exogenous LH to exogenous FSH administrated during ovarian stimulation for in vitro reproduction (IVF) important for improving the treatment outcome?

Summary answer: Exogenous LH/FSH ratio, independent of age and AMH, was positively correlated with the number of oocytes and embryos, that independently predicted the clinical pregnancy rate.

What is known already: It was previously suggested that the addition of exogenous LH to exogenous FSH during ovarian stimulation for IVF could improve the pregnancy rate, probably attenuating the increase of the late follicular progesterone level, which could impair the endometrial receptivity. The sweet spot ratio between exogenous FSH and LH it seemed to be 0.30-0.60. There are studies corelating the premature rise of woman serum progesterone during ovarian stimulation for IVF with this FSH/ LH ratio.

Study design, size, duration: We conducted a retrospective study in the department of reproductive medicine of a private hospital. 912 consecutive patients with all causes fertility (mean age $34,65 \pm 4,29$ years) underwent conventional IVF or ICSI between January 2013 – December 2016. We used the same culture system and a maximum of three embryos were transferred. Only one clinician established the ovarian stimulation protocol for each case in particular according with age, history, BMI, AMH and AFC.

Participants/materials, setting, methods: Reproductive outcome was evaluated by oocytes and embryos number and clinical pregnancies rate. Controlled ovarian hyperstimulation was performed using mixt protocols (human menopausal gonadotropin in association with recFollitropinum alpha or beta) The ratio between exogenous LH and FSH was calculated based on total dose of each medication. SPSS 13 was use for statistics.

Main results and the role of chance: We found that the oocytes and embryos number were negatively correlated with age, total FSH and total LH dose and positively correlated with AMH values. In turn LH/FSH ratios was positively correlated with oocytes ($r = 0.41$, $p < 0.0001$) and embryos number ($r = 0.22$, $p < 0.0001$). In multivariate regression model total LH and total FSH doses were independent negative predictors of oocytes and embryos numbers after adjustment for age and AMH. However, the LH/FSH ratio was positively and independently associated with oocytes (beta $= 0.235$, $p < 0.0001$) and embryos number (beta $= 0.109$, $p = 0.004$) after adjustment for age and AMH value. Although LH/FSH ratio was higher in patients who obtained pregnancy in comparison to those without pregnancy, after adjustment for covariates only age and oocytes/embryos number independently predicted clinical pregnancy.

Limitations, reasons for caution: Our results need to be evaluated in a prospective study including subgroups of patients according to age. We used in our study exogenous LH from human menopausal gonadotropin (HMG) which is completely different pharmacokinetic from recombinant LH, which it will be interesting to study separately.

Wider implications of the findings: Our data suggests that the clinician could influence the clinical outcome in IVF, by using a certained ratio of exogenous FSH/LH. This exogenous LH activity of HMG, probably determine the thecal conversion of progesterone to androgens precursors, avoiding late follicular progesterone rise that could impair endometrial receptivity.

Trial registration number: Not applicable.

P-409 Obstetric management of women who conceive following IVF: a systematic review of the more controversial aspects

Y. Jeve[1], T. Gelbaya[2], L. Nardo[3]

[1]University Hospitals of Leicester NHS rust, obgy, LEICESTER, United Kingdom
[2]University Hospital Leicester, Gynaecology, Leicester, United Kingdom
[3]Reproductive Health Group UK, Reproductive Medicine, Daresbury, United Kingdom

Study question: The aim of this systematic review is to formulate evidence based obstetric management strategy for women who conceive following IVF.

Summary answer: Women who conceive following assisted conception are at risk of obstetric complications should have high risk consultant-led individualised care during pregnancy to optimise pregnancy outcome.

What is known already: Pregnancy as a result of IVF or ICSI is associated with an increased incidence of several obstetrical and perinatal complications. It could be due to maternal and paternal characteristics, underlying medical conditions associated with subfertility and infertility, the use of fertility medications, sperm factors, laboratory conditions, culture medium, cryopreservation and thawing, prenatal genetic diagnosis, multiple gestations or a combination of these factors. Difference in obstetric management strategies is a significant factor contributing the outcome. This systematic review is aimed to provide evidence based obstetric management plan for controversial aspects.

Study design, size, duration: Evidence synthesis was done by performing a systematic literature search using Medline (1980-Aug 2016), Embase (1980-Aug 2016) and The Cochrane Library (Aug 2016) for relevant citations. Two reviewers independently reviewed the papers. Total, 394 citations were included in this study. Quality assessment analysis was performed using Newcastle-Ottawa scale.

Participants/materials, setting, methods: All studies comparing various obstetric interventions and surveillance strategies to reduce perinatal complications in IVF and ICSI pregnancies with a predefined control group for comparison were included. Primary outcome measure was neonatal morbidity and mortality. Secondary outcome measures were maternal morbidity including preeclampsia, risk of caesarean section, and development of gestational diabetes, placental insufficiency, and preterm delivery.

Main results and the role of chance: The risk of developing perinatal complications is significantly higher in the IVF conception. However we found paucity of evidence derived from interventional studies to reduce these risks. Based on current literature, obstetric management was subdivided into a) Pre pregnancy optimization, b) First trimester c) second trimester d) third trimester and e) postpartum. We reviewed 23 citations for calculating expected date of delivery, 42 citations to study role of induction of labour and 28 citations for growth scan. The risk of perinatal mortality was high with IVF (OR 1.87, CI 1.48-2.37). IVF conception was associated with two-fold increased risk of preterm birth and low birth weight in singleton pregnancies. The chances of induction of labour (OR 1.5, 95% CI 1.3-1.6) are high with IVF conception. In absence of consensus, it would be a good practice to establish the expected date of delivery based on embryo age and date of transfer. The risk of hypertensive disorders with donor egg is significantly high (OR 3.92; CI 3.21-4.78), therefore low dose aspirin could be used as primary prevention. In absence of evidence, use of serial growth scans and routine induction of labour at term should be weighed against benefits. Obstetric management should be personalised.

Limitations, reasons for caution: Evidence synthesis is mainly based upon prospective observational studies. Some heterogeneity between studies was observed. Only published data was included in the review.

Wider implications of the findings: IVF or ICSI conception should be treated as an independent risk factor for various pregnancy complications. Couples should be counseled carefully about the risks before treatment and antenatal visits. Appropriate surveillance strategies should be in place. IVF or ICSI pregnancies should be treated in standardised way to optimise perinatal outcome.

Trial registration number: na.

P-410 Influence of body mass index on the relationship between endometrial thickness and pregnancy outcome in frozen blastocyst embryo cycles

D. Crosby, Y. O'Brien, L. Glover, F. Martyn, M. Wingfield

Merrion Fertility Clinic, National Maternity Hospital, Dublin, Ireland

Study question: Is there a positive correlation between endometrial thickness (ET) and body mass index (BMI), and does this impact pregnancy outcome?

Summary answer: BMI correlates significantly with ET. ET < 8 mm does not compromise pregnancy outcome in women with lower BMI, but may do so in those with higher BMI.

What is known already: Endometrial thickness (ET) has been shown to significantly affect clinical pregnancy and live birth rates in FET cycles, particularly those with ET < 8 mm (El Toukhy et al. Fertil Steril 2008). Rates of obesity are rising worldwide and it is known that success rates for all pregnancy outcomes in fresh IVF cycles are most favourable in cohorts with low and normal BMIs and progressively worsen as BMI increases (Provost et al. Fertil Steril 2016). However, there is limited data in the literature assessing whether BMI has an impact on ET and whether this impacts on pregnancy outcomes in blastocyst FET cycles.

Study design, size, duration: Retrospective analysis of data regarding FET cycles, prospectively entered into a computerised database over a 5 year period from 2012 until 2016 inclusive in our unit.

Participants/materials, setting, methods: All FET cycles with blastocyst transfer were included. Patient age, BMI, BMI category (underweight, normal weight, overweight, obese: WHO), use of hormone replacement therapy, ET prior to FET and number of embryos transferred were studied. Pregnancy outcomes included: positive pregnancy test rate, clinical pregnancy rate (ultrasound evidence of pregnancy:ESHRE) and livebirth rate per embryo transfer. We excluded women with a very difficult transfer. Data was analysed using one-way ANOVA, Chi-Squared and Pearson correlation.

Main results and the role of chance: During the 5 years, 560 FET cycles met the inclusion criteria. The mean age was 36.2 years (SD 3.0). 88.9% (n = 498) used HRT. 12.3% (n = 83) had two embryos transferred, the remainder had one. The mean BMI was $23.4 \, kg/m^2$ (SD 3.1) and mean ET was 8.6 mm (SD 1.6). Overall, 54.1% (n = 303) had a positive pregnancy test, 36.3% (n = 203) had a clinical pregnancy and 26.4% (n = 148) had a live birth.

Mean ET increased with increasing BMI category (7.2 mm, 8.4 mm, 8.9 mm, 9.7 mm; p < 0.0001). Despite this, there were no differences between BMI groups in positive pregnancy test, clinical pregnancy or live birth rates.

There were significant positive correlations between increasing BMI and ET on positive pregnancy test, clinical pregnancy and live birth rates (r = 0.243 (p<0.0001); r=0.241 (p = 0.001); r=0.197 (p = 0.017)).

Pregnancy outcomes for ET<8 mm were compared with ET≥8 mm for BMI<25 kg/m^2 and ≥25 kg/m^2. There was a trend for a lower rate of positive pregnancy test in women with BMI≥25 kg/m^2 and ET<8 mm when compared with ET≥8 mm (50.0% vs. 60.6%;p = 0.19). However, this difference was lost in rates of clinical pregnancy (34.3% vs. 37.6%;p = 0.62) and live birth in this cohort (26.2% vs 26.6%;p = 1.00). In those with BMI<25 kg/m^2 there was no reduction in any oucome when ET was <8 mm.

Limitations, reasons for caution: Our clinic policy of optimising BMI prior to FET treatment means that very few patients were outside the extremes of BMI. Embryos did not undergo pre-implantation genetic screening. Ultrasound scanning may have been subject to inter-observer bias in measurement of ET.

Wider implications of the findings: Individual BMI should be taken into consideration when deciding on optimal ET for embryo transfer. ET < 8 mm may not jeopardise pregnancy outcome in women with BMI <25 kg/m^2. The development of a norm referenced test for BMI and ET may prove to be a helpful adjunct in clinical IVF setting.

Trial registration number: Not applicable.

[4]University of Aberdeen, Institute of Applied Health Sciences, Aberdeen, United Kingdom
[5]University of Adelaide, Robinson Research Institute, Adelaide, Australia

Study question: How do the predicted chances of live birth change over time in couples with unexplained subfertility accounting for different fertility treatments?

Summary answer: Average chance of pregnancy (leading to live birth) within six months without treatment is 14% at three months post-fertility clinic registration (10% at twelve months).

What is known already: Couples who experience fertility problems but who have no absolute barrier to conception (unexplained infertility) can get pregnant naturally making it difficult for clinicians to decide when to commence active treatment and what that treatment should be. The use of assisted reproductive technology continues to increase and as healthcare costs rise it is important that fertility care is used appropriately. Our aim was to dynamically predict live birth whilst accounting for the commencement of fertility treatment in couples with unexplained subfertility.

Study design, size, duration: In this retrospective cohort study, a record-linked population based database containing fertility diagnosis, treatment and outcome information from 1,521 couples with unexplained subfertility was developed and analysed. Couples from the Grampian region of Scotland who were referred to a single fertility clinic in Aberdeen between 1998 and 2011 were included.

Participants/materials, setting, methods: Dynamic prediction using a land-marking approach was used to predict a pregnancy (leading to a live birth) within six months after registration at the fertility clinic. Prognosis was then updated monthly from three months post-registration up to 24 months. Predictors included female age, duration of infertility, and initiation of fertility treatment (clomifene, intra-uterine insemination (IUI) or in-vitro fertilisation (IVF)), the latter as a time-varying covariate.

Main results and the role of chance: Out of 1521 women with unexplained subfertility, 889 (58%) women did not need/receive any fertility treatment during follow-up. A total of 911 (60%) achieved a pregnancy leading to live birth over a maximum of 14 years, of which 640 (70%) were treatment independent pregnancies. In couples with a previous pregnancy, couples treated with superovulation and IUI had a higher chance of a live birth over 6 months (Hazard ratio (95% CI) =2.51 (1.47 to 4.30); for IVF HR=1.53 (0.82 to 2.85)) compared to those who were untreated. In couples with no previous pregnancy, those treated with IVF had almost twice the chance of a live birth compared with couples receiving expectant management (HR=1.93 (1.26 to 2.95). Empirical clomifene with treatment had no beneficial effect. Three months after registration at the fertility clinic, a 30 year-old with two years of primary subfertility has a 20% chance of becoming pregnant over the next 6 months (leading to live birth) without treatment. Her probability would increase to 41% if she started IVF at three months (37% with superovulation and IUI, 29% with clomifene). Twelve months after registration these chances decrease to 15%, 30%, 26% and 21% respectively.

Limitations, reasons for caution: This study was conducted using single centre data and may not be generalizable to other centres. We were unable to adjust for potential predictors including ethnicity and antral follicle count.

Wider implications of the findings: In women with secondary infertility our results show that IUI treatment is effective. For those with primary infertility, IVF can result in higher chances of success over the next 6 months compared to expectant management.

Trial registration number: not applicable.

P-411 A dynamic approach to estimating the chances of a live birth in couples with unexplained subfertility with and without treatment: a population-based record-linkage study

Study question: We examined a large multi-centre data set to investigate the value of AMH levels in predicting clinically usable embryos and ongoing pregnancy.

Summary answer: The relationship between AMH levels and clinically usable embryos or ongoing pregnancy rates is not linear and depends on the AMH level ranges.

What is known already: AMH is a useful marker of quantitative aspects of ovarian reserve and response to ovarian stimulation; however, no large-scale studies have investigated the relationship between AMH levels and metrics related to oocyte quality such as number of clinically usable embryos or ongoing pregnancies. Therefore, we analyzed a large multi-centre data set to investigate AMH's predictive value for these outcomes.

Study design, size, duration: We performed a retrospective cohort study on 15,788 patients undergoing IVF at 13 centres in the United States (2010-2016). We included each patient's first IVF retrieval and excluded cycles using cleavage stage embryos or preimplantation genetic screening (PGS). Ongoing pregnancy analysis (defined by fetal heartbeat upon discharge to obstetrician) included fresh single or double embryo transfer cycles. Clinically usable embryos included transferred and cryopreserved embryos in each retrieval cycle.

Participants/materials, setting, methods: To investigate the relationship between AMH levels and usable embryos, we performed Poisson regression using piecewise-cubic splines to capture non-linear relationships. We performed logistic regression using piecewise-cubic splines on AMH levels and ongoing pregnancy. Each model controlled for age groups (<35, 35-37, 38-40, 41-42, >42 years) and the model of ongoing pregnancy controlled for number of embryos transferred. Because of sample size, analysis of AMH levels exceeding 5 ng/mL only included patients under 41 years.

Main results and the role of chance: When we controlled for patient age, we found that AMH levels were correlated with both clinically usable embryos and ongoing pregnancy in a non-linear manner (p<0.0001). While patient age was also a significant predictor of both outcomes, there was no interaction between age and AMH levels.

As AMH levels increase, the number of usable embryos predicted increases at varying rates: for an AMH level increase from 0 to 1 ng/mL, the predicted number of usable embryos increases by ~0.4; for an AMH level increase from 1 to 5 ng/mL, the predicted number increases by ~1; and for an AMH level increase from 5 to 10 ng/mL, the predicted number increases by ~0.2.

In contrast, the relationship between AMH levels and the likelihood of ongoing pregnancy exhibited a different non-linear curve. While we also observed that the likelihood of pregnancy rose with increasing AMH levels, the relationship was mainly limited to AMH levels between 0.5-3 ng/mL: likelihood of pregnancy increases by 6-7% as AMH levels increase from 0.5 to 3 ng/mL. Interestingly, for AMH levels >3 ng/mL, predictions were observed to plateau, with no additional increase in the likelihood of pregnancy, despite the number of useable embryos predicted being higher.

Limitations, reasons for caution: Analysis was performed across multiple centers and included measurements from multiple laboratories. Our study excluded PGS cycles, which are becoming more routine in the United States. The impact of this and other protocol and assay differences on the predictive value of AMH will need to be further tracked.

Wider implications of the findings: Our results show that AMH has value in helping to set patient expectations for IVF outcomes. Although patients with high AMH are predicted to have higher numbers of clinically usable embryos, this outcome does not necessarily translate into higher ongoing pregnancy rates for AMH levels above 3 ng/mL.

Trial registration number: Not applicable.

POSTER VIEWING SESSION
IMPLANTATION AND EARLY PREGNANCY

P-413   HLA-E was involved in the inhibition of NK cell cytotoxicity toward JEG-3 by progesterone

H. Zhongying[1], W. Fan[2], Q. Ma[3], T. Deng[3]

[1]West China Second University Hospital Sichuan University, Department of Obstetrics and Gynecology, Chengdu, China
[2]West China second Hospital- Suchuan University, Department of Obstetrics and Gynecology, chengdu, China
[3]West China 2nd Hospital- Suchuan University, Department of Obstetrics and Gynecology, chengdu, China

Study question: To investigate if HLA-E, one of the MHC-Ib molecules plays a role in the regulation of NK cell cytotoxicity toward trophoblasts by pogesterone.

Summary answer: Progesterone inhibited NK cell cytotoxicity toward trophoblast cell line JEG-3, while the silence of HLA-E expression diminished the inhibitory effect of progesterone.

What is known already: Progesterone was known to play essential roles in maintaining local immune tolerance at the maternal-fetal interface during pregnancy, while the underlying mechanisms are largely unknown. HLA-E, one of the MHC-Ib molecules expressed in trophoblsts, was suggested to be contributed to the establishment of immune tolerance at maternal-fetal interface. In our preliminary study, progesterone was found to inhibit the NK cell cyotoxicity toward trophoblast cell JEG-3. We performed this study to determine if HLA-E plays a role in the regulation of NK cell cytotoxicity toward JEG-3 by progesterone.

Study design, size, duration: In this control study, the JEG-3 cells were divided into 5 groups: the blank control, progesterone treatment, transfection of lentivirus carrying siRNA targeting HLA-E before progesterone treatment, transfection of lentivirus carrying siRNA targeting HLA-E and transfection of the negative control siRNA. Independent experiments were repeated three times with triplicates for each treatment.

Participants/materials, setting, methods: The JEG-3 cells were purchased from Cell Resource Center, IBMS, CAMS/PUMC (China). The expression silence of HLA-E in JEG-3 cells was induced through transfection with the lentivirus carrying siRNA targeting HLA-E. JEG-3 cells were treated as described above and collected as target cells 48 h after different treatments. The NK cells were obtained from peripheral blood mononuclear cells of non-pregnant healthy women. The cyotoxicity of NK cells toward JEG-3 was evaluated using Lactate Dehydrogenase (LDH) assay.

Main results and the role of chance: In this study, we found that progesterone decreased NK cell cytotoxicity toward JEG- 3. The NK cell cyotoxicity against JEG-3 transfected with lentivirus carrying siRNA targeting HLA-E was highly enhanced compared to the controls. Further, Silence of HLA-E expression before progesterone treatment diminished the inhibitory effect of progersterone on NK cell cytotoxicity toward JEG-3. Our data suggested that HLA-E was involved in the inhibition of NK cell cytotoxicity toward JEG-3 by progesterone.

Limitations, reasons for caution: Here JEG-3, an extravillous trophoblast cell model was used as target cells to investigate the regulation of NK cell cytotoxicity. Further studies are needed to determine if HLA-E plays a role in the regulation of NK cell cytotoxicity toward trophoblasts from early gestational placenta.

Wider implications of the findings: HLA-E, although not fully understood, contributes to the immunologic tolerance at maternal-fetal interface. We found that HLA-E was involved in the inhibition of NK cell cytotoxicity toward JEG-3 trophoblast cells by progesterone, which may provide a new clue to investigate the mechanisms of immunologic tolerance at maternal-fetal interface.

Trial registration number: This study was supported by grants from the National Natural Science Foundation of China (81200453), and Science & Technology Department of Sichuan Province (2014SZ0001).

P-414   A prospective study on reproductive outcome following oral antibiotic treatment for chronic endometritis in infertile women with a history of repeated implantation failure

K. Kitaya, H. Matsubayashi, Y. Takaya, K. Yamaguchi, R. Nishiyama, T. Takeuchi, T. Ishikawa

Reproduction Clinic Osaka, IVF Center, Osaka, Japan

Study question: Is antibiotic treatment effective for histopathologic cure of chronic endometritis (CE) and improvement of reproductive outcome in infertile women suffering from repeated implantation failure (RIF)?

Summary answer: Oral antibiotic treatment is a safe and effective therapeutic option to improve the live birth rate in infertile women with RIF/CE.

What is known already: CE is an oligosymptomatic local inflammatory disease characterized by plasmacyte infiltration within the endometrial stromal areas and found in substantial population of infertile women with a history of RIF (14% - 31%) as well as unknown etiology (28%) and recurrent pregnancy loss (9% - 13%). A retrospective study showed that antibiotic treatment significantly improves the reproductive outcome in the subsequent embryo transfer (ET) cycle in women suffering from RIF, but the impact of CE on embryo implantation remains controversial.

Study design, size, duration: Prospective longitudinal study. From November 2011 to July 2014, endometrial biopsy was performed in 421 infertile women with RIF. CE was histopathologically diagnosed using immunohistochemistry. The infertile women with RIF/CE desiring treatment were given a 14-day consecutive administration of oral antibiotic agents. The histopathologic cure of CE was evaluated in the second/third-look endometrial biopsy obtained during the following menstrual cycle. Their reproductive outcome in the subsequent three fresh/cryopreserved-thawed ET cycles was followed-up until March 2016.

Participants/materials, setting, methods: The sections of the paraformaldehyde-fixed paraffin-embedded endometrial biopsy samples were immunostained with a monoclonal antibody against CD138, a specific marker for plasmacytes. Under a light microscope, the immunoreactive cells were enumerated in at least 20 non-overlapping high-power fields within the stromal areas. The endometrial stromal plasmacyte density index (ESPDI) was calculated as the sum of the CD138+ cell counts divided by the number of the high-power fields evaluated. CE was diagnosed as ESPDI ≥ 0.25.

Main results and the role of chance: CE was identified in 142 out of 421 (33.7%) infertile women with a history of RIF. Oral doxycycline was finally administered to 118 women with RIF/CE (83.1%). The histopathologic cure rate of CE in the second-look endometrial biopsy was 92.3%. Meanwhile, nine women resistant to doxycycline in the RIF/CE group were further treated with a combination of oral metronidazole and ciprofloxacin hydrochloride. The overall cure rate following two-step oral antibiotic treatment strategy was 99.1%. The cumulative clinical pregnancy rate up to three ET cycles (p = 0.032, RR 1.34, 95%CI 1.02-1.76) was significantly higher in the cured RIF/CE group (45.7%) than in the RIF/non-CE group (34.1%). The miscarriage rate in the first ET cycle (p = 0.96, RR 0.97, 95%CI 0.34-2.79) and cumulative three ET cycles (p = 0.73, RR 0.87, 95%CI 0.38-1.94) was similar between the cured RIF/CE group (4.3% and 6.9%, respectively) and RIF/non-CE group (4.4% and 8.0%, respectively). The live birth rate in the first ET cycle (p = 0.031, RR 1.48, 95%CI 1.03-2.12) and cumulative three ET cycles (p = 0.037, RR 1.39, 95%CI 1.02-1.90) was significantly higher in the cured RIF/CE group (32.8% and 38.8%, respectively) than in the RIF/non-CE group (22.1% and 27.9%, respectively).

Limitations, reasons for caution: The limitation of this study is that the design is not a randomized controlled trial. A potential bias is that compared with the RIF/non-CE group, the RIF/CE group underwent more endometrial biopsy, which potentially affected the reproductive outcome in the RIF/CE group via its endometrial scratching effect.

Wider implications of the findings: In this prospective study, we found CE in about one-third of infertile women with a history of RIF. The histopathologic cure rate and live birth rate in the fresh/cryopreserved-thawed ET cycles following oral antibiotic treatment are encouraging in patients with RIF/CE. Randomized controlled trials are required to confirm these results.

Trial registration number: UMIN-CTR 000006536

P-415   The effect of endometrial scratch on implantation and pregnancy rate for patients undergoing natural-cycle frozen-thawed embryo transfer: a randomized study

S.M.J. Mak, C.H.S. Chung, J.P.W. Chung, G.W.S. Kong, L.P. Cheung, T.C. Li

The Chinese University of Hong Kong, Obstetrics & Gynaecology, Hong Kong, Hong Kong

Study question: Can endometrial scratch (ES) improve the implantation and pregnancy rate for patients undergoing natural-cycle frozen-thawed embryo transfer (FET)?

Summary answer: Endometrial scratch does not have any beneficial effect on an unselected group of women undergoing FET in natural cycles.

What is known already: A recent Cochrane review included 14 RCTs concluded a favourable effect of ES with an increased clinical pregnancy rate based on polled results from 13 RCTs including 1972 women and an increase in live birth or ongoing pregnancy rate from 9 RCTs including 1496 women (Nastri et al. 2015). Whilst the studies included in the Cochrane review were based on fresh ET cycles, there have been 3 studies examining the impact of ES in FET cycles (Dunne and Taylor 2014, Aflatoonian et al. 2016, Kanazawa et al. 2016) but they were mostly HRT-FET and each of them presented different results.

Study design, size, duration: This is a prospective double-blind randomized control study conducted among patients who were scheduled for FET cycles using non-donor oocytes in the Assisted Reproductive Unit, the tertiary referral centre affiliated with the Department of Obstetrics and Gynecology, The Chinese University of Hong Kong, during the period of March 2013 to April 2016.

Participants/materials, setting, methods: Women who were suitable for natural-cycle FET were recruited. Patients who had uterine anomaly or pathology such as endometrial polyp, endometriomas >4 cm and hydrosalpinx were excluded. A total of 299 patients were randomized to receive endometrial scratch (n = 115) or endocervical manipulation as control (n = 114), and 196 patients had embryo transfers (93 patients in each group). Endometrial scratch or endocervical manipulation would be performed at the mid-luteal phase of preceding menstrual cycle before FET.

Main results and the role of chance: Our study showed no significant difference in the implantation (ES group 36.5% versus control group 32%, P = 0.458; RR 1.143, 95% CI 0.802-1.627) and pregnancy rate (ES group 48.4% versus control group 40.3%, P = 0.462; RR 1.125, 95% CI 0.822-1.540), as well as the clinical implantation (ES group 41.9% versus control group 37.6%, P = 0.549; RR 1.114, 95% CI 0.782-1.588) and ongoing pregnancy rates implantation (ES group 34.4% versus control group 32.3%, P = 0.756; RR 1.067, 95% CI 0.710-1.602) between the two groups.

Limitations, reasons for caution: Our study included patients with variable numbers of previous IVF or ET attempts, while it is recognised that ES is more likely to have beneficial effect in women with 2 or more ET failures, subgroup analysis of our cases would inevitably lacks sufficient power to draw any conclusion.

Wider implications of the findings: This is the first RCT to evaluate the impact of ES on clinical outcomes in women undergoing natural-cycle FET. And we have found that ES did not have any beneficial effect or adverse impact, with implantation and pregnancy rates very similar between those who did and did not have ES.

Trial registration number: ChiCTR-TRC-12002389

P-416   Frozen-thawed embryo transfer cycles have a lower incidence of ectopic pregnancy compared with fresh embryo transfer cycles

X. Zhang, C. Ma, Z. Wu, L. Tao, R. Li, P. Liu, J. Qiao

Peking university third hospital, reproductive medical center, beijing, China

Study question: To compare the incidence of ectopic pregnancy in women undergoing frozen-thawed embryo transfer cycles and fresh embryo transfer cycles.

Summary answer: The risk of ectopic pregnancy is lower in frozen-thawed embryo transfer cycles than fresh embryo transfer cycles, and blastocyst transfer could further decrease the rate.

What is known already: Infertility has been considered to be an important risk factor of ectopic pregnancy and undesirable pregnancy outcomes. In IVF-ET, the embryos are directly transferred into the uterine cavity, but a significant

number of ectopic localizations of gravidity occurred. A recent review describes that the incidence of ectopic pregnancy occurring after IVF ranges from 2.1% to 8.6% of all clinical pregnancies.

Study design, size, duration: A retrospective cohort study on the incidence of ectopic pregnancy in fresh and frozen-thawed embryo transfer cycles from January 1st, 2010 to January 1st, 2015.69,756 in-vitro fertilization- embryo transfer (IVF-ET) cycles were analyzed

Participants/materials, setting, methods: Infertile women underwent frozen transfer cycles or fresh transfer cycles

Main results and the role of chance: The clinical pregnancy rate per embryo transfer was lower in fresh embryo transfer cycles compared with frozen-thawed embryo transfer cycles (40.8% vs. 43.1%, p<0.001). Frozen-thawed embryo transfer is associated with a lower incidence of ectopic pregnancy per clinical pregnancy, compared with fresh embryo transfers (OR=0.306; 95%CI 0.244-0.386). Female age and body mass index (BMI) have no influence on ectopic pregnancy. In the frozen-thawed embryo transfer cycles, blastocyst transfer shows a lower incidence of ectopic pregnancy (0.8% vs. 1.8%, p = 0.02) compared with day3 cleavage embryo transfer.

Limitations, reasons for caution: descriptive, only in one reproductive medical center

Wider implications of the findings: agreement with literature

Trial registration number: 2014-1-4091

P-417 Function and hormonal regulation of the serum and glucocorticoid inducible kinase 1 in the human trophoblast-derived HTR-8/SV neo cells

A. Liu[1], W.H. He[2], H.J. Gao[3], M.M. Jin[4], Y.M. Zhu[4]

[1]Women's Hospital- Zhejiang Unviersity, department of reproductive endocrinology, hangzhou, China
[2]First Affiliated Hospital- Zhejiang University College of Medicine- Hangzhou-Zhejiang 310003, Department of Obstetrics and Gynecology, Hangzhou, China
[3]Women's Hospital- Zhejiang University School of Medicine- Hangzhou- Zhejiang 310006, Department of Reproductive Endocrinology-, Hangzhou, China
[4]Women's Hospital- Zhejiang University School of Medicine- Hangzhou- Zhejiang 310006, Department of Reproductive Endocrinology, Hangzhou, China

Study question: Whether E2/P4 stimulation has influences on SGK1 expression and cellular function in the human trophoblast-derived HTR-8/SV neo cells and what is the related molecular mechanism.

Summary answer: It indicates that SGK1 may be partly responsible for the effect of hormone on cell proliferation, differentiation, metastasis, and vessel remodeling in HTR-8/SV neo cells.

What is known already: Hormone including estrogens (E2) and progesterone (P4) were reported to profoundly affect trophoblast cellular changes in the human first trimester placentation. The serum- and glucocorticoid-inducible kinase 1 (SGK1) is also known to exerts embryonic function in cell differentiation, maturation, and vascular remodeling during the embryo development.

Study design, size, duration: We used in vitro human trophoblast-derived HTR-8/SV neo cells culture system. All experiments were performed three times individually. The study was approved by the Ethics Committee of Women's hospital,Zhejiang University.

Participants/materials, setting, methods: Cell viability, differentiation, metastasis, vessel remodeling ability and apoptosis were detected in HTR-8/SV neo cells after treated with E2/P4. Dual luciferase reporter gene assay and siRNA-mediated SGK1 knockdown were performed. We also evaluated the role of SGK1 in the E2/P4 stimulation in the mixture of HTR-8/SV neo cells and decidual cells as well as chick embryo.The expression of SGK1, VEGF, TGF-β, MMP2, MMP9, phosphorylation of AKT and STAT3 were demonstrated by qRT-PCR and/or estern blot.

Main results and the role of chance: The results suggested the combination of E2(10 nM)+ P4(100 nM) resulted in an elevated cell viability, differentiation, metastasis, and vessel remodeling ability compared with the other groups. Simultaneously, the treatment of E2(10 nM)+ P4(100 nM) protect HTR-8/SV neo cells from apoptosis. Consistent with this result, the treatment of E2(10 nM)+ P4(100 nM) also promoted the expression of SGK1, VEGF, and TGF-β demonstrated by qRT-PCR and western blot. Next, we performed Dual luciferase reporter gene assay and siRNA-mediated SGK1 knockdown to explore the effect of E2/P4 on SGK1 transcriptional activity. Our findings indicated that combination of E2(10 nM)+P4(100 nM) significantly promotes the proliferation, invasion, migration, and vessel remodeling of HTR-8/SV neo cells via upregulating SGK1. E2/P4 treatment caused a rapid increase in the level of MMP2, MMP9, and phosphorylation of AKT and STAT3, and inhibition of SGK1 resulted in a decreased response for the treatment of E2/P4 demonstrated by western blot. Moreover, we evaluated the role of SGK1 in the E2/P4 stimulation in the mixture of HTR-8/SV neo cells and decidual cells as well as chick embryo. The data revealed that the promoted invasion, migration (in the mixture of HTR-8/SV neo and decidual cells), and angiogenic remodeling ability (in chick embryo) induced by E2/P4 was mediated by SGK1.

Limitations, reasons for caution: The present study is only in vitro experiment. In our further study, we will build an spontaneous abortion animal model to demonstrate the fundamental role of SGK1 in embryo implantation and placentation during early pregnancy and its' related disease in vivo.

Wider implications of the findings: Our study revealed the importance of SGK-1 on cell proliferation, differentiation, metastasis, and vessel remodeling in the human trophoblast-derived HTR-8/SV neo cells, which may provide us a better understanding of the complexity of molecular dynamics in the key processes of implantation and placentation during early pregnancy.

Trial registration number: N/A.

P-418 Impact of Galectin-1 on Trophoblast stem cell differentiation and invasion during embryo implantation

M. Tang, J. You, W. Wang, Y. Lu, A. Liu, Y. Zhu

Women's Hospital- School of Medicine- Zhejiang University, Department of Reproductive Endocrinology, Hangzhou, China

Study question: What's the role of Galectin-1 in Trophoblast stem cell differentiation and invasion during embryo implantation?

Summary answer: Co-culture with endometrial epithelium cells or its secretion can elevate the expression of Gal-1 in TSCs, and promote the differentiation and invasion of TSCs.

What is known already: Trophoblast stem cells differentiation in an orderly manner, which plays an important role in the process of embryo implantation, placentation and maintenance of early pregnancy. At the maternal-fetal interface, the dialogue is crucial between trophoblast cells and endometrial epithelial cells. Galectins constitute a growing family of lectins with carbohydrate recognition domains (CRDs) sharing a consensus sequence of 130 amino acids. Gal-1 exerts biological effects including cell adhesion, metastasis, cell growth regulation and apoptosis in various tissues and cells by recognition of glycan ligands. Previous studies shows differentially expression in pathological and normal placenta.

Study design, size, duration: In the present study, we used the co-culture model to simulate the normal physiological process, aiming to identify galectin-1 expression in the trophoblast stem cells during the implantation, and to see whether the expression of galectin-1 is affected by the endometrial epithelial cells. Moreover, to better understand the pathophysiologic role of Gal-1 during implantation, we investigated the effect of gal-1 on differentiation and invasion in TSCs during implantation.

Participants/materials, setting, methods: In this study we used the trophoblast-endometrium co-culture model. We induced the differentiation of trophoblast stem cells in differentiation medium. qRT-PCR was used to detect the mRNA level of each cell type markers, fusion markers and Gal-1 during differentiation of TSC cells. Wound healing and transwell invasion assay were used to detect the migration and invasion ability in each group. Recombination Gal-1 was used to stimulate TSCs in differentiation, wound healing and transwell invasion assay.

Main results and the role of chance: The differentiation status of cultured cells was indicated by the relative mRNA levels of TSC marker genes (Esrrb, Eomes), TGC marker genes (Plf, Ctsq), SpT marker (Tpbpa), and fusion marker (E-cadherin). To explore whether secreted factors derived from endometrial epithelial cells stimulate the invasion capacity of TSCs, we set up a Wound healing assay and a chemotactic Matrigel invasion assay. Co-culture with IK cells or IK cells secretion can elevate the expression of Gal-1 in TSCs, and promote the differentiation and invasion of TSCs. Specifically, we demonstrated that

recombinant Gal-1 can also promote the differentiation and invasion of TSCs. This finding suggests that during implantation, some of IK cells secretion increase the expression of Gal-1 in TSC, which in turn induces trophoblast differentiation and invasion in vitro.

Limitations, reasons for caution: he experiments were mainly carried out in vitro. Animal models may be further applied in the following research.

Wider implications of the findings: Our research reflects the physiological response of TSCs to endometrial epithelium cells at the implantation and very early placentation stage. The present study provides new experimental evidence for a pivotal role for Gal-1 in promoting TSCs differentiation and invasion during implantation and suggests a potential therapeutic approach for recurrent miscarriage.

Trial registration number: Our study is not a cliical trial.

P-419 Crosslinked hyaluronan gel can improve clinical pregnancy rate of IVF/ICSI patients with moderate to severe intrauterine adhesion

X. Mao, Y.P. Kuang, S.Z. Zhang

Shanghai Ninth People's Hospital- Shanghai Jiaotong University School of Medicine, Department of Assisted Reproduction, Shanghai, China

Study question: Severe intrauterine adhesion (IUA) may lead to frequent implantation failure. Will crosslinked hyaluronan gel application after adhesiolysis improve embryo implantation outcome in patients with severe IUA?

Summary answer: Data in current study show that multiple application of hyaluronan (HA) gel reduced intrauterine adhesion, improved endometrial receptivity, and increased pregnancy rate after embryo implantation.

What is known already: Severe IUA is characterized by extended scar adhesion between endometrial mucous and fibrosis (non-functional scar tissue), and frequently results in infertility and implantation failure. Although adhesiolysis is performed to eliminate adhesions and create environment beneficial to embryo implantation, reoccurrence of adhesion often develops after surgery and the quality and receptivity of endometrium may not be enhanced for effective embryo implantation. HA materials have been reported to prevent adhesion and improve quality of endometrium due to its ability to facilitate angiogenesis and modulation of inflammatory reactions. HA enriched embryo transfer medium improved implantation after IVF procedures and increased clinical pregnancy rate.

Study design, size, duration: In this consecutive case study, 48 patients diagnosed as moderate to severe IUA according to the standard of American Fertility Society (Score $\geq$ 5) due to previous different intrauterine procedures and experienced multiple embryo implantation failure of IVF were enrolled from May to September of 2016 at our Center. This study was approved by the hospital ethics committee. All patients received written informed consent. Quality frozen embryos for each patient were available during this procedure.

Participants/materials, setting, methods: Adhesions were separated using hysteroscopic scissors until normal uterine anatomy was achieved; then an IUD and 3 ml of crosslinked HA gel (MateRegen® gel) were implanted into the uterine cavity. HA gel was installed again into uterine cavity when IUD was removed one month later and then one week thereafter. Endometrium samples were collected for histology examination. Embryo transfer was performed according to standard methods. Endometrium thickness was measured and the clinical pregnancy rate was monitored.

Main results and the role of chance: Using HA gel effectively reduced reoccurrence of intrauterine adhesion. The AFS score dropped from 8.5 preoperatively to 1.2 postoperatively. Observed under hysteroscopy, endometrial mucous appears much normal with rich blood supply. Histological evaluation under microscopy revealed that the number of mucous glands per scope (×10) increased from 15 prior to HA gel application to 29 afterward. The average thickness of endometrium at implantation was 7.64 mm for patients received HA gel, in contrast to the 7.40 mm without using HA gel (historical data). The clinical pregnancy rate reached 29% with multiple application of HA gel, in contrast to the 18% without using HA gel (historical data). All of those data indicated that application of HA gel improved the quality and receptivity of the endometrium, achieved a favorable microenvironment for embryo implantation, and eventually enhanced the clinical pregnancy rate. Many women with

severe IUA develop thin endometrium even after surgical intervention. The minimum optimal thickness of endometrium for implantation is 7 mm. Hormonal therapy and growth factors have been employed to stimulate endometrial regeneration to prepare implantation. HA gel might play multiple roles including adhesion prevention, inflammation modulation, and angiogenic regeneration; altogether HA gel contributed to the enhanced clinical pregnancy rate in current study.

Limitations, reasons for caution: This is a consecutive case study. The results from this study were compared with the historical data in the authors' institute and literatures. Therefore, a randomized multiple center study with control group is desired in order to achieve a comprehensive conclusion.

Wider implications of the findings: When women with moderate to severe IUA are treated to receive IVF, comprehensive approaches are needed. Preventing adhesion, regenerating endometrium, and improving quality and receptivity of endometrium should be focused. Crosslinked HA gel is able to stay inside uterine for up to 2 weeks and could achieve those therapeutic purposes.

Trial registration number: N/A.

P-420 Unusual twinning resulting in chimerism: a systematic review on monochorionic dizygotic twins

H. Peters[1], T. König[1], M. Verhoeven[1], R. Schats[1], V. Mijatovic[1], J. Ket[2], C. Lambalk[1]

[1]*VU Medical Center, Obstetrics and Gynaecology, Amsterdam, The Netherlands*
[2]*VU University, Medical Library, Amsterdam, The Netherlands*

Study question: What are the possible causes and (clinical) consequences of a monochorionic dizygotic (MCDZ) pregnancy?

Summary answer: Assisted reproductive technology is responsible for the origin of most MCDZ pregnancies. Chimerism is demonstrable in 90.3% of the twins, leading to various diagnostic difficulties.

What is known already: Traditionally it is understood that dizygotic twins always have a dichorionic placenta. Recently, several studies have reported dizygotic twins with an unusual placentation: MCDZ twins. Vascular anastomoses in the monochorionic placenta can connect the two different fetal circulations, resulting in blood chimerism. This means that in one organism two blood cell lines exist, from two genetically different zygotes. This is a well-known phenomenon in cattle, where chimerism is recognized as the origin of the *freemartin* (an infertile female calve lacking the Müllerian duct derivatives). In human, little attention has been devoted to monochorionic placentation in dizygotic twins and clinical consequences.

Study design, size, duration: We performed a systematic review of the literature, in accordance with the PRISMA guidelines. The search was conducted using PubMed, Embase.com and ISI/Web of Science, with use of the following terms (including synonyms and closely related words): "dizygotic twins and monochorionic", "twins and chimerism" and "freemartinism".

We considered all case reports and case series of MCDZ twins. We selected only papers in which a specific description of the placenta was available.

Participants/materials, setting, methods: By this literature search 1877 records were identified. After removal of the duplicates, 1219 records were assessed against our criteria, based on their titles and abstracts. We identified 31 unique cases of MCDZ twin pregnancies, reported in 27 articles.

From all included cases the following data were extracted: baseline data, method of conception, pregnancy data, birth outcomes, testing for chimerism and physical examination of the twins. Relative frequencies were calculated and expressed in percentages.

Main results and the role of chance: Assisted reproductive technology (ART) was responsible for the origin of the MCDZ pregnancy in 82.1% of the cases, especially double embryo transfer in IVF/ICSI cycles seems a risk factor.

Most (83.9%) of the reported MCDZ twin pregnancies lead to a live birth of twins. Pregnancy loss under 24 weeks occurred in 6.5%. Twin-to-twin transfusion syndrome was reported in 16.1% of the pregnancies, in two cases followed by laser therapy.

In all 31 cases an ultrasound in early pregnancy had reported absence of the lambda sign, confirming a monochorionic diamniotic placenta. However, when

sex-discordance was noted on a following ultrasound, 7.4% of these pregnancies were nonetheless assumed to be dichorionic.

Blood chimerism was demonstrable in 90.3% of the twins, leading to various diagnostic difficulties, pre- and postnatally. One case describes erroneous sex differentiation due to chimerism, this lead to a gonadectomy because of suspected gonadal dysgenesis in a completely normal healthy girl.

In 15.4% of the sex-discordant MCDZ twins a genital anomaly is reported in one of the twins, including one girl with aplasia of the Müllerian derivatives – possibly resembling the freemartinism in animals.

Limitations, reasons for caution: An association of MCDZ twinning and ART is confirmed in this review, whether there is a causal effect remains uncertain. Moreover, it is possible that placental transfusion between sex-discordant twins results in genital anomalies. A publication bias, especially regarding ART pregnancies and clinical consequences of MCDZ twinning, must be considered.

Wider implications of the findings: Most MCDZ twins are discovered by accident, it can be argued that it is more common than has been assumed. Awareness is important, with subsequently correct medical strategy in pregnancy measures and diagnostic testing. A challenging task for research is to identify the causes and long-term consequences of twin chimerism.

Trial registration number: Not applicable.

P-421 Endometrial and embryo exosomes for embryo-endometrial cross talk at implantation

H.M. Wu, C.L. Chang, H.Y. Huang, Y.K. Soong, H.S. Wang

Chang Gung Memorial Hospital, Obstetrics and Gynecology, Taoyuan, Taiwan R.O.C.

Study question: embryonic stem cells would selective incorporate several biologically active components (including glycosphingolipids, GSLs) in exosomes, and their role as preventing the embryo from being attacked by the maternal immune system

Summary answer: GSLs were significant expressed in exosomes derived from ESC, indicating the GSLs have potential modulatory role on embryo implantation and decidual programming of human pregnancy

What is known already: Establishment of pregnancy requires synchronized growth between the endometrium and the blastocyst. Functional interaction between these occurs both during the pre-implantation phase of embryo implantation and during placentation. Pregnancy is a unique event in which a fetus, despite being genetically and immunologically different from the mother, develops in the uterus. Successful pregnancy implies avoidance of rejection by the maternal immune system. Exosomes released from the endometrium and the embryo are present in uterine fluid.

Study design, size, duration: In this in vitro study, we examined whether GSLs could be transfected from exosomes derived from ESC to human immune cells. To demonstrate the immunomodulatory capacity of exosomes derived from ESC. To test macrophage M1/M2 polarization, indicating the role of exosomes in embryo implantation and pregnancy.

Participants/materials, setting, methods: Human villus trophoblast cells were isolated from the abortus tissue from healthy women undergoing pregnancy termination of a pregnancy at 6- to 12-wk gestation, after informed consent. Embryonic stem cells (ESC) were from ESC cell lines. GSLs transfected from exosomes derived from ESC to monocytes. Macrophage M1/M2 polarization was tested by flow cytometry with CD68/CD80/CD163 markers. Transmission electron microscopy (TEM) images of isolated exosomes were performed.

Main results and the role of chance: GSLs were successfully transfected from exosomes derived from ESC to monocytes. Pretreatment with exosomes derived from ESC significantly induced macrophage M2 polarization. Moreover, isolated exosomes from villus trophoblast cells were confirmed by transmission electron microscopy images. Pretreatment with exosomes derived from villus trophoblast cells of a normal pregnancy significantly induced macrophage M2 polarization compared with anembryonic pregnancy.

Limitations, reasons for caution: Functional interaction between these occurs both during the pre-implantation phase of embryo implantation and during placentation

Wider implications of the findings: exosomes derived from ESC and villus trophoblast cells of a normal pregnancy significantly induced macrophage M2 polarization. Our findings represent a new concept regarding the immunomodulatory capacity of exosomes from embryos and villi, suggesting that exosomes have potential modulatory role on embryo implantation and decidual programming of human pregnancy.

Trial registration number: Non.

P-422 A randomized double-blinded controlled trial of human chorionic gonadotropin as luteal phase support in natural cycle frozen embryo transfer

E.H.Y. Ng, V.C.Y. Lee, R.H.W. Li, W.S.B. Yeung, P.C. Ho

Faculty of Medicine, O&G, Hong Kong, China

Study question: Does the use of human chorionic gonadotropin (hCG) as luteal phase support in natural cycle frozen embryo transfer (FET) increase the ongoing pregnancy rate?

Summary answer: The use of hCG in natural cycle FET did not improve the ongoing pregnancy rate.

What is known already: The use of luteal phase support in stimulated cycles was associated with higher live-birth rate and the results were similar using hCG or progesterone.

Study design, size, duration: This is a randomised double-blinded controlled trial of 450 women recruited between July 2012 and October 2015.

Participants/materials, setting, methods: Women with regular cycles undergoing natural cycle FET were recruited. Serial serum hormonal concentrations were used to time natural ovulation and at most two day 2 cleavage embryos were replaced. They were randomised into one of the two groups: (1) the treatment group receiving 1500 IU hCG on the day of FET and 6 days after FET and (2) the control group receiving normal saline on these two days.

Main results and the role of chance: The ongoing pregnancy, implantation and miscarriage rates were comparable between the two groups. In the treatment group, there were significantly more cycles with top quality embryos transferred and a significantly higher serum oestradiol level but a comparable serum progesterone level 6 days after FET. No significant differences were observed in serum oestradiol and progesterone levels 6 days after FET between pregnant and non-pregnant women. In the multivariate logistic regression, the number of embryos transferred is the only significant factor predictive of the ongoing pregnancy rate of natural cycle FET.

Limitations, reasons for caution: This study only included FET with cleavage stage embryos and hCG was used as luteal phase support, but not vaginal progesterone.

Wider implications of the findings: The findings in this study did not support the use of hCG as luteal phase support in natural cycle FET.

Trial registration number: NCT01931384.

P-423 Detection for chromosomal aberrations in early miscarriages following assisted reproductive technology (ART) treatment Using array-CGH

T. Zhang[1], Y. Sun[2], Y. Hong[3]

[1]*Renji Hospital- School of Medicine-Shanghai Jiaotong University, reproductive center, Shanghai, China*
[2]*Ren Ji Hospital- School of Medicine- Shanghai Jiao Tong University, Center for Reproductive Medicine-, shanghai, China*
[3]*Ren Ji Hospital- School of Medicine- Shanghai Jiao Tong University, Center for Reproductive Medicine, shanghai, China*

Study question: Whether array-CGH (Array comparative genomic hybridization) is a better diagnosis tool for chromosomal aberrations detection in product of conception (POC) of first trimester miscarriages following ART treatment?

Summary answer: ART treatment does not increase the risk of chromosomal aberrations in those who miscarry. Array-CGH could detect additional genetic abnormalities compared with conventional karyotyping.

What is known already: Of these first trimester miscarriages, about 50% are due to the presence of large-scale chromosome abnormalities. Maternal cell contamination (MCC) and suboptimal quality of chromosome preparations are adjunctive limiting factors to karyotype analysis. Array CGH is a powerful molecular cytogenetic technique for quickly scanning through an entire genome for imbalances. Till now there are no well-designed studies for miscarriage POC sample detection in ART patient.

Study design, size, duration: 102 patients with first-trimester miscarriages were investigated by array-CGH using a 100-Kb resolution platform. Patients be collected who refer to reproductive center of Renji Hospital, Shanghai from Aug 2015 to Feb 2016 because of clinical abortion with a subsequent dilation and evacuation performed.

Participants/materials, setting, methods: Patients grouped by type of conception as follows: conventional IVF (in vitro fertilization) (n = 35), ICSI (intracytoplasmic sperm injection) (n = 31), and control (natural conception or intrauterine insemination [IUI]) (n = 36); All couples have normal karyotypes. The results were visualized with Genomic Workbench Standard Edition 5.0.14 (Agilent), annotated against build NCBI 37 (human genome assembly UCSC hg19, Feb.2009).

Main results and the role of chance: There is no statistic difference in the abnormality rate between three study groups. Trisomy constitutes most of the abnormalities, followed by micro duplications/deletions, monosomy, et al. The abnormality rate is significantly higher in mild stimuli group. The frequency of normal embryonic karyotype increase as the number of miscarriages increases. 20 copy number variants (CNVs) were identified. 9 CNVs were submicroscopic genomic gains and 11 were losses. Nineteen CNVs were defined as common CNVs. Only one CNV was classified as unique. Some CNVs shows more than once. The common CNV in the 15q11.2 region resulted in being the most frequent CNVs, followed by common CNVs in the14q11.2, Xq22.2, 1p36.13, 14q11.1, and 15q22.31 regions.

Limitations, reasons for caution: Array CGH cannot detect balanced chromosome abnormalities. We still cannot apply it to POC of multiple pregnancies. Sometimes, the findings fall into "variant of unknown significance (VOUS)", then the clinical significance of the observed change is uncertain. And it is more expensive than traditional cytogenetic.

Wider implications of the findings: The contribution of CNVs to miscarriages seems to be complex. Genes involved in these CNVs may be interesting for the study of early human development and pregnancy effects. Future studies should record a complete CNV burden and characteristics for a more comprehensive assessment of their role in miscarriage.

Trial registration number: N/A.

P-424 Endometrial-embryo crosstalk via extracellular vesicles pathway

Z. Niu, R.T. Pang, W. Liu, W.S. Yeung

The University of Hong Kong, Obstetrics and Gynecology, Hong Kong, Hong Kong

Study question: To study whether endometrial extracellular vesicles (EVs) are involved in embryo-endometrial cross-talk.

Summary answer: EVs are presented in the mouse ULF and could transfer microRNAs into embryos and exert functions.

What is known already: EVs are membrane-bound vesicles released by a variety of cells into the extracellular microenvironment. They can transfer proteins, small RNAs and mRNAs via the extracellular environment to cells at distant sites to promote inter-cellular communication.

Study design, size, duration: Mouse model were applied in this study. The experiments were repeated for at least five times and at least three mice were included in each examination group.

Participants/materials, setting, methods: ULF-EVs were isolated from mouse ULF by sedimentation. The morphology, size, marker expression and microRNA expression of the EVs were characterized. Besides, the roles of EVs in embryo implantation were analyzed by in-vitro and in-vivo models respectively.

Main results and the role of chance: The ULF-EVs have a mean diameter of 59.6 ± 20.3 nm and expressed the exosome enriched proteins CD63, HSP70 and TSG101. CD63 was also detected in the mice uterine epithelium at different pregnancy stages suggesting that epithelium is a source of ULF-EVs.

Transmission electronic microscopy(EM) discovered EV-shaped vesicles in the uterine cavity and glandular cavity of the endometrium. MicroRNA let-7a expression was higher in dormant stage mouse embryo, endometrial epithelial cells and ULF-EVs than the respective samples from receptive stage or estradiol-activated stage. Moreover, there was a positive association of let-7a expression between the blastocysts and ULF-EVs, suggesting that let-7a could be transferred from endometrial epithelial cells to the embryos by EVs. Scanning EM showed EV-shaped vesicles were attached to the surface of the embryo. Confocal microscopy showed internalization of labelled EVs to the blastocysts. Coculture of let-7a enriched EVs with blastocysts inhibited the expression of c-Myc, a let-7a target gene, and decreased DNA synthesis in the embryos. Taken together, these results demonstrated that the EVs could be internalized into the mouse embryo and exerted function. Finally, we showed that exosome inhibitor GW4869 suppressed EVs generation and lead to reduction in attachment rate and implantation rate in in vitro and in vivo.

Limitations, reasons for caution: Our observations are based only on mouse and in-vitro model. Different situations may apply in humans.

Wider implications of the findings: As EVs appear to have a crucial role in the course of reproduction, they are excellent research candidates for a better understanding of the underlying molecular activities associate with the developing of endometrial receptivity and their potential role as markers of endometrial receptivity.

Trial registration number: NA.

P-425 Low dose bisphenol compounds affect development and reproductive ability of offspring mice by prenatal exposure

H. Fan, Y. Sb, L. Kf

The University of Hong Kong, Obstetrics & Gyneacology, Hong Kong Island, Hong Kong

Study question: Whether bisphenol compounds (BPA, BPF and BPS) have similar effect on developmental and reproductive capacity of F1 mice when exposed to bisphenol compound prenatally.

Summary answer: BPA affects development and fertility of offspring mice with higher potency than BPF and BPS, which suggests that BPF and BPS are safer than BPA.

What is known already: Growing evidence suggest that BPA affects humans and rodent endocrine and reproductive system. It also affect the behavior or development of children when they are exposed to BPA perinatally. With the restricted usage of BPA in some countries, chemicals structurally similar to BPA (e.g. BPF and BPS) are used as without thorough investigation on their effect on human reproduction.

Study design, size, duration: Adult female ICR mice were fed with corn oil (vehicle), diethylstilbestrol (DES) 5 μg/kg/day, BPA or BPF or BPF 500 μg/kg/day for 30 days, and then mated with untreated male. Treatment was continued until delivery (N = 3-5 for each group). The reproductive ability of F1 offspring was studied.

Participants/materials, setting, methods: Body weight of F1 offspring was measured from postnatal day 21 (PD21) to 42 (PD42). Onset of puberty of female F1 offspring was determined on the day of vaginal opening. Length of estrous cycle of female F1 offspring was studied. The number of implantation site on pregnancy day 7 was investigated in three mating groups: (1) treated female mated with untreated male, (2) treated female intercross with male, (3) untreated female mated with treated male.

Main results and the role of chance: Vehicle and bisphenol groups produced similar litter size. While no offspring was found in DES group. The body weight of BPA/BPF/BPS treated female and male F1 offspring was much lower than the vehicle group on PD21, and the body weight of the F1 offspring exposed to BPA was the lowest among all bisphenol treatment groups. However, the body weight of female F1 offspring in all groups was comparable on PD42; however, the male offspring from the BPA and BPS groups were lighter than vehicle group. The date of puberty onset of female offspring from the BPA group was delayed and the estrous cycle length was longer when compared to vehicle group. In the BPA group, the number of implantation site on PD7 of treated female offspring mated with untreated male mice was significantly higher than the vehicle group; while the implantation site of treated female offspring mated with treated male was fewer than the vehicle group. However, untreated female mice mated with treated male

offspring have similar number of implantation site to the vehicle group. In BPF and BPS treated F1 offspring, the number of implantations site in three mating groups was similar to vehicle group.

Limitations, reasons for caution: In this study, limited number of pregnant mice were exposed to bisphenol compounds. Only observation of affected reproductive ability was investigated. Mechanism is still unclear. And the effect of these bisphenol compounds in other endocrine systems need further investigation.

Wider implications of the findings: Since the toxicity of BPA to human beings is wildly recognized. BPA substitutes have weaker potency than BPA in development and reproductive ability of mice. Our preliminary data suggested these substitutes have less detrimental effects on human reproductive function.

Trial registration number: Nil.

P-426   Double endometrial scratching = double benefit for pregnancy rate?

D.M. Baston-Büst, S.J. Pour, S. Schu, A.P. Bielfeld, J.S. Krüssel

Medical Center University of Düsseldorf, Department of OB/GYN and REI UniKiD, Düsseldorf, Germany

Study question: Can a double endometrial scratching in two consecutive menstrual cycles in the luteal phasesversus one prior to embryo transfer improve the pregnancy rate in patients withv recurrent implantation failure (RIF)?

Summary answer: RIF patients do benefit from double endometrial scratching and reveal a statistically significant higher pregnancy rate compared to RIF patients with a single scratch.

What is known already: Pregnancy rates in RIF patients remain unsatisfactorily low although the embryo culture methods in ART programs have improved. The main problem of RIF patients seems to be caused by an insufficient endometrial receptivity. Even when a triple lining and sufficient growth of the endometrium detected by ultrasound controls during the stimulation phase and a minimum of one top quality embryo was transferred a pregnancy does only appear unsatisfactory low percentages. Up to date the identification of the correct individual window of implantation remains expensive.

Study design, size, duration: Retrospective case-control study of 14 RIF patients with double endometrial scratching in consecutive cycles before embryo transfer versus 42 RIF patients with only one scratching in the luteal phase before the embryo transfer was performed, university setting, 2.5 years (April 2014-November 2016).

Participants/materials, setting, methods: The study was approved by the ethical committee of the university of Düsseldorf and patients gave a written consent. RIF patients had a minimum of 2 previous embryo transfers (maximum 10 transfers). Control RIF patients conducted scratching only once. Statistical analysis: Student´s T-Test and odd´s ratio. Age of patients, number of previous embryo transfers, day of transfer, number of good quality embryos did not vary.

Main results and the role of chance: Consecutive double endometrial scratching before the embryo transfer improves the pregnancy rate in RIF patients with an odd of 3.8 (95% confidence interval 1.0633 to 13.2787). Double scratching can easily be performed in 2 consecutive menstrual cycles in the luteal phases and is not cost-intensive for the patients.

Limitations, reasons for caution: Retrospective case-control study.

Wider implications of the findings: This new approach raises more questions about the endometrial signature and a possible memory of endometrial and immune cells within the endometrium. Furthermore it questions the current approach of a single endometrial scratching in patients with RIF to improve the implantation and live birth rates.

Trial registration number: Medical Center of Düsseldorf study number 4394 R.

P-427   Addition of prednisolone and low molecular weight heparin (LMWH) in patients with repeated implantation failures (RIF): a cohort study

C. Siristatidis[1], K. Dafopoulos[2], W. El-khayat[3], G. Salamalekis[4], T. Vrantza[4], M. Elsadek[5], G. Anifandis[2], N. Papantoniou[6]

[1]Medical School-National and Kapodistrian University of Athens, Assisted Reproduction Unit- 3rd Department of Obstetrics and Gynecology, Athens, Greece
[2]University of Thessaly- School of Health Sciences- Faculty of Medicine, Assisted Reproduction Unit- Department of Obstetrics and Gynaecology, Larissa, Greece
[3]Faculty of Medicine- Cairo University, Middle East Fertility centre, Cairo, Egypt
[4]Medical School- National and Kapodistrian University of Athens, Assisted Reproduction Unit- 3rd Department of Obstetrics and Gynaecology, Athens, Greece
[5]Faculty of medicine- Cairo University, Middle East Fertility centre, Cairo, Egypt
[6]Medical School- National and Kapodistrian University of Athens, 3rd Department of Obstetrics and Gynaecology, Athens, Greece

Study question: Can the co-administration of prednisolone and LMWH be an effective treatment for RIF patients undergoing ART?

Summary answer: The co-administration of prednisolone and LMWH does not seem an effective treatment, in terms of improved clinical pregnancy rates, in RIF patients undergoing ART.

What is known already: Both LMWH and prednisolone have been tested as separate adjuncts for the improvement of the clinical outcomes in RIF patients undergoing IVF/ICSI, with negative results. The rationale for using both concurrently was based on their promoting role in the implantation and placentation processes, where they promote a better tolerance of the immune system toward the embryo and a reduction of the local inflammatory reaction to the transfer procedure. In a previous pilot study, we observed a trend favoring the co administration in terms of improved pregnancy outcomes that could not reach statistical significance.

Study design, size, duration: This is a three-center retrospective cohort study conducted at three Universities. A total of 115 patients were recruited from February 2012 to July 2016. Definition of RIF was based on the failure of implantation in at least two IVF/ICSI attempts, where two high-grade quality embryos were transferred. Sample size calculation was based on the pilot study, ending up with 57 participants in each group to provide a significance of 0.05 and a power of 0.8.

Participants/materials, setting, methods: All patients underwent the same COH protocol that they had undergone in the previous cycle. Our primary analysis was performed to provide a direct comparison between groups. In order to reveal potential independent predictors that contributed to the change of the primary outcomes, we planned to perform logistic regression analysis, if differences were observed. The primary outcome measures were clinical pregnancy and miscarriage rates. Secondary outcome parameters included embryological and ICSI cycle characteristics.

Main results and the role of chance: Patients and basic cycle characteristics were comparable between groups, in terms of age, smoking habits, duration and type of subfertility, basal FSH and AFC values, parity, total dose of gonadotrophins and number of previous RIF cycles, oocytes retrieved and embryos transferred (all p values>0.05). Biochemical and clinical pregnancy rates were similar for both groups [23/57 (40.4%) vs. 14/58 (24.1%), and 17/57 (29.8%) vs. 11/58 (19%), p = 0.063, and 0.175, respectively], although the first parameter did not marginally reach statistical significance. Similarly, miscarriage rates were comparable between groups (35.7% vs. 34.8%), as well as live birth rates [15/57 (26.3%) vs. 9/58 (15.5%), p = 0.154].

Limitations, reasons for caution: The lack of blinding and randomization are linked with unknown confounders and selection bias. Another limitation is the reduced cohort size, together with the addition of other arms, comparing LMWH and prednisolone, separately.

Wider implications of the findings: The differences observed of 16% and 10% in clinical pregnancy and live birth rates using the co-administration of both drugs did not manage to reach statistical significance, so that we cannot recommend it for routine use in this category of subfertile patients. A full-scaled RCT would definitely be more accurate.

Trial registration number: N/A.

P-428   Gene expression profiling of human peri-implantation endometria before and after hysteroscopic polypectomy in subfertile patients with endometrial polyps

S. Yung, T. Chan, C. Lee, E. Ng, W. Yeung

The University of Hong Kong, Department of Obstetrics and Gynaecology, Hong Kong, Hong Kong

Study question: Does hysteroscopic polypectomy affect endometrial gene expression in subfertile women?

Summary answer: No consistent effect was found in the gene expression in the paired endometrial samples prior to and after polypectomy.

What is known already: Endometrial polyps may negatively impact endometrial receptivity through various mechanisms, and surgical removal of the polyps may improve fertility outcome in subfertile patients. Some studies showed that hysteroscopic polypectomy reduces nuclear factor-kappa B expression, increases concentrations of insulin-like growth factor binding protein-1, tumour necrosis factor α and osteopontin in the endometrium. No published study has examined the effect of hysteroscopic polypectomy on global gene expression, and we aimed at studying this.

Study design, size, duration: This was a prospective observational study in a university-affiliated hospital. We recruited 9 subfertile women who were found to have endometrial polyp on saline infusion sonohysterogram and scheduled for hysteroscopic polypectomy before in-vitro fertilisation.

Participants/materials, setting, methods: For each patient, endometrial biopsies were taken before and after hysteroscopic polypectomy 7 days after luteinizing hormone surge (LH+7). We compared the gene expression profiles of the paired endometria from 3 women using Affymetrix Gene 2.0 ST Array. Quantitative-PCR on TaqMan assays was used to confirm the microarray result. Furthermore, 8 selected receptivity genes were used to compare the gene expression profiles with natural (LH+7, n = 8) and stimulated (hCG+7, n = 8, excessive responders) endometrial samples.

Main results and the role of chance: Microarray analysis demonstrated that no genes were commonly differentially expressed in all 3 paired samples. The expression of 16 genes (hERα, hERβ, OLFM1, OLFM2, IL15, CXCL14, GPX3, CCL4, UPKIB, PAEP, MMP26, SLC1A1, MUC15, MUC16, TM4SF4 and TFPI2) that were differentially expressed (≥2-fold) in 2 of the 3 paired samples were confirmed with quantitative-PCR in all 9 paired samples. No consensus change on 8 receptive genes (OLFM1, IL15, CXCL14, GPX3, PAEP, MMP26, SLC1A1 and MUC16) expression was found after polypectomy when compared to endometrial samples taken on LH+7 or hCG+7.

Limitations, reasons for caution: The main limitation of the present study was the small sample size.

Wider implications of the findings: This was the first study in the literature evaluating the effect of hysteroscopic polypectomy on endometrial receptivity by microarray evaluation of global gene expression. Polypectomy may modulate other endometrial environment conducive to embryo implantation. Further study with larger sample size is needed.

Trial registration number: Not applicable.

P-429   Is the peripheral blood transcriptome profile 9 days after blastocyst transfer in pregnancy destined to miscarriage different from pregnancy which subsequently progressed to live birth?

J. Huang[1], N. Jin[2], W. Zhu[1], W. Cheung[1], Y. Liu[1], C. Wang[1], T. Chan[2], T. Li[1]

[1]The Chinese University of Hong Kong, Department of Obstetrics and Gynaecology, Hong Kong, Hong Kong
[2]The Chinese University of Hong Kong, School of Life Sciences, Hong Kong, Hong Kong

Study question: Are there any differences in the peripheral blood transcriptome profiles 9 days after single blastocyst transfer between pregnancies which subsequently progressed to live birth or miscarriage?

Summary answer: There were significant differences in peripheral blood transcriptomic profile 9 days after single blastocyst transfer between pregnancies which subsequently progressed to live birth or miscarriage.

What is known already: In women who received IVF treatment, serum human chorionic gonadotrophin (hCG) measurement 14 days after oocyte retrieval or 9 days after blastocyst transfer can establish if pregnancy has occurred. The majority of pregnancies progress to live birth but some end up in miscarriage. Women who later miscarried appeared to have lower serum hCG level 9 days after blastocyst transfer compared with those which progressed to live birth. However, there is significant overlap in hCG levels between the two groups for the hCG measurement to be of significant discriminatory value.

Study design, size, duration: This is a prospective, cross-sectional, observational study. 100 women who underwent IVF treatment had blood sample taken 9 days after blastocyst transfer for hCG measurement and a portion of the blood sample stored for later transcriptome study. Six samples from women whose pregnancy progressed to live birth and 6 women whose pregnancy later miscarried were randomly chosen for transcriptome study.

Participants/materials, setting, methods: Total RNA were extracted from peripheral blood, and purified for RNA sequencing. Differential gene expression and transcriptome patterns were studied by using DESeq2 package.

Main results and the role of chance: The two groups had comparable hCG levels 9 days after blastocyst transfer but there were 143 significantly differential expressed genes in the miscarriage group. These deferentially expressed genes were mainly enriched in the immune related pathways.

Limitations, reasons for caution: Quantitative PCR study is in progress to validate the differentially expressed genes.

Wider implications of the findings: Peripheral blood transcriptome study 9 days after blastocyst may reflect the success or failure of the implantation process. The panel of differentially expressed genes may be used to predict the outcome of pregnancy.

Trial registration number: None.

P-430   Inner cell mass splitting in 8-shaped blastocysts does not increase monozygotic twinning and negative effects on newborns in PGD/PGS patients

Y.F. Gu[1], S.P. Zhang[1], S.N. Dong[2], C.F. Lu[1], K.L. Luo[1], F. Gong[1], G.X. Lu[1], G. Lin[1]

[1]Institute of reproductive and stem cell engineering, Central South University, Changsha, China
[2]IVF Laboratory, Reproductive & Genetic Hospital of CITIC-XIANGYA, Changsha, China

Study question: Does inner cell mass (ICM) splitting in 8-shaped blastocysts increase monozygotic twinning and negative effects on newborns compared to fully hatched blastocysts in PGD/PGS patients?

Summary answer: ICM splitting in 8-shaped blastocysts does not increase monozygotic twins and negative effects on newborns compared to fully hatched blastocysts in PGD/PGS patients.

What is known already: The use of assisted reproductive technology (ART) has been reported to increase the incidence of monozygotic twinning (MZT), especially after blastocyst transfer. It has been reported that 8-shaped hatching of blastocyst increased the ICM splitting in mouse, which may provide insights into the increased risk of human MZT after blastocyst transfer. In PGD/PGS patients based on blastocyst biopsy, 8-shaped hatching of blastocyst is frequently seen because zona openings were made on day 3 embryos, and ICM may be trapped and splitted in a small zona opening.

Study design, size, duration: Patient selection standard: 1) PGD/PGS based on blastocyst biopsy; 2) frozen cycle and single blastocyst transfer. Seventy 8-shaped blastocysts with ICM splitting and 571 fully hatched blastocysts (control group) were selected from Mar-1-2013 to Dec-31-2015. This clinical outcomes and neonatal parameters were retrospectively analyzed. tocyst biopsy, 8-shaped hatching of blastocyst is frequently seen because zona openings were made on day 3 embryos, and ICM may be trapped and splitted in a small zona opening.

Participants/materials, setting, methods: Patients underwent controlled ovarian stimulation in CITIC-Xiangya Reproductive and Genetic Hospital. Oocytes were collected 35-36 hours after hCG trigger and fertilized by ICSI. A 20μm hole was made on zona of day 3 embryo by laser. Blastocysts were biopsied and vitrified on day 5 or 6. The biopsied TE cells were analyzed by SNP array, FISH or PCR. A tested blastocyst was thawed and transferred to each patient in the frozen cycle.

Main results and the role of chance: Seventy 8-shaped blastocysts with ICM splitting and 571 fully hatched blastocysts were thawed and transferred to patients by single blastocyst transfer. No significant difference was found in respect of clinical pregnancy/implantation (61.4% vs. 58.8%), MZT pregnancy (2.1% vs. 2.3%), miscarriage (20.9% vs. 16.5%) and live birth rate (47.9% vs. 48.0%) between the two groups. Totally, 34 and 276 infants were born in the two groups, respectively. No significant difference was found in respect of MZT birth (0% vs. 0.73%), gender ratio (percentage of boys, 52.9% vs. 62.3%), mean

gestational age (wk)(38.8 ± 1.7 vs. 38.9 ± 1.7), preterm birth (8.8% vs. 7.7%), mean birth weight (kg)(3.38 ± 0.50 vs. 3.42 ± 0.53), low birth weight infant (5.9% vs. 2.9%), birth defect (5.9% vs. 1.4%) between the two groups.

Limitations, reasons for caution: The results of this study should be regarded with caution because of its limitations, mainly the retrospective design, confounding factors, and small sample size.

Wider implications of the findings: This study does not support the hypothesis that ICM splitting by a small zona opening is a potential mechanism of MZT in human.

Trial registration number: No. 31171379 approved by the Ethical Committee of CITIC-Xiangya.

P-431 Patients with RPL history undergoing PGS have a lower rate of miscarriage

S. Sawarkar[1], S. Wang[1], H. Nisson[2], A. Jordan[2], J. Barritt[3], Z. Peter Nagy[4], A. Beltzos[5], J. Zhang[6], A. Becker[7], S. Chen[8], D. Ball[9], A. Coates[10], J. Grifo[11], J. Cohen[1], S. Munné[1]

[11]New York University, Reproductive Endocrinology and Infertility, New York- NY, U.S.A.

Study question: Should PGS be offered to patients with a history of recurrent pregnancy loss (RPL)?

Summary answer: The study demonstrates that PGS results in similar to lower miscarriage rates than non-RPL patients and therefore could be beneficial for RPL patients.

What is known already: Patients with a history of recurrent pregnancy loss (RPL) have traditionally been offered expectant management (EM) as standard of care. Aneuploidy is prevalent and leads to clinical miscarriage (CM). In an effort to reduce CM we are suggesting PGS as an alternative strategy, at least to older patients to improve live birth rates.

Study design, size, duration: This retrospective cohort study included a total of 430 cycles of PGS in patients with a history of RPL resulting in pregnancy (+sac) from 30 fertility clinics. The cycles were attempted between 2011 and Dec 2015. Centers reporting substantial number of procedure pregnancy follow up were included in the study.

Participants/materials, setting, methods: Blastocyst biopsies from cycles performed at multiple fertility clinics were referred to the same reference laboratory for analysis. Genetic analysis was performed by array Comparative Genome Hybridization (aCGH) or NGS. CM Rates were compared to 2014 SART data for all patients who underwent ART (frozen cycles) not limited to those with history of RPL, controlling per clinic and age.

Main results and the role of chance: A total of 430 patients who had a history of RPL reported a positive pregnancy test (PPT). The overall PPT rate in our dataset was similar to that of the national ART average. The study looked at CM among patients of different age groups. For PGS-RPL patients under 38, an average of about 12.45% embryos were lost post-implantation, either as empty sacs or clinical losses after FHB was detected. This rate was higher for patients up to 38 years in SART data (17.70%, p<0.05). In contrast, patients in the age group of 38-40 showed a miscarriage rate of only 9% while SART

miscarriage rate was almost 23% (p<0.05). Similarly for the age group of 41-42 within the PGS-RPL group, miscarriage rate was about 9% while it was almost 27% in SART data (p<0.05). Finally for patients older than 42;PGS-RPL patients fared better with miscarriage rates of about 22% while SART data showed a miscarriage rate of about 33%. Embryo loss per center was measured and it ranged from as low as 5% (1/22) to as high as 13.5% (5/37). The miscarriage rate for individual centers was significantly lower for RPL-PGS group versus the regular ART group from SART (p<0.05).

Limitations, reasons for caution: Dataset does not include details of luteal support, biopsy methods, size of the embryo biopsy, and freezing methods. Comparison of the PGS-RPL group was not done with non-PGS RPL group due to unavailability of such data.

Wider implications of the findings: The results indicate an advantage for RPL patients, which should miscarry more than non-RPL patients. PGS-RPL patients of all ages had a clear advantage with significantly lower miscarriage rates compared to all ART patients. These results advocate for judicious use of PGS for RPL patients of all ages.

Trial registration number: Not applicable.

P-432 PSG1 protein stimulates natural killer cell proliferation via the NKP44- and DAP12-associated signaling pathways

Y.C. Hsu, S.Y. Huang, T.H. Chin, Y.K. Soong, C.L. Chang

Chang Gung Memorial Hospital Linkou Medical Center, Obstetrics and Gynecology, Taoyuan, Taiwan R.O.C.

Study question: We hypothesize that pregnancy-specific glycoproteins (PSGs) could regulate immune cell functions during trophoblast invasion via interactions with the natural killer (NK) cell receptor-mediated signaling pathways.

Summary answer: The PSG1-mediated NK cell proliferation was significantly reduced following the knockdown of natural cytotoxicity triggering receptor 2 (NCR2/NKP44) or DNAX activation protein 12 (DAP12).

What is known already: Human PSGs are secreted carcinoembryonic antigen (CEA)-related cell adhesion molecule-related members of the immunoglobulin superfamily. PSG family proteins are among the most abundant trophoblast-derived proteins in human maternal blood in late pregnancy, and select PSG proteins have been shown to regulate the proliferation and migration of trophoblast, endothelial, and immune cells. In addition, dysregulation of PSG expression has been associated with gestational pathology and cancer-related angiogenesis. Furthermore, PSG proteins could mediate these events by interacting with the Smad- and integrin αIIbβ3-associated signaling pathways.

Study design, size, duration: To investigate how PSGs regulate the proliferation and migration of immune cells during trophoblast invasion, we analyzed the effects of a recombinant PSG1 protein on the proliferation of human NK92-MI cells with or without knockdown of the NKP44 or DAP12 protein.

Participants/materials, setting, methods: Cultured human NK92-MI cells were treated with different concentrations of a recombinant PSG1 protein following transfection with a control vector or a shRNA knockdown vector (NKP44-shRNA-pGPU6 or DAP12-shRNA-pGPU6). The expression of NKP44 and DAP12 proteins in cells were analyzed by Western blotting analysis; whereas cell proliferation was quantified by the MTS assay.

Main results and the role of chance: Recombinant PSG1 protein significantly stimulated the proliferation of human NK92-MI cells dose-dependently. Western blotting analysis showed that the transfection of NKP44 or DAP12 shRNA vector significantly decreases the levels of endogenous NKP44 or DAP12 protein, respectively (p < .05). Importantly, knockdown of NKP44 or DAP12 protein in NK92-MI cells significantly reduced the PSG1-mediated cell proliferation (p < .05); whereas the transfection with an empty vector had no effects on cell proliferation. These data indicated that PSGs might directly or indirectly interact with NCR-associated signaling pathways to affect the functions of NK or trophoblast cells during embryo implantation.

Limitations, reasons for caution: Because the receptor(s) for PSG proteins remain to be identified, it is not clear how PSG1 mechanically affects NK cell proliferation via the NKP44/DAP12 signaling pathway.

Wider implications of the findings: Our observation provides the first evidence that PSGs may regulate immune cell proliferation and migration by

signaling in conjunction with the NK cell receptor pathways. This action may represent an important regulatory step in the process of trophoblast invasion and maternal tolerance of the semi-allogenic fetus during pregnancy.

Trial registration number: Not applicable.

P-433 Freeze-all policy is not correlated with improved IVF outcomes in poor responders

M. Roque[1], M. Valle[1], M. Sampaio[2], S. Geber[3]

[1]ORIGEN - Center for Reproductive Medicine, Reproductive Medicine, Rio de Janeiro, Brazil
[2]ORIGEN - Center for Reproductive Medicine, Reproductive Medicine, Belo Horizonte, Brazil
[3]Universidade Federal de Minas Gerais - UFMG, Gynecology and Obstetrics, Belo Horizonte, Brazil

Study question: Does the freeze-all strategy improve in vitro fertilization (IVF) outcomes in poor responders?

Summary answer: Although the freeze-all policy has been related to better IVF outcomes in normal and high responders, poor ovarian responders don´t benefit from the freeze-all strategy.

What is known already: Although fresh embryo transfer is still the routine method in IVF cycles, elective frozen–thawed embryo transfer – the freeze-all policy – has emerged as an alternative for selected IVF treatments. Many questions have been arisen concerning the adverse effects of controlled ovarian stimulation (COS) on the endometrium and endometrial receptivity. Thus, the implementation of the freeze-all policy would avoid these possible deleterious effects of COS and embryo transfer could be performed in a more physiologic uterine environment. However, it is still uncertain whether this strategy might be beneficial for all patients undertaking IVF treatments, especially poor ovarian responders.

Study design, size, duration: This was a retrospective cohort study conducted between January 2012 and December 2016. A total of 433 poor responder patients (following Bologna criteria) fulfilled the inclusion/exclusion criteria and were included in the study. Accepting an alpha risk of 0.05 and beta risk of 0.2 in a two-sided test, it was necessary 149 patients per group to obtain statistically significant results. There were 277 patients in the fresh group and 156 in the freeze-all group.

Participants/materials, setting, methods: The patients were submitted to COS with gonadotropin-releasing hormone (GnRH) antagonist protocol, and cleavage stage embryo transfer. Data were described as the mean ± standard deviation or percentages. The statistical analysis was performed using Student's t test, the chi-square test, and logistic regression models. A P value of <0.05 was considered statistically significant. The main outcome measure was ongoing pregnancy rate. The secondary outcomes were implantation and clinical pregnancy rates.

Main results and the role of chance: The patient's mean age in the freeze-all group was 39.5 ± 3.6 and 39.7 ± 3.8 in the fresh group (P = 0.54). The mean number of embryos transferred (nET) was 1.53 ± 0.6 and 1.60 ± 0.6 (P = 0.12) in the freeze-all and fresh groups respectively. The ongoing pregnancy rates did not significantly differ between freeze-all and fresh group (9.5% versus 10.1%, Odds Ratio [OR] 0.95, 95% CI 0.49-1.83; P = 0.87) and also the clinical pregnancy rates (14.1% versus 13.7%, OR 1.03, 95% CI 0.59-1.82; P = 0.91). The implantation rates were 9.6% and 10.3% (P = 0.77) in the freeze-all and fresh groups respectively. In the logistic regression analysis (including age, AFC, number of retrieved oocytes, number of mature oocytes, nET, and fresh versus freeze-all strategy), the age (P < 0.001) and the nET (P = 0.039) were the only independent variables associated with ongoing pregnancy rates.

Limitations, reasons for caution: This was a retrospective study, which rendered it subject to bias.

Wider implications of the findings: The results of this study emphasize the importance to evaluate adequately the patients that really benefit from the freeze-all strategy, concerning the improved IVF outcomes. Although this strategy may benefit some patients, there are no benefits in implementing the freeze-all strategy in poor ovarian responders.

Trial registration number: -.

P-434 Implantation rate following frozen embryo transfer in leukaemia inhibitory factor supplemented medium

A. Mironova[1], E. Kalinina[1], K. Kiriyenko[1], M. Kharitonova[1], V. Apryshko[1,2], A. Naumova[1], E. Lukyanenko[1], A. Biryukov[1], M. Troshina[1], A. Strashnova[1], E. Simonenko[3], S. Yakovenko[3]

[1]AltraVita IVF Clinic, Embryology, Moscow, Russia C.I.S.
[2]Lomonosov Moscow state University, Faculty of Biology, Moscow, Russia C.I.S.
[3]Lomonosov Moscow state University, Faculty of Physics- Chair of Biophisics, Moscow, Russia C.I.S.

Study question: The aim of the study was to determine whether leukemia inhibitory factor (LIF) enriched transfer medium improves implantation and pregnancy rates in frozen embryo transfer (FET) cycles.

Summary answer: Supplementing transfer medium with 10 ng/ml LIF does not appear to improve implantation and pregnancy rates following FET.

What is known already: Leukemia inhibitory factor plays a central role in the control of implantation. LIF regulates multiple processes prior to and during implantation such as endometrial transformation into receptive state, embryo-endometrial interaction, stromal decidualization, tropfoblast invasion, blastocyst growth and development and uterine leukocyte infiltration. Abberant LIF production is linked to implantation failure.

Study design, size, duration: Prospective controlled study. Results are presented for 1542 IVF cycles with FET between April, 2014 and September, 2015.

Participants/materials, setting, methods: 1712 blastocysts with a grade of BB or higher were cryopreserved on day 5 or day 6 by vitrification technique. Warming was performed at least two hours prior the FET. 798 blastocysts (737 cycles) were then cultured and transferred in global HP medium containing 10 ng/ml LIF. The rest 914 blastocysts (812 cycles) cultured and transferred in global HP medium served as controls. The volume of medium injected with the embryos didn't exceed 20mkl.

Main results and the role of chance: The mean female age and number of embryos per transfer were comparable between two groups. Clinical pregnancy was confirmed by the sonographic observation of a gestational sac. Implantation and clinical pregnancy rates were statistically analyzed using Chi-square test.

Results are summarized in Table 1.

Table 1. Group characteristics and cycle outcomes.

	Global HP	Global HP + 10 ng/ml LIF	Chi-square test
Mean age	35.2 ± 2.4	34.6 ± 2.8	-
#blastocysts transferred	914	798	-
#ET cycles	812	737	-
#blastocyst transferred/ET cycles	1,1	1,1	-
implantaion rate(%)	39,6%	39,2%	NS (p > 0.05)
Clinical pregnancy rate%	42,5%	41,8%	NS (p>0.05)

Limitations, reasons for caution: Due to data absence at the time of this abstract submission, we didn't compare ongoing pregnancy rates.

Wider implications of the findings: There is strong evidence that leukemia inhibitory factor (LIF) is related to embryo development and implantation. In our study LIF in concentration of 10 ng/ml did not improve the implantation rate. Futher studies with use of other LIF concentrations are required in order to detect its positive effect.

Trial registration number: NA.

P-435 Technique with intrauterine fiberscope and curettage of the endometrium (IFCE) improves the pregnancy rate for infertile patients with repeated embryo implantation failures-a randomized controlled trial

M. Funabiki[1], S. Taguchi[2], M. Karita[2], H. Terumi[2], Y. Tada[2], Y. Iwaki[2], Y. Nakamura[2]

[1]Oak Clinic Inc., ART, Osaka, Japan
[2]Oak Clinic Inc., ART, Osaka, Japan

Study question: Does our technique with intrauterine fiberscope and curettage of the endometrium (IFCE) improve the reproductive outcome for infertile patients with repeated embryo implantation failures?

Summary answer: The clinical pregnancy rate for infertile patients with repeated embryo implantation failures was improved by IFCE.

What is known already: Although two randomized controlled trials (RCTs) showed that the use of intrauterine fiberscope did not improve live birth rate, some reports have shown that local injury by endometrial biopsy increases the pregnancy rate in infertile patients with repeated embryo implantation failures. Although we have developed a new technique with IFCE, the clinical efficacy is unclear.

Study design, size, duration: A randomized controlled trial was conducted [IFCE group (n = 448) and non-IFCE group (n = 448)] from December 2013 to August 2016. The patients were randomized using computer-generated randomization. All infertile patients with repeated embryo implantation failures (mean age, 37.9 years) provided informed consents at our clinic. The study was approved by the Institutional Review Board. The primary outcome was the clinical pregnancy rate.

Participants/materials, setting, methods: IFCE was performed in the follicular phase. After observation using intrauterine fiberscope, an original thin metal curette was inserted through the cervical os and advanced gradually into the uterine cavity until resistance was felt. Furthermore, after a single scratch was made in the uterine cavity, the curette was removed to confirm endometrial sampling. If found, endometrial polyps were removed prior to embryo transfer. All patients were given antibiotics. $P < 0.05$ was considered as statistically significant.

Main results and the role of chance: The mean clinical pregnancy rate was 41.74 % in the IFCE group and 6.03 % in the non-IFCE group. Multiple logistic regression analysis indicated that the clinical pregnancy rates were influenced by the conduction of IFCE ($P < 0.001$, odds ratio 11.17, 95% confidence interval: 7.27–17.16), regardless of the patient's age ($P = 0.09$) and BMI ($P = 0.95$). Therefore, regardless of the patient's age and BMI, the clinical pregnancy rate was significantly higher in the IFCE group than in the non-IFCE group. There was no difference in adverse events in both groups.

Limitations, reasons for caution: The sample size in our RCT was sufficient. However, the reproducibility of our study should be investigated by other studies in the near future.

Wider implications of the findings: Our RCT has shown that our new technique with IFCE improves the clinical pregnancy rate for infertile patients with repeated embryo implantation failures. Therefore, our new technique with IFCE will help for the improvement of reproductive outcomes in infertile patients.

Trial registration number: UMIN000025679.

P-436 Pregnancy outcomes of women with a congenital unicornuate uterus after in vitro fertilization-embryo transfer

X. Li[1], Y. Ouyang[2], Y. Wen[2], F. Gong[3], G. Lin[3], G. Lu[3]

[1]Citic-Xiangya Reproductive& Genetic Hospital, Imaging department, Changsha, China
[2]Reproductive and Genetic Hospital of CITIC-Xiangya., imaging department, Changsha, China
[3]Reproductive and Genetic Hospital of CITIC-Xiangya., reproductive center, Changsha, China

Study question: Are the pregnancy outcomes of women with a unicornuate uterus worse than those of women with a normal uterus?

Summary answer: A unicornuate uterus was associated with an increased risk of early pregnancy loss, premature delivery,perinatal mortality, low birth weight (LBW) and low live birth rate

What is known already: Although normal pregnancies can occur in some patients with a clinically asymptomatic unicornuate uterus, this condition has been related to miscarriage, premature delivery, low birth weight, perinatal mortality and other complications.

Study design, size, duration: A retrospective, single-center cohort study was conducted of 238 women with a unicornuate uterus and 818 women with a normal uterus who experienced a clinical pregnancy after in vitro fertilization-embryo transfer (IVF-ET) treatment.

Participants/materials, setting, methods: This study was conducted at the Reproductive and Genetic Hospital of CITIC-Xiangya (Changsha, China). Two hundred and thirty-eight patients with a unicornuate uterus were chosen as the study group (183 with singleton and 55 with twin pregnancies), and 818 patients with a normal uterus were selected as the control group (567 with singleton and 251 with twin pregnancies). The outcome measures included pregnancy and obstetric outcomes, which were compared between the unicornuate and control groups.

Main results and the role of chance: A unicornuate uterus was associated with an increased risk of early pregnancy loss [adjusted odds ratio (aOR) 1.88, 95% CI 1.25-2.83; p = 0.002], premature delivery (aOR 2.11, 95% CI 1.45-3.07; p < 0.001), perinatal mortality (aOR 3.35, 95% CI 1.89-5.94; p < 0.001), LBW (aOR 1.43, 95% CI 1.04-1.79; p = 0.005) and very low birth weight (VLBW, aOR 2.58, 95% CI 1.53-4.34; P < 0.001). Additionally, significantly lower rates of term delivery (aOR 0.43, 95% CI 0.31-0.58; p <0.001) and live birth (aOR 0.27, 95% CI 0.13-0.57; p = 0.001) were observed in women with a unicornuate uterus compared to those of the controls.

Limitations, reasons for caution: Our center was only a reproductive center; thus, all pregnancy outcomes were obtained via telephone calls or faxes. Therefore, some detailed obstetric complications were not studied here. Additionally, this was a retrospective study, and the control group was not screened randomly, which may cause selection and confounding biases.

Wider implications of the findings: Our findings can be used to counsel women whose pregnancies are complicated by a unicornuate anomaly and help guide appropriate antenatal treatment and surveillance.

Trial registration number: None.

P-437 Glycodelin-A interacts with L-selectin on CD16-CD56bright natural killer cells to induce endothelial cell angiogenesis and trophoblast invasion

C.L. Lee[1], W.S.B. Yeung[2], P.C.N. Chiu[1]

[1]The University of Hong Kong, Department of Obstetrics and Gynaecology, Hong Kong, Hong Kong
[2]The University of Hong Kong, Department of Obstetrics and Gynaecolog, Hong Kong, Hong Kong

Study question: How does glycodelin-A (GdA) regulate the action of CD16-CD56bright natural killer (NK) cells on trophoblast and endothelial cell functions?

Summary answer: GdA binds to L-selectin of the CD16-CD56bright NK and induces secretion of angiogenic factors, which in turn regulate endothelial cell angiogenesis and trophoblast invasion.

What is known already: Glycodelin-A (GdA) is an abundant glycoprotein in the decidua. The carbohydrate chains of GdA interact with sialylated glycan receptors such as selectin and siglec of resident decidual leukocytes and invading trophoblasts, modulating their functions for a successful pregnancy. Aberrant expression of GdA in serum, endometrial tissue and uterine flushing is associated with unexplained infertility, pregnancy loss, and preeclampsia. CD16-CD56+ natural killer (NK) cells are the most abundant leukocyte population in the decidua. These cells regulate trophoblast invasion during spiral arteries remodeling, and mediate the homeostasis and functions of the endothelial cells.

Study design, size, duration: Human CD16-56bright NK cells were isolated from female peripheral blood by immuno-magnetic beads and fluorescence

activated cell sorting. They were cultured with GdA at a physiological dose of 5 μg/mL. The phenotypes, the secretion of angiogenesis-related soluble proteins and the biological activities of the resulting NK cells were studied.

Participants/materials, setting, methods: GdA was purified from human amniotic fluid by affinity chromatography. Secretion of angiogenesis-related soluble proteins were determined by cytokine array and flow cytometry. The effect of the identified angiogenic proteins were studied by corresponding blocking antibodies. Endothelial cell angiogenesis was determined by tube formation assay. Cell invasion and migration were determined by trans-well invasion/migration assay. GdA binding on the NK cells and the expression of decidual NK cell markers were analyzed by flow cytometry.

Main results and the role of chance: GdA treatment increased secretion of vascular endothelial growth factor (VEGF) and insulin-like growth factor-binding protein 1 (IGFBP-1) from the CD16$^-$CD56^{bright} NK cells, the suggested immature precursors of tissue-specific NK cells, but not the CD16$^+$CD56^{dim} NK cells. Serum-free conditioned medium derived from GdA-treated CD16$^-$CD56^{bright} NK cells induced tube formation of of HUVEC endothelial cells in vitro, and this effect was nullified by anti-VEGF antibody. Similarly, data suggested that IGFBP-1 mediated the stimulatory activities of the conditioned medium on invasion of primary extravillous trophoblast isolated from 1st trimester termination of pregnancy and trophoblastic cell line JEG-3. Fluorescently labeled GdA has a significantly stronger binding to CD16$^-$56^{bright} NK cell than the CD16$^+$CD56^{dim} NK cell. The sialic acid-dependent glycan receptor L-selectin was expressed in former but not the latter NK cells. The binding was sialic acid dependent, and desialylated GdA failed to bind to both NK cell subsets. Anti-L-selectin function blocking antibody (CD62L) treatment prevented the binding of fluorescently labeled GdA to the CD16$^-$56^{bright} NK cells, and abolished the actions of GdA on NK cells in terms of VEGF and IGFBP-1 secretion. GdA enhanced the expression of decidual NK cell marker CD9 in the CD16$^-$CD56^{bright} NK cells.

Limitations, reasons for caution: Most of the conclusions were based on human peripheral blood CD16$^-$56^{bright} NK cells. Confirmation of these results using human decidual natural killer cells is required. on.

Wider implications of the findings: This is the first study on the role of GdA in CD16$^-$56^{bright} NK cell functions. Further study on the glycosylation of GdA and its biological role will provide better insight of its molecular nature, and thus offer opportunity for development of new preventive intervention and treatment approach for pregnancy complications.

Trial registration number: Nil.

P-438 Collagen mixed with epidermal growth factor promotes the endometrial HOXA10 expression as well as endometrial growth in patients with thin endometrium

C. Kim[1], Y. Jeung[2], J.W. Moon[3], S.H. Kim[2], H.D. Chae[2], B.M. Kang[2]

[1]Asan Medical Center- University of Ulsan, Obstetrics and Gynecology, Seoul, Korea-South
[2]Asan Medical Center- University of Ulsan, Obstetrics and Gynecology, Seoul, Korea-South
[3]M Fertility Center, Obstetrics and Gynecology, Seoul, Korea- South

Study question: Does collagen mixed with epidermal growth factor (EGF) increase the expression of endometrial *HOXA-10* in the mid-luteal phase of infertile patients with thin endometrium, compared with EGF alone?

Summary answer: EGF-loaded collagen stimulates the endometrial *HOXA10* expression in the mid-luteal phase and improves the endometrial growth effect of EGF in infertile patients with thin endometrium.

What is known already: Treatment of poorly developed thin endometrium is still challenging. Several growth factors and cytokines including EGF and granulocyte colony-stimulating factor (G-CSF) have been shown to stimulate the endometrial growth in patients with thin endometrium. In 2016, we have presented that collagen enables sustained release of EGF and improves the treatment effect of EGF on thin endometrium of infertile women. However, study on the effect of EGF-loaded collagen on endometrial receptivity markers including *HOXA10* in patients with thin endometrium has not been reported.

Study design, size, duration: We analyzed the results of a total of 87 consecutive infertile women with thin endometrium < 6 mm who underwent

intrauterine treatment with either EGF-loaded collagen solution (study group, n = 50) or EGF alone solution (control group, n = 37) between March 2014 and November 2016 for this retrospective study. Endometrial tissue in the mid-luteal phase was obtained in 15 patients included in the study group and 12 patients included in the control group in the same period.

Participants/materials, setting, methods: In the study group, slow intra-uterine infusion of 0.8% collagen gel (Collabarrier, Dalimtissen. Co. Ltd., Seoul, Korea) in which 200 ng/ml EGF was loaded was performed every 2-3 days during the follicular phase of 4 to 5 menstrual cycles. In the control group, EGF alone solution with same concentration was used during same period. Endometrial biopsy was performed in the mid-luteal phase of last treatment cycle. Endometrial *HOXA10* mRNA was analyzed by realtime RT-PCR.

Main results and the role of chance: Study and control groups were similar with respect to patient's characteristics. The treatment duration and number were also comparable between the two groups. The peak endometrial thickness was significantly higher in the study group of 7.51 ± 0.68 mm compared with 6.86 ± 0.66 mm in the control group ($p < 0.001$) and resistance index (RI) of subendometrial artery (SEA) was also significantly lower in the study group ($p < 0.001$). Proportion of patients with blood flow of subendometrial artery (SEA) after treatment was also significantly higher in the study group ($p = 0.021$). Relative amount of HOXA-10 mRNA in the endometrium was significantly higher in the study group of 15.85 ± 5.76 compared with 3.21 ± 2.70 in the control group ($p < 0.001$)

Limitations, reasons for caution: This study may have a limitation due to a small number of sample available. Inaddition, it is difficult to know whether the positive effect of EGF-loaded collagen on endometrial *HOXA-10* expression is caused by the collagen itself or by the sustained release of EGF.

Wider implications of the findings: This new treatment regimen may not only promote endometrial growth but also enhance embryo implantation by increasing endometrial *HOXA-10* expression in infertile patients with thin endometrium.

Trial registration number: No.

P-439 Clinical signification of low-grade blastocyst among sibling embryos from the same cohort

S. Kokeguchi, Y. Matsumoto, K. Furuhashi, Y. Tsuji, J. Ohtsuki, E. Okamoto, Y. Mizusawa, S. Yamada, K. Katayama, T. Iwasaki, M. Shiotani

Hanabusa women's clinic, Reproductive Medicine, Kobe- Hyogo, Japan

Study question: How do we select and transfer the low-grade stage blastocysts which make up about 40% of all blastocysts in ART treatment.

Summary answer: Each low-grade blastocyst has moderate hatch potential. The pregnancy rate of the other embryos after successful first transfer is moderate except for women over 40.

What is known already: We can obtain some morphological types of blastocyst with oocyte retrieval. Usually, the best blastocysts are selected from the same cohort and are transferred in order. In Japan we are not permitted to perform PGS. According to the Gardner classification, expanded blastocysts (G3 to G5) have a higher pregnancy rate than low-grade blastocysts (G1 and G2). Of the blastocysts we come across, 17.4% are G1 and 24.9% were G2. We often have to think about what to do with surplus low-grade blastocysts after an unsuccessful result of the first embryos transfer from the same cohort.

Study design, size, duration: This is retrospective, single center study (conducted January 2015 to December 2016).

Participants/materials, setting, methods: This study included 329 vitrified blastocyst in the G1 stage and 670 in the G2 stage, and all blastocysts were vitrified at day 5. Pregnancy rate was detected after thawed single embryo transfer. For experimental analysis, we examined the hatch potential of 63 low-grade blastocysts. Back ground of the groups are no significantly difference.

Main results and the role of chance: The hatching rate of vitrified G1 blastocysts in vitro was 31.3% (10/32), and that of vitrified G2 blastocysts was 88.5% (23/26), p<0.001. The ongoing pregnancy rates of G1 and G2 blastocysts were significantly different (25.1% (231/919) and 12.7% (55/432), respectively, p<0.001). Blastocysts were divided into two groups according to the situation. Group A was the low-grade blastocysts that deserved the second

grade ranking of their cohort that remained after successful single higher-grade blastocyst transfer. Group B was also the low-grade blastocysts that deserved second-grade ranking of their cohort that remained after failed single higher-grade blastocyst transfer. The ongoing pregnancy rates of G2 blastocysts in Group A and Group B were 33.6% (47/140) and 23.4% (43/184), respectively, p<0.05. The ongoing pregnancy rates of G1 blastocysts in Group A and Group B were 18.6% (13/70) and 6.0% (6/100), respectively, p<0.01. The ongoing pregnancy rates of G2 blastocysts from patients 39 and under and G2 blastocysts from patients 40 and over were 30.7% (206/670) and 9.8% (25/255), respectively, p<0.01. The ongoing pregnancy rates of G1 blastocysts from patients 39 and under and G1 blastocysts from patients 40 and over were 15.2% (50/329) and 4.5% (5/110), respectively, p<0.01.

Limitations, reasons for caution: There is the opinion that G1 and G2 grade blastocysts should be cultured and undergo PGS for analyzing euploid embryos. However, in Japan PGS is not permitted to any ART treatment. In this study, we evaluated the pregnancy rates from the morphological blastocyst status.

Wider implications of the findings: We need to carefully consider whether we should transfer the remaining low-grade blastocysts or try to do another retrieval according to the pregnancy rates of those low-grade blastocysts. Except for G1 low-grade blastocysts from women 40 and over it might be beneficial to transfer low-grade blastocysts.

Trial registration number: self-funded

P-440 Subchorionic hematomas are associated with hormone replacement treatment, but do not have any negative impact on pregnancy and miscarriage rates

Y. Tsuji, J. Otsuki, T. Iwasaki, K. Furuhashi, Y. Matsumoto, S. Kokeguchi, M. Shiotani

Hanabusa Women's Clinic, Reproductive Medicine, Kobe- Hyogo, Japan

Study question: Are subchorionic hematomas (SCH) associated with hormone replacement treatment (HRT) and do they influence ongoing pregnancies?

Summary answer: It was found that SCH was associated with HRT, but no negative influence on pregnancy and miscarriage rates was detected.

What is known already: SCH in pregnancies with first-trimester vaginal bleeding is the most common sonographic abnormality in the presence of a live embryo. First-trimester bleeding is notably higher in pregnancies following IVF/ICSI as compared to natural births. However, several reports have shown that pregnancies derived from IVF/ICSI are not associated with an increased risk of spontaneous abortion. On the other hand, other reports have shown that the incidence of preterm delivery (<37 gestational week) after fresh embryo transfers (ET) is higher in patients with first trimester bleeding as compared to patients without first trimester bleeding.

Study design, size, duration: This retrospective study of 4,835 pregnancies was conducted between January 2011 and December 2015, including 684 fresh ET and 4,835 frozen- thawed ET (ovulatory cycles: n = 476, and HR cycles: n = 4,359), all of which achieved the development of a gestational sac (GS) following single embryo transfer. Identical twin pregnancy was excluded from this study. The presence of SCH was defined by transvaginal ultrasound, which was observed by15 gestational weeks.

Participants/materials, setting, methods: The occurrence of SCH after fresh ET was compared with the occurrence of SCH after frozen-thawed ET. Among frozen-thawed ET cycles, the risk of SCH was compared between ovulatory cycles and HRT cycles. Furthermore, the fetal heart beat (FHB) and the birth rates were compared between patients with SCH and without SCH among HRT cycles.

Main results and the role of chance: The occurrence of SCH after frozen-thawed ET was significantly higher as compared to SCH after fresh ET (16.3% vs. 8.2%; p<0.001). Among frozen-thawed ET cycles, the incidence of SCH with HRT was significantly higher than that without HRT (17.1% vs. 8.8%; p<0.001). Among the HRT cycles, the positive FHB rate was significantly higher in patients with SCH as compared to patients without SCH (95.7% vs. 86.9%; p<0.001). Similarly, birth rates in HRT cycles were significantly higher in patients with SCH than in patients without SCH (84.4% vs. 74.0%; p<0.001). Regarding pre-term birth rates in HRT

cycles, there was no significant difference between patients with SCH and patients without SCH (7.6% vs 8.5%; p = 0.49).

Limitations, reasons for caution: Other factors, such as high blood pressure, prior obstetrical complications and family history, which may be associated with SCH, are under investigation following this study.

Wider implications of the findings: A higher incidence of SCH with HRT may indicate excessive hormonal levels in the endometrium. Although no negative impact on pregnancy and miscarriage rates was detected in patients with SCH, careful treatment for SCH is necessary to ensure successful live birth.

Trial registration number: Not applicable.

P-441 CD147 regulates human extravillous trophoblast invasion via Wnt/β-Catenin Signaling Pathway

Y. Guo, C.L. Lee, W.S.B. Yeung, P.C.N. Chiu

The University of Hong Kong, obstetrics and gynaecology, Hong Kong, Hong Kong

Study question: What are the underlying mechanisms that CD147 regulates human extravillous trophoblast invasion?

Summary answer: CD147 on the plasma membrane and extracellular vesicles (EVs) of human extravillous trophoblast enhances trophoblast invasion through the activation of Wnt/β-Catenin signaling pathway.

What is known already: CD147 (basigin or EMMPRIN) is a transmembrane glycoprotein exists as protein complexes on the plasma membrane of human trophoblasts. It regulates trophoblast invasion by modulating matrix metalloproteinases (MMPs) and enzymes of the urokinase plasminogen activator (uPA) system. Secretory CD147 is mainly generated by microvesicle shedding. Reduced placental CD147 expression is associated with pre-eclampsia, but the mechanism of actions remains unclear. A key feature in preeclampsia is the defect in trophoblast invasion during early placentation process.

Study design, size, duration: The expression of CD147 on human extravillous trophoblasts and trophoblast-derived EVs was studied. Their roles and mechanism on trophoblast functions were assessed.

Participants/materials, setting, methods: Trophoblast invasion was evaluated by transwell invasion assay. The spent medium from placental explants, isolated trophoblasts or trophoblastic cell-line JEG-3 was collected for EV isolation by differential centrifugation. EVs uptake and trafficking were assessed by flow cytometry and live cell confocal imaging. CD147 expression on EVs was determined by immune-electron microscopy. CD147 suppression on trophoblasts was achieved by siRNA knockdown or functional blocking antibody. The involvement of Wnt pathway was confirmed by pharmacological activators/inhibitors.

Main results and the role of chance: CD147 was demonstrated to be expressed on the trophoblast plasma membrane or trophoblast-derived EVs in form of protein complex. Inhibition of CD147 suppressed trophoblast invasion and β-catenin activation. The involvement of Wnt pathway in the effects of CD147 was further supported by the studies using Wnt activator or inhibitor. We further demonstrated that the isolated trophoblast-derived EVs could be uptake by other trophoblasts in a time-dependent manner which acted as a cargo for CD147 trafficking.

Limitations, reasons for caution: Most of the above findings are based on *in vitro* model. Their possible association with pathological placental development during early pregnancy needs to be confirmed.

Wider implications of the findings: The outcome of this project gives a better understanding on the role of CD147 in regulating early placentation. Our findings also indicate the possible use of trophoblasts-derived CD147, including both cell surface CD147 and secretory CD147, as test for early prediction of trophoblast functions.

Trial registration number: Not applicable.

P-442 Exposure to Mancozeb impairs embryo implantation via disrupting embryo- epithelium interaction in vitro trophoblast/ endometrial cells co-culture model

Z. Wang[1], K.S.A. Kottawatta[2], S.P. Kodithuwakku[3], K.F. Lee[4]

[1]The University of Hong Kong, Obstetrics and Gynaecology, Hong Kong Island, Hong Kong

[2]The University of Peradeniya, Department of Veterinary Public Health and Pharmacology- Faculty of Veterinary Medicine and Animal Science, Peradeniya, Sri Lanka
[3]The University of Peradeniya, Department of Animal Science- Faculty of Agriculture, Peradeniya, Sri Lanka
[4]The university of Hong Kong, Obstetrics and Gynaecology, Hong Kong, Hong Kong

Study question: Will Mancozeb affect implantation using spheroid-endometrium co-culture model? What is the underlying mechanism that Mancozeb affect endometrium receptivity?

Summary answer: Mancozeb decreased spheroid attachment onto endometrial epithelial cells in vitro and modulated steroid hormone receptor expression and in turns embryo implantation.

What is known already: Mancozeb, is a manganese/zinc containing fungicide belonging to the ethylene bisdithiocarbamate (EBDC) family. Mancozeb has already been classified as a potential endocrine disrupting chemical (EDC), which is reported to modulate androgen and thyroid hormone receptor pathways in recent years. It is widely used in agriculture to protect the fruits, crops and vegetables from fungal diseases. Mancozeb has short half-life (1~3 days) and very low acute mammalian toxicity. However, the role of Mancozeb on human reproductive process especially embryo implantation remains largely unknown.

Study design, size, duration: We used the JEG-3 and endometrial adeno-carcinoma Ishikawa cells lines to mimic embryo implantation. Methotrexate (5 μM) was used as a positive control. JEG-3 and/or Ishikawa cells were treated with different concentrations of Mancozeb (0.01 μg/ml, 0.1 μg/ml, 1 μg/ml and 3 μg/ml) for 24 or 48 hours.

Participants/materials, setting, methods: Total RNA and protein were extracted from Ishikawa and JEG-3 cells. The attachment rate of JEG-3 spheroids and the expression of adhesion molecules (N-catenin and E-cadherin) were measured. The expression of Wnt/β-catenin signaling molecules and steroid receptors (ER, PR and AR) transcripts and proteins in Ishikawa cells were measured by qPCR and Western blotting, respectively. The function role of ERb receptor on implantation was confirmed by inhibitor.

Main results and the role of chance: Mancozeb did not suppress cell proliferation at concentration less than 10 μg/ml. Mancozeb (>1 μg/ml) could decrease the attachment rates when both JEG-3 and Ishikawa cells were treated. The decrease in attachment rate was more prominent by treating the Ishikawa than JEG-3 cells only. Mancozeb affected the expression of N-cadherin in JEG-3 but not in Ishikawa cells, and down-regulated ERβ transcript and protein levels in Ishikawa cells. No change was observed for the expression of ERα, PR and AR. To confirm the role of ERβ in embryo implantation, we used highly selective ERβ antagonist PHTPP (10 μM) on Ishikawa cells and found PHTPP could reduce the attachment rate in spheroids attachment assay which indicate the association of ERβ in implantation. However, in Wnt/β-catenin signaling pathway, no significant change was observed under environmental conditions.

Limitations, reasons for caution: As Mancozeb has a relative short half-life in the cells and environment, its metabolite ethylene thiourea (ETU) should be evaluated. Present study was laboratory study, data from in vivo studies and concentration of Mancozeb and its metabolite in patient with fertility problem should be investigated.

Wider implications of the findings: This study indicates that fungicide Mancozeb could affect implantation process through steroid hormone receptor. Countries with high usage on Mancozeb should be investigated in women with high serum Mancozeb level seeking for infertility treatment since exposure to Mancozeb happens via food chain easily.

Trial registration number: N/A.

P-443 Endometrial receptivity assessment using transcriptomic approach 'Win-test' for personalized embryo transfer

D. Haouzi[1], F. Entezami[2], A. Ferrieres Hoa[3], L. Delaroche[4], E. Vintejoux[3], S. Hamamah[5]

[1]INSERM U1203, IRMB- Hôpital St-Eloi- CHRU Montpellier, MONTPELLIER, France
[2]Laboratoire Eylau-UNILABS-La Muette, Clinique de La Muette-Ramsay-Générale de Santé, Paris, France

[3]Hôpital Arnaud de Villeneuve- CHU Montpellier, Département de Médecine et Biologie de la Reproduction, Montpellier, France
[4]Laboratoire Eylau-UNILABS-Cherest, Clinique Pierre Cherest, Neuilly sur Seine, France
[5]Hôpital Arnaud de Villeneuve- CHU Montpellier, Département de Médecine et Biologie de la Reproduction, Montpellier, France

Study question: The aim of this study was to optimize pregnancy outcome using personalized care management by combining embryo replacement according to the endometrial receptivity evaluation in patients with repeated implantation failures.

Summary answer: Individual evaluation of endometrial receptivity allows a personalized patient care management and improves pregnancy outcome for patients with repeated implantation failures (RIFs)

What is known already: Many approaches for human endometrial receptivity including microarray has been previously reported. However, efficiency of the tests according to the clinical results is still debated. The aim of this study is to evaluate the endometrial receptivity (ER) in RIFs patients who have had at least 3 to 7 implantation failures using Window implantation test (Win Test). The principal of concept which consisting for screening for 13 specific genes of implantationwindow.

Study design, size, duration: An endometrial biopsy is performed during the implantation windows. According to the Win-test result, the embryo transfer strategy was established: transfer at the blastocyst stage at the specific day during the implantation windows where endometrium has been diagnosed as 'receptive'; or transfer at day 2 or day 3 post-fertilization where endometrium is considered as 'partially receptive'. Clinical pregnancy was defined by visualization of a gestational sac with a positive foetal heartbeat.

Participants/materials, setting, methods: The Win Test consists to measuring the expression level of 13 genes predictive of endometrial receptivity in endometrial biopsies. RNAs were extracted and determination of the mRNA expression levels of our biomarkers was performed by qRT-PCR. Then data were converted into a score by using algorithms.

Main results and the role of chance: Analyses of endometrial receptivity status (n = 799) in a large cohort of infertile patients revealed that a strong inter-patient variability i) of the moment of the opening of the implantation window, as well as ii) of the duration of this implantation. Then, as soon as the cycle day where endometrium was said receptive, a personalized embryo transfer can to be perform in the respect of the synchronization of the fœto-maternal dialogue. Using this strategy, the biochemical and clinical pregnancy rate in this group of patients (n = 151) with previous RIFs were 38.3 and 32.7 %, respectively.

Limitations, reasons for caution: Personalized embryo transfer has been performed in 151 RIFs patients only. The benefits of this innovative strategy will be analyzed in PGS patients.

Wider implications of the findings: A personalized embryo transfer according to the endometrial receptivity status diagnosed by transcriptome approach improves pregnancy outcome

Trial registration number: Not applicable.

P-444 Comparative evaluation of Notch signaling pathway in the endometrium of women with PCOS, endometriosis, RIF and healthy fertile controls during luteal phase

E. Salehi[1], F. Amjadi[2], Z. Zandieh[2], M. Rashidi[3], R. Aflatoonian[4], M. Mehdizadeh[5]

[1]Tehran University of Medical Science- School of Medicine, Department of Anatomy, Tehran, Iran
[2]Iran University of medical science-School of Medicine, Department of Anatomy, Tehran, Iran
[3]Iran University of Medical Science-Shahid Akbarabadi hospital, IVF center, Tehran, Iran
[4]Royan Institute for Reproductive Biomedicine- ACECR, Department of Endocrinology and Female Infertility at Reproductive Biomedicine Research Center, Tehran, Iran
[5]Iran University of medical science, Cellular and Molecular Research Center- Department of Anatomy, Tehran, Iran

Study question: Does Notch signaling pathway alter in women with polycystic ovary syndrome (PCOS), endometriosis and Repeated Implantation Failure (RIF) compared to healthy fertile women?

Summary answer: Notch signaling components show different expression in PCOS, endometriosis and RIF patients in comparison with normal women.

What is known already: Prior evidence have suggested Notch signaling pathway plays important role in endometrial remodeling, decidualization, and implantation

Study design, size, duration: In this case–control study, human endometrial biopsies were taken from ten PCOS patients, ten endometriosis, 10 RIF patients and ten healthy fertile women in the secretory phase.

Participants/materials, setting, methods: Total mRNA were extracted from endometrial tissues of PCOS, endometriosis and RIF patients (on day 3-5 after ovulation, n = 10) and healthy fertile individuals (on day 3-5 after ovulation, n = 10) during luteal phase, then the expression of Notch1, -2, -3, Jagged1, -2 and survivin as a downstream target of Notch signaling pathway were measured by QRT-PCR.

Main results and the role of chance: All the endometrial samples expressed Notch1, Notch2, Notch3, Jagged1,2 and survivin. There were significant differences (p<0.05) for Notch1,Jagged1,2 and surviving between free-disease and disease groups.

Limitations, reasons for caution: The main limitation of this study is a low number of human endometrial samples.

Wider implications of the findings: This study provides new insights into the role of Notch signaling pathway in endometrial receptivity.

Our data also indicate that Notch signaling may be promising molecular pathway for the assessment of implantation capacity in several female reproductive diseases.

Trial registration number: N/A.

P-445   Cumulative live birth rate after preimplantation genetic screening in repeated implantation failure: is there still a place for replacing genetically uncreened embryos?

M. Devesa Rodriguez de la Rua, B. Coroleu, M. Parriego, L. Coll, D. Rodríguez, F. Martínez, I. Rodríguez, P.N. Barri

Dexeus Women's Health- Hospital Universitario Dexeus, Obstetrics- Gynecology and Reproductive Medicine, Barcelona, Spain

Study question: What is the cumulative ongoing and live birth rate after preimplantation genetic screening (PGS) with trophoectoderm biopsy and array comparative genomic hybridization (aCGH) analysis in repeated implantation failure (RIF)?

Summary answer: Per patient cumulative ongoing pregnancy and live birth rate after PGS was 76.3%. Euploidy rate was 52.4%.

What is known already: Not much neither known nor published.

A uniform definition is still lacking and, even though embryo aneuploidy is by far the most important factor in RIF, PGS benefit is still questioned.

Unfortunately, the few RCT that we are aware of assessing PGS in RIF, performed D3 biopsy and FISH analysis and a recent non-randomized trial performing trophoectoderm biopsy and comprehensive chromosome screening (CCS), focused on implantation and pregnancy rates.

We consider that RIF studies using PGS should refer to trophoectoderm biopsy and CCS and that success rates, also in RIF, should be reported as cumulative ongoing / live birth rates.

Study design, size, duration: Retrospective study carried out in a University-affiliated fertility clinic (January 2015 - June 2016).

N = 38 couples with RIF: absence of implantation after consecutive embryo transfer (ET) of at least 4 D3 embryos or 2 blastocysts of good quality, as recently defined. Cases with abnormal karyotype, trombophilia, autoimmune disorders, uterine abnormalities, hydrosalpinx or severe male factor were excluded. Women aged >38 were excluded as at those ages, >50% of embryos have been reported to be aneuploid.

Participants/materials, setting, methods: 38 couples with RIF underwent one PGS cycle. Trophoectoderm biopsy was performed when embryos reached the blastocyst stage (D5, D6, D7). Blastocysts were subsequently vitrified. CCS was done with aCGH analysis.

Frozen ET was scheduled either on natural (16%) or artificial cycle (84%). ET was always done under ultrasound guidance.

Main results and the role of chance: Mean woman's age was 35.5 ± 2.4 and mean number of previously transferred embryos was 6 ± 2.7.

With a mean number of 15.2 ± 5.3 inseminated oocytes per patient, fertilization rate was 79.4% and blastocyst rate was 53.1%. Mean number of biopsied blastocysts per patient was 6.4 ± 3.5. Observed euploidy rate was 52.4%. All cases reached ET.

Interestingly, 25% of D3 good quality embryos did not reach the blastocyst stage and 51% of those that reached it were found to be aneuploid.

A total of 50 frozen ET were performed (12 patients with unsuccessful 1st ET underwent a 2nd ET, still no 3rd ET). Mean number of transferred embryos was 1.4 ± 0.5 (single ET was performed in 58% of cases, in 56% of them >1 euploid embryo was available). Clinical pregnancy rate per ET was 68% (34/50) with a miscarriage rate of 14.7% (5/34). Out of 50 ET, 11 are currently ongoing pregnancies (>20 weeks, 22%) and 18 have resulted in a live birth (36%). Globally, 6 multiple pregnancies have been observed.

Implantation rate was 56.3%. Per patient cumulative ongoing / live birth rate was 76.3%. Out of the 9 patients that haven't achieved an ongoing pregnancy / live birth, 6 still have frozen euploid embryos.

Limitations, reasons for caution: Our main limitations are the retrospective nature of the study and the small sample size.

Wider implications of the findings: According to our results, PGS should be offered in RIF patients. Furthermore, shouldn't embryo euploidy be a prerequisite to be considered in a future RIF definition?.

Other factors should be identified in RIF patients that don't succeed after ET of euploid blastocysts and mosaicism cannot be ruled out.

Trial registration number: NCT03001648.

P-446   The absence of ovulation negatively impacts endometrial receptivity: results from an experimental model of anovulation

B. Tarasconi[1], F. Ferreira[1], M. Nichi[2], E. Motta[1]

[1]*Federal University of Sao Paulo - Paulista School of Medicine, Department of Gynecology, São Paulo, Brazil*
[2]*University of Sao Paulo, Department of Animal Reproduction, São Paulo, Brazil*

Study question: Does anovulation induced by continuous light exposure adversely affect the expression of endometrial receptivity markers in rats?

Summary answer: Induced anovulation in rodents reduces expression of LIF and PROKR1, crucial endometrial receptivity molecules, even though anovulatory rats show exuberant development of the uterine structure.

What is known already: Infertile patients due to ovulatory disorders have sub-optimal pregnancy rates when they undergo assisted reproductive technology as compared to normal ovulatory patients. Yet, they present a wealth of clinical and laboratory features in common with women displaying recurrent implantation failures. The complex endocrine-metabolic milieu of the anovulatory patient constitutes an obstacle in the evaluation of the specific effect of anovulation on endometrial function. Whether anovulation itself is the main cause of endometrial receptivity disturbance in this subset of patients remains to be further investigated.

Study design, size, duration: 14 rats displaying anovulation induced by continuous light exposure were compared to 13 ovulatory rats, exposed to natural light 12/12 hours, concerning biomolecular and histological parameters of endometrial receptivity and function. The average experimental period of each included animal was 2 months. The analysis and comparisons between animals' uteri was done after precise establishment of the estrus cycle phases through serial vaginal cytology. A single experienced operator performed all cytological and histologic evaluations.

Participants/materials, setting, methods: 27 adult females Rattus norvegicus albinus (Wistar) were sorted into 2 groups: experimental group, n = 14, under continuous illumination and anovulatory cycles; and control group, n = 13, under natural 12/12 light/dark alternation and ovulatory cycles. The uterine samples were assessed as to the concentration of LIF and PROKR1 by sandwich ELISA. Further, transversal uterine sections stained in hematoxylin and eosin were studied for endometrial thickness, myometrial thickness, glandular surface and vascular surface.

Main results and the role of chance: Rats in both groups presented similar weight, number of vaginal cytological smears and uterine mass. Animals in the experimental group were significantly older than those in the control group (84 days vs. 74 days, P = 0.01). In addition, anovulatory rats showed exuberant uterine structural development with hypertrophy of the epithelial, muscular, glandular and vascular elements, which were easily noted by histological analysis. Specifically, anovulatory rats displayed greater endometrial thickness (712 µm vs. 399 µm, P < .0001), myometrial thickness (228 µm vs. 151 µm, P < .0001) and vascular surface (60,354 µm^2 vs. 43,066 µm^2, P = 0.029). There was a tendency to statistical signification (P = 0.096) in the glandular surface comparison toward the anovulatory group. It is noteworthy that anovulation was associated with a decline of expression of endometrial receptivity markers LIF (385,921 ng/ml vs. 517,567 ng/ml, P = 0.009) and PROKR1 (1,643 pg/ml vs. 3,337 pg/ml, P < .0001), meaning that structural development itself doesn´t mean, necessarily, a favorable uterine environment for embryo implantation in terms of molecular expression pattern.

Limitations, reasons for caution: As an experimental study in rodents, results can´t be directly extrapolated to humans. Anovulatory rats were 11% older, which could have partially influenced results. The low reproducibility of histological measurements needs to be noticed, even though its effect was minimized by single operator evaluations.

Wider implications of the findings: The lower activity of fetal-maternal LIF-PROKR1 signaling pathway could have an influence in the lower implantation rates among anovulatory patients. This study raises new questions concerning the role of LIF and PROKR1 in the diagnosis of endometrial factor infertility, and also as whether they could be used as targeted therapies.

Trial registration number: Not applicable.

P-448 A randomized controlled clinical trial: the treatment of tamoxifen with patients of thin endometrium undergoing frozen-thawed embryo transfer

Q. Sun, H. Li, J. Xu, B. Yao, L. Chen

Nanjing Jinling Hospital, Reproductive Medical Center, Nanjing, China

Study question: Endometrial thickness <7 mm is always a criterion for fresh IVF cycle cancellation and all embryos will be cryopreserved. However, improving endometrial growth in such patients is very difficult.

Summary answer: Tamoxifen compared with letrozole drugs in patients of thin endometrium undergoing frozen-thawed embryo transfer (FET) can increase endometrial thickness and improve implantation rate.

What is known already: Up to now, ther are no standard treatment guidelines for thin endometrium. Tamoxifen, Some research supported that tamoxifen (TAM) compared with clomiphene for ovulation induction can significantly improve the endometrial thickness,but there are few reports about the use of tamoxifen with patiens having thin endometrium in frozen-thawed embryo transfer.

Study design, size, duration: A total of 133 women with thin endometrium scheduled for FET (January 2014–June 2016) were enrolled in an open-label randomized clinical trial to ovarian stimulation with letrozole per oral (n = 72,2.5 mg/day from Day3-7) or tamoxifen per oral (n = 61,40 mg/day from Day 3-7)

Participants/materials, setting, methods: We studied subfertile couples undergoing FET. Further inclusion criteria were female age ≤40 years, number of embryos transferred ≤2 and at least one of good quality, failure of grownth of endometrium in hormone replacement therapy. The primary end-point was clinical pregnancy.

Main results and the role of chance: The serum estradiol level of LE group both on HCG and transfer day [(1193.80 ± 629.64)ng/L vs(2776.30 ± 157.34) ng/L;(1195.90 ± 820.30)ng/L vs (2129.40 ± 1208.71) ng/L,p = 0.000] were statistically lower, serum luteinizing hormone level were statistically higher than TAM group [(20.48 ± 15.50)IU/L vs (10.59 ± 8.34)IU/L,p < 0.05]; implantation rate of LE group were statistically lower than TAM (39.32% vs 45.83%, p = 0.001). The endometrial thickness and serum E2 and P levels in TAM cycles were significantly higher compared with those in hormone replacement therapy cycle [(8.49 ± 1.36)mm vs (6.43 ± 0.96) mm, p = 0.018].

Limitations, reasons for caution: Since the sample size is small, this conculusion needs confirmation with large one.

Wider implications of the findings: Tam compared with LE for patients of thin endometrium undergoing FET can increase endometrial thickness and improve implantation rate, thus providing a new solution.

Trial registration number: ChiCTR-INR-16007965

P-449 Placental chorionic villi of the first trimester human placenta: a lectin study

R. Focarelli[1], P. Piomboni[2], V. De Leo[2], G. Morgante[2], A. Luddi[2], F. Ietta[3], L. Ricci Paulesu[3], R. Romagnoli[3], V. Pavone[3]

[1]*University of Siena, Evolutionary Biology, Siena, Italy*
[2]*University of Siena, Department of Molecular and Developmental Medicine, Siena, Italy*
[3]*University of Siena, Department of Life Sciences, Siena, Italy*

Study question: How does the glycocode of the human chorionic villi changes during the first trimester of pregnancy?

Summary answer: A significant modification in the distribution of carbohydrate epitopes bearing fucose and sialic acid could be revealed during the first trimester of pregnancy

What is known already: Although several studies have been published on sugar distribution in human placenta, they are mainly limited to terminal placentae and also lead to conflicting results. A few studies addressed the glycosylation status of different placental cells with particular reference to macrophage-like cells called Hofbauer cells in terminal placentae.

Study design, size, duration: We approached the study of cellular glycosylation in human placenta by using chorionic villi explants obtained by microdissection. A total of 24 placentae were obtained from women undergoing voluntary abortion and signing an informed consensus according to the guidelines of the University of Siena Ethical Committee.

Participants/materials, setting, methods: Isolated chorionic villi explants from first trimester human placentae (weeks 7, 9, 10, 12) were fixed and embedded in paraffin for histochemical analysis using biotinylated Concanavalin A (ConA), *Maackia amurensis* (MAA), *Sambucus nigra* (SNA) and *Lotus tetragonolobus* (LTL) lectins. Alternatively, samples were solubilized and analyzed by two dimensional electrophoresis followed by lectin blotting with the same probes.

Main results and the role of chance: The two methodological approaches used in this study allowed us to provide general information on the expression of selected carbohydrate epitopes in the whole tissue and on their specific localization in the cellular compartments. Glycoconjugates bearing fucose and sialic acid terminal epitopes are almost absent in seven weeks placenta explants while they became expressed in weeks 9 to 12 with a specific localization on endothelial and Hofbauer cells with MAA reactivity extending to the throfoblast. On the other side ConA reactivity was consistently found on throphoblast cells, their glycocalix and the stroma. By two dimensional electrophoresis followed by lectin blotting we could reveal non only exposed epitope carbohydrates but also processing and/or stored glycoproteins. As expected ConA labeling revealed several dozens of glycoproteins bearing N-linked oligosaccharides at all different stages of pregnancy. On the other side MAA, SNA and LTL lectins are restricted to few glycoproteins with a tendency to a reduction in the periods under analysis (weeks 7 to 12). Careful controls were performed and a significant role for chance may be excluded.

Limitations, reasons for caution: This has to be considered a pilot study. It has to be completed with a more specific analysis of the tentatively identified glycoproteins with specific antibodies and/or with protein identification by mass spectrometry

Wider implications of the findings: These preliminary results suggest that changes in endothelial cells may allow selective migration of Hofbauer cells from the blood flow in the first trimester of pregnancy and a more general role in stromal cells maturation and differentiation.

Trial registration number: None.

P-450 Construction of gel based 3D endometrial co –culture systems: Can human mesenchymal stem cells be an alternative?

S. Karahuseyinoglu[1], K. Sari[2], G.N. Sahin[2], D. Yucel[3], A. Kocabay[4], A.C. Taskin[4]

[1]*Koç University School Of Medicine, Histology & Embryology, Istanbul, Turkey*

[2]Koc University Graduate School of Health Sciences, Reproductive Biology, Istanbul, Turkey
[3]Acibadem University School of Medicine, Histology-Embryology, Istanbul, Turkey
[4]Koç University, Animal Research Facility- College of Sciences, Istanbul, Turkey

Study question: Which is more effective for construction of gel based 3D endometrial co–culture systems, endometrial cells or human mesenchymal stem cells?

Summary answer: Mesenchymal stem cells obtained from human umbilical cord can also be used for the same purpose and in a more efficient manner in some ways.

What is known already: Implantation is a complex process consisting of three phases: apposition, attachment-adherence and penetration. The rate of implantation failure in first trial of spontaneous pregnancies is 25-40%. It is very difficult to mimic implantation in vitro since the process takes place in a 3D environment. 3D co-cultures are more convenient for blastocyst behavior, during invasion. The perfect 3D culture has not been revealed successfully yet. One of the methods for 3D cultures is use of endometrial cells in a gelatinous matrix. On the other hand mesenchymal stem cells were also demonstrated to have positive effects on the developing embryo.

Study design, size, duration: This study reveals the comparative effects of two different gel-like extracellular matrix based 3D endometrial co-culture systems, one constructed with mouse endometrial stromal and epithelial cell, the other with human mesenchymal stem cells obtained from human umbilical cord matrix. The comparative analysis was held at hours 48 and 72 by IF, WB and qRTPCR and by confocal and multiphoton microscopy for Invasion depth.

Participants/materials, setting, methods: Mouse blastocysts were cultured in three groups as: i. routine IVF drop culture group, ii. the group that holds mouse blastocysts ongel decorated with endometrial epithelial cells and endometrial stromal cells, iii. the group that holds mouse blastocysts on immnunocompetent human mesenchymal cell decorated gel based 3D co-culture. The groups were compared in terms of structure, function and invasion by e-cadherin, LIF, MMP9 and progesterone receptor Caspase-9 and live/dead cell assay were also performed.

Main results and the role of chance: Here we propose two very effective gel-based 3D in-vitro implantation models supported by either mesenchymal stem cells or endometrial cells, compared with each other and compared with a routine ivf culture. Both of them can be used to see the in-vitro development and survival of the blastocyst together with the newly differentiating trophoblasts. The comparative analysis was made between groups and also in the group itself from 48 to 72 hours. From 48 to 72 hours e-cadherin decreased in all groups with a high amount of decrease in endometrial cell decorated group. At the end of 72 hours endometrial co-culture was found to be very effective for expression of progesterone receptors, while human MSC supported balstocysts for production of LIF efficiently. Invasion parameter MMP9 expression was high with both cultures, while routine group has also increased MMP9 interestingly. Endometrial co-cultures supported the blastocyst to invade horizontally under the implantation area as depicted by the increase of dead cells, and human MSC also supported the blastocysts for invasion, implicating that human MSC can be used in vitro for generation of 3D endometrial co-cultures, with a further impact for effective in vivo use.

Limitations, reasons for caution: This study is based on use of mouse endometrial epithelial and stromal cells, though human MSCs are also used. The limitation is the inter-species implantation differences between of mouse and human. Human blastocysts were intentionally not used for such trial, since there is a major ethical concern

Wider implications of the findings: 3D culture for embryos still stands for an unsolved problem. Though the comparative methods proposed here are based on mouse blastocyst implantation, they provide information about the effects of human mesenchymal stem cells on implantation models, which can be alternatively tried for human embryos on 3D cultures before embryo transfer.

Trial registration number: This is not a clinical trial.

P-451   A Retrospective Comparative Study of Lymphocyte Immunotherapy With and Without Aspirin: Pregnancy Outcomes of Patients With Unexplained Recurrent Miscarriage

H. Wang[1], L. Li[2], J. Qiao[1], P. Liu[1], C. Ma[1], X. Chen[1], R. Li[1]

[1]Reproductive Medical Center- Peking University Third Hospital, Department of Obstetrics and Gynecology, Beijing, China
[2]Reproductive Medical Center–Peking University Third Hospital, Department of Obstetrics and Gynecology, beijing, China

Study question: To evaluate the efficacy and safety of lymphocyte immunotherapy (LIT) with and without aspirin for patients with unexplained recurrent spontaneous abortion (URSA)

Summary answer: LIT combined with aspirin improved the pregnancy outcomes of patients with URSA. The combination therapy was also relatively safe.

What is known already: Lymphocyte immunotherapy (LIT), a possible treatment for URSA, in which the prospective mother is tolerized by subcutaneous injections with paternal or third party lymphocytes. The aim is to induce female immunosuppression and thereby reduce the abortion rate.Another possible reason for URSA may be excessive coagulation in the mother. There is evidence that the placental vasculature of women with URSA bears microthrombi and infarctions.Daily low-dose aspirin inhibits platelet aggregation and can thereby prevent thrombotic disorders such as coronary artery disease.It is also logical to hypothesize that combining the two approaches might yield better pregnancy outcomes in women with URSA.

Study design, size, duration: This retrospective cohort study included all consecutive patients with URSA who were treated with LIT alone or with aspirin in 2009–2014 in a tertiary care hospital. The rates of successful pregnancy (defined as a pregnancy that continues past 20 weeks' gestation) and live birth were determined. The factors that influenced these pregnancy outcomes were identified by multiple logistical regression analysis. The partum maternal complications were recorded. The offspring were followed up for 1–6 years.

Participants/materials, setting, methods: The cohort consisted of all consecutive patients with URSA who were treated with LIT with or without aspirin in the Peking University Third Hospital between January 2009 and December 2014. Patients were excluded if they had not become pregnant within 1 year after the end of LIT or their medical records were not complete.Aspirin, 100 mg was administered daily starting at the beginning of LIT and continuing until 20 weeks' gestation.

Main results and the role of chance: Of the 61 patients in the LIT-alone group, 36 had a successful pregnancy (30 term deliveries, four preterm deliveries, and two induced labors due to fetal malformations). Of the 109 patients in the combination-therapy group, 82 had a successful pregnancy (73 term deliveries, five preterm deliveries, two induced labors due to fetal malformation and two induced labors due to fatal cord accidents). Thus, the pregnancy success rates of the LIT-alone and combination-therapy groups were 59% and 75.2%, respectively. This difference was statistically significant ($P < 0.05$). To calculate the live birth rate, the six patients who underwent induced labor because of fetal malformation or fatal cord accidents were not counted. Thus, 34 (55.7%) patients in the LIT-alone group and 78 (71.6%) patients in the combination-therapy group gave birth to a live infant. This difference was statistically significant ($P < 0.05$). Multiple logistical regression analysis indicated that aspirin acted as an independent factor that protected gestation. Neither LIT nor aspirin associated with excessive maternal and fetal complications.The present study compares for the first time the pregnancy outcome of patients with URSA who underwent LIT with or without aspirin.

Limitations, reasons for caution: The limitation of our study is a retrospective analysis, and RCTs of the two therapies are needed.

Wider implications of the findings: Women with URSA were treated with LIT, it yielded significantly higher rates of successful pregnancy and live birth when it was combined with aspirin.The low rates of complications in our cohort also suggest that LIT combined with aspirin is relatively safe. Hence, this method deserves more clinical recognition and application

Trial registration number: Not applicable.

P-452   Intrauterine infusion of human autologous peripheral blood mononuclear cells in patients with repeated failed attempts of optimum endometrial development in FET cycle: A Pilot study

B. Chakravarty[1], S. Wasim[2], S. Ghosh[2], S.K. Goswami[2], S. Chakraborty[2], S.N. Kabir[3], R. Chattopadhyay[2]

[1]Annex of Institute of Reproductive Medicine, ART, Kolkata, India
[2]Institute of Reproductive Medicine, ART, Kolkata, India

Study question: Does autologous peripheral blood mononuclear cells (PBMC) help in optimum endometrial development in patients with several failed FET cycles due to inadequate endometrial thickness and vascularity?

Summary answer: Intrauterine infusion of PBMC resulted improvement of endometrial development in 27 amongst 37 patients studied, with 5 pregnancies following 15 transfer results declared so far.

What is known already: Autologous PBMC is one of the most convenient source for stem cells generation. This process is non-invasive, cost effective and causes minimal discomfort to the patient. PBMC has been shown as a source of pluripotent stem cells for regeneration of blood cells, nerve cells, epithelial cells, myofibroblast, muscle cells, bone cells and endometrial cells. There are studies depicting the role of PBMC with or without hCG priming for increasing the invasive potential of embryos as a therapeutic modality in recurrent implantation failure. There is a case report of regeneration of endometrium using PBMC in case of Asherman syndrome.

Study design, size, duration: Prospective study, with sample size of 37 patients, from August 2016 and continuing till date of submission of this abstract. The study was designed to evaluate possible improvement in endometrial thickness and vascularity following intrauterine autologous PBMC compared to the mean of their previous records in failed IVF attempts (min. 3 and max. 10) due to inadequate endometrial development. Mononuclear cells were isolated from patient's peripheral blood by density gradient centrifugation using commercially available lymphoprep.

Participants/materials, setting, methods: Setting: Institute of Reproductive Medicine, Kolkata, India

Patients received oestradiol valerate 6.0 mg daily from day2 till endometrial thickness reached ≥6.5 mm with significant increase in blood flow, when progesterone was administered. End diastolic velocity(EDV) was considered as the main marker of endometrial vascularity. On day5, isolated mononuclear cells suspended in 500 µL normal saline were infused into uterine cavity and embryo transfer was performed around day25. Inadequate endometrial response (thickness/vascularity) resulted in cancelation of embryo transfer.

Main results and the role of chance: The patients were categorized in 4 groups with regard to their response to therapy;- a) Significant increase in thickness (6.2 ± 0.8 vs 7.3 ± 0.9, P = 0.003) and vascularity (8.55 ± 1.79 vs 10.05 ± 1.66, P = 0.04) in 12 patients (44.44%) b) significant increase in vascularity (7.68 ± 1.62 vs 9.24 ± 1.66, P = 0.02) but not in thickness (6.8 ± 0.7 vs 7.2 ± 0.7, NS) in 2 patients (7.4%) c) significant increase in thickness (6.7 ± 1.2 vs 7.9 ± 1.3, P = 0.02) but not vascularity (7.84 ± 1.32 vs 8.68 ± 1.47, NS) in 13 patients (48.14%) d) no significant increase either in thickness (6.5 ± 0.8 vs 7.2 ± 1.1, NS) or in vascularity (7.45 ± 1.13 vs 8.22 ± 1.31, NS) in the rest 10 patients.

5 pregnancies were achieved out of 15 embryo transfer results declared so far. 4 pregnancies occurred when both thickness and vascularity improved and in one, than vascularity rather thickness showed improvement. No pregnancies were recorded in other two groups.

The probability of events happening due to chance is low although effect of catheter insertion and invoking cytokine production accelerating the endometrial development in presence of estrogen supplementation cannot be ruled out.

It is still premature to ascertain the increase in endometrial thickness and vascularity due to PBMC because some other factor like catheter insertion might have resulted in identical endometrial changes.

Limitations, reasons for caution: Number of patients studied till now is not adequate to make a valid conclusion. But results achieved already appear promising. However, there were patients whose cycles were cancelled implying that some unknown patient or endometrial characteristics may exist which may influence in achieving optimum endometrial preparation for successful blastocyst implantation.

Wider implications of the findings: Till date other than surrogacy, there is no proven treatment of repeated thin endometrium in FET cycles.

It is cost effective and minimally invasive procedure and can result in pregnancy without taking recourse to surrogacy.

Trial registration number: Not applicable.

P-453   Thin endometrium transcriptome analysis reveals a potential mechanism of implantation failure

H. Asada, M. Okada, H. Tamura, N. Sugino

Yamaguchi University Graduate School of Medicine, Obstetrics and Gynecology, Ube, Japan

Study question: To investigate the molecular mechanisms how thin endometrium is involved in implantation failure.

Summary answer: Implantation failure in the thin endometrium appears to be associated with aberrantly activated inflammatory environment and aberrantly decreased response to oxidative stress.

What is known already: Women with thin endometria have lower pregnancy rates, largely due to implantation failure. We recently found high blood impedance in the uterine radial artery in patients with a thin endometrium, and that vitamin E, l-arginine, and sildenafil citrate treatments, which increase blood flow of the uterine radial artery, helped to thicken the endometrium. This suggests that low blood flow to the endometrium reduces its thickness. However, little information is available regarding the molecular mechanisms how a thin endometrium caused by low blood flow of the uterine radical artery is involved in implantation failure.

Study design, size, duration: A total of six women with a history of infertility were recruited into the study. The patients were classified into two groups: normal-thickness endometrium group and thin endometrium group. The cutoff value of endometrial thickness between normal and thin endometrium was defined as 8 mm based on our previous studies.

Participants/materials, setting, methods: Thin and normal endometrial tissue was obtained from a total of six women during the midluteal phase of the menstrual cycle. The transcriptomes were analyzed with a microarray containing 54,120 probes supporting 18,599 genes. Differentially expressed genes were classified according to Gene Ontology (GO) terms and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways.

Main results and the role of chance: The hierarchical dendrogram clearly separated the thin and control endometria in the mRNA expression profiles. We identified 318 upregulated genes and 322 downregulated genes in the thin endometrium compared to the control endometrium. The upregulated genes in the thin endometrium were related to immunity processes such as 'response to external stimulus", 'defense response", 'leukocyte mediated immunity", 'immune response", 'immune effector process" and 'regulation of immune system process". GO and KEGG pathway analyses indicated that the thin endometrium possessed aberrantly activated immunity and natural killer cell cytotoxicity accompanied with increased inflammatory cytokines such as interferon gamma (IFN-γ). The downregulated genes in the thin endometrium were related to metabolic processes such as 'small molecule catabolic process", 'single-organism catabolic process", 'organic acid catabolic process" and 'carboxylic acid catabolic process". The GO terms include carnitine palmitoyltransferase 1 (CPT1), 3-Hydroxy-3-Methylglutaryl-CoA synthase 2 (HMGCS2) and 3-oxoacid CoA-transferase 1 (OXCT1), which are known to play important roles in generating energy in cells and tissues. Two KEGG pathways that have a strong association with the downregulated genes are 'butanoate metabolism" and 'metabolic pathways". These pathways include HMGCS2, OXCT1, xanthine dehydrogenase (XDH), isocitrate dehydrogenase 1 (IDH1) and carbonyl reductase 3 (CBR3).

Limitations, reasons for caution: A higher sample size design could be used in future studies to corroborate the current findings.

Wider implications of the findings: This study revealed that thin endometrium possesses an aberrant Th1-pro-inflammatory/Th2-anti-inflammatory balance and increased cytotoxic condition, and that a protective response to oxidative stress is impaired in the thin endometrium. These aberrant molecular mechanisms in thin endometrium may be associated with implantation failure.

Trial registration number: None.

P-454   The effect of hydrosalpinx volume various pretreatments on clinical pregnant rate of FET Cycle

P. Xia[1], L. Keli[2], G. Fei[2]

[1]CITIC Xiangya Reproductive and Genetic hospital, reproductive center, changsha Hunan, China
[2]Institute of Reproductive & Stem Cell Engineering, reproductive center, Changsha, China

Study question: To assess the extent of hydrosalpinx which affect outcomes of frozen embryo transfer(FET) and the effect of difference pretreatments of hydrosalpinx prior to FET cycle.

Summary answer: Patients with hydrosalpinx more than 3 cm have lower clinical conception rate. The effect of the four different pretreatments of hydrosalpinx has no significant differences.

What is known already: The hydrosalpinx secreted by epithelial cells in dilated fallopian lumens are toxic to embryos. They interfere with embryonic implantation, conception, and increase abortion rate. However, whether all the hydrosalpinx need to be deal with and what is the optimal pretreatment of hydrosalpinx have not been conclusive.

Study design, size, duration: A retrospective analysis of 716 patients was performed in this study. The data of the extent of hydrosalpinx and the effect of difference pretreatment groups(including Hydrosalpinx clamps, ligation, salpingectomy and Fallopian tube embolization) were collected from FET cycles which were carried out from January 2013 to April 2016 at CITIC Xiangya Reproductive and Genetic hospital.

Participants/materials, setting, methods: Infertile females with hydrosalpinx were divided into exposed group (pretreated before FET cycle, n = 557) and control group (untreated before FET cycle, n = 159). Patients in exposed group were further divided into four subgroups by difference pretreatments, including hydrosalpinx clamps, ligation, salpingectomy and fallopian tube embolization. Clinical pregnant rate in exposed group was compared to control group. We also compared the clinical outcomes among different pretreatments subgroups in exposed group.

Main results and the role of chance: All participants who met the following criteria were included: (i) both ovaries present; (ii) basal FSH<10 IU/l, estradiol<80 pg/ml; (iii) normal uterine cavity; (iv) frozen embryos better than 6II; and (v) no current or past diseases affecting the administration of gonadotrophins. There is no significant differences between exposed group and control group in general conditions, including age of female patient, duration of infertility, as well as the level of BMI, FSH, LH and E_2. In the first FET cycle, there was no significant difference in clinical pregnancy rate between exposed group (60.68%, 338/557) and comparison group (57.23%, 91/159).However, for cumulative clinical pregnancy rate, the exposed group was much higher than comparison group (68.4% vs. 58.5%, p<0.05).In exposed group, the was no significant difference in clinical pregnancy rate among the four different pretreatments subgroups (P > 0.05)In comparison group, the clinical pregnant rate of female patient with hydrosalpinx more than 3 cm was significantly lower than patient with hydrosalpinx less than 3 cm (p<0.05).But in exposed group, there was no significant difference of clinical pregnant rate between the patient with hydrosalpinx more than 3 cm and less than 3 cm (p>0.05).

Limitations, reasons for caution: A new treatment scheme was put forward and the effect of four difference pretreatment groups was compared in this study. However, the small sample size of exposed women might lack sufficient power for the investigation of differences in pretreatment groups.

Wider implications of the findings: The present study is the first indicating the correlation of pretreatments with the volume of hydrosalpinx.The female patient with the volume of hydrosalpinx more than 3 cm should receive any one kind of pretreatment prior to IVF.

Trial registration number: NA.

P-455   Differential microRNA profile in the endometrial fluid (EF) in natural cycles, HRT, and controlled ovarian stimulation (COS) triggered with hCG (COS+hCG) or GnRHa (COS+GnRHa)

A. Grasso[1], R. Navarro[2], I. Moreno[3], M. Herrero[3], P. Alama[4], F. Vilella[5], C. Simon[6]

[4]Igenomix S.L.- Parque Tecnologico Valencia University- Valencia- Spain, IVI Valencia- Valencia- Spain., Valencia, Spain
[5]Igenomix- Valencia University and Instituto Universitario IVI/ INCLIVA- Valencia- Spain // Department of Obstetrics & Gynecology- Valencia University School of Medicine and Department of Obstetrics & Gynecology- Stanford University Medical School, Rese,
[6]Igenomix S.L- Valencia- Spain. // IVI Valencia- Valencia University and Instituto Universitario IVI/ INCLIVA- Valencia- Spain // Department of Obstetrics & Gynecology- Valencia University School of Medicine and Department of Obstetrics & Gynecology- St.

Study question: What is the miRNAs profile in the EF in the same patients undergoing consecutively a natural cycle, a HRT cycle, a COS+hCG and finally COS+GnRH-a cycle?

Summary answer: We identify significant differences in miRNAs patterns among natural cycle, HRT, COS+GnRH-and COS+hCG throughout the luteal phase in the same group of patient.

What is known already: It has been demonstrated that aspiration of EF in the same transfer cycle does not affect pregnancy rate and is being used for the search of minimally invasive biomarkers of endometrial function. We have already demonstrated that miRNAs are produced in the glandular epithelial endometrium and secreted into the EF. Specifically, we have identified 20 differentially expressed miRNAs throughout the natural menstrual cycle (Development, 2015). But the impact of hormonal replacement therapy (HRT) or controlled ovarian stimulation triggered with hCG (COS+hCG), or GnRHa (COS+GnRHa) on EF miRNA signature in the same patient has not been yet explored.

Study design, size, duration: EF aspirates (n = 114) were obtained from healthy ovum donors volunteers (n = 47), aged 18-34 with regular menstrual cycle, normal karyotype, and BMI between 19-29 Kg/m2. Each patient underwent consecutively a natural cycle, a HRT cycle, then a COS cycle in which final oocyte maturation was induced by hCG (COS+hCG), and finally a COS cycle in which GnRH-a was used for final maturation trigger (COS+ GnRHa).

Participants/materials, setting, methods: EF were collected in natural cycle at days LH+0 (n = 9), LH+3 (9), LH+5 (7), and LH+7 (2). HRT at P+0 (9), P+1 (8), P+3 (8) and P+5 (6). COS+hCG at hCG+0 (10), hCG+3 (3), hCG+5 (3), hCG+7 (4). Finally, COS+GnRHa at GnRHa+0 (10), GnRHa+3 (9), GnRHa+5 (9), GnRHa+7 (8). Total RNA was sequenced using Illumina HISeq2000/100 and bioinformatically analyzed. The gene expression profiles from the Endometrial Receptivity Analysis (ERA) were used for target analysis.

Main results and the role of chance: A comparative analysis revealed significant differences (p<0.05) in miRNAs secreted in EF between natural cycle and HRT/COS cycles. In the non-receptive phase (LH+0; P+0; hCG+0 and GnRH-a+0), natural cycles differed from COS cycles in 24 miRNAs, and HRT and COS cycles exhibit 27 differential expressed miRNAs. In the pre-receptive phase (LH+3/LH+5; P+1/P+3; hCG+3/hCG+5 and GnRHa+3/GnRHa+5), HRT and COS+GnRH-a displayed 10 miRNAs differentially expressed. The biggest differences were found during the receptive phase (LH+7; P+5; hCG+7 and GnRHa+7) where 26 miRNAs were differentially expressed between HRT and COS+GnRH-a, 21 miRNAs in natural vs. COS+GnRH-a, etc,. Thereby, HRT and COS+GnRHa displayed the most dissimilar profiles along luteal phase, while HRT and natural cycles the most similar. MiRNAs obtained from the comparisons of pre-receptive vs. receptive phase were considered as biomarkers candidates. In detail, hsa-miR-708-5p, hsa-miR-30d-5p, hsa-miR-4446-3p, hsa-miR-873-3p, hsa-miR-30b-3p as candidates in natural cycles, hsa-miR-1299, hsa-miR-7974, miR-409-5p) in COS+GnRH-a, in HRT (miR-324-5p, miR-223-3p), and in COS+hCG (hsa-miR-203a-3p). Functional analysis evidenced 41 ERA genes target. Annotation of these genes in KEGG, showed 56 pathways, which could be involved in endometrial receptivity such as FoxO signaling, Wnt signaling, focal adhesion, and cell adhesion molecules.

Limitations, reasons for caution: Aspiration of EF is considered minimally invasive. However, the introduction of a catheter into the uterine cavity carries a slightly risk of infection. Another critical aspect is the small amount of sample recovered, for this reason, maximum care must be taken to minimize contamination with blood and endometrial tissue.

Wider implications of the findings: This NGS-based study demonstrates for the first time the differential miRNA profile in EF in natural cycle versus different hormonal treatments. It offers the basis to understand how miRNAs are involved the human endometrial biology. This work identifies differential expressed miRNAs that could serve as new diagnostic for endometrial receptivity.

Trial registration number: It was consider as a biomedical study (Non clinical Trial with drug or medical device). FV and CS contributed equally.

P-456   Clinical pregnancy outcome after double dose intrauterine instillation of granulocyte colony-stimulating factor(G-CSF) in the unresponsive thin endometrium in frozen embryo transfer

U. Sen, G. Khastgir

Bengal Infertility and Reproductive Therapy Hospital, Reproductive Medicine, Kolkata, India

Study question: Does double dose intrauterine instillation of G-CSF in patients with unresponsive thin endometrium improve clinical pregnancy outcome following frozen embryo transfer.

Summary answer: Double dose intrauterine G-CSF instillation results in higher clinical pregnancy rates in patients with unresponsive thin endometrium undergoing frozen embryo transfer.

What is known already: G-CSF, a biologic response modifier has the beneficial effect on clinical pregnancy outcome in Assisted Reproductive Technology (ART). However, some studies failed to demonstrate such benefit. Possible reasons for this, as concluded in a recent meta-analysis are the use of the relatively low dose of G-CSF and one-time administration. They also concluded that cohort studies are required to investigate the appropriate route and dose of G-CSF administration.

Study design, size, duration: A prospective observational cohort study over 6 months, carried out on 200 patients undergoing FET, aged between 23-40 years. All patients had two cancelled cycles due to thin endometrium (<5 mm on day 12/13 of cycle) after receiving conventional treatment with oral and topical oestrogen. 3 patients were lost to follow up.197 patients underwent 300 microgram intrauterine G-CSF instillation (97 patients received second dose). Primary and secondary outcome measures were endometrial thickness and clinical pregnancy.

Participants/materials, setting, methods: All patients received oral and topical oestrogen from day 2/3 of cycle, endometrial thickness (ET) was reassessed on day12/13 by transvaginal ultrasonography. Subjects having ET 4-5 mm received intrauterine instillation of 300 microgram G-CSF. After 72 hours patients having an ET increase of 1.5 mm or more underwent FET; others received 2nd dose of G-CSF after another 72 hours. Those with 1.5 mm ET increase from day 12/13, underwent FET, others having cycle cancelled.

Main results and the role of chance: Out of 197 subjects, 100 (50.76%) had ET increase more than 1.5 mm after 72 hours of the 1st dose of G-CSF (mean 6.17 mm ± SD 0.81), significantly higher than value after conventional treatment (p value<0.001).Out of 97, receiving the 2nd dose of G-CSF, 70 (72.16%) had minimum ET increase of 1.5 mm after another 72 hours (mean 6.5 mm+SD 0.74), significantly higher than value after conventional therapy(p value<0.001). 27 out of 197(13.70%) had their cycles canceled.

Out of 100 patients undergoing FET after 1st dose of G-CSF 49(49%) had clinical pregnancy documented by transvaginal ultrasonography. Rest 97 received the 2nd dose of G-CSF of which 70 underwent FET. Out of this 97 receiving the second dose,23(23.71%) had the clinical pregnancy. Overall 197 patients with unresponsive thin endometrium receiving either 1 or 2 doses of G-CSF 72((36.55%)attained clinical pregnancy.

Limitations, reasons for caution: The absence of control, the safety of 2nd dose of G-CSF instillation.

Wider implications of the findings: This study reaffirms utility of G-CSF instillation in unresponsive thin endometrium in ART. It opens the feasibility of using 2nd dose of G-CSF to enhance clinical pregnancy outcome in such cases. Furthermore, endometrial thickness of less than 5.5 mm may be considered for G-CSF administration to proceed to clinical pregnancy.

Trial registration number: Not applicable.

P-457   Higher incidence of colonization with Gardnerella vaginalis and gram-negative anaerobes in patients with recurrent miscarriage and elevated peripheral natural killer cells

R.J. Kuon[1], R. Togawa[1], K. Vomstein[1], T. Göggl[1], T. Strowitzki[1], U. Markert[2], V. Daniel[3], A. Dalpke[4], B. Toth[5]

[1]University Hospital, Department of Gynecological Endocrinology and Fertility Disorders, Heidelberg, Germany
[2]University Hospital Jena, Placenta-Lab, Jena, Germany
[3]University Hospital, Transplantation-Immunology, Heidelberg, Germany
[4]University Hospital, Department of Infectious Diseases- Medical Microbiology and Hygiene, Heidelberg, Germany
[5]University Hospital, Gynecological Endocrinology and Reproductive Medicine, Innsbruck, Austria

Study question: Are there associations between the vaginal microbiota and peripheral/uterine natural killer cells (NK cells) in patients with recurrent miscarriage (RM).

Summary answer: Patients with RM and elevated peripheral NK cells suffer more often from colonization by Gardnerella vaginalis and gram-negative anaerobes.

What is known already: Screening of vaginal microbiota in RM is not included in international guidelines. However, there are subgroups of RM patients with a history of gestational disorders like preterm rupture of the membranes or late miscarriage that are associated with vaginal infections. So far it is unknown whether changes in the vaginal microbiota are also reflected by the composition of immune cells in the peripheral blood. NK cells are major players during early pregnancy and therefore predisposed as a target of scientific interest when associations between vaginal microbiota and immunologic effects are focused.

Study design, size, duration: Between November 2011 and March 2016, n = 243 couples with ≥ 3 consecutive RM were included in this study.

Participants/materials, setting, methods: Vaginal swabs were taken and send to the Department of Infectious Diseases, Medical Microbiology of the University of Heidelberg for analysis by microscopy and culture. Further, a cervical swab was taken in n = 187 patients and the presence of Chlamydia trachomatis was evaluated by a molecular assay. In addition, peripheral blood levels of CD45+CD3-CD56+CD16+ peripheral NK cells (determined by four-color fluorescence flow cytometry) and CD56+ uterine NK cells (uterine biopsy, determined by immunohistochemistry) were evaluated.

Main results and the role of chance: The prevalence of *Gardnerella vaginalis* colonization in RM patients was 19.0%, *gram-negative anaerobes* 20.5%, *Candida* species 7.9%, group B *Streptococcus* 11.0% and *Enterobacteriaceae* 14.8%. Commensal *lactobacilli* were absent in 14.5% of the women. *Chlamydia trachomatis* was detected in n = 1 case (0.53%). The prevalence of *Gardnerella vaginalis* in RM patients with elevated peripheral NK cells (> 280/ μl) was significantly higher compared to patients with normal peripheral NK cells (29.0 vs. 14.9 %, Odds ratio (OR) 2.32, 95% Confidence interval (CI) 1.19 to 4.52, p = 0.012). In addition, in these subgroups, a higher prevalence of *gram-negative anaerobes* was detected (29.0 vs. 17.2 %, OR 1.96, 95% CI 1.02 to 3.76, p = 0.041). No difference of the vaginal microbiota was detected between the subgroups of RM patients with normal vs. elevated uterine NK cells.

Limitations, reasons for caution: The lack of a control group hints comparisons to healthy individuales.

Wider implications of the findings: RM patients with elevated peripheral NK cells suffer more often from colonization by *Gardnerella vaginalis* and *gram-negative anaerobes*. This might indicate an association between the vaginal microbiota, local inflammation, changes in immune parameters and recurrent miscarriage.

Trial registration number: n.a.

P-458   The effects of oxygen, pH and temperature in mammalian reproduction and their importance in human reproduction

K.Y.B. Ng[1], R. Mingels[2], H. Morgan[2], N. Macklon[1], Y. Cheong[1]

[1]University of Southampton, Academic Unit of Human Development and Health, Southampton, United Kingdom
[2]University of Southampton, Institute of Life Sciences, Southampton, United Kingdom

Study question: What are the modulators and effects of oxygen, pH and temperature in mammalian reproduction?

Summary answer: Modulators of biophysical parameters in the female reproductive tract are multifactorial; fine control is crucial in optimal fertilisation, implantation and development of the early conceptus.

What is known already: Despite advances in IVF techniques and ovarian stimulation regimens, implantation rates per embryo transfer still remain low, and pregnancy rates have not risen accordingly. IVF laboratories strive to ensure that the process of handling gametes *in-vitro* closely mimics the *in-vivo* environment. However, ironically, a limiting step to improving outcomes is the lack of knowledge and data on the actual *in vivo* oxygen concentration, pH and temperature within the reproductive tract, which are likely to be dynamic rather than constant.

Study design, size, duration: A systematic review.

Participants/materials, setting, methods: A systematic literature search was performed using electronic databases including Medline, Embase, Cochrane Library and Pubmed to identify original and review articles addressing the biophysical parameters (pO2, pH and temperature) in the female reproductive tract. The search included all listed studies published between 1946 to November 2015. Search terms included 'oxygen', 'pH', 'hydrogen ion concentration', 'acid base' and others terms. We also used special features and truncations to identify synonyms and broaden the search.

Main results and the role of chance: Our search generated 18, 685 records and 60 articles were included. pO2 (oxygen tension) within the female reproductive tract shows cyclical variation and minute to minute oscillations which may be influenced by uterine contractility, hormones, the autonomic system, cardiac pulsatility, and myometrial and smooth muscle integrity. Fine balanced control of pO2 and avoidance of overwhelming oxidative stress is crucial for embryogenesis and implantation. The pH in the female reproductive tract is graduated, with lowest pH in the vagina (pH 4.42) increasing towards the Fallopian tubes (pH 7.94), reflecting the variation in site-specific microbiome and acid-base buffering at the tissue/cellular level. The temperature variation in humans is cyclical by day and month. In humans, it is biphasic, increasing in the luteal phase; with the caudal region of the oviduct 1-2 degrees cooler than the cranial portion. Temperature variation is influenced by hormones, density of pelvic/uterine vascular beds and effectiveness of heat exchange locally, crucial for sperm motility and embryo development. We have identified significant deficiencies and inconsistencies in the methods used to assess these biophysical factors within the reproductive tract. We have suggested technological solutions including the development of methods and models for real time, *in-vivo* recordings of biophysical parameters.

Limitations, reasons for caution: Due to the heterogeneity of studies, a valid meta-analysis of data was not possible within this systematic review.

Wider implications of the findings: The notion of 'back to nature' in assisted conception was suggested 20 years ago. However, the strategy for embryo culture to mimic nature has largely been ignored. Our inability to assess the *in-vivo* reproductive tract environment in real time is contributory; addressing this will enable precise and personalised fertility treatment.

Trial registration number: N/A.

P-459   High prevalence of chronic endometritis in women diagnosed with hydrosalpinx during in vitro fertilization treatment

P.E. Bouet[1], L. Lapensée[2], J. Lefebvre[2], G. Legendre[1], P. May-Panloup[1], H. El Hachem[2]

[1]Angers University Hospital, Reproductive Medicine, Angers, France
[2]Ovo Clinic, Reproductive Medicine, Montreal, Canada

Study question: Should women diagnosed with hydrosalpinx during in vitro fertilization (IVF) treatment be screened for concurrent chronic endometritis (CE)?

Summary answer: Women diagnosed with hydrosalpinx during IVF treatment have a high prevalence (32%) of immunohistochemically confirmed CE, and should thus be screened for concurrent CE.

What is known already: Hydrosalpinges represent a chronic inflammatory condition that adversely affects implantation and pregnancy rates in IVF cycles, by altering endometrial receptivity. When diagnosed during IVF treatment, hydrosalpinges are surgically treated before embryo transfer. CE is defined as a persistent inflammation of the endometrial lining, and is best diagnosed with immunohistochemical identification of plasma cells in the endometrial stroma. Studies suggest CE negatively impacts fertility outcomes by altering endometrial receptivity, and its prevalence is higher in patients with infertility, recurrent implantation failure and recurrent pregnancy loss. However, it remains unclear whether there is a relationship between hydrosalpinges and CE.

Study design, size, duration: A pilot prospective observational study at the IVF center and the department of Reproductive medicine of Angers University Hospital, between June 2015 and September 2016.

Participants/materials, setting, methods: Patients aged 18 to 42 years, undergoing IVF for various indications, in whom a hydrosalpinx was diagnosed before or during cycles, were included. A laparoscopy was scheduled for the removal of hydrosalpinges and an endometrial biopsy performed to rule out CE. The diagnosis of hydrosalpinx was confirmed by histological examination while CE was diagnosed using immunohistochemistry stains for CD138 ($\geq$5 plasma cells/field). Women with CE were treated with Doxycycline 100 mg bid for 14 days.

Main results and the role of chance: 25 patients were included. Mean age was 34.2 $\pm$ 4.4 years. The causes of infertility were: Tubal factor (36% [9/25]), endometriosis (28% [7/25]), poor ovarian reserve (16% [4/25]), anovulation due to polycystic ovarian syndrome (20% [5/25]). Hydrosalpinx was bilateral in 56% (14/25) and unilateral in 44% (11/25) of cases. 48% (12/25) of patients had a unilateral salpingectomy, 44% (11/25) had a bilateral salpingectomy and 8% (2/25) had bilateral tubal ligation with filshie clips. The diagnosis of hydrosalpinx was histologically confirmed in 92% (23/25) of women. All patients had an endometrial biopsy, and the prevalence of immunohistochemically confirmed CE was 32% (8/25). Median follow-up after surgery was 10.9 $\pm$ 5.9 months. Three patients were lost to follow-up. Following IVF and embryo transfer in 22 patients, eight clinical pregnancies (fetal heartbeat at 7 weeks) (36%), one ectopic (4.5%) and one biochemical pregnancy (4.5%) were recorded. Out of the eight patients treated for CE, two were lost to follow-up, three had an endometrial biopsy after treatment which confirmed the absence of CE, and one clinical pregnancy was achieved (17%).

Limitations, reasons for caution: Our pilot study was limited by the small number of participants, and was not powered enough to compare pregnancy rates between women without CE and the ones treated. Moreover, randomized controlled trials are needed to assess the impact of CE treatment on pregnancy rates and outcomes in IVF cycles.

Wider implications of the findings: Our study shows a high prevalence of CE in patients diagnosed with hydrosalpinx during IVF treatment. Patients with hydrosalpinges should thus be screened for concurrent CE before embryo transfer, and treated accordingly.

Trial registration number: Not applicable.

P-460   Effect of intra-uterine G-CSF on endomerial thickness in patients with persistently thin endometrium: A retrospective study of 244 thawed embryo transfer cycles

S. Singh[1], S. Singh[2], M. Ashraf[2], D. Laddad[2]

[1]Craft Hospital And Research Center, reproductive medicine, Thrissur, India
[2]craft hospital, Reproductive Medicine, Kodungallur, India

Study question: Does intra-uterine G-CSF infusion increase endometrial thickness in women with earlier cancelled embryo transfer cycles due to thin endometrium despite using estradiol validate, pentoxiphylline,vitamin E and Sildenafil citrate?

Summary answer: Use of intra uterine G-CSF results in significant improvement in endometrial thickness from 7.19 $\pm$ 0.52 mm to more than 8.10 $\pm$ 1.09 mm.

What is known already: Persistently thin endometrium represents a therapeutic challenge for the physicians. It leads embryo transfer in suboptimal conditions, cancelled transfer and transfer to gestational surrogates; leading to emotional and financial burden.

The mainstream treatment for improving endometrial thickness is estrogen supplementation. However few patients are refractory to estrogen supplementation and require other modalities. Inconsistent response has been seen with sildenafil citrate, low dose aspirin, pentoxifylline, and tocopherol etc, with no established roles.

Earlier case reports have been published showing significant improvement in endometrial thickness after intrauterine instillation of granulocyte colony stimulating factor.

Study design, size, duration: This is a historical case control study of 192 women with persistently thin endometrium in previous 2 estrogen replacement therapy(ERT).

All cases were recruited at Craft Hospital and Research Centre over a period of 3 years from January 2013 to December 2015.

All women had endometrial thickness less than 7 mm at day 20 of previous 2 estrogen replacement cycle and it failed to improve even with addition of above mentioned adjuvants

Participants/materials, setting, methods: After initial failed attempt all women were started on ERT (8 mg /day) from day 2 of period and serial ultrasound monitoring was performed from 10 th day onwards at interval of 3-5 days.

Intra uterine instillation of 300 mcg/1 ml of G-CSF (Endokine, Filgrastim, INTAS) was done if endometrial thickness was less than 7 mm after 18 days of high dose ERT.

Main results and the role of chance: Before infusion of G-CSF the mean ET of the cohort was 7.19 ± 0.52 on day 18.1 ± 3.7 of high dose ERT.

After 48 hours of infusion the mean endometrial thickenss of the cohort increased by 0.57 mm and reached 7.76 ± 0.96 mm.

At second review after 4.9 ± 2.7 days of G-CSF infusion the mean endometrial thickness of the cohort reached 8.10 ± 1.09 mm showing increase of 0.91 mm.

Out of 244 cycles, 115 cycles (47%) showed improvement in endometrial thickness upto and beyond 8 .0 mm. The average increase in endometrium seen in these 115 cycles was 1.75 ± 0.62 mm on last day of ERT.

In other 119 cycles the improvement in endometrial thickness was less than 1 mm and did not reach threshold for embryo transfer.

There were 10 more cycles where reduction in endometrial thickens was noted after G-CSF infusion.

Total 127 frozen-thawed embryo transfer was performed i.e. 52% of treated cycles. The implantation rate, clinical pregnancy and live birth rate per transfer procedure were 27.5%, 44% and 29.9% respectively for these women.

Limitations, reasons for caution: t is a retrospective study with small sample size.The women acted as their own controls.

Wider implications of the findings: This study supports the use of intrauterine -G-CSF for patient with persistently thin endometrium.

But overall improvement in endometrial thickness is less than 1.75 mm.

Further robust data in terms of large multicentric randomised controlled trials are needed to substantiate the findings.

Trial registration number: Not applicable as it is a retrospective analysis.

P-461   The reproductive outcome following Atosiban administration around the time of embryo transfer: a systematic review and meta-analysis

L. Craciunas[1], M. Kollmann[2], N. Tsampras[3], N. Raine-Fenning[4], M. Choudhary[5]

[1]Newcastle University, Newcastle Fertility Centre, Newcastle upon Tyne, United Kingdom
[2]Medical University of Graz, Department of Obstetrics and Gynecology, Graz, Austria
[3]Saint Mary's Hospital- Central Manchester University Hospital NHS Trust, Reproductive Medicine, Manchester, United Kingdom
[4]University of Nottingham, Division of Child Health- Obstetrics and Gynaecology- School of Medicine, Nottingham, United Kingdom
[5]Newcastle upon Tyne Hospitals NHS Trust, Newcastle Fertility Centre, Newcastle upon Tyne, United Kingdom

Study question: Does administration of Atosiban around the time of embryo transfer improve the reproductive outcome in subfertile women undergoing assisted reproduction?

Summary answer: Atosiban administered around embryo transfer increases the clinical pregnancy rate and does not influence the miscarriage rate. There are insufficient data related to live birth.

What is known already: Uterine contractions at the time of embryo transfer are negatively correlated with the outcome of assisted reproduction treatment. Ovarian stimulation associates an increase in the frequency of uterine contractions, possibly because supraphysiological serum estradiol levels may induce endometrial production of oxytocin and formation of oxytocin receptors. Oxytocin antagonists (ie: Atosiban) are being used for the treatment of imminent premature birth with minimal side effects.

Study design, size, duration: The present study is a systematic review and meta-analysis of randomised controlled trials (RCTs) investigating the role of Atosiban administered around the time of embryo transfer. It was conducted according to the published Cochrane Protocol (CD012375) with the last systematic search performed on 26th of January 2017.

Participants/materials, setting, methods: Participants were women undergoing embryo transfer as part of their assisted reproduction treatment irrespective of the cause of subfertility, age, previous treatments, obstetric and gynaecological history or city/country of origin. Women from the intervention group received Atosiban around the time of embryo transfer and were compared to women from the control group who received placebo or no intervention. The endpoints were clinical pregnancy, miscarriage, live birth and adverse events rates.

Main results and the role of chance: Seven moderate quality RCTs met the inclusion criteria and were meta-analysed. There were 963 women in the intervention group and 1015 women in the control group. The administration of Atosiban around the embryo transfer increased the clinical pregnancy rate (RR 1.25, 95% confidence interval (CI) 1.10 to 1.41, seven RCTs, n = 1978, $I^2 = 30\%$, p < 0.0004, moderate quality evidence) and did not influence the miscarriage rate (RR 1.05, 95% CI 0.75 to 1.47, five RCTs, n = 1756, $I^2 = 0\%$, p = 0.79, moderate quality evidence). One study reported similar live birth rates between the intervention and control groups (RR 1.046, 95% CI 0.874 to 1.253, n = 800, p = 0.612, low quality evidence). None of the RCTs reported differences in adverse events between the study groups.

Limitations, reasons for caution: There was significant clinical (women characteristics) and methodological (Atosiban regimes, stage of embryo, embryo processing) diversity between RCTs. The effect of Atosiban on clinical pregnancy is promising; however, future studies should report on live birth as a primary outcome prior to the incorporation of the intervention in routine clinical practice.

Wider implications of the findings: Previous retrospective and non-randomised studies reported conflicting effects of the intervention. The present meta-analysis of seven RCTs presents the most up to date evidence and supports future research aiming to establish the optimal regime and identify the patient groups that could benefit the most from Atosiban around embryo transfer.

Trial registration number: Not applicable.

P-462   Next generation RNA sequencing on human trophectoderm cells reveals competent blastocysts for single embryo transfer in in vitro fertilisation cycles

P. Ntostis[1], G. Kokkali[2], J. Huntriss[1], E. Kanavakis[3], H. Picton[1], K. Pantos[2], D. Miller[1]

[1]LICAMM, Reproduction and Early Development, Leeds, United Kingdom
[2]Genesis Athens clinic, IVF, Athens, Greece
[3]University of Athens, Medical Genetics, Athens, Greece

Study question: Can trophectoderm (TE) transcriptome patterns predict successful Day 5 blastocyst (BC) implantation?

Summary answer: Our transcriptome analysis revealed twenty-three RNAs significantly over-expressed in successfully implanted BCs, mainly involved in steroidogenesis and eight RNAs highly expressed in non-implanted BCs.

What is known already: Previous studies have attempted to establish the relationship between gene expression profile and BC implantation in in vitro fertilization (IVF) utilising microarrays (Jones et al., 2008) or a next generation RNA Sequencing (RNA-Seq) approach (Kirkegaard et al., 2015). None of these studies performed aneuploidy screening on the analysed BCs and there are currently no predictive molecular markers of IVF BC implantation competence.

These findings suggested a principal difference in the gene expression related to clinical outcome, which would potentially allow for a new approach to refine and improve existing criteria for selecting viable BC for single embryo transfer (SET).

Study design, size, duration: To determine the TE transcriptome patterns linked to successful BC implantation, ten BCs were biopsied from 6 couples and subsequently transferred into the female uterus. The compared groups were: i. BCs that successfully implanted into the female uterus and ii. BCs that failed to implant. The samples were collected within a three-month period.

Participants/materials, setting, methods: Infertile couples (34-46 years) with no uterine abnormalities underwent fertility treatment in Genesis Athens IVF clinic, Athens, Greece. Day 5 TE biopsy were followed by fresh uterine transfer. RNA and DNA respectively of TE cells from each BC, underwent RNA-Seq using the latest Clontech single cell (SMART) approach and aneuploidy detection by QF-PCR for chromosomes X,Y and autosomes 13, 18 and 21 following whole genome amplification (WGA). Bioinformatic analysis involved Bioconductor packages in R.

Main results and the role of chance: The current study employed a more precise approach to reveal the patterns of the TE transcriptome that accompany successful implantation determined by the detection of CP. Following library construction and RNA sequencing, the data were processed and analysed statistically using the edgeR Exact test with an FDR of 0.05. Two of the analysed BCs were excluded as outliers. A total of thirty-one transcripts were significantly differentially expressed between the TE cells from embryos going on to generate successful versus unsuccessful CPs. Of these, twenty-three transcripts were significantly up-regulated in the successfully implanted BCs, including HSD17B1 and CYP11A1, while the remaining eight transcripts were significantly up-regulated in non-implanted BCs, including WNK3 and BAK3. Ontological analysis revealed pathways involved mainly in steroid biosynthesis and sterol metabolic process with high confidence. Samples with detected chromosomal aneuploidies were excluded from this study.

Limitations, reasons for caution: Sample size is the main limitation of the current study. However, RNA-Seq is a robust method and although embryo implantation is a multifactorial biological process it can address the study question for the particular samples analysed.

Wider implications of the findings: The current methodology is probably more reliable to investigate single TE biopsies, compared with the previous approaches employed. The detected transcripts could be used in a diagnostic aid for selecting the most viable BC, with the best potential to support full term pregnancy following SET, among a morphologically similar cohort.

Trial registration number: Not applicable.

P-463 Interactome between embryo trophectoderm cells and endometrial epithelial and stromal cells: novel insights into implantation process in human

M. Koel[1], K. Krjutškov[1], A. Reddy[2], M. Saare[3], S. Katayama[2], L. Kumar[4], K. Gemzell Danielsson[4], F. Lanner[5], E. Einarsdottir[6], D. Blesa[7], C. Simon[8], J. Kere[2], A. Salumets[1], S. Altmäe[1]

[7]Igenomix, Igenomix, Valencia, Spain
[8]Valencia University/INCLIVA & Igenomix, Valencia University/INCLIVA & Igenomix, Valencia, Spain

Study question: Which cell surface proteins mediate interactions between polar-trophectodermal blastocyst cells and the receptive endometrial epithelial and stromal cells during embryo implantation?

Summary answer: A complex network of surface proteins on endometrial epithelial/stromal cells and polar-trophectodermal cells participate in the first interactions between the developing embryo and receptive uterus.

What is known already: Human embryo implantation is a dynamic process that requires a dialogue between the receptive uterine lining (endometrium) and blastocyst-stage embryo. As it is ethically and technically impossible to study human embryo implantation in vivo, the molecular processes taking place during implantation are not well known. The few studies of embryo-endometrium molecular interactions conducted so far are based on endometrial whole-tissue, that consists of different cell types. This obvious limitation creates a need for cell-type specific approach to predict the very first molecular interactions between the surfaces of the blastocyst and receptive endometrial epithelial and stromal cells.

Study design, size, duration: Paired endometrial tissue samples from 17 women were obtained from pre- and receptive menstrual cycle phase. The biopsies were dissociated, CD9-positive epithelial cells and CD13-positive stromal cells were separated with FACS sorting and full transcriptome analysis was performed by RNA-sequencing. The interaction partners from embryo side were obtained from our previously published human embryo transcriptional map, which is based on RNA-sequencing of 1529 single cells of 88 embryos (Petropoulos et al., 2016).

Participants/materials, setting, methods: Protein-protein interaction (PPI) networks were constructed using data on upregulated genes from receptive endometrial epithelium/stromal cells and polar-trophectodermal cells. The detected mRNAs were converted into corresponding proteins, the subset of proteins localized in cell membrane and surface were extracted, and PPI networks were created based on interactions in STRING 10.0 database. The biological processes of cell-type specific interaction networks were identified by enrichment analyses and assembled together into super-clusters.

Main results and the role of chance: Endometrial epithelial-trophectodermal cell network contains 157 and endometrial stromal-trophectodermal network 138 interacting cell surface proteins. Several of the genes in the cell-specific networks were unique to the corresponding cell types, such as epithelial genes S100 calcium-binding protein P (S100P), mucin 20 (MUC20), prostasin (PRSS8) and CD44 antigen (CD44); and stromal genes laminin subunit beta 1 (LAMB1), lipid phosphate phosphohydrolase 3 (LPP3), supervillin (SVIL) and decorin (DCN). Biological processes related to cell attachment and proliferation like single organismal cell-cell adhesion, cell division and establishment or maintenance of cell polarity were detected in both blastocyst-epithelial and blastocyst-stromal cell-specific PPI networks. The largest super-cluster in stromal-specific cell network was related to the positive regulation of kinase activity and extracellular matrix organization, while in epithelial-specific cell network blood coagulation and cell junction assembly clusters were detected. The hyaluronan metabolism pathway, known to be important in embryo implantation, was uniquely enriched in epithelial cell network, underlining the cell type specific nature of human embryo implantation process.

Limitations, reasons for caution: As it is unethical and technically challenging to study human embryo implantation in vivo, we lack appropriate tools to validate in silico predicted interactions in humans.

Wider implications of the findings: New understanding about the molecular processes that lead to successful embryo implantation allow us to detect new relevant marker genes for receptive endometrium and maturing blastocyst, thus allowing to predict the best timing for embryo transfer in in vitro fertilization cycles.

Trial registration number: not applicable.

P-464 The impact of difficult embryo transfer on implantation, clinical pregnancy and live birth rates following single blastocyst replacement

E. Coats[1], N. Raine-Fenning[2]

[1]The Fertility Partnership, Nurture Fertility, Nottingham, United Kingdom
[2]University of Nottingham, Obstetrics & Gynaecology, Nottingham, United Kingdom

Study question: What is the impact of difficult embryo transfer (ET) on in vitro fertilisation (IVF) outcomes following the transfer of a single fresh blastocyst?

Summary answer: This is the first study to show that difficult embryo transfer is more detrimental to a high-quality embryo than those with lower potential to implant.

What is known already: Difficult ET has been shown to decrease implantation and clinical pregnancy rates. It is unclear what defines a 'difficult' transfer as there are no universally agreed classification systems and because it is generally judged subjectively. The number and quality of embryos replaced is accepted to affect pregnancy rates, though the significance of these factors in the context of difficult embryo transfer is not well understood. The impact of difficult ET on IVF outcomes has largely been tested in cycles where multiple embryos of differing qualities have been replaced at different stages as opposed to when a single blastocyst is transferred.

Study design, size, duration: In this study 754 fresh single blastocyst transfers were undertaken between June 2009 and April 2014. Three different levels of difficulty were identified based on the steps taken to overcome resistance. A fourth group (Group M) was identified when clinicians anticipating a difficult ET and electively chose to insert the firm malleable stylet from the outset. Embryo quality was judged subjectively by the embryologist using our simplified grading system (A best – C worst).

Participants/materials, setting, methods: Embryo transfers were performed under ultrasound guidance using an 18-centimetre soft embryo replacement catheter. If the soft catheter could not be passed with ease, the outer sheath was advanced and if this did not overcome the resistance the catheter was withdrawn and a firmer malleable stylet catheter introduced. Each embryo transfer documentation record was classified by two experts. Primary clinical outcomes were implantation, clinical pregnancy and live birth rates.

Main results and the role of chance: Documentation of ET was incomplete in 16 cases (2.1%), and in 86 cases (11.4%) a malleable stylet was used electively before threading the soft catheter (group M): these cases were excluded from the analysis leaving 652 single blastocyst transfers, which formed the study group. There were no significant differences in patient characteristics. For all embryos, implantation rates and clinical pregnancy rates fell significantly (p < 0.05). Live birth rates fell from 51.4% to 43.2% when an embryo transfer was difficult but this was not significant (p = 0.202). Accounting for embryo grade, implantation rates (IR) fell by a magnitude of 25% from 84.3% to 62.0% for the highest quality (grade A) embryos during difficult transfers (p = 0.001). Whilst the decrease was significant for the best quality embryos it was not the same for the lower quality grade B and C embryos. Clinical pregnancy (CP) and live birth rates fell for all grades of embryo as transfer difficulty increased. Despite this clear fall in CP and LB rates the results did not reach statistical significance (P< 0.05).

Limitations, reasons for caution: The limitations of this research is the subjective interpretation of ET difficulty and embryo quality. A larger prospective study is needed with more accurate grading systems of ET and embryo quality to explore whether the prognostic potential of a single blastocyst is significantly changed by the difficulty of ET.

Wider implications of the findings: This study has shown that a difficult embryo transfer has a significant impact on the potential of single high quality (Grade A) blastocyst to implant. This fall in prognostic potential affects all embryos to some degree but the highest quality blastocysts seem most affected.

Trial registration number: Not applicable.

P-465   The optimal endometrial thickness to reduce miscarriage and maximise live birth in in-vitro fertilisation treatment: A multicentre cohort study

I. Gallos[1], M. Khairy[1], M. Rajkhowa[2], A. Tobias[1], A. Campbell[3], K. Dowell[4], S. Fishel[3], A. Coomarasamy[1]

[1]Tommy's National centre for Miscarriage Research- Institute of Metabolism and Systems Research IMSR, University of Birmingham, Birmingham, United Kingdom
[2]Birmingham Women's Hospital, Birmingham Women's Fertility Centre, Birmingham, United Kingdom
[3]CARE Centres for Assisted Reproduction, Embryology, Nottingham, United Kingdom
[4]CARE Centres for Assisted Reproduction, Reproductive Medicine, Nottingham, United Kingdom

Study question: What is the association between endometrial thickness and reproductive outcomes following in vitro fertilisation treatment and the endometrial thickness threshold that optimises the IVF outcome

Summary answer: An endometrial thickness threshold of 10 mm or more is suggested to maximise the chances of a live birth and minimise miscarriage.

What is known already: The NICE guideline on Fertility suggests performing an embryo transfer in in-vitro fertilisation (IVF) treatment if the endometrial thickness is more than 5 mm. However, there is uncertainty on the optimal endometrial thickness.

Study design, size, duration: Design Observational multicentre cohort study.

Participants/materials, setting, methods: Setting Data from CARE Fertility Group; including six main and seven satellite centres in the UK.

Participants 25,427 women undergoing fresh cycle of IVF in the CARE centres who have had an endometrial thickness measurement and a recorded reproductive outcome, between 2007 and 2016.

Main outcome measures Primary outcomes: Miscarriage and live birth; Secondary outcomes: Biochemical and clinical pregnancies, implantation rate, biochemical pregnancy loss, and clinical pregnancy loss.

Main results and the role of chance: Endometrial thickness is strongly associated with miscarriage and live birth in an IVF cycle. The risk of a miscarriage was 41.7% with 5 mm endometrial thickness and gradually decreased to 26.5% with an endometrial thickness of 10 mm or more. On the other hand, live births increased from approximately 15% to more than 33% with increasing endometrial thickness. Statistical modelling for optimal endometrial thickness threshold found 10 mm or more maximised live birth while minimising miscarriage.

Limitations, reasons for caution: Ultrasound measurements of endometrial thickness are inherently subjective even though the technique is standardised across the CARE units. We have not linked the fresh cycles to subsequent frozen-thawed cycles and they are not taken into account for the cumulative live birth rate.

Wider implications of the findings: Live births are recorded even with 5 mm maximum endometrial thickness. However, since the live birth rates double when the thickness is 10 mm or more may be preferable to decide not to transfer an embryo within this cycle and opt for a subsequent frozen embryo transfer.

Trial registration number: None.

P-466   Hysteroscopic placement of Tornado microinsert in paitients with hydrosalpinx before in vitro fertilization-embryo transfer

H. Chen

Reproductive and Stem Cell Engineering Institute -Central South University, IVF unit, Changsha-Hunan, China

Study question: To evaluate the feasibility and IVF outcomes of Tornado microinserts placement for infertile women with hydrosalpinx

Summary answer: Tornado placement is an effective method for occlusion of hydrosalpinges when laparoscopy is hard to be performed.

What is known already: Laparoscopic proximal tubal occlusion or salpingectomy is an option for infertile women with hydrosalpinx. However, less injured and safer method remains to be investigated.

Study design, size, duration: A prospective, single-arm, clinical study including 152 women with hydrosalpinges (unilateral or bilateral) from May 2014 to May 2016 was analyzed.

Participants/materials, setting, methods: A total of 152 women undergoing hysteroscopic Tornado inserts placement were included in the analysis. The main outcomes were live birth rate in subsequent cycles

Main results and the role of chance: The success rate of Tornado microinserts placement was 98.4% (240/244). 118 women had a total of 159 embryos transferred. The clinical pregnancy rate was 57.63% (68/118) and the live-birth rate was 36.44 % (43/118). There were two cases of ectopic pregnancy even after Tornado microinserts placement.

Limitations, reasons for caution: Due to the small sample size, larger studies should be needed for the confirmation of effectiveness and safety of Tornado microinserts placement.

Wider implications of the findings: The results suggest that Tornado microinserts placement might be an option for the management of women with hydrosalpinx before ART

Trial registration number: None.

P-467 The effect of endometrial injury on VEGF expression in patients with Repeated Implantation Failure: A randomized control trial

S. Aghajanpour[1], E. Amirchaghmaghi[2], A. Yahyaei[3], M. Ashrafi[4], R. Aflatoonian[5]

[1]Royan Institute for Reproductive, Department of Endocrinology and Female Infertility at Reproductive Biomedicine Research Center, Tehran, Iran
[2]Royan Institute for Reproductive Biomedicine-ACER, Department of Endocrinology and Female Infertility- Reproductive Biomedicine Research Center, Tehran, Iran
[3]Royan Institute for Reproductive Biomedicine- ACECR-, Department of Endocrinology and Female Infertility- Reproductive Biomedicine Research Center-, Tehran, Iran
[4]1Royan Institute for Reproductive Biomedicine- ACECR-2 Iran University of Medical Science, Dep11Dartment of Endocrinology and Female Infertility- Reproductive Biomedicine Research Center-2 Department of Obstetrics and Gynaecology- Faculty of Medicine
[5]Royan Institute for Reproductive Biomedicine- ACECR, Department of Endocrinology and Female Infertility- Reproductive Biomedicine Research Center, Tehran, Iran

Study question:: Does endometrial injury really effect on VEGF expression as a pivotal marker of implantation in patients with Repeated Implantation Failure?

Summary answer: Endometrial injury during proliferative phase of menstrual cycle before embryo transfer can improve VEGF gene expression in case group compared to control.

What is known already: Based on previous studies, local injury to endometrium in luteal and /or proliferative phases of menstrual cycle has conflicting effect on implantation and clinical outcomes, however, little is known about molecular aspects of injury in patients with Repeated Implantation failure preceding IVF/ICSI.

Study design, size, duration: A total of twenty women with repeated implantation failure (RIF) who failed to conceive during two or more IVF/ICSI cycles and embryo transfer (ET) participated in this randomized controlled trial (RCT) study. Pipelle endometrial sampling was done twice: One in the follicular phase and again in the luteal phase in case group (N = 10) but it was done once in control group (N = 10) just in the luteal phase for genomic evaluation.

Participants/materials, setting, methods: Total RNA were extracted from endometrial tissues, Then VEGF gene expression was investigated by quantitative real-time PCR.

Main results and the role of chance: VEGF gene expression was detected in endometrial samples of both groups. The mean relative expression of VEGF gene was higher in the case group compared with control group.

Limitations, reasons for caution: The number of subjects who participated in this study is low.

Wider implications of the findings: As a whole, our study provided molecular evidence that patients with repeated implantation failure can benefit from local injury during an ongoing IVF cycle, in addition, it seems VEGF as an angiogenic factor plays an important role in regulating human endometrial receptivity.

Trial registration number: NCT02480127.

P-468 Altered expression of Na+- and Cl- ion channels in endometrium of women with recurrent implantation failure (RIF)

B. DavoodiNik[1], R. Favaedi[1], B. Movaghar[2], F. Ramazanali[3], M. Ashrafi[3], M. Shahhosseini[1]

[1]Department of Genetics- Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine- ACECR, Tehran, Iran
[2]Department of Embroylogy- Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine- ACECR, Tehran, Iran
[3]Department of Endocrinology and Female Infertility, Royan Institute for Reproductive Biomedicine- ACECR, Tehran, Iran

Study question: Is there any correlation between the expression of Na+- and Cl- ion channels in endometrium and implantation failure?

Summary answer: Result revealed increased expression of CFTR but decreased expression of SCNN1A, SCNN1B, SCNN1G (coding subunits of ENaC) in endometrium of RIF patients vs. fertile women.

What is known already: Successful implantation of the embryo is an important stage in human reproduction. During implantation, the uterine undergoes fluid absorption in preimplantation phase. The critical role of ion channels on reproduction, mainly on embryo implantation, have been reported in various aspects. The amiloride-sensitive epithelial sodium channel (ENaC) is a Na+ channel that encoded by SCNN1 genes and Cystic fibrosis transmembrane conductance regulator (CFTR) is a Cl- channel that are expressing in the epithelial cells of a numerous kinds of tissues, such as human endometrium. ENaC and CFTR may play a main role in absorption of uterine fluid in embryo implantation period.

Study design, size, duration: A case control study with 20 patients in recurrent implantation failure and 9 fertile women(oocyte donors).

Participants/materials, setting, methods: Consent was obtained from patients according local ethical approval. Endometrial injury obtained from 20 infertile women (22-35 years old) in window of implantation (19th -24th days of menstrual cycle) by pipelle. As control group, endometrial injury obtained from 9 fertile women between 22-35 years old through oocyte donation procedure before stimulation in window of implantation phase by pipelle. expression of CFTR, SCNN1A, SCNN1B,SCNN1G in endometrial,all of the sampels were evaluated quantitatively by real-time PCR.

Main results and the role of chance: Quantitative PCR analysis showed that mRNA expression of CFTR gene was increased and SCNN1A, SCNN1B and SCNN1G genes was decreased significantly in endometrium of RIF patients vs. fertile group.(P-Value$\leq$0.01)

Limitations, reasons for caution: For getting more information we need to investigate large number of RIF patients and control group.

Wider implications of the findings: These data imply the potential role of ion channels in implantation failure.

Trial registration number: -.

P-469 Assessment of endometrial receptivity using the endometrial receptivity array (ERA) in women affected by latent genital tuberculosis (LGTB) undergoing In Vitro Fertilization (IVF)

P. Naidu[1,2], N. Mahajan[3], J. Kaur[3], K. Rani[3], S. Kaur[3]

[1]Milann The Fertility Centre, Reproductive Medicine, NEW DELHI, India
[2]Honorary consultant -Mother and Child Hospital, Infertility and IVF, New Delhi, India
[3]Mother and Child Hospital, Infertility and IVF, New Delhi, India

Study question: Does latent genital tuberculosis diagnosed by DNA Polymerase chain Reaction (PCR) of endometrial tissue,affect endometrial receptivity in women undergoing IVF as evaluated by ERA

Summary answer: There is no significant difference in endometrial receptivity as assessed by ERA,in women with or without LGTB

What is known already: Genital Tuberculosis is an important cause of infertility and IVF failures in India. Studies suggest that LGTB affects endometrial thickness and causes changes at a molecular and biochemical level altering the window of implantation (WOI). This can lead to implantation failures in IVF. ERA is a customised microarray test which evaluates the transcriptomics of WOI using 238 genes that are differentially expressed.ERA is a superior test compared to other markers of endometrial receptivity having a sensitivity of 88.57 % and specificity of 99.7 % and helps us to understand the personalized window of implantation with a high accuracy.

Study design, size, duration: Retrospective study. Records of frozen embryo transfer (FET) patients between 2014-2016 were scanned.165 patients included in our study underwent endometrial biopsy for diagnosis of LGTB

using DNA PCR,Koch's culture and ERA for assessment of endometrial receptivity before FET.Of these 25 patients were positive for LGTB. Comparison was done between LGTB positive patients (both treated and untreated) and controls(DNA PCR negative and no previous exposure to ATT).Kochs culture positive (active tuberculosis) were excluded.

Participants/materials, setting, methods: Patients were evaluated for LGTB using DNA PCR and Koch's culture and Endometrial receptivity was assessed by ERA in a hormone replacement cycle (HRT).Estrogen priming was started on cycle day 2/3 with estradiol valerate. When the endometrial lining was 7 mm or the maximal achievable thickness, vaginal progesterone 400 mg twice a day was added. Endometrial biopsy was taken after five days of progesterone. Patients with endometrium <5.5 mm were excluded from the study.

Main results and the role of chance: Patients divided into three groups based on DNA PCR results and exposure to ATT.Group A: DNA PCR positive, untreated (n = 11),Group B: DNA PCR positive, treated (n = 14) and Group C (controls): DNA PCR negative and no previous exposure to ATT (n = 140),Endometrial receptivity assay results interpreted as Receptive(P+5) or Non receptive. Patients with altered WOI(Pre or Post receptive) had repeat ERA with suggested progesterone replacement resulting in correction of the WOI.Group A: 7 patients (63.6%) showed no change in the WOI and 4 (36.3%) had a changed WOI Group B :11(78.5%)patients had no change in the WOI while 3 (21.4%) had a changed WOI. Group C: 109 (77.8%) had no change in WOI and 31 (22.1%) had changed WOI. Comparison amongst the 3 groups was done using Fischer Exact test. Group A vs Group B - p-valve 0.652., Group A vs Group C - p-valve 0.283, Group B vs Group C - p-valve 1.00, Group A vs Group B vs Group C p-valve-0.543.p valve of </0.05 -statistically significant.No significant difference seen in the endometrial receptivity of patients who had LGTB compared to controls

Limitations, reasons for caution: Small number of patient in group A & B

Wider implications of the findings: LGTB does not seem to alter the endometrial receptivity. Anti tubercular treatement for LGTB in endemic areas solely to improve the endometrial receptivity maynot be helpful,though larger prospective randomized studies are needed to confirm the above results.

Trial registration number: Nil.

P-470 iTraq proteomic analysis of endometrium from fertile donors, IUD carriers and patients with recurrent implantation failure (RIF) reveals differential proteomic profiles

S. Pérez-Debén[1], J. Bellver[2], P. Alama[2], S. Salsano[3], A. Quiñonero[3], C. Simón[4], F. Domínguez[5]

[1]IVI FOUNDATION, Department of Obstetrics and Gynecology, Paterna Valencia, Spain
[2]IVI VALENCIA, Department of Obstetrics and Gynecology, Valencia, Spain
[3]IVI FOUNDATION, Department of Obstetrics and Gynecology, Valencia, Spain
[4]IVI FOUNDATION/Standford University, Department of Obstetrics and Gynecology, Valencia, Spain
[5]IVI FOUNDATION/INCLIVA, Department of Obstetrics and Gynecology, Valencia, Spain

Study question: Are there any proteomic differences among a receptive endometrium, a refractory (IUD) one and an endometrium from RIF patients?

Summary answer: Our results revealed clear proteomic differences between RIF/IUD and receptive/ IUD comparisons but no differential profile was found in RIF/receptive comparison.

What is known already: The human endometrial transcriptome has been extensively investigated in the last decade resulting in the development of new diagnostic tests based on the transcriptomic signature of the window of implantation (WOI). Much less is known about the proteomics derived from the transcripts present during the WOI.

Study design, size, duration: This study is a basic proteomic analysis of human endometrial biopsies taken from twenty-eight IVF patients. Human endometrial samples (n = 28) were collected from fertile donors (n = 10), IUD carriers (n = 10), and RIF patients with at least 3 previous IVF failures (n = 8) at the same day during the window of implantation (WOI) (Hormonal Replacement Therapy; P+5).

Participants/materials, setting, methods: Protein identification and quantification were performed using isobaric tags for relative and absolute quantification analysis (TRAQ 8-plex) and mass spectrometry, followed up by 'in silico' functional analysis (KEGG database) and correlation networks using Gene Ontology (GO). Statistical analyses were carried using an ANOVA and T-test analyses. Validation by Western blot (WB) was performed for the Plastin 2 (PLSL), Lactotransferrin (TRFL) and Lysozyme C (LYSC) proteins.

Main results and the role of chance: iTRAQ analysis identified 1,873 differentially expressed proteins among the three groups. ANOVA analysis revealed 188 significant proteins, while t-test showed 133 statistically significant proteins between receptive vs. IUD endometria. RIF vs. IUD comparison revealed 158 significant proteins and 54 differentially expressed were shared between the two comparisons. Surprisingly, no differential expressed protein was found between receptive vs. RIF groups. Validation by WB for PLSL, TRFL and LYSC confirmed our iTRAQ results. KEGG functional analysis revealed 12 and 17 significant pathways for receptive vs. IUD and RIF vs IUD respectively (10 shared pathways). These 10 common pathways were related to aspects of amino acids and fatty acids metabolisms. RIF/IUD comparison's specific pathways were those related to the Complement and coagulation cascades and pathways related to the Ribosome and Spliceosome were the specific ones for receptive/ IUD comparison. RIF/IUD correlation network showed two main functional groups, the Immune System and the Ion Transport Process. In the case of receptive/IUD correlation network, one important group appeared related to transcription, translation and proteins regulation processes, supporting the results obtained by 'in silico" functional analysis by KEGG.

Limitations, reasons for caution: This is mainly a descriptive study with no functional studies on the proteins found. We also used a moderate number of human endometrial samples for the iTRAQ analysis.

Wider implications of the findings: Our study demonstrate a differential proteomic profile between receptive compared to IUD endometria, showing key proteins related to receptivity status. No differences were detected between RIF patients and fertile donors, suggesting that RIF´s endometrium is not pathological, reinforcing the hypothesis of a Window of implantation (WOI) displacement.

Trial registration number: 'not applicable'.

P-471 Novel cell-type specific RNA-seq analysis provides new insights into the molecular processes of receptive phase endometrium and identifies sensitive biomarkers

S. Altmäe[1], M. Koel[1], M. Saare[1], A. Reddy[2], G.K. Kuum[1], K. Samuel[1], D. Lubenets[3], S. Katayama[2], E. Einarsdottir[2], P. Albero[4], D. Blesa[4], C. Simón[5], J. Kere[2], K. Krjutskov[1], A. Salumets[6]

[1]University of Tartu, Competence Centre on Health Technologies, Tartu, Estonia
[2]Karolinska Institutet, Biosciences and Nutrition, Stockholm, Sweden
[3]University of Tartu, Institute of Molecular and Cell Biology, Tartu, Estonia
[4]iGenomix, iGenomix, Valencia, Spain
[5]Valencia University/INCLIVA, iGenomix, Valencia, Spain
[6]University of Tartu/Helsinki University, Competence Centre on Health Technologies, Granada, Estonia

Study question: Does RNA-seq analysis of single endometrial epithelial and stromal cells provide novel insights into the molecular processes of endometrial development from pre-receptive into receptive phase?

Summary answer: Cell-type specific RNA-seq is a powerful approach for unravelling molecular processes of endometrial receptivity, and to detect novel sensitive biomarkers of receptivity.

What is known already: Molecular profile of receptive phase endometrium has been extensively studied during the last decades, but most of the studies have focused on transcriptome analyses of endometrial whole-tissue biopsies. Endometrium, however, is a complex tissue composed of multiple cell types, epithelial and stromal cells being the most abundant among them. So far, only one group has analysed endometrial cell-specific transcriptome (Evans GE et al), and they clearly show cell-type-specific transcriptome profiles. They used laser capture microdissection for cell-type isolation, which has limitations,

mainly the decrease of RNA integrity. Therefore, new state-of-the-art techniques should be applied in order to overcome these limitations.

Study design, size, duration: Paired endometrial tissue samples from pre-receptive (n = 20) and receptive phase endometria (n = 20) from Estonia and Spain were collected.

Participants/materials, setting, methods: 40 endometrial biopsies were dissociated, CD9-positive epithelial cells and CD13-positive stromal cells were isolated with fluorescent activated cell sorting (FACS) and full transcriptome analysis was performed by RNA-seq. The single-cell tagged reverse transcription (STRT) RNA-seq protocol was followed. The STRTprep pipeline version 3.0.0 was used for processing raw sequencing reads, aligning to the hg19 genome. g:Profiler software was used for enrichment analyses. RNA-seq results were validated using real-time PCR.

Main results and the role of chance: A total of 675 epithelial cell-specific genes and 756 stroma cell-specific genes were detected as up-regulated, while 130 epithelial cell-specific genes and 133 stroma-specific genes were down-regulated in receptive phase endometria when compared to pre-receptive endometria. Rigorous filtering was applied on the differentially expressed genes in order to identify true cell-type specific molecules (e.g. genes detected in 75% of samples, significant expression difference between two cell types). After the filtering, 141 epithelial-specific genes and 372 stroma-specific genes remained as significantly up-regulated, and 6 epithelial-specific genes and 99 stroma-specific genes remained as down-regulated in receptive endometria. The receptive epithelium marker genes with the highest score of cell-specificity were *TNSFF10*, *TGFB2*, *DDX52*, *GPR160*, *CLU*, *CDH1*, *ARHGEF38*, *MAP7*, *SGK1*, *SPP1* and *RORC*. The top stromal cell-specific marker genes of receptive endometrium were *LMOD1*, *CFD*, *APOD*, *PROK1*, *HAND2*, *NR2F1*, *IGF2*, *TEX40*, *ZEB1*, *ANGPTL1* and *APOC1*. Receptive phase epithelial cell-specific marker genes were enriched in processes related to multicellular organismal homeostasis, cell activation involved in immune response and plasma membrane organization. Receptive phase stroma-specific genes were enriched in rRNA metabolic process, activation of immune response, regulation of cell adhesion, apoptotic signalling pathway, and processes involved in smooth muscle cell proliferation.

Limitations, reasons for caution: Rigorous statistical analysis could result in the failure to identify some molecules and molecular pathways involved in the receptive phase endometria and some potentially relevant biomarkers of receptivity.

Wider implications of the findings: With our novel RNA-seq approach new molecules and molecular processes of receptive phase endometria were detected, but also already known molecules and pathways were confirmed. The cell-specific RNA-seq analysis could provide the long-sought-after sensitive biomarkers of endometrial receptivity.

Trial registration number: na.

P-472　　The risk for extrauterine gravidity (EUG) in IVF treatment

A. Damko, M. Schuff, B. Wirleitner, F. Hagen, J. Okhowat, M. Murtinger

IVF Centers Prof. Zech, Bregenz, Austria

Study question: What is the general risk for EUG after fresh or frozen blastocyst transfer in IVF treatment and can we elucidate potential risk factors?

Summary answer: The risk for EUG after transfer was found to be as low as after spontaneous conception.

What is known already: The spontaneous occurrence of EUG in an unselected population after spontaneous conception is around 1-2%. EUG is a severe complication for woman, requesting immediate medical treatment or surgery. Suggested risks factors to develop an EUG are advanced maternal age, tubal surgery, appendectomy, cesarean section, inflammation of the fallopian tubes, smoking and last but not least ART. ART was reported to be associated with EUG rates ranging from 3.3% up to 8.6% of all clinical pregnancies. Among the risk factors in ART, suboptimal transfer techniques and time-point of transfer (cleavage stage transfer) are regularly discussed.

Study design, size, duration: A retrospective study was conducted in our fertility clinic in Bregenz / Austria, including all IVF-cycles with blastocyst transfer resulting in a positive pregnancy test between January 2010 and December 2015. Clinical data were extracted by using the DynaMed® software, statistics were performed using SPSS statistics.

Participants/materials, setting, methods: In total 4.003 IVF-cycles with fresh blastocyst transfer resulting in a positive pregnancy test were analyzed. Patient's history was analyzed in regard to IVF-cycle characteristics, previous EPs, type of infertility, previous in-house cycles and outcome as well as abdominal and tubal or uterine surgeries.

Main results and the role of chance: Out of 4.003 blastocyst transfers resulting in an elevation of urine or blood beta-hCG levels and a positive pregnancy test 43 patients (1,1%) were diagnosed with EUG. Thereby, 12 EUG occurred after vitrification/warming and 31 after fresh blastocyst transfer with no statistical difference between the two groups. In 74.4% blastocyst transfer was performed easily without using additional guidance. The mean female age of patients diagnosed with EUG was 37.1 years (37.3 in the reference group) with eight patients younger than 35 years. The reasons for infertility treatment in EUG patients were 30.2% female factors, 34.9% male factors, 16.3% a combination of male and female factors and 18.6% idiopathic infertility. The incidence of uterine malformations in the EUG group was 11.7%, abdominal surgery was even reported for 44.2% and 6 patients reported a previous EUG (14.0%). Interestingly, 55.8% of the EUG group revealed sub-optimal endometrium build-up in the transfer cycle.

Previous EUG, uterine malformations, abdominal surgeries and inadequate endometrium build-up are potential main risk factors for an ectopic pregnancy.

Limitations, reasons for caution: As EUG seems to be a rare situation in after ART when using blastocyst transfer, further analysis on large data sets should confirm our results.

Wider implications of the findings: Our data analysis shows that ART and blastocyst transfer per se does not increase the risk for EUG. Specific risk groups (including patients with previous EUG and abdominal surgery should be advised for the increased risk. Endometrial build-up should be continuously controlled and possibly improved in frozen/warmed blastocyst transfer.

Trial registration number: not applicable.

P-473　　Endometrial thickness is associated with the clinical pregnancy rate in unstimulated menstrual cycles – a study based on Natural Cycle IVF

V. Mitter[1], A.S. Kohl Schwartz[1], M. Faeh[1], G. Griesinger[2], M. Von Wolff[1]

[1]*University Women's Hospital- Inselspital- University Hospital, Division of Gynaecological Endocrinology and Reproductive Medicine, Bern, Switzerland*
[2]*University Women's Hospital- University Hospital- Lübeck, Division of Gynaecological Endocrinology and Reproductive Medicine-, Lübeck, Germany*

Study question: Does the endometrial thickness (EMT) correlate with the pregnancy and live birth rate in unstimulated menstrual cycles?

Summary answer: EMT does correlate with the clinical pregnancy rate in unstimulated menstrual cycles – according to data generated in Natural Cycle IVF (NC-IVF) treatment cycles.

What is known already: Several IVF studies have indicated that pregnancy rate correlates with EMT. Thin endometrium has been described to result in lower pregnancy rates. However, all these findings are based on conventional, gonadotropin stimulated IVF therapies. One small study reported on unstimulated frozen embryo transfer cycles and described a decreased pregnancy rate in thin endometrium patients, suggesting EMT to be a stimulation independent predictive factor for pregnancy. Data based on unstimulated fresh embryo transfer are still missing.

Study design, size, duration: Retrospective, observational single center study, performed 2011 to 2016. In women 18-42 years of age with regular menstrual cycles (24-32 days) and basal FSH concentrations <10IU/L undergoing their first NC-IVF cycle were identified. Only the first cycle, leading to an

embryo was considered for analysis. Couples with endometriosis > rASRM II° or sperm collection by Testicular Sperm Extraction (TESE) were excluded.

Participants/materials, setting, methods: 225 women undergoing a NC-IVF cycle were identified. 111 women (49.3%) were excluded due to missing transfer, 5 women (2.2%) due to severe endometriosis and 4 women (1.8%) due to TESE resulting in 105 women to be included in the analysis. EMT at the time of follicle aspiration as well as biochemical and clinical pregnancy rates and live birth rate were analysed. Furthermore, week of gestation, birth weight and birth weight percentiles were evaluated.

Main results and the role of chance: Age of participants was 34.7 ± 3.8 years (range 21-42 years). 20 women (19%) had performed previous IVF therapies without pregnancy. Infertility factors were male factors (n = 53, 50.5%), endometriosis rASRM I-II° (n = 15, 14.3%), tubal factors (n = 19, 18.1%) and idiopathic infertility (n = 17, 16.2%). AMH concentrations were 15.6 ± 14.4 pmol/L (0.5-94 pmol/L).

Follicle aspiration was performed on day 13.9 ± 2.3 (range 9-22 days) of the menstrual cycle. Endometrial thickness was 8.7 ± 1.7 mm (range 6-16 mm). Total biochemical pregnancy rate was 29.5%, clinical pregnancy rate 24.8% and live birth rate 15.2% per transfer.

To analyse the effect of EMT on clinical pregnancy rate, women were divided into three percentile groups (25th percentile group: endometrium ≤ 7 mm (n = 27), 25th -75th percentile group: endometrium >7 mm (n = 48) and < 10 mm, 75th percentile group: endometrium ≥ 10 mm (n = 30). The percentile groups did not differ regarding age, AMH and cycle day of aspiration.

Clinical pregnancy rate was in the lower percentile group 7.4%, in the medium group 27.1% and the upper group 36.7%. Pregnancy rates were significantly different in the three groups (P = 0.034) as analysed by Chi-Square test. In a multi-variate regression analysis, none of the candidate predictors was significantly associated with clinical pregnancy achievement.

Limitations, reasons for caution: The number of participants is limited due to strict inclusion and exclusion criteria. The number of participants is too small to identify EMT as a potentially independent predictor of success.

Wider implications of the findings: The study provides evidence that EMT not only correlates with pregnancy rate in stimulated but also in unstimulated cycles. Accordingly the thickness of the endometrium should be considered in any infertile couples even if ovarian stimulation is not performed.

Trial registration number: Not applicable.

P-474 Can mtDNA copy number assessment be a valid embryo selection tool over morphology-based embryo scoring?

M. Gultomruk[1], N. Findikli[2], K. Boynukalin[3], T. Aksoy[2], M. Bahceci[3]

[1]Bahceci Fulya IVF Center, R&D Laboratories, Istanbul, Turkey
[2]Embryology Laboratory, Istanbul, Turkey
[3]Infertility Clinic, Istanbul, Turkey

Study question: This study is designed to evaluate if embryo selection by mtDNA copy number can bring any additional benefit over classical embryo scoring on clinical outcome.

Summary answer: Our results can indicate that a better clinical outcome can be predicted if mtDNA copy number is prioritized for embryo selection in single embryo transfers.

What is known already: Numerous studies have been performed to analyze and document the importance of mitochondria in mammalian preimplantation development. Recently, besides comprehensive chromosomal screening (CCS), several groups have investigated the possibility of using mtDNA copy number assessment as a clinical viability score in cases undergoing preimplantation genetic screening (PGS). Although promising results obtained in these reports, new data also indicate that such an assessment may still be in its infancy and more studies are needed. There are still many unknowns regarding the methodology and clinical conditions in which the mtDNA copy number assessment should be performed.

Study design, size, duration: Our study has been designed as a retrospective cohort study including 230 consecutive SETs performed after PGS by next

generation sequencing (NGS) between October 2015-December 2016 in Bahceci Fulya IVF Centre.

Participants/materials, setting, methods: In all cases, embryos were cultured to the blastocyst-stage and suitable embryos on day 5/6 of embryo development were biopsied and individually vitrified. According to their PGS results and the availability of mtDNA copy number data, SETs were performed as frozen embryo replacements. Data were grouped with respect to embryo selection strategy prioritized as group I (156 cases, based on known mtDNA copy number) and group II (74 cases, based on embryo morphology).

Main results and the role of chance: In total, 783 hatching-stage blastocysts were biopsied and processed for CCS analysis by next generation sequencing (NGS). Among 399 embryos that were found to be chromosomally normal, WGA material of 286 embryos subsequently used also for mtDNA copy number analysis by qPCR. Main case demographics, such as female age ($35.0 \pm 4,5$ vs. $35.5 \pm 4,4$) and the number of oocytes collected ($12.9 \pm 7,6$ vs. $12.3 \pm 6,4$) were found to be similar in both groups. Also, additional cycle and laboratory characteristics such as the number of previous ART trials, total dose of gonadotropins used and sperm concentration and motility were found to be statistically similar (p>0.05). Distribution of blastocyst grades in both groups also displayed very similar pattern. In group I, biochemical pregnancy, clinical pregnancy and ongoing pregnancy/live birth rates were found to be 80.1%, 72.6% and 65.6% respectively. In group II, these values were 67.5%, 63.9% and 47.8%. Although higher clinical pregnancy and ongoing/live birth rates were obtained in the former, the difference were found to be statistically not significant.

Limitations, reasons for caution: Number of cases included can be the main limitations of the study. Although our results indicate a better clinical outcome when mtDNA copy number is prioritized, further studies with higher number of cases are required to draw a firm conclusion.

Wider implications of the findings: Our study indicates that mtDNA copy number assessment can be a better embryo selection tool over classical morphology-based scoring systems in terms of predicting cycle outcome in SET cases after PGS.

Trial registration number: None.

P-475 Endometrial injury does not affect the endometrial transcriptomic profile during the window of implantation

J. Miravet[1], M. Ruiz-Alonso[1], S. Taguchi[2], M. Clemente[1], M. Funabiki[2], E. Gomez[1], C. Marin[1], Y. Nakamura[2], C. Simon[1,3]

[1]IGENOMIX, Research Department, Valencia, Spain
[2]Oak Clinic, Department of Obstetrics & Gynecology, Osaka, Japan
[3]University of Valencia INCLIVA, Department of Obstetrics & Gynecology, Valencia, Spain

Study question: Is the endometrial transcriptomics analyzed by the molecular endometrial receptivity analysis (ERA) modified after an injury provoked by an endometrial biopsy?

Summary answer: Endometrial transcriptomic profile analyzed by ERA is not affected after a previous endometrial biopsy obtained 48 hours before in the same patient.

What is known already: Mechanical injury of the endometrial cavity or scratching is being used by many clinicians aiming to modify the endometrial conditions to improve embryo implantation. No scientific evidences of the effect of such intervention in endometrial transcriptomics has been demonstrated yet. The endometrial receptivity analysis (ERA) is a commercial available test based on the transcriptomic signature of 238 genes that allows to diagnose the personalized window of endometrial receptivity defining the profiles of pre-receptivity, receptivity and post-receptivity in each patient. Bioinformatics data on these transcriptomic profiles from >12,000 patients worldwide have been accumulated and curated in the last 6 years.

Study design, size, duration: In thirty-six patients, two endometrial biopsies from the uterine fundus were obtained two-days apart in the same patient under hormonal replacement therapy cycle (HRT). The first was taken after proper estradiol priming leading to a trilaminar endometrium measuring

>6.5 mm adding 5 days of progesterone administration (P+5 - 120 hours), and the second 48 hours later (P+7 - 168 hours). Samples were collected from January to November 2016 at Oak Clinic, Japan.

Participants/materials, setting, methods: RNA was extracted and quality assessed by an A2100 Bioanalyzer (Agilent Technologies). Only samples with RIN (RNA Integrity Number) >7 were hybridized onto the customised ERA array (Diaz-Gimeno, et al., 2011), scanned in an Axon 4100 A scanner (Molecular Devices), and analysed by ERA computational predictor. Limma package was used to compute the analysis of differentially expressed (DE) genes of the endometrial samples investigated versus our curated data base obtained from >12,000 patients worldwide.

Main results and the role of chance: No relevant differentially expressed (DE) genes were found in the expected endometrial transcriptomic profiles obtained in two consecutive endometrial biopsies, in the same patient under the same HRT cycle at P+5 and P+7. They were not different from the expected transcriptomic profile at the indicated days obtained from single biopsies reported in our curated data base. Therefore, tissue injury provoked by an endometrial biopsy does not affect the transcriptomic signature of the second biopsy obtained 48 hours later.

Limitations, reasons for caution: Limitation for the present study is the number of patients analyzed with two consecutive endometrial biopsies.

Wider implications of the findings: Our study demonstrates that the injury provoked by an endometrial biopsy does not modify the expected transcriptomics and therefore, proteomics/function of the endometrial tissue. Clinical interventions based on modifications of the endometrium due to tissue injury must be considered with caution since no real biological effect is observed.

Trial registration number: Not apply.

P-476　Immunoregulatory effects of the Blastocyst Conditioned Media: focus on the control of the inflammatory response

R. Ramhorst[1], E. Grasso[1], D. Paparini[1], E. Soczewski[1], L. Fernandez[1], M. Irigoyen[2], G. Martinez[2], C. Ruhlmann[2], C. Perez Leiros[1]

[1]IQUIBICEN-CONICET, Dpto Química Biológica- School of Sciences- University of Buenos Aires, Buenos Aires, Argentina
[2]Fertilidad San Isidro, UNIFER, Buenos Aires, Argentina

Study question: Could the human Blastocyst Conditioned Media (BCM) control the initial inflammatory response during the peri-implantation period toward a tolerogenic one?

Summary answer: Decidualized cell responded differentially to BCM, accordingly their quality, by reducing reticular stress-associated inflammation, recruiting regulatory T lymphocytes (Tregs) and allowing blastocyst-like spheroids invasion.

What is known already: The decidualization program of human endometrial cells involves a physiological reticular stress (RE) and unfolded protein response (UPR), allowing them to expand their endoplasmic reticulum and change their secretome increasing the production of immunomodulators. This physiological RE and UPR response would allow the activation of one of the 3 RE sensing proteins, IRE1, which induces kinase / RNase TXNIP expression, and activates the inflammasome generating a sterile inflammatory response with production of IL-1b. This sterile inflammatory response, associated to the implantation period, should be later controlled in favor of a tolerogenic microenvironment by maternal and blastocyst-derived factors.

Study design, size, duration: Human endometrial stromal cell line (HESC) were decidualized or not with medroxiprogesterone+dbcAMP during 8 days, and used to evaluated RE and UPR. Then, HESC cells were treated with human Blastocyst-condition-media (BCM), previously classified accordingly their quality, for 24 h. An in vitro implantation model based on co-culture of blastocyst-like spheroids (BLS) from Swan-71 trophoblast cells line over decidualized-HESC cells and a transwell migration system for Tregs recruitment were used to evaluate decidual functionality.

Participants/materials, setting, methods: Mature oocytes were inseminated (conventional IVF or ICSI was applied according to male evaluation). After 3 days, embryos were transferred individually to drops of G2 plus-

medium. At day 5, BCM were retrieved and embryos classified following Istanbul concensus. Maternal monuclear cells were obtianed by pheripheral blood and Tregs frequency quantified by intracellular Foxp3 staining and FACS analysis. Gene and protein expression was evaluated by PCR or FACS respectively. BLS invasion was evaluated by fluorescence microscopy.

Main results and the role of chance: We observed a significantly increase in the expression of CXCL8, CXCL12 and IL-1b after the decidualization Since IL-1b can act as a 'double edge' mediator in early pregnancy, we evaluated BCM effect on IL-1b production. BCM reduced IL-1b intracellular production in decidualized cells (p < 0.05, Student T-test). This was accompanied by a decreased mRNA of reticular stress sensors as PERK and ATF6 expressions (p < 0.05, Anova, Sidak).

When we studied the inflammasome activation pathway, TXNIP was not modulated but NLRP3 and IL1b levels were both significantly decreased after BCM treatment (p < 0.05, Anova Sidak). These results, suggest that BMC is able to reduce the UPR on decidualized cells. Using the in vitro implantation model, we observed that BCM obtained from developmentally impaired blastocysts decreased the invasion index of BLS on decidualized cells and Tregs recruitment. Similar results were observed when UPR was previously inhibited using STF-083010, suggesting that decidual UPR may be relevant for trophoblast initial invasion (p < 0.05 Anova, Sidak).

Since, decidual cells are able to control immunological microenvironment partially by recruiting Tregs, we evaluated whether BCM was able to modulate this mechanism. We observed that decidualized-HESC treated with BCM from developmentally impaired blastocysts significantly reduced Treg recruitment (p < 0.05, Anova, Sidak).

Limitations, reasons for caution: The present results were obtained using immortalized cell lines and in vitro implantation and invasion models. Further studies are necessary to elucidate whether the mechanisms operate similarly in vivo and rule out any factor not contemplated in vitro.

Wider implications of the findings: The results presented provide new clues whether the blastocyst soluble factors (represented by BCM) might contribute to the cross-talk with decidualized cells controlling the inflammatory response and allowing blastocyst invasion accordingly with their quality. This could contribute to a better undestanding of reproductive dissorders such as in vitro implantation failures.

Trial registration number: N/A.

P-477　Reprogramming of the hCG signalling profile in human endometrial stromal cells from recurrent miscarriage patients

S. Khanjani[1], C. West[2], S. Lavery[3], J. Brosens[4], P. Bennett[3], A. Hanyaloglu[3]

[1]Imperial College- London, Reproductive Medicine, London, United Kingdom
[2]Imperial College London, Reproductive Biology, London, United Kingdom
[3]Imperial College, Reproductive Medicine, London, United Kingdom
[4]Warwick University, WMS - Cell and Development Biology, Warwick, United Kingdom

Study question: To identify the LHCGR signalling pathways activated by hCG in the endometrial stroma, during deciqualization in control and recurrent miscarriage (RM) patients.

Summary answer: Collectively, our data strongly suggests that control and RM patients have opposing signalling pathways.

What is known already: Cross-talk between an implanting embryo and the uterine endometrium is vital for successful implantation. Locally secreted factors within the uterine environment play a vital role in this feto-maternal communication. Human chorionic gonadotrophin (hCG), a glycoprotein hormone secreted by the embryo, plays key functions in the ovary and endometrium via its cognate G protein-coupled receptor (LHCGR). The signal pathways activated by LHCGR within the endometrium are largely unknown. Perturbations in hCG action in endometrial stromal decidualization has been shown to be associated with recurrent miscarriage (RM), a key mechanism in perturbed embryo quality control at the feto-maternal interface in these patients.

Study design, size, duration: This is a laboratory based study performed on n = 6 patients in each group; normal versus recurrent miscarriage.

Participants/materials, setting, methods: Human endometrial stromal cells (HESCs) from either control patients or RM patients were decidualised for 72 hours, or left undifferentiated. Expression of LHCGR was confirmed in both patient groups. Cells were stimulated at 0, 5 and 30 minutes with hCG. The resulting protein lysates were used to probe phospho-MAPK array membranes that detect 26 different phospho-MAPKs. Fold change over basal for each target at the 5 and 30 minutes time points was calculated.

Main results and the role of chance: Collectively, the array data strongly suggests that control and RM patients have opposing signalling pathways. In control, many pathways activated by hCG in undifferentiated cells are decreased in decidualised cells and only a subset of pathways are activated. In RM, the same pathways are either not activated or not deactivated following decidualisation.

Limitations, reasons for caution: None

Wider implications of the findings: Our data shows that decidualisation reprograms the signalling profile in control but not recurrent miscarriage HESCs. The failure of RM HESCs to reprogram their hCG signalling upon decidualisation could be an important defect which contributes to erroneous embryo selection at the time of implantation that can lead to pregnancy loss.

Trial registration number: This was not a trial.

P-478 New transcriptomic insight improves endometrial Recurrent Implantation Failure (RIF) diagnosis and distinguishes clearly between a displaced and a disrupted Window Of Implantation (WOI)

P. Diaz-Gimeno, P. Sebastian-Leon, J. Remohi, N. Garrido, A. Pellicer

Instituto Valenciano de Infertilidad- Universidad de Valencia / INCLIVA, Fundacion IVI, Paterna Valencia, Spain

Study question: Endometrial Recurrent Implantation Failure (RIF): a matter of timing or a disrupted Window of implantation signature? Is it possible to diagnose both types of RIF?.

Summary answer: The proposed transcriptomic prediction design resolves the understanding of endometrial RIF diagnoses and distinguishes at least two RIF main causes: displaced and disrupted WOI.

What is known already: Endometrial transcriptomics prediction has been applied to human WOI in two main works: Simon (Diaz-Gimeno et al., 2011) and Macklon groups (Koot et al., 2016). Diaz-Gimeno considers endometrial RIF as a displacement and is not distinguishing a disrupted WOI signature. Nerveless, Koot considers endometrial RIF as a disrupted WOI removing the LH timing effect. Both of the models are considering LH as gold standard in the prediction design, however, Diaz-Gimeno signature clinical application have been demonstrated approximately 25% of RIF discrepancies between transcriptomics profile and LH in the expected WOI (LH+7) (Ruiz-Alonso et al., 2013).

Study design, size, duration: Retrospective analysis comparing WOI endometrial transcriptomics and prediction in controls (n = 72) versus RIF patients (n = 43) in samples collected from LH+5 to LH+8. Raw data was downloaded from GEO database (GSE58144) (Koot et al, 2016). In the same dataset we compared both predictor methodologies, Diaz-Gimeno and Koot, and we proposed a new transcriptomics insight to fill the gap between both studies and be able to detect and distinguish both types of RIF.

Participants/materials, setting, methods: Data was pre-processed and normalized using quantile method from limma R-package. Different designs for SVM predictors using caret R-package were performed: one considering RIF versus Controls removing and not removing LH variations, and the other one stratifying samples by transcriptomics and predicting RIF displacement. The predictive value was compared between Diaz-Gimeno and Koot signatures and a new diagnostic algorithm that distinguishes between both types of RIF in the same sample cohort is proposed.

Main results and the role of chance: WOI samples were classified by unsupervised transcriptomic methods (K-means) in ER: Early Receptive, R: receptive and LR: Late-Receptive profiles. Comparing transcriptomics with LH as gold standard we found some discrepancies and displaced samples, but LH+5 were mostly in ER, LH+8 were mostly in LR, LH+6 were mainly in ER

and LH+7 were many of them in R but some samples were displaced to ER and PR profiles. WOI displacement predictor supervised by transcriptomic profiles classified RIF samples in ER, R or PR for Koot signature with an accuracy (ACC) of 0.90 and with Diaz-Gimeno with an ACC of 0.98.

RIF samples that were not displaced could be detected using a second model called disrupted WOI which is supervised only by control and RIF R samples. With this design, Koot signature obtained an ACC=1 (Specificity (Sp) of 1, Sensibility (S) of 1); and Diaz-Gimeno signature an ACC=0.789 (Sp 1, S 0.38).

Macklon statistical procedure for removing LH time effect is not as efficient as using transcriptomics as gold standard. Transcriptomic menstrual cycle timing is a confounding variable that should be controlled for distinguishing clearly between disrupted and displaced RIF samples.

Limitations, reasons for caution: The main objective of this study is to show both types of RIF causes to understand the gap between the both hypotheses suggested. Therefore, the prediction parameters in absolute values are not important. By other hand, clinical relevance of each transcriptomic profile has not been analysed in this study.

Wider implications of the findings: Besides of understanding the gap between both works, the main insight of this study is how to design predictors to distinguish clinically between the patient that could receive a personalised embryo-transfer day and the patient with a disrupted WOI that should be studied for developing new treatments.

Trial registration number: not applicable.

P-479 New approach for assigning endometrial receptivity using RNA sequencing

M. Suhorutshenko[1,2], V. Kukushkina[3], K. Krjutshkov[4], A. Velthut-Meikas[2], T. Laisk-Podar[2], R. Mägi[3], H. Teder[2], S. Altmäe[2], M. Peters[2], A. Salumets[1,2]

[1]University of Tartu, Faculty of Medicine, Tartu, Estonia
[2]Competence Center on Health Technologies, Competence Center on Health Technologies, Tartu, Estonia
[3]University of Tartu, Estonian Genome Center, Tartu, Estonia
[4]University of Helsinki, Molecular Neurology Research Program, Helsinki, Finland

Study question: Can low-read whole-transcriptome RNA-seq approach be used for endometrial receptivity biomarker analysis?

Summary answer: The results suggest that Single-cell Tagged Reversed Transcription (STRT) RNA-seq approach can be used as a sensitive and cost-effective method for endometrial receptivity assignment.

What is known already: Up-to-date microarray-based gene expression analysis of endometrial tissue has been the only clinically applied technique to predict the receptiveness of uterine lining in women undergoing IVF. The microarray approach is limited to previously well-described genes with no respect to isoform variation. It highlights that RNA-seq is the potential assay for routine gene expression analysis. Recent study on individual endometrial cells of different types introduces new RNA-seq approach for whole transcriptome analysis of endometrial tissue using low read count, that significantly reduces the cost for RNA-seq.

Study design, size, duration: In this study we investigated transcriptome profiles of early and mid-secretory endometrial tissue from healthy women using STRT RNA-seq method and compared it with Illumina Paired-End RNA-seq (PE RNA-seq). STRT method was preferred as a high-plex RNA sequencing technique that is beneficial in decreasing batch effect.

Participants/materials, setting, methods: Endometrial biopsy was obtained from a cohort of 35 healthy fertile volunteers (aged 23-36) on day one and day seven post ovulation, confirmed by LH testing. STRT 48-plex RNA-seq library was synthesized from whole-tissue total RNA using oligo-T primer, Unique Molecular Identifiers (UMI), and sequenced by Illumina HiSeq2000. Independently of this study, PE RNA-seq analysis was performed using Illumina Stranded TruSeq technique with participant inclusion criteria and RNA isolation procedures similar to the present study.

Main results and the role of chance: The differential expression analysis of mid-secretory and early secretory phase endometrium showed up to three-fold difference in the number of significantly differentially expressed genes

(DEGs) between two approaches. Quantitative analysis showed that 724 DEGs identified by STRT (64% of STRT DEGs) overlapped with PE RNA-seq.

Functional analysis revealed similar within-dataset distribution of molecular functions and biological processes affected by DEGs, with the prevalence of genes associated to cellular processes (44,7% in STRT and 43,8% in PE RNA-seq) and metabolic events (36,3% in STRT and 34,7% in PE RNA-seq). Among the genes with the highest expression rate change were many recognized endometrial receptivity markers, such as *PAEP, GPX3, LAMB3, DPP4, SERPING1*. The abundance of DEGs identified by STRT (>40%) appeared to be common endometrial markers or genes previously associated with endometrial functioning.

Limitations, reasons for caution: STRT use in endometrial gene expression profiling is most justified for the analysis of well-described transcriptomic markers for endometrial receptivity, while low sequencing depth may be an issue in *de novo* marker analysis.

Wider implications of the findings: Prospectively, the method can be adopted for RNA isoform analysis that augments its potential in diagnostic field.

Trial registration number: not applicable.

P-480   Idiopathic recurrent pregnancy loss - role of pre implantation genetic screening

V.S. Vellanki[1], D.G. Rao[2], K. Mantravadi[3]

[1]Oasis Centre for reproductive Medicine, Reproductive medicine, VIJAYAWADA, India
[2]Oasis Centre for reproductive Medicine, Reproductive medicine, Hyderabad, India
[3]Oasis centre for reproductive medicine, Clinical embryology, Hyderbad, India

Study question: Is there a role for preimplantation genetic screening (PGS) in management of idiopathic recurrent pregnancy loss(RPL)?

Summary answer: Considering high mean aneuploidy rate in young (<35years) women with RPL, PGS identifies euploid embryos for transfer resulting in better ongoing pregnancies and live births.

What is known already: Chromosome abnormalities are extremely common in human oocytes and embryos and are associated with a variety of negative outcomes for both natural cycles and those using assisted conception techniques. Aneuploid embryos may fail to implant in the uterus, miscarry, or lead to children with serious medical problems (e.g., Down syndrome). Preimplantation genetic screening (PGS) is suggested in patients with advanced maternal age or RIF to improve the outcomes of assisted reproductive treatments by ensuring that the embryos chosen for transfer to the uterus are chromosomally normal.

Study design, size, duration: Observational study of fifteen couple under age of 35 years with idiopathic recurrent miscarriage who were managed at our institute from 1/6/2016 to 31/12/2016.

Participants/materials, setting, methods: Women under 35years and couples with normal karyotyping and normal RPL profile investigations were included in study. Couples who had two or more first trimester miscarriages were considered as RPL.

All oocytes were subjected to ICSI. All embryos were cultured till Blastocyst stage and were subjected to trophectoderm biopsy. PGS was done through Next Generation Sequencing. Mean percentage of Anueploidy per case was calculated and compared against age matched aneuploidy rates of embryos reported in literature.

Main results and the role of chance: Mean embryo anueploidy rate in RPL group (N = 15) was 79.25% with mean clinical pregnancy rate and ongoing pregnancy rate of 71.4%. All the cases except one had atleast one euploid embryo for transfer. One woman had a early miscarriage. All these women have ongoing pregnancies that have successfully crossed the first trimester. Zachary et al., 2016 reported embryo aneuploidy rates in women under the age of 35 to be around 55% in general population. Results in the study group seem to show higher incidence of embryo aneuploidy in women under the age of 35 when compared against the general population. This further emphasizes the role of PGS in RPL women to optimize reproductive outcomes.

Limitations, reasons for caution: Limitation of this study was low numbers of women included. These are preliminary results and we are continuing follow up of these women with ongoing pregnancies to assess the livebirth rate.

Further broad based clinical application of PGS in RPL is required to define its significance.

Wider implications of the findings: Considering the higher mean aneuploidy rate in young (<35yrs) RPL group, this data supports the use of PGS to select euploid embryo for transfer that could result in better ongoing pregnancies and live birth.

Women with RPL seem to benefit from PGS of embryos.

Trial registration number: not applicable.

P-481   Does urinary luteinizing hormone surge provide more accurate pregnancy dating than last menstrual period in women with Recurrent Pregnancy Loss?

C. Burks[1], D. McQueen[2], S. Cueva[3], M. Thakkar[4], M.D. Stephenson[5]

[1]Univeristy of Illinois at Chicago, Obstetrics & Gynecology, Chicago, U.S.A.
[2]University of Illinois at Chicago, Obstetics and Gynecology, Chicago, U.S.A.
[3]University of Illinois at Chicago, Obstetrics and Gynecology, Chicago, U.S.A.
[4]University of Illinois at Chicago, Obstetrics & Gynecology, Chicago, U.S.A.
[5]University of Illinois at Chicago, Reproductive Endocrinology & Infertility, Chicago, U.S.A.

Study question: Determine if use of urinary luteinizing hormone surge corresponds better with crown rump length than last menstrual period for dating pregnancies under 10 weeks in women with recurrent pregnancy loss.

Summary answer: Study reveals that urinary LH surge corresponds better with CRL than LMP in dating pregnancies before 10 weeks in women with a history of RPL.

What is known already: The use of LMP is the gold standard for pregnancy dating. Recently, the reliability of LMP to accurately predict the estimated due date (EDD) has been called into question. The use of LMP relies on maternal recall, which can often be problematic. Many women do not recall their LMP or are unsure of the date of LMP. Differences in cycle length also affect the reliability of LMP. The use of urinary LH surge has not been well studied in regards to pregnancy dating, it could more reliably predict the EDD since it is an accurate indicator of date of conception.

Study design, size, duration: Observational cohort study from two academic RPL clinics. Women seen between July 2005 and September 2015 were eligible for inclusion. First ultrasound with CRL≥ 5 mm was used to estimate gestational age (GA), by using the Hadlock Formula. GA by LH surge was calculated as the number of days from LH surge to date of ultrasound + 13 days. GA by LMP was calculated as the number of days from LMP to date of ultrasound.

Participants/materials, setting, methods: IRB approval was obtained. Inclusion criteria included: women with ≥2 "unexplained" pregnancy losses <10 weeks size and 1 or more subsequent pregnancy(ies) of at least 10 weeks size; subsequent pregnancies were conceived using timed intercourse to LH surge, without the use of fertility medications. Continuous variables were compared with a student's t-test. Correlation coefficients were compared using a Fisher's Z-test.

Main results and the role of chance: 120 women met inclusion criteria with 122 subsequent ongoing pregnancies. The mean number of prior pregnancy losses <10 weeks was 3.6 (SD 1.6, range 2-10). The mean maternal age at time of subsequent pregnancy was 35 years (SD 3.6, range 26-46). The mean BMI at initial ultrasound was 25.5 kg/m^2 (SD 5.2, range 16.8-45.8). Of the 122 subsequent pregnancies, the mean GA by CRL was 49.9 days (SD 4.9, range 41-65). The mean absolute difference between GA by CRL and GA by LH surge was 1.6 days, whereas the mean absolute difference between GA by CRL and GA by LMP was 2.6 days, P< 0.0001. GA by LH surge more closely correlated to the CRL compared to LMP, with a correlation coefficient of 0.81 versus 0.69, P = 0.02.

Limitations, reasons for caution: Generalizability should be determined by evaluating a cohort of fertile women without a history of RPL.

Wider implications of the findings: This preliminary data suggests that urinary LH surge rather than LMP should be the gold standard in pregnancy dating if LH surge is known.

Trial registration number: Not applicable.

P-482 Does follicular phase length impact pregnancy outcome in women with a history of Recurrent Pregnancy Loss?

C. Burks[1], D. McQueen[2], S. Cueva[3], M. Thakkar[2], M.D. Stephenson[4]

[1]Univeristy of Illinois at Chicago, Obstetrics & Gynecology, Chicago, U.S.A.
[2]University of Illinois at Chicago, Obstetrics & Gynecology, Chicago, U.S.A.
[3]University of Illinois at Chicago, Obstetrics and Gynecology, Chicago, U.S.A.
[4]University of Illinois at Chicago, Reproductive Endocrinology & Infertility, Chicago, U.S.A.

Study question: To determine whether follicular phase length could impact pregnancy outcome in women with Recurrent Pregnancy Loss (RPL).

Summary answer: In this study, the length of the follicular phase in the conception cycle did not significantly impact pregnancy success in women with RPL.

What is known already: During the follicular phase, the endometrium undergoes reconstruction and growth in preparation for implantation in the luteal phase. In a typical 28-30 day cycle, the follicular phase is usually 13-15 days, although it can have considerable variability. Much of the observed intercycle variability is secondary to differences in the follicular phase since the luteal phase, in comparison, is more constant. The relationship between follicular phase length and pregnancy outcome has not been well studied.

Study design, size, duration: Observational cohort study from two academic RPL clinics. Women seen between July 2005 and September 2015 were eligible for inclusion. Ovulation was defined as the day after luteinizing hormone surge. The follicular phase was defined as the number of days from the 1st day of menses to ovulation. Pregnancy was defined as a positive hCG at time of missed menses. Pregnancy success was defined as a term, preterm or an ongoing pregnancy >10 weeks size.

Participants/materials, setting, methods: Inclusion criteria included: 1) women seen between July 2005 to September 2015 with a history of ≥2 "unexplained" pregnancy losses <10 weeks size and 1 or more subsequent pregnancy(ies); 2) subsequent pregnancies were conceived using timed intercourse to the luteinizing hormone (LH) surge, without the use of fertility medications.

Main results and the role of chance: 175 women met inclusion criteria with 195 subsequent pregnancies. The mean number of prior pregnancy losses <10 weeks was 3.8 (SD 1.8, range 2-13). The mean maternal age at time of subsequent pregnancy was 35.6 years (SD 3.8, range 26-46). The mean BMI at initial pregnancy visit was 25.4 kg/m^2 (SD 4.9, range 16.8-45.8). Of the 195 monitored pregnancies, 68% resulted in a success and 32% resulted in a pregnancy loss <10 weeks size. The mean follicular phase length in the cycle of conception was 15.1 days (SD 3.9, range 5-39 days). The pregnancy success rate was 74% (62/84) in women with a follicular phase length of 13-15 days, compared to 60% (26/43) in women with a follicular phase of <13 days and 65% (45/69) in women with a follicular phase of >15 days, P = 0.2.

Limitations, reasons for caution: In order to demonstrate a difference of 15% in the ongoing pregnancy rate between groups, a sample size of 350 pregnancies would be required. Therefore, a larger cohort is needed to definitively answer this question.

Wider implications of the findings: Although the length of the follicular phase in the conception cycle did not significantly impact pregnancy success in women with RPL, there was a trend towards a higher pregnancy success rate with a follicular phase length of 13-15 days. As stated above, a larger cohort is needed.

Trial registration number: Not applicable.

P-483 Determining embryo developmental competence by measuring expressivity of the paternal epigenome

N. Pereira, A. Parrella, S. Cheung, C. O'Neill, Z. Rosenwaks, G. Palermo

Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.

Study question: To profile the transcriptome of men with unexplained infertility and to identify key sperm-specific RNAs that contribute to post-fertilization embryonic developmental competence.

Summary answer: Transcriptome profiling of human spermatozoa using next generation sequencing (RNA-Seq) can reveal genes products that are critical to embryonic development and assisted reproductive treatment outcomes.

What is known already: Although semen analyses are useful in diagnosing male infertility, a normal semen analysis does not guarantee fertility and does not provide functional information about the sperm. While new infertility biomarkers such as SCSA, TUNEL, FISH and Comet assays may provide additional information, they do not reflect an individual's fertility potential. Upon fertilization, the sperm provides a complete, highly structured, and epigenetically marked genome into the oocyte. It is thought that characterization of sperm RNAs may be suited to better understand the contribution of the paternal epigenome, and the regulatory roles these RNA transcripts play in post-fertilization embryo development.

Study design, size, duration: During a 15-month period, RNA-Seq was performed on ejaculated semen samples provided by 25 consenting men undergoing infertility screening. All men had normal semen parameters and their female partners <35 years had normal infertility screening. Following RNA extraction, the relative abundance of RNA transcripts was compared between men who were or not able to achieve conception with intracytoplasmic sperm injection (ICSI). The profiles of these RNA transcripts were then related to embryo development characteristics.

Participants/materials, setting, methods: RNA was isolated from 25×10^6 spermatozoa using a hybrid isolation protocol with TRIzol® Reagent (ThermoFisher Scientific, USA) and a spin column kit (RNeasy Mini Kit, QIAGEN, Germany). Pilot sequencing was carried out at 2×36 bp to determine library quality and expanded to 50-60 M reads at 2×76 bp utilizing an Illumina platform (NextSeq 500). Data was processed and analyzed using the Tuxedo Protocol. Expression values were calculated in FPKM (Fragments Per Kilobase of Exon Per Million Fragments Mapped).

Main results and the role of chance: The 25 consenting men had the following semen parameters: $37.3 \pm 17 \times 10^6$/mL (concentration), 46.6 ± 10% (motility), and normal morphology. The average concentration of RNA extracted was 14.3 ± 6 ng/μL. The age demographics were comparable among couples who conceived i.e., fertile (men = 37.6 ± 3 years; women = 34.8 ± 3 years) and did not conceive i.e., infertile (men = 38.3 ± 5 years; women = 33.6 ± 7 years) with ICSI. The fertilization rates with ICSI and number of embryos transferred were also similar. RNA expression analysis revealed 86 differentially expressed genes between the groups (P < 0.001) – 24 overexpressed and 62 unexpressed. The expression profiles of these RNA transcripts were compared with embryo development profiles. The blastomere cleavage characteristics was similar between the two groups and was consistent with the expression of RANBP2, a gene involved in the assembly of cytoskeletal elements. A higher embryonic fragmentation rate (14.3%) was noted in the infertile group that corresponded to a higher magnitude of BOK RNA transcripts (P < 0.001), a gene which is known to regulate apoptosis during the cell cycle. As expected, PLK4 and BUB1, which dictate chromosome stability and mitotic segregation by regulating centrosome development, had decreased expression in the infertile group (P < 0.001), therefore leading to increased aneuploidy and impaired implantation.

Limitations, reasons for caution: The small sample size of our study represents a limitation, and therefore, our findings need further validation in a larger cohort. The contribution of the paternal genome in embryonic aneuploidy needs confirmation via genomic sequencing of pre-implantation embryos or cytogenetic analysis of miscarriage specimens.

Wider implications of the findings: The application of sperm RNA-Seq can extend beyond microscopic evaluation, morphometric assessment, and diagnostic assays to help predict the contribution of the male gamete to early pre-implantation development. This novel technique can further classify the transcripts that play an influential role in pre and post fertilization and embryo developmental competence.

Trial registration number: Not Applicable.

P-484 Effect of raised serum progesterone level on the day of ovulation trigger on micro RNA expression in endometrium in stimulated cycles

E. Patel[1], S. Reddy[1], V. Vettriselvi[1], M. Kalagara[2]

[1]Sri Ramachandra University, Reproductive Medicine and Surgery, Chennai, India
[2]Vijaya Medical Center, Laboratory Medicine, Vishakhapatnam, India

Study question: Is there a difference in expression of m RNAs in the endometrium in patients with high progesterone on the day of ovulation trigger in controlled ovarian hyper stimulation cycles?

Summary answer: There is a difference in expression of micro RNAs in the endometrium in patients with high progesterone on the day of ovulation trigger.

What is known already: Elevated serum progesterone (P) on the day of human chorionic gonadotrophin (hCG) has been reported to occur in 20%-40% of in vitro fertilization (IVF) cycles. The impact of this is still being debated. Lower pregnancy rates with high progesterone concentration on the day of hCG administration has been reported. Elevated progesterone might induce premature endometrial maturation. MicroRNAs (miRNAs) are small, non-coding RNAs that are able to regulate gene expression at the post-transcriptional level. miRNA expression profile reflects the receptivity status of human endometrium. Therefore, miRNAs are potential biomarkers for endometrial receptivity and may help optimize the protocol for IVF treatment.

Study design, size, duration: It is a prospective study with 4 patients undergoing IVF/ICSI,divided them into 2 groups. First group being patients with P ≤1.5 ng/ml and second group with P > 1.5 ng/ml on the day of ovulation trigger. An endometrial biopsy was taken on the day of oocyte retrieval and a second one 5 days after retrieval for each patient i.e. a total of 8 biopsies.

Participants/materials, setting, methods: Controlled ovarian hyperstimulation was done for all the patients with antagonist protocol. Serum Progesterone was measured on the day of ovulation trigger and oocyte retrieval was done 36 hours later. The biopsies were divided in two halves for histological staining and to evaluate for the expression of micro RNA.MicroRNA (miRNA) sequencing was carried out using Illumina NextSeq500 Single-end sequencing. Alignment against miRBASE database, reporting known and novel miRNA with expression analysis and comparison was done.

Main results and the role of chance: In the retrieval day biopsy,1007 miRNAs were expressed in both the groups. 182 miRNAs were expressed only in group I whereas 186 miRNAs were expressed only in group II. 26 miRNAs were significantly upregulated in the Group II when compared to Group I. Similarly, in the Day 5 biopsy, a total of 961 miRNAs were expressed in both the groups. 137 miRNAs were expressed only in group I whereas 250 miRNAs were expressed only in group II. 36 miRNAs were significantly upregulated in the Group II when compared to Group I. Sequences not showing hits with known miRNA's were extracted and were considered for novel miRNA prediction. In the retrieval day biopsy, 50 novel miRNAs were expressed in both the groups, 165 only in Group I and 361 only in Group II. Whereas in the day 5 biopsy, 41 novel miRNAs were expressedin both the groups, 186 only in Group I and 374 only in Group II, MicroRNAs with copy number > = 10 were considered for target prediction. These miRNA sequences were fed as input along with reference mRNA sequences to miRanda 3.3a6 tool. miRNA hits having minimum free energy < = -20 are assumed to be the targets for reported miRNA.

Limitations, reasons for caution: The main limitation of this study is the small sample size. A study with more samples is required for validation. Also, in this study only patients with antagonist protocol were recruited.There may be differences in the endometrial receptivity profile according to various stimulation protocols

Wider implications of the findings: Through this study we were able to demonstrate that raised progesterone affects endometrial receptivity. Hence, it would be ideal to proceed with fresh embryo transfer in cases with P ≤1.5 ng/ml. However, when P > 1.5 ng/ml, freezing the embryos and transferring in a later cycle would give a better pregnancy rate.

Trial registration number: Not applicable.

P-485   Predictive value of plasma human chorionic gonadotropine measured 14 days after Day-2 single embryo transfer

A. Oldenburg-Lauritzen[1], K. Løssl[2], M. Toftager[2], J. Bogstad[2], L. Prætorius[2], A. Zedeler[2], C.Y. Andersen[3], M.L. Grøndahl[4], A.B. Pinborg[5]

[1]Copenhagen University Hospital- Hvidovre, Department of Obstetrics and Gynaecology, Copenhagen, Denmark
[2]Copenhagen University Hospital- Hvidovre, The Fertility Clinic- Department of Obstetrics and Gynaecology, Copenhagen, Denmark
[3]Copenhagen University Hospital- Rigshospitalet, Laboratory of Reproductive Biology, Copenhagen, Denmark
[4]Copenhagen University Hospital- Herlev, The Fertility Clinic, Copenhagen, Denmark
[5]Copenhagen University Hospital- Hvidovre, The Fertility Clinic and the Department of Obstetrics and Gynaecology, Copenhagen, Denmark

Study question: How does plasma human chorionic gonadotropine (p-hCG) measured exactly 14 days after day-2 single embryo transfer (SET) predict pregnancy, delivery and perinatal outcome?

Summary answer: Plasma-hCG is a significantly better predictor of clinical pregnancy than of ongoing pregnancy and delivery and was neither related to birth weight nor gestational age.

What is known already: Prediction of pregnancy outcome as soon as possible after Assisted Reproductive Technologies (ART) is important for patients and clinicians. Early p-hCG levels are the best known predictor of pregnancy outcome, but no studies investigating p-hCG after ART have been restricted to SET of Day-2 embryos.

Study design, size, duration: This is a sub-study to an RCT comparing the short GnRH-antagonist protocol with the long GnRH agonist protocol including 1050 women undergoing their first IVF/ICSI treatment. The first patient was enrolled in 2009. In the current study we included all women with SET, who had p-hCG measured exactly 14 days after Day-2 SET (n = 466).

Participants/materials, setting, methods: A total of 466 women, 243 (52.1%) in the GnRH-antagonist group and 223 (47.9%) in the GnRH-agonist group, fulfilled the inclusion criteria of fresh Day-2 SET and p-hCG measured exactly 14 days after ET. Receiver operating characteristic (ROC) curves were generated using a nonparametric distribution method to assess the predictive value of p-hCG for reproductive outcomes.

Main results and the role of chance: The p-hCG levels 14 days after SET were similar after GnRH-antagonist (282.8 (198.6) IU/L) and GnRH-agonist (266.0 (206.3) IU/L) protocol (p = 0.48); after IVF (291.3 (218.3) IU/L) and ICSI (249.2 (169.2) IU/L) (p = 0.28); and whether (278 (238.5) IU/L, n = 152) or not (278 (238.5) IU/L, n = 33) a high quality embryo was transferred. P-hCG predicted clinical pregnancy (AUC=0.953; 95% CI 0.915-0.992) significantly better than it predicted ongoing pregnancy (AUC=0.803, 95% CI; 0.717-0.890) and delivery (AUC=0.772, 95% CI; 0.691-0.854). Women with p-hCG levels in the lowest quartile had significantly lower clinical pregnancy, ongoing pregnancy, and delivery rates ($p < 0.001$), whereas the pregnancy outcome and post-clinical pregnancy loss remained similar throughout the three highest p-hCG quartiles. The p-hCG level was neither related to birthweight nor gestational age at delivery.

Limitations, reasons for caution: The use of prospectively collected data derived from an RCT limits the sample size.

Wider implications of the findings: A clinical pregnancy was optimally predicted by a p-hCG value of 123 IU/L (sensitivity 86.1%, specificity 96.3%). Discriminatory cutoff values are useful in guiding clinicians identifying pregnancies with high risk of adverse outcomes and instituting more intensive pregnancy surveillance in this population.

Trial registration number: For the initial randomized controlled trial (Toftager et al.,2016): EudraCT #: 2008-005452-24, ClinicalTrial.gov: NCT00756028.

P-486   Proteomic assessment of the signatures underlying human placental vascular development

M. Taggart[1], S. Robson[2], Z. Zhang[1], J. Taggart[1], A. Treumann[3], N. Europe-Finner[1], P. Palmowski[1]

[1]Newcastle University, Institute of Genetic Medicine, Newcastle upon Tyne, United Kingdom
[2]Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom
[3]Newcastle University, NUPPA, Newcastle upon Tyne, United Kingdom

Study question: Can proteomics inform us of the molecular signatures underlying human placental vasculogenesis and maturation?

Summary answer: 3586 proteins were identified and quantified from placental arterial biopsies and 1078 were differentially expressed between 1st and 3rd trimester of pregnancy.

What is known already: The regulation of human placental organogenesis is crucial for ensuring normal fetal growth and successful pregnancy outcome.

This depends on the *de novo* formation in first trimester, and maturation throughout gestation, of the placental vasculature. It is of interest, therefore, to establish the breadth of molecular signatures that may underlie placental vasculogenesis. Much information regarding this comes from transcriptomic studies or non-human model systems. As such, we have performed a proteome-wide examination of the molecular changes that occur during the in vivo maturation of human placental blood vessels.

Study design, size, duration: We performed proteome-wide assessments of chorionic plate arterial samples isolated from placental biopsies obtained following delivery (LREC 10/H0906/71) in normal pregnant women.

Participants/materials, setting, methods: Biopsies were obtained from women undergoing termination of pregnancy in 1st trimester (7-12 weeks, n = 9) and vaginal delivery at term of 3rd trimester (39-40 weeks, n = 7) of normal pregnancy. Arterial homogenates were trypsin-digested and the resultant peptides examined by LC-MS-based, label-free quantification using SWATH (Sciex TripleTOF 6600). Proteins were quantified on the basis of at least two, and at most five, unique peptides per protein.

Main results and the role of chance: Dynamic regulation of the human placental vascular proteome was evident with 1078 proteins differing between 1st and 3rd trimester (t-test with multiple comparison correction, FDR < 0.01). 710 proteins were up-regulated at term and pathway analysis revealed many linked to components of myofilament/cytoskeletal integrity and of metabolic-contraction coupling (e.g. glycolysis). 368 proteins were down-regulated with many key to gene splicing and protein synthesis including ribosomal proteins, spliceosome proteins and translation initiation/elongation factors. There was a trend towards increased expression of 50 proteins as gestation progressed between 6-12 weeks of 1st trimester pregnancy; 39 of which were differentially expressed in between 1st and 3rd trimesters and included proteins potentially involved in extracellular matrix deposition (LAMA4, LAMB2), dense body formation (PDLIM3, ACTN1) and myofilament integrity (MYH11, CNN1).

Limitations, reasons for caution: Future work that enabled collection of samples from broader gestational settings will be beneficial for further examining chronological trends.

Wider implications of the findings: Our study gives a comprehensive description of major proteome changes accompanying human placental vascular development. This provides a useful platform from which to (i) investigate how these may be altered in situations of placental-mediated disease and (ii) examine if other situations of human vasculogenesis/vascular remodelling involve similar proteomic changes.

Trial registration number: not applicable.

P-487   Assessment of endometrial receptivity by Endometrial Receptivity Array (ERA) in patients with adenomyosis and previous implantation failure

S. Kaur[1], N. Mahajan[2], P. Naidu[3], K. Rani[2], J. Kaur[2]

[1]Mother And Child Hospital- Defence Colony- New Delhi, Infertility and IVF, South, India
[2]Mother and Child Hospital- Defence Colony- New Delhi, Infertility and IVF, Delhi, India
[3]Milann the Fertility Center, Infertility and IVF, South, India

Study question: Does adenomyosis alter endometrial receptivity(ER) leading to displaced window of implantation (WOI) in patients with previous implantation failure in IVF,as determined by ERA.

Summary answer: In patients of adenomyosis with implantation failure, Endometrial Receptivity (WOI) is significantly altered (47.22%) compared with controls 21.60% (patients with no adenomyosis).

What is known already: Adenomyosis is known to be associated with subfertility but there is paucity of studies on alteration of endometrial receptivity with adenomyosis.ERA is a customised microarray test evaluating the transcriptomics of WOI using 238 genes that are differentially expressed. ERA is accurate and reproducible compared to other markers of endometrial receptivity with sensitivity of 88.57 % and specificity of 99.7 %. Studies have shown WOI displacement in RIF patients leading to the concept of personalized embryo transfer(pET) as a therapeutic strategy but so far there are no studies evaluating endometrial receptivity in patients with adenomyosis with ERA.

Study design, size, duration: Retrospective study. 374 patients with one or more previous IVF failures who underwent ERA test between 2013-2016 were enrolled in the study. Patients were grouped according to the presence (Group 1, n = 36) or absence of adenomyosis (Group 2, n = 338 (controls). Alteration in endometrial receptivity determined by ERA, between the two groups was compared. Further analysis was done between patients with previous one IVF failure and RIF.

Participants/materials, setting, methods: All patients underwent ERA test in hormone replacement cycle (HRT). Estradiol valerate was started in a dose of 2 mg, this was increased to 6 mg or more till an appropriate endometrial thickness (≥7 mm) was achieved. Vaginal progesterone suppository 400 mg twice a day was then started for a period of 5 days (P + 5). Endometrial biopsy for ERA was taken after complete 5 days of progesterone and sent to igeonomix for analysis

Main results and the role of chance: Endometrial receptivity assay results were interpreted as Receptive(P+5) or Non receptive (displaced window of implantation, Pre/Post Receptive)

Basic demographic features between the two groups were similar. Mean age of patients with adenomyosis group was 34.5 years while in non adenomyosis it was 33.5 yrs (p-.166) WOI was displaced (Non Recptive ERA result) in 47.2% (17/36) patients with adenomyosis (group 1) compared to only 21.6% (73/338 pts) without adenomyosis (group 2) which was statistically significant (p < 0.001, CI-8.7%-42.5%) with risk ratio of displaced WOI in adenomyosis vs non adenomyosis to be 2:1 Subgroup Analysis was done to compare incidence of RIF between Adenomyosis group and Non Adenomyosis group. Incidence of RIF was 66.67% (24/36) in adenomyosis group while only 35% (118/338) had RIF in non adenomyosis group which was statistically significant (p<0.001, CI-15.5 to 47.9%).

Limitations, reasons for caution: retrospective nature of the study

Wider implications of the findings: Results indicate patients with adenomyosis have higher chance of having displaced WOI (altered endometrial receptivity) which could be responsible for implantation failure in IVF. ERA can be used electively in patients with adenomyosis for personalized embryo transfer (pET).

Trial registration number: not applicable.

P-488   Impact of airplane travel after an embryo transfer procedure in the reproductive outcome of oocyte donation cycles

J.C. Castillo, J. Ortiz, L. Martí, R. Nataloni, B. Moliner, A. Bernabeu, J. Llacer, R. Bernabeu

Instituto Bernabeu, Reproductive Medicine, Alicante, Spain

Study question: Does airplane travel have any impact after an embryo transfer procedure in the reproductive outcome of oocyte donation cycles?

Summary answer: Taking a plane within 72 hours after an embryo transfer appears to have a negative impact on the clinical pregnancy rate in oocyte donation cycles.

What is known already: Cross-border ART is rapidly increasing worldwide, especially within European countries. A recent Cochrane Systematic Review suggests that there is insufficient evidence to support any specific length of time for women to remain recumbent, if at all, following embryo transfer (ET). However, there is a paucity of information on the possible impact of airplane travel after an embryo transfer procedure.

Study design, size, duration: This is a prospective, observational, single center, cohort study. The hypothesis assumes a 15% decrease in reproductive outcomes in patients flying back to their countries using air transportation within 72 hours following embryo transfer. A sample size of 134 patients per group was estimated for the primary outcome: pregnancy / clinical pregnancy rates per ET. The study was performed during years 2015-2016.

Participants/materials, setting, methods: In total, 402 ET cycles were analyzed. The study group (A) (n = 134) included recipients using airplane transportation within 72 hours after ET; control group B (n = 134) included recipients flying back to their countries >72 hours post-ET and control group C (n = 134) included patients whose transportation post-ET did not involve air travel. Patients were 1:1 matched according to: type of ET (fresh/frozen) and

number of transferred embryos (one/two). The procedures were done at the blastocyst stage.

Main results and the role of chance: Globally, pregnancy rates were similar among groups (57.5, 61.2 and 60.4; in groups A, B and C respectively). However, clinical pregnancy rates were significantly lower in the study group (37.6%) vs controls (52.2%, p = 0.01 and 54.1% p = 0.007; groups B and C, respectively). The clinical pregnancy rates remained similar between groups B and C. Logistic regression analysis showed that patients taking air transportation within 72 hours after ET were 1.83-1.99 times more likely to experience a decrease in clinical pregnancy outcome when compared either to patients taking a plane >72 hours (CI:1.12-3.00) and local recipients (CI:1.21-3.27) respectively.

Limitations, reasons for caution: The biological plausibility of a factor existing in the study group at the peri-implantatory period affecting only clinical pregnancy but not implantation remains controversial. Larger studies including a wider range of residual or other possible confounders (e.g. embryo quality; travel distance) are needed in order to confirm our data.

Wider implications of the findings: Cross-border reproductive treatments are steadily increasing especially within European countries. The information from this study may have important logistic implications for recipients and may also help clinicians to properly counsel patients about the impact of airplane travel after ET. Finally, our conclusions might boost controversies regarding post-ET interventions for ART.

Trial registration number: Not applicable.

P-489   Subsequent Pregnancy outcomes following Tubal Ectopic pregnancy Management- A 2 year follow up study in a University Hospital

V. Kandavel[1], M. Lokman[1], J. Odendaal[1], M.F. Izzat[1], P.S. Quenby[2]

[1]UHCW NHS Trust, Obstetrics and Gyanecology, Birmingham, United Kingdom
[2]University of Warwick- UHCW NHS Trust, Obstetrics and Gyanecology, Birmingham, United Kingdom

Study question: Does the method of management of tubal ectopic pregnancy affect the subsequent pregnancy outcome including the past obstetric history

Summary answer: High Intra-uterine pregnancy rates across the management groups.

No increase in repeat ectopics in non-surgical groups.

No co-relation between previous livebirth and subsequent pregnancy outcomes. What is known already: The incidence of ectopic pregnancy is 11/1000 pregnancies with tubal ectopic being the most common. A range of options are available for managing a tubal ectopic including expectant; methotrexate and surgical methods. NICE guidelines on ectopic pregnancy and miscarriage (CG154) however, does not recommend expectant management where as recently published RCOG/AEPU guideline on Diagnosis and Management of Ectopic Pregnancy (No. 21)considers this as an option.

Increased availability of EPAU units and improvement in scanning the diagnosis of ectopic pregnancies happens at an earlier stage of pregnancy. Surgical method is a favoured option followed by medical management.

Study design, size, duration: Retrospective follow up cohort study of subsequent pregnancy outcomes following tubal ectopic pregnancy. Data was obtained from electronic reporting systems and clinical documentation.

PUL was recorded as ectopic outcomes. Patients with a scan diagnosis of ectopic pregnancy between 01/01/2013 and 31/12/2-14 were included in the study

Subgroup analysis was undertaken and comparison made between previous livebirth and no previous pregnancy prior to the ectopic pregnancy.

Participants/materials, setting, methods: The Early pregnancy unit is a 5-day service and accepts referrals from GP and self referrals managed according to the trust guideline.

Expectant management is offered to asymptomatic women with hcg less than 2000iu/l and mass less than 3 cm.

Medical management is offered to women with hcg between 2000iu to 4000iu/l and mass less than 3 cm and who are compliant.

Any patient with live ectopic, free fluid, pain or hcg>4000iu/l are managed surgically.

Main results and the role of chance: Conservative group: 55/95 (57.9%) became pregnant. 8 had repeat ectopic, 7 miscarriages and 40 had a live birth.

The ectopic recurrence rate was 14.54% (8/55) with IUP rate of 85.45%.

Medical group: 50/89(56.17%) achieved pregnancy. 9 had repeat ectopic, 2 miscarriages and 39 had a live birth.

The ectopic recurrence rate was 18% (9/50) with IUP rate of 82%.

Surgical group: 48/101(47.52%) had a subsequent pregnancy. 9 had repeat ectopic, 3 miscarriages and 36 had a live birth.

The ectopic recurrence rate was 18.75% (9/48) with IUP rate of 81.25%.

The outcomes from our study are comparable between the management groups and to the published evidence (1, 2).

Subgroup analysis: There were 79 patients within the total of 126 patients (62.69%) in 2013 whose index pregnancy was an ectopic pregnancy. Their subsequent outcomes were:

8/79 had a repeat ectopic (10%)
32/79 patients did not achieve a subsequent pregnancy until 2016.(40.50%)
39/79 had a subsequent IUP(49.36%)
47 patients within the ectopic pregnancy had a previous live birth. however their outcomes were similar to the patients with an ectopic pregnancy as the index pregnancy. The repeat ectopic rate was 10.63% and the subsequent IUP rate was 46.80%

Limitations, reasons for caution: Retrospective study with loss to follow up.

Data is unavailable regarding patients who voluntarily chose not to have further pregnancies.

Subgroup analysis was performed for only one year.

Will need to extend the study period of subgroup analysis to be confident of the lack of correlation with past obstetric history.

Wider implications of the findings:
- High subsequent IUP rates across management groups with no increase in repeat ectopics and no influence from previous pregnancy outcomes.
- Reassuring that 40.3% had a live birth within 2-3 years
- The data will reassure women and will be useful for counselling women regarding their options of management and aid decision making

Trial registration number: Not applicable.

P-490   Influence of the ABO blood group of males and females on the results of in vitro fertilization cycles

R. Valdes Gallardo, J.C. Garcia Lozano, B. Sanchez Andujar, M.D. Lozano Arana, J. Guisado Fernandez, M.A. Calvo Galldo, J.L. Moliní Rivera, J.M. Ledesma Maestre, S. Borrego Lopez, G. Antiñolo Gil

Hospital Virgen del Rocio, Reproduccion, Sevilla, Spain

Study question: Does the AB0 group of males and females influence the results of in vitro fertilization (IVF/ICSI) cycles?

Summary answer: Cycles with embryo transfers in couples whose blood types are both 0, have a higher rate of clinical pregnancy, live births and implantation rate

What is known already: In the literature a possible association has been suggested between the antigens of the ABO groups of females and the results of the IVF/ICSI cycle, with contradictory results. Group A has been associated with an increased risk of early hyperstimulation and group 0 as a risk factor for low ovarian reserve. Likewise, the presence of A or B antigens in spermatozoa has been associated with an increased risk of infertility. We do not know of any studies concerning the results of IVF/ICSI cycles in relation to the ABO blood group of males and females.

Study design, size, duration: A retrospective descriptive observational study in which 2.414 IVF/ICSI cycles were carried out in couples with primary infertility between January 2007 and December 2015. Among them, embryo transfer was performed in 1.873 cycles. Two groups were defined according to the combination of the AB0 groups of males and females. Group O: Both women and men are blood group 0. Group No0: Women or men with blood group AB.

Participants/materials, setting, methods: Of 2414 IVF/ICSI cycles fresh transfers were performed in 1.873. Of these, 286 (15.27%) belonged to group 0 and 192 (10.25%) to group No0. The main variables studied were: clinical pregnancy rate per transfer, biochemical pregnancy rate per transfer, newborn rate per transfer and implantation rates. Other variables studied were women's age, oocytes obtained, fertilized oocytes, embryos at +2 or +3, and number of embryos transferred.

Main results and the role of chance: The groups 0 and No0 were similar for possible confounding variables: age (34.37 vs 34.41 years, ns), oocytes recovered (10.9 vs 10.4 ns), fertilized oocytes (4.5 vs 4, 8; ns), total embryos (4.35 vs 4.68; ns) and number of embryos transferred (1.83 vs 1.82; ns).

The live birth rate (20.6% vs 13.7%, p = 0.05) and the clinical pregnancy rate (36.4% vs 27.5%, p = 0.046) was higher in group 0 than in the Group No0, although the biochemical pregnancy rate was similar in both groups (46.2% vs 39%, p = 0.287). These results could be explained by the fact that the implantation rate was significantly higher in group 0 (25.35% vs 17.8%, p < 0.001). Similarly, the newborn rate per embryo transferred was higher in group 0 (13.7% vs 8.5%, p <0.001).

Limitations, reasons for caution: This is a retrospective descriptive study with a limited sample size. The study has only focused on the combination of 0/0 couples with pairs having at least one individual AB blood group. In the future it will be necessary to extend this study to all possible combinations.

Wider implications of the findings: This study reveals that embryos from couples whose blood group is 0 have higher implantation rates than others whose progenitors are carriers of A or B alleles. This may be related to immune response due to fact the presence of antigen A or B results in lower embryo implantation rates.

Trial registration number: Non applicable.

P-491   Cutoff points of serum beta-hCG levels to predict pregnancy after different in vitro fertilization treatments

M. Fernandez Perez, E. Martín-Díaz, C. Monedero-Mora, M. García Sánchez, E. Pérez de la Blanca

Hospital Quiron Salud Málaga, Assisted Reproduction Unit, Málaga, Spain

Study question: Can different predictive values of β-hCG levels be stablished depending on the in vitro fertilization treatment and the pregnancy outcome?

Summary answer: Highly predictive beta-hCG levels cutoff points can be proposed for pregnancy outcomes.

What is known already: Pregnancies that occurred after in vitro fertilization treatment present an increased risk for an adverse outcome. Thus, there is a necessity for markers that precisely diagnose the pregnancy helping to determine appropriate follow-up guidelines during the first trimester. In this sense, levels of beta-hCG are highly predictive for pregnancy after in vitro fertilization treatment, albeit prognostic values and beta-hCG thresholds are not consistent. We hypothesized that some threshold levels of serum beta-hCG could be stablished for different conditions (fresh or frozen embryo transfer) with accurate predictive value of pregnancy outcomes (no pregnancy, single or twin, first trimester abortion).

Study design, size, duration: A single-centre retrospective cohort study was performed in the Assisted Reproduction Unit of Hospital Quironsalud Málaga (Spain). A total of 435 in vitro fertilization cycles in the time period from 2011 to 2016 were included. Only couples undergoing fresh or frozen-embryo transfer with positive of beta-hCG levels measured in our laboratory on day 14 after eggs collection (EC) and with available data on pregnancy outcome were included regardless of age.

Participants/materials, setting, methods: Serum beta-hCG concentration on day 14 after EC was measured using VIDAS® kit. Pregnancy was assessed by ultrasonic examinations at 6th and 12th week of pregnancy. Analyses were performed using the R software. Receiver operating characteristic (ROC) curve analyses were performed to determine optimal cutoffs values. Student's-t test was used to assess quantitative variables. Chi-squared test or Fisher exact test were used to compare differences in frequencies. Statistical significance was set at p <0.05.

Main results and the role of chance: A total of 435 Embryo Transfer (ET) with positive value of b-hCG were included. There were 288 (66%) ongoing pregnancies (12 weeks after ET), 83 (19%) biochemical pregnancies and 64 (15%) miscarriages (before 12 weeks). According to the ROC curve, a concentration of beta-hCG ≥ 117.5mIU/mL predicted ongoing pregnancy with a sensitivity of 80% and specificity of 70% (AUC = 0,82, p < 0.0001). A beta-hCG level ≥ 170.5 mIU/mL sensitivity 80% and specificity 62% (AUC = 0.78, p < 0.0001) predicted the probability of twin pregnancies. In order to study the treatment effect, cycles were grouped into fresh ET (n = 198) and frozen ET (n = 237), there were no differences in ongoing pregnancy rates 69% for fresh cycles and 64% for frozen cycles. A cuttof point of ≥123.5.00 mIU/mL with a sensitivity of 80% and specificity of 68% (AUC=0,82, p < 0.0001) and a value of ≥116.5 mIU/mL sensitivity or 82% and specificity or 70% (AUC=0,82, p < 0.0001) can predict ongoing pregnancy for fresh s and frozen cycles respectively. Finally, a cutoff level of beta-hCG < 66.5 mIU/mL can predict miscarriage outcome before 12 weeks with a sensitivity of 67% and specificity of 43% (AUC=0.77, p<0.0001).

Limitations, reasons for caution: Our study is limited by its retrospective design and the possible selection bias, due to the restriction of data available for b-hCG levels at day 14 after EC.

Wider implications of the findings: The results of this study provide data on the use of beta-hCG as reliable early indicator of pregnancy after in vitro fertilization treatment, which could be useful in counseling patients after ET, not only regarding conception, but also about the prognosis of such pregnancy.

Trial registration number: not applicable.

P-492   The natural history of pregnancy related enhanced myometrial vascularity

K. Grewal[1], M. Al-Memar[1], H. Fourie[2], V. Djapardy[2], T. Bourne[1]

[1]Imperial College London, Early pregnancy unit, London, United Kingdom
[2]Queen Charlotte's and Chelsea Hospital, Early pregnancy unit, London, United Kingdom

Study question: What is the natural history of pregnancy related enhanced myometrial vascularity (EMV)?

Summary answer: We have shown that EMV after a pregnancy resolves in the majority of cases without the need for surgery, those surgically managed had minimal complications.

What is known already: Enhanced myometrial vascularity (EMV) is a term used to describe an abnormal connection between the arterial and venous system within the uterus leading to high velocity blood flow and risk of haemorrhage. Currently there is no clear guidance on the management of such cases. Recent evidence suggests that those with a high peak systolic velocity (PSV) may require intervention with embolization, whereas the lower velocity cases could be managed conservatively. Nevertheless, the lack of robust evidence surrounding this condition means the information given to women regarding outcome is often limited.

Study design, size, duration: A prospective audit of practice in a London teaching hospital between October 2015 to January 2017. The clinical course of twenty-six women was documented and followed up until discharge from the unit.

Participants/materials, setting, methods: Women attending the early pregnancy unit with abnormal bleeding and ultrasound features of EMV were included. The diagnostic criteria involved the subjective identification of an area in the myometrium with increased vascularity and a PSV greater than 20 cm/sec within the collection of vessels. The clinical presentation, bleeding score, PSV, intervention (if required) and time to resolution were all documented.

Main results and the role of chance: Twenty-six patients with a diagnosis of EMV were followed up. Mean age was 33 (range, 22-43), twelve women had at least one previous miscarriage. The initial presentation included incomplete miscarriage (n = 11), missed miscarriage (n = 4), retained products of conception following failed surgical management of miscarriage (n = 5), failed medical termination of pregnancy (n = 4), failed expectant management of miscarriage (n = 1) and postpartum retained products (n = 1). 24/26 presented with bleeding at the time of diagnosis, with 15/26 reporting heavy bleeding with clots (bleeding score 4). The outcome data for twenty-three patients is available and the mean number of days taken to resolve was 41 (range 2 to 140). The majority of patients (15/26) reported minimal bleeding whereas two patients had a blood loss of 500 ml. One patient required a blood transfusion. In patients surgically managed the average PSV associated with minimal blood loss was 34 cm/sec and 66 cm/sec when blood loss reached 500 ml blood loss. Those

that underwent expectant management took 60 days (range 14 to 140) to resolve. 8/26 cases opted for surgery to remove retained products in the first instance, and resolution in this group took a mean of 23 days (range 2 to 59).

Limitations, reasons for caution: This is a small observational review of clinical cases. However, it is the largest prospective case series in the current literature. The subjective assessment involved in highlighting those with enhanced myometrial vascularity is a potential bias.

Wider implications of the findings: These findings suggest expectant management is successful but can take up to 60 days to resolve. EMV itself may be an iatrogenic diagnosis that is associated with the pathophysiology of miscarriage, and resolves with resolution of bleeding. However, more work is required to establish the underlying mechanism at play.

Trial registration number: not applicable.

P-493 Chronic endometritis therapy following autologous platelet-rich plasma treatment

K. Sfakianoudis[1], N. Nitsos[2], Y. Nikas[3], A. Pantou[1], A. Grammatis[1], A. Konstantopoulos[1], G. Kokkali[1], L. Lazaros[4], K. Pantos[1]

[1]Genesis Athens Clinic, Reproductive Medicine Unit, Chalandri-Athens, Greece
[2]Genesis Athens Clinic, Microbiology-Biochemical Department, Chalandri-Athens, Greece
[3]Athens Innovative Microscopy, Microscopy, Athens, Greece
[4]Genesis Genoma lab, Molecular Genetics, Chalandri-Athens, Greece

Study question: To explore whether autologous intrauterine platelet-rich plasma (PRP) treatment could eliminate uterine stroma inflammation, offering an alternative therapeutic approach to women suffering from chronic endometritis.

Summary answer: Our data demonstrated the successful effect of autologous intrauterine PRP treatment in women suffering from chronic endometritis with subsequent positive IVF outcomes and live births.

What is known already: Chronic endometritis, a persistent inflammatory condition of the inner lining of the uterine cavity, is caused by ascending infections from organisms normally present in the indigenous vaginal flora, sexually transmitted infections, tuberculosis and medical procedures that permit bacteria intrusion to the uterus through the cervix. Chronic endometritis therapy is based on oral antimicrobial treatment, however not all cases respond to the above medications, rendering necessary the need of alternative therapeutic approaches. The antimicrobial and anti-inflammatory effects of platelet-rich plasma have led clinicians to administer PRP as an efficient treatment for several medical issues, including osteoarthritis and tendinitis.

Study design, size, duration: Seven women, aged 42.17 ± 5.34 years, with unexplained infertility or ≥ 2 recurrent implantation failures referred to our IVF centre from January to July 2015. Chronic endometritis was diagnosed by hysteroscopy and microbiological analysis. Following the appropriate antibiotic therapy, 4 patients underwent in vitro fertilization (IVF) with embryo transfer (ET) resulting in only one clinical pregnancy which was spontaneously aborted. All women underwent a second hysteroscopy that certified the persistence of chronic endometritis.

Participants/materials, setting, methods: All women underwent autologous intrauterine PRP treatment. The autologous PRP was prepared using the RegenACR®-C Kit according to manufacturer's instructions. The endometrial infusion was performed using a non-surgical, transvaginal ultrasound-guided injection with an appropriate catheter. After the PRP treatment the patients underwent a third hysteroscopy and a simultaneous endometrial sampling at the luteal phase of the menstrual cycle in order to perform microbiological analysis. Within the next three months all women underwent new embryo transfers.

Main results and the role of chance: Following the autologous intrauterine PRP treatments, hysteroscopy and microbiological analyses revealed no remaining signs of chronic endometritis in 5 women (71.43%) of which four (80%) achieved 2 singleton and 2 twin clinical pregnancies resulting four live births and one ongoing twin pregnancy.

The delivery of high concentrations of platelet-derived factors to damaged tissues is considered to promote tissue healing and regeneration. These bioactive factors, including proteins with antibacterial and fungicidal effects, coagulation factors and membrane glycoproteins that control the synthesis of interleukins and chemokines, are capable of confronting the inflammation

processes. Furthermore, dense granule-derived factors, such as adenoside diphosphate, adenoside triphosphate, serotonin, histamine, dopamine and calcium ions, can promote tissue homeostasis, whereas alpha granule-released growth factors play fundamental roles in wound healing and tissue regeneration. The intrauterine PRP treatment has modulated the local inflammatory response of mares with chronic degenerative endometritis, while it has promoted the endometrial growth in patients with thin endometrium improving the pregnancy outcome. In the light of the above analysis, we could assume that the autologous, intrauterine PRP treatment of our patients probably modulated the aberrant inflammatory processes of chronic endometritis and promoted the endometrial stroma healing.

Limitations, reasons for caution: Our investigation was based on seven women of advanced maternal age suffering from chronic endometritis. Further studies in larger population groups, analyzing chronic endometritis patients of all ages are needed to confirm our findings.

Wider implications of the findings: After the verification of our finding in larger patient groups, PRP could be used as a first line treatment for chronic endometritis patients, especially for those that do not correspond to conventional antibiotic schemes.

Trial registration number: none.

P-494 Impact of embryo group culture on early ICSI outcomes

K.F. Kacem[1], S. Chtourou[1], S. M'nallah[1], B. Marouen[2], E. Hanene[1], M. Khrouf[2], M. Ben Meftah[2], F. Zhioua[2], A. Zhioua[1]

[1]Aziza Othmana Hospital, Center of Reproductive Medecine, Tunis, Tunisia
[2]Aziza Othmana Hospital, Gynecology and Obstetrics, Tunis, Tunisia

Study question: Could embryo development, be better if embryos were cultured in small groups rather than individually in a medium drop?

Summary answer: Group culture has positive impact on early embryo development. This could promote embryo quality, especially if transfer is planned in early cleavage stage.

What is known already: Embryo culture is one of the most delicate links in Intra-Cytoplasmic-Sperm-Injection(ICSI) cycles. As they grow in culture medium, embryos are being deprived of different growth factors naturally present in women genital tract. Some authors, suggested that grouping embryos for culture could enhance their devolpement by providing autocrine or paracrine factors.

Study design, size, duration: This prospective randomized study, conducted in a single center, took place between April 2015 and July 2016.

Patients who had less than 6 fertilized oocytes were included.

A total number of 291 ICSI cycles were randomly divided into two groups depending on the day of oocyte retrieval.

Participants/materials, setting, methods: -Groupe A (retrieval took place on: Monday, Wednesday or Friday) included 141 couples whom zygotes were cultured, in groups of 2 to 3 in the same drop.

-Group B (retrieval took place on: Tuesday, Thursday or Saturday) included 150 patients whom zygotes were cultured, in individual drops.

Embryo development was evaluated in both groups after culture with regards to: CRs, EQ, BRs and BURs.

Main results and the role of chance: Grouped embryos had significant higher CRs when compared to individual embryos (respectively 96.10% vs 91.80%; **p = 0.012**). Same results were noticed for embryo quality on day 2 or day 3, where group culture provided significant better embryo grades, and the mean number of good quality embryos was greater for embryos gathered in a same drop (EQ: respectively 40% vs 31.76%, p = 0.067; mean number of good quality per cycle: 1.29 vs 0.94, **p = 0.009**).

Although better BRs and BURs were obtained for group culture (respectively 20.95% vs 19.81% and 54.17% vs 44.74%), no statistical differences were found for both parameters.

This study suggests that group culture can promote embryo development at the early stages. Those findings could be beneficial for patients who had previous failure in ICSI cycles, or patients who had reduced number of oocyte retrieval.

Limitations, reasons for caution: Because of the difficulties found for morphological follow up of embryos, some could be reticent to adopt embryo group culture. Though, some devices have been invented to combine group culture with embryo identification.

Wider implications of the findings: Identifying the different autocrine/paracrine factors could be intersting for producing culture medium that are well adapted for embryo culture.

Trial registration number: None.

P-495 Quantitative βHCG concentrations at defined outcome points are predictive of likelihood of ongoing pregnancy

C. Fairbairn[1], T. Hamilton[2], M. Gaudoin[3], R. Fleming[4]

[1]GCRM Ltd., GCRM, Glasgow, United Kingdom
[2]GCRM Ltd, GCRM Ltd, Glasgow, United Kingdom
[3]GCRM- Glasgow Centre For Reproductive Medicine, IVF Unit, Glasgow, United Kingdom
[4]GCRM Ltd., GCRM Ltd., Glasgow, United Kingdom

Study question: To determine the predictive power of serum βHCG concentrations regarding the likelihood of ongoing pregnancy.

Summary answer: Serum βHCG concentrations on trigger+17 have a strong predictive power for pregnancy outcome, leading to earlier identification of a non-continuing pregnancies and improved patient preparation.

What is known already: Serum βHCG levels 2 weeks after embryo transfer are a reliable marker to predict the pregnancy outcome in ART patients. Although the range is considerable, lower βHCG levels are associated with pregnancy failure. It is known that there is a predictive capacity related to quantitative βHCG concentration and the eventual outcome of the pregnancy. Following implantation, the βHCG concentrations increase rapidly in the mid-late luteal phase and the test signal strength obtained in both serum and urine can guide the likelihood of outcome.

Study design, size, duration: Serum βHCG concentrations on day-17 after trigger in 1846 consecutive ART cases where the pregnancy test was "positive" (βHCG > 10 IU/L) were examined. Categories of βHCG concentration were matched to the clinical outcomes at scan (7-8 weeks). The defined outcomes were: 'biochemical' pregnancy (bleeding and failure prior to scan), non-continuing pregnancy (no bleeding but empty sac/absent fetal heartbeat at scan) and clinical pregnancy (single positive heartbeat at scan). Twin pregnancies were excluded from analyses.

Participants/materials, setting, methods: The absolute βHCG concentrations were assessed for sample values from ART cycles resulting in "positive" pregnancy (defined as (βHCG > 10 IU/L), effected using one commercial platform (Beckman Coulter Access 2®) within an ISO accredited testing laboratory.

Main results and the role of chance: When the βHCG concentration on trigger+17 was <30 IU/L (n = 82), 93% resulted in a biochemical pregnancy, 4% in a non-continuing pregnancy and only 2% in an ongoing clinical pregnancy. With βHCG concentrations of 30-50 IU/L (n = 68), these figures were respectively 59%, 15% and 24%. If the βHCG concentration was 50-70 IU/L these figures were respectively 36%, 11% and 52%. With βHCG concentrations >70 IU/L these figures were 8%, 5% and 86% (P < 0.01, Anova), respectively.

Limitations, reasons for caution: Further analyses are required for natural and constructed frozen embryo transfer cycles, and also for days other than trigger+17.

Wider implications of the findings: Further investigations, based on βHCG concentrations wουλδ improve our understanding of implantation, perhaps related to embryo quality or endometrial receptivity. When lower concentrations are identified, patients can be advised of likely outcomes with more precision and can be psychologically better prepared for the greater likelihood of a non-continuing pregnancy.

Trial registration number: N/A.

P-496 Uterine contractility is the only ultrasound marker of implantation at the moment of the embryo transfer in substituted cycles

B. Moliner[1], J. Llacer[2], E.M. Garcia[3], J.C. Castillo[1], A. Bernabeu[1], R. Bernabeu[1]

[1]Instituto Bernabeu, Reproductive Medicine, Alicante, Spain
[2]Instituto Bernabeu. Alicante, Reproductive Medicine, Alicante, Spain
[3]Ib. Biotech, Biotech, Alicante, Spain

Study question: Can we determine some ultrasound marker at the moment of embryo transfer (ET) at the blastocyst stage in substituted cycles?

Summary answer: High uterine contractility correlates with lower pregnancies rates. Endometrial flow velocimetry and endometrial volume were no correlated with outcomes of the treatment.

What is known already: It is known that uterine contractions (UC) at the time of the ET adversely affect IVF outcomes when fresh embryos are transferred during the stimulated cycle. Some studies have found that uterine contractility is much higher in stimulated cycles than in natural or substituted cycles. To date, influence of UC in substituted cycles has not been studied. Other functional ultrasound data like endometrial flow velocimetry and endometrial volume have been proposed as predictive markers of endometrial receptivity at the moment of the ET.

Study design, size, duration: We recovered prospectively ultrasound data of 89 egg recipients receiving embryos at the blastocyst stage in our center between February 2015 and September 2016. Patients included fulfilled medical and legal criteria for oocyte donation and followed the standard preparation protocol using transdermal estradiol and progesterone (subcutaneous or vaginal). All the embryo transfers were performed at the blastocyst stage after 5 days of progesterone.

Participants/materials, setting, methods: The same morning of the embryo transfer an ultrasound evaluation was performed.For the UC assessment 2D scan of the uterus was recorded while a 6 min video.The records were analysed at 20× regular speed using a VLC media player and examined. Endometrial volume and subendometrial and endometrial vascularization 3D parameters (VI,FI,VFI) were measured.The association between Pregnancy Test and uterine contractions and 3D parameters above mentioned was assessed by Student's T-test and Logistical Regression analysis.

Main results and the role of chance: Mean number of UC per minute was significantly lower in the group with positive pregnancy test, 1,22 UC/min in patients with positive test (PT) and 1,55 UC/min in patients with negative test (NT) p = 0,023 OR 2.806 (CI 95%: 1.11-7.08). Results of fluxometric index didn't achieve statistical differences in patients with PT or NT. (see table 1)

Table 1.

	Positive Test (Mean ± SD)	Negative Test (Mean ± SD)	p
Endometrial volume (ml)	4.89 ± 4.57	3.93 ± 2.65	0.386
Uterine contractions (per minute)	**1.22 ± 0.49**	**1.55 ± 0.67**	**0.023**
Endometrial-uterine volume	9.69 ± 12.93	8.68 ± 5.67	0.744
Endometrial Flow Index (FI)	23.45 ± 8.2	22.90 ± 8.30	0.803
Subendometrial Flow Index (FI)	23.65 ± 8.95	23.49 ± 8.33	0.947
Endometrial vascularisation-flow index (VFI)	0.41 ± 0.84	0.36 ± 0.42	0.82
Subendometrial vascularization-flow Index (VFI)	0.67 ± 1.43	0.56 ± 0.59	0.748
Endometrial Vascularization Index (VI)	1.26 ± 2.42	1.01 ± 1.14	0.659
Subendometrial Vascularization Index	2.00 ± 4,27	1.77 ± 2.04	0.823

Limitations, reasons for caution: Sample size was limited.

Wider implications of the findings: Evaluation of UC is useful for endometrial receptivity assessment in substituted cycles. Interventions to minimize

uterine contractility could be helpful to improve clinical outcomes in egg dona-tion or frozen embryo transfers.

Trial registration number: Data were extracted from clinical trial regis-tered. EudraCT: 2014-004784-20; ClinicalTrials: NCT02363127.

P-497   Endometrial Immunophenotype Profiles in Patients with Adverse Reproductive Outcomes

C. Harrity[1], J. Kennedy[1], D. Walsh[2], K. Marron[3]

[1]Sims International Fertility Clinic, Dublin, Ireland
[2]Sims IVF, Medical, Dublin, Ireland
[3]Sims IVF, Zentra Laboratories, Dublin, Ireland

Study question: Reproductive immunology is an evolving, and controversial field. This study aims to assess the endometrial lymphocytes populations in patients with poor reproductive outcome, and correlate levels with aetiology.

Summary answer: Different endometrial immunophenotype profiles are seen in patients with recurrent miscarriage or repeated implantation failure. Further research is needed to determine potential clinical applications.

What is known already: Miscarriage and implantation failure are frequently occuring undesired outcomes of assisted reproduction.Causes include embryo genetic abnormalities or an abnormal endometrial environment. PGS has revo-lutionised embryo screening, but there is still debate and controversy about the gold standard test to assess endometrial function. An endometrial biopsy has the ability to simultaneously test both receptivity and hostility, however, a com-plete uterine immunophenotype is not currently well described, and there is no fully validated technique to completely assess the cellular populations.

Study design, size, duration: An observational study was design to assess endometrial populations in patients with poor reproductive outcomes 250 patients attending for endometrial scratch prior to commencing an ART cycle between Jan 2015 and October 2016 agreed to have their endometrial immu-nophenotype analysed in addition to the procedure Patients were stratified based on their reproductive outcome, and centile ranges were developed for the overall population and separate subgroups.

Participants/materials, setting, methods: An endometrial biopsy immu-nophenotype was developed to investigate by flow cytometry the various lymphocyte populations: peripheral blood type NK (pNK): [CD16+,CD56 dim], decidual/uterine tissue specific type (uNK):CD16-,CD56bright], natural killer-Tcell type (NK-T):[CD16-,CD3+,CD56dim], B-cells (CD5+,CD19+), Plasma cells(CD45+,CD138+), T cells (either CD4+,CD8+), T-regulatory cells (Treg, CD4+,CD127dim,CD25+), Th1-type Tcells (CD4+,CD183+) and Th2-type Tcells (CD4+,CD183-). Centile based reference ranges were established, and sub-groups determined for repeated implantation failure (RIF, >3 unsuccessful ETs) and recurrent miscarriage (RM, > 2 consecutive miscarriages).

Main results and the role of chance: Reference ranges for the lymphocyte populations were established in 250 endometrial biopsies. The overall popula-tion median levels were pNK 1.2%, uNK 41.3%, and NKT 2.7%. The patients were then characterised by reproductive history, and divided into subgroups for further analysis. Different lymphocyte levels were seen in these groups. In patients with recurrent miscarriage, mean levels were: pNK 6.4%, uNK 32.0% and NKT 6.6%.Patients with repeated implantation failure had different results: pNK 3.3%, uNK 43.1% and NKT 2.4%. interestingly, overall Treg and B Cell results were similar between groups, which is different to some existing data.T Cells were predominantly the Th1 subtype in all groups (50.8% Th1: 8.0% Th2 overall)

Cell Type	Overall	Recurrent Miscarriage	Implantation Failure
pNK	1.2	6.4	3.3
uNK	41.3	32.0	43.1
NKT	2.7	6.6	2.4
Treg	2.6	4.0	4.9

Limitations, reasons for caution: This study is limited by the lack of ran-domisation, as patients were recruited based on attendance for endometrial scratch. Analysis of the endometrium from fertile controls would further valid-ate this data.

Wider implications of the findings: Patients with recurrent miscarriage demonstrated a different endometrial immunphenotype profile to the overall population. Further work is needed to assess if these differences are causative or incidental, and whether the application of personalised treatment regimes can improve outcomes

Trial registration number: Not applicable.

P-498   Recurrent pregnancy loss evaluation combined with 23-chromosome testing of miscarriage tissue explains the cause of pregnancy loss in over 90% of all miscarriages

W.H. Kutteh[1], F. Popescu[2], R.W. Ke[3], P.R. Brezina[1], A. Bailey[1], C.R. Jaslow[2]

[1]Vanderbilt University Medical Center, Obstetrics and Gynecolocy, Memphis-Tennessee, U.S.A.
[2]Rhodes College, Biology, Memphis- Tennessee, U.S.A.
[3]Vanderbilt University Medical Center, Obstetrics and Gynecolocy, Memphis-Tenessee, U.S.A.

Study question: Will the addition of 23-chromosome microarray testing on miscarriage tissue combined with the standard evaluation for recurrent miscar-riage explain most losses?

Summary answer: Over 90% of recurrent miscarriages can be explained when combining genetic testing on miscarriage tissue with the standard evalu-ation for recurrent miscarriage.

What is known already: Recurrent pregnancy loss (RPL) is estimated to occur in 2 to 4% of reproductive age couples. Various etiologies, either alone or in combination, have been demonstrated to contribute to RPL including paren-tal chromosomal translocations, congenital and acquired uterine anomalies, endocrine imbalances, autoimmune factors including antiphospholipid syn-drome, as well as infectious and thrombophilic causes. We sought to determine if the evaluation of miscarriage tissue at the time of the second or subsequent loss would explain the majority of "unexplained" losses. Also, we desired to determine if our proposed algorithm of evaluating all miscarriage tissue after the second loss was valid.

Study design, size, duration: Single-center, prospective study included patients seen in a private Recurrent Pregnancy Loss clinic from 2013 to 2016. All sixty-five women had two or more consecutive losses and had a complete evaluation for RPL as defined by the ASRM, and had miscarriage tissue evalu-ated by 23-chromosome micro array after their second or subsequent miscarriage.

Participants/materials, setting, methods: Frequencies of abnormal results for evidence-based diagnostic tests considered definite or probable causes of RPL (karyotyping for parental chromosomal abnormalities, and 23-chromosome microarray on miscarriage tissue; pelvic sonohysterography, hys-terosalpingogram, or hysteroscopy for uterine anomalies; immunological tests for lupus anticoagulant, anticardiolipin and antiphosphatidyl serine antibodies, and beta2 glycoprotein antibodies; hormonal tests for TSH, mid-luteal proges-terone, and hemoglobin A1c; cultures for microbial infection). We excluded cases where there was maternal cell contamination of the miscarriage tissue.

Main results and the role of chance: The majority of losses 42/65 (64.5%) were aneuploid. In those women with an aneuploid loss, the majority 29/42 (69%) had a normal RPL workup. However, 13/42 (31%) had an evidence-based test result that would have been overlooked if the recommended evalu-ation was eliminated. Conversely, 23/65 (34.5%) of women had a euploid loss. Of these, 21/23 (91%) had an abnormal finding on the evidence based testing for RPL. Overall, 29/65 (44.6%) had an aneuploid loss and a normal RPL workup; 13/65 (20%) had an aneuploid loss and an abnormal RPL workup; 21/65 (32.3%) had a euploid loss and an abnormal RPL workup; and only 2/65 (3.1%) had a euploid loss and a normal workup. Thus only 2 out of 65 women who were evaluated in this study had a completely unexplained pregnancy loss. All other losses were explained by aneuploidy in the miscarriage tissue or an abnormal finding on an evidence-based test for RPL or both. In this study we

were able to explain 96.7% of pregnancy losses based on the testing algorithm. If evidence-based tests were not performed and only genetic testing of miscarriage tissue took place, 13/65 or 20% of proven causes for RPL would not have been identified

Limitations, reasons for caution: This is a single-center study on a small group of well-characterized women with RPL. The age of patients varied from 20 to 40 years. More aneuploid pregnancy losses would be expected in older women. A larger study is ongoing to confirm and expand these results.

Wider implications of the findings: Genetic evaluation on miscarriage tissue obtained at the time of the second and subsequent pregnancy losses should be recommended to all couples with two or more consecutive pregnancy losses. The combination of a genetic evaluation on miscarriage tissue with an evidence-based evaluation for RPL will explain over 90% of miscarriages.

Trial registration number: Not applicable.

POSTER VIEWING SESSION
MALE AND FEMALE FERTILITY PRESERVATION

P-499   The influence of letrozole on oocyte quality in breast cancer patients

N. Donadio, A. Rocha, R. Portela, V. Rodrigues Alves, T. Santos, F. Cavagna, A. Dzik, M. Cavagna

Hospital Perola Byington, Division of Human Reproduction, Sao Paulo, Brazil

Study question: Does letrozole affect oocyte quality in breast cancer patients undergoing fertility preservation?

Summary answer: Oocytes retrieved from breast cancer patients stimulated with letrozole exhibit higher degree of central granulation, increased number of refractile bodies and increased perivitelline space.

What is known already: Controlled ovarian stimulation using letrozole and gonadotropins for oocyte cryopreservation is a well-established procedure aiming at fertility preservation in breast cancer patients with reproductive wishes after chemotherapy treatment. Letrozole has been demonstrated to be effective as ovulation inductor and was shown to have comparable results to conventional ovarian stimulation protocols.

Study design, size, duration: Observational retrospective study conducted from January 2015 to December 2016. We analysed 651 oocytes obtained from 69 breast cancer patients undergoing ovarian stimulation for fertility preservation. In addition, 698 oocytes from 92 aged-matched healthy women undergoing ovarian stimulation for ICSI indicated for male factor infertility were studied for comparison.

Participants/materials, setting, methods: The present study was performed at a public tertiary hospital. In breast cancer patients, ovarian stimulation was carried out with letrozole, recombinant FSH and a GnRH antagonist. oocytes obtained were analysed for the presence of refractile bodies, ooplasm colour and regularity, degree of central granulation, zona pellucida thickness, size of perivitelline space, presence of vacuoles in the ooplasm and oocyte retraction. The results obtained were compared with the age matched control group.

Main results and the role of chance: In comparison with oocytes obtained from healthy women undergoing conventional ovarian stimulation, the oocytes retrieved from breast cancer patients stimulated with letrozole and recombinant FSH exhibited a higher degree of central granulation (p = 0.005), an increase in the number of refractile bodies (p = 0.003) and increased size of perivitelline space (p = 0.019). No statistically significant differences were found between the groups with respect to ooplasm colour and regularity, presence of vacuoles in the ooplasm, zona pellucida thickness and oocyte retraction.

Limitations, reasons for caution: It is not clear whether we can extrapolate results obtained in healthy women to breast cancer patients. Furthermore, some patients of the study group started ovarian stimulation in the luteal phase, which could be a confounding factor.

Wider implications of the findings: Even if there is evidence in medical literature suggesting that the use of letrozole throughout ovarian stimulation is an

efficient procedure, our findings alert to the possibility of a deleterious influence of letrozole on oocyte quality. Further studies are needed to clarify this fact.

Trial registration number: Not applicable.

P-500   Preservation of ovarian follicle by concomitant administration of GnRH agonist or GnRH antagonist during cyclophosphamide or paclitaxel chemotherapy in mice

H.S. Yang[1], M.W. Kim[2]

[1]*Dongguk Univarsity College of Medicine, OB & Gyn, Kyeongju, Korea- South*
[2]*Dongguk University College of Medicine, Anesthesiology, Kyeongju, Korea- South*

Study question: There was evaluated whether GnRH-induced ovarian function suppressing preserves primordial follicles in the administration of cyclophosphamide or paclitaxel.

Summary answer: GnRH analogues block destruction of primordial follicles caused by cyclophosphamide and paclitaxel in mouse ovaries.

What is known already: Although chemotherapy improves the survival rate of women in reproductive age who have malignant cancers, it has been reported that cytotoxic chemotherapeutic agents may induce premature ovarian failure and infertility among patients of reproductive age.

Study design, size, duration: The degree of destruction of primordial follicles was analyzed following the administration of cyclophosphamide or paclitaxel respectively in mouse ovaies. In addition, there was evaluated whether GnRH-induced ovarian function suppressing preserves primordial follicles in the administration of cyclophosphamide or paclitaxel.

Participants/materials, setting, methods: Saline or cyclophosphamide (50, 75 mg/kg), paclitaxel(12.5, 19 mg/kg)were intraperitoneally injected into seven-week old female ICR mice. GnRHa (Leuplin®) and GnRH antagonist (Cetrotide®) were injected into mice, and administered with 50 mg/kg and 75 mg/kg of cyclophosphamide following 9 days treatment with GnRH analogues. H&E staining and TUNEL assay was performed. Apoptotic index was defined as the proportion of stained nuclei to total of 400 granulosa cells that were counted.

Main results and the role of chance: Cyclophosphamide and paclitaxel cause destruction of primordial follicles in mouse ovaries. The number of primordial follicles decresed in the group of high dose compared to the group of low dose treated with cyclophosphamide or paclitaxel(13.3 ± 2.1 vs 16.0 ± 2.4, 11.5 ± 2.9 vs 8.4 ± 2.6). Treatment with GnRHa and GnRH antagonist significantly increased the number of primordial follicles at a low concentration of cytotoxic agents (p < 0.05), whereas the number of primoridal follicle increased only in GnRHa I antagonist treated group at a high concentration of cyclophosphamide or paclitaxel(p = 0.030, p = 0.043). Decreased apoptotic indices were shown in all types of GnRH analogues co-treated groups (p < 0.05). For the comparisons of GnRHa vs. GnRH antagonist GnRHa was relatively effective in their follicle preserving effects.

Limitations, reasons for caution: By assessing the number of primordial follicles in each experiment, we compared the protective effects of specific GnRH analogues, but we could not find the significant differences among each other. The comparisons of apoptotic index showed the significant differences among each type of GnRH's.

Wider implications of the findings: GnRH analogues block destruction of primordial follicles caused by cyclophosphamide and paclitaxel in mouse ovaries, suggesting that GnRH analogues may be applicable to increase fertility opportunity in malignant cancer patients of reproductive age planning future pregnancies.

Trial registration number: N-R

P-501   Letrozole supplementation during ovarian stimulation alters oocyte maturation rates in breast cancer candidates for fertility preservation

M. Grynberg[1], J. Calvo[2], J. Benard[2], C. Sifer[3], N. Sermondade[3], C. Sonigo[2]

[1]*Hôpital Jean Verdier, Reproductive Medicine & Fertility Preservation, Bondy, France*
[2]*Hôpital Jean Verdier- APHP, Reproductive Medicine & Fertility Preservation, Bondy, France*
[3]*Hôpital Jean Verdier- APHP, Reproductive Biology, Bondy, France*

Study question: To investigate whether controlled ovarian stimulation with letrozole supplementation (COSTLES) modifies ovarian response and follicle responsiveness to exogenous FSH in breast cancer (BC) patients?

Summary answer: Despite similar response to exogenous FSH, BC patients having undergone COSTLES show reduced oocyte maturation rates in comparison with those having received standard stimulation regimen.

What is known already: Oocyte and/or embryo vitrification after controlled ovarian stimulation (COS) represents the most established and efficient method of fertility preservation (FP) before cancer treatment. However, traditional COS regimens are associated with supraphysiologic serum estradiol and are therefore not recommended in estrogen-sensitive diseases such as BC. To protect the patients from the potential deleterious effects of elevated estrogen levels during ovarian stimulation for FP, protocols using aromatase inhibitors (letrozole) were developed. However, COSTLES outcomes and follicle responsiveness to exogenous FSH in comparison with conventional protocol have been poorly evaluated in BC patients candidates for FP.

Study design, size, duration: This is the first investigation comparing COSTLES and standard ovarian stimulation in BC patients. From July 2013 to December 2016, we prospectively studied 133 breast cancer patients, 25 to 40 years of age, candidates for FP using oocyte and/or embryo vitrification following COS. Of these, 68 patients underwent COSTLES while 65 had standard GnRH antagonist protocol.

Participants/materials, setting, methods: All women had 2 ovaries, no history of chemotherapy, BMI < 30 Kg/m^2 and a breast tumor that was surgically removed. Measurement of serum anti-Müllerian (AMH) levels and antral follicle count (AFC) were systematically performed before exogenous FSH administration (d0). Follicle responsiveness to FSH was assessed by the Follicular Output Rate (FORT) calculated from the ratio between the pre-ovulatory follicle count (PFC, 16-20 mm) on the day of oocyte triggering (dOT) and the d0 AFC.

Main results and the role of chance: Women in the COSTLES and control groups were comparable in terms of age 33.4 ± 4.7 vs. 33.8 ± 3.5 years, respectively), BMI (21.6 ± 3.1 vs. 22.6 ± 2.4 Kg/m^2) and ovarian reserve tests (AMH: 2.2 ± 1.8 vs. 2.7 ± 2.3 ng/mL; AFC: 18.5 ± 10.5 vs. 17.9 ± 10.7 follicles). After comparable starting doses and total amount of exogenous FSH (3046 ± 1332 vs. 2996 ± 1344IU, respectively), the FORT index did not differ significantly between groups (33.8 ± 24.6 vs. 37.2 ± 19.8%, respectively), leading to a similar number of oocyte recovered (12.3 ± 8.3 vs. 12.5 ± 8.7 oocytes, respectively). However, oocyte maturation rates were significantly lower in COSTLES compared to standard protocol (67.3 ± 19.7 vs. 76.3 ± 20.1%, p<0.02). As a result, the number of metaphase 2 oocyte vitrified was lower in patients having received letrozole supplementation (8.1 ± 2.6 vs. 9.6 ± 3.4 oocytes, p<0.05 respectively).

Limitations, reasons for caution: Notwithstanding the limited sample size, our findings provide new data on COSTLES in BC patients. Whether the present results will impact the overall success rates of the FP procedures after oocyte thawing is still unclear. A particular vigilance on this issue will be required.

Wider implications of the findings: At present, there is no evidence that standard COS promotes the proliferation of residual tumoral cells following breast surgery. If not, the confirmation of our results would lead reconsidering the real interest of COSTLES before adjuvant chemotherapy.

Trial registration number: Not applicable.

P-502　Six children born after 15 ovarian tissue transplantations: the French protocol for the development of ovarian tissue autograft in order to restore ovarian function (DATOR)

C. Amiot[1,2,3,4], J.B. Pretalli[4], S. Frontczak[1,3], P. Piver[5,6], C. Roux[1,2,3,4], &. DATOR group[7]

[1]Centre Hospitalier Régional Universitaire, Service de Biologie et Médecine de la Reproduction- Cryobiologie - CECOS, Besançon, France
[2]INSERM, UMR 1098, Besançon, France
[3]Université de Bourgogne - Franche-Comté, UFR SMP, Besançon, France
[4]Centre Hospitalier Régional Universitaire, CIC 1431, Besançon, France
[5]Centre Hospitalier Régional Universitaire, Service de Gynécologie et Obstétrique, Limoges, France
[6]INSERM, UMR 850, Limoges, France
[7]Centres Hospitaliers Universitaires, Besançon- Limoges- Toulouse- Rouen- Bordeaux- Clermont-Ferrand - Strasbourg- Clamart, Nantes- Marseille- Lille- Reims- Bondy- Grenoble- Nancy- Tenon- Poissy, France

Study question: To assess the efficiency of cryopreserved ovarian tissue autograft in terms of reproductive outcome in women who underwent gonadotoxic treatments.

Summary answer: Between December 2007 and September 2016, ovarian tissue transplantation was performed in 15 patients, and 5 women gave birth to 6 children.

What is known already: Ovarian cryopreservation is one of the available options for preserving fertility prior to potentially sterilizing treatments; it's even the only possible option in prepubertal girls or when there is an urgent need to start the treatment. The prospect of restoring fertility by retransplantation is becoming increasingly real: in France, the first live birth after orthotopic ovarian autograft, was obtained by Roux et al. in 2009; the exact number of live births is unknown but according to a recent update from Jensen et al. (2016), worldwide approximately 95 children have been born or will be born in the near future.

Study design, size, duration: This is a prospective multicentric cohort study of 15 women who had frozen-thawed ovarian tissue transplanted since 2007. None of the patients were lost to follow-up.

Participants/materials, setting, methods: Patients aged from 18 to 43 years, who have cryopreserved their ovarian tissue, cured from their initial disease, with child desire but premature ovarian failure, were included. A two-step orthotopic autotransplantation was performed, and a monthly follow-up was carried out during a period of one year. The data collected concerned the restoration of ovarian function and live births, the need for assisted reproductive techniques, the pregnancy follow-up and the perinatal outcome of the children.

Main results and the role of chance: Fifteen patients benefited from cryopreserved ovarian tissue autograft.

The indications for ovarian cortex autoconservation were Hodgkin's lymphoma (9 patients), non-Hodgkin's lymphoma (2), Ewing's sarcoma (1), systemic mastocytosis (1), sickle cell disease (1) and periarteritis nodosa (1).

The patient mean age (SD) at the time of grafting was 34 (5) years.

Seven patients succeeded in becoming pregnant. Five women delivered a child/children (6 children in total); this included one patient who gave birth to 2 children two years apart. A first trimester miscarriage occurred in one case. Two patients in 5 conceived with the assistance of in vitro fertilization.

Among the 5 patients who conceived, 3 had received chemotherapy before ovarian tissue cryopreservation, and the longest time of tissue harvesting was 8 years and 4 months.

All the babies born were healthy; one congenital diaphragmatic hernia was diagnosed and successfully cured. No relapse of the initial disease occurred.

Limitations, reasons for caution: Autograft of cryopreserved ovarian tissue must be performed with caution in women suffering from malignancies that may metastasize to the ovaries. Ischemic tissue damages occurring after retransplantation are currently another major problem. The full lifespan of grafts is still being evaluated.

Wider implications of the findings: In our series, the success rate was 33.3% with a majority of natural conceptions. These results constitute a good argument in favor of cryopreservation of ovarian tissue and its subsequent reuse by orthotopic autograft to restore ovarian function and fertility in women who experience ovarian failure due to gonadotoxic treatments.

Trial registration number: The study is registered in ClinicalTrials.gov under the number NCT02846064.

P-503　Residual ethylene glycol (eg) and dimethyl sulfoxide (dmso) concentration in human ovarian tissue during warming steps of vitrification method and slow freezing method

K. Kyono[1,2], Y. Nakamura[1], C. Sasaki[1], S. Shibasaki[1], R. Obata[2], N. Okuyama[2], Y. Ogura[2], N. Aono[1,2], T. Hashimoto[2]

[1]Kyono ART Clinic, Department of Obstetrics and Gynecology, Sendai, Japan
[2]Kyono ART Clinic Takanawa, Department of Obstetrics and Gynecology, Tokyo, Japan

Study question: Is there concern whether all the cryoprotectants, which may be toxic in the human body, can be washed out at the time of transplantation in vitrification and slow freezing methods?

Summary answer: Around 10 mg/g DMSO and 10 mg/g EG in vitrification method whereas 0 mg/g in slow freezing method remained in ovarian tissue after warming just before transplantation.

What is known already: There have been 60 births after transplantation of cryopreserved ovarian tissue (Donnnez J and Dolmans MM, 2015): 58 using the slow freezing method, and two using the vitrification method. In the warming protocols of vitrification method, the concentration of cryoprotectants is four times higher and warming time is four times shorter than in slow freezing. We have discussed time, cost, histology of follicles and stroma, viability test, and follicular development in both methods; however, we did not examine the residual amount of cryoprotectants in human ovarian tissue after warming just before transplantation and did not discuss about safety of patients.

Study design, size, duration: This study was approved by the ethics committee of our clinics. Four patients who cryopreserved by vitrification method had Gender Identity Disorder and one who cryopreserved by slow freezing method had uterine cancer. We measured the amount of cryoprotectants before warming (I), after TS (II), after DS (III), and after WS2 (IV) in the vitrification method, and before warming (I), after TS3 (II), and after WS2 (III) in the slow freezing method.

Participants/materials, setting, methods: Four ovarian tissue (10x10x1 mm) were cryopreserved by the vitrification method using 6.4 mol/l EG and DMSO (Kagawa et. al., 2009) and one ovarian tissue (8x4x1 mm) was frozen by the slow freezing method using 1.5 mol/l DMSO (Isachenko V., et al., 2012). The concentrations of DMSO and EG were analyzed by Shimadzu Techno-Research Inc., Kyoto, Japan. Concentrations in the ovary tissues were quantified using GCMS-QP2010Ultra (Shimadzu) with InertCap Pure-WAX column (0.25 mm×30 m, 0.50μm thickness; GL Science).

Main results and the role of chance: The maximum amount of DMSO and EG in vitrification method vs. slow freezing method was 130.0 ± 8.2 mg/g and 112.5 ± 15.0 mg/g vs. 70 mg/g and < 0.050 mg/g before warming, respectively. In the slow freezing method, most of the cryoprotectants were washed out and the amount reached zero after thawing. In the vitrification method, there was a 30 to 50% reduction in after each step in warming, however, never reaching undetectable limits. We found around 10 mg/g DMSO and 10 mg/g EG in ovarian tissue after warming just before transplantation. The amount of cryoprotectant of ovarian tissue when cryoprotectants were not used was <0.050 mg/g. We believe that cryoprtectants should be completely washed out when we transplant ovarian tissue into the human body after warming. Safety is crucial in clinical medicine.

Limitations, reasons for caution: We found most of the residual cryoprotectants in ovarian tissue were washed out and approached the detection limit in the case of slow freezing method. However, in the vitrification method by Cryotissue kit, around 10 mg/g DMSO and 10 mg/g EG remained in ovarian tissue after warming just before transplantation.

Wider implications of the findings: We do not know the risk of toxicity of the cryoprotectants in detail, however, we are afraid of toxicity for mother and child. So, we use slow freezing method in our human ovariantissue preservation enterprise 'HOPE" for fertility preservation.Further research for improvement of cryopreservation method are needed.

Trial registration number: None.

P-504 Comparison of the rate of intact embryos after thawing and clinical outcomes in the human embryo vitrification using Cryo-loop and Hemi-straw

Y.Y. Kim[1], K.H. Lee[2], I.H. Park[2], H.G. Sun[2], J.W. Kim[2], S.G. Kim[1], J.Y. Park[1], C.S. Yoo[1], H.J. Chi[1]

[1]Mamapapa&baby obstetrics and Gynecology, Infertility Lab., ULSAN, Korea- South
[2]Mamapapa&baby obstetrics and Gynecology, Infertility clinic, ULSAN, Korea- South

Study question: Can Cryo-loop increase the rate of intact embryos after thawing and clinical outcomes by complementing the weakness of Hemi-straw?

Summary answer: Cryo-loop with high thermal conductivity significantly improved the rate of intact embryos after thawing and clinical outcomes compared to Hemi-straw.

What is known already: To increase the success rate of vitrification technology, a carrier with high thermal conductivity that can minimize vitrification solution volumes is essential. With the Hemi-straw, it is difficult to adjust vitrification solution volumes, and thermal conductivity is affected by the external environment and the skill level of embryologists. On the other hand, Cryo-loop has ultra-rapid cooling rate (>20,000/min) even when it is directly exposed to LN2, and the volumes can be adjusted to the minimum volume (<1ul). In our study, we aimed to determine whether Cryo-loop can improve the survival rate and clinical outcomes of embryos compared to the Hemi-straw.

Study design, size, duration: The non-donor in the transfer cycles of vitrified-thawed embryos performed from January 2015 through January 2016 (n = 208) was included in this study. A total of 101 patients underwent the procedure using Cryo-loop while 107 patients underwent the procedure using Hemi-straw.

Participants/materials, setting, methods: After day 3 embryos transfer, the surplus embryos were randomly vitrified with Cryo-loop or Hemi-straw. After thawing, the embryos were cultured in vitro for 24 hours to select the embryos showing subsequent development for transfer. The survival rate of the vitrified-thawed embryos was assessed with the proportion of the embryos that has intact blastomeres without any damage. After transfer, the pregnancy and implantation rates were compared between the Cryo-loop and Hemi-straw groups.

Main results and the role of chance: Patient characteristics were similar in the two groups. In each group, age (Cryo-loop: 35.7 $\pm$ 3.9 vs. Hemi-straw: 35.5 $\pm$ 3.4 P = 0.38), endometrial thickness (9.6 $\pm$ 2.1 vs.9.7 $\pm$ 1.7 mm p = 0.40) and number of embryo transferred (1.9 $\pm$ 0.4 vs. 1.9 $\pm$ 0.3 p = 0.17) did not show significant differences. However, the number of thawed embryos (3.0 $\pm$ 1.3 vs. 5.1 $\pm$ 2.1 p < 0.001) revealed a significant difference. In the Cryo-loop group, the rate of intact embryos after thawing (77.9% vs. 62.4% p<0.001), the rate of subsequent development (60.5% vs. 31.6% p<0.036), pregnancy rate (56.4% vs. 42.1% p = 0.038) and ongoing pregnancy rate (50.0% vs. 36.4% p = 0.041) were all significantly higher than those in the Hemi-straw group.

Limitations, reasons for caution: Since our clinic mainly performs day 3 cryopreservation, they were only a small number of day 5 cryopreservation cases, and the results have not been compared.

Wider implications of the findings: The Cryo-loop group showed significantly higher rates of survival, pregnancy and subsequent development than that of Hemi-straw group. Cryo-loop can freeze a small number of embryos, and the survival rate of embryos is higher. Therefore, Cryo-loop can reduce unnecessary freezing of embryos and provide more chances of conception.

Trial registration number: none.

P-505 Freezing and thawing of ovarian cortical patches induces differential profiles of microRNAs in the holding media to non frozen patches

N. Islam, R. Alhamdan, U.P. Sunday, W.E. Maalouf, P. Marsters

University of Nottingham, Child Health- Obstetrics and Gynaecology, Nottingham, United Kingdom

Study question: Does the process of cryopreservation alter the expression profile of microRNAs in the holding media for ovarian cortical patches?

Summary answer: Cryopreservation alters the expression profile of microRNAs in the holding media for ovarian cortical patches

What is known already: Ovarian cortical patch (CP) cryopreservation has been suggested as a novel approach to preserving fertility in women suffering from cancers. However the effects of freezing-thawing are not fully understood and ways to assess the tissue's potential to perform normally after thawing, are an important research goal. MicroRNA expression pattern in holding media may be useful in determining variation in tissue suitability which may obviate the need for further analysis of tissue itself. Specific miRNAs have already been identified, distinguishing disease states from normal tissue. Recently miRNAs, have been recognised in human ovarian follicles thought to play fundamental roles in folliculogenesis.

Study design, size, duration: CPs were collected from ovine ovaries. Some (n = 20) were fixed and stained, some (n = 20) were cultured and some

(n = 20) were freeze-thawed, cultured in rotatory cell culture system (RCCS) for 5 days and then fixed. Each day, holding media from RCCS were collected for MiR-24, 193b and 320a determination and compared between non-frozen and frozen cultured groups. Follicles were counted on fixed patches and compared between three groups (fresh, non-frozen, cultured and frozen-thawed, cultured).

Participants/materials, setting, methods: After collection, some CPs were fixed in 4% paraformaldehyde (PFA) and stained with haematoxylin and eosin (H&E). Some were cultured and some were freeze-thawed, cultured in RCCS for 5 days followed by fixing and staining. Each day, 6mls of holding media were collected and replaced by fresh medium. MicroRNAs were determined in holding media using QIAGEN kits and were evaluated using real time polymerase chain reaction (PCR). Follicles were counted in all fixed, stained patches.

Main results and the role of chance: MiR-24 was upregulated on day 1, decreased until day 3, then remain almost constant until day 5 for both frozen and non-frozen cultured patches. MiR-193b decreased till day 3, then increased from day 4 till day 5 for non-frozen cultured patches. In frozen-thawed, cultured patches, MiR-193b was detected on day 1 only. MiR-320 A decreased from Day 1 till day 3, increased sharply on day 4, again decreased on day 5 in non-frozen cultured patches. In frozen-thawed, cultured patches, it constantly decreased until Day 5. Significant difference was noted between two groups for MiR-24, 193b and 320 A (P < 0.05). Total number of follicles counted in fresh, non-frozen cultured and frozen-thawed, cultured patches were 884 (primordial 68%, transitory 20.39%, primary 6%,secondary 2.9% antral 20.17%), 779 (primordial 48%, transitory 33.78%, primary 6%,secondary 7.13% antral 4.77%)and 526 (primordial 37%, transitory 37.32%, primary 13%,secondary 7.8% antral 5%) respectively. Significant differences were noted in case of primordial, transitory, secondary and antral follicles (P > 0.05) for non-frozen cultured patches and in case of primordial follicles (P > 0.05) for frozen-thawed, cultured patches when compared with fresh patches.

Limitations, reasons for caution: This study has been limited to comparing the effects of treatment over time due to difficulties of normalising against the differences in size of patches and variability of follicle numbers and stages of development. Use of ovine ovaries resulting in species-specific differences, causing inability to directly compare to humans.

Wider implications of the findings: Down-regulated MiR-193b together with up-regulated MiR-24 could have a synergistic role in cell apoptosis /damage. Thus, there appears to be an interesting interplay between these miRNAs and cell injury/damage which could further explored as novel markers of cell damage following cryopreservation.

Trial registration number: N/A.

P-506　SLUSH VS LIQUID NITROGEN VITRIFICATION OF HUMAN OVARIAN TISSUE PRESERVES GENE EXPRESSION AND IMPROVES POST WARMING IN VITRO CULTURE

R. Talevi[1], V. Barbato[2], T. Capriglione[2], M.M. Pallotta[2], S. Braun[2], S. Sudhakaran[2], A. Merolla[2], R. Ferraro[3], M. Di Nardo[2], G. Catapano[4], R. Gualtieri[2]

[1]Università degli studi di Napoli Federico II, Dipartimento di Biologia, Napoli, Italy
[2]University of Naples Federico II, Biology, Naples, Italy
[3]Genesis Day Surgery, IVF unit, Caserta, Italy
[4]University of Calabria, Environmental- Territory and Chemical Engineering, Rende CS, Italy

Study question: Does slush (SN) vs liquid nitrogen (LN) vitrification unalter stress/toxicity gene expression, and improve follicle health and progression during human ovarian tissue in vitro culture?

Summary answer: Data demonstrated a substantially lower up-regulation of stress-toxicity genes and better follicle survival, quality, and progression after SN compared to LN vitrification (LNV, SNV).

What is known already: Although vitrification emerged as an optimal method for oocyte cryopreservation, it was only recently applied to ovarian tissue and two live births have been reported. We previously demonstrated that histology, ultrastructure, and viability of human ovarian follicles and stromal cells were better preserved after SNV compared to LNV. However, damage to the follicle developmental potential by toxicity of cryoprotectants and the stress of

vitrification/warming procedure could affect gene expression and recovery of ovarian function during reimplantation or long term in vitro culture.

Study design, size, duration: Human ovarian cortical strips 5x2×1 mm were vitrified/warmed (V/W) in SN or LN as previously reported. Fresh, SNV and LNV strips 1×1×0.5 mm per patient (n = 6) were cultured in oxygen-permeable dishes 1-9 days (D1, D9). Single-strand cDNA of fresh, and V/W tissues, were processed for analysis of 84 genes involved in stress and toxicity pathways and results were validated through qRT-PCR. Follicle quality, progression and viability were assessed through histology and live/dead assay under confocal microscopy.

Participants/materials, setting, methods: Ovarian biopsies, from six consenting patients (aged 20-39) were dissected using a tissue chopper, for V/W and culture in alpha-MEM plus supplements. Samples were fixed for histology or labelled with live-dead and Hoechst 33342 for confocal analysis or processed for analysis of gene expression. mRNAs, extracted through NucleoSpin RNA kit, were retro-transcribed by RT[2] First Strand kit, and analysed by Stress and Toxicity RT[2] Profiler[TM] PCR Array The data of interest were validated by qRT-PCR

Main results and the role of chance: The impact of vitrification on ovarian tissue function was evaluated through comparison of gene expression in V/W samples cultured 24 h vs fresh tissue. RT-PCR arrays demonstrated a general up-regulation of genes (up-regulated more than 3-fold: threshold-value) in LN (DDB2, RAD51, IL6, IL1A, IFNG, TNF, CD40LG, CFTR, CRP, AQP2, CA9, MMP9, EPO) and not in SN samples. qRT-PCR confirmed high upregulation of 13 genes after LNV and showed a markedly slighter up-regulation of only 5 genes after SNV (LN vs SN upregulation: CD40LG, 29.1 vs 4.3; CFTR, 13.1 vs 4.11; CA9, 35.6 vs 6.5; AQP2, 9.7 vs 3.6; EPO, 23 vs 7.8).

Overall 3840 follicles were analysed. In fresh tissues (D9 vs D0), follicle quality (grade 1: 41 vs 54.2%) and viability (70.8 vs 92.7%) decreased and progression to the secondary stage increased (26.8 vs 2.6%). In V/W tissues (D9), SNV better preserved follicle quality (SNV vs LNV: 55 vs 16.4, P < 0.001) and viability (SNV vs LNV: 55.5 vs 34.8, P < 0.01). Interestingly, vitrification improved follicle progression compared to fresh samples at D9 (SNV and LNV vs Fresh: 51.4, 42.6 vs 26.8, P < 0.001)

Limitations, reasons for caution: Data has been collected on a limited number of patients and should be clinically validated.

Wider implications of the findings: Data confirmed that SNV better preserves ovarian follicles. SNV could be applied for fertility preservation of oncological patients. The culture system adopted promotes the progression of a high number of follicles to the secondary stage and could be used for in vitro folliculogenesis.

Trial registration number: none.

P-507　Ovarian stimulation and oocyte cryopreservation in women with Turner syndrome: Is it safe and effective?

Abstract withdrawn by the author

P-508　Selection of the most suitable ovarian cortex fragments for autotransplantation by non-invasive imaging using Reflectance Confocal Microscopy (RCM)

R. Peek[1], M. Schleedoorn[2], M. Peppelman[3], I. Beerendonk[2], W. Nelen[2], D. Braat[2], K. Fleischer[2]

[1]Radboud University Medical Center, Obstetrics and Gynecology, Nijmegen, The Netherlands
[2]Radboud university medical centre, Obstetrics and Gynecology, Nijmegen, The Netherlands
[3]Radboud university medical centre, Dermatology, Nijmegen, The Netherlands

Study question: Is it possible to use RCM for the selection of ovarian cortex fragments that contain the highest number of primordial follicles?

Summary answer: Using RCM we were able to visualize follicles in living ovarian cortex fragments of bovine and human origin without compromising the vitality of the tissue.

What is known already: There is an extreme variation in the distribution of primordial follicles across the surface of the ovary. As a result individual ovarian cortex fragments cryopreserved for fertility preservation purposes may vary

considerably with respect to the number of primordial follicles they contain. Assessing the number of follicles in a cortex fragment by standard histology renders the fragment unsuitable for subsequent auto transplantation purposes. This emphasizes the need for a non-invasive technique to select the most promising ovarian cortex fragments before auto transplantation.

Study design, size, duration: Cortex fragments of bovine and human ovaries were prepared using standard techniques. The tissue fragments were cryopreserved using DMSO. After thawing the tissue fragments were subjected to imaging using RCM. To validate the RCM imaging technique, the RCM images were compared to the haematoxylin eosin stained sections of the same tissue fragments. The possible adverse effects of RCM were determined by assessing the vitality of the tissue and follicles before and after RCM imaging.

Participants/materials, setting, methods: Experiments were performed with ovarian tissue from patients that had donated their ovarian tissue after informed consent. Bovine tissue was derived from an abattoir. For *en face* RCM imaging a VivaScope 1500 was used. The vitality of the ovarian tissue was determined by a glucose-uptake assay and the survival of ovarian follicles was assessed by staining with Neutral Red.

Main results and the role of chance: The results show that with the use of RCM it is possible to image follicles in living ovarian tissue to a depth of maximal 200 μM. By comparing RCM images and haematoxylin eosin stained sections of the same ovarian tissue fragment we show that RCM is capable of visualizing all stages of follicle development, including primordial follicles. However, follicle visibility was generally better in bovine tissue compared to human tissue. Analysis of tissue and follicle viability before and after RCM indicate that the imaging procedure has no detectable negative effects on the ovarian cortex fragments.

Limitations, reasons for caution: The maximum depth at which follicles could be visualized with RCM is 200 μM, leaving some follicles undetected. RCM had no effect on viability of the tissue. However, it is unknown whether RCM has negative effects on follicular development after auto transplantation.

Wider implications of the findings: Our results indicate that it is possible to assess the number of follicles by RCM in cortex fragments intended for fertility preservation. By using this non-invasive imaging technique, fragments can be identified with the highest number of follicles. These fragments are the best candidates for reproductive success after autotransplantation.

Trial registration number: not applicable.

P-509 Effect of human recombinant vascular endothelial growth factor (VEGF-165) on testicular tissue xenografts from prepubertal boys

E. Ntemou[1], P. Kadam[1], D. Van Saen[1], E. Vicini[2], E. Goossens[1]

[1]Vrije Universiteit Brussel, Biology of the Testis- Research Laboratory for Reproduction- Genetics and Regenerative Medicine, Brussels, Belgium
[2]Sapienza University of Rome, Department of Anatomical- Histological-Forensic and Orthopaedic Sciences- Section of Histology and Medical Embryology, Rome, Italy

Study question: Does human recombinant VEGF-165 have an impact on the integrity of seminiferous tubules, germ cell survival and differentiation in human prepubertal testicular tissue xenografts?

Summary answer: VEGF improves the integrity of seminiferous tubules through an enhanced vasculature after long-term xenografting. It has no significant effect on germ cell survival and differentiation.

What is known already: Testicular tissue autotransplantation has been proposed as potential fertility preservation strategy for prepubertal boys undergoing gonadotoxic treatments. Before any clinical application, further optimization of the technique is required. So far, xenografting of human prepubertal tissue resulted in limited spermatogonial survival and lack of complete spermatogenesis. Hypoxia, as a result of insufficient blood supply, could be the aetiology for the spermatogonial loss observed in testicular grafts. VEGF stimulates the formation of new blood vessels and promotes neovascularisation. Studies in other species indicate a role for VEGF on the improvement of germ cell survival and proliferation in immature testicular grafts.

Study design, size, duration: Frozen-thawed testicular tissue fragments from three prepubertal boys were cultured for five days with VEGF-165, followed by xenografting into the testicular parenchyma of 48 Swiss Nu/Nu mice.

Retrieval of the grafts and evaluations were performed after a short (four-month) and a longer (nine-month) time-period.

Participants/materials, setting, methods: Histological assessment and immunohistochemical analysis for specific markers, including melanoma-associated antigen 4 and von Willebrand factor, was performed and seminiferous tubule integrity, number of spermatogonia and vascularisation were assessed. Most advance germ cell type present was identified morphologically and meiotic activity was determined using the meiotic marker BOLL. Maturation and functionality of the niche were evaluated by the expression of anti-Müllerian hormone (AMH), androgen receptor and inhibin a, by Sertoli cells.

Main results and the role of chance: Treatment of testicular tissue fragments from prepubertal boys prior to xenografting with 100 ng/ml of human recombinant VEGF-165 resulted in higher percentage of intact tubules ($P = 0.006$) after nine months. The result was accompanied by a positive long-term effect of VEGF on the percentage of vascular surface ($P = 0.020$) and vessel density ($P = 0.001$) of the grafts. The number of spermatogonia did not differ significantly between the treated and untreated group. While four months after grafting, spermatogonia were the most advanced germ cells in the grafts, pachytene spermatocytes were present after nine months irrespective the treatment. Sertoli cells were still expressing AMH after nine months, but a lower level of expression was noticed in tubules containing spermatogonia and spermatocytes indicating higher maturation level.

Limitations, reasons for caution: Scarcity of human immature testicular tissue for research purposes does not permit a more comprehensive study. Additionally, the different age of the donors and the treatment that two of them received before the biopsy may have influenced the outcome of grafting experiments.

Wider implications of the findings: The present study demonstrates for the first time the long-term effectiveness of VEGF on the tubular integrity of human prepubertal testicular tissue xenografts by enhancing the vascularisation of the grafts. Although further studies are required, VEGF may be considered as a potential candidate for the improvement of testicular tissue grafting.

Trial registration number: N/A.

P-510 Comparison of in vitro fertilization (IVF) and in vitro maturation (IVM) in a fertility preservation (FP) program for cancer patients

H. Creux[1], P. Monnier[2], W.Y. Son[2], W. Buckett[2]

[1]Bordeaux University Hospital, Reproductive centre, Bordeaux, France
[2]McGill University Health Centre, Reproductive centre, Montreal, Canada

Study question: To compare IVF and IVM results in terms of collection's parameters and, where applicable, pregnancy rates in a fertility preservation program.

Summary answer: IVF seems to be more efficient than IVM regarding collection's parameters, but no statistical difference appears in pregnancy rates despite tendency in favor of IVF.

What is known already: FP offers to young women with cancer in case of gonadotoxic therapy the potential to become pregnant with their own oocytes. Currently, cryopreservation of oocytes and/or embryos after controlled ovarian hyper stimulation (conventional IVF) represents the established method. Nevertheless, IVM is an interesting alternative method when chemotherapy can not be delayed or when ovarian stimulation is contraindicated. Although a few studies have reported clinical outcomes between IVF and IVM cycles in polycystic ovary syndrome (PCOS) patients, to date there is no report on the clinical outcomes comparing the two procedures in women with cancer undergoing FP.

Study design, size, duration: Retrospective cohort study from January 2003 to April 2016 in a University teaching hospital; 394 cycles of IVF and IVM treatments in 353 women with cancer.

Participants/materials, setting, methods: Three hundred fifty three women underwent 394 FP cycles: 187 IVF cycles (47.5%) and 207 IVM cycles (52.5%). Oocyte cryopreservation was performed in 236 cycles (60%), embryo cryopreservation in 147 cycles (37.2%), and oocyte + embryo cryopreservation in 11 cycles (2.8%). Out of the 353 patients, 23 patients returned (6.5%) to use

oocytes or embryos cryopreserved in 34 cycles (19 after IVF cycles and 14 after IVM cycles).

Main results and the role of chance: The IVF group consisted of 187 cycles for 171 patients and the IVM group of 205 cycles for 182 patients. The two groups were comparable in terms of FSH level and antral follicle count, but a significant difference appeared in median [25th-75th] in age (29 [25-33] in IVF group versus 30 [27-35] in IVM group). Between IVF and IVM treatments, significant differences were found regarding the number of oocytes collected (12 [8-18] and 7 [5-12.5]; respectively), the total number of metaphase II oocytes (10 [7-15] and 5 [2-8]; respectively) and the number of oocytes cryopreserved (10 [6-15]; 5 [2-8]; respectively). Similarly, where applicable, the number of embryos cryopreserved (5 [3-7] and 3 [2-5]; respectively) was significantly different, whereas no significant difference was found in fertilization rates (79 [67-88] and 75 [58-100]; respectively). Concerning the comparison of the obstetrical outcomes, implantation rates were significantly lower in the IVM group (21.9 and 3.7, p = 0.04) but no statistical difference appeared in clinical pregnancy (36.8 and 14.3, p = 0.15) and live birth rates (31.6 and 7.1, p = 0.09). When comparing the type of material thawed (oocyte or embryo) according to the procedure (IVF or IVM), no difference was found in obstetric outcome.

Limitations, reasons for caution: The main limitation is the small size of IVF and IVM populations concerning obstetric data. Other limitations include the low use of frozen material, the large number of lost to follow-up and the study's retrospective and single centre nature leading to possible treatment and referral bias.

Wider implications of the findings: Oocyte and embryo cryopreservation after both IVF and IVM procedures are viable options in a FP program in women with cancer, even if IVF seems to be more efficient than IVM. However, more data, a longer follow-up and better interdisciplinary communication are needed.

Trial registration number: 16-089 MUHC

P-511   Experience in women with cancer: obstetrical outcomes after twelve years of oocytes and embryos cryopreservation following in vitro fertilization and in vitro maturation treatments

P. Monnier[1], W. Buckett[2], W.Y. Son[2], H. Creux[3]

[1]McGill University Health Centre, Reproductive centre, Montréal, Canada
[2]McGill University Health Centre, Reproductive centre, Montreal, Canada
[3]Bordeaux University Hospital, Reproductive medicine, Bordeaux, France

Study question: To evaluate the use and the obstetric outcomes of oocyte and embryo cryopreservation following in vitro fertilization (IVF) and in vitro maturation (IVM) treatments.

Summary answer: Oocyte and embryo cryopreservation after both IVF and IVM treatments are effective strategies in women with cancer.

What is known already: Fertility preservation (FP) offers to young women with cancer the potential to become pregnant with their own oocytes. FP has being used routinely for relatively few years. Consequently, little is known about the proportion of patients who come back to use the frozen material and about the performance of these techniques in terms of pregnancy rates. To date, besides some case-reports, only few cohort studies were published after conventional IVF. All agree on a low use of frozen material and satisfactory pregnancy rates. Two live births have been reported after FP with IVM.

Study design, size, duration: Retrospective cohort study from January 2003 to April 2016 in a University teaching hospital; 394 cycles of IVF or IVM treatments were analyzed in 353 women with cancer.

Participants/materials, setting, methods: Three hundred fifty three women underwent 394 FP cycles: 187 IVF cycles (47.5%) and 207 IVM cycles (52.5%). Oocyte cryopreservation was performed in 236 cycles (60%), embryo cryopreservation in 147 cycles (37.2%), and oocyte + embryo cryopreservation in 11 cycles (2.8%).

Main results and the role of chance: Out of the 353 patients, 23 patients came back (6.5%) to use oocytes or embryos cryopreserved in 34 cycles. Only 21 patients underwent an embryo transfer. The median lapse of returning to attempt pregnancy was 4.6 [3.1-6.1] years. On the 34 embryo transfers, the cumulative clinical pregnancy rate per patient was 47.6% (10/21) and the live birth rate per patient was 38.1% (8/21). The miscarriage rate was 20% (2/10). Among the 8 deliveries, 5 followed embryo cryopreservation after IVF

treatment, 1 followed oocyte cryopreservation after IVF treatment, 1 followed embryo cryopreservation after IVM treatment and 1 followed embryo cryopreservation after IVF+IVM treatment. Nine babies were born: one twin pregnancy who delivered prematurely and 7 term healthy babies after singleton pregnancy. The twin pregnancy rate was 12.5%.

We report the third live birth after IVM procedure in patients with cancer, and the first one after IVM and oocyte cryopreservation in cancer.

Limitations, reasons for caution: Due to the recent nature of FP techniques and the poor use of the frozen material, obstetric data are still limited. The performance of these techniques needs further follow-up. Other limitations include number of lost to follow-up and the retrospective and single centre nature responsible for treatments bias.

Wider implications of the findings: Our study shows that in case of FP for cancer, 6.5% women come back and pregnancies occur. Oocyte and embryo cryopreservation after both IVF and IVM procedure are viable options in a FP program in cancer women. However, more data, a longer follow-up combined with interdisciplinary communication are needed.

Trial registration number: 16-089 MUHC

P-512   Anti-Müllerian hormone, antral follicle count and number of oocytes retrieved in cancer patients compared to healthy women: A multiple linear regression model

R. Pesce[1], M. Uzal[2], J. Nagy[2], N. Nicolaevsky[3], V. Cerisola[2], S. Gogorza[4], G. Perman[5]

[1]Hospital Italiano de Buenos Aires, Reproductive Medicine, C.A.B.A., Argentina
[2]Hospital Italiano de Buenos Aires, Reproductive Medicine, C.A.B.A- Buenos Aires, Argentina
[3]Hospital Italiano de Buenos Aires, Reproductive Medicine, C.A.B.A - Buenos Aires, Argentina
[4]Hospital Italiano de Buenos Aires, Gynecology Department, C.A:B:A Buenos Aires, Argentina
[5]Hospital Italiano de Buenos Aires, Public Health Department, C.A.B.A- Buenos Aires, Argentina

Study question: Are markers of ovarian reserve associated with the number of oocytes retrieved after controlled ovarian hyperstimulation in women with cancer?

Summary answer: Ovarian reserve markers are positively correlated with the total number of oocytes and MII retrieved in cancer patients. There were no differences with healthy women.

What is known already: The number of oocytes retrieved and cryopreserved for fertility preservation is associated with clinical pregnancy and life birth rates.

Medical literature describe a suboptimal ovarian response after controlled ovarian hyperstimulation (COH) in cancer patients.

Ovarian reserve markers (age, FSH, and specially Anti-Müllerian hormone -AMH- and antral follicle count -AFC) are associated with ovarian response and correlated with de number of oocytes retrieved in ART patients.

The correlation of these ovarian markers and the number of oocyte retrieval in cancer patients is unknown.

Study design, size, duration: Retrospective cohort study from 01/01/2014 to 31/12/2016.

A total number of 107 women were included. There were no losses to follow-up.

The number of total oocytes and MII retrieved in the cohort of healthy women and cancer patients were analyzed using a multiple linear regression model, accounting for disease condition, age, stimulation and trigger protocols, basal FSH, AMH and AFC.

Participants/materials, setting, methods: We included 55 women planning to undergo oocyte criopreservation for social reasons and 52 cancer patients at high risk of sterilizing treatments in a university hospital.

Exclusion criteria: Previous ovarian surgery; previous radio/chemotherapy treatment; diagnosis of infertility, endometriosis or polycistic ovaries; life threatening condition.

Ovarian stimulation was performed using gonadotophins (FSHr–HMG) within a GnRH antagonist protocol. In hormone dependent tumors, we added Letrozole. The final trigger was done with either HCG or agonist GnRH.

Main results and the role of chance: Baseline characteristics in the 52 cancer patients (CP) before oncological treatment versus the 55 healthy women that cryopreserved oocytes for social reasons (SR) were: mean age: 30.4 years (SD 6.0) vs 37.7 (2.0), p <0.001; FSH: 5.3 mUI/ml (3.1) vs 6.7 (4.6) p 0.116; AMH: 23.5 pmol/l (18.7) vs 14.9 pmol/l (17.5), p <0.037; AFC: 16.2 (11.7) vs 12.0 (7.8), p<0,030. All patients were stimulated with a gonadotrophin/antagonist protocol, except for 44% of CP that also received Letrozole. In CP, 44% were triggered with HCG vs 89% in SR group (p<0.001).

Mean number of oocytes retrieved was (CP vs SR): 12.7 (SD 11.4) vs 10.0 (7.2), p 0.143. The mean number of M-II oocytes was: 9.8 (9.1) vs 7.7 (6.1), p 0.176.

Results of multiple linear regression models for total number of oocytes retrieved and for MII oocytes were similar. We report here beta coefficients (SE) and p values for each of the covariates included in the MII model: AFC 0.325 (0.089) p 0.001; AMH 0.152 (0.055) p 0.008; FSH -0.414 (0.176) p 0.022; age 0.238 (0.167) 0.159; cancer patients 3.384 (2.134) p 0.118; Letrozole -9.612 (2.399) p <0.001; HCG -5.575 (1.870) p 0.004.

Limitations, reasons for caution: It is a retrospective cohort with a relatively small number of patients due to the characteristic of included participants. Nevertheless, this study is important for the design of prospective studies that could confirm results.

We excluded patients with life threatening conditions, so results do not apply to these patients.

Wider implications of the findings: Oocyte reserve markers were significantly associated with oocytes retrieved in cancer patients (specially AFC and AMH). There were no differences in the adjusted number of MII retrieved in cancer patients compared to healthy women.

Interestingly, the use of Letrozole and final trigger with HCG significantly affected oocyte retrieval.

Trial registration number: -.

P-513   Comparison of residual dimethyl sulfoxide (DMSO) and ethylene glycol (EG) concentration in bovine ovarian tissue during warming steps between slow freezing and vitrification methods

R. Obata[1], Y. Nakamura[2], N. Okuyama[1], C. Sasaki[2], Y. Ogura[1], N. Aono[1,2], S. Hamano[3], T. Hashimoto[1], K. Kyono[1,2]

[1]Kyono ART Clinic Takanawa, Obstetrics and Gynecology, Tokyo, Japan
[2]Kyono ART Clinic, Obstetrics and Gynecology, Sendai, Japan
[3]Livestock Improvement Association of Japan Inc., Animal Bio Technology Center, Tokyo, Japan

Study question: How much cryoprotectant is removed from cryopreservation ovarian tissue during warming steps of slow freezing and vitrification?

Summary answer: Slow freezing had more cryoprotectant removed from cryopreserved ovarian tissue than vitrification, and was considered safer for transplantation.

What is known already: There are slow freezing and vitrification methods for ovarian cryopreservation. In vitrification methods, the concentration of cryoprotectants is higher and warming time is shorter than in slow freezing. Therefore, with the warming protocols in vitrification, there is concern that all the cryoprotectants, which may be toxic in the human body, should be washed out at the time of transplantation. Our aim is to measure residual DMSO and EG concentration in ovarian tissue during warming steps following the slow freezing and vitrification method (Cryotissue and Ova Cryo Kit TypeM).

Study design, size, duration: In this study, we used five bovine ovaries with an average age of 24.2 months. We measured the residual DMSO and EG concentrations ① before warming, ② during warming, ③ after warming in slow freezing, Cryotissue and Ova Cryo Kit Type M.

Participants/materials, setting, methods: We analyzed the residual DMSO and EG concentration in slow freezing (EG is not included), Cryotissue and Ova Cryo Kit Type M (DMSO is not included) in the bovine ovarian tissue by gas chromatograph mass spectrometer (GC-MS) (Shimadzu Techno-Research, Inc.).

Main results and the role of chance: Residual DMSO concentration: slow freezing ①52.2 ± 7.6 mg/g ②1.2 ± 0.5 mg/g ③0.6 ± 0.9 mg/g, Cryotissue ①84.8 ± 12.0 mg/g, ②34.6 ± 4.7 mg/g ③10.3 ± 2.7 mg/g. Residual EG concentration Cryotissue: ①83.2 ± 11.2 mg/g ②34.2 ± 6.3 mg/g ③10.7 ± 2.7 mg/g, Ova Cryo Kit Type M ①124.0 ± 18.2 mg/g ②82.2 ± 14.7 mg/g ③33.4 ± 9.7 mg/g.

Slow freezing was significantly lower in residual DMSO in all steps compared to Cryotissue(①52.2 ± 7.6 mg/g vs 84.8 ± 12.0 mg/g ②1.2 ± 0.5 mg/g vs 34.6 ± 4.7 mg/g ③0.6 ± 0.9 mg/g vs 10.3 ± 2.7 mg/g; p<0.01). Ova Cryo Kit TypeM was significantly higher in residual EG in all steps compared to Cryotissue.(①124.0 ± 18.2 mg/g vs 83.2 ± 11.2 mg/g ②82.2 ± 14.7 mg/g vs 34.2 ± 6.3 mg/g ③33.4 ± 9.7 mg/g vs 10.7 ± 2.7 mg/g; p<0.01).

Limitations, reasons for caution: We found residual cryoprotectants when warming cryopreserved ovarian tissues. However, we do not know the degree of toxicity of the residual cryoprotectants we found in this study.

Wider implications of the findings: Of the three methods compared in this study, slow freezing had more cryoprotectants removed from the ovarian tissue. However, it was suggested that further studies such as the effect of residual amount of cryoprotectants on ovarian tissue should be made.

Trial registration number: None.

P-514   Evaluation of a novel rotary cell culture system for primordial activation of ovarian cortical patches

T.Y.T. Nguyen[1], B.K. Campbell[2], I. Sfontouris[2]

[1]School of Medicine- Vietnam National University Hochiminh city, Obstetrics and Gynecology, Ho Chi Minh, Vietnam
[2]The University of Nottingham, Division of Child Health- Obstetrics and Gynaecology, Nottingham, United Kingdom

Study question: Can a rotary cell culture system provide an effective culture environment for primordial and pre-antral follicles within the cortical patches to survive and develop?

Summary answer: The rotary cell culture system offered high survival rates for follicle within patches and sustained high levels of primordial and transitory population.

What is known already: Optimizing the culture system for the maturation of primordial follicles within ovarian tissue has been considered a promising strategy of fertility preservation for cancer survivors at pre-pubertal and reproductive ages. Rotary cell culture systems have been achieved success in culturing stem cells and cancer cells, which indicates prospective systems for the survival and growth of follicles enclosing in ovarian tissue.

Study design, size, duration: The experiment was replicated three times. A total of 8 ovine cortical strips were retrieved from the same ovary, in which 2 patches served as fresh controls, while others were cultured 7 days in rotary cell culture system.

Participants/materials, setting, methods: Cortical patches were allocated in four groups including fresh control group and three culture groups: i) base media, ii) base media plus 5 µM PS48, and iii) base media plus 5 µM PS48 and 25 µg/mL 740Y-P. Following 7 day culture period, cortical strips underwent histological analysis to examine follicle count. Immunocytochemical analysis were also performed to assess the expression of Ki67, AMH, GDF-9 and BMP-15.

Main results and the role of chance: Significant increases in the survival rate of follicles and in the density of transitory follicles were found in ovarian patches cultured with PS48 plus 740Y-P as compared to those other groups (p > 0.05). The expressions of proliferating marker (Ki67) and recruitment marker (AMH) of granulosa cells were also higher in this treatment group as opposed to control group. There were no statistically significant difference in the number of follicles expressed positive staining for GDF-9 and BMP-15 between control and cultured groups.

Limitations, reasons for caution: Small sample size and conducting on ovine model were main limitations of this study, leading to restrict the ability to compare and generalize results to humans.

Wider implications of the findings: The present findings provided evidences for *in vitro* follicular growth that may generate a large supply of mature oocytes for future assisted reproduction of infertile women with premature ovarian failure. This culture system, if it works effectively, could replace

conventional stimulation protocols for IVF, which revolutionizes the treatment of infertility.

Trial registration number: Non.

P-515 A clinical protocol for isolating human preantral follicles using a good manufacturing practices grade collagenase NB6

E. Mouloungui[1,2,3], T. Zver[1,2], A. Berdin[4], C. Roux[1,2,3,5], C. Amiot[1,2,3,5]

[1]Centre Hospitalier Régional Universitaire, Biologie et Médecine de la Reproduction-Cryobiologie - CECOS, Besançon, France
[2]INSERM, UMR 1098, Besançon, France
[3]Université de Bourgogne - Franche-Comté, UFR de Sciences Médicales et Pharmaceutiques, Besançon, France
[4]Centre Hospitalier Régional Universitaire, Service de Gynécologie - Obstétrique, Besançon, France
[5]Centre Hospitalier Régional Universitaire, CIC 1431, Besançon, France

Study question: Is collagenase NB6 good manufacturing practices (GMP) grade able to isolate viable human preantral follicles for ovarian reconstructions after gonadotoxic treatments in case of cancer?

Summary answer: A high yield of viable preantral follicles, free from leukemic cells, has been isolated with collagenase NB6 GMP grade.

What is known already: Ovarian tissue transplantation is associated with a risk of reintroducing malignant cells (i.e. in case of leukemia).

This risk could be eliminated by grafting isolated follicles.

Isolation techniques following GMP are available but evaluating the contamination of the follicular suspension by leukemic cells is a crucial step.

Study design, size, duration: The efficiency of collagenase NB6 GMP grade was evaluated, in comparison with collagenase type IA, in terms of yield, morphology, viability and short-term in vitro culture of isolated follicles in a prospective experimental design. The presence of leukemic cells in follicular suspensions was determined using fluorescence microscopy and multicolor flow cytometry (MFC).

Participants/materials, setting, methods: Frozen-thawed ovarian biopsies obtained from 16 consenting women (25-37 years old) undergoing laparoscopic ovarian drilling for polycystic ovary syndrome were used. Enzymatic digestion of ovarian biopsies (n = 26) was performed using either collagenase type IA or collagenase NB6 (200UI/mL). Leukemic cells from blood or bone marrow of acute leukemia patients (n = 8) were added to initial follicular suspensions. Follicles were manually isolated. The 24 follicular suspensions thus obtained were analyzed by MFC before and after 3 washes.

Main results and the role of chance: Collagenase NB6 GMP grade has allowed the isolation of a high number of human preantral follicles (n = 1365), in comparison to collagenase type IA (n = 828) for 50 mg of tissue (p = 0.37). The survival rate of isolated follicles was 93.4% (n = 254/272) using collagenase NB6 GMP grade versus 92.6% (n = 276/298) using collagenase type IA, and their mean diameter was 31.66 ± 6.79 µm with collagenase NB6 (n = 317 follicles) versus 36.77 ± 7.69 µm with collagenase type IA (n = 273 follicles).

Even after 3 days of in vitro culture in a fibrin scaffold (50 mg/ml of fibrinogen and 10 UI/ml of thrombin), most of the isolated follicles were still alive (90.7% of viable follicles on 339 analyzed). The level of minimal residual disease was negative in 23 suspensions analyzed out of 24 after 3 washes. In 23 out of 24 follicular suspensions analyzed, less than 20 events corresponding to leukemic cells were present even if 10^6 of leukemic cells were previously added (in the 24th suspensions, 22 events were detected). Washes had no significant impact on follicles viability (96.1% on 323 follicles analyzed).

Limitations, reasons for caution: The efficiency of collagenase NB6 and the level of minimal residual disease have not been performed on cryopreserved ovarian biopsies from leukemia patients. We still have to work on the best way of reusing isolated preantral follicles, either by direct injection or seeding in a hydrogel for ovarian reconstruction.

Wider implications of the findings: Collagenase NB6 is a GMP clinical-grade enzyme which, in combination with the present isolation technique, will allow the use of isolated human preantral follicles for future clinical applications.

Trial registration number: Not applicable.

P-516 Effects of vitrification on functional morophology and viability of ovarian tissue

I.V. Malinova[1], V.V. Yuzhakov[2], M.V. Kiseleva[1], E.V. Komarova[3], L.N. Bandurko[2], L.E. Sevankaeva[2], A.D. Kaprin[3]

[1]Division of Innovative Medical Technology, A. Tsyb Medical Radiological Research Centre, branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation
[2]Laboratory of Radiologic Pathomorphology, A. Tsyb Medical Radiological Research Centre, branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation
[3]National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Obninsk, Russian Federation.

Study question: What is the effect of vitrification on viability and functional morphology of ovarian tissue (OT) after thawing and in vitro cultivation in the incubation medium?

Summary answer: The comprehensive histological and morphofunctional analysis revealed a good preservation of follicles in vitrified OT and a quick restoration of the follicle viability after thawing

What is known already: Preservation of the reproductive function in women having cancer diseases in anamnesis is of current importance and remains one of challenging areas of oncology. It was found that chemotherapy and radiotherapy can severely affect the ovarian follicle reserve and lead to fertility loss and premature menopause. Cryopreservation of ovarian tissue before cancer therapy followed by autotransplantation of thawed ovarian tissue was found to be effective to preserve the ovarian reserve in female patients with malignant neoplasms. Currently, the main method of cryopreservation of ovarian tissue is slow freezing. Vitrification method is experimental

Study design, size, duration: The study was performed on cortical ovarian fragments obtained from 17 patients ranging from 20 to 47 years old during diagnostic laparoscopy after getting their written informed consent. Research material comprising native tissue as a control was obtained immediately, at 30 min, 1, 2, 4, 8 and 22 h after thawing and fixed then during 24 h in Bouin's acid liquid and 10% neutral buffered formalin with subsequently standard histological processing and embedding in Histomix.

Participants/materials, setting, methods: General histology of OT, follicle count, verification of their stage and morphology were studied on haematoxylin and eosin. For investigating functional morphology and viability of follicles, fibroblasts and endothelium of OT immunohistochemical studies were performed by using antibodies to proliferating cell nuclear antigen (PCNA), a marker of endothelial cells of capillaries (CD34), a protein of intermediate filaments of cells of mesenchymal origin – vimentin, a cyclin (Ki-67), and a marker of vascular endothelium (CD31).

Main results and the role of chance: Investigations of vitrified tissue after thawing and cultivation for up to 4 hours in the incubation medium indicated that cortical architectonics remained essentially unchanged. The results of a comparative analysis demonstrated that the percentage of morphologically normal follicles decreased to 64%. However, the relative pool of structurally unchanged primordial follicles exceeded 90%.

The study of functional morphology of native OT revealed an intense positive reaction of nuclei of fibroblasts, vascular endothelium and granulosa cells in secondary follicles with antibodies to proliferation markers: PCNA and Ki-67. Expression of CD31 and CD34 was observed in endothelium of vessels and capillaries. Vimentin was found in fibroblasts of the ovarian stroma and endothelium. Up to 4 hours of cultivation of thawing tissue proliferative activity of endothelial and stromal cells differed little from that in native control. CD31 and CD34 immunostaining provided evidence of a good preservation of tissue vascularization. Expression vimentin showed high viability of fibroblasts and vascular endothelium. A cultivation more 8 h resulted in irreversible morphological changes in OT. Death of most cortical cells with pyknotic nuclei occurred. Detachment of endothelial cells was observed. Almost all follicles were classified as degenerated. Vimentin expression was dramatically reduced in the cytoplasm of stromal cells.

Limitations, reasons for caution: None

Wider implications of the findings: The comprehensive histological and morphofunctional analysis revealed a good preservation of follicles in vitrified OT and a quick restoration of the viability of its cellular components after

thawing. These data clearly demonstrate that preserving fertility by vitrification OT is a successful and safe clinical option for cancer patients.

Trial registration number: NA.

P-517 The majority of women who bank their oocytes conceives naturally

E. Balkenende, T. Dahhan, F. Van der Veen, S. Repping, M. Goddijn

Academic Medical Center, Center for Reproductive Medicine, Amsterdam, The Netherlands

Study question: How many women conceive after oocyte banking for fertility preservation and with which mode of conception?

Summary answer: After a mean follow-up of 34 months, 31% of women who banked their oocytes reported a pregnancy of which 79% were achieved through natural conception.

What is known already: Women at risk for premature ovarian insufficiency (POI) due to a medical condition or gonadotoxic treatment and women who face age-related fertility decline may increase their chances of future childbearing by banking oocytes. Follow-up of reproductive outcomes of women who had fertility preservation through oocyte banking is limited.

Study design, size, duration: We performed a prospective follow-up study of a cohort of 327 women who banked oocytes for all fertility preservation indications between July 2009 and August 2015 in a University Hospital.

Participants/materials, setting, methods: We retrieved medical data, i.e. clinical indications for fertility preservation and outcomes of ovarian stimulation from medical files. We asked all women to fill out an additional questionnaire on demographics, diagnosis, gonadotoxic treatment or ovarian surgery received, menstrual cycle and contraception, status of their relationship, pregnancy attempts and intended use of banked oocytes at time of follow-up.

Main results and the role of chance: A total of 234 of the 326 women (72%) responded and 219 of the 326 women (67%) consented to participate and returned the questionnaire. Mean time to follow-up of respondents was 34.1 months. Indications for fertility preservation were age-related fertility decline 96/219 (44%), gonadotoxic therapy 86/219 (39%), genetic predisposition or POI 19/219 (9%), ovarian surgery 11/219 (5%) and chemotherapy in the past 7/219 (3%). Almost half of the women responding (44%) were trying or had tried to become pregnant after oocyte banking. Sixty-seven of the 219 women (31%) reported 84 pregnancies after oocyte banking. Sixty-six of these pregnancies (79%) were naturally conceived. The remaining 18 pregnancies (21%) were conceived with ART of which six pregnancies (7%) were conceived with banked oocytes. The 84 pregnancies resulted in 39 (46%) live births, 18 (21%) ongoing pregnancies at time of follow-up, 23 (27%) miscarriages, three (4%) induced abortions and one (1%) termination of pregnancy.

Limitations, reasons for caution: Large-scale follow-up studies, including natural conception rates, from other centres are needed to conclude if our results are generalizable to other settings and populations. A longer follow-up of these women is needed.

Wider implications of the findings: Our results suggest that most women wish to become pregnant in the next few years after cryopreservation of oocytes. Considering that nearly 80% of the women in our study conceived naturally, the chances of natural conception should be discussed during the counseling of oocyte banking.

Trial registration number: Not applicable.

P-518 Gender and educational disparities underlying elective egg freezing: results from the first major qualitative study of oocyte cryopreservation in the United States and Israel

M. Inhorn[1], D. Birenbaum-Carmeli[2], L. Westphal[3], J. Doyle[4], N. Gleicher[5], M. Dirnfeld[6], D. Seidman[7], A. Kahane[8], D. Meirow[9], P. Patrizio[10]

Study question: Why are educated professional women in the United States and Israel increasingly turning to oocyte cryopreservation as a way to preserve their fertility?

Summary answer: Highly educated professional women undergo oocyte cryopreservation for lack of partners to marry, not for educational or career ambitions, as media reports suggest.

What is known already: In the United States and Israel, so-called "social" (elective) egg freezing is increasingly being adopted by professional women as a means of fertility preservation. Extensive media coverage suggests that educational and career ambitions are the main determinants of professional women's fertility postponement, especially as they "lean in" to their careers. But is this true? To date, no major qualitative study of women's egg freezing experiences has been undertaken to assess whether women are using egg freezing to postpone their fertility in pursuit of their professions, or whether other factors in women's lives are more important in egg freezing decisions.

Study design, size, duration: This study is the first binational, qualitative comparison of women's egg freezing decisions and experiences. It was undertaken from June 2014 to August 2016 in the United States and Israel, and involved in-depth interviews conducted by senior medical anthropologists in both countries. An identical interview guide was used in both countries, but translated into Hebrew in Israel.

Participants/materials, setting, methods: In-depth, ethnographic interviews were conducted with 150 women who had undertaken elective egg freezing in the United States (114) and Israel (36). Women were recruited from a total of 8 IVF clinics (4 in each country; 3 academic, 5 private), located in several major American and Israeli cities (e.g., New York, San Francisco, Washington, DC, Haifa, and Tel Aviv).

Main results and the role of chance: In both the US and Israel, women freezing their eggs for elective reasons were highly educated professionals (>80% with graduate degrees) in their late 30 s/early 40 s. Most of these women (>90%) were not intentionally "postponing" their fertility because of education or careers. Rather, they were desperately "preserving" their fertility beyond the natural end of their reproductive lives, because they were single without partners to marry. In most cases, these women were unable to find educated men willing to commit to family life—the reflection of a growing, but little-discussed gender trend, with women increasingly outnumbering male college graduates in both countries. Because of this dearth of educated men to marry, women resorted to egg freezing as a technological concession to the "man deficit." However, egg freezing was not seen by most women as a "revolutionary" technology—one that creates new gender norms or family formations (e.g., single motherhood "by choice"). Rather, almost all of the women in this study who employed egg freezing were heterosexual and wanted to become married mothers. Women lamented the "missing men" in their lives, viewing egg freezing as a way to buy time while on the continuing (online) search for a committed partner.

Limitations, reasons for caution: Participation in this study was voluntary, sampling was not random, and the response rate was unquantifiable. Still, the study sample was heterogeneous in terms of ethnicity and religion, particularly in the US, where egg freezing does not appear to be limited to professional white women, as media reports would suggest.

Wider implications of the findings: Increasing numbers of highly educated professional women around the world are single. They may turn to egg freezing to preserve their fertility in the absence of male partners to marry. Egg freezing is thus a technological "fix" to a growing problem of "leftover" educated women and "missing" educated men.

Trial registration number: Not applicable.

P-519 Comparison of ovarian reserve and ovarian response to hyperstimulation in women undergoing oocyte vitrification according to the type of malignancy

T. Lefebvre[1,2], M. Jegu[1], S. Mirallié[1], F. Leperlier[1], P. Barrière[1,2,3], T. Fréour[1,2,3]

[1]Hospital University of Nantes, Department of Reproductive Medicine, Nantes, France
[2]University of Nantes, Faculty of Medicine, Nantes, France
[3]INSERM UMR 1064, INSERM, Nantes, France

Study question: Is there a difference between women suffering from breast cancer, lymphoma or other solid cancers in terms of ovarian reserve and ovarian response to hyperstimulation?

Summary answer: The type of cancer did not significantly affect ovarian reserve and ovarian response to controlled ovarian hyperstimulation (COH) in women undergoing oocyte vitrification cycle.

What is known already: Cancer treatment, and particularly chemotherapy, is generally associated with ovarian reserve alteration failure. However, whether cancer itself affects ovarian function in women remains controversial in the literature. While some studies reported lower ovarian reserve and/or ovarian response to COH in women with cancer compared with controls, this was not definitively confirmed, as some studies suffered from some limitations such as limited population or heterogeneous stimulation protocols. Moreover, no study evaluated the potential impact of the type of cancer on ovarian response to COH.

Study design, size, duration: This retrospective cohort study was conducted in 105 women aged 18-40 years referred to our Department of Reproductive Medicine for fertility preservation (oocyte vitrification) between 2013 and 2016. All of them had just been diagnosed with cancer with gonadotoxic treatment scheduled.

Participants/materials, setting, methods: Women were grouped according to cancer type: 58 women with breast cancer, 25 with lymphoma and 22 women with other solid cancer. Each woman underwent ovarian reserve evaluation with AMH and Antral Follicle Count. Ovarian stimulation was performed with an antagonist protocol with random-start to reduce risk of delay in treatment of their malignancy. Oocyte retrieval was performed 36 hours after final oocyte maturation by hCG or GnRH agonist administration. All mature oocytes were vitrified.

Main results and the role of chance: Baseline AFC and AMH were not different between women with breast cancer, lymphoma or other cancer (AFC: $23{,}6 \pm 13{,}6$ vs $17{,}7 \pm 7$ vs $22{,}9 \pm 13{,}4$ respectively, $p = 0{,}35$; AMH: $4{,}9 \pm 3{,}4$ vs $4{,}1 \pm 3{,}2$ vs $4{,}7 \pm 3{,}1$ respectively, $p = 0{,}8$). The number of mature oocyte (MII) was also comparable between the three groups (11 ± 6 vs $10{,}6 \pm 5{,}4$ vs $10{,}2 \pm 5{,}6$, $p = 0{,}96$). As well as oocyte maturity rate defined as MII/oocyte retrieved ($0{,}7 \pm 0{,}2$ vs $0{,}7 \pm 0{,}2$ vs $0{,}7 \pm 0{,}2$, $p = 0{,}96$). The number of FSH units per mature oocyte was comparable in the three groups ($274{,}9 \pm 254{,}9$ vs $272{,}2 \pm 210{,}5$ vs $285{,}0 \pm 228{,}5$, $p = 0{,}9$). We also reported comparable number of MII ($10{,}5 \pm 6{,}6$ vs $11 \pm 4{,}3$, $p = 0{,}7$) and oocyte maturity rate ($0{,}7 \pm 0{,}2$ vs $0{,}8 \pm 0{,}2$, $p = 0{,}4$) between conventional start and random-start ovarian stimulation protocols.

Limitations, reasons for caution: As most women in this study still do not have permission for pregnancy, we could not analyze subsequent embryo development and pregnancy rates after ART cycle with frozen-thawed oocytes

Wider implications of the findings: As the type of cancer does not appear to impact significantly ovarian reserve and ovarian response to COH, our results do not support the relevance of integrating this parameter when establishing ovarian stimulation protocol for oocyte vitrification cycle in women with cancer.

P-520 Novel technology identifies significant rise in sublethal single strand DNA damage in oocytes following chemotherapy exposure which correlates with increased fetal malformations and pregnancy failure

Abstract withdrawn by the author

P-521 Prediction of ovarian function recovery after ovarian protection with gonadotropin-releasing hormone agonist during chemotherapy in young breast cancer patients

D.Y. Lee, C.W. Mok, D. Choi

Samsung Medical Center, Obstetrics and Gynecology, Seoul, Korea- South

Study question: What factors are predictive for recovery of ovarian function after ovarian protection by gonadotropin-releasing hormone (GnRH) agonist during chemotherapy in young breast cancer patients?

Summary answer: Age, tamoxifen use, pretreatment follicle-stimulating hormone (FSH) and anti-Müllerian hormone (AMH) are useful markers for predicting recovery of ovarian function after GnRH agonist.

What is known already: Growing evidence indicates that treatment with GnRH agonist during chemotherapy is a reliable option for fertility preservation in breast cancer. However, no study to date has investigated the predictive factors for recovery of ovarian function after GnRH agonist treatment for ovarian protection.

Study design, size, duration: Prospective cohort study. Between January 2013 and May 2015, 105 young breast cancer patients were included.

Participants/materials, setting, methods: Participants were diagnosed with breast cancer and received GnRH agonist during cyclophosphamide-based chemotherapy for ovarian protection. Serum levels of AMH, FSH, and estradiol were measured before and after completion of chemotherapy. Associations between pretreatment hormones, clinical factors, and recovery of ovarian function (resumption of menstruation or AMH $\geq$ 1 ng/mL) were evaluated at 12 months and long-term follow-up after completion of chemotherapy.

Main results and the role of chance: Mean age was 32 years (range: 23-42 years). Ninety-four patients (89.5%) experienced resumption of menstruation at 12 months, and proportion of patients with AMH $\geq$ 1 ng/mL at 12 months was 71.4%. After long-term follow-up (mean: 737 days, N = 69), 98.6% patients resumed menstruation, and 78.2% had AMH $\geq$ 1 ng/mL. In multivariate analyses, tamoxifen use (P = 0.035) and pretreatment FSH (P = 0.032) were predictive of resumption of menstruation, and age (P = 0.019), tamoxifen use (P = 0.022), pretreatment FSH (P < 0.001) and AMH (P = 0.040) were predictors for AMH $\geq$ 1 ng/mL at 12 months. In addition, pretreatment AMH was a predictor for AMH $\geq$ 1 ng/mL after long-term follow-up. Receiver-operator characteristics curve analyses gave area under curve of 0.805 for resumption of menstruation and 0.903 for serum AMH concentration $\geq$ 1 ng/mL at 12 months, when age, tamoxifen use, pretreatment FSH and AMH were combined.

Limitations, reasons for caution: Although mean follow-up duration was 2 years, long-term data are needed to confirm our results. Larger study is needed to establish meaningful cut-off values for prediction. Pregnancies and live births are not addressed although ovarian function is not a perfect surrogate marker for fertility.

Wider implications of the findings: This finding can support decision making about options for fertility preservation. Based on the prediction for successful recovery of ovarian function by GnRH agonist for ovarian protection, whether cryopreservation is necessary or not could be determined.

Trial registration number: None.

P-522 Optimizing in vitro activation and maturation of primordial follicles in transgender and oncological patients

C. De Roo[1], S. Lierman[1], G. T'Sjoen[2], R. Cornelissen[3], S. Weyers[1], K. Tilleman[1], P. De Sutter[1]

[1]Ghent university hospital, Division of Reproductive Medicine- Department of Gynaecology, Ghent, Belgium
[2]Ghent university hospital, Department of Endocrinology and Centre for Sexology and Gender, Ghent, Belgium
[3]Ghent university, Department of Basic Medical Science- Faculty of Medicine and Health Science, Ghent, Belgium

Study question: What are the targets of optimization to make the in vitro culture of ovarian cortex clinically useful in a fertility preservation setting?

Summary answer: The focus for optimization of in vitro maturation of follicles starting from ovarian tissue is the limited preantral follicle development following primordial follicle activation.

What is known already: The ability to activate and grow human primordial follicles in vitro has been shown possible using a two–step culture system. In this model, ovarian cortical strips were cultured for 6 days, from which secondary follicles could be isolated for further growth in a 4 day culture period (E. Telfer, 2008). Although very promising, the current model is not efficient enough for implementation in a clinical setting. The proposed system still requires improvement, for which the targets need to be defined. Since the follicle pool is heterogeneous, we want to know what follicle classes are not supported in their development.

Study design, size, duration: Cryopreserved ovarian tissue of 3 trans men (23.3+/-1.53 years) and 3 oncological patients (29.29+/-4.34) was thawed and prepared for in vitro culture. Trans men underwent a hysterectomy with oophorectomy after a period of intramuscular testosterone undecanoate (55.3 +/-1.15 weeks). Oncological indications for fertility preservation comprised acute lymphoblastic lymphoma, breast cancer and acute myeloid leukaemia. Cortical strips were cultured for 6 days and 2 pieces per patient were collected for follicle count (hematoxylin/eosin staining) every second day.

Participants/materials, setting, methods: Ovarian cortex was pulled mechanically and cut into small interconnecting strips. The strips were cultured individually in 24-well plates containing supplemented McCoy's 5a medium with bicarbonate for 6 days at 37°C, humidified air and 5% CO_2. The strips were fixed in 10% paraformaldehyde and embedded in paraffin for hematoxylin and eosin staining. Follicles were classified by 2 independent observer according to the Gougeon (1986) classification. Statistical analysis (Independent samples Kruskal-Wallis test) was performed (SPSS v23).

Main results and the role of chance: The mean count of the 2 observers showed a total of 2099.00 follicles, with a mean of 699.67+/-242.06 follicles per patient (N = 3) and a mean of 524.75+/-166.04 follicles per culture day (N = 4) in trans men and a total of 481.5 follicles, with a mean of 160.50 +/-92.00 follicles per patient (N = 3) and a mean of 120.38+/-56.47 follicles per culture day (N = 4) in oncological patients. The total number of follicles did not differ significantly over the different culture days (P = 0.230 and P = 0.682 in transgender and oncological patients respectively). In trans men, a progressive decrease in number of primordial follicles was seen with a significant difference between culture day 0 and 6, (P = 0.01). A statistically significant decrease in primordial follicles was not noted in the oncological group. In both groups a shift towards the more mature stages was visible, however no significant change per follicle class was seen. Unfortunately, in both groups, limited secondary follicle and no antral follicle growth was observed.

Limitations, reasons for caution: The heterogeneous cortical follicle distribution undoubtedly affects the interpretation of the results described in this study. Also, we were not able to include a culture of ovarian tissue obtained during caesarean section to compare our data with the published results of E. Telfer et al. (2008) in a similar setting.

Wider implications of the findings: This culture model supports the primordial follicle activation in cortex. However, the preantral follicle development is limited and a focus for further culture optimization. Also, follicle activation and the support of follicle growth might require subtle adaptations in tissue preparation or culture amongst different patient groups.

Trial registration number: UZ Ghent reference: 2012/780 – Belgian registration number: B670201215468.

P-523   Optimizing cryopreservation methods for immature mouse testicular cell suspensions

J. Onofre Meza[1], K. Faes[2], P. Kadam[2], E. Vicini[3], A. Van Pelt[4]

[1]Vrije Universiteit Brussel- Biology of the testis, Reproduction Geneticts and Regenerative Medecine, Brussels, Belgium
[2]Vrije Universiteit Brussel- Biology of the testis, Reproduction- Genetics and Regenerative Medicine, Brussels, Belgium
[3]University of Rome "La Sapienza", Histology and Medical Embryology, Rome, Italy
[4]University of Amsterdam- Academic Medical Center, Reproductive Medicine-Women's and Children's Hospital, Amsterdam, The Netherlands

Study question: In view of a future clinical application of spermatogonial stem cell (SSC) autotransplantation in patients with threatened fertility, what is the best method to cryopreserve testicular cell suspensions (TCS)?

Summary answer: Cryopreservation in DMEM supplemented with 1.5 M dimethyl-sulfoxide, 10% fetal calf serum and 60 µM of z-VAD(Oe)-FMK in vials with a freezing rate of 1°C/min was optimal.

What is known already: Slow freezing is the endorsed method to cryopreserve SSCs. In the calf, SSC cryopreservation has resulted in a post-thaw viability of 68 ± 3% permitting a repopulation efficiency of 43% after SSC transplantation (Izadyar et al.,2002). However, the best post-thaw viability of human TCSs obtained so far is only 55 ± 24% (Sà et al.,2012). The development of an optimal procedure is urgently needed in perspective of a future clinical application.

Study design, size, duration: In a first quick screening, we have studied the effect of (1) different freezing rates, (2) the addition of sugars, (3) different vessels and (4) the addition of an apoptotic inhibitor on the efficiency of TCS cryopreservation. After thawing, TCSs were transplanted to recipient mice for further functional assay. After selection of the optimal cryopreservation procedure, a second experiment was initiated to compare transplantation efficiency between the selected freezing protocol and fresh TCSs.

Participants/materials, setting, methods: Donor prepubertal SV129xC57BL green fluorescent protein-positive (GFP+) mice testes were digested to obtain TCSs, which were frozen under different conditions. The percentage of recovered viable cells was assessed immediately after digestion (fresh), cryopreservation and thawing. Thawed cells were transplanted to adult busulfan-treated recipient mouse testes to evaluate SSC functionality. The number of testis presenting donor-derived spermatogenesis and the number of donor-derived colonies per testis were recorded.

Main results and the role of chance: Multiple and single rate controlled slow freezing procedures did not differ significantly in terms of recovered viable cells (41 ± 37% and 38 ± 25%), thus we opted for the best time- and cost-efficient procedure. Adding a non-permeating cryoprotectant (sucrose) did not result in a higher recovery of viable cells (38 ± 20%). Cells frozen in vials recovered better than those frozen in straws (50 ± 18% vs 35 ± 13%; P = 0.046). The inclusion of a broad spectrum anti-apoptotic factor (z-VAD(Oe)-FMK) significantly increased the recovery of viable cells after thawing (64 ± 12% vs 48 ± 12%; P = 0.034). After thawing, samples from each condition were transplanted to recipient mice to assay for stem cell activity of frozen/thawed cells. Testes transplanted with cells frozen with the optimal protocol presented donor-derived spermatogenesis in 75% (3/4) of the transplanted testes. When comparing the optimal cryopreservation procedure with fresh TCSs, donor-derived spermatogenesis was completed in 75% (3/4) of the transplanted testis with a lower number of donor-derived SSC-colonies per testis (18 ± 3 versus 46 ± 23; P = 0.0334). No differences were found in terms of colony length.

Limitations, reasons for caution: Since human testicular tissue is scarce, the present protocol was first developed in the mouse model. As the paramount perspective of this study is the translation of this protocol to human testicular cell suspensions, supplementary research is required to develop xenofree cryopreservation media.

Wider implications of the findings: The development of an easy, reproducible and cost-effective cryopreservation method is a pivotal step in the future clinical application of SSC autotransplantation in view of fertility restoration in patients for whom sperm freezing is not an option (e.g prepubertal boys undergoing gonadotoxic treatments).

Trial registration number: not applicable.

P-524   Fertility preservation in women with malignancies: the accuracy of AFC collected randomly during the menstrual cycle in predicting the number of mature oocytes retrieved

F. Filippi[1], M. Reschini[1], A. Paffoni[1], F. Martinelli[2], A. Busnelli[1], E. Somigliana[1]

[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Infertility Unit, Milan, Italy
[2]IRCCS Istituto Nazionale dei Tumori- Milano, U.O. Ginecologia Oncologica, Milan, Italy

Study question: Is Antral Follicle Count collected at any time during the menstrual cycle (random AFC) reliable in predicting the number of collected mature oocytes?

Summary answer: Random AFC is as reliable as serum AMH in predicting ovarian responsiveness to treatment.

What is known already: In young women with cancer who are scheduled for chemotherapy, there is the need to provide prompt counseling on future fertility issues including a reliable estimate of the possible benefits of fertility preservation techniques. Unfortunately, hormonal assessments such as serum FSH or AMH take time to be available and FSH needs to be taken in a particular menstrual phase. AFC is conversely immediately available but its use is claimed to be reliable only if collected in the early follicular phase (day 3-5 of the cycle).

Study design, size, duration: Retrospective case series of young women with malignancies undergoing ovarian hyperstimulation aimed at oocytes cryopreservation between July 2014 to December 2016. Random AFC and serum AMH was systematically recorded prior to initiate the therapy. All women received a standardized "random start" regimen of ovarian hyperstimulation.

Participants/materials, setting, methods: Seventy-two women were ultimately included. The total number of retrieved mature oocytes was the primary outcome. A good response was defined as ≥ 10 retrieved mature oocytes. The predictive capacity of AFC was evaluated using receiver operating characteristic (ROC) curves.

Main results and the role of chance: Indication to oocytes cryopreservation was breast cancer in 42 women (58%), lymphoma in 20 (28%) and other malignancies in the remaining 10 (14%). The mean ± SD age and AFC of the selected women was 31.4 ± 5.6 years and 18.7 ± 10.7, respectively. The median (interquartile range) serum AMH was 3.2 (1.3 - 4.2) ng/ml. Thirty-four women (47%) were in the follicular phase, 32 (45%) in the luteal phase and the remaining six (8%) were assuming oral contraceptives. Three cycles were cancelled for poor response. The mean ± SD number of mature oocytes retrieved in the remaining 69 women was 11.2 ± 7.7. Thirty-five women collected ≥10 oocytes (49% of the whole cohort).

The c-statistics for the prediction of ≥10 mature oocytes using AFC and serum AMH were similar. Specifically, the area under the curve (AUC) was 0.76 (95%CI: 0.66-0.87; p<0.001) and 0.82 (95%CI: 0.72-0.92; p<0.001), respectively. Similarly, when considering the subgroup of women who were not assuming oral contraceptives and who were recruited after day 5 of the cycle (proper random start, n = 49), the AUC resulted 0.77 (95%CI: 0.64-0.89; p = 0.001) and 0.83 (95%CI: 0.72-0.95; p<0.001), respectively.

Limitations, reasons for caution: Even if the accuracy of serum AMH and AFC resulted similar, larger series are required to rule out mild but potentially clinically relevant differences.

Wider implications of the findings: Random AFC should be systematically performed prior to counsel women with malignancies. It is a simple assessment and can be obtained rapidly. Moreover, one may even question whether random AFC may become a standard also in women without malignancies who need ovarian reserve assessment.

Trial registration number: not applicable.

P-525 Induction of spermatogenesis by grafting neonatal mouse testicular tissue into epididymal fat of castrated adult mouse

H. Eyni Seen[1], Z. Mazaheri[2], M. Movahedin[2], H. Sadri-Ardekani[3]

[1]Tarbiat Modares University, Anatomical Science, Tehran, Iran
[2]Tarbiat Modares University, Anatomical Sciences, Tehran, Iran
[3]Wake Forest School of Medicine, Wake Forest Institute for Regenerative Medicine, Winston-Salem- NC, U.S.A.

Study question: Is the epididymal fat an appropriate site for spermatogenesis induction of stored prepubertal testis tissue?

Summary answer: Post-meiotic markers expression on transcriptional and protein in grafted neonatal testis proofed successful spermatogenesis induction 8 weeks after implantation to castrated adult mouse epididymal fat.

What is known already: Chemo- and radiation treatments used for childhood cancer can cause irreversible infertility in many of cancer survivors. Testicular grafting of stored tissue prior to cancer treatment has the potential to become a method to preserve fertility in this people. However,

spermatogenic arrest at the pachytene spermatocyte stage is the main remaining challenge that failed this process. It has been known that epididymal fat is necessary for spermatogenesis, therefore in this study; spermatogenesis development was evaluated after grafting of fresh and frozen-thawed neonatal mouse testicular tissue fragments to epididymal fat region of bilateraly castrated adult mouse.

Study design, size, duration: Six neonatal (3-5 days old) male mice as the donors and six adult (6-8 weeks old) male mice as the recipients were used. After bilateral castration of recipient's mice, four pieces of fresh or frozen-thawed neonatal testis tissue fragments (approximately 1 mm³ each) were grafted into recipient epididymal fat. Eight weeks after implantation, grafted testicular tissue were evaluated.

Participants/materials, setting, methods: After scarifying of recipients mice and collecting of grafted testicular tissues, hematoxylin and eosin (H&E) staining was used to evaluate the morphology of seminiferous tubules and level of spermatogenesis. Real time PCR (PLZF, TEKT1 and TNP1) and immunohistochemistry staining (PLZF, SYCP3 and Acrosin Binding Protien) were used to assess the germ cell development in grafted neonatal mouse testis tissue. TUNEL assay was used for detecting DNA fragmentation and defining the apoptosis level of grafted tissue.

Main results and the role of chance: Vascular anastomoses were seen at the graft site. At the time of grafting, spermatogonial cells were the only germ cells present in the seminiferous tubules. However eight weeks after implantation a gradient of different types of germ cells from spermatogonia up to the elongated spermatid were seen. The meiotic (TEKT1) and post-meiotic (TNP1) genes were upregulated in both fresh and frozen grafted groups. Presence of SYCP3 and Acrosin Binding Protien positive cells also confirmed the meiosis and post meiotic progression in grafted seminiferous tubules. Expression of PLZF as an undifferentiated spermatogonial cell marker stayed stable post grafting. TUNEL assay showed no significant differences between control and experimental groups.

Limitations, reasons for caution: The functionality of induced elongated spermatids in grafted tissues needs to be investigated by Intra Cytoplasmic Sperm Injection (ICSI).

Wider implications of the findings: The previous studies showed the spermatogenesis arrest in meiosis process. Due to the appropriate hormonal and temperature conditions of epididymal fat, it seems immature testicular tissue grafting to epididymal fat may be a powerful site to support the spermatogenesis and may pave way for fertility preservation in prepubertal cancer patients.

Trial registration number: Not applicable.

P-526 Relationship between primordial follicle density, ovarian reserve tests and the number of oocytes matured in vitro in candidates for fertility preservation

N. Sermondade[1], C. Sonigo[2], C. Sifer[1], M. Ziol[3], F. Eustache[1], M. Grynberg[2]

[1]Jean Verdier Hospital, Department of Reproductive Biology, BONDY, France
[2]Jean Verdier Hospital, Department of Reproductive Medicine, BONDY, France
[3]Jean Verdier Hospital, Department of Histo-Pathology, BONDY, France

Study question: Is primordial follicle density within ovarian cortex associated with markers of the follicular status and the number of oocytes cryopreserved after *in vitro* maturation (IVM)?

Summary answer: Primordial follicle density is significantly correlated with antral follicle count (AFC), anti-Müllerian hormone (AMH) levels and the number of oocytes recovered and matured following IVM.

What is known already: Oocyte vitrification after IVM and ovarian tissue cryopreservation may constitute alternative options for fertility preservation (FP) when ovarian stimulation is unfeasible. Since both techniques are considered experimental, their combination might increase the overall success rate. AFC and AMH levels are commonly used to assess the number of growing follicles. In addition, these markers may be significantly correlated with the number of immature oocytes recovered from small antral follicles and the number of mature oocytes obtained following IVM. Few data is available on the relationship between markers of the follicular ovarian status and the primordial follicle density estimated from ovarian tissue.

Study design, size, duration: From July 2013 to December 2016, we prospectively studied 67 patients, 18 to 39 years of age, and candidates for FP using ovarian tissue cryopreservation associated with oocyte vitrification following IVM.

Participants/materials, setting, methods: All women had both ovaries present, deprived of morphological abnormalities. Exclusion criteria were ovarian or pelvic disease and history of gonadotoxic treatment. Transvaginal AFC and serum AMH levels were systematically measured before FP. Cumulus-oocyte complexes (COC) were recovered under ultrasound guidance, and incubated for IVM. Ovarian tissue was laparoscopically harvested and cryopreserved. For each patient, at least one fresh sample of cortex was processed for pathological analysis, including primordial follicle density assessment.

Main results and the role of chance: Among the 67 included patients, 61 were diagnosed with breast cancer, 4 had lymphoma and 2 underwent the procedure for other indications. Overall, the mean age of the population was 30.7 ± 4.7 years. In addition, mean AFC and serum AMH levels were 14.8 ± 9.7 follicles and 2.6 ± 2.7 ng/mL, respectively. As expected, AFC and AMH levels were strongly correlated with the number of COC recovered (r=0.65 and 0.63 for AFC and AMH, respectively, p<0.0001), as well as with the number of mature oocytes obtained after IVM (r=0.56 and 0.51 for AFC and AMH, respectively, p<0.0001). Likewise, a significant correlation was found between primordial follicle density and both markers of the follicular ovarian status (r=0.38 and 0.49 for AFC and AMH, p<0.003 and <0.0001, respectively), but also with the number of COC and in vitro matured oocytes (r=0.37 and 0.32 for COC and mature oocytes, p<0.003 and 0.008, respectively).

Limitations, reasons for caution: This study was conducted in a limited number of patients. The possible heterogeneity of primordial follicle density within the ovarian cortex may limit the relevance of assessing this parameter on a single sample. The outcome of ovarian tissue transplantation endowed with low follicle density, even in young patients, remains unknown.

Wider implications of the findings: Our findings indicate that AFC and serum AMH levels may reflect not only the pool of growing follicles, but also the primordial follicle stockpile. Further analysis are required to confirm the relevance of performing IVM and ovarian tissue cryopreservation in young women with low values of AFC and/or AMH levels.

Trial registration number: N/A.

P-527   Role of SIRT1 in the adaptive response of mouse ovaries to radiotherapy (X ray radiations)

G. Di Emidio[1], G. Rossi[1], M. Placidi[1], P.G. Artini[2], G. Carta[1], G.L. Gravina[3], A.M. D'Alessandro[1], C. Tatone[1]

[1]University of L'Aquila, Dept. of Life- Health and Environmental Sciences, L'Aquila, Italy
[2]University of Pisa, Dept. of Clinical and Experimental Medicine, Pisa, Italy
[3]University of L'Aquila, Dept. of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy

Study question: Is SIRT1 involved in ovarian adaptive response to gonadotoxic damage induced by radiotherapy in adult, prepubertal and aged mice?

Summary answer: SIRT1 orchestrates the adaptive response of mouse ovaries against radiotherapy in adult but not in prepubertal and aged mice.

What is known already: Radiotherapy is one of the most effective anticancer therapies and causes damage in both cancer and surrounding healthy tissues via ionization, formation of reactive oxygen species (ROS) and subsequent impairment of DNA double-strand integrity and oxidative stress (OS) establishment. Ovaries are very sensitive to radiation-related damage, which may cause premature ovarian failure and menopause. SIRT1, a histone deacetylase involved in oocyte and ovarian adaptive response to OS and chemotherapy, is activated by changes in the redox state and promotes cell survival/apoptosis. Saffron-derived crocetin is an antioxidant molecule with anti-tumor effects that protects non-malignant tissues against chemotherapy-induced toxicity.

Study design, size, duration: Part I) CD1 female mice aged 3-4 weeks (n = 12, Prepubertal mice); 8-10 weeks (n = 12, Adult) or 48-52 weeks (n = 6, Aged) were exposed to 3 Gy total body irradiation.

Part II) Ovaries from postnatal day 4 (PND4) CD1 mice were cultured in MEM-alpha with 3 mg/ml BSA supplemented with or without 50 μM crocetin

for 24 hrs. Then ovaries were exposed to 2 Gy and cultured for further 24 hrs in medium with or withouth crocetin.

Participants/materials, setting, methods: Prepubertal, adult and aged mice were sacrificed at 24 hr after radiotherapy. Ovaries were removed and processed for protein analysis. The relative abundance of SIRT1, HuR, and pFOXO3a was investigated by Western blotting (WB). To investigate potential beneficial effect of a natural antioxidant, crocetin, on damage induced by radiotherapy, PND4 ovaries were processed at 24 hr after the irradiation and the expression of SIRT1, HuR and PGC1-alpha was assessed by WB analysis.

Main results and the role of chance: In ovaries from adult mice exposed to radiotherapy, we observed an increase of SIRT1 and SIRT1 mRNA stabilizer, HuR, demonstrating an early involvement of SIRT1 signalling to counteract damage by radiations (One-way ANOVA and Student-Newman-Keuls Multiple comparison p<0.05). By contrast in prepubertal or aged ovaries we observed that SIRT1 has a different expression level according to the class of age and decreases after radiations.

FOXO3A is a factor involved in the maintenance of follicle quiescence. Its inactive form pFOXO3a was found to increase in both adult and prepubertal mice after radiations, indicating a wave of primordial follicle activation.

PND4 ovaries are endowed of primordial follicle as unique follicle population. In these ovaries SIRT1 and HuR decreased in response to radiations, as observed in prepubertal mice. Medium supplementation with crocetin decreased SIRT1 expression but increased HuR, demonstrating a partial response to damage. Furthermore, since mitochondria have a central role in the regulation of redox state, we investigated the effects of radiations on PGC1-alpha, marker of mitochondria biogenesis and function. Crocetin supplementation prevented the decreased expression of PCG1-alpha induced in PND4 ovaries by radiations.

Limitations, reasons for caution: This mouse model only offers information on short-term effects of radiation, and how these ovaries would look a few weeks later is still a question.

Wider implications of the findings: This study increases the knowledge on the adaptive response orchestrated by SIRT1 in response to gonadotoxicity induced by radiotherapy and highlights the beneficial effect of saffron-derived crocetin, an antioxidant molecule with anticancer properties. Radiosensitivity is associated with a reduced ability to activate an adaptive response mediated by SIRT1 and HuR.

Trial registration number: not applicable.

P-528   BRCA 1 / 2 gene mutations do not affect the capacity of cumulo-oocyte complexes to mature in vitro in breast cancer candidates for fertility preservation

C. Sonigo[1], J. Bénard[2], B. Dagher Hayeck[2], A. Benoit[2], C. Sifer[3], N. Sermondade[4], M. Grynberg[5]

[1]Hôpital Jean Verdier, Reproductive Medicine, Bondy, France
[2]Jean Verdier Hospital, Reproductive Medicine and Fertility Preservation, Bondy, France
[3]Jean Verdier Hospital, Reproductive Biology and IVF laboratory, Bondy, France
[4]Jean Verdier Hospital, Reproductive Biology- IVF laboratory - CECOS, Bondy, France
[5]Jean Verdier Hospital, Reproductive Medicine and Fertility Preservation, Bondy, France

Study question: To compare the maturation rates of oocytes recovered from small antral follicles breast in cancer patients, carriers or not for BRCA 1/2 gene mutation.

Summary answer: BRCA 1/2 gene mutations do not affect the capacity of cumulo-oocyte complexes (COC) to mature in vitro in breast cancer candidates for fertility preservation.

What is known already: Mutation in BRCA1 and BRCA2 genes are associated with an increased risk for developing breast and ovarian cancer. Controversy exists about ovarian reserve and fertility in BRCA mutation carriers. Studies suggest that these patients may have low ovarian reserve and poor response to ovarian stimulation. The impaired ability of the mutated BRCA gene to repair double-strand breaks in DNA may prompt oocyte aging, apoptosis and meiotic errors. IVM of COC retrieved at germinal vesicle stage, followed by vitrification of metaphase 2 oocytes, has recently emerged as an

option for young women seeking fertility preservation, when ovarian stimulation is unfeasible.

Study design, size, duration: We retrospectively analyzed a cohort of 115 breast cancer candidate for fertility preservation using IVM between January 2009 to December 2016.

Participants/materials, setting, methods: Inclusion criteria were: age 18 – 40 years; two ovary presents; no history of chemotherapy. Before immature oocyte retrieval, all follicles measuring 2-9 mm in diameter were precisely counted on both ovaries and serum anti-Müllerian hormone was measured irrespective of the phase of the cycle. Number of COC retrieved, maturation rate and number of metaphase 2 oocyte cryopreserved were compared according to BRCA mutation status.

Main results and the role of chance: Overall, BRCA mutation carriers (n = 28) and controls (n = 87) were comparable in terms of age (31.9 ± 3.4 vs. 31.7 ± 4.0 years, respectively, NS), BMI (22.5 ± 4.5 vs. 23.0 ± 4.8 Kg/m^2, respectively, NS) and ovarian reserve tests (antral follicle count: 20.0 ± 9.4 vs. 21.4 ± 9.8 follicles, NS; serum AMH levels: 3.0 ± 1.6 vs. 3.7 ± 2.1 ng/mL, NS, respectively). The number of COC retrieved did not differ significantly between BRCA gene mutation carriers (9.0 ± 6.1 vs. 10.1 ± 7.4 oocytes, NS). After similar in vitro maturation rates (68.7 ± 20.4 vs. $60.0 \pm 17.0\%$, NS), the number of metaphase 2 oocytes cryopreserved was similar in BRCA mutation carriers and patients not mutated (5.1 ± 3.1 vs. 5.9 ± 4.9, NS, respectively).

Limitations, reasons for caution: The main limitation of our investigation remains the small sample size. In addition, although oocyte cryopreservation following IVM is a promising method of fertility preservation, especially when ovarian stimulation is unfeasible, the true competence of these oocytes remains unknown.

Wider implications of the findings: Although patients who carry the BRCA mutation are known to have an altered DNA repair mechanism, their oocyte capacity to mature in vitro remains intact. Given the low incidence of the mutation, multi-center studies on BRCA mutation carriers who utilize IVM are needed to corroborate these preliminary findings.

Trial registration number: N/A.

P-529 Glycol ethers and semen quality: a cross regional study among infertile men workers in Tunisia

F. TURKI[1], Y. Chaaben[2], O. Bedoui[2], R. Abdelhedi[2], N. Abdellaoui[2], K. Trigui[2], W. Ltaif[2], S. Aloulou[2], R. Louati[2], Y. Kaabi[2], W. Smaoui[2], R. Frikha[2], W. Ben Romdhane[2], J. Jabeur[2], N. Abdelmoula Bouayed[2]

[1]Laboratoire d'histologie-embryologie, departement de génétique, Sfax, Tunisia
[2]Medical University, Department of Histology- Embryology and Genetics, Sfax, Tunisia

Study question: The aim of our study was to investigate the relation between male infertility and occupational exposures, particularly to glycol ethers.

Summary answer: For this reason, one priority of research in industrial countries is to identify these factors and to reduce the occurrence of infertility through preventive means.

What is known already: In industrial countries, 15% of couples of reproductive age have difficulty to conceive naturally. A male factor is involved in half of these couples, and the etiology remains unknown in 25% of male infertility cases. Because medical history cannot explain all male infertility cases, these observations may be linked to a growing impact of potential occupational and environmental factors.

Study design, size, duration: A cross-sectional descriptive study was conducted at the Department of Histology, Embryology and Genetics of the Medical University of Sfax (Tunisia) involving male patients who require genetic counselling as part of their infertile condition during the period between 2007 and 2008.

Participants/materials, setting, methods: 250 infertile men gave semen and blood samples. Data on work history, occupational and non-occupational exposure to chemicals were obtained through an interview. According to the job-exposure matrix (Matgéné and Sumex2 programs), men were classified as either occupationally exposed or non-exposed. A standard karyotyping and semen analysis were investigated. The statistical analysis and correlations were conducted using SPSS IBM 20 for Windows. The significance in the differences was evaluated by using Student and ANOVA tests.

Main results and the role of chance: Of 250 infertile men, 48 were exposed to Glycol ethers: 17 patients suffered from azoospermia, 11 from extreme oligoasthenoteratospermia (OAT) and 10 from severe and very severe OAT. The 10 remaining men had moderate OAT or had one or two altered semen parameters. Major chromosomal abnormalities were detected in men whereas 41 had a 46,XY karyotype.

We found significant associations between occupational exposure to Glycol ethers and semen impairment (p = 0,028) as well as karyotyping abnormalities (p = 0,001).

Limitations, reasons for caution: Our findings support the results of previous studies regarding the association between occupation and semen abnormalities, particularly for Glycol ethers.

But this retrospective estimation of occupation using the job exposure matrix to Glycol ethers was likely to be imprecise. Thus, conclusions derived from such studies should be interpreted with caution.

Wider implications of the findings: Further studies are necessary to evaluate the association between occupational exposures to other reprotoxic agents and impaired semen parameters. Preventive measures must be established and could be completed by the use of biomarkers to a better characterization of exposure to chemicals and their spermiotoxic effects.

Trial registration number: Not applied.

P-530 Human Umbilical Cord Perivascular Cells (HUCPVCs) maintain mesenchymal stromal cell characteristics and regenerative properties after chemotherapy exposure: A promising candidate for prevention of chemotherapy-induced gonadotoxicity

K. Zohni[1,2], L. Lopaz[1], P. Szaraz[1], M. Filice[1], B. Wyse[1], M. Garcia[1], I. Gat[1,2], K. Glass[1,2,3], A. Gauthier-Fisher[1], C. Librach[1,2,3,4,5]

[1]CReATe Fertility Centre, Research, Toronto, Canada
[2]University of Toronto, department of obstetrics and gynecology, Toronto, Canada
[3]Women's College Hospital, Department of Gynecology, Toronto, Canada
[4]University of Toronto, Institute of Medical Sciences, Toronto, Canada
[5]University of Toronto, Department of Physiology, Toronto, Canada

Study question: Do first trimester (FTM) and term HUCPVCs resist chemotherapy-induced cytotoxicity, and maintain mesenchymal stromal characteristics including their ability to support regeneration through paracrine mechanisms?

Summary answer: Human umbilical cord perivascular cells exposed to gonadotoxic chemotherapeutic agents resist cytotoxicity, maintain mesenchymal stromal cell properties in vitro, and exhibit prolonged survival in vivo.

What is known already: Various sources of human MSCs (bone marrow, adipose tissue or umbilical cord derived) have shown remarkable restorative effects in rodent models of cytotoxic gonadal injury. However, it remains unclear whether MSCs could be delivered prior to gonadotoxic chemotherapy regimens as a means of fertility preservation. While BMSCs and aMSCs have been shown to be relatively resistant to the effect of chemotherapy, little is known about the effect of chemotherapy on HUCPVCs, a novel young source of MSCs with increased regenerative potential compared to older MSC sources.

Study design, size, duration: We treated FTM and term HUCPVC and BMSC cultures with moderate (150 µmol/L) and high (300 µmol/L) doses of cyclophosphamide (CTX) for 6 and 24 hours, and cultured them for up to 2 additional passages. Untreated cells served as controls. Outcomes measured were viability, proliferative capacity, mesenchymal cell lineage differentiation capacity, immunogenicity, and paracrine-associated gene expression. We assessed cell survival in Wistar rats (n = 6) treated with CTX following intra-ovarian injection of FTM HUCPVCs.

Participants/materials, setting, methods: Viability and MSC-associated markers were measured by flow cytometry. Commercial kits were used for osteogenic, chondrogenic and adipogenic differentiation in vitro. Immunogenicity was assessed by measuring LDH release in lymphocyte:MSC co-cultures. The expression of 107 paracrine-associated genes was assessed by targeted RNAseq (Ion Torrent). The survival of HUCPVCs in vivo was assessed

qualitatively using human AluI FISH. All experiments were repeated at least 3 times. ANOVA was performed to determine statistical significance.

Main results and the role of chance: The viability of FTM and term HUCPVCs following cyclophosphamide treatment was comparable to that of BMSCs at each dose and each time point (78 and 79 vs 77%, 52 and 55 vs 59% after 150 μmol/L after 6 and 24 hour exposures respectively, and 74 and 77 vs 79%, and 55 and 63 vs 59% after 300 μmol/L for 6 and 24 hours respectively). FTM and Term HUCPVCs continued to express the MSC-associated markers, CD105, CD29 and CD44 after treatment and after 2 passages. Proliferative rates were comparable between the three treated cell types and controls. Following treatment with 150 and 300 μmol/L for 24 hours, FTM and term HUCPVCs maintained their ability to differentiate towards chondrogenic, adipogenic and osteogenic lineages, their low immunogenic properties, their expression of paracrine-associated genes that are known to mediate the ability of MSCs to promote angiogenesis and cell survival, as well as their immunomodulatory and anti-inflammatory properties. FTM HUCPVCs were detected in female rats 7 and 21 days after loading dose of CTX.

Limitations, reasons for caution: Although a main component of chemotherapeutic protocols, cyclophosphamide is typically used in combination with other cytotoxic agents. Additional studies are needed to evaluate the effect of combinations of cytotoxic agents on FTM and Term HUCPVCs, and to determine whether their regenerative capacity is maintained following combination chemotherapy exposure *in vivo*.

Wider implications of the findings: Our findings suggest that both FTM and term HUCPVCs are viable and maintain many of their key regenerative properties following chemotherapy exposure. This suggest that HUCPVCs, a potent source of MSCs for regenerative medicine, are promising cell candidates for fertility preservation strategies.

Trial registration number: not applicable.

P-531 follicular response and outcomes for women diagnosed with cancer having fertility preservation, comparison of random start protocol and early follicular phase stimulation

C. Muteshi[1], M. Fatum[1]

[1]University of Oxford, Nuffield Department of Obstetrics and Gynaecology, Oxford, United Kingdom

Study question: is response to gonadotropin stimulation in a random start protocol comparable to early follicular phase stimulation for fertility preservation in women at risk of ovarian failure due to gonadotoxic treatment

Summary answer: response to gonadotropin for controlled ovarian stimualtion is comparable between women stimulated randomly and those starting in the early follicular phase of the menstrual cycle

What is known already: the desire for fertility preservation is ever increasing as the long term survival in women with cancer continues to improve. As the prognosis depends on prompt and eraly initiation of cancer therapy, time available to consider fertilitypreservation is always limited, therfore, women wishing to undertke ovarian stimulation are often offered the short antagonist protocol. Response to ovarian stimulation in the early follicular phase is comparable to women having routine fertility treatment. Studies have shown that stimulation starting in the luteal phase may result in lower oocyte yield and higher gonadotropin usage, though this is not uniform across studies.

Study design, size, duration: A retrospective case control study comparing ovarian response to gonaotropin stimulation on the antagonist protocol started in early follicular phase or randomly at any time in the cycle in all women referred for fertility preservation between February 2003 and June 2016. A total of 138 electronic records were reviewed.

Participants/materials, setting, methods: The primary end point was the number of mature oocytes retrieved resulting in stored oocytes and/ or embryos for future use. Secondary outcome measures were duration of stimulation and total gonadotropin used and a composite of untoward adverse events including any delay in starting cancer therapy. We also assessed the outcomes of the cryopreserved gametes and/ or embryos. Multivariate logistic regression analysis was performed. $P < 0.05$ was considered statistically significant.

Main results and the role of chance: There were no statistically significant differences in baseline characteristics between women who started ovarian stimulation in the early follicular phase compared to those who started randomly at any time in the menstrual cycle. 103 women started stimulation in the early follicular phase whereas 24 started randomly, in addition, nine used the long agonist protocol and 2 had in-vitro maturation (IVM). The mean number of eggs retrieved in the early follicular phase group was 12 .0 (SD 8.1) and 12.9 (SD 7.9) in the random start group ($P = 0.6016$). It required 11.6 days (SD 2.1) for the early follicular start and 12.2 days (SD 3.5) for the random start group ($P = 0.2690$) using a total dose of 2543.4 iu (SD 1100) of gonadotropin and 2812.02 iu (SD 1707.7) respectively ($P = 0.3391$). There was no difference in duration from initial consultation for fertility preservation and the day of oocyte retrieval 33.5 days (SD 2.8) and 33.9 days (SD 4.3) respectively. Only one cycle was cancelled due to failed fertilisation, however, none of the patients needed hospitalisation for treatment of complications following the fertility procedures. 89 women had oocytes and/ or embryos still in storage and 15 had attempted a pregnancy, 11 were deceased.

Limitations, reasons for caution: The study groups together women with difference types of cancers who may not necessarily have a similar clinical approach to treatment.

Wider implications of the findings: Our study agrees with previuos work that ovarian stimulation can be started at any point in the menstrual cycle highlighting that folliculogenesis and recruitment maybe a continous process. There did not appear to be a difference in the number of mature oocytes or total gonadotorpin dose used as previously reported.

Trial registration number: not applicable.

P-532 Fertility preservation. Anatomopathological analysis of ovarian cortex metastasis in a large cohort of patient undergoing fertility preservation through ovarian cortex cryopreservation

N. García Camuñas[1], S. Vázquez[2], N. Pellicer[3], S. Jesica[3], A. Garcia Belda[4], M. Andres[5], S. Herraiz[4], A. Pellicer[6], C. Díaz García[3]

[1]Valencia, Spain,
[2]La Fe University Hospital., Department of Obgyn. University of Valencia, Valencia, Spain
[3]La Fe University Hospital, Department of Obgyn- University of Valencia, Valencia, Spain
[4]La Fe University Hospital, Department of Obgyn- University of Valencia., Valencia, Spain
[5]La Fe University Hospital, Department of Pediatrician. University of Valencia, Valencia, Spain
[6]Instituto Valenciano de Infertilidad, IVI Roma, Roma, Italy

Study question: How frequent is to find metastasis of malignant cells in the ovarian cortex of oncological patients undergoing fertility preservation by means of ovarian cortex cryopreservation?

Summary answer: Detection of malignant cells is a rare event although it cannot be excluded a priori. Hematological malignancies are the condition at higher risk

What is known already: The increasing survival rates and success of oncological treatments make FP procedures a key step in the holistic management of the oncologic patient. Ovarian cortex cryopreservation is the preferred technique in prepubertal girls since they cannot undergo ovarian stimulation for egg retrieval. Nevertheless, the risk of contamination of the ovarian cortex with malignant cells can be a limiting factor for this techniques to be applied. Different cases have been reported in the literature mainly related to hematological conditions and sarcoma.

Study design, size, duration: The aim of the present study was to describe the pathological findings of the ovarian biopsies of our patients undergoing ovarian cortex cryopreservation for medical reasons. A small biopsy of 2×2 mm is always sent for pathological analysis at the moment of ovarian cortex retrieval. Expert pathologists do the examination of such biopsy to assess the presence of malignant cells. A second biopsy was taken from the cryopreserved-thawed tissue and subsequently analyzed at the moment of reimplantation.

Participants/materials, setting, methods: A cohort of 735 patients underwent ovarian cortex cryopreservation in our fertility preservation

program between 2005 and 2015. All the biopsies were paraffin-embedded and sections were made every 4 microns. All sections were stained with hematoxilin-eosin and also using immunohistochemistry techniques depending on the underlying condition motivating the fertility preservation. A subset of 8 pediatric patients with leukemia also under went minimal residual disease (MRD) detection by RT-PCR.

Main results and the role of chance: Breast cancer was the most prevalent condition in our series (n = 618 -60.3%-), followed by Hodgkin lymphoma (145 -14.2%-), non-Hodgkin lymphoma (61 -6.0%-), gynecological conditions (44 -4.3%-), sarcoma (16 -1.6%-), leukemia (12 -1.2%), autoimmune diseases (8 -0.8%-) and other solid tumors (120 -11.7%-). Malignant cells were only detected in three patients (0.4%) during the pathological analysis of the biopsies: lymphoma malignant cells were found in the ovarian cortex of one patient aged 18 y.o. with Burkitt lymphoma and in another patient aged 33 y.o. with diffuse large B-cell lymphoma. Ovarian adenocarcinoma cells were also found in one breast cancer patient aged 36 y.o. who turned-out to be a BRCA-2 mutation carrier. Among the 8 pediatric patients with leukemia undergoing RT-PCR for detection of MRD, three of them were positive (all acute lymphoblastic leukemia).

No malignant cells were detected in the second biopsy of the 44 patients undergoing ovarian transplantation of the cryopreserved tissue.

Limitations, reasons for caution: Technologies such as RT-PCR or flow cytometry could improve the detection rate of malignant cells in the ovary. The small proportion of tissue retrieved in a biopsy, can imply a false-negative rate that can result in an underestimation of the presence of malignant cells.

Wider implications of the findings: Pathological examination of the ovarian cortex must always be done in order to exclude the presence of malignant cells, even if the prevalence of such event is very low.

Trial registration number: N/A.

P-533   Oocyte numbers in relation to age and specific malignant and non-malignant diseases – analysis of >1.000 ovarian stimulation cycles performed for fertility preservation

A. Germeyer[1], A. Freis[1], T. Bruckner[2], S. Hecht[1], T. Strowitzki[1], M. Von Wolff[3]

[1]University Gynecological Hospital, Gyn. Endocrinology and Reproductive Medicine, Heidelberg, Germany
[2]University of Heidelberg, Bioinformatics, Heidelberg, Germany
[3]University Gynecological Hospital, Gyn. Endocrinology and Reproductive Medicine, Bern, Switzerland

Study question: Is the number of collected oocytes after ovarian stimulation for fertility preservation purposes age and disease dependent?

Summary answer: Oocyte numbers are negatively correlated with age but are similar in different malignant diseases with lower oocyte yield in stimulation for non-malignant diseases.

What is known already: Ovarian stimulation to freeze fertilized and non-fertilized oocytes is still the most efficient procedure to preserve fertility. The number of collected oocytes in the fertility preservation programme remained equal over the years, indicating that the procedure is already very efficient. However, identification of prognostic factors for high or low oocyte yield depending on the underlying diseases is helpful in the patient consultation setting and may help to adjust stimulation dosages to increase the individual oocyte yield.

Study design, size, duration: A retrospective analysis was performed of 1,068 patients (18-40y) undergoing ovarian stimulation for fertility preservation purposes before gonadotoxic therapies due to underlying malignant as well as benign diseases in 75 centers in Germany, Austria and Switzerland. Stimulation cycles were documented in the fertility preservation network FertiPROTEKT from 1/2007-3/2016.

Participants/materials, setting, methods: From 1,200 stimulations 16 women were excluded due to age (1.3%), 6 due to missing data (0.5%), 10 due to cancelled stimulations (0.8%) and 100 due to incomplete data sets (8.3%). The number of oocytes and gonadotropin dosage were analysed according to age (≤25, 26-30, 31-35, 36-40y) and disease (992 (92.9%) malignant; 76 (7.1%)

non-malignant). Statistical significance was analyzed using the analysis of covariance (Ancova), age adjusted.

Main results and the role of chance: Women with malignant diseases were on average 29.5+/-5.6 years old while women with benign disease were significantly younger with 26.5+/-4.9 yrs (p<0.0001). Despite this fact women with malignant diseases had a significantly higher oocyte yield with 12.8+/-8.4 compared to women with a non-malignant disease with 9.7+/-6.6 oocytes (p<0.0006). As known from general ovarian stimulation protocols, the number of retrieved oocytes was age dependant in women with malignant disease with an average of 15.2+/-8.8 oocytes in women <26y and 9.7.+/-7.8 in women 36-40y (p< 0.002). Within the disease categories however the oocyte yield was similar with only a non-significant higher oocyte yield in cerebral carcinomas and other malignancies and lower number in gynaecological malignancies.

Limitations, reasons for caution: The analysis is based on the number of oocytes but not on pregnancy rates. Data on fertilisation rates are missing.

Wider implications of the findings: Our data indicate which diseases result in higher and lower number of collected oocytes. Therefore, ovarian stimulation protocols and gonadotropin dosages can be adapted to increase efficacy of ovarian stimulations and therefore to improve the success rate of this fertility preservation procedure.

Trial registration number: Not applicable

POSTER VIEWING SESSION
PARAMEDICAL - LABORATORY

P-534   Morphokinetic analysis of human cleavage-stage embryos as related to the cell-size stage specificity

V. Muyshond, S. De Gheselle, K. Tilleman, E. Van Den Abbeel, P. De Sutter

Ghent University Hospital, Department for Reproductive Medicine- Ghent Fertility And Stem cell Team G-FAST, Ghent, Belgium

Study question: Are there differences in morphokinetics between cell-size stage-specific (SS) and cell-size not-stage-specific (NSS) human cleavage-stage embryos?

Summary answer: Human cell-size stage-specific (SS) embryos show slower developmental cleavages towards the 3-cell, 5-cell, 6-cell and 7-cell stage in comparison to cell-size not-stage-specific (NSS) cleavage-stage embryos.

What is known already: Static morphological assessment of human cleavage-stage embryos revealed that a substantial number of cleavage-stage embryos have an incorrect relation between cell size and embryo developmental stage. The incorrect relation was substantially higher in day 3 embryos as compared to day 2 embryos. Furthermore their in vitro developmental potential to the blastocyst stage is reduced (Muyshond et al, 2016). Culture of human embryos in time-lapse incubators (TLI), in contrast to standard incubators (SI), allows to observe embryo developmental morphokinetics and can define the precise timings of embryo development in relation to insemination time.

Study design, size, duration: This study is an observational, retrospective analysis of time-lapse monitored embryos between March 2013 and September 2016. In annotated ICSI embryos (n = 257), cell-stage specificity was determined on day 2 (D2) and on day 3 (D3). Embryos having a correct relation between the cell size and the developmental stage were determined SS and if this correlation was not correct NSS. All embryos were cultured in sequential culture media formulations (Cook Medical) until day 5 (D5).

Participants/materials, setting, methods: Four embryo categories were identified according to the static morphological SS/NSS score of the embryos on D2 and D3. Group 1: SS embryos on D2 and D3; group 2: SS embryos on D2 but that developed to NSS embryos on D3; group 3: NSS on D2 and SS on D3; group 4: NSS on D2 and D3.

Statistical analysis was performed by Fisher´s exact-test and linear regression analysis (mixed models) on log-transformed morphokinetic timings (SPSSv23)(p≤0.05).

Main results and the role of chance: Of the 257 annotated embryos, 62.6% (161/257) were SS embryos on D2 and 37.4% (96/257) were NSS embryos. On D2, t5, the time from insemination to the 5-cell stage, was significantly different in the SS group (Median (M)=51.3 h) as compared to the NSS group (M=47.2 h) (p = 0.001). On day 2 there were no statistical differences for t2, t3 and t4.

In the 161 D2 SS embryos 69.6% developed further to SS embryos on D3 (group 1) and 30.4% developed further to NSS embryos (group 2). In the 96 D2 NSS embryos 17.7% of the embryos developed further to SS embryos on day 3 (group 3) and 82.3% developed further to NSS embryos (group 4). On D3, time-lapse data was analyzed between the 4 groups. Significant differences in embryo developmental timings were found at t3, t5, t6 and t7 in group 1 (Mt3 = 38.2 h, Mt5 = 52.3 h, Mt6 = 55.3 h and Mt7 = 57.6 h) as compared to group 2 (Mt3 = 36.2 h, Mt5 = 48.9 h, Mt6 = 51.6 h and Mt7 = 53.9 h). More specifically, timings were always faster in group 2. There were no significant differences in embryo morphokinetics at t2, t4 and t8 in group 1 as compared to group 2. When analyzing the time-lapse images, we also observed reversed cleavage during embryo development.

Limitations, reasons for caution: This was a retrospective analysis and the annotations and the scoring of the relation between cell size and embryo developmental stage was done by several embryologists. For this study, SS and NSS embryos were identified only by a static morphological observation on D2 and D3.

Wider implications of the findings: Our study reveals differences between SS and NSS embryos in developmental morphokinetics in the asynchronous embryo cleavages which might explain a possible cause for cell-size not-stage specificity. We also confirm embryonic reversed cleavage with the potential to repair incorrect relations between cell size and cell stage.

Trial registration number: EC/2017/0086.

P-535 Real time pH monitoring shows important information about embryo culture conditions

S. Geelhood[1], E. Rhead[1], L. Crecraft[2]

[1]SAFE Sens, Product Management, Seattle, U.S.A.
[2]SAFE Sens, Seattle, U.S.A.

Study question: Is spot checking pH once a month or once a week sufficient to understand incubator performance?

Summary answer: No, several incubator conditions are investigated with pH monitoring. Some incubator conditions can result in pHs that are outside the desired levels for embryo development.

What is known already: The pH of media is important to control because embryos are unable to regulate internal pH and pH plays an important role in embryo metabolic activity. Spot checking practices in embryo culture are typically done after only one day of media equilibration in an incubator. Embryos are cultured with media in incubators for more than one day. It is important to understand the pH at times longer than one day and in various incubator conditions that can occur in the laboratory normally.

Study design, size, duration: This is a limited size study evaluating the effect of culture environment changes on the pH of media used for embryo culture. Three different types of incubators are evaluated.

Participants/materials, setting, methods: SAFE Sens TrakStation and TrakPods are placed in various incubator types including benchtop and a cabinet with thermal conductivity CO_2 sensor and a cabinet with infrared CO_2 sensor. pH monitoring is performed using an IVF media. Various external stimuli are applied to the incubator environment. The resulting pH measurements from those impacts are recorded and trended. pH values are also spot checked against a blood gas analyzer at various points in time.

Main results and the role of chance: Sufficient time for the initial equilibration of media in a CO_2 environment is critical to achieve the desired pH. In many cases, at least 24 hours is needed for pH to reach steady state levels. The CO_2 adsorption into media is slow due to the use of an oil overlay in normal culturing conditions.

Benchtop incubators do a very good job of maintaining pH during a 7 day period of time. Lid openings and temperature fluctuations in benchtop incubators do have an impact on the pH monitored.

Cabinet style incubators have some pH variability due to fluctuations in CO_2 levels. Those incubators which use thermal conductivity CO_2 sensors to maintain CO_2 levels show much greater pH changes when humidity changes and when temperature changes. Door openings cause pH changes in the media.

Several figures showing pH profiles will be presented for full understanding of the impacts determined.

Limitations, reasons for caution: The technology looks only at a surrogate media sample that is similar to the media that embryos are cultured in during normal practice. There were no embryos cultured in these tests to show embryo development outcomes.

Wider implications of the findings: These studies educate us about fundamental mechanisms during embryo culture. The culturing environment is well known to be an important variable in embryo development. The impact on pH from these incubator variables studied can now be understood and improvements to culture environments can be made by any lab.

Trial registration number: NA

POSTER VIEWING SESSION
PARAMEDICAL - NURSING

P-536 Known, anonymous or known-anonymous oocyte donation: decision making in parents and prospective parents

S. Somers[1], V. Provoost[2], I. Raes[2], A. Ravelingien[2], H. Van Parys[3], E. Wyverkens[3], I. Stuyver[1], A. Buysse[3], G. Pennings[2], P. De Sutter[1]

[1]Ghent University Hospital, Department of Reproductive Medicine, Ghent, Belgium
[2]Ghent University, Bioethics Institute Ghent BIG- Department of Philosophy and Moral Sciences, Ghent, Belgium
[3]Ghent University, Department of Experimental-Clinical and Health Psychology, Ghent, Belgium

Study question: Why do heterosexual couples opt for known, anonymous or known-anonymous oocyte donation and how do parents experience this decision post-treatment?

Summary answer: Irrespective of the type of oocyte donation, being able to experience a pregnancy and being responsible for the education of the child was highly valued.

What is known already: The literature suggests that the genetic link between donor and recipient woman and clear boundaries and roles are important motivations to choose a donor. Couples are also led by their intention to maintain secret about or disclose the mode of conception to the child.

The strength of this study, compared to previous research, is the in-depth exploration of three types of oocyte donation preferences. Further to that, the data were not gathered during a counselling session but as a part of a research project by interviewers working independently from the fertility clinic where the participants were recruited.

Study design, size, duration: For this study, 19 heterosexual couples were recruited at the Department of Reproductive Medicine of a University Hospital. They consented for an in-depth, semi-structured couple interview. One couple was interviewed separately, from two couples only the woman participated. The interviews were conducted between June 2013 and May 2014. Data were analysed through step-by-step inductive thematic analysis. Approval of the clinic's Ethics Committee was obtained.

Participants/materials, setting, methods: 6 couples became parents after known sister-to-sister oocyte donation, 6 couples opted for known-anonymous donation (= the couple introduced an oocyte donor and in return they received oocytes from an anonymous donor) and 2 couples opted for anonymous donation. We also included prospective parents: 4 couples were pregnant after or awaiting treatment with known-anonymous donation. One additional couple opted for mirror donation (= the male partner donated sperm to reduce the waiting time for oocytes).

Main results and the role of chance: Known oocyte donation was mostly performed because the donor suggested this as an option. For the couples it

was important to know where the genes came from. They were glad that the mother had a genetic link with the child through the donor (sister-to-sister oocyte donation) but the presence of this genetic link was also challenging for some (e.g. when the child resembled the donor).

Known-anonymous donation was mostly performed to avoid the waiting list for anonymous donation. The latter was the only option left when the couple had no available donor to perform known-anonymous donation. The benefits of either anonymous or known-anonymous donation were the protection of the position of the mother and of the family as a whole. Known donation was not an option because it was unclear how the relationship between the couple and the donor would evolve, because of feelings of obligation towards the donor afterwards and because they feared that known donation would be confusing for the child. For most couples, a genetic link between parent and (future) child was of no importance.

Limitations, reasons for caution: Although different types of oocyte donation were studied, sample sizes in subgroups were sometimes very small. It should be taken into account that known donation between sisters is different from known donation between non-relatives because of the presence of an indirect genetic link between mother and child in the former.

Wider implications of the findings: In countries where different types of oocyte donation are permitted, insight into the couple's motivations is an important basis for the counselling sessions. The counsellor can support the couples in their decision by discussing the consequences of each type of donation, even if they already made up their mind beforehand.

Trial registration number: Not applicable.

P-537   Easy-to-use software interface for family medical tree construction

K. Ueta[1], S. So[2], M. Matsu-ura[3], S. Mochizuki[4], W. Yamaguchi[2], O. Mochizuki[5], N. Kanayama[6], F. Tawara[2]

[1]Tawara IVF clinic, Information technology, Shizuoka, Japan
[2]Tawara IVF clinic, medical office, Shizuoka, Japan
[3]Tawara IVF clinic, Medical Clark, Shizuoka, Japan
[4]Tawara IVF clinic, IVF laboratory, Shizuoka, Japan
[5]Seirei-Mikatabara Hospital, Department of Obstetrics and Gynecology, Hamamatsu, Japan
[6]Hamamatsu University School of Medicine, Department of Obstetrics and Gynaecology, Hamamatsu, Japan

Study question: To develop family medical tree construction software for genetic counseling

Summary answer: We have developed software that can be used to construct a family medical tree.

What is known already: A family medical tree is a method for tracing the way genes are passed through families. However, no easy-to-use software tool for this purpose exists as of yet.

Study design, size, duration: Development of family medical tree construction software for genetic counseling

Participants/materials, setting, methods: The Pedigree-Builder-System (PBS) consists of two components: the PBS database and PBS tree viewer. The PBS database stores the recorded content of genetic counseling, including family and personal medical history. The PBS tree viewer visually constructs the family medical tree based on the information in the PBS database. The PBS database and PBS tree viewer were developed using FileMaker and Excel Visual Basic for Application (VBA), respectively. The tree construction algorithm was written using VBA.

Main results and the role of chance: People with a family history of a genetic disease can be concerned they have inherited it and/or that they could pass it on to their children. Genetic counseling provides information about genetic conditions and birth defects. Genetic counselors can use the family medical tree to understand the significance of genetic disorders in the context of personal and familial situations. Thus, we have developed software that can be used to construct a family medical tree. This system provides an easy-to-use, graphic interface that can be used by genetic counselors and other genetics professionals.

Limitations, reasons for caution: None

Wider implications of the findings: In recent years, the use of assisted reproductive technology (ART) has increased dramatically worldwide. The genetic causes of infertility are varied and include chromosomal abnormalities, single-gene disorders and phenotypes with multifactorial inheritance. Using our system, genetic counselors and other genetics professionals can visualize hereditary patterns efficiently.

Trial registration number: N.A.

P-538   Education on age related fertility decrease in women: who, what, when?

D. Garcia[1], S. Brazal[2], A. Prat[3], R. Vassena[2], A. Rodríguez[2]

[1]Fundació Eugin, EUGIN, Barcelona, Spain
[2]Clínica EUGIN, EUGIN, Barcelona, Spain
[3]Universidad de Barcelona, Medicina, Barcelona, Spain

Study question: How should education on age-related fertility decrease (ARFD) in women be provided to new generations for preventing future infertility problems?

Summary answer: Education on ARFD should be provided to young women and men by healthcare professionals and using online materials that encompass a personal risk evaluation.

What is known already: Ageing is against fertility in both men and women, mainly due to the diminution of gamete's quantity and quality with the passing of the years. Woman's age over 35 is the main risk factor for suffering from infertility, but the general public is not sufficiently aware of the age related fertility decrease in women. Moreover, there is a general overconfidence in the success of assisted reproductive technologies at any age. The aim of this study is to compile quantitative and qualitative studies focused on ARFD knowledge and the interventions performed to increase this knowledge and direct further education.

Study design, size, duration: Systematic narrative review of scientific studies published between January 2000-January 2017 in English, Spanish, French and Portuguese, with no country restriction. The search was conducted in 4 databases. We evaluated ARFD knowledge worldwide, highlighting those studies describing interventions aimed to increase it. ARFD knowledge was conveyed through questionnaires, interviews, focus groups and RCTs. Papers focused on contraceptives use, sexual behavior, STIs, cancer and consequences of aging on pregnancy and perinatal outcomes, were excluded.

Participants/materials, setting, methods: The initial search gave 1204 studies; 78/1204 were finally included; 34/78 asked for ARFD knowledge; 14/68 were interventional studies and 4/14 had an RCT design. Geographical distribution was: Europe (32, 41%), North America (24, 30.8%), Asia (10, 12.8%), Australia (8, 10.3%), other countries (2, 2.9%); international (2 2.9%). Gender distribution was: men and women (38, 48.7%), only women (47.4%), only men (3, 3.8%). Twenty-five (32.1%) were performed in university students; 5 (6.4%) in healthcare professionals.

Main results and the role of chance: ARFD knowledge was evaluated by the correct identification of the most fertile age for a woman (20-25 years) and the ages when a slight (25-29 years) and marked (35) fertility decrease occurs. The range of correct answers within the studies varies between 16% and 89.4% for the most fertile age, between 6% and 62.4% for the slight decrease and between 5.6% and 56.9% for the marked decrease. More than half of participants were usually able to identify the most fertile age for a woman, but less than half recognized the slight and marked decreases. In general, worse answers were obtained from people with lower education and from men. Tailored interventions aimed to increase fertility knowledge included printed and online materials, slide presentations and personal risk evaluation. In general, the interventions evaluated were effective in the short-term, but not maintained in the long term, nor resulted in a change in childbearing attitudes. This could be due to a lack of perceived susceptibility to suffer infertility in young people or a perception of lack of choice among the oldest women.

Limitations, reasons for caution: The interventions to measure and increase ARFD knowledge evaluated in this work had a setting of scientific research (original articles published in scientific journals). Surveys performed at other levels and the effect of information provided outside of educational interventions have not been investigated.

Wider implications of the findings: ARFD knowledge could be increased through targeted campaigns to educate the general population about infertility risks and fertility protection, especially in younger people and enhancing personal risk evaluation. Collateral effects that ARFD information may cause (e.g. anxiety) may also be prevented by targeting interventions to younger people than currently done.

Trial registration number: NA.

P-539   What factors influence the timing of infertility treatment for a second child?

M. Fujii, S. Akamatsu, T. Iwasaki, S. Kokeguchi, M. Shiotani

Hanabusa Women's Clinic, reproductive health, Kobe, Japan

Study question: What factors affect a woman's decision to begin fertility treatment for a second child after the birth of the first?

Summary answer: Second fertility treatment was delayed if the cause of the first infertility was unknown, and if the first birth was at a young age.

What is known already: Ninety percent of couples want a second child, according to surveys in Japan. However, previous studies suggest that the fertility rate decreases when the second pregnancy is not started within 3 years after the first birth. The pregnancy rate also diminishes in women aged over 40, even for those who have given birth previously. Therefore, the interval between the first and second conceptions is considered important for a second pregnancy.

Study design, size, duration: This was a qualitative, cross-sectional, paper-based questionnaire study. The respondents were 246 women planning to have a second child after having received infertility treatment before the first pregnancy. The study was conducted in Hanabusa Women's clinic in Kobe, Japan, from July 2015 to January 2016.

Participants/materials, setting, methods: The questionnaire included the woman's age, first child's age, number of years from the first birth to the start of the second fertility treatment, previous experience of infertility treatment or ART, and the cause of infertility at the first conception. The questionnaire was given to patients after they provided informed consent. The women were assured that they would experience no invasion of privacy and no disadvantages if they did not wish to respond.

Main results and the role of chance: The response rate was 81.5%. The average age of respondents was 36.7 years. The average age of the first child was 1.8 years and the most frequent age was between 1 and 2 years old. The average interval between the first birth and the start of the second fertility treatment was 1.6 years and the most frequent interval was 1 to 2 years (45.1%). Older women tended to start the second fertility treatment earlier than younger women: those aged under 29 waited an average of 1.9 years, whereas women over 40 waited only 1.1 years. The causes of infertility at the first child included fallopian tube abnormality, male factors, uterus factors, and unknown factors. The most frequent cause of infertility in women who started second fertility activity within three years after the first birth was fallopian tube abnormality (27.5%), whereas in women who waited longer than three years it was unknown cause (26.1%).

Limitations, reasons for caution: The study was based on a questionnaire with a limited sample size. Future studies should increase the number of patients recruited from multiple facilities to confirm this preliminary conception. Clinical outcomes should also be examined.

Wider implications of the findings: Unknown cause of infertility at first conception and having a first baby at a young age delay the start of second fertility treatment. Analyzing these factors may encourage women to start fertility treatment for the second child early as possible.

Trial registration number: N/A

P-540   Nursing protocol for the risk identification and prevention of Ovarian Hyperstimulation Syndrome (OHSS) in patients undergoing IVF treatment

T. Figueiredo[1], L. Silva[2], T. Bonetti[3], E. Motta[4], P. Serafini[5], M. Panzan[6], F. Torelli[6], J. Assi[7]

[1]*Huntington Medicina Reprodutiva, Nursing, Campinas, Brazil*
[2]*Huntington Medicina Reprodutiva, Nursing coordnator, Sao Paulo, Brazil*
[3]*Huntington Medicina Reprodutiva / Universidade Federal de São Paulo, Scientific / Gynecology Endocrinology Discipline- Gynecology Department, São Paulo, Brazil*
[4]*Huntington Medicina Reprodutiva / Universidade Federal de São Paulo, Clinical Director / Gynecology Endocrinology Discipline- Gynecology Department, Sao Paulo, Brazil*
[5]*Huntington Medicina Reprodutiva / Universidade de São Paulo, Clinical Director / Gynecology Discipline- Obstetrics and Gynecology Department, São Paulo, Brazil*
[6]*Huntington Medicina Reprodutiva, Clinical, Campinas, Brazil*
[7]*Huntington Medicina Reprodutiva, Nursing coordinator, Sao Paulo, Brazil*

Study question: Can the nursing protocol identify the risk of ovarian hyperstimulation syndrome (OHSS) for women undergoing controlled ovarian stimulation (COS) for an *in vitro* Fertilization (IVF) cycle?

Summary answer: The OHSS nursing protocol propose to identify the risks and monitor signs of OHSS to prevent occurrence, signaling clinicians and allowing safer treatment protocols.

What is known already: OHSS is an iatrogenic and serious complication of COS, with estimated prevalence of 20%-33% in mild, 3%-6% moderate and 0.5%-5% severe. The prevalence might even be higher in women presenting risk factors. OHSS is clinically characterized by abdominal tenderness and swelling due to multi-follicular growth and increased ovarian volume. If the condition progresses to severe OHSS, the augmented vascular permeability results in a shift of fluid to the extravascular space and several haemodynamic changes take place, leading to severe morbidity. Early recognition of risk factors and identification of OHSS mild signs can help clinicians tailor treatment regimens and prevent occurrence.

Study design, size, duration: This study aim to propose an OHSS nursing protocol (OHSS-NP) to recognize risk factors for OHSS and monitor patients during COS in order to identify mild sign of this condition as early as possible, and prevent the occurrence of this syndrome. This tool will be initially applied for 30 patients undergoing COS to validation. After any necessary adjustment, the OHSS-NP will be implemented for all patients undergoing COS in the IVF clinic.

Participants/materials, setting, methods: The OHSS-NP construction was founded on evidence based medicine. A team composed by reproductive medicine nurses reviewed the literature to stablish all risk factors, signs and symptoms of OHSS. Based of those findings, the nursing team created the OHSS-NP to identify risks and monitor patients undergoing COS during IVF treatment. The tool was reviewed by reproductive medicine specialists with recognized experience in OHSS management.

Main results and the role of chance: The OHSS-NP will be set into two steps. Step-1 intend to identify the OHSS risk based on patient's history, infertility factors, antral follicle count, anti-mullerian hormone measurement, age, body mass index and others conditions associated. It will be applied before the COS starting and patients will be classified as high, moderated or low risk. The step-1 outcomes will guide the initial dose of gonadotrophin for COS aiming to decrease the risk for patient develop OHSS. The step-2 will be placed in the moment of fourth ultrasound during the COS, before the trigger, and it will include the monitoring of OHSS signs. This step will evaluate the number of follicles with 12-14 mm in diameter, serum estradiol measurement and any clinical sign reported by the patient. If the patient present risk or any sign of OHSS, the treatment protocol can be adapted in order to prevent occurrence or evolution. Also, nursing care post-operatory protocol will be applied to contact patients regularly and monitor symptoms. The efficacy of the OHSS-NCI will be evaluated by comparing OHSS rates occurred during 2016 (mild: 5.6%, moderated: 4.9%, severe: 2.1%) with the rates observed after the implementation of this instrument in a population with same clinical characteristics.

Limitations, reasons for caution: This is a study proposing a tool for risk identification and monitoring patients under COS aiming early identification of OHSS, allowing a tailor treatment regimens and avoid it progression and more severe complications. However, this tool was not implemented yet and it efficacy will be possible in the future.

Wider implications of the findings: The nursing care is essential in IVF treatment. Nurses have a closer relationship with the patient and monitoring strict protocols. Our OHSS-NCI can help the early identification of OHSS and

prevents it progression and complications, by quick treatment tailor, reducing the incidence of moderate and severe forms of the syndrome.

Trial registration number: not applied

P-541 Mental health profile of infertile women seeking ART in China

H. Yao[1], H.Y. Chan[1,2], Y.J. Tam[2], H.P. Lau[4], R. LI[3], H.Y. Ng[2]

[1]The University of Hong Kong, Department of Social Work and Social Administration, Hong Kong, Hong Kong
[2]The University of Hong Kong - Queen Mary Hospital, Centre of Assisted Reproduction and Embryology, Hong Kong, Hong Kong
[3]Center of Reproductive Medicine, Department of Obstetrics and Gynecology, Peking University Third Hospital, Beijing, China
[4]Faculty of Social Science, The University of Hong Kong, Hong Kong, Hong Kong

Study question: What is the mental health profile of infertile women and implications on the utilization of assisted reproductive technology in China?

Summary answer: 10.0% exhibited moderate to severe levels of depression, while 27.6% experienced significant marital stress. These outcomes were related to previous pregnancy experiences and childbearing expectations.

What is known already: Studies have shown that women in who sought infertility treatment had an impaired psychological well-being. Under the One Child Policy, infertile women in China experienced further deterioration in mental health following failed treatment. Since 2016, the revised Two-Child policy allow any married couples to have two children, however, the impact of policy change on the mental health status of infertile individuals remain unknown.

Study design, size, duration: This was a cross-sectional study. Female patients aged 20-45 years old attending outpatient clinics for non-malignant infertility problems were approached. 1142 completed the questionnaire. The study spanned two years.

Participants/materials, setting, methods: Participants were recruited from 7 outpatient clinics for reproductive health in Mainland China. Their average age was 32.0 (SD=5.2) and married for 6.1 years (SD=5.1). The majority of them had received tertiary education (80.1%) and engaged in full-time employment at the time of study. 52% had prior ART experience. Measurements include General Health Questionnaire 9, Kensus Marital Scale, Traditional Childbearing Belief Scale and Childbearing Importance Index.

Main results and the role of chance: The mean scores of GHQ-9 and KMS were 4.4 and 17.8, respectively. Slightly more than 50% of women experienced minimal depression, 32.9% with mild depression, and 10.0% having moderate to severe depression. Marital stress was significant in 27.6% of couples. Greater age (wives and husbands) and longer marriage were related to more marital stress. Confidence in reaching the ideal number of children by a desired age, subscription to traditional childbearing beliefs and greater perceived importance of childbearing were related to better marital adjustment. While longer treatment years and previous induced abortion were associated with poorer marital adjustment, spontaneous abortion and stillbirth history was however related to greater marital satisfaction but also depression. The status of infertility was related to greater depression, but concurrent childlessness was associated with better marital adjustment. While the presence of female cause was associated with greater depression, presence of male cause was however related to less depression. Attribution of childlessness to the development of personal interest was associated with less depression, but economic reasons was related to more depression and marital stress. Health reasons were related to greater depression but better marital adjustment. Statistical significance was indicated by P < .05.

Limitations, reasons for caution: The current study included only female patients of an outpatient obstetric and gynecology clinic, which may render the results less representative of a general female population of China. Depression was measured by a self-report instrument rather than a clinical interview.

Wider implications of the findings: Results highlights the mental health and relational implications of childlessness, infertility and ART treatment among women in the Mainland China. The perceived intentionality of childlessness, confidence in achieving ideal parity and the ability to turn reproductive loss to a relational lesson appears to determine the mental health and relational outcomes.

Trial registration number: Nil.

P-542 Myself, my family and the donor; the experiences and views of adult donor conceived persons

K.R. Daniels[1], A. Mostyn[2]

[1]University of Canterbury, Department of Social Work, Christchurch, New Zealand
[2]University of Canterbury, School of Psychology, Christchurch, New Zealand

Study question: How do adult donor conceived persons view and experience themselves, their family and the donor

Summary answer: Adult donor conceived persons view themselves as positively distinctive, view their families positively and see the donor as significant but not 'dad".

What is known already: Many donor conceived persons desire information and possible contact with their donor and genetic and half-siblings and research has shown generally positive outcomes when contact with the donor has taken place. There is some emerging research that describes how adult donor conceived persons make sense of their family building history and in particular the importance and significance of genetic and non-genetic relationships. Little is known about how this impacts on their view of family however.

Study design, size, duration: A convenience sample of 21 adult donor conceived persons who were born in New Zealand participated in the study which involved in-depth semi-structured interviews. The qualitative design enabled the experiences, meanings and perspectives of the participants to be ascertained. Interviews were conducted over a 5 month (February-July) period in 2016.

Participants/materials, setting, methods: 15 females and 6 males aged between 19 and 46 (mean age of 30) who were born in New Zealand participated in the study. All but one were born into heterosexual led dual parent families. Thirteen of the interviews were Skype video calls, one was a Skype audio call and seven were phone calls. Interviews were recorded, transcribed and thematic analysis conducted.

Main results and the role of chance: Three main themes emerged regarding the view of donor conception.1) positive distinctiveness, 2) gratitude to the donor, 2) appreciation of family. Family was defined by love, connectedness and shared experience. The main theme that emerged regarding the role of the donor in relation to the family was one of dual importance but distinctiveness e.g. dad and donor were seen as very different, donor and half-siblings were special, important and 'like family but different" because the bond is based on genes and not emotion. A second less commonly described theme emerged in which interest in or seeking information or contact with the donor was seen as a sign of disloyalty or ungratefulness to their parents. At the time of the interview half had attempted or made contact with the donor with three having met him. Reasons for seeking information/contact were curiosity about shared traits, medical and cultural history. A sense of uneasiness was a common theme amongst those who had little information and had not made contact with the donor and this sometimes leads to seeing the desire for information as an obsession.

The role of chance in these results is minimal.

Limitations, reasons for caution: The study was based on a convenience sample and is not likely to represent all donor conceived adults. The New Zealand culture and policy regarding donor conception will have impacted on participants experiences. As with all qualitative research the ability to generalise from the findings should be treated with caution

Wider implications of the findings: The findings have the potential to reassure parents concerning the positive way in which adult donor conceived persons are likely to see themselves, their families and the donor. Counsellors

will be able to use these findings as part of preparing would be parent/s for family building using donor conception.

Trial registration number: This was not a clinical trial.

P-543   Decision control preference of Chinese infertile women

W. Liu[1], F. Gong[2]

[1]Central South University-Basic Medical College, Reproductive and Stem Cell Engineering Institute, Changsha-Hunan, China
[2]-Central South University-Basic Medical College, Reproductive and Stem Cell Engineering Institute, Changsha-Hunan, China

Study question: This study was the first of its kind in China, to assess decision control preferences (DCPs) of Chinese infertile females and the influential factors.

Summary answer: Majority of Chinese infertile women had high and medium DCPs. Age, education, living area and severity of infertility were factors associated with DCPs.

What is known already: Shared decision making is one of the key issues in patient-centered care. DCPs is the quantity of control patients prefer to have over their medical decisions. Control Preference Scale by Ende J is a widely used instrument to measure patients' DCPs. DCPs can be defined as high (patients want to make all decisions on their own), medium (patients share decisions-making with their doctors) and low (patients leave all decisions to their doctors). Low DCPs among the general population estimate to be 13% to 44%. Factors as age, gender, education and health status might affect DCPs.

Study design, size, duration: 270 infertile females seeking assisted reproductive techniques (ART) procedures because of tubal occlusion were asked and 237 women were agreed to participate in the study (corresponding rate 87.78%). Some tubal occlusion women complicated with endometriosis, low ovarian reserve, premature ovarian failure (POF) or polycystic ovary syndrome (PCOS). Those illiterate patients and women with male factors infertility partners were excluded from the study. Prospective survey was performed during Oct, 2014 to April, 2016

Participants/materials, setting, methods: A cohort of 237 infertile female patients were recruited to participate in the study. A modified decision control preferences was used to assess the degree of control the infertile women prefer over their ART decisions. The original DCPs were modified to create a trilevel variable: patient-led (original option 1 or 2, high DCPs), shared decision making (medium DPCs, option 3) and physician-led (low DCPs, option 4 or 5)

Main results and the role of chance: Of the 237 patients,161 (67.9%) had tubal occlusion without other abnormalities, 68 (28.7%) were Minorities, 149 (62.9%) had college education or up, 154 (65%) living in city and 99 (41.8%) had previous medical decision-making experience as surgical operation, laparoscopy or ART. 46.8% (n = 111) preferred to share decision making (medium DCPs) while 23.6% (n = 56) preferred patient-led (high DCPs) and 29.5% (n = 70) physician-led (low DCPs). The mean age of patients with low,medium and high DCPs was 37 ± 5.1, 30 ± 3.4 and 29 ± 3.6,respectively. Of the 70 patients with low DCPs, 52 (59.72%) were more than 36 years old, 58 (82.9%) living in rural area, 60 (85.7%) with low education ,46 (65.7%) had no previous decision experience and 59 (84.3%) had abnormalities other than tubal occlusion. Of the 56 patients with high DCPs, 42(75%) were younger than 30 years old, 49 (87.5%) with college and up education ,53 (94.6%) living in city. Age (r=-0.610), education (r=0.574), severity of infertility(r=-0.653) and living in city (r=0.610) were correlated to DCPs (all p = 0.000)

Limitations, reasons for caution: Though the patients of our Hospital coming all over the country, the sampling limited to our hospital might affect the generalizability. The cross-sectional design of the study might not clarify the causality

Wider implications of the findings: Older age, low education,living in rural area and severity of infertility were demonstrated to play important roles in low DCPs of Chinese infertile women. More attention need to be paid to those females to help them improving their self-advocacy and thus improve the quality of patient-centered infertility care

Trial registration number: none.

P-544   The impact of psychological counselling on dyadic outcomes for infertile couples: a common fate analysis

Z. Donarelli[1], L. Salerno[1], G. Lo Coco[2], A. Volpes[3], A. Marino[3], A. Allegra[3], D.M.J. Kivlighan[4]

[1]ANDROS Day Surgery Clinic, Psychology Unit, Palermo, Italy
[2]University of Palermo - Italy, Department of Psychology and Educational Sciences, Palermo, Italy
[3]ANDROS Day Surgery Clinic, Reproductive Medicine Unit, Palermo, Italy
[4]University of Maryland, Department of Counseling- Higher Education and Special Education, MD, U.S.A.

Study question: Do dyadic quality of life, marital satisfaction and need for parenthood differ for couples in infertility treatment who do or do not receive psychological counselling?

Summary answer: Couples who received psychosocial counselling had a higher level of dyadic quality of life and a lower level of dyadic need for parenthood.

What is known already: An important issue in delivering care to infertile couples is to improve treatment compliance and overall patient wellbeing during treatment. Tailored psychological interventions have been developed specifically for infertile patients to deal with the stressful experience of Assisted Reproduction Treatment (ART) and also to optimize the treatment experience.

Previously published reviews examined the efficacy of psychological interventions for infertile patients, obtaining different results. Unfortunately, most evaluations of couples' counselling focuses on outcomes or changes in the individual members of the couple, but do not focus on the couple-as-a-whole as the outcome variable.

Study design, size, duration: A longitudinal study, with a quasi-experimental design, was conducted on 34 infertile couples that received, and 34 matched (propensity scores) infertile couples that did not receive, psychosocial counselling during their infertility treatment, from February 2013 to November 2014.

The Common Fate Model (CFM) was used to examine dyadic changes in quality of life, need for parenthood and marital satisfaction. The CFM assesses whether the dyad has changed as a result of counselling.

Participants/materials, setting, methods: Patients undergoing ART at the ANDROS Day Surgery Clinic, Reproductive Medicine Unit in Palermo (Italy), filled in questionnaires on Quality of Life (QoL -Fertility Quality of Life Questionnaire), Need for Parenthood (NP - 'Need for Parenthood" subscale of the Fertility Problem Inventory) and Marital Satisfaction (MS - ENRICH Marital Inventory) at two points during infertility treatment (before treatment and on the day of IUI or Embryo-Transfer).

Main results and the role of chance: Both the male (T1=.76, P < .001; T2=.75, P < .001) and female (.62, P < .001; T2=.60, P < .001) partner's QoL had significant loadings on dyadic QoL at times 1 and 2. Time 1 dyadic QoL was significantly related to time 2 dyadic QoL (T1 = 1.05, P < .001). Couples receiving counselling had higher dyadic QoL at time 2 compared to couples not receiving counselling (0.14, p=.04).

Both the male (T1 = .78, p < .001; T2 = .80, p < .001) and female (.75, P < .001; T2=.80, P < .001) partner's NP had significant loadings on dyadic NP at time 1 and 2. Time 1 dyadic NP was significantly related to time 2 dyadic NP (0.93, P < .001). Couples receiving counselling had lower dyadic stress due to NP at time 2 compared to couples not receiving counselling (-0.17, p=.04).

Finally, both the male (T1=.86, P < .001; T2=.75, P < .001) and female (.81, P < .001; T2=.84, P < .001) partner's MS had significant loadings on dyadic MS at time 1 and 2. Time 1 dyadic MS was significantly related to time 2 dyadic MS (T1 = 0.83, P < .001). Contrary to our hypothesis, couples receiving counselling did not have higher dyadic MS at time 2 compared to couples not receiving counselling (0.03, p=.74).

Limitations, reasons for caution: The study has several limitations. Firstly, the low number of couples analyzed. Secondly, the couples receiving or not receiving counselling were not randomly assigned. Finally, the couples' counselling was brief; with longer-term, more intensive counselling there may have been more counselling-related changes in the dyadic effects.

Wider implications of the findings: The CFM allows researchers to examine how the dyad-as-a-whole responds to counselling, highlighting relational

dynamics. The findings provide support for continued research into the interpersonal and intrapersonal dynamics that can change as a result of couple counselling, especially when a stressful situation such as infertility and ART has been experienced.

Trial registration number: Not necessary.

P-545 What is the reproductive health of former egg donors a decade after their donation?

J.M. Gonzalo[1], **M. Perul**[1], **M. Corral**[1], **M. Caballero**[1], **C. Conti**[1], **S. Brazal**[1], **D. García**[2], **R. Vassena**[1], **A. Rodríguez**[1]

[1]Clínica EUGIN, EUGIN, Barcelona, Spain
[2]Fundación EUGIN, EUGIN, Barcelona, Spain

Study question: What is the long-term reproductive health of oocytes donors a decade after donation?

Summary answer: The long-term reproductive health of former oocyte donor does not differ from the expectations for their age group.

What is known already: The short term physical and psychological outcomes of oocyte donors have been studied extensively and are well established. However, there are very few reports studying the long term reproductive outcomes of former oocyte donors. Additionally, most such studies are both small in number of women included, and focused mostly on the psychological aspect of the donation. As thousands of oocyte donations are performed worldwide each year, there is an urgent need to analyze the long-term impact of this technique on donors' reproductive health. This study evaluates the reproductive health of former oocyte donors a decade after their donation.

Study design, size, duration: Structured anonymous telephone survey, consisting of 12 questions covering several aspects of reproductive health, such as number of pregnancies and outcomes, gynecological disorders after donation, menopause symptoms and contraceptive use. The survey was performed by 3 trained reproductive nurses between June and November 2016. A total of 141 former oocyte donors were contacted by phone and 121 agreed to participate in the survey (Response rate: 85.8%).

Participants/materials, setting, methods: Former donors were contacted chronologically (oldest donations first); inclusion criteria were to be ≥40 y.o. to encompass most of their reproductive life and speaking Spanish. Most participants were Spanish nationals (99.2%), and were 41.6 ± 1.9 y.o. at the time of interview (range: 40-49); they were 32.2 ± 2.2 y.o. at the time of their first donation (range: 26-35); 5 to 16 years had elapsed on average since the donations, which had been on average 2.5 ± 1.8 for each donor.

Main results and the role of chance: At the time of interview, 84 former donors (69%) had children and 64 (53%) were already mothers at the time of their donation (number of children 1.1 ± 0.9; range: 0-3). In the decade following oocyte donation, 95 women (78.5%) reported having used hormonal contraceptive methods and most (81%) attended annual well-woman exams. In the years following the donation, 22 women (18%) reported losing a pregnancy, either spontaneously (9%) or by medical intervention (9%). Of the 39 pregnancies resulting in live births, 6 complications were reported by 5 donors: 3 preterm births at week 35-36, 1 minor bleeding with amniotic fluid loss, and 1 minor preeclampsia. Currently, 2 of 121 (1.6%) former donors reported being in menopause (ages 41 and 45). Twenty-three women (19%) reported gynecological events in the years since donating: the most frequent being myomas (7), ovarian cysts (4) and endometriosis (2). Five women (4.1%) had experienced infertility, and 2 of them considered this a direct result of their donation. These 5 women were younger than 40 at the time of infertility. At the time of interview, 1 of them had achieved a pregnancy. One woman reported being told by her physician that her myomas were caused by the donation.

Limitations, reasons for caution: A limitation of the current study is the inclusion only of donors who spoke Spanish, which might have limited the diversity of the population. However, this ensured a high level of understanding with the nurses contacting the participants, ultimately adding to the quality of the study.

Wider implications of the findings: This study represents one of the largest so far on the long-term reproductive health of former oocyte donors, and the only one following them into the post reproductive years. Former donors

present low incidence of gynecological/fertility problems. Long term reproductive health seems adequate and no specific alteration could be evidenced.

Trial registration number: NA.

P-546 Why undertaking parenting alone? Single gay men's experiences and decisions of having a child by surrogacy

N. Carone[1], **R. Baiocco**[1], **V. Lingiardi**[2]

[1]Sapienza University of Rome, Department of Developmental and Social Psychology, Rome, Italy
[2]Sapienza University of Rome, Department of Dynamic and Clinical Psychology, Rome, Italy

Study question: Which factors contribute to gay men's decision of having a child by surrogacy as a sole parent?

Summary answer: Factors are: right time, having 'worked through" their own internalised homophobia, being tired of waiting for the 'right" relationship, desire for a child, social support.

What is known already: As it is only recently that single people, whether they are heterosexual, lesbian or gay, have been accepted by clinics as candidates for using assisted reproduction to become parents, no studies have yet examined single gay men's decisions of having a child by surrogacy. Earlier studies on single mothers through donor insemination may inform us partly, showing that relevant factors to 'go it alone" are financial security, the right time in their career, the sense that time is running out, the feeling that they have sufficient social support, and the desire of being a mother.

Study design, size, duration: Twelve Italian single gay fathers (aged 41–55 years) who conceived their children (aged 1–4 years) by gestational surrogacy in California (n = 8), Canada (n = 3), and Thailand (n = 1) participated. Participants were recruited from an association of gay parents (n = 6), Facebook groups of single parents (n = 3), and snowballing (n = 3) between November 2016–January 2017. Three aspects were discussed: decision and timing of becoming parents through surrogacy; satisfaction with their reproductive choice; reactions of family and friends.

Participants/materials, setting, methods: In-depth semi-structured interviews were conducted in family homes (n = 8) or over Skype (n = 4) by a research psychologist trained in the study techniques. The interviews lasted approximately 60–90 minutes, were audio recorded with the participants' consent and transcribed verbatim. Data were analysed through inductive thematic analysis with the aid of the software package, MAXQDA and a continuous auditing process by the co-authors resulted in themes that were grounded in the data.

Main results and the role of chance: The decision to have a child by surrogacy as a sole parent was prompted by five main factors: timing felt right, in terms of career and financial security, as well as of fear of getting older; sense that they had 'worked through" their internalised homophobia; being tired of waiting for the 'right" relationship; desire of raising a child on their own; feeling of sufficient social support. Although all of the men were happy with their decision to go it alone, over half of them (n = 8) would have preferred to have a child within the context of a relationship. When directly asked, the majority (n = 10) stated that they had support by their family and/or part-time nanny as much as was needed, with only 2 participants wishing more support. From the start 3 and 7 participants received supportive reactions to their reproductive choice from their families of origin and from friends, respectively. The remaining reported that initial reactions were mixed, with families (n = 9) and friends (n = 5) having questions or feeling confused about both surrogacy and single parenthood, but then embracing the child when he or she finally arrived.

Limitations, reasons for caution: This study was limited due to the small sample size. Furthermore, there is a risk of selection bias, with fathers who had a negative surrogacy experience less likely to participate in research, although diverse recruitment strategies were used.

Wider implications of the findings: As prior to this study we didn't know the reproductive experience of single gay men using surrogacy, this study highlighted the complexity of factors affecting their decisions to become fathers in this way. Findings are of relevance to clinics and professionals supporting intended single fathers before, during and after treatment.

Trial registration number: Not applicable.

P-547 A Randomized Controlled Trial of the Impact of Music Therapy on Pain and Stress Reduction During Transvaginal Ultrasound-guided Oocyte Retrieval

C.W.C. Cheung[1], G.W.S. Kong[1], A.W.Y. Wong[1], S.H. Saravelos[1], L.P. Cheung[1], T.C. Li[1]

[1]The Chinese University of Hong Kong, Department of Obstetric and Gynaecology, Shatin, Hong Kong

Study question: Does music therapy reduce pain and stress scores during transvaginal ultrasound-guided oocyte retrieval (TUGOR)?

Summary answer: Both group of women had similar stress score but women in the music group experienced significantly less pain score.

What is known already: A recent randomized controlled trial demonstrated that music therapy reduced anxiety in patients undergoing embryo transfer. However, it is not known if music therapy may help in women undergoing TUGOR.

Study design, size, duration: A randomized controlled open label study of 180 women (music group n = 60, headphone only group n = 60, no intervention group, n = 60) undergoing TUGOR over a 12 months period in an IVF unit of a university based teaching hospital.

Participants/materials, setting, methods: Women undergoing TUGOR were recruited and randomized into 3 groups (music group, headphone only group and no intervention group). Patient's psychological status was systematically assessed through various instruments including visual analog scale of pain (VAS-P), state-trait anxiety inventories (STAI), Beck depression inventory (BDI) and general health questionnaire (GHQ). Salivary alpha amylase (sAA) was examined before and after TUGOR.

Main results and the role of chance: There was no difference in mean ($\pm$ SD) psychological scores between 3 groups in (STAI, music group: 54.8 $\pm$ 9.4, headphone only group: 56.9 $\pm$ 10.3, no intervention group: 54.9 $\pm$ 10.2; BDI, music group: 6.6 $\pm$ 6.2, headphone only group: 6.8 $\pm$ 6.4, no intervention group: 8.1 $\pm$ 8.2; GHQ, music group: 2.3 $\pm$ 2.5, headphone only group: 2.8 $\pm$ 2.8, no intervention group: 2.5 $\pm$ 2.6). There was also no difference in the change of mean ($\pm$ SD) sAA level (U/ml) between 3 groups (music group: 4.5 $\pm$ 0.7, headphone only group: 4.7 $\pm$ 0.6, no intervention group: 4.6 $\pm$ 0.7). However, the mean ($\pm$ SD) vaginal pain scores in women receiving music therapy (19.3 $\pm$ 22.4) was significantly (P< 0.034) lower than those receiving headphone only (29.4 $\pm$ 26.9) and no intervention (30.6 $\pm$ 28.2).

Limitations, reasons for caution: Due to the nature of the study, double blinding was not possible.

Wider implications of the findings: This is the first randomized controlled trial to demonstrate that music therapy significantly reduced the perception of pain during TUGOR. Music therapy, being simple and inexpensive, is now routinely offered in our unit during TUGOR.

Trial registration number: This study was registered at Centre for Clinical Research And Biostatistics (Primary Registry and Trial Identifying Number: ChiCTR-TRC-11001657).

P-548 Resilience and Psychological stress after more than two IVF cycles failure

P. Llaneza[1], C. Fernandez-Ferrera[2], D. Llaneza-Suarez[3], D. Fernandez-Garcia[4], V. Castañon[5], P. De la Fuente[6]

[1]FIV, HUCA, Oviedo, Spain
[2]HUCA, Gynecology, Oviedo, Spain
[3]CEFIVA, Biology, Oviedo, Spain
[4]Aviles, Medicine, Aviles, Spain
[5]HUCA, FIV, Oviedo, Spain
[6]CEFIVA, Gynecology, Oviedo, Spain

Study question: Does higher Resilience levels in women help to cope with or overcome deterioration of emotional wellbeing after IVF treatment failure?

Summary answer: After more than two IVF cycles failure psychological stress levels were similar in women with high and normal/low Resilience.

What is known already: Previous cross-sectional studies on the course of emotional response to fertility problems have revealed curvilinear relationships between length of treatment and emotional distress with a positive relationship between distress and the number of unsuccessful treatment cycles. Resilience it is a measure of how individuals cope with, overcome, or become positively strengthened by changes and challenge. Furthermore, complex relationships between depressive symptoms and resilience exist. It has not been study yet if infertile women who display higher resilience may adapt better to emotional distress after IVF cycles failure.

Study design, size, duration: A prospective longitudinal, observational study on 202 couples during IVF-ICSI cycle was carried out between January of 2015 and December 2016 at the Asturias Central University Hospital (Oviedo, Spain) and In Vitro Fertilization Center of Asturias (CEFIVA). The research protocol of the study was reviewed and approved by the Asturias Ethical Committee, Oviedo, Spain.

Participants/materials, setting, methods: Ninety two couple were in first IVF cycle, 68 in second IVF cycle and 38 in third IVF cycle. Before starting the controlled ovarian hyperstimulation with a GnRH antagonist protocol, patients were asked to fill out an itemized general questionnaire (personal and partner sociodemographic data), the Connor Resilience Scale, the Center for Epidemiologic Studies Depression Scale (CESD-10) and the 10 items Cohen Stress Scale.

Main results and the role of chance: Women who showed higher resilience levels according to Connor Resilience Scale showed lower mean psychological stress levels (11.3 $\pm$ 6.1 SD).than women with normal/low resilience (16.3 $\pm$ 5.9 SD) p <0.001. After three IVF cycles failure no significant changes in psychological stress levels were detected in women with normal/low resilience levels (14.9 $\pm$ 6.2 SD vs 17.5 $\pm$ 5.5 SD) p= ns, but in women with higher resilience levels a significant increase in psychological stress levels were detected (9.6 $\pm$ 5.1 SD vs 15.3 $\pm$ 6.4 SD) p = 0.005. No changes in CESD-10 were detected in both arms of the study

Limitations, reasons for caution: The short length of the follow-up period is a study limitation due to long-term psychological consequences. Moreover, there was a high rate of non-respondents and this might have introduced a reporting bias, since it could be that women who experienced more symptoms were less likely to fill in questionnaires

Wider implications of the findings: Women who showed higher resilience levels deal with psychological stress associated to IVF cycles during their first cycle, but after three IVF cycles failure have high psychological stress levels, similar to women with normal/low resilience levels. Higher resilience levels did not protect from psychological stress associated to IVF failure.

Trial registration number: N/A.

P-549 "I don't believe in statistics": Why do women keep choosing ineffective fertility treatments?

A. Tsafrir[1], H. Holzer[1], A. Revel[2], A. Weissman[3], A. Hurwitz[4], M. Gal[5], A. Ben-Chetrit[5], A. Weintruab[5], T. Miron-Shatz[6]

[1]Shaare Zedek Medical Center, IVF unit, Jerusalem, Israel
[2]Hadassah Hebrew University Hospital- Ein Kerem, Department of Obstetrics and Gynecology, Jerusalem, Israel
[3]Edith Wolfson Medical Center, IVF Unit- Department of Obstetrics and Gynecology, Holon, Israel
[4]Hadassah Hebrew University Medical Center- Mt Scopus, IVF Unit- Department of Obstetrics and Gynecology, Jerusalem, Israel
[5]Shaare Zedek Medical Center, IVF unit- Department of Obstetrics and Gynecology, Jerusalem, Israel
[6]Ono Academic College, Center for Medical Decision Making, Kiryat Ono, Israel

Study question: Why do women over age 43 choose to pursue ART treatments using their own eggs, while the chances for success are extremely low?

Summary answer: Despite being informed, most advanced age ART patients have extremely unrealistic expectations of ART and actually ignore their estimated prognosis when making decision regarding treatments.

What is known already: Delivery rate per IVF cycle at age 43-5 is 5% at the most, and cumulative delivery rates are estimated at 15%. Patients often make decisions based on preconceptions, ignoring established medical knowledge. However, whether this happens in the context of ART is unknown.

Study design, size, duration: An anonymous questionnaire was distributed to patients during the years 2015-6. The participants filled it out on their own,

responding to closed-ended questions, such as – what their success rates are according to their physicians and to themselves, and open ended questions, such as whether they had any personal characteristics that increased their fertility chances.

Participants/materials, setting, methods: Women having fertility treatments at age 43-5 using their own oocytes were asked to fill an anonymous questionnaire. Setting was seven fertility clinics. The recruiter asked the women to fill out a questionnaire, and made it clear that participation would have no influence on their care and that their attending physician would not be informed of their responses. Participants were 72 women, scheduled for ART treatments using their own oocytes at mean age 43.8 ± 0.7.

Main results and the role of chance: 60 (83%) respondents had previous treatments before participation in the study. Participants estimated delivery rates in the next treatment cycle at $48 \pm 32\%$, and cumulative delivery rates after all treatments they will undergo at $62 \pm 34\%$. Only 15% reported they received no information from their providers regarding estimated success rates, while 73% reported they were given verbal and /or numerical/quantitative information. 41 (59%) women described how their providers estimated their chances. Of those, 24 (58%) said they had been given a very low estimation of success in a clear way, either numerically (1-5% delivery rate) or verbally ("very low chances" etc.). 14 (34%) had been given verbal description which may be interpreted as less pessimistic ("low chances", "possible chance"). Only three women (7%) claimed they had been given optimistic delivery prospects. When asked "had you known your estimated chance for delivery is lower than a given value, would you avoid having treatment in the first place?" 80% responded they would have attempted treatments regardless. 65% of respondents would like their providers to inform them about estimated success rates even when those are very low. In contrast, 30% would like to receive such information only if they ask directly about it.

Limitations, reasons for caution: This study was performed in Israel where fertility treatments are fully reimbursed until age 45, without capping their number. Findings may have been different where patients pay fully for ART, or where caps exist, which send a message of how many IVF treatments are enough.

Wider implications of the findings: While advanced age was chosen as an inclusion criterion, findings may be applicable to other subgroups of ART patients facing ineffective treatments. Complex psychological factors seem to affect decision making of ART patients facing a poor prognosis. These findings may contribute to developing strategies aimed for better decision making.

Trial registration number: not applicable.

P-550   Relationship between psychological stress and assisted reproduction outcomes in Tunisian infertile women

M. Ajina[1], A. Sallem[1], H. Ben Mustapha[1], O. Kacem[2], M. Harzallah[1], F. Hachani[1], A. Saad[3]

[1]Farhat Hached University Teaching Hospital, Unit of Reproductive Medicine, Sousse, Tunisia
[2]Faculty of Medicine, Department of Histology, Tunis, Tunisia
[3]Farhat Hached University Teaching Hospital, Department of Cytogenetics and Reproductive Biology, Sousse, Tunisia

Study question: Is there any association between anxiety and assisted reproduction outcomes in Tunisian women undergoing IVF treatment?

Summary answer: Anxiety as assessed by cortisol level is correlated to assisted reproduction outcomes in Tunisian infertile women.

What is known already: The powerlessness to conceive children and the process of assisted reproduction technologies leads to a high level of anxiety. The impact of psychological stress on assisted reproduction outcomes is still a matter of controversy. The few available data on this topic especially in developping countries such as Tunisia don't seem to be sufficient to make conclusions concerning the possible benefits of stress management in infertile couples. The present study forms at the best of our knowledge the first one which was carried out in Tunisia to assess in which extent may stress influence reproductive outcome in couples seeking infertility treatment.

Study design, size, duration: This was a prospective study on women undergoing their in vitro fertilization (IVF) or intracytoplasmic sperm injection

(ICSI) at the Reproductive Medicine Unit at Farhat Hached University Hospital (Sousse, Tunisia).

Participants/materials, setting, methods: We recruited 64 infertile women. All patients who had an existing psychological problem were excluded. Participants were asked to fill out the Beck anxiety inventory (21 items) on the day of oocyte retrieval. Three blood samples were collected to assess free cortisol by radioimmunoassay (RIA) at three timepoints during the IVF treatment cycle (T1: before commencing IVF/ICSI treatment; T2: on the day of oocyte retrieval and T3: on the day of embryo transfer).

Main results and the role of chance: As clinical pregnancy is the ultimate goal in assisted reproduction, the most important finding in our study was that cortisol level on the day of embryo transfer was negatively correlated with clinical pregnancy rate ($p = 0.039$; $r = -0.309$). All patients that succeed to achieve pregnancy had an easy embryo transfer.

Cortisol level at T1 was negatively correlated with both fertilization and segmentation rates ($p = 0.02$; $r = -0.309$ and $p = 0.05$; $r = -0.257$). Patients with a long past of infertility have the highest cortisol levels on the day of oocyte retrieval (T2) ($p = 0.044$; $r = 0.273$). A positive correlation was also found between the follicle stimulating hormone level and cortisol value at T2 ($p = 0.015$; $r = 0.326$). Interestingly, there were no correlations between Beck score and neither cortisol level nor IVF/ICSI outcomes.

Limitations, reasons for caution: Patient groups included in the study were heterogeneous: women starting ART treatment for the first time and those who underwent repeated ART treatments.

Wider implications of the findings: This study is the first to evaluate the impact of anxiety on ART outcomes in Tunisian women. Our results show that stress management is of great importance and should be part of treatment protocol.

Trial registration number: This study was approved by the ethics commetee of Farhat Hached University teaching hospital (IRB00008931).

P-551   Reliability of FertiQoL in assessing fertility related quality of life in the Indian population

S. Gurunath[1], M.M. Gopireddy[2], R. Biliangady[1]

[1]Cloudnine Fertility, Reproductive Medicine, Bangalore, India
[2]Evidencian Research Foundation, Epidemiology, Bangalore, India

Study question: Is FeriQOL reliable in estimating quality of life in Indian sub fertile couples and to assess the impact of infertility on quality of life in Indian sub fertile couples

Summary answer: The FertiQol instrument has demonstrated high overall reliability in the Indian population, though some of the subscales had poor internal consistency.

What is known already: Fertility adversely affects the quality of life in multiple domains and FertiQOL has been reliable in assessing the same in many population across the globe.

Study design, size, duration: The study was a cross sectional study and was conducted on 166 infertile couples. The data collection for the study was conducted over a period of 18 months from April 2015 to September 2016.

Participants/materials, setting, methods: The participants were infertile couples seeking treatment from a speciality reproductive centre in metropolitan city of Bangalore, India, selected by convenient sampling. Informed written consent was obtained and confidentiality of the participants was maintained. FertiQoL, a fertility specific quality of life assessment instrument, was used. Internal consistency of each item of the questionnaire was assessed by Cronbach's alpha (CA). Mean and standard deviation of each subscale score and the overall score was presented as recommended.

Main results and the role of chance: Majority of the women were between 26 to 35 years of age. More than 50% of the husbands were aged between 31 to 35 years. In majority of the subjects (65.7%) the duration of infertility was between 1 to 5 years. PCOS was the most common cause of infertility, seen in 50 (30.1%) couples, which was followed by unexplained (24.7%) and male factor (12.7%). Among the study population, majority (71.1%) of the women had primary infertility.

Among the 6 subscales of FertiQoL questionnaire, emotional and mind body components had shown highest internal consistency (CA of 0.75 and 0.79

respectively). Social and tolerability components have shown moderate internal consistency (CA of 0.54 and 0.67 respectively). The components which have shown poor reliability were relational and environment subscales (CA of 0.38 and 0.37 respectively). When grouped together into core and treatment components the items have shown good internal consistency (CA of 0.86 and 0.62). The overall internal consistency of the entire instrument was 0.87. The mean subscale scores indicted that relational, environmental and social aspects of quality of life to be worse than emotional, mind body and tolerability aspects.

Limitations, reasons for caution: Generalizability of study findings is limited, considering the single centre and predominantly urban nature of study population. The effect of various sociodemographic and fertility related parameters on reliability could not be evaluated, due to limited sample size.

Wider implications of the findings: Will help in drawing the attention of clinicians towards importance of addressing the quality of life related aspect of infertility, through appropriate interventions. This in turn may help the subfertile couple to cope better.

Trial registration number: Not applicable.

P-552   Experiences of and wishes on guidance of donor-conceived offspring

A. Schrijvers[1], H. Bos[2], F. Van Rooij[2], T. Gerrits[3], F. Van der Veen[4], M. Mochtar[4], M. Visser[5]

[1]University of Amsterdam, Center for Reproductive Medicine, Amsterdam-Zuidoost, The Netherlands
[2]University of Amsterdam, Child Development and Education, Amsterdam, The Netherlands
[3]University of Amsterdam, Sociology and Anthropology, Amsterdam, The Netherlands
[4]University of Amsterdam, Centre for Reproductive Medicine, Amsterdam, The Netherlands
[5]University of Amsterdam, Center for Reproductive Medicine, Amsterdam, The Netherlands

Study question: How do donor-conceived offspring experience guidance and what are their wishes for guidance?

Summary answer: Donor-conceived offspring wished that their parents would have received specialist guidance before donor sperm treatment, appreciated peer-support and the availability of specialist guidance for themselves.

What is known already: Most studies on donor-conceived offspring focus on psychological well-being and family relationships. These studies have shown that secrets in families about the genetic origin of the child can harm the parent-child relationship and as a consequence early disclosure of donor conception is recommended. Whether donor-conceived offspring wish to have guidance to cope with their questions and feelings related to being a donor-child is not known.

Study design, size, duration: We performed a qualitative in-depth interview study from October 2015 until February 2016 with 24 Dutch donor-conceived offspring. They were recruited by two network organisations where donor-conceived offspring can be matched with half siblings and the donor and who facilitate peer contact for donor-conceived offspring. Recruitment was also done through snowball sampling.

Participants/materials, setting, methods: We held semi-structured in-depth interviews with male and female donor-conceived offspring ($M_{age} = 26.9$, range 17-41) born within father-mother ($n = 11$), two-mother ($n = 7$), or single mother families ($n = 6$). The interviews were fully transcribed and analysed using the constant comparative method.

Main results and the role of chance: All donor-conceived offspring would have appreciated openness from their parents about being a donor-child and assistance in getting access to trustful information about characteristics and identifying information of their donor. Most donor conceived offspring had visited peer meetings and had exchanged feelings and experiences with other donor-conceived offspring. Most of them wished that their parents would have received adequate specialist guidance before donor sperm treatment to prepare them to talk openly with their child about donor conception. All wished to know where to find specialist counsellors for guidance when needed.

Limitations, reasons for caution: Recruitment was done through networks where donor-conceived offspring can be matched with half siblings and the donor and who facilitate peer contact, which may have led to selection bias. This may have been reinforced -by default- by the absence of donor-conceived offspring who are not informed about their genetic origins.

Wider implications of the findings: Specialist guidance should be available for all intended parents to share donor conception more easily with their partner, with people around them and with their future child. Furthermore it is highly recommended that peer-support and specialist guidance will be available and provide easy access for all donor-conceived offspring.

Trial registration number: Not applicable. Ethical clearance by Medical Ethical Committee of the Academic Medical Centre of the University of Amsterdam (NL53349.018.15).

P-553   Using or refusing 'social oocyte freezing': A qualitative analysis

M. Schick, R. Sexty, B. Ditzen, T. Wischmann

Institute of Medical Psychology, University Hospital Heidelberg, Heidelberg, Germany

Study question: Goal of this qualitative study was the analysis of multiple reasons of men and women for using or refusing 'social oocyte freezing'.

Summary answer: Participants reported a wide spectrum of attitudes toward 'social oocyte freezing', with distinct misjudgment regarding fertility decline and men being much more critical than women.

What is known already: 'Social oocyte freezing', the human oocyte cryopreservation for non-medical purposes offers healthy women a medical procedure to postpone having children for 'social' reasons, like career intentions or lack of a partner. Since 'social oocyte freezing' is a relatively new and originally for cancer patient designed reproductive procedure, it stirs up many ethical and social debates. In the last years, there has been a growing research investigating intentions and fertility knowledge of potential freezers and non-freezers. However, qualitative studies exploring and analyzing 'social' reasons thoroughly, particular for men, are still missing.

Study design, size, duration: The qualitative study was part of a quantitative online study, approved by the Ethics Committee of the Heidelberg Medical Faculty. The study took place from April to June 2015 with a total of $N = 643$, thereof $N = 144$ participants in the qualitative part.

Participants/materials, setting, methods: The qualitative study was part of a quantitative online study, approved by the Ethics Committee of the Heidelberg Medical Faculty. The study took place from April to June 2015 with a total of $N = 643$, thereof $N = 144$ participants in the qualitative part.

Main results and the role of chance: In total, $N = 85$ women ($\varnothing$ age: 36.1; 15,4% of total female sample) and $N = 59$ men ($\varnothing$ age: 38.8; 65,6% of total male sample) noted 197 reasons for and against cryopreservation for non-medical purposes. Men and women showed distinct differences in their attitudes towards 'social oocyte freezing', with men having a much more negative attitude than women. Whereas women wrote 107 free-text reasons, among these 85 reasons in favor and 22 reasons against this technique; men reported 90 reasons, amongst 27 reasons in favor and 63 reasons against 'social oocyte freezing'. Qualitative analysis revealed that having no partner was the most mentioned reason by women, followed by fertility decline (in retrospective view) and early onset of menopause. Only few women indicated career issues and no woman reported reproductive autonomy or coverage - contrary to men, for whom those were the most mentioned reasons. Statements against human oocyte cryopreservation contained particularly ethical factors like being 'evolutionary nonsensical' and 'technically dangerous' for both sexes. Women noted additionally age factors, while men pointed out exploitation, a wrong societal development and indeterminate medical consequences.

Limitations, reasons for caution: Generalization of findings is limited due to the nature of online surveys and a possible motivational bias regarding the willingness to answer additional items.

Wider implications of the findings: The major differences between men and women reasons for and against 'social oocyte freezing', have to be investigated further to clarify specific needs necessary for future counseling. Furthermore, several statements indicated huge information deficits about reproductive techniques in the society, especially on fertility decline, that need to be dissolved.

Trial registration number: None.

P-554 Six years of experience with DNA-linking donor-conceived offspring and sperm donors

A.J.B.M. Maas, D. Postema, A. Van Loon

Stichting Fiom, Donor relationships, 's-Hertogenbosch, The Netherlands

Study question: Aim of this study was to describe expectations and experiences of donor-conceived adults (DCO) and donors who registered in a DNA-database to search for genetic relatives.

Summary answer: Donor-conceived offspring feel they have the right to know their genetic relatives. Donors waive their anonymity in order to know more about their offspring.

What is known already: DCO are in search for information about or contact with those to whom they are genetically related through donor conception. This also applies to previously anonymous donors, they have a desire to know more about the results of their donations. Fiom is an independent knowledge center for questions related to people's descent and provides assistance with searching for genetic relatives in and outside the Netherlands. In 2010 Fiom established together with the Canisius-Wilhelmina Hospital, a DNA-database for DCO and sperm donors who have anonymously donated prior to 2004 (since 2004 DCO have the legal right to know their donor's identity).

Study design, size, duration: Qualitative data were collected during a six-year period in which support was provided to DCO and donors seeking genetic relatives. In addition, a questionnaire-based survey was used to generate information about DCO and sperm donors who enrolled in the voluntary DNA-database (Fiom KID-DNA Databank) between May 2015 and December 2016.

Participants/materials, setting, methods: Up to December 2016, 747 DCO and 316 donors have registered in the DNA-database. For 154 people, a family relationship was determined with at least one other person. These were 119 DCO and 35 donors involved in successful DNA-linking. Quantitative data were available for 213 DCO and 85 sperm donors. They answered a questionnaire with items regarding their demographic background, motives and expectations.

Main results and the role of chance: The mean age of DCO was 29 years and 71% of them were women. A third of the DCO were informed over their origins in early childhood (< 6 years), whereas 43% was informed at the age of 17 of older. DCO register themselves because they are curious and find that they have a right to know who they are descended from. They want information about their donor and seek recognition. Some DCO indicate that they experience a loss, others are just looking for medical information. Two third of the DCO are supported by their parents in their search for genetic relatives. The mean age of the donor is 63 years and 62% of them have done more than 10 donations. Their registration was supported by 83% of their partners and just more than one third of the children in the donors' family was informed about the donation and were supportive. Donors agree with DCO that they have the right to ask questions about them and they are interested in information about or contact/meeting with DCO. On a scale of 1 until 10 about the importance of a DNA-link between DCO and donor, DCO reported 7,8 and donors reported 6,4.

Limitations, reasons for caution: Although ending of donor anonymity in 2004 has increased openness around donor conception in the Netherlands, it is important to recognize that these findings only account for DCO who are informed about their conception and are actively searching for their genetic relatives. This may limit the generalization of the results.

Wider implications of the findings: This study provides useful information about DCO and donors who want to be found by genetic relatives. Because DCO and donor increasingly start a search for each other, these findings hold important implications for practice and policy.

Trial registration number: Not applicable.

P-555 Marital satisfaction and social support in infertile women with and without polycystic ovary syndrome seeking assisted reproduction treatment

M. Mohammadi, B. Navid, R. Omani Samani, N. Bagheri Lankarani

Reproductive Epidemiology Research Center- Royan Institute for Reproductive Biomedicine- ACECR- Tehran- Iran., Department of Epidemiology and Reproductive Health, Tehran, Iran

Study question: Is there any difference in marital satisfaction or social support between infertile women with and without polycystic ovary syndrome seeking assisted reproduction treatment?

Summary answer: The results showed that there is no significant difference between marital satisfaction and social support among infertile women with or without polycystic ovary syndrome (P > 0.05).

What is known already: Polycystic ovary syndrome has been found to have impaired sexual function, irregular menstrurations, hirsutism, acnes, and obesity. Previous studies showed Polycystic ovary syndrome reduces sexual satisfaction in women which is a component of marital satisfaction. Social support is often referred to as peoples' receiving of social and mental helps in critical life conditions. Due to the importance of marital satisfaction in the overall satisfaction of the person and family and its impacts on the society's health, it is necessary to investigate the effects of this syndrome on marital satisfaction and social support in infertile women.

Study design, size, duration: A cross-sectional survey was conducted on 300 (150 PCO and 150 non-PCO) infertile women referred to the Royan institute, a referral infertility clinic in Tehran, the capital of Iran, between 2015 and 2016.

Participants/materials, setting, methods: The study was conducted in Royan Institute, a referral clinic in Tehran capital of Iran. Participants completed three questionnaires: The demographic questionnaire, the marital satisfaction Scale developed by Enrich, and Zeman et al.'s and Perceived Social Support Scale (MSPSS).

Main results and the role of chance: Data analysis was carried out by Uman-Wietni tests and dependent t-test. The results showed that there is no significant difference between marital satisfaction and social support among infertile women with or without polycystic ovary syndrome (P > 0.05). According to the results, it can be said that although polycystic ovary syndrome may have negative effect on women in different aspects, it cannot reduce social support and marital satisfaction in infertile women. Moreover, after adjusting for the association among response variables in multivariate model, and enter demographic variable such as age, occupation, education, causes of infertility and BMI in the model, the same results were found.

Limitations, reasons for caution: Because this study was cross-sectional, no conclusions on causality were inferred. We relied on patients coming to only one center, which is a referral clinic for infertility. So, the sample may net be a good representative of infertile women in Iran.

Wider implications of the findings: It seems that infertility has big negative effects on the women and psychological impacts of PCO is overwhelmed by infertility.

Trial registration number: none.

P-556 Fertility quality of life for patients undergoing IVF depends on infertility diagnosis

T. Shavit[1], A. Hershko-Klement[2], H. Joseph[3], T. Shaukov[3], T. Tulandi[3], S. Tannus[3], W. Buckett[3], J. Takefman[3]

[1]MUHC Reproductive Center- McGill University, Reproductive center, Montreal, Canada
[2]Meir Medical Center- Tel-Aviv University, Obstetrics and Gynecology- IVF Unit, Kfar-Sava, Israel
[3]McGill University, MUHC Reproductive center, Montreal, Canada

Study question: Does type of infertility diagnosis influence the fertility quality of life (FertiQoL) of couples undergoing fertility treatments?

Summary answer: Endometriosis and anovulation have negative effect on FertiQoL compared to other infertility diagnosis. Women's age, and duration of infertility also have negative impact on FertiQoL

What is known already: The association between infertility and substantial personal distress is well established. Infertility treatments may worsen the stress of the infertile couple and decrease their quality of life. Only a few studies have tried to evaluate whether types of infertility diagnosis have an influence on fertility quality of life. Women with PCOS were found to have lower FertiQoL compared to couples with unexplained infertility, whereas endometriosis was not found to have negative impact on FertiQoL compared to patients without endometriosis.

Study design, size, duration: Questionnaires were distributed to patients attending a public academic reproductive center between February 2015 and April 2016. All couples of infertility, who attended the clinic, were invited to complete questionnaires on quality of life. Questionnaires included socio-demography and the validated Fertility Quality of Life (FertiQoL). Overall, 1006 patients completed the questionnaires, 630 women and 376 male partners.

Participants/materials, setting, methods: Patients reported their infertility diagnosis in this survey and FertiQoL was evaluated according to infertility diagnosis. The male questionnaires were divided between male and non-male factor diagnosis. In the women's group comparison of FertiQoL according to the fertility diagnosis was calculated. Comparison between study groups was performed using t-test and Chi-square test. We performed logistic regression analysis to evaluate additional factors which may influence FertiQoL including age, parity, infertility duration, socioeconomic status and education.

Main results and the role of chance: Ninety-three (24.7%) males reported male factor as their infertility diagnosis, whereas 283 others (75.3%) reported infertility due to non-male related cause. Among females patients, self-reported infertility diagnosis were male factor in 114 cases (18.1%), anovulation in 120 (19.0%), tubal factor in 41 (6.5%), diminished ovarian reserve in 44 (7.0%), unexplained infertility in 200 (31.7%), endometriosis in 15 (2.4%), combined female and male infertility in 35 (5.6%), other reasons in 35 (5.6%) and unaware of the diagnosis in 26 (4.1%). Demographic characteristics of males with different fertility factors including age, parity, duration of infertility and education were comparable. However, age and duration of infertility among females with different infertility factors were different. The total FertiQoL scores of male patients with male or non-male related fertility diagnosis were comparable. Low core scores were found among women with endometriosis (p = 0.045 CI 95% 0.2, 18.5), and those with anovulation had lower treatment score (p = 0.047 CI95% 0.05, 8.8). Logistic regression analysis (ANOVA) revealed that age, infertility duration and education level significantly affect female's FertiQoL score. After adjusting for those factors, low FertiQoL scores among women with endometriosis and anovulation remained.

Limitations, reasons for caution: Not all patients agreed to participate. Not all males completed the questionnaire, most likely due to low number accompanying their spouses to the clinic. Also male patient may feel uncomfortable reporting on their FertiQoL. In addition, fertility diagnosis was based on the patient self-reporting that may lead to inaccurate diagnosis.

Wider implications of the findings: This is the largest study evaluating the impact of infertility diagnosis on fertility quality of life for patients undergoing fertility treatments. Male factor infertility does not seem to affect male's FertiQoL. Females with endometriosis and anovulation have significantly reduced FertiQoL and may need additional psychological support during the treatment.

Trial registration number: None.

P-557 The effect of mind body-based interventions on anxiety in infertile women undergoing IVF: a systematic review

I.M. Streuli, H. Gaitzsch, J. Benard, P. Pirtea, J. Hugon-Rodin

University Hospitals of Geneva, Gynecology and obstetrics, Geneva, Switzerland

Study question: Do mind body-based interventions improve anxiety state in infertile women undergoing IVF?

Summary answer: Mind/body based interventions improve anxiety-state measured by the State-trait Anxiety Inventory (STAI) in women undergoing IVF treatment.

What is known already: Infertility and its treatments can be emotionally and physically challenging. Anxiety has a negative impact quality of life during treatments and leads to treatment discontinuation.

The goal of mind-body based interventions is to achieve a state of alert, focused relaxation by deliberately paying attention to thoughts and sensations without judgment allowing stress reduction in numerous physical and psychological conditions. This promising approach has been developed and used in infertile patients. Different dedicated programs have been developed for infertile patients including discussion, breathing exercises, yoga positions, relaxation and meditation.

Study design, size, duration: This study is a systematic review. A comprehensive and systematic search of literature was conducted in October 2016. We identified records by electronic searches in the following databases: PubMed, PsychINFO, EMBASE, the Cochrane Library. When conducting the searches we combined the keywords representing the two primary concepts infertility and mind body based interventions.

Participants/materials, setting, methods: Studies were considered eligible if they 1) reported data on infertile participants, 2) evaluated the effect of a mind-body intervention (mindfulness, mindfulness stress reduction programs (MBSR), yoga), 3) included baseline and post intervention measures of anxiety by the State-trait Anxiety Inventory (STAI) or another anxiety questionnaire, 4) used a quantitative search approach.

Main results and the role of chance: In total 8 publications met the eligibility criteria. One was excluded since only the congress abstract was available without access to full data. There were two uncontrolled studies with a pre and post intervention evaluation of state anxiety, 3 non-randomized controlled studies and 2 randomized controlled trials assessing pre and post intervention state anxiety levels in the intervention and control groups. The timing of the intervention in regard to the infertility treatment differed between studies. The 2 uncontrolled studies reported a significant reduction in STAI-state scores before and after the completion of the intervention. The 5 controlled studies all reported a significant improvement in anxiety state in the intervention group in comparison to the control group. We calculated the effect size for mean differences of groups with unequal sample sizes with a pre-post-control (PPC) design. The intervention had a small effect on anxiety state in 4 studies (Effect size d of 0.19, 0.23, 0.29, 0.34, respectively) and a large effect (Effect size d of 1.52) in one study.

Limitations, reasons for caution: Only two studies had a randomized controlled design and all studies except one included women only. The timing of the intervention differed between studies; it is therefore not possible to evaluate the optimal timing of the mind-body intervention during IVF treatments.

Wider implications of the findings: Mind body based interventions, based on relaxation, breathing and meditation, could be a useful approach in anxiety reduction in women undergoing IVF treatments. Future studies should focus on the timing of these interventions during IVF treatments.

Trial registration number: not applicable.

P-558 Long-term effects of the Mindfulness Based Program for Infertility (MBPI): A seven-year follow-up study

A. Galhardo[1], M. Cunha[1], J. Pinto-Gouveia[2]

[1]*Instituto Superior Miguel Torga- CINEICC-Faculty of Psychology and Educational Sciences of the University of Coimbra, Psychology, Coimbra, Portugal*
[2]*Faculty of Psychology and Educational Sciences of the University of Coimbra, CINEICC, Coimbra, Portugal*

Study question: Are there long-term term effects of the Mindfulness Based Program for Infertility (MBPI) regarding emotion regulation processes such as mindfulness skills and experiential avoidance and in depression and anxiety symptoms?

Summary answer: In the seven-year period after the MBPI there were sustained benefits in emotion regulation processes as well as in psychopathological symptoms of depression and anxiety.

What is known already: Mindfulness based interventions have been broadly applied and proved effective in several health conditions (e.g., chronic pain, cancer, endometriosis, anxiety disorders, depression). Specifically in infertility, the MBPI showed to be effective in improving mindfulness skills and infertility self-efficacy and in reducing depressive symptoms, shame, entrapment and defeat feelings.

Study design, size, duration: This was a longitudinal study encompassing four assessment moments: pre-MBPI (T1), post-MBPI (T2), six-months follow-up (T3) and seven-year follow-up (T4). Fifty-five women completed the MBPI and were recruited through a website announcement posted at the national patients association. Data collection took place between October 2009 and December 2016.

Participants/materials, setting, methods: Fifty-five infertile women completed the MBPI. All participants filled in a paper-pencil set of self-report

instruments for the assessment of depressive symptoms, anxiety symptoms, experiential avoidance and mindfulness competencies pre, post and six-months after the program completion. Concerning the seven-year assessment, participants were contacted by email and completed the self-report measures online. For T4 there was a response rate of 73% (n = 40). Analyses were conducted through repeated measures ANOVAs.

Main results and the role of chance: Significant direct effects of time with medium effect sizes were found in mindfulness skills (F = 7.16; p < .001; $\eta^2 p$ = .24), experiential avoidance (F = 10.75; p < .001; $\eta^2 p$ = .22), depressive symptoms (F = 11.68; p < .001; $\eta^2 p$ = .23), and anxiety symptoms (F = 7.31; p < .001; $\eta^2 p$ = .16). Mean comparisons showed that benefits achieved after the MBPI completion were maintained for the seven-year follow-up. Mean scores in experiential avoidance showed to be increasingly lower over time and in mindfulness skills increasingly higher. As for depressive symptoms there was a significant decrease from T1 (M = 10.75; SD = 7.27) to T2 (M = 5.93; SD = 4.18) and from T1 (M = 10.75; SD = 7.27) to T3 (M = 4.45; SD = 4.63) but not to T4 (M = 7.35; SD = 7.26). Concerning anxiety symptoms there was a significant decrease from T1 (M = 47.53; SD = 13.28) to T3 (M = 40.00; SD = 10.82) and to T4 (M = 39.07; SD = 11.39).

Limitations, reasons for caution: Further research is needed to replicate or even expand these findings through a randomized controlled trial. Participants in the control group showed a dropout rate of 50% at six-month assessment and were not included at seven-year follow up. Therefore time comparisons were only examined for participants who completed the MBPI.

Wider implications of the findings: The current study highlights sustained benefits of MBPI seven years after the intervention on mindfulness skills and experiential avoidance. Moreover therapeutic gains were also maintained in terms of depression and anxiety symptoms, contributing to emotional well-being. The MBPI benefits seem to persist over a long period of time.

Trial registration number: ClinicalTrials.gov Identifier - NCT03012412.

P-559 Communication modalities between centers and patients should decrease stress and costs by limiting errors: results of a large survey

P. Barriere[1], C. Avril[2], A. Benmahmoud-Zoubir[3], S. Dejager[3], N. Bernard[3], M. Velkoski-Rouyer[3]

[1]CHU de Nantes, Biologie de la Reproduction, Nantes Cedex 01, France
[2]Clinique Mathilde, ART Center, ROUEN, France
[3]MSD France, Santé de la femme, Courbevoie, France

Study question: The study aimed to examine patients' perception, comprehension and execution of physician's instructions for a first *in vitro* Fertilization (IVF) cycle.

Summary answer: The understanding of patients, dialogue between physician and patients, and means of transmission for instructions could lead to fear of errors and some misinterpretation.

What is known already: Even though the clinical pregnancy rate varies from about 29-33% after assisted reproductive techniques in Europe, a significant proportion of couples discontinue fertility care before achieving a pregnancy. The pregnancy rate following an injection error is estimated at only 7%. Burden of the treatment, errors in administration of treatment, lack of adherence and success, psychological stress, fear of adverse events, lack of patient-centered care, difficulty to contact assisted reproductive technology (ART) services play a great role in influencing the decision to discontinue treatment.

Study design, size, duration: A non-interventional, descriptive, longitudinal study was conducted from August 2013 to Octobre 2015 in ART centres located in France where patients could have a first IVF attempt.
A total of 39 ART centres participated in the enrollment of 502 patients.

Participants/materials, setting, methods: Women having a first IVF attempt for ART, and accustomed to use applications were recruited. Treatment-related instructions on duration, prescriptions, laboratory tests required were received by the patient from physicians, nurses, mid-wives or other healthcare providers through a smartphone application (Fertilisim). Questionnaires including visual analogue scales (VAS) were completed by patients and physicians before the first cycle (Visit [V] 1), on the day of oocytes retrieval (V2), and before the second cycle (V3).

Main results and the role of chance: A total of 488 patients (mean age: 32 years) were eligible before the start of the first IVF cycle.
According to the patients' opinion (N = 305), deviations to injection schedules (doubtful injection dose: 13.6%, and error on injection dose: 1%) were documented.

However, discrepancies about modalities of treatment administration were reported in 89.9% and 92.1% of patients at V1 and V3, respectively, mainly due to transcription error in dose or excess in gonadotrophins.

Compliance to treatment rated by physicians was considered good in 94.3% of patients, but extra hormonal tests and pelvic scans were performed by 38.3% and 30.5%, respectively.

Despite high rates of discrepancies, understanding of injections schedule (86.2), exams schedule (84.9), instruction transmission means (86.1) assessed through a VAS were considered satisfactory by patients at V1. Similarly, understanding of words used and answers given by the medical team were considered high (86.4 and 90.4, respectively).

Overall, 95.2% of patients (N = 305) reported to be satisfied to very satisfied with the mean of transmission for instructions during treatment at V2. Instructions sent were assessed as totally or rather understandable by most patients (94.4%). A total of 69.9% of physicians (N = 76) reported that the smartphone application allowed a better traceability.

Limitations, reasons for caution: This open and observational study could potentially affect physician and patient behaviors. This survey could be limited by a selection bias, as the sample of participating physicians was not randomly selected, leading to a possible lack of representativeness. Moreover, the reported findings regarding questions asking patients' opinion were subjective.

Wider implications of the findings: Unlike well-studied IVF laboratory potential errors, errors during treatment are underestimated as their impact on success rate. Areas for improvement may include the development of an IVF Smartphone application. This stress-limiting solution enables to send treatment instructions using a secure process, improve monitoring and should reduce costs induced by errors.

Trial registration number: The study was supported by MSD France, a Subsidiary of Merck & Co., Inc, MSD (France).

Trial Registry number
The trial registry number was MK#308-00.

P-560 Implantation rate remains stable when patient anxiety is reduced after embryo transfer

A. Garcia-Faura[1], M. Asensio[2], A. Moreno[1], F. Moffa[1], C. Castello[2], M. Lopez-Teijon[1]

[1]Institut Marques, Reproductive Medicine Service, Barcelona, Spain
[2]Institut Marques, Reproductive Biology Service, Barcelona, Spain

Study question: Is it possible to actively reduce a patient's anxiety levels following embryo transfer, and in this way improve the success rate of fertility treatment?

Summary answer: Active management of the patient from the embryo transfer until the pregnancy test reduces patient levels of anxiety, but doesn't improve the embryo implantation rate.

What is known already: The level of anxiety felt by patients undergoing any type of fertility treatment is high, and it increases in the 10 days between embryo transfer and the pregnancy test. In recent years patients and professionals in the field have shown a growing interest in therapies to reduce anxiety between embryo transfer and the pregnancy test, for example using acupuncture or psychotherapy to try to improve the patient's experience at the stage of the treatment where the degree of anxiety reaches its maximum.

Study design, size, duration: Between June 2015 and November 2016, 431 patients on IVF treatment were recruited to a prospective trial, to evaluate their degree of anxiety on the days between embryo transfer and pregnancy test. They were randomised to one of 3 groups: 'ON', each patient used a Babypod[TM] device that emits music via the vagina twice daily for 20 minutes; 'OFF', double blind allocation of a Babypod[TM] that didn't play music; 'NO', control group without Babypod[TM].

Participants/materials, setting, methods: We evaluated the patient's degree of anxiety on day +1 (D+1) after transfer with an intial test that scored

from 0 up to 5. The day before of the pregnancy test, on day +9 (D+9), all patients repeated the same test to be able to compare the degree of anxiety.

We compared the results of the 3 groups for: reduction in the degree of anxiety, patient pregnancy rate and miscarriage rate.

Main results and the role of chance: Of the 431 patients recruited, 165 were randomly assigned to the ON group, wearing music with Babypod[TM], 145 to the OFF group, wearing the same device without music, and 121 to the control group, that didn't use any device. A homogenicity study was completed within the 3 groups and no significant differences were found between the groups with regard to all the IVF treatment parametres.

There were no significant differences between the 3 groups regarding the pregnancy rate per transfer (65% ON, 60% OFF, 64% NO), nor the miscarriage rate (12% ON, 16% OFF, 14% NO).

In the ON group, feedback from the patients showed however a 78% reduction in the anxiety felt by patients, between D+1 and D+9. In the OFF group 80% of patients also noted lower levels of anxiety. Furthermore, there were significant differences in anxiety levels between groups that had undergone active anxiety management by means of the Babypod[TM] when compared with the NO group that didn't use the musical device (11%, p = 0.0012)

The fact that there was an ON and an OFF group, both in themselves active management using the Babypod[TM], allows us to verify that it was not the musical stimulus itself that modified the success rates.

Limitations, reasons for caution: The main limiting factor of the study is that only the level of anxiety related to the treatment undertaken was assessed. No other possible extrinsic factors that could have modified the result of the studies were evaluated.

Wider implications of the findings: Active management signficantly reduces the degree of anxiety felt by the patient following embryo transfer. This reduction in anxiety does not influence the embryo implantation rate. However, we shall continue investigating alternative methods of active management because they do significantly improve the patient's experience of the treatment process.

Trial registration number: Not applicable.

P-561 Patient experience of IVF, watching their embryos develop in real time and online

V. Walker, A. Garcia-Faura, M. Lopez-Teijon, F. Moffa

Institut Marques, Reproductive Medicine Service, Barcelona, Spain

Study question: What is the emotional response of patients to a program that allows them to view the evolution of their embryos online and in real time?

Summary answer: Watching their embryos develop lowers patient anxiety levels, and gives them a better understanding of what is happening to their embryos.

What is known already: The laboratory phase of the IVF cycle is a time of anxiety for patients, principally because they do not know what is happening to their embryos. The Embryoscope[TM] time lapse technology allows embryologists to make continuous embryo observations without removing them from the incubator. This provides precise information about embryo development that is of great therapeutic and diagnostic value. We have designed a software program that allows patients undergoing IVF to follow the evolution of their own embryos from their computer or mobile telephones in order to help them establish the first emotional link with their future child.

Study design, size, duration: Between January 2012 to December 2016, 387 patients who had chosen to do IVF with additional use of the Embryoscope[TM] incubator were randomly selected to access in real time the images of their developing embryos. They were asked to complete a short questionnaire about this experience, in particular their emotional response to the images and degree of anxiety. We also asked them to select what they thought was the embryo with the best quality.

Participants/materials, setting, methods: On the day of their egg collection and ICSI fertilisation, an e-mail was sent to patients with a user name and password to allow access to an encrypted website where they could see their embryos in the time-lapse incubator. The patients were then able to follow embryo development in real time from their computers or mobile devices until the embryo transfer. On the same web page they were asked to complete the study questionnaire.

Main results and the role of chance: A 100% of patients considered watching their embryo development to be a positive experience that allowed them to feel involved in the laboratory process; of these patients, 88% considered it a highly positive experience and kept watching, and 12% decided to stop watching out of fear or respect; this latter group were worried about detecting non-evolutive embryos. 91% of patients said they felt calmer watching the embryo development.

We evaluated how many times per day patients would connect to watch their embyos: 23% of them connected only once, 27% between 2-4 times, and 43% 5 or more times every day (average 3,8 connections / day).

We asked patients if they felt they could select the embryo of best quality: 23% did not answer, 26% answered no, and 51% of the patients selected the best embryo from their point of view. 74% of these patients chose correctly the embryo that was finally used for transfer or vitrification.

Limitations, reasons for caution: The main limiting factor in this study is that it's a descrpitive trial based on an on-line questionnaire.

Wider implications of the findings: Giving patients direct access to the development of their embryos in the laboratory is a unique experience and reduces the anxiety often felt by patients at this stage in the treatment process. It boosts the bonding process as the parents watch the embryos make their first steps in life.

Trial registration number: Not applicable.

P-562 Psychopathological status, previous fertility treatment results and treatment adherence in men of infertile couples

L. Jurkowski[1], P. Balbi[2], N. Bossi[3], C. Granados[4], E. Polak de Fried[5]

[4]*CER Medical Institute. Affiliated to the School of Medicine- University of Buenos Aires, Human Reproduction, Buenos Aires, Argentina*
[5]*CER Medical Institute. Affiliated to the School of Medicine- University of Buenos Aires., Human Reproduction, Buenos Aires, Argentina*

Study question: Does the psychopathological status relate to previous treatment results and treatment adherence in men of infertile couples?

Summary answer: Men of infertile couples with failed treatment presented higher scores of Depression, and those that did not continue the treatment had higher scores of Hostility

What is known already: There are few studies that describe psychological and psychosocial symptoms of men in infertile couples. Most studies worldwide are about women's experiences and psychopathology, and what happens to men when facing an infertility diagnosis and treatment remains unknown.

As far as we know there is no evidence that describes Hostility in men of infertile couples.

Study design, size, duration: Prospective, relational study. First stage of a wider research. During two months, March-May 2016, 51 men of 51 new infertile couples from the CER Medical Institute from Buenos Aires, Argentina completed a questionnaire.

Participants/materials, setting, methods: Fifty-one men from infertile couples (Age:$\bar{x}$ 39.48 +/-7.42 years) agreed to complete the Symptom Checklist-90-R (SCL-90-R)(Derogatis, 1994), a self-report questionnaire, in the waiting room before their first appointment at the fertility clinic. The SCL-90-R is a standardized instrument that assesses a wide range of current psychological symptoms and emotional distress divided in 9 dimensions and 3 global indexes.

Non-parametric analysis was made with Mann–Whitney U test, with the SPSS 20. Statistical significance = $p < 0.05$.

Main results and the role of chance: Data obtained from medical records: 58.8% previous failed treatment, 15.68 % male factor; 45.09% female factor; 31.37% combined, 7.84% unexplained diagnosis.

The sample obtained higher scores in the following SCL-90-R dimensions: Somatization ($\bar{x}$48.22 +/- 10.24), Depression ($\bar{x}$45.20 +/- 8.60) and Obsessive- compulsive ($\bar{x}$ 45.06 +/- 10.9). The lower score was in Phobic Anxiety ($\bar{x}$ 40.25 +/- 12.35).

Men that did not continue with the fertility treatment obtained statistically significant higher scores in Hostility than men who continued (45.10 versus 40.25 x̄ respectively, p = 0.035). They also presented higher scores in the Index of Positive Symptoms than men who continued with the fertility treatment (44.67 versus 39 x̄ respectively, p = 0.038).

Men with previous failed treatment had higher scores of Depression than those for whom it was the first consultation (7.5 versus 41.9 x̄ respectively, p = 0.034).

Limitations, reasons for caution: It was a small sample and limited in time so results should be generalized with caution.

Wider implications of the findings: We found new evidence that suggests that high levels of Hostility might relate to treatment abandonment. This could be a first approach to study male psychological predictors of treatment adherence to develop specific interventions

Trial registration number: N/A.

P-563   A double-edged sword: the attitudes of men and women towards fertility education

E. Koert, C. Harrison, J. Boivin

Cardiff University, School of Psychology, Cardiff, United Kingdom

Study question: What are the attitudes of men and women towards fertility education?

Summary answer: Men and women speak positively about fertility education and believe it should be accessible at a time when fertility is relevant to the individual.

What is known already: Research shows there are considerable gaps in fertility knowledge. Recent efforts to increase fertility knowledge through public education strategies have been unsuccessful in promoting lasting change in fertility knowledge levels and fertility intentions (e.g., timing of pregnancy). Lack of change could be due to unfavourable attitudes and unmet preferences towards fertility education, calling for more research on views of fertility education.

Study design, size, duration: Individual qualitative interviews in the 5th year of a mixed methods longitudinal study concerned with planning for parenthood with university students and staff in a large urban centre. At study entry participants were childless, not pregnant and wanted children in the future. The present assessment took place with participants that were still childless. Participants were randomly assigned to receive control or fertility information. Interviews lasted on average 45 minutes, and were recorded and transcribed verbatim.

Participants/materials, setting, methods: Participants in the longitudinal study were invited to the interview study. 37 expressed an interest and 18 attended an interview (17 women, 1 man). On average those attending were 29.68 (SD: 3.62) years old. The main area of questioning was their opinion about fertility education. Participants completed the Cardiff Fertility Knowledge Scale (CFKS, Bunting et al., 2013). Qualitative data was analyzed using a thematic analysis. Differences according to knowledge level and intervention group were examined.

Main results and the role of chance: The average knowledge score was 70.9% correct (SD: 13.9, range: 38.5-92.3). Regardless of knowledge level or intervention group, respondents expressed positive attitudes towards fertility education, with descriptions of its usefulness and its importance in promoting informed decision-making about parenthood options and its timing. Key themes included attitudes about preferred timing of exposure to fertility education (i.e., when it is relevant, such as being on "the cusp of readiness" to conceive, during sex education in school, or during contraceptive visit to doctor). Preferred sources of information were doctors, popular media/television and online sources. Participants highlighted the necessity of information being provided by a reputable source. Preferred content included information on age-related fertility decline, lifestyle factors with risks to fertility, parenthood options (e.g., adoption, third party reproduction), and types of assisted reproduction. Respondents highlighted the "double edged sword" of fertility education citing its importance along with the concern that it would increase people's anxiety about being able to have children and encourage people to have children before they were ready. Of note, participants with lower knowledge levels reported a lack of access to fertility education prior to the study.

Limitations, reasons for caution: This is a qualitative study on a self-selected university sample of men and women of reproductive age having agreed to participate in a study of parenthood planning. The results may not be generalizable to the larger population. Future examination with larger, more representative samples is needed.

Wider implications of the findings: Educational efforts should take the target audience's attitudes and preferences into account and should be easily accessible and appropriate for a lay audience. Future research needs to determine how to reach audiences with lower levels of knowledge and how to provide education without increasing the pressure to have children.

Trial registration number: Not applicable.

P-564   Fertility-related knowledge in clusters of German women and men determined by fertility intentions and cultural milieus

R. Sexty, M. Schick, B. Ditzen, T. Wischmann

Heidelberg University Hospital, Institute of Medical Psychology, Heidelberg, Germany

Study question: What differences do clusters of women and men based on fertility intentions and cultural values show concerning fertility-related knowledge?

Summary answer: Self-oriented persons before family planning had the most realistic fertility-related knowledge. Especially, self-oriented participants close to the end of reproductive lifespan gave pessimistic answers.

What is known already: Studies revealed generally poor fertility-related knowledge in young people, especially in university students who tend to underestimate the age-related fertility decline and overestimate the chance of successful IVF-treatments. Satisfactory knowledge was found in females, graduates, well-paid employees and those from developed countries. In actual family planners, more realistic knowledge was also correlated with absence of consultation with a fertility expert. A combination of fertility plans and social positions and values may reflect other important connections between beliefs and preconceptions and fertility facts.

Study design, size, duration: An online survey was conducted between April and June 2015 and was approved by the Ethics Committee of the Heidelberg University Hospital.

Participants/materials, setting, methods: 643 participants living in Germany answered all the questions encompassing fertility-related knowledge, fertility intentions, basic values in terms of Delta-Milieus (defined by a combination of social classes from lower to upper class and values from traditional to self-orientation) and sociodemographic data. With hierarchical cluster analysis, different clusters were identified on the basis of fertility intentions and social milieus. Differences between the clusters in sociodemographics and fertility knowledge were described with chi-squares and analyses of variance.

Main results and the role of chance: Four clusters could be found: Cluster 1 before family planning (N = 166) consisted of more self-oriented milieus with a general fertility intention in the future. Cluster 2 close to the end of reproductive lifespan (N = 242) contained also respondents from self-oriented milieus with an actual (62%) or without (38%) wish for a child. In this group, 48% struggled with fertility problems (chi^2 = 60.83, p<0.001), the average age was the highest of all four clusters (39.11 ± 10.57, F=54.18, p<0.001). The rate of university degree was the highest in the self-oriented clusters (81% and 74%, chi^2 = 74.98, p<0.001). Cluster 3 with traditional participants (N = 62) came from conservative and middle class milieus. Cluster 4 (N = 89) contained respondents from mainly self-managed milieus. In the two latter groups, there was a variety of family planning from general and actual to no fertility intentions.

81% of all participants gave correct answers to only 1-3 from the 7 questions connected to fertility-related knowledge.

Members of Cluster 1 had more correct answers regarding fertility-related questions than those of Cluster 4 (F=3.13, p<0.05), and less pessimistic (negative over-/ or underestimation) answers than persons from the Cluster 2 (F=7.51, p<0.001).

Limitations, reasons for caution: Respondents represented about the three-quartered of the original groups of Delta-Milieus. Experiencing fertility problems plays a role to be more pessimistic in rating the success of pregnancy

naturally or per IVF, but the numbers of pessimistic answers were also salience among participants without fertility problems.

Wider implications of the findings: Acquiring proper fertility knowledge is shaped by several factors, as well as by which social and basic value-cluster a person belongs to. Therefore, fertility education programs should target on women and men with different cultural background and parenting attitudes.

Trial registration number: -.

P-565   Single or double embryo transfer? Decision-making process in patients participating in an oocyte donation programme

M. Roca, E. Clua, I. Rodríguez, M. Tresánchez, F. Martínez, M. Boada, P.N. Barri, A. Veiga

Hospital Universitari Dexeus, Obstetrícia- Ginecología y Reproducción, Barcelona, Spain

Study question: Does the information provided to oocyte recipients on the consequences of multiple pregnancy influence the decision on the number of embryos to be transferred?

Summary answer: After being informed about treatment success rates and the consequences of multiple pregnancy, a significant number of recipients changed their preference to single embryo transfer.

What is known already: In IVF/ICSI programs, it has been demonstrated that, after receiving the information about the similar cumulative live birth rate after single embryo transfer (SET) and double embryo transfer (DET) and the obstetric and perinatal risks of multiple pregnancy, a significant number of patients opt for SET. Up to date, no comparable studies have been published in oocyte recipients. Although similar results are expected, this group includes a significant proportion of women of advanced age, thus involving a distinctive medical, psychological and social context which can affect their expectations and preferences.

Study design, size, duration: Longitudinal, prospective study of 38 cycles. Recipients' preferences on the number of embryos to be transferred and the relevance for the decision-making process that they attribute to certain factors were analysed through an anonymous questionnaire. Recipients completed the questionnaire at two distinct times of the cycle: before receiving the information about success rates and the possible risks of DET and after counselling was provided. A 6 months study period was expected.

Participants/materials, setting, methods: Patients undergoing their first oocyte donation cycle expressed their preference on SET or DET pre and post-counselling. Preference changes were analysed by McNemar's test. According to the relevance for their decision, recipients scored from 1 (less relevant) to 10 (more relevant) different factors: partner's opinion, age, previous ART, temporary urgency, desire for singleton/twins, desire for healthy pregnancy, probability of pregnancy, mother/child risks, cost and medical recommendation. The mean scores of pre and post-questionnaires were compared.

Main results and the role of chance: Before counselling, from 38 recipients that completed the questionnaire, 20 preferred DET, 11 preferred SET and 7 were undecided. From the 20 recipients who initially preferred DET, 10 (50%) maintained their preference after counselling, 8 (40%) changed their decision to SET and 2 (10%) changed to undecided. The McNemar's test showed the intervention had a significant impact on the decision ($p<0.05$). For each factor analysed in the questionnaire, the mean score's difference (MSD) between pre and post-questionnaires showed the influence of counselling, with a negative MSD meaning an increasing importance of the specific factor. In recipients who changed their preference from DET to SET, the counselling had an impact on the following factors: mother risks, previous ART, probability of pregnancy and temporary urgency. While the relevance attributed to mother risks increased (MSD=-3.13), the previous ART (MSD=3.00), the probability of pregnancy (MSD=2.38) and the temporary urgency (MSD=2.25) became less important. Conversely, in the recipients who maintained their DET preference, the scores barely changed between pre and post-counselling questionnaires.

Limitations, reasons for caution: Although the sample size is sufficient to answer whether counselling influence the oocyte recipients' decision on the number of embryos to be transferred, more cases would be needed for an in-depth analysis of the specific factors that affect this change in the decision.

Wider implications of the findings: This study provides valuable information on the decision-making process on the number of embryos to be transferred in oocyte recipients. It is especially useful to reinforce and improve the information strategy for this kind of patients, in order to help them make a more reasoned decision.

Trial registration number: In progress.

P-566   Expecting the best but experiencing the worst: The effect of dispositional optimism on psychological adjustment after IVF treatment failure

L. Pasch[1], S. Holley[2], P. Katz[3], N. Adler[1]

[1]University of California San Francisco, Psychiatry, San Francisco, U.S.A.
[2]San Francisco State University, Psychology, San Francisco, U.S.A.
[3]University of California San Francisco, Institute for Health Policy Studies, San Francisco, U.S.A.

Study question: What is the effect of dispositional optimism on depression and anxiety after IVF?

Summary answer: After a failed IVF cycle, patients high in dispositional optimism experience similar levels of depression and anxiety as those who had successful cycles.

What is known already: While IVF provides the opportunity for pregnancy for couples who otherwise would not have been able to conceive, it still fails more often that it succeeds. Few longitudinal studies have addressed the psychological consequences of failed IVF. In particular, we know little about psychological factors that might increase or decrease the negative effects. Dispositional optimism, defined as the tendency to expect the future to turn out well, is a robust predictor of positive mental and physical health. However, little research attention has addressed what happens when optimistic people experience objectively negative outcomes (such as a failed IVF cycle).

Study design, size, duration: A prospective longitudinal cohort study over an 18 month period was employed. Women were recruited from five fertility practices. Women completed interviews and questionnaires at baseline (shortly after their initial fertility consultation) and 4, 10, and 18 months later. This report concerns the 201 women who initiated their first IVF cycle during the study period.

Participants/materials, setting, methods: Dispositional optimism (Life Orientation Test, Revised; LOT-R), depression (Center for Epidemiological Study of Depression scale; CESD; > 15 is at risk), and anxiety (State Trait Anxiety Inventory; STAI; > 39 is at risk) were measured at baseline. CESD and STAI were repeated at follow-ups. IVF outcome was categorized as "success" (pregnancy) or "failure" (incomplete, not pregnant, or miscarriage). For this report, post-IVF depression and anxiety scores were taken from the first follow-up after the IVF.

Main results and the role of chance: Mean baseline CESD was 10.96 (SD=9.02) and mean post-IVF CESD was 14.73 (SD=10.50). Mean baseline STAI was 40.06 (SD=11.54) and mean post-IVF STAI was 42.05 (SD=13.54). The first IVF cycle was successful for 28% of the women. Regression models were used to assess study questions, with post-IVF CESD and post-IVF STAI scores entered as the outcome variables, respectively. Age, years trying to conceive, ethnicity, educational level, and baseline CESD and STAI (respectively) were entered as covariates; LOT-R, IVF outcome, and their interaction were entered as explanatory variables. Regarding post-IVF depression, after accounting for covariates, IVF outcome had a significant effect on CESD, such that women who had failed cycles had higher CESD scores compared to those with successful cycles (B = -3.89; p < .05). There was also a significant interaction effect (B = 0.58, p < .05), such that women with failed cycles who were high in LOT-R experienced similar CESD levels to women with successful cycles. The results followed an identical pattern for post-IVF anxiety, with the model showing a significant main effect for IVF outcome (B = -5.98; p < .01), as well as a significant interaction effect (B = 0.84; p < .05.).

Limitations, reasons for caution: This study was not a randomized trial, nor did we attempt to manipulate any variables. Therefore, we cannot provide proof regarding a causal relationship of any variables. Also, we do not know if these findings extend to fertility treatments other than IVF or to those who experience ongoing failure.

Wider implications of the findings: The expectation of positive outcomes does not put women at risk for poor psychological adjustment when IVF fails; instead it seems to protect them from elevated distress. The ability to imagine positive outcomes in the future could be a modifiable cognitive target for preventive mental health interventions for IVF patients.

Trial registration number: NA.

P-567   A systematic review and narrative report of the profound psycho-socio-cultural consequences of the growing burden of infertility in developing countries

M. Dahiya[1], M. Bhatia[2], S. Egbert[2]

[1]Nova IVI Fertility, Reproductive Medicine, New Delhi, India
[2]Nova IVI Fertility, Clinical Counselling, New Delhi, India

Study question: Does the growing incidence of infertility have a detrimental psycho-socio-cultural impact on the well-being of individuals particularly in developing countries?

Summary answer: Citizens of developing countries distinctively face negative consequences of infertility like social stigma, lack of economic security and taboos against adoption to a greater degree.

What is known already: Infertility has a negative impact on the psycho-socio-cultural being of individuals both in developed and developing countries. The degree of availability of reproductive technology plays a major role in shaping perceptions of and responses to infertility thereby distinguishing between the psycho-socio-cultural impact in developed and developing nations. Infertility is treated as a medical condition with psychological consequence rather than a socially-constructed reality. In developing countries, bearing children is considered necessary for marital completion. Childlessness is associated with poorer adjustment and greater intra-personal vulnerability. Intrinsic religiosity, sexual satisfaction and familial support are associated with better coping and adjustment.

Study design, size, duration: Online databases were searched for articles published from January 1990 till October 2016 regarding the psycho-socio-cultural effects of infertility in consultation with a search methodologist using the desired key-words. In the case of double publications, the latest study was included. Studies published only as abstracts and those from other parts of the world apart from developing countries were excluded. Relevant journals and conference abstracts that were not covered in the databases were also hand searched.

Participants/materials, setting, methods: There were 120 studies on the psycho-socio-cultural impact of infertility that met the inclusion/ exclusion criteria. It was not possible to pool the data due to heterogeneity in the study design and methods, therefore, a systematic review and narrative report was compiled. After a primary screen of all titles and abstracts retrieved, the full texts of all potentially eligible studies were retrieved. Study investigators were contacted if clarification was needed for study eligibility.

Main results and the role of chance: Children are considered as indicators of wealth and prosperity in a community Parenthood is highly emphasized in developing societies as children are required for care and maintenance of older parents. In childless couples, the status, respect and authority are compromised. Features like lack of economic security and care in old age, social stigma, concerns based on ideology and religious beliefs, hindrance in adoption and ethical concerns are unique to the societies of developing countries which face the negative consequences of infertility to a greater degree. The infertile couples are treated as outcasts and lack equal opportunities in social and religious functions. The psychological effects manifest in form of anxiety, depression, feelings of blame and guilt when the couples feel that the reality of life without children is too much to handle. Social consequences range from stigmatization, alienation and strained social interactions. Partners and families may be abusing the women as a result of childlessness. Culturally, taboos against adoption, donor gametes, embryo freezing impede the treatment. All these features put together shape the consequences of infertility. Hence, infertility is a poorly controlled chronic stressor especially in the developing countries where the poor cannot access reproductive techniques.

Limitations, reasons for caution: Prospective case-control studies would overcome the retrospective nature of our study. Heterogeneity in the design

and methods of the selected studies making it difficult to pool the data is another limitation.

Wider implications of the findings: There is a dire need for addressing the infertility crisis by facilitation and prioritization of treatment and bringing about a radical change in the attitude to the problem of infertility in developing countries. Efforts should be tailored towards empowering women especially to handle domestic abuse

Trial registration number: not applicable.

P-568   The effect of introducing Reproductive Life Plan-based counselling during men's sexual health visits: a randomized controlled trial

M. Bodin[1,2], T. Tydén[1], L. Käll[2], M. Larsson[1]

[1]Uppsala University, Department of Women's and Children's Health, Uppsala, Sweden
[2]Uppsala University, Centre for Gender Research, Uppsala, Sweden

Study question: Can reproductive life plan-based counselling during a sexual health visit increase men's fertility awareness?

Summary answer: Three months after the counselling session, fertility awareness was moderately increased.

What is known already: Several studies indicate that many men have limited fertility awareness and are in need of preconception health counselling. Still, preconception counselling directed towards men is unavailble in several European countries. The Reproductive Life Plan (RLP) is a tool that was developed in the US to encourage people in reproductive age to reflect on their reproductive intentions and find strategies to reach their goals. No studies have as far as we know evaluated the use of RLP during health consultations with men.

Study design, size, duration: A randomized controlled trial took place in Sweden October 2014-February 2016. In total 229 men were recruited to the study and randomized; 118 to intervention (IG) and 111 to control group (CG). The randomization was blind to the participant. All participants received standard care. The intervention group also received brief information about preconception health guided by the RLP-tool. The health visit lasted about 15 minutes. Follow-up was made by telephone after three months.

Participants/materials, setting, methods: Recruitment took place at two sexual health clinics located in two major cities. Most men attended the clinics at drop-in hours for STI-testing. Fertility awareness was measured by a questionnaire, before the intervention and at follow-up. The participants were also asked about their impression of the intervention. To evaluate the effectiveness of the intervention on fertility awareness, knowledge scores were calculated and the difference between baseline and follow-up was analyzed by Paired samples t-test.

Main results and the role of chance: The baseline measurements include 201 men (28 men dropped out/had to be excluded after randomization). Mean age was 28 years. Twenty-one men were fathers already, and 71% wanted to have (more) children in the future. There was no difference in background characteristics between IG and CG. The follow-up sample consisted of 78 men from IG and 82 men from CG. The total score measuring fertility awareness, which was based on 6 questions (maximum 12 points), increased from 4.6 ± 2.1 to 5.5 ± 2.2 points ($p = 0.004$) in IG. There was no improvement in the CG (4.6 ± 1.9 to 4.7 ± 2.3, $p = 0.693$). The average number of lifestyle factors affecting male fertility mentioned by the participants increased from 3.6 ± 1.9 to 4.4 ± 1.6 ($p < 0.001$) in IG. There was no improvement in CG (3.4 ± 1.7 to 3.5 ± 1.5). The intervention had now effect on at what age men wanted to become fathers. In IG, 76% had a fairly or very positive experience of the counselling and 76% had received new information. Almost all men (95%) agreed that it is important to educate men about these matters.

Limitations, reasons for caution: The generalizability is limited by the fact that recruitment took place in urban areas and the sample consisted of men who already proved some health awareness by attending an STI-clinic. Long waits at the clinics could explain why some men dropped out before the intervention took place.

Wider implications of the findings: The effectiveness of the intervention is comparable to a similar study with female university students (Stern et al, 2015).

The counselling was positively received and led to new thoughts about fertility and reproductive health. Discussing RLP during health visits could thus be a gateway to increased fertility awareness.

Trial registration number: ClinicalTrials.gov Identifier: NCT02736214.

P-569   A re-examination of the factor structure of Traditional Chinese FERTIQOL with subfertile women undergoing ART

B. Lau, C. Chan, M. Tam, Q. Wong

University of Hong Kong, Department of Social Work and Social Administration, Pokfulam, Hong Kong

Study question: What is the factor structure of the Traditional Chinese FertiQOL for Chinese women undergoing ART?

Summary answer: Five factors were revealed for the 24 core items of the Traditional Chinese FertiQoL, whereas a 2-factor structure was recovered for the 10 treatment items.

What is known already: FertiQOL has been widely used to measure quality of life in cases of subfertility. Validation studies have been conducted with Dutch, Korean and Taiwanese samples. However, the factor structure of the core and optional treatment items have yet to be scrutinized. A re-examination of the factor structure of FertiQOL will help reveal how Chinese subfertile women understand and construe the impacts of subfertility on their quality of life.

Study design, size, duration: This was a cross-sectional study. 477 Chinese female subfertile patients were approached and 246 completed the questionnaire (response rate: 51.6%). Their average age was 37.2 (SD = 3.4), married for 7.3 years (SD = 3.8) and diagnosed with subfertility for 4.0 years (SD = 2.5). Majority of them had prior experience with ART (66.3%), with a mean ART treatment history of 3.2 years. The study spanned two years.

Participants/materials, setting, methods: Participants were recruited from fertility clinic of a university-affiliated hospital in Hong Kong. Those who have given consent to participate were asked to complete a set of questionnaire including their demographics, reproductive history, ART treatment history and fertility related quality of life (FertiQoL).

Main results and the role of chance: A confirmatory factor analysis (CFA) was conducted to re-examine the fit of the 4-factor structure of the core items (Boivin et al., 2011) on the local dataset. The model fit was insufficient [chi-sq = 590.927, df = 246, p = .000. CFI = .882, RMSEA = .075]. The core items were then submitted to a principle component analysis with promax rotation. A 5-factor solution was recovered with 61.4% total variance explained [F1: "Emotion-physical impact" (items 1, 2, 3, 7, 8, 9, 16, 18, 23, 24); F2: "Social alienation" (items 10, 12, 13, 15, 17, 22); F3: "Couple coping efficacy" (items 19, 20); F4: "Satisfaction with relationships" (items 5, 6, 11, 21); F5: "General coping efficacy" (items 4, 14). Another CFA was run for the 2-factor structure (tolerability and environment) of the 10 treatment items, and an adequate model fit was found [chi-sq = 85.169, df = 34, p = .000, CFI = .939, RMSEA = .078]. Significant correlations with anxiety and depression scores supported the convergent validity of the core and treatment subscales (ps <.05). Results of sensitivity analyses suggest that older age and previous pregnancy was related to higher scores on tolerability, environment, emotion-physical impact and social alienation.

Limitations, reasons for caution: The 2 subscales with the lowest eigenvalues (satisfaction with relationships, general coping efficacy) in the core FertiQOL had low Cronbach alphas. The resultant factor solution requires verification with future studies. Self-selection bias and self-report nature of the survey is a concern.

Wider implications of the findings: Our alternative factor structure revealed how Chinese sub-fertile women construe their fertility related quality of life. While the emotional and physical impacts were merged into a single factor, the presence of four social-relational factors demonstrate a nuanced categorization of the social-relational impacts of subfertility.

Trial registration number: not applicable.

P-570   Does illness cognition mediates the adverse impact of traditional childbearing beliefs on mental health? - Directions for psychosocial interventions for women undergoing assisted reproduction technologies

M. Tam, C. Chan, B. Lau, Q. Wong

The University of Hong Kong, Department of Social Work and Social Administration, Hong Kong, Hong Kong

Study question: Does illness cognition mediate the adverse impact of traditional childbearing beliefs on anxiety and depression among Chinese women undergoing IVF?

Summary answer: Illness cognition (helplessness, acceptance, perceived benefits) significantly mediated the effect of childbearing beliefs on anxiety and depression among Chinese women undergoing IVF.

What is known already: The emphasis on honouring the family through procreation has contributed to the plight of sub-fertile couples and stigmatization of fertility treatment in many cultures. According to the stress and coping model of Lazarus and Folkman, appraisals of the stressor determine the outcomes of the stressful event. However, such theoretical framework has seldom been applied to examining the coping processes of sub-fertile women. This study fills the knowledge gap by exploring the mediation effects of patient's appraisal of their sub-fertility (i.e., illness cognition) on the adverse mental health impacts of adhering to traditional childbearing ideals among Chinese women.

Study design, size, duration: This was a longitudinal questionnaire study. Questionnaire data was collected at three time-points: baseline (T0), six weeks after (T1) and 3 months after (T2) with 151 infertile female patients. The study spanned two years.

Participants/materials, setting, methods: Participants were recruited from a fertility clinic in Hong Kong. On average, they were 37.2 years old (SD=3.3), married for 7.2 years (SD=3.7) and diagnosed with subfertility for 3.8 years (SD=2.3). At the time of study, majority had experience with ART (66.3%) and a 3.2 years mean treatment history. Measurements include Chinese Childbearing Belief Scale; Illness Cognition Questionnaire and Hospital Anxiety Depression Scale.

Main results and the role of chance: The mediation effects were explored by path analysis with 5000 bootstrapped samples using the PROCESS macro on SPSS 19.0. The summary score of the childbearing belief scale was entered as the independent variable. Illness cognitions (helplessness, acceptance, and perceived benefits) were entered as mediating variables. The dependent variables were the anxiety and depression subscales of HADS. Six models were conducted. Results show that helplessness and acceptance completely mediated the effect of childbearing beliefs on anxiety as well as depression, as the indirect effects were found to be significant (ps<.05) whereas the direct effects were not (ps > .05). The mediating effects of perceived benefits on anxiety and depression were significant but incomplete, with significant indirect and direct effects (ps<.05).

Limitations, reasons for caution: Self-selection bias at recruitment and self-reporting nature of the survey remains a concern.

Wider implications of the findings: Our findings highlight the importance of acknowledging the mental health impact of cultural ideals on adjustment to infertility. Our results also call for future psychosocial support to empower patients through reducing their sense of helplessness and capitalizing on their ability of acceptance and benefit-finding in the tormenting treatment journey.

Trial registration number: Nil.

P-571   Intrapersonal and interpersonal predictors of fertility-related distress - constructing holistic interventions for women undergoing ART treatments

H.Y. Chan[1], H.P. Lau[2], Y.J. Tam[1], S. Wong[1], H.Y. Ng[1]

[1]The University of Hong Kong - Queen Mary Hospital, Centre of Assisted Reproduction and Embryology, Hong Kong, Hong Kong
[2]The University of Hong Kong, Faculty of Social Science, Hong Kong, Hong Kong

Study question: Do psychospiritual and cultural factors predict subfertility related stress during ART treatments? How will such findings inform frontline practices in fertility counselling and psychosocial interventions?

Summary answer: Psychospiritual and cultural factors provided significant incremental predictability to subfertility stress beyond clinical factors among women receiving ART treatments

What is known already: ART treatments have long been understood as a stressful process for subfertile couples. For women in particular, not only does the clinical treatment physically demanding, the process is also known to inflict poor mental health outcomes, including depression and anxiety. Subfertility is a medical condition embedded with strong socio-cultural implications. Not being able to extend the family bloodline through reproduction is traditionally viewed as a biological, social, and moral failure in many cultures. In this light, this study examined the psychospiritual and cultural factors related to subfertility related stress among a group of Chinese women receiving ART.

Study design, size, duration: This was a cross-sectional study. 536 female subfertile patients who were going to undergo ART treatment were approached. 271 completed the questionnaire (response rate: 51.6%). The study spanned two years.

Participants/materials, setting, methods: Participants were recruited from a fertility clinic at a university hospital in Hong Kong. Their average age was 36.5 (SD = 3.2), married for 6.7 years (SD = 3.2) and received diagnosed for 3.8 years (SD = 2.4). Majority(68.3%) had prior ART experience (mean treatment history of 3.4 years).

Measurements include Fertility Problem Inventory (FPI), Holistic Well-being Scale (WHS), Traditional Childbearing Belief Scale (TCBS) and Childbearing Importance Index (CII).

Main results and the role of chance: A step-wise multiple linear regression was conducted with global FPI as the criterion variable. Statistical significance was indicated by $p < .05$. In Step 1, clinical characteristics including age, frequency of previous treatment, subfertility year, and causes of subfertility (unexplained, number of female causes, number of male causes) were entered. The 7 subscale scores of HWS were entered in Step 2. Lastly, child-bearing attitude was added to Step 3. Results showed that all three steps contributed significant incremental explanatory power to subfertility stress (Step 1: r2 change = .079, p = .008; Step 2: r2 change = .362, p = .000; Step 3: r2 change = .101, p = .000). In Step 1, younger age, unexplained cause, and female causes were significantly associated with greater subfertility stress. In Step 2, only younger age and female causes remained as significant clinical characteristics. Psychospiritual attributes including emotional vulnerability, spiritual disorientation, non-attachment, and spiritual self-care were significant predictors. Except for younger age, all the significant predictors of Step 2 preserved their statistical significance at Step 3. Childbearing attitudes added significant explanatory power after controlling for psychospiritual and clinical characteristics.

Limitations, reasons for caution: Self-selection bias and self-reporting nature of the survey remained a serious concern. The current study followed an ecumenical perspective in measuring spirituality. Future studies may explore how religious activities and affiliation impact subfertility stress.

Wider implications of the findings: Our findings showed psychospiritual and cultural factors offer significant incremental explanatory power on subfertility related stress beyond established clinical attributes. Support services should assist clients to draw on their psychospiritual strength and cope with cultural pressure imposed on their physical condition. An intervention model addressing multidimensional well-being will be discussed.

Trial registration number: Nil.

P-572   The importance of genetic parenthood for infertile men and women

S. Hendriks[1], K. Peeraer[2], I. Thijs[2], H. Bos[3], S. Repping[4], E. Dancet[5]

[1]Academic Medical Center- University of Amsterdam, Center for Reproductive Medicine, Amsterdam, The Netherlands
[2]Leuven University Hospital, Leuven University Fertility Centre, Leuven, Belgium
[3]University of Amsterdam, Faculty of Social and Behavioral Sciences- Research Institute of Child Development and Education, Amsterdam, The Netherlands
[4]Academic Medical Center- University of Amsterdam, Center for Reproductive Medicine, Amsterdam, The Netherlands
[5]Leuven University, Department for Reproduction and Regeneration, Leuven, Belgium

Study question: Do men and women turning to a fertility clinic prefer genetic over non-genetic parenthood and if so, what are their motivations?

Summary answer: Nearly all infertile men and women prefer genetic parenthood. The majority indicated that for nearly all motivations for becoming a parent, genetic parenthood was important.

What is known already: Clinicians assume that all infertile couples prefer genetic parenthood and, therefore, treatments with donor gametes are considered a last resource option. The exact strength of the preference of infertile men and women for genetic over non-genetic parenthood remains unclear, as do their precise motivations. Previous studies identified 30 motivations for genetic parenthood, and 51 motivations for parenthood for which a genetic link between the parents and their child is not strictly necessary, but might be deemed required. The relative importance of all these motivations has yet to be examined.

Study design, size, duration: A questionnaire was developed based on literature review, assessed by professionals with different backgrounds and pilot tested among patients. A postal cross-sectional survey disseminated the coded questionnaire among both the female and male partner of 201 heterosexual infertile couples after their first consultation at one of two Belgian fertility clinics. The study was carried out between October 2015 and May 2016

Participants/materials, setting, methods: The survey addressed: (i) the overall preference for genetic parenthood for themselves and for their partner, (ii) the importance of 30 motivations for genetic parenthood, (iii) the importance of 51 motivations for parenthood and whether genetic parenthood was, according to the respondent, necessary to attain these. To simplify presentation of the results, all 81 motivations were grouped into reliable categories of motivations using psychometric analyses.

Main results and the role of chance: A total of 104 women and 91 men completed the survey (overall response rate: 49%). Almost all respondents (98%) favoured genetic over non-genetic parenthood for both their partner and themselves. One third of the respondents stated they only wanted to parent a genetic child. Achieving genetic parenthood for their partner was considered significantly more important than achieving genetic parenthood for themselves. In univariate analysis, being male and not university educated were significantly associated with finding genetic parenthood important; in multivariate only educational level remained significant. The 30 motivations for becoming a genetic parent clustered into eleven categories of which 'to experience a natural process' was deemed most important. The 51 motivations for becoming a parent for which a genetic link between the parent and child is not strictly necessary clustered into fourteen categories of which 'to contribute to a child's well-being' and 'to experience the love of a child' were most important. For 40 out of 51 of these motivations for parenthood, the majority of respondents indicated that being the genetic parent was needed to attain them.

Limitations, reasons for caution: We included couples that visited the fertility clinic for the first time, and the preference for genetic parenthood over non-genetic parenthood and motivations therefore might change during the course of treatment. Moreover, what prospective parents expect to be important for their future well-being might not really define parents' well-being.

Wider implications of the findings: The presumed preference of couples for genetic parenthood was confirmed. Resistance against using donor gametes is more likely among lower educated individuals. Researching whether non-genetic parents actually achieved their 51 motivations for parenthood for which a genetic link is not strictly necessary, could be a basis for developing patient information.

Trial registration number: Not applicable.

P-573   Online guidance through ART: design, development and qualitative evaluation of 'myFertiCare'

E.M. Sparidaens, K. Fleischer, A. Van Dongen, D. Braat, W. Nelen

Radboudumc, Obstetrics and gynaecology, Nijmegen, The Netherlands

Study question: Is it feasible to develop an online application to support couples undergoing Intracytoplasmic Sperm Injection with surgically retrieved sperm during their treatment trajectory?

Summary answer: A multi-faceted online application, called myFertiCare, has been designed, developed and qualitatively evaluated. It provides personalized and interactive features, tailored to patient- and professional preferences.

What is known already: The infertile patient population, mostly consisting of young, highly educated couples, wishes both partners to participate actively in their diagnosis and treatment process and values use of the Internet for health-related purposes. We hypothesized that an online application can be a suitable instrument to support couples during their full treatment trajectory. By providing personalized information and offering the opportunity of communication we aim to decrease infertility-specific anxiety and stress, increase knowledge, enhance patient-centred care and thus improve patient well-being.

Study design, size, duration: A qualitative study to identify patients' needs regarding E-health by means of a literature review and semi-structured in-depth interviews with 11 couples. Based on this, a functional design for the application was developed in collaboration with medical and technical professionals. Pilot-testing took place through 9 think aloud sessions in which patients executed tasks in myFertiCare, whereafter the functional design has evolved. Finally, later this year myFertiCare will be quantitatively evaluated in a larger population.

Participants/materials, setting, methods: The study started in 2014 in the Radboud university medical center in Nijmegen, the Netherlands. Eligible for participation were couples undergoing PESA/TESE-ICSI in this period. Consulted were professionals from both the urology and reproductive medicine department. For technical aspects of the design, both internal and external technical specialists with experience in E-health were involved. Currently, myFertiCare counts more than hundred unique users.

Main results and the role of chance: A multi-faceted online application, called myFertiCare, has been developed, which can be accessed using a computer, tablet or smartphone. The application is tailored to patient- and professional preferences based on qualitative research. It contains personalized features like the visualized treatment trajectory of each individual, which forms the base of the application. This provides insight into scheduled and yet unscheduled future appointments, accompanied by information tailored to the specific phase of the treatment trajectory. Furthermore, couples are provided access to their diagnostic results and to a personal checklist to help them comply with the prescribed regimens before being eligible for treatment. The application also provides interactive features, namely a forum where couples can interact with peers, which is joined by care providers. It is also possible to target private questions to an individual care provider.

During the pilot phase, myFertiCare has been qualitatively evaluated and based on these results the functional design has evolved. The login method was simplified to improve accessibility. Furthermore, improvements mainly consisted of small textual changes. Later, a quantitative evaluation will be performed according to an established framework focused on human, organization and technology factors to conclude successful implementation.

Limitations, reasons for caution: Although myFertiCare has been thoroughly designed and successfully pilot-tested, the quantitative evaluation will indicate if the application is successfully implemented. Limitations of the study include the single center design and the relatively small subgroup of infertile patients, namely couples undergoing PESA/TESE-ICSI.

Wider implications of the findings: By providing personalized and interactive features, we speculate that myFertiCare will enhance patients' participation with their treatment. This way, it offers the opportunity to improve patient-centeredness in fertility care. After successful implementation for couples undergoing PESA/TESE-ICSI, the concept can probably be extended to all infertile patients and other fertility clinics.

Trial registration number: not applicable.

P-574   Impact of Assisted Reproductive Technologies (ART) on sexual behaviors in infertile couples

S. Mendret-Pellerin[1], S. Ploteau[2], P. Massart[1], P. Barriere[1], T. Freour[1,3,4]

[1]Hospital University of Nantes, Department of Reproductive Medicine, Nantes, France
[2]Hospital University of Nantes, Department of gynecological surgery, Nantes, France
[3]INSERM, UMR 1064, Nantes, France
[4]University of Nantes, Faculty of Medicine, Nantes, France

Study question: How and when does ART impact sexual life of infertile couples?

Summary answer: The prevalence of sexuality impairment is relatively high in infertile couples, both in men and women, the most critical period being ovarian stimulation.

What is known already: Infertility diagnosis is often experienced as a major stressor by couples, exposing them to a high risk of impaired sexual function and subsequently degraded quality of life.

Data about the sexuality of infertile couples undergoing ART are sparse, most studies being conducted in limited samples and using heterogeneous methods. Moreover, the most critical period for couples, as well as the respective impact of ART on women and men have not been clearly identified. As the use of ART increases worldwide, it is essential to explore the sexual outcomes associated with fertility treatments in order to improve medical support and counselling.

Study design, size, duration: This multicentric cross-sectional study was conducted in 31 French ART centers over a 7-month period in 2009. A multi-disciplinary panel of specialists (psychologists, gynecologists, midwives) selected relevant items previously reported in the literature in order to develop a new questionnaire specifically designed to evaluate sexual behaviours in couples undergoing ART cycles. A total of 1442 questionnaires were distributed to both members of 721 infertile couples.

Participants/materials, setting, methods: The questionnaire was distributed to both members of heterosexual couples who recently experienced live birth after ART cycle (either IVF, IVF/ICSI or IUI). After oral explanation and consent obtainment, men and women were strongly asked to fill out the questionnaire separately. No demographic or medical selection criteria was applied. Questionnaires were then collected and sent for centralized statistical analysis.

Main results and the role of chance: Participation rate was high, with 647 women (89.7%) and 615 men (85.3%) filling out the questionnaire. Both members of the couple completed the questionnaire in 615 cases, leading to an overall participation rate of 85.3%. The majority of couples suffered from primary infertility (77% of women, 75% of men) and obtained live birth after IVF (or IVF-ICSI) cycle.

Patients were first asked to indicate how important they considered sexuality in their current lives. The majority of women and men reported that sexuality was quite important (45% in women, 48% in men). However, the proportion of men reporting that sexuality was very important was significantly higher than in women (29% vs 19%, $p < 0.0001$), whereas the proportion of women reporting that sexuality was moderately important or of little importance was higher than in men (30% vs 20%, $p = 0.0001$ and 5.5% vs 3%, $p = 0.04$). The overall proportion of couples reporting sexuality impairement was 72% in women and 54% in men. Most participants identified ART treatment, i.e. controlled ovarian hyperstimulation, as the most critical period (31% in men and women). No significant difference could be observed in men and women according to the etiology of infertility (male, female, mixed or idiopathic) and its duration.

Limitations, reasons for caution: First, we chose not to use a validated questionnaire such as Female Sexual function index or GRISS, as these questionnaires might not be absolutely relevant in our study. Second, our results should not be extrapolated to all infertile couples, as we only included couples who had a live birth.

Wider implications of the findings: We confirm the relatively high prevalence of sexuality impairement in infertile couples. ART treatment seems to be the most critical period for infertile couples' sexuality, while infertility type or duration does not seem to impact significantly sexuality.

Trial registration number: not applicable.

P-575   Mindfulness-based intervention for lifestyle modification and weight loss in infertile women: randomized controlled trial

E.M. Sant'Anna[1], S.P.C. Paiva[1], R.P. Santos[1], A.M. Rodrigues[2], S.F. Nery[1], F.P. Maia[2], A.V.M. Ferreira[2], F. Reis[3]

[1]Universidade Federal de Minas Gerais, Division of Human Reproduction, Belo Horizonte, Brazil
[2]Universidade Federal de Minas Gerais, Department of Nutrition, Belo Horizonte, Brazil

[3]Hospital das Clinicas da Universidade Federal de Minas, Dept. of Obstetrics and Gynecology, Belo Horizonte, Brazil

Study question: Does a mindfulness-based stress reduction program improve weight loss through lifestyle modification in infertile women?

Summary answer: Mindfulness-based intervention does not improve weight loss during a short term (12 weeks) lifestyle modification program.

What is known already: Weight loss is a first line therapeutic goal for infertile women who are overweight or obese. This is particularly important in the polycystic ovary syndrome, as weight loss may contribute significantly to reduction of circulating levels of insulin and androgens. However, compliance to lifestyle modification is usually poor. Strategies based on psychological support and complementary interventions have been developed in order to improve adherence and maintenance of a healthy lifestyle. In this study, we evaluated the short-term impact of a mindfulness-based stress reduction program on the body measurements of overweight/obese infertile women seeking weight loss through lifestyle modification.

Study design, size, duration: The participants were randomly assigned to 8 consecutive weekly sessions of mindfulness-based intervention (n = 51) or no intervention (n = 49). All participants from both groups received a customized dietary plan and instructions to perform regular physical exercise. Body measurements were performed at baseline and 12 weeks later. The primary outcome was body weight. Secondary outcomes were waist circumference, hip circumference, and quality of life (QOL).

Participants/materials, setting, methods: The participants were infertile women aged 18-48 years (median 37 years) with body mass index > 25 Kg/m^2 (median 31 Kg/m^2) attending a reproductive endocrinology unit of a teaching hospital between January 2015 and March 2016. Body measures were obtained by trained personnel, blinded to the patient intervention group. QOL was assessed by the Psychological General Well-Being Index (PGWBI) questionnaire.

Main results and the role of chance: There was a mean reduction of 1.8 kg in the intervention group (p = 0.002, paired Wilcoxon's test) and mean reduction of 1.0 kg in the control group (p = 0.022). There was an average reduction of 1.5 cm of waist circumference in the intervention group (p = 0.007) and 0.8 cm in the control group (p = 0.633). Hip circumference shortened 2.0 cm in the intervention group (p = 0.002) and 0.3 cm in the control group (p = 0.100). The intervention group also showed a significant improvement in QOL (23 percent gain in PGWBI total score, p = 0.001), which was not observed in the control group (0.9 percent variation, p = 0.829).

Limitations, reasons for caution: This was a short term program, therefore the lack of benefit of mindfulness intervention on weight loss compared to no intervention may only reflect the limited follow-up. This is reinforced by the fact that only the intervention group had a significant (although modest) reduction of waist and hip circumferences.

Wider implications of the findings: Although we did not observe an impact on body weight, this study shows that mindfulness-based intervention favors waist and hip circumference reduction and improves the patient QOL. An extension study should evaluate if these benefits last longer and eventually contribute to weight loss.

Trial registration number: RBR-7by76r

P-576   The effectiveness of mindfulness-based stress reduction program on infertility stress, psychiatric symptoms and quality of infertile women's life

N. Bagheri Lankarani[1], **M. Aslezaker**[2], **S. Abbas Pour**[2], **P. Mohamad Khani**[2]

[1]Royan Institute, Department of Epidemiology and Reproductive Health- Reproductive Epidemiology Research Center- Royan Institute for Reproductive Biomedicine- ACECR, Tehran, Iran
[2]university of social welfare and rehabilitation sciences, Department of clinical Psychology, Tehran, Iran

Study question: What is the effectiveness of mindfulness-based stress reduction program on infertility stress, psychiatric symptoms and quality of infertile women's life?

Summary answer: Intervention of mindfulness-based stress reduction decreases the Infertility stress, the psychological symptoms & increases quality of life in infertile women.

What is known already: Studies that have examined the impact of psychological factors on infertility treatment, indicate that psychological factors not only in times have got far-reaching impact on the daily lives of the infertile patients, but they also affect treatment outcomes and in some cases they hinder the success of treatment.One of the variables that affect the response to treatment in patients with infertility treatment and should be considered is the stress of infertility.Infertility experience that some have called it Infertility crisis is associated with physical, economic, psychological and social stresses that affect all aspects of a person's life.

Study design, size, duration: The method of this study is quasi-experimental (pre-test and post- test) with a randomly assigned control group. The population is the entire women who referred to Royan Institute. In this study, sampling is targeted and the sample size is 150 persons that after pre-test evaluations were randomly assigned to two experimental groups and one control group that eventually the number of people in each group had 75 patients.

Participants/materials, setting, methods: 24 people of the total 75 patients in the experimental group were excluded due to lack of participation in the course of the study and a total of 51 for final data analysis in the group were tested. 49 people of 75 patients in the control group finally attended to complete the post-test and retained criteria for participation in the study.

Main results and the role of chance: *The results indicated that one can say with 95% confidence that overall score of concise syndrome and infertility stress (social concerns, worries about relationships, rejecting childless life, need for parenthood) in the two groups with controlling the effect of pre-test suggest that after the presence of infertile women in the mindfulness-based stress reduction sessions, the scores has had a significant decrease compared to the members of the control group. Also one can say with 95% confidence that the quality of infertility life score (quality of mind-body life, quality of relationship life, quality of social life and quality of life all in all) in the two groups with controlling the effect of pre-test suggest that after the presence of infertile women undergoing ICSI / IVF in mindfulness-based stress reduction sessions, the score of the members who participated in the experimental group has had a significant increase (005/0 P <, 007/33 = (1.94) F) compared with the control group.*

Limitations, reasons for caution: the incidence of personality conflicts in these couples, especially those who have experienced treatment failure is dramatic, that these factors also affect the treatment outcome.

Wider implications of the findings: the therapeutic components of mindfulness-based stress reduction techniques such as running the meditation, mindfulness techniques, increasing awareness and inner consciousness, increasing distress tolerance, identifying physical and emotional sensitivity, training to identify and replace dysfunctional and negative beliefs and thoughts and increasing health and inner peace.

Trial registration number: not applicable.

P-577   Psychosocial guidance of mothers of donor-children

F.B. Van Rooij[1], **A. Schrijvers**[1], **M. Mochtar**[2], **H. Bos**[1], **E. De Reus**[3], **G. Overbeek**[1], **M. Visser**[2], **F. Van der Veen**[2]

[1]University of Amsterdam, Child Development and Education, Amsterdam, The Netherlands
[2]Academic Medical Centre Amsterdam, Centre for Reproductive Medicine- University of Amsterdam, Amsterdam, The Netherlands
[3]MCK medical centre child wish, Psychology, Leiderdorp, The Netherlands

Study question: Are there associations between unmet needs for guidance of mothers of donor-children in father-mother, two-mother, and single-mother families and their parenting experiences and wellbeing?

Summary answer: Mothers in father-mother families have more unmet needs for guidance and the lack of guidance is associated with more parenting problems and less wellbeing.

What is known already: Previous studies showed that most mothers of donor-children have questions and needs in relation to donor conception (e.g., how to disclose, relationship with non-biological parent, influence of possible

contact with donor). It is unclear whether mothers find appropriate guidance for these needs and whether there is a relation between unmet needs for guidance of mothers of donor-children and parenting experiences and mothers' and childrens' wellbeing.

Study design, size, duration: Cross-sectional study (online questionnaire) among 223 Dutch mothers of donor-children born since 2004, the year in which Dutch law prohibited donor sperm treatment with anonymous donor sperm. We recruited mothers between January 2016 and January 2017 both inside and outside the Dutch clinics.

Participants/materials, setting, methods: Mothers (N = 223; Mage = 36.85, SD=4.63) in father-mother (n = 60), two-mother (n = 75) and single-mother (n = 82) families with a donor-child between 0-15 years old (Mage=3.00, SD=2.29, range=0-15) filled out an online questionnaire. This questionnaire existed of validated instruments to measure unmet needs for guidance, parenting experiences (subscales: co-parenting satisfaction, parental burden, emotional involvement, parental concern), mother's wellbeing (subscales: psychosocial problems, partner relationship satisfaction), child's wellbeing (only for children aged 1,5 and older).

Main results and the role of chance: Mothers reported the highest unmet needs for guidance regarding the future contact between the donor and the donor-child and possible impact of this contact on the relationship with the non-biological parent. We found significant correlations between the mothers' unmet needs for guidance and family type, negative parenting experiences, co-parenting satisfaction, psychosocial problems of the mother, partner relationship satisfaction, and psychosocial problems of children aged 1,5-5. The more unmet needs for guidance related to being a parent of a donor-child mothers had, the less co-parenting satisfaction, the more parenting stress, the more concerns about their children by the mothers, the more psychosocial problems of the mother, the less partner relationship satisfaction and the more psychosocial problems for the child. Mothers in father-mother families had more unmet needs for guidance than those in two-mother families.

Limitations, reasons for caution: Causality can not be assessed, due to the cross-sectional design. Most mothers had children between 1,5 and 5 years old (0-1,5: n = 42, 1,5-5: n = 150, 6≥ n = 31). Therefore, caution is needed by generalizing these results to mothers of older and younger donor-children.

Wider implications of the findings: Guidance to help mothers cope with the uncertainties regarding possible future contact between their child and the donor should be made available.

Trial registration number: Not applicable. Ethical clearance by Medical Ethical Committee of the Academic Medical Centre of the University of Amsterdam (NL53349.018.15)

POSTER VIEWING SESSION
REPRODUCTIVE (EPI)GENETICS

P-578 The development and clinical evaluation of non-invasive chromosomal screening (NICS) assay

S. Lu[1], L. Cai[2], B. Yao[3], X.S. Xie[4]

[1]Yikon Genomics Co.- Ltd., Department of Clinical Research, Shanghai, China
[2]Wuxi Maternity and Child Health Hospital Affiliated to Nanjing Medical University, Reproductive Medical Center, Wuxi, China
[3]Nanjing University School of Medicine, The Reproductive Medical Center of Nanjing Jinling Hospital and the Collaborative Innovation Platform for Reproductive Biology and Technology, Nanjing, China
[4]Harvard University, Department of Chemistry and Chemical Biology, Cambridge, U.S.A.

Study question: This study involves the development and clinical evaluation of a biopsy-free and non-invasive preimplantation genetic screening (PGS) technique.

Summary answer: Both *in vitro* and clinical study demonstrated that the NICS assay was a reliable approach for chromosomal analysis of *in vitro* fertilized embryos.

What is known already: Conventional PGS involves the blastomere or trophectoderm biopsy from embryos at an early developmental stage. These procedures are invasive and technically challenging. Plus, the long-term effect of embryo biopsy has not been fully investigated. A prior study showed that the genetic materials from the blastocoele fluid could be an alternative source for PGS testing. In addition, genomic and mitochondrial DNA was detected in embryo culture medium, which suggested the possibility of using culture medium for preimplantation chromosomal screening.

Study design, size, duration: We developed a non-invasive chromosomal screening assay that used embryo culture medium for identifying chromosomal abnormalities of *in vitro* fertilized embryos. The technique was first validated by *in vitro* experiments followed by a clinical study.

Participants/materials, setting, methods: 16 couples undergoing *in vitro* fertilization (IVF) cycles were enrolled for the clinical study. 14 of them experienced idiopathic recurrent pregnancy loss or were diagnosed with chromosomal abnormalities including translocation, insertion, deletion, or duplication. Intracytoplasmic sperm injection (ICSI) was performed and embryos were screened for chromosomal abnormalities using the NICS assay before embryo transfer. Amniocentesis was performed at a later stage to confirm the karyotype of fetuses.

Main results and the role of chance: Among 16 couples, 14 of them had embryos passing the NICS assay. 1 or 2 embryos were selected to be transferred for each couple. A total of 20 embryos were transferred and 12 (60%) of them were successfully implanted. The pregnancy success rate of PGS using the NICS assay reached 78.6% (11/14). 5 pregnant participants received amniocentesis and all test results were normal. 5 babies were delivered and the cytogenetic analyses showed that the newborns were completely normal.

Limitations, reasons for caution: A larger scale clinical study may be helpful to further validate this technique.

Wider implications of the findings: This non-invasive and more simplified NICS assay may enable a wider application of PGS at IVF centers with different clinical settings.

Trial registration number: N/A.

P-579 Effects of high progesterone level on the day of human chorionic gonadotrophin administration in in-vitro fertilization cycles on epigenetic modification of endometrium in peri-implantation period

Y.J. Xiong[1], J.Z. Wang[1], L. Liu[2], X.Y. Chen[1], T.C. Li[1], C.C. Wang[1], S.Y. Zhang[2]

[1]The Chinese University of Hong Kong, Department of Obstetrics and Gynaecology, Hong Kong, Hong Kong
[2]Sir Run Run Shaw Hospital, Department of Obstetrics and Gynaecology, Zhejiang, China

Study question: Does high progesterone on the day of human chorionic gonadotrophin (hCG) administration in IVF cycles affect epigenetic modification of endometrium in the peri-implantation period?

Summary answer: DNA methylation, histone modification levels were increased in the endometrium of patients with high progesterone level on the day of hCG administration in IVF cycles.

What is known already: Epigenetic modification in the endometrium plays an important role in the regeneration, proliferation, angiogenesis and implantation, but the underlying mechanism is still not fully understood.

Study design, size, duration: A single-centre, retrospective cohort study between June 2013 and December 2013 included 40 infertile women, 20 women with normal progesterone and 20 women with high progesterone on the day of hCG administration after controlled ovarian hyperstimulation in an in vitro fertilization cycles.

Participants/materials, setting, methods: Endometrial tissues were collected 7 days after hCG administration in women with normal or high progesterone levels on the day of hCG administration. Immunohistochemical staining of DNA methylation (5-methylcytosine, 5-mC), histone methylation (H3K4me2/3, H3K9me2, H3K27me3) and histone acetylation (H3K4ac, H3K9ac) were performed.

Main results and the role of chance: In luminal epithelium, the expression of H3K9me2 in high progesterone group was significantly higher than that in normal progesterone group. In glandular epithelium, the expression of 5-mC,

H3K9me2, H3K9ac in high progesterone group were significantly higher than that in normal progesterone group. In stroma, the expression of H3K27me3 in high progesterone group was significantly higher than that in normal progesterone group. 5-mC in glandular epithelium, H3k9me2 in glandular and luminal epithelium and H3K27me3 in stroma were significantly correlated with progesterone levels. H3K9me2 in glandular epithelium were significantly correlated with estrogen levels.

Limitations, reasons for caution: The expression was examined with immunohistochemical staining which was semi-quantitative. The sample size was not sufficiently large to permit in depth analysis of confounding variables.

Wider implications of the findings: Altered epigenetic modification status of the endometrium may dysregulate the expression of genes which then adversely affect endometrial receptivity in women with high progesterone on the day of hCG administration.

Trial registration number:

P-580   A novel mutation in the C10orf2 gene causes Perrault Syndrome with primary ovarian insufficiency

S. Zhao, G. Li, W. Wang, Y. Qin, Z.J. Chen

Shandong University, Center for Reproductive Medicine, Jinan, China

Study question: To determine the genetic cause of a family with Perrault syndrome.

Summary answer: A novel mutation in the *C10orf2* gene was identified and resulted in functional defects of mitochondria.

What is known already: Primary ovarian insufficiency (POI) occurs in either isolated or syndromic forms. Perrault Syndrome is characterized by typical POI and sensorineural hearing loss. The causative mutations have been identified in five genes including *HSD17B4, HARS2, LARS2, CLPP* and *C10orf2*.

Study design, size, duration: Genetic and functional studies were performed to illustrate the etiology and pathogenesis of Perrault Syndrome.

Participants/materials, setting, methods: Whole exome sequencing was completed on five members of the Perrault syndrome family, and Sanger sequencing was used to confirm the results. The immortalized cell lines were generated by infecting lymphocytes from the family members with Epstein-Barr (EB) virus *in vitro*, and the subsequent experiments were carried out to measure ATP level, reactive oxygen species (ROS), mtDNA copy number and oxygen consumption rate.

Main results and the role of chance: A new homozygous mutation c.1388 G>A (p.R463Q) was identified in the helicase domain of the *C10orf2* gene, which encodes a hexameric DNA helicase in mitochondria and plays a critical role in mtDNA replication. The results of the functional studies *in vitro* showed that this homozygous alteration decreased the mtDNA copy number, ATP production, and especially the maximal respiration potential in the immortalized lymphocytes. However, the ROS level and mitochondrial ultrastructure remained unaffected.

Limitations, reasons for caution: The functional studies were carried out using immortalized lymphocytes but not oocytes or ovarian cells, which may not display direct impairment of the ovarian function.

Wider implications of the findings: Our study provided the evidence that the *C10orf2* gene mutation caused Perrault Syndrome with functional defects of mitochondria, suggesting the important role of mitochondria in ovarian function and POI pathogenesis.

Trial registration number: None.

P-581   Paternal parameters do not affect embryo ploidy: male age, semen quality, and PGS/NGS outcomes in oocyte-donors with normal karyotyping

T.H. Chuang[1], C.Y. Chen[2], M.J. Lee[2], H.H. Lai[1], H.L. Wang[1], C.L. Hsieh[1]

[1]*Stork Ladies Clinic, Stork Fertility Center, Hsinchu, Taiwan R.O.C.*
[2]*Stork Fertility Center, Medical Research, Hsinchu, Taiwan R.O.C.*

Study question: What is the correlation between paternal parameters and embryonic/individual euploid rates in oocyte-donors with normal karyotyping?

Summary answer: Paternal parameters do not affect euploid rate while oocyte quality was good, and donated-oocyte recipient with lower euploid rates do not have poor semen quality.

What is known already: The correlation between advanced male age and decreasing sperm quality has been indicated in the previous report, but the effect to embryonic chromosomal constitution remains unclear. Although increasing risk of sex chromosome aneuploidy was reported in the suboptimal sperm samples, no significant effect of paternal parameters to final reproductive outcomes in the oocyte-donor cycles was observed.

Study design, size, duration: A retrospective cohort study during 2015 to 2016, a total of 526 embryos screened by next-generation sequencing (NGS) from 131 oocyte-donor cycles were included.

Participants/materials, setting, methods: The association among male age, semen parameters (volume, concentration, percentage of progressive motility, total progressively motile sperm count, morphology), and embryo ploidies diagnosing by high-resolution NGS (aneuploid, mosaic, euploid) was analyzed in the oocyte-donor cycles (mean donor age: 25.6 years, all the donors went through chromosomal karyotyping). The initial semen state in patients with lower euploid rates than the average was compared with that of controls.

Main results and the role of chance: No significant relationship between male age and embryonic euploid rate was found: 57.0% in < 34 years, 57.3% in 35-40 years, 63.0% in 41-45 years, 55.9% in 46-50 years, 57.7% in >50 years; and the pure mosaicism rate (diploid/aneuploid mixture) did not decrease with increasing male age. With cutoffs according to WHO 2010 semen analysis guidelines, no differences in ploidy distribution were observed between the groups with normal and poor semen parameters. On the other hand, the means of each parameter showed no different among the aneuploid, mosaic, and euploid embryos. In patients with lower euploid rate than the average (< 58.2%), their paternal parameters displayed similar with those of controls (age: 42.7 years vs. 42.5 years; volume: 2.9 ml vs. 3.1 ml; concentration: 55.1×10^6 vs. 59.0×10^6; progressive motility: 22.4% vs. 25.9%; morphology: 1.4% vs. 1.4%; total progressively motile sperm count: 3598×10^4 vs. 4634×10^4). Moreover, no differences were found between the twice semen states in 11 patients taking the second oocyte-donor cycle due to poor euploid rate at the first cycle.

Limitations, reasons for caution: Half of cycles (47.1%) used frozen sperm samples which would be bias due to poorer viability after thawing. ICSI was mostly performed for both the patients with frozen-sperm and patients with poor semen parameters, and thus the outcomes could be masked.

Wider implications of the findings: The present study suggested that paternal parameters do not significantly affect embryonic chromosomal constitution in the oocyte-donors with normal karyotyping, indicating that good oocyte quality could withstand the adverse potential of poor sperm samples.

Trial registration number: Not applicable.

P-582   Preimplantation genetic diagnosis in Portuguese patients with Corino de Andrade disease

R. Lopes[1,2], M. Sousa[1], J. Silva[3], V. Paulo[3], C. Oliveira[3], J. Teixeira da Silva[3], L. Ferraz[4], T. Coelho[5], F. Carvalho[6], @.AS.UP.PT] Barros[3,6]

[3]*Centre for Reproductive Genetics A. Barros (CGR) Av. do Bessa, 240, 1° Dto. Frente*
[4]*Department of Urology, Hospital Eduardo Santos Silva, Hospital Centre of Vila Nova de Gaia*
[5]*Department of Neurophysiology, Research Center of Corino de Andrade (Paramyloidosis) Hospital Centre of Porto, Largo Prof. Abel Salazar*
[6]*Department of Genetics, Faculty of Medicine, University of Porto and Institute of Health Research an Innovation I3SUP*

Study question: Do patients with Corino de Andrade disease, either asymptomatic or after treatment, have normal reproductive capacity?

Summary answer: Female patients (clinical pregnancy) and transplanted patients (implantation, clinical pregnancy, live birth delivery and newborn) show worst clinical outcomes.

What is known already: There are no large studies on clinical outcomes of patients with Corino de Andrade disease treated with preimplantation genetic diagnosis (PGD) for the prevention of the disease. Previous studies on the subject refer to the first 7 cases treated with PGD, where authors established the molecular diagnostic test, and a later a case report.

Study design, size, duration: Retrospective evaluation of 47 consecutive treatment cycles using PGD for the treatment of patients with Corino de Andrade disease (Portuguese patients presenting Transthyretin-related hereditary amyloidosis-ATTR). This study was conducted at the Centre for Reproductive Genetics A. Barros between 2000 and 2013 (13 years).

Participants/materials, setting, methods: The groups analysed were: total cases (28 patients, 47 cycles), cases with female ATTR (11 patients, 22 cycles), cases with male ATTR (17 patients, 25 cycles), asymptomatic cases (14 patients, 19 cycles), symptomatic cases (14 patients, 28 cycles), liver transplanted cases (10 patients, 22 cycles) and Tafamidis treated patients (4 patients, 6 cycles). Demographic, stimulation, embryological, clinical and newborn outcomes were evaluated for each group.

Main results and the role of chance: Comparisons between female (11 patients-P, 15 embryo transfer cycles-ETC) and male (17 P, 16ETC) patients revealed, in female patients, a significant higher dose of gonadotropins used, a lower number of high quality embryos (AB: **87%** vs 94%) and a lower clinical pregnancy rate (CP: **33%** vs 69%). No significant differences were found for the rates of fertilization (FR: 74% vs 76%), embryo cleavage (ECR: 98% vs 100%), blastocysts (BL: 42% vs 47%), implantation (IR: 29% vs 46%), live birth delivery (LBDR: 33% vs 63%) and newborn (NB: 8-53% vs 10-63%).

Comparisons between asymptomatic (14 P, 14ETC) and symptomatic (14 P, 17ETC) patients, revealed no significant differences for the rates of FR (78% vs 72%), ECR (98% vs 100%), AB embryos (91% vs 91%), blastocysts (44% vs 45%), IR (53% vs 33%), CP (64% vs 41%), LBDR (57% vs 41%) and NB (10-71% vs 8-47%).

Comparisons between transplanted (10 P, 14ETC) and Tafamidis taking (4 P, 3ETC) patients revealed no significant differences for the rates of FR (72% vs 77%), ECR (99% vs 100%), AB embryos (90% vs 96%) and blastocysts (43% vs 56%). Transplanted patients presented significant lower IR (**20%** vs 75%), CP (**29%** vs 100%), LBDR (**29%** vs 100%) and NB (5-**34%** vs 3-100%).

Limitations, reasons for caution: The major limiting factor is the low number of patients. However, CGR is one reference European center for performing PGD for patients with ATTR, and these are all cycles performed during this period of time.

Wider implications of the findings: Female patients presented a significant lower rate of high quality embryos and a significant lower clinical pregnancy rate, and a no significant lower rate of implantation and LBD. Transplanted patients presented a significant lower rate of implantation, clinical pregnancy, live birth delivery and newborn.

Trial registration number: None.

P-583   Comparison of blastocysts in PGD with GnRH antagonist and agonist protocol

K.L. Luo[1], G. Fei[2], H. Guo[3], G. Lin[4], G. Lu[4]

[1]Institute of Reproduction and Stem Cell Engineering-Central South University, ART centre, Changsha- Hunan, China
[2]Institute of Reproduction and Stem Cell Engineering-Central South University, ART centre, Changsha, China
[3]Reproductive & Genetic Hospital CITIC-Xiangya, the ART centre, Changsha, China
[4]Institute of Reproduction and Stem Cell Engineering, Central South University, the ART centre

Study question: To investigate the differences of blastocyst formation rate and aneuploidy rate between PGD with GnRH antagonist and agonist protocol.

Summary answer: For women performed PGD, antagonist protocol show advantages in both blastocyst formation rate and aneuploidy rate albeit with less MII oocytes and fertilized eggs.

What is known already: Whether blastocyst formation rate and aneuploidy rate are different in GnRH antagonist and agonist protocol is in dispute while most studies show that decreased number of eggs and embryos result in

decreased OHSS rate with uncompromised pregnancy rate in GnRH antagonist group.

Study design, size, duration: A before-after study in the same patient was conducted on 109 couples performed PGD from December 2012 to November 2016. PGD was performed to each patient for the reason of chromosomal aberrance. GnRH flexible antagonist protocol was applied to the patient if she failed the first cycle with agonist protocol or reversibly. The interval between the two cycles was limited to less than one year.

Participants/materials, setting, methods: The study was conducted at a Reproductive and Genetic Hospital. Blastocysts were scored according to the standard Gardner blastocyst grading system and laser assisted trophectoderm biopsy was performed on day 5 or 6 post oocytes retrieval. Comprehensive chromosome screening was performed with single-nucleotide polymorphisms or next generation sequencing. T-tests and chi-square test was used for statistical analysis.

Main results and the role of chance: Follicles with diameter$\geq$14 mm (9.78 $\pm$ 4.09) and MII oocytes recovered(8.08 $\pm$ 4.64) of antagonist group are statistically less than those of agonist group (12.19 $\pm$ 4.33 and 9.67 $\pm$ 4.23, respectively) (p < 0.01). Fertilized eggs of antagonist group are also less than that of agonist group (6.4 $\pm$ 4.28 vs. 7.91 $\pm$ 4.49, p<0.05). But there are no statistical differences between the two groups with the number of blastomeres (5.83 $\pm$ 4.11, 6.65 $\pm$ 4.13, p = 0.13), blastocysts (2.74 $\pm$ 2.65, 2.25 $\pm$ 2.24, p = 0.57) and aneuploidy blastocysts (0.679 $\pm$ 0.99, 0.954 $\pm$ 1.33, p = 0.21). Nevertheless, number of high-quality blastocysts is higher in antagonist group than in agonist group (1.073 $\pm$ 1.66, 0.679 $\pm$ 1.33, p<0.05). There are also statistical differences between the two groups (antagonist vs. agonist) with blastocyst formation rate (42.4% vs. 32.6%, p<0.01) and high-quality blastocyst rate (39.5% vs. 26.6%, p<0.01). Aneuploidy rate (newly-occurred chromosome aberrance rate) is lower in antagonist group compared with agonist group (25.0%vs. 33.09%, p<0.05).

Limitations, reasons for caution: The study is limited for its before-after study in the same patient design and limited sample size.

Wider implications of the findings: Our results suggest that GnRH antagonist protocol show advantages in formation of high-quality and euploid blastocysts in PGD.

Trial registration number: None.

P-584   High carrier frequency of GJB2 related non-syndromic sensorineural hearing loss and assisted reproductive technique

J.J. Guillen[1], D. García[2], R. Vassena[1], A. Rodríguez[1]

[1]Clínica EUGIN, EUGIN, Barcelona, Spain
[2]Fundación EUGIN, EUGIN, Barcelona, Spain

Study question: What is the carrier frequency of autosomal recessive non-syndromic sensorineural hearing loss in the assisted reproductive technique population?

Summary answer: This study shows that 4.5% of analyzed individuals are carriers of mutations in the GJB2 gene related with non-syndromic sensorineural hearing loss.

What is known already: Hearing loss is the most frequent sensorineural impairment, affecting 5% of the world population. Congenital hearing loss occurs in approximately 1 in 1000 births. In 95% of cases, the parents of children with hearing loss have normal audition. Genetic causes account for up to 60% of hearing loss cases, both syndromic and non-syndromic. Non-syndromic sensorineural hearing loss is a heterogeneous genetic condition with different patterns of heritage; the autosomal recessive pattern (SNHLAR) accounts for 80% of the cases. More than 10% of SNHLAR cases are induced by GJB2 mutations.

Study design, size, duration: Retrospective cohort of 3,366 individuals attending to an ART clinic between March 2015 and November 2016. The study consisted of 2,380 women and 986 men. We also analyze 894 genetics match between oocyte donors and patients (747), oocyte donor and sperm donor (114) and infertile couples (33).

Participants/materials, setting, methods: An expanded carrier-screening blood test was performed (CarrierMap® by Recombine®), covering 2647 mutations implicated in 311 diseases. Briefly, DNA samples were prepared and

purified following the QIAamp DNA Purification Protocol via QIAcube (QIAGEN). Samples were assayed using the Infinium iSelect HD Custom Genotyping BeadChip platform (Illumina). Regarding SNHLAR, the test screens for 30 mutations related with GJB2 gene, 2 related with LOXHD1 and 10 with MYO15A.

Main results and the role of chance: We found that 43% of our population has at least one genetic mutation (1458/3366). This percentage was similar in women (43% = 1012/2380) and in men (45% = 446/986). 43% of carriers for any mutations identified themselves as Europeans, 20% Mediterranean and the rest Latin American (15%), African (4%) and Asian (1.5%). Mutations in the GJB2 gene were the second most common ones among carriers, representing 10% (152/1458) of the total carriers, resulting in a carrier frequency of 1:22. This percentage was not statistically different between women (4% = 97/2380) and men (2% = 55/986; p>0.05). The vast majority of GJB2 mutation carriers were Europeans (54%) and Mediterranean (21%). No carriers were identified for mutations in the LOXHD1 and MYO15A genes. When considering the attempted genetic matching, 26 of 894 were of high reproductive risk (2,9%); of them 4/26 (15%) were related with GJB2 mutations.

Limitations, reasons for caution: The carrier frequency of SNHLAR is likely underestimated, because the test we applied screens for 30 specific mutations in GJB2, while more than 200 mutations have been described related with this gene alone.

Wider implications of the findings: The World Health Organization (WHO) considers hearing impairment a disability. Identification of couples where both partners are carriers will provide us with the opportunity to decrease their reproductive risk. Awareness programs directed towards reproductive aged people and healthcare professionals alike should be developed and implemented.

Trial registration number: NA.

P-585 MPS-based preconception carrier screening: development, verification and user experience

R. Vasilyev[1], S. Viatkina[1], M. Strizhova[1], N. Kornilov[2], A. Pavlov[3], T. Simakova[3], J. Vnuchkova[3], M. Glushkova[3], A. Bragin[3]

[1]NGC Research Lab, Department of Genetics, Saint-Petersburg, Russia C.I.S.
[2]Next Generation Clinic, Department of ART, Saint-Petersburg, Russia C.I.S.
[3]ParSeq Lab, R&D department, Saint-Petersburg, Russia C.I.S.

Study question: Massive parallel sequencing (MPS) is a powerful tool in service of clinical genetics. What application can reproduction clinic find for such an instrument?

Summary answer: MPS-based preconception carrier screening reduces the risk of delivery a child with genetic disorder.

What is known already: The only mandatory genetic test for gamete donors in Russia is karyotyping. Therefore, personal and family history for genetic conditions of given donor remains unknown or vague. Some clinics offer carrier screening for common pathogenic variants of selected genetic disorders, leaving rare mutations undetected. Implementation of MPS-based carrier screening provides simultaneous deep analysis of numerous genes associated with inherited conditions at affordable turn-around time and in a cost-effective way. Obtained data allows genetic counselor to evaluate reproductive risks for referring couple and help them make informed decisions.

Study design, size, duration: NextGen21 genetic test includes 21 genes associated with most frequent, severe genetic disorders with no cure existing and/ or lifelong treatment. Target regions were selected based on genes' structure and function knowledge alongside with international guidelines and recommendations where applicable. Our database consist of over 16000 variants of established clinical significance, aggregated from various reliable databases and other sources. NextGen21 was verified by means of both human DNA standards (NIST, 1000 Genomes) and Sanger sequencing.

Participants/materials, setting, methods: Sample consisted of 1 NIST human standard DNA, 22 specimens from 1000 Genomes project (British population), 32 oocyte donors, 10 sperm donors and 6 patients. Carriers of X-linked and autosomal-dominant conditions with late-onset were excluded from donor programme. Patients underwent genetic counseling to establish if both partners were carriers for the same condition.

Main results and the role of chance: Overall 1096 unique genetic variants were detected, 14 of which were pathogenic/ likely pathogenic according to ACMG guidelines. Number of variants in one sample ranged from 139 to 259 with mean value of 192. Resulting rate 1 in 5,8 person being carrier at least of one genetic condition corresponds with estimated value 1 in 5, calculated from each disorder carrier frequency. 2 oocyte donors carrying X-linked disorders (Duchenne muscular dystrophy, hemophilia A) were excluded from donor programme. Surprisingly detected variants are single nucleotide polymorphisms while common type of genetic changes for given disorders are copy number variations (65-85% of DMD) and structural variations (around 55% of hemophilia A cases). During verification period NextGen21 was once used as a tool for detection of causative variant in 56 years old Ashkenazi Jewish woman with Hereditary Breast and Ovarian Cancer. Common pathogenic variant 6174delT in BRCA2 gene was found alongside with incidental findings of 2 pathogenic variants R241H and N409S in genes PAH and GBA respectively. Rare pathogenic variants found in genes CFTR, PAH, GBA, DMD and F8 emphasize advantages of test design based on structural and functional role of genetic regions over design targeting common mutations for given genetic disorder.

Limitations, reasons for caution: Major problem MPS-based carrier screening rises are variants of unknown clinical significance. Complexity of method requires appropriate pre- and post-testing genetic counseling. Patients should understand advantages, limitations and application NextGen21 has.

Wider implications of the findings: We plan to validate NextGen21 on samples with complex variants for genes traditionally challenging for MPS. Depending on validation outcomes we may change the list of genes screened by our test. We also consider adding several genes frequently requested by our patients.

Trial registration number: Not applicable.

P-586 INCREASED FIRST-TRIMESTER FALSE-POSITIVE ANEUPLOIDY SCREENING FOLLOWING ART

S. Rodrigues-Pereira, S. Santos-Ribeiro, A. Meira, C. Calhaz-Jorge

Centro Hospitalar Lisboa Norte- Hospital Santa Maria, Department of Obstetrics-Gynecology and Reproductive Medicine, Lisboa, Portugal

Study question: Do assisted reproductive technologies (ART) modify the predictive value of first-trimester aneuploidy screening?

Summary answer: ART is associated with a higher false-positive aneuploidy screening rate for trisomy 21, 18 and 13 when compared to spontaneously pregnant women.

What is known already: Previous studies on the effect of ART on first trimester aneuploidy screening have shown conflicting results. Specifically, while ART does seem to significantly change the levels of trisomy 21 serum markers, the repercussion of these changes on the overall risk of false-positive screenings remains elusive. Furthermore, no study has previously assessed the effect of ART on the false-positive rate of combined trisomy 21,18 and 13 screening.

Study design, size, duration: Retrospective cohort analysis including 1128 women with a singleton pregnancy who performed their first-trimester combined aneuploidy screening for trisomy 21, 18 and 13 at our tertiary hospital between February 2013 and July 2016. We only included women with known final pregnancy and/or neonatal outcomes. Patients were divided according to whether they conceived spontaneously (n = 876) or following ART (n = 252; n = 152 IVF, n = 67 ICSI and n = 33 FET). Vanishing-twins were excluded from the analysis to minimize bias.

Participants/materials, setting, methods: All serum samples were processed under the same conditions (Elecsys®, Roche) and using the same combined risk calculation algorithm certified by the Fetal-Medicine-Foundation. This algorithm gives a combined adjusted-risk for trisomy 21, 18 and 13 accounting for: presence of aneuploidy markers diagnosed during the first-trimester ultrasound, serum levels of PAPP-A and βhCG, and other relevant female risk-factors (including age). Trisomy 21, 18 and 13 risks were considered elevated whenever above 1:300, 1:150 and 1:150, respectively.

Main results and the role of chance: Women performing ART group were significantly older (36,0 vs 32,3 years-old) and performed their first-trimester ultrasound sooner (at the gestational age of 85,0 vs 88,0 days) when compared

to those who conceived spontaneously. Gestational-age-adjusted PAPP-A MoM levels were significantly lower in the hormonally-stimulated IVF/ICSI groups (median 0,7, 0,7 and 1,0 for conventional IVF, IVF-ICSI and spontaneous conceptions, respectively). Meanwhile, the MoM of βhCG and nuchal translucency did not vary significantly among the groups. Most importantly, ART pregnancies had a significantly higher chance of having a high-risk aneuploidy screening (11,2%, 11,9% and 5,6% for conventional IVF, IVF-ICSI and spontaneous conceptions, respectively) and also a higher risk of a false-positive result (9,9%, 11,9%, and 5,0% for conventional IVF, IVF-ICSI and spontaneous conceptions, respectively).

Limitations, reasons for caution: Our results cannot be extrapolated to older women or blastocyst transfers given the fact that our sample only included women under 40 years of age performing cleavage-stage embryo transfers. Furthermore, we cannot exclude the possibility that other cases of aneuploidy may have been missed amongst the women lost to follow-up.

Wider implications of the findings: These results could prompt the development of newer aneuploidy screening algorithms accounting for the type of conception, potentially reducing the number of unnecessary invasive diagnostic tests. Given the potential risk of miscarriage following these invasive diagnostic procedures, such algorithms could be beneficial for couples who conceived after ART.

Trial registration number: Not applicable.

P-587 Pre-implantation genetic testing does not decrease cumulative drop-out rate when compared to standard in-vitro fertilization in women with advanced maternal age

S. Mumusoglu[1], M. Polat[2], I. Yarali[3], G. Bozdag[1], L.K. Sokmensuer[4], H. Yarali[1,2]

[1]Hacettepe University School of Medicine, Reproductive Endocrinology and Infertility, Ankara, Turkey
[2]Anatolia Women Health and IVF Centre, Reproductive Endocrinology and Infertility, Ankara, Turkey
[3]Anatolia Women Health and IVF Centre, Embryology, Ankara, Turkey
[4]Hacettepe University School of Medicine, Histology and Embryology, Ankara, Turkey

Study question: Does performing pre-implantation genetic testing (PGT) influence the drop-out rate from in-vitro fertilization (IVF) treatment in women with advanced maternal age (AMA)?

Summary answer: Female age, but not performing PGT, significantly contributes to drop-out decision from further IVF treatment in women with AMA.

What is known already: Discontinuation from IVF treatment is frequent (17-70%) and contributes to compromised cumulative pregnancy rates in IVF. Pre-implantation genetic testing with single frozen euploid embryo transfer (SFEET) increases the live birth rate per embryo transfer and decreases the multiple pregnancy rate in AMA cases. Since poor prognosis and failure to achieve embryo transfer are among the main known contributors of drop-out from further IVF treatment, we aimed to evaluate whether IVF treatment coupled with PGT have any influence on drop-out rates compared to standard IVF in AMA patients.

Study design, size, duration: Longitudinal cohort comparison of pre-intervention (standard IVF; June 2013-October 2014; 198 couples) and post-intervention (PGT with SFEET; April 2015-June 2016; 203 couples) periods in AMA (≥38 yr-old) cases undergoing IVF, regardless of ovarian reserve. Exclusion criteria were azoospermia and no follicular growth to ovarian stimulation with no further treatment advised by the physician. Only AMA patients with their first cycle at our center during defined time periods were included.

Participants/materials, setting, methods: In both arms, all started stimulation cycles (with/without cycle cancellation) were counted as separate cycles. In the PGT arm, ovarian stimulation and first SFEET was counted as one cycle; all other frozen replacement cycles, in both arms, were counted as separate cycles. Not commencing a new treatment cycle 6 months after failing to achieve an ongoing pregnancy was defined as drop-out. The incidence and factors related to drop-out from three IVF cycles with/without-PGS were studied.

Main results and the role of chance: Female age (40.9 ± 2.2 vs. 40.7 ± 2.2, p = 0.506), antral follicle count (8.0 ± 5.3 vs. 7.7 ± 6.2, p = 0.518),

number of previous IVF attempts (1.0 (0-3.0) vs. 1.0 (0-3.0), p = 0537), number of patients with previous childbirth (24.7% vs. 21.2%, p = 0.233) were comparable among the with-PGT or without-PGT arms, respectively. The drop-out rates following 1st failed IVF cycle were 62.8% vs. 70.2% in the with-PGT or without-PGT arms, respectively (p = 0.143). The respective figures for the 2nd cycle were 57.4% and 69.6% (p = 0.209). Cumulative drop-out rates for 3-planned cycle were not significantly different (69.7% and 77.3%, p = 0.090, respectively) with an overall rate of 73.8%. Cumulative ongoing pregnancy rate per patient was comparable between the two arms (20.7% vs. 16.2%, p = 0.369). However, ongoing pregnancy/live birth per embryo transfer was significantly higher in the PGT arm (42.2% vs. 16.4%, p < 0.001). As expected, multiple pregnancy per ongoing pregnancy was significantly less in the PGT arm [1/41 (2.4%) (mono-zygotic twin) vs. 5/33 (15.1%), p = 0.046]. When Cox-regression analysis was performed, only the female age was the significant contributor to drop-out (HR 1.07; 95% CI, 1.09–1.13). However, previous childbirth, antral follicle count, cycle cancellation, number of metaphase-2 oocytes, failure to achieve embryo transfer and performing PGT, were not significant contributors.

Limitations, reasons for caution: Retrospective study design is a limitation. These data reflect drop-out rates from a single private-based IVF center; hence, the results may not be extrapolated to drop-out rate from IVF treatment elsewhere. Rates might also be affected by type of payment, patient/insurance/government based, which cannot be addressed with the current series.

Wider implications of the findings: ~ 75% of AMA cases, not achieving an ongoing pregnancy, discontinue IVF program before completing 3 cycles. Performing PGT, does not reduce such drop-out rate. Female ageing is the only significant contributor with the hazard of discontinuation from further IVF treatment by 7% with female ageing of 1-yr.

Trial registration number: None.

P-588 Directly distinguish chromosome balanced rearrangement carrier embryos from truly normal embryos in 56 PGD cycles

C. Dehua[1,2], H. Liang[2,3,4], G. Fei[2,5], L. Changfu[2], T. Yueqiu[2,6], L. Keli[2], W. Xianhong[2], X. Pingyuan[2,3], F. Tao[7], Y. Kai[8], L. Guangxiu[2,3,5], L. Ge[2,3,5]

[7]Peking Jabrehoo Med Tech.- Ltd., Peking Jabrehoo Med Tech.- Ltd., Beijing, China
[8]Peking Jabrehoo Med Tech.- Ltd., Peking Jabrehoo Med Tech.- Ltd.-, Beijing, China

Study question: We established a clinical applicable approach to identify rearrangement breakpoint region linkage specific single nucleotide polymorphisms (SNPs) haplotype and to further directly distinguish truly normal embryos in PGD.

Summary answer: Our results suggest that microdissecting junction region (MicroSeq) can accurately evaluate the balanced or normal status of each embryo of chromosome balanced rearrangement(CBR) carriers.

What is known already: Preimplantation genetic diagnosis (PGD) is widely applied in chromosome balanced rearrangement(CBR) carriers to increase the chance for a successful live birth. However, carrier embryos were seldom discriminated from the normal ones mainly due to the technique restriction.

Study design, size, duration: This was a prospective study for 56 CBR carrier couples, who were treated by D5 or D6 biopsed PGD-CCS between July 2014 and December 2016.

Participants/materials, setting, methods: The study was set at the Reproductive and Genetic Hospital of CITIC-Xiangya. Totally 56 carrier couples were recruited, including reciprocal translocation(n = 44), Robsonian

translocation(n = 8), and inversion(n = 4). Before performed PGD, rearrangement breakpoint region and adjacent specific SNPs were characterized by next-generation sequencing following microdissecting junction region (MicroSeq) from 56 carriers. In the clinical phase of embryo analysis, specific SNPs of junction region were chosen for linkage analyses to identify the truly normal embryos.

Main results and the role of chance: Totally performed 63 OR cycles and biopsied 259 blastocysts(actually detected 233 blastocysts). Totally 101 blastocysts diagnosed to be chromosomal balanced, 57 blastocysts were identified to be carriers and 44 to be normal.The proportions of normal karyotype embryos obtained in reciprocal, Robertsonian and inversion carriers' cuoples were 13.33% (24/180), 33.33%(11/33) and 45%(9/20), respectively. The proportions of carriers karyotype embryos obtained in reciprocal, Robertsonian and inversion carriers' cuoples were 23.89% (43/180), 30.30%(10/33) and 20%(4/20), respectively. Cumulative 38 FET cycles were carried and resulting 24 pregnancy.Eight cycles late prenatal diagnoses(PND) for five carriers and three normal fetus confirmed the carrier diagnosis results. Other predicating eight carriers and five normal fetus is still in pregnancy without performe PND.

Limitations, reasons for caution: The final outcomes of 10 PGD cycles still have not been obtained.We cannot exclude differences between the final data and the data in the present submitted abstract.

Wider implications of the findings: MicroSeq technique is suitable for almost all CBR carrier couples PGD treatment.

Trial registration number: Not applicable.

P-589 Relationship between ´´high normal´´ CGG repeats of the FMR1 gene and response to gonadotropin stimulation in fertile women

G. Koustas[1], L. Bruhn-Madsen[2], C. Burke[2]

[1]Cryos International, Aarhus, Denmark
[2]Cryos International – Orlando, FL, USA

Study question: Is there an association between a specific range within the high normal CGG repeats (36-45) of the FMR1 gene and response to gonadotropin stimulation?

Summary answer: The range between 36-45 CGG repeats on the FMR1 gene was not correlated with suboptimal response to gonadotropin stimulation and impaired oocyte maturation.

What is known already: The Fragile X mental retardation 1 (FMR1) gene contains a variable number of trinucleotide (CGG) repeats. The majority of the population has 29-32 CGG repeats (normal range). Full mutation and premutation with >200 and 55-200 CGG repeats, respectively, are associated with diminished ovarian reserve. Within the high normal range (>32) smaller expansions of CGG repeats generate different clinical manifestations. Therefore, the relationship between 36-45 CGG repeats (included in the high normal CGG repeat zone) anti-Müllerian hormone (AMH), response to gonadotropin stimulation and oocyte maturation following retrieval, has yet to be assessed.

Study design, size, duration: A retrospective study involving 65 egg donors participating in a total of 82 donation cycles, who donated to a large private sperm and egg bank from March 2016 to January 2017. The egg donors were categorized into two groups i) donors with ≤35 CGG repeats in allele 1 and ii) donors with ≥36 CGG repeats in allele 1 of the FMR1 gene.

Participants/materials, setting, methods: All egg donors underwent FMR1 screening and AMH testing. Once approved, the egg donors began controlled ovarian stimulation utilizing a gonadotropin-releasing hormone (GnRH) antagonist protocol following a GnRH agonist (GnRHa) to induce oocyte maturation when follicles reached >17 mm in diameter in order to schedule oocyte retrieval, 36 hours later. Oocytes were denuded and metaphase II (MII) oocytes were assessed and vitrified. Serum estradiol (E_2) and progesterone were measured on cycle day 1, 4 and 7.

Main results and the role of chance: The majority of egg donors (59%) were Caucasian with mean age 24 ± 3.7 years (range 18-30 years), non-smokers with BMI ≤ 27 kg/m^2. The AMH (7.4 vs 6.6 ng/mL) and age (24.6 ± 3.7 vs 21.1 ± 3.1 years) were not significantly different between the two groups (p> 0.05). In contrast to allele 2 (26.6 ± 4.3 vs 30.7 ± 0.8; p> 0.05), the number of CGG repeats in allele 1 of the FMR1 gene for groups i)

and ii) differ significantly (30.9 ± 1.4 and 41 ± 3.2; p < 0.05). There was no significant correlation between the amount of exogenous follicle-stimulating hormone (FSH) required for ovarian stimulation (184.2 ± 66.1 vs 220.80 ± 71.8 IU) and duration of stimulation between the two groups (9.4 ± 1.6 vs 9.30 ± 1.3 days; p> 0.05). The peak E_2 was not significantly associated with the number of CGG repeats (2147.8 ± 905 vs 2205.6 ± 1021.6 pm/mL; p> 0.05). No statistical difference was observed in the number of oocytes retrieved between the two groups, however a significant relationship was evident between increased number of CGG repeats and proportion of MII oocytes (74.2 vs 82.0 %; p < 0.001).

Limitations, reasons for caution: A limitation is the sample size of this still ongoing study, extended data will be available at the ESHRE meeting. In addition, egg donors is a homogeneous selected group so these results might not be extrapolated to other groups of women undergoing fertility treatment.

Wider implications of the findings: This is the first study to investigate in a population of healthy women, a specific range of the high normal CGG repeat numbers of FMR1 allele 1 that doesn't impair ovarian function, highlighting the importance of donor candidate assessment and provides valuable information on predicting risk towards premature ovarian insufficiency.

Trial registration number: N/A.

P-590 Comparative analyses of AZF microdeletions in leukocytes and testis tissue of TESE patients reveals cellular mosaicism impairing their sperm prognosis

P.H. Vogt[1], U. Bender[2], J. Zimmer[2], J. Dietrich[3], T. Strowitzki[4]

[1]Heidelberg University, Reproduction Genetics Unit- Depart. Gynecological Endocrinol. & Reproductive Medicine, Heidelberg, Germany
[2]University Women Hospital, Department of Gynecol. Endocrinology and Reproductive Medicine- Reproduction Genetics Unit, Heidelberg, Germany
[3]University women hospital, Department of Gynecol. Endocrinology and Reproductive Medicine, Heidelberg, Germany
[4]University women hospital, Department Gynecol. Endocrinology and Reproductive Medicine, Heidelberg, Germany

Study question: Why do patients with non-obstructive azoospermia and complete AZFa,b,c deletions found in leukocytes do have variable testicular pathologies ranging from Sertoli-cell-only syndrome (SCO) to hypospermatogenesis?

Summary answer: Genomic extensions of AZF deletions in patients Y DNA extracted from leukocytes and testicular tissue are variable due to cellular heterogeneities and probably mosaicisms.

What is known already: Azoospermia Factor (AZF) locus causes male infertility when disrupted. It includes 14 protein encoding Y genes located in three distinct Y regions designated AZFa, AZFb, AZFc, respectively. They are expressed during different phases of human spermatogenesis. Accordingly, complete deletion of an AZF region is associated with a distinct testicular pathology. This can be used for sperm prognosis of patients suffering from non-obstructive azoospermia who decided for testicular sperm extraction (TESE). Complete AZFa or AZFb deletions suggest, they have no sperms in their testicular tubules, whereas patients with complete AZFc deletion are believed to have a good prognosis for sperm detection.

Study design, size, duration: Comparative analysis of the extension of AZF microdeletion found in the genomic DNA samples of leukocytes and testicular tissue extracted from patients with non-obstructive azoospermia asking for testicular sperm extraction. Extension of PCR multiplex assays according to EAA/EMQN guidelines to recognize each AZF gene deletion separately and to distinguish the genomic breakpoints in the proximal and distal AZF deletion border regions.

Participants/materials, setting, methods: From 110 TESE patients DNA samples from leukocytes and testis tissue samples were collected between years 2009-2016. Comparative analyses for presence of partial or complete AZFa,b,c microdeletions were performed according to Vogt & Bender (Meth. Mol. Biol. Vol 927: 187-204, 2012). Any Y gene deletion result was confirmed by single STS PCR assays. Novel genomic AZF breakpoint regions were elaborated by PCR cloning and confirmed by sequence analyses.

Main results and the role of chance: Comparison of genomic extensions of AZF deletions in patients Y DNA of leukocytes and testicular tissue revealed

some heterogeneities suggesting cellular mosaicism. We found one complete AZFa deletion, one partial AZFb + complete AZFc deletion and 7 complete AZFc deletions in leukocytes but not any of these AZF deletions in the same patients' genomic testis DNA. Quantitative analysis of the AZF gene markers used in testis tissue by appropriate TaqMan assays indicated cellular heterogeneities. In most but not all cells in the testis tissue the Y chromosome did not display the same AZF deletions found in leukocytes and maybe even absent. By FISH analysis with appropriate Y-DNA probes we confirmed this cellular heterogeneity. We assume that probably only germ cells do have the AZF deletions found in the patients leukocytes. The molecular mechanisms causing AZF microdeletions by non-homologous recombination events may thus only occur in germ cells due to complete decondensation of the human Y chromosome before meiosis.

Limitations, reasons for caution: Comparative analyses of extensions of AZF deletions in leukocytes and testis tissue of 110 TESE patients includes till now only 9 AZF mutation events in the total cohort. Large heterogeneities of their testicular tissue pathologies might also depend on the variable age of these patients probably interfering with our results.

Wider implications of the findings: Our results can probably explain the large heterogeneity of testicular pathologies found in patients with complete AZF deletions in their leukocytes and are important for their clinical counseling when asking for sperm prognosis before performing their testis biopsy.

Trial registration number: Not applicable.

P-591 Pregnancy rate per transfer in women over 38 years is improved by PGD-A after Polar Body (PB) biopsy. A study on 159 embryo transfers

G. Filippini-Cattaneo[1], E. Crugnola[1], S. Cuomo[2], M. Jemec[2], L. Risch[3], M. Bellavia[2]

[1]procrealab SA, molecular genetics laboratory, lugano, Switzerland
[2]Procrea SA, Swiss fertility center, lugano, Switzerland
[3]labormedizinisches zentrum Dr Risch AG, medizinische und chemische Labordiagnostik, Bern-Liebefeld, Switzerland

Study question: Is PGD-A on PB a valid alternative to trophectoderm biopsy in order to increase the pregnancy rate per transfer?

Summary answer: PGD-A on PB was shown to increase the pregnancy rate per transfer in older women, via selection of euploid oocytes.

What is known already: PGD-A is an established technique for increasing the chance of pregnancy, especially in women older than 36. The techniques for both genetic analysis and for biopsy have greatly improved. Blastocyst biopsy and comprehensive analysis of all chromosomes using aCGH or NGS has come to be considered the gold standard. Despite its safety and suitability for screening for maternally-derived aneuploidy, PB biopsy has been almost abandoned because of the higher costs and the higher biopsy skills requested. Consequently, there is a shortage of data concerning the effectiveness of PGD-A on PB.

Study design, size, duration: The result in terms of percentage of pregnancy rate (biochemical and ongoing pregnancy) in 80 embryo transfers after PGD-A on the first and second PB and resulting from 66 ICSI cycles was retrospectively compared to 79 embryo transfers without PGD-A, resulting from 79 matched randomized ICSI cycles performed in the same period in our clinic (2014-2016). All cycles were considered except for patients requesting PGD for monogenic diseases or chromosomal translocations.

Participants/materials, setting, methods: First and second PBs were taken simultaneously about 20 hours after ICSI. PB were individually amplified by WGA and chromosomes were analysed by array-CGH. One or two embryos were transferred freshly at day 3, or frozen 22 hours after ICSI and transferred after thawing. Pregnancy was considered if bHCG was higher than 10 IU/L at day 14. Pregnancy rates in control and PGD-A groups were compared by Fisher's two tailed exact test

Main results and the role of chance: Mean patient age was 37 years for both groups. 967 PB from 488 oocytes were analysed. 40% of PB were euploid, 47% were aneuploid and for 12% the result was not available (indeterminate). By considering all the transfers (n = 80), the pregnancy rate per transfer in the PGD-A group was 38% versus 31% in the control group (p = 0.05). Considering only women ≥38 years at pick-up (n = 43 in PGD-A group, n = 41

in control group), the pregnancy rates were 47% (PGD-A) versus 22% (controls; p = 0.0003). For women ≥39 at pick-up (n = 34 in both groups), pregnancy rates were 45% (PGD-A) versus 18% (controls); p = 0.0004).

Limitations, reasons for caution: This study is based on a limited number of subjects (80 cases, 79 controls). It will be necessary to confirm these data on a larger cohort of subjects.

Wider implications of the findings: PGD-A is a widely-used screening method in older women to prevent IVF failure caused by chromosomally-abnormal oocytes, and to avoid aneuploid pregnancies. Aneuploidy testing in PB is an effective alternative. Main advantages are 1) the possibility of transfer at day 2-3; 2) the absence of artifacts due to embryonic mosaicism

Trial registration number: none.

P-592 Alterations of methylation are reversible by developmental reprogramming in kidney tissue of Intracytoplasmic sperm injection (ICSI) mice

Q. Zhan[1], F. Jin[2]

[1]Women's Hospital- School of Medicine- Zhejiang University, Department of Reproductive Endocrinology, Hangzhou- Zhejiang, China
[2]Women's Hospital- School of Medicine- Zhejiang University, Department of Reproductive Endocrinology, Hangzhou, China

Study question: Does the effect of Intracytoplasmic sperm injection (ICSI) on methylation continue during the development?

Summary answer: We found that ICSI manipulation and early embryo culture resulted in alterations of methylation, and the alterations were reprogrammed by developmental reprogramming.

What is known already: Although the prevalence of ICSI has increased year by year, there remains concern about the safety of these procedures because of reports of the increased risk for imprinting disorders. Previous research has demonstrated that gonadotropin stimulation contributes to an increased incidence of epimutations in ICSI-derived mice. However, the epimutations in ICSI offspring after removing the effect of gonadotropin stimulation and the possibility that epimutations are reversible by developmental reprogramming has not been investigated.

Study design, size, duration: Kidney tissues form twenty two-cell embryos transfer (TCET) mice (10 adults and 10 olds) and sixteen ICSI mice (8 adults and 8 olds) were analyzed. We quantitatively examined the DNA methylation patterns of a number of CpGs in the differentially methylated region (DMRs) of imprinted genes, since these are involved in kidney diseases.

Participants/materials, setting, methods: We used mice derived by TCET as control group to exclude the effect of gonadotropin stimulation. A key difference between ICSI and TCET mice is that manipulation and injection of oocytes and culture during the ICSI program are removed during the TCET process and replaced by in vivo fertilization. Kidney tissues obtained from adults or olds were used to analyze DNA methylation and expression of kidney-disease related imprinted genes including *H19*, *Snrpn*, *Mest* and *Peg3*.

Main results and the role of chance: We found reduced methylation and up-regulated expression of the imprinted genes, H19, Mest and Peg3, in adult ICSI mice (e.g. H19 methylation 58.71% ± 1.49% in ICSI mice vs. 62.77% ± 1.56% in TCET, p < .01, H19 mRNA expression 1.80 ± 0.35 in ICSI mice vs.1.00 in TCET, P < .01). But the above alterations observed in adult mice were not detected in old ICSI mice (e.g. H19 methylation 63.29% ± 1.97% in ICSI mice vs. 61.67% ± 0.98% in TCET, p>.05, H19 mRNA expression 1.03 ± 0.10 in ICSI mice vs.1.00 in TCET, p>.05). At the Snrpn DMR, methylation status was not altered in adult ICSI-derived mice (methylation 53.00% ± 2.30% in ICSI mice vs. 54.50% ± 0.70% in TCET, p>.05), but hypermethylation and correlated down-regulated expression of Snrpn were observed in old mice (methylation 57.70% ± 1.50% in ICSI mice vs. 54.10% ± 1.05% in TCET, p < .01, mRNA expression 0.85 ± 0.08 in ICSI mice vs.1.00 in TCET, P < .01).

Limitations, reasons for caution: Assessment of renal function in the blood and immunohistochemistry of the kidney tissue were not been carried out, which might provide more evidences for the alteration.

Wider implications of the findings: We are the first to find that alterations of methylation caused by ICSI itself exist after excluding the effect of

gonadotropin stimulation, and the alterations might be corrected by developmental reprogramming in kidney tissues. But the mechanism under the reversible change and other tissues still needs further investigation.

Trial registration number: Not a clinical trial.

P-593 Comparison of livebirth delivery rates as a function of PGD use by IVF centers in the United States: Analysis of new national CDC data

E.S. Sills[1], X. Li[2]

[1]Center for Advanced Genetics, Reproductive Research Section, Carlsbad- CALIF, U.S.A.
[2]Paralian Technology- Inc., Quantitative Research Division, MIssion Viejo- CALIF, U.S.A.

Study question: What is the impact of including PGD with IVF on reproductive outcome in the United States?

Summary answer: Livebirth delivery rates were not significantly different among IVF clinics with high uptake of PGD compared to clinics with low PGD use.

What is known already: Recognizing the limitations of embryo selection based on morphology alone, PGD has emerged as another assessment method aiming to improve IVF efficiency. Array comparative genome hybridization is a widely used PGD method, but this is gradually being replaced by massive parallel sequencing. In the meantime, there is still controversy regarding the clinical value of PGD even as it becomes used more often with IVF.

Study design, size, duration: This analysis was based on the 'Fertility Clinic Success Rates Report" from U.S. CDC. Data were reviewed from 208,604 treatment cycles performed at IVF units in the United States (n = 458) during 2014.

Participants/materials, setting, methods: Patient data from reporting clinics were stratified by level of PGD utilization: Group 0=PGD not performed, Group 1=PGD used in ≤5% of IVF, and Group 2=PGD used in >5% of IVF. Delivery rates for the three categories were compared by Chi-squared test.

Main results and the role of chance: For Group 0 (n = 7761), delivery rate after IVF cycle was reported as 37.9%. Patients in Groups 1 (n = 24897) and 2 (n = 6915) had IVF delivery rates of 36.7% and 37.6%, respectively (p = 0.27, for all three groups).

Limitations, reasons for caution: This dataset did not stratify PGD application by biopsy stage, infertility diagnosis, or patient age, and the PGD technique was unspecified. Data on fresh vs. frozen embryo transfers after PGD also could not be disaggregated. Other factors besides PGD uptake will influence reproductive outcome with IVF.

Wider implications of the findings: While preimplantation assessment of embryos can help select euploid embryos for transfer, more information is required to quantify exactly how this impacts outcomes with IVF. More precise ascertainment of PGD applications by national reporting platforms is essential to provide proper surveillance, particularly as PGD becomes more widely utilized.

Trial registration number: N/A.

P-594 Introduction of a novel, universal NGS-based research method for Preimplantation Genetic Diagnosis and Screening

B. Devogelaere

Agilent Technologies, Diagnostics & Genomics Group, Santa Clara, U.S.A.

Study question: Is it possible to design a universal end-to-end NGS workflow that enables performing PGD (for Single Gene Disorders and Translocations) combined with PGS in the same embryo biopsy?

Summary answer: Our approach provides a universal end-to-end NGS workflow for PGD and demonstrates the power of combining PGD with PGS on the same embryo biopsy.

What is known already: Over the past few years, several new technologies have been developed for the high resolution molecular cytogenetic analysis of embryos prior to implantation. Although technologies such as STR-PCR, SNP arrays and aCGH have been utilized for the detection of mutations associated with Single Gene Disorder (SGD) and/or translocations for Preimplantation Genetic Diagnosis (PGD), significant challenges persist. To overcome these challenges, we have developed a novel NGS-based method coupled with specific algorithms that utilize parental haplotype information to detect SGD-associated mutations and translocations.

Study design, size, duration: In this retrospective research study, we compared the results obtained with the proposed approach to the results obtained with a validated reference method that is run in a reference lab. The analyses were performed throughout 2015-2017 on a diverse set of embryos from families with various PGD indications.

Participants/materials, setting, methods: We processed embryo biopsies harboring SGD-associated mutations, translocations and aneuploidies. Biopsies included blastomeres and trophectoderm cells. The data were analyzed using the novel algorithms we developed, and the results were compared to those obtained using a validated technology in a reference lab. Additionally, we also evaluated the performance of our assay using cell lines that harbor aneuploidies.

Main results and the role of chance: Our analysis on a diverse set of embryos that included single blastomeres and trophectoderm biopsies showed excellent concordance with results from the previously validated reference method. Additionally, we observed excellent concordance for a wide range of chromosome aneuploidies from cell lines. Our approach does not require gene-specific spike-ins, thereby making it a highly versatile assay. As our approach can concurrently detect aneuploidies, this effectively combines PGD and Preimplantation Genetic Screening (PGS) in one method.

Limitations, reasons for caution: The presented data represent the results obtained during a retrospective research study. Further verification and validation will be needed to assess the performance of the product.

Wider implications of the findings: This represents a novel Preimplantation Genetic Test approach that will enable combining PGD and PGS on the same embryo biopsy using a universal end-to-end NGS workflow that does not require gene-specific spike-ins.

Trial registration number: NA.

P-595 A cost-effectiveness analysis of preimplantation genetic screening with in vitro fertilization in Ontario, Canada

R. Zwingerman[1], W. Isaranuwatchai[2], H. Shapiro[1], N. Okun[1]

[1]University of Toronto, Department of Obstetrics & Gynaecology, Toronto, Canada
[2]University of Toronto, Institute of Health Policy- Management & Evaluation, Toronto, Canada

Study question: What is the cost-effectiveness of preimplantation genetic screening (PGS) with IVF compared to IVF alone in terms of additional live births?

Summary answer: PGS becomes increasingly cost-effective as both the age of the woman and the number of available blastocysts increases.

What is known already: Many embryo transfers fail to result in an ongoing pregnancy because the embryos are aneuploid, and this occurs more as female reproductive age advances. PGS allows the transferable cohort of embryos to be limited to euploid embryos, which have been shown to have a higher implantation rate and lower early pregnancy loss rates when compared to the transfer of an unscreened embryos. Very little is known, however, about the cost-effectiveness of PGS compared to IVF alone for women of varying ages and blastocyst cohort numbers.

Study design, size, duration: A decision analytic model was created using TreeAge Pro to compare IVF with PGS to IVF alone for women of different ages with one to ten blastocysts from the societal perspective, encompassing all relevant costs including time off work. Time to conception was not modelled. Sequential single embryo transfers of all blastocysts from a single oocyte retrieval were modelled until all blastocysts were exhausted, treatment was discontinued or a live birth was achieved.

Participants/materials, setting, methods: Clinical parameters were obtained from provincial and national databases, peer-reviewed literature and expert opinion. Cost parameters were obtained from the Ontario Case Costing Initiative, the Ontario physician schedule of benefits and fertility clinics in Ontario, Canada. Productivity costs were estimated using data from Statistics Canada and expert opinion. One-way and probabilistic sensitivity analyses were

performed to characterize the uncertainty around the estimates and to test the robustness of the model to various input parameters.

Main results and the role of chance: Compared to IVF alone, the cost-effectiveness of PGS depends both on female age and the number of available blastocysts. PGS became both incrementally less expensive and more effective as the number of blastocysts and the age of the woman increased. IVF alone was the superior strategy – more effective and less costly - for all women under age 35. This was also true when 3 or fewer blastocysts were available regardless of age. For women aged 35 to 40, PGS was more expensive than IVF alone regardless of blastocyst cohort size but PGS was slightly more effective in this age group once the cohort size exceeded 7-8 blastocysts. For women aged 41 to 42, IVF alone was the superior strategy when the cohort size was 5 or fewer. The two strategies were comparable when 6 – 8 blastocysts were available. PGS was the superior strategy only once the cohort size reached 9 blastocysts. For women above age 42 with a cohort size of at least 4, PGS was less costly with comparable effectiveness compared to IVF alone. One-way sensitivity analysis showed that the model was most sensitive to the implantation rates and early pregnancy loss rates.

Limitations, reasons for caution: There was a lack of high quality data to inform some of the model inputs, including implantation and pregnancy loss rates after PGS, to which the model was most sensitive. Data on dropout rates and time off work due to treatment and potential complications were also limited.

Wider implications of the findings: Using currently available data, PGS does not appear to be cost-effective in most scenarios when examined from a societal perspective in Ontario, Canada. PGS may be cost-effective for women over age 35 with a large number of blastocysts. Future research should focus on creating more robust population-based PGS outcome data.

Trial registration number: N/A.

P-596   Clinical application of low coverage massively parallel sequencing for chromosome aneuploidy and copy number variation screening in 6333 embryos

J. Wang, Y. Li, M.Y. Zhang, Y.Y. Yuan, P. Liu, F. Chen, H.Y. Zhang

BGI-Shenzhen, Beijing Genomics Institute, Shenzhen, China

Study question: Evaluation in terms of Preimplantation genetic screening (PGS) for aneuploidy and CNV detection, how the next-generation sequencing along with low-pass whole-genome sequencing, which provides the ability to assess many biopsied trophectoderm cells in order to confirm which normal embryos are ready-to-transfer in an IVF cycle.

Summary answer: Next-generation sequencing(NGS) is an emerging technology that provides a high-throughput parallel analysis of multiple embryos and high-resolution data for chromosomal analysis.

What is known already: Chromosome abnormality is a leading cause of repeat implantation failure and recurrent miscarriages. PGS enables the assessment of the numeral and structural chromosomal errors of embryos before transfer in patients undergoing IVF. NGS has been demonstrated to be an accurate PGS method and in present is thought to be effective.

Study design, size, duration: Retrospective cohort study of 6333 embryos obtained from 1699 couples performed between Feberary 2013 and December 2016 at Beijing Genomics Institute, Shenzhen, China.

Participants/materials, setting, methods: Trophectoderm biopsy were performed for the embryos. NGS was used for chromosome aneuploidy and copy number variation analysis, with an average of 0.07 depth and 5.5% coverage of the human genome.

Main results and the role of chance: Reliably identified with the NGS-based protocol were 3044 (48.1%) abnormal derived from 6333 embryos, with the smallest detectable chromosomal segment being 4 Mb in size. Within the 3044 abnormal embryos analysed, 1187(38.99%) were aneuploidies only, 1374 (45.12%) were just CNVs, 483(15.87%) were both CNV and aneuploidy, In terms of aneuploidy abnormality, chromosome anomalies, including chromosome 22(10.68%), 21(8.05%), 16(7.62%), 15(5.98%), 13(5.19%), 14(5.19%), X (4.04%) were of high frequencies.

Among all the couples, 513(513/1699) couples were balanced rearrangement carries, 3054 embryos obtained from them, 1381(45.22%, 1381/3054) were abnormal(translocation alone, related aneuploidies), 405(13.3%,405/3054) were spontaneous and inherited abnormalities. Also, the most common abnormalities were CNVs, followed by whole autosomal trisomies and monosomies, segmental imbalances of nontranslocation chromosomes.

But within non-balanced rearrangement couples, 3279 embryos obtained, 1258(38.4%,1258/3279) were abnormal. Compared with two groups, couples with balanced rearrangement showed higher frequency to produce chromosome anomaly embryos.

Limitations, reasons for caution: This method detects chromosomal aneuploidy and DNA deletion or duplication larger than 4 Mb. This method cannot detect point mutation, balanced translocation, inversion, ploidy change, low proportion mosaicism, uniparental disomy, methlytion alternation, and other variations that are not covered by this method.

Wider implications of the findings: NGS combined with WGA and bioinformatics analysis can effectively detect aneuploidies and CNVs in trophoctoderm cells, meanwhile NGS will play an increasingly significant role in clinical laboratories for human-assisted reproduction applications and studies. This strategy is rapid, highly accurate, robust, sensitive, easily reproducible, and cost-effective in contrast to other methods.

Trial registration number: no.

P-597   Factors associated with chromosomal mosaicism in trophoectoderm cells

J.A. Ortiz[1], B. Lledo[1], R. Morales[1], E.M. García-Hernández[1], J. Ten[2], J. Llácer[3], R. Bernabeu[3]

[1]*Instituto Bernabeu, Biología Molecular y Genética, Alicante, Spain*
[2]*Instituto Bernabeu, Biología de la Reproducción, Alicante, Spain*
[3]*Instituto Bernabeu, Medicina de la Reproducción, Alicante, Spain*

Study question: Which paternal and maternal variables do increase the probability of chromosomal mosaicism in the trophectoderm cells?

Summary answer: Paternal age and embryo quality are associated with embryonic mosaicism.

What is known already: There is a high incidence of chromosome abnormalities in human embryos that leads to failure of IVF cycles. The chromosomal mosaicism consists of a mixture of more than one cell line with different karyotype in the same embryo. The main factors that may increase the incidence of embryo mosaicism have not yet been established.

Study design, size, duration: We retrospectively reanalyzed array-CGH results from trophectoderm biopsies of day 5 and 6 blastocysts (from January 2013 to January 2017). We analysed 1923 blastocysts from 704 IVF cycles. We considered a mosaic embryo when the percentage of mosaicism, calculated by the log2 ratio, was higher than 25%. We evaluated the relationship between several paternal and maternal factors and embryo mosaicism.

Participants/materials, setting, methods: Chromosomal comprehensive screening was performed to couples who attended the Instituto Bernabeu with advanced maternal age, abnormal sperm FISH and/or a clinical history of recurrent miscarriage or implantation failure. Array-CGH analysis was performed using Agilent SurePrint G3 8×60 K CGH microarrays with previous whole genome amplification of genomic DNA. The association between variables and mosaicism was evaluated by logistic regression and chi-square (SPSSv20.0).

Main results and the role of chance: Trophoectoderm biopsies on day 5 and 6 blastocysts (n = 1923) were analysed by array-CGH. We have detected chromosomal mosaicism in 239 blastocysts (12.4%).

There are not statistically significant differences between the maternal ages of mosaic versus non-mosaic embryos (32.56 vs 32.77; p = 0.679). On the other hand, the age of the male is higher in the group of mosaic embryos (40.83 years) compare to non-mosaic embryos (39.93 years); (p = 0.037). In fact, the percentage of mosaic embryos for men aged 40 years or older is 14% and 10.7% when the male age is less than 40 years (p = 0.030).

Male factor is not related with blastocysts mosaicism. No significant difference was reported according to semen parameters (WHO 2010 criteria), sperm FISH (7 chromosomes analyzed) and sperm DNA fragmentation (p = 0.667, p = 0.176 and p = 0.292).

Finally, the embryo quality is associated with the trophoectoderm mosaicism. A better embryo quality in D+5 is related with a lower percentage of mosaic embryos. Embryos of quality A (Istanbul Criteria) have a mosaic percentage of 8.2%, B of 13.8%, C of 24.1% and finally D of 22.4% (p = 0.000001).

Limitations, reasons for caution: The study is limited by its retrospective nature. It is unknown if the mosaicism is confined to trophoectoderm. A prospective randomized design should be used in future studies to corroborate the current findings. More data are needed to conclude which mechanisms are involved in the development of these mosaic embryos.

Wider implications of the findings: The knowledge of the parameters that determine the mosaicism are of great relevance so that patients who undergo an IVF cycles know the risk of appearance of mosaic embryos.

Trial registration number: Does not apply.

P-598　Comprehensive analysis of methylation of whole genome of blastocysts by culturing with four different constituents after In Vitro Fertilization in mice

Y. Horibe[1], K. Hashimoto[1], H. Matsui[1], K. Hata[2], K. Nakabayashi[2]

[1]Tokyo Women's Medical University, Obstetrics and Gynecology, Tokyo, Japan
[2]National Center for Child Health and Development, Maternal-Fetal Biology, Tokyo, Japan

Study question: Would methylation of Imprinted gene be specifically disturbed by different constituent of amino acid in medium?

Summary answer: Different constituent of amino acid in medium may cause aberrant methylation at specific gene locus.

What is known already: Since Assisted Reproductive Technology(ART) established, various methods were examined to improve rate of implantation and further subsequence: terms of ovum collection, type and quantity of ovarian stimulation, technic of fertilization such as In Vitro Fertilization (IVF) and Intracytoplasmic Sperm Injection (ICSI), and medium. Pregnancy rate has been improved for long term investigation and examination, whereas imprinting disorders have been pointed out. This is because that ART would perturb methylation of specific imprinted gene. Relationship of ART and imprinting disorders have studied, whereas examination doesn't reach clear answer.

Study design, size, duration: First of all, we prepared four media which contained different constituent of amino acid. embryo was cultured with each media by blastocyst stage. Because rate of methylation reaches lowest level due to reprogramming. If different constituent of amino acid influence reprogramming, we would discover aberrant condition of methylation. Furthermore there is no study of comprehensive methylation analysis with culturing by blastocyst with different amino acid constituent.

Participants/materials, setting, methods: Oocytes and sperms were collected from 8 weeks ICR mice. Fertilization was operated by In Vitro Fertilization. Embryo was cultured by four different constituent media: KSOM medium, KSOM medium with essential amino acid, KSOM medium with non-essential amino acid and KSOM medium with essential and non-essential amino acid. Derived blastocysts were analyzed, and rate of methylation was calculated by next generation sequencer through Reduced Representation Bisulfite Sequence(RRBS).

Main results and the role of chance: At all media, there is less methylation change in promoter and exon than other region such as intergenic. This implies that genetically important region would have methylation protection mechanism from outer stimulation. Furthermore, there is more hyper-methylated region in NEAA than other medium. In other word, non-essential amino acid would protect methylation status from outer stimulation such as reprogramming.Next, we extracted all imprinted gene from in mapped 3 million CpG site. As a result, 3304 points in paternal gene and 2777 points in maternal gene were extracted. In addition, we extracted specific points which changed over 25% methylation change compared with NoAA in promoter and exon. Then imprinted gene, Mcts2, Nnat, Nespas, Peg10, Mest, Peg3, Snrpn, Snurf, H19, Igf2r and etc were extracted. These genes were previously reported as relationship between ART and aberration of methylation

Limitations, reasons for caution: RRBS focuses on point of CpG rich region and CpG island such as promoter and exon. This means that analysis of

methylation at other region such as intergenic would be poor study compared with whole genome bisulfite sequencing.

Wider implications of the findings: Management of constituent of amino acid with media would improve rate of fertilization, quality of blastocyst, and reduce aberrant methylation condition and frequency of occurrence of imprinting disorder.

Trial registration number: This study is not clinical trials.

P-599　Polymorphism on chromosome 21 does not affect ovarian reserve but clinical outcomes after in vitro fertilization treatments

C. Rubio LLuesa[1], M. Cruz[2], C. González-Ravina[3], M. Fernández-Sánchez[4], E. Oquiñena[5], A. Requena[6]

[1]iGenomix SL, Preimplantation Genetic Diagnosis, Valencia, Spain
[2]IVI Madrid, IVF Laboratory, Madrid, Spain
[3]IVI Sevilla, Andrology Laboratory, Sevilla, Spain
[4]IVI Sevilla, Gynecologist, Sevilla, Spain
[5]Biokilab, Laboratory, Vitoria, Spain
[6]IVI Madrid, Gynecologist, Madrid, Spain

Study question: To assess the effect of polymorphic chromosome variants in female fertility and assisted reproductive treatment (ART) outcome.

Summary answer: Polymorphisms on chromosome 21 affect oocyte and embryonic quality leading to worse gestational outcomes in women undergoing ART cycles.

What is known already: Polymorphic chromosome variants are more common in infertile women and seem to influence clinical outcomes after ART. Polymorphisms were considered as a variant when the chromosome region was greater or smaller than the same region on the homologous chromosome; as a minimum, twice the size on the other homologue. The apparently lower implantation and clinical pregnancy rates observed in female carriers has been related to a higher oocyte and embryo aneuploidy rate. However, not all authors find this negative effect, so it remains a controversial subject to date.

Study design, size, duration: This retrospective study was performed in 11 private clinics belonging to IVI group from January 2012 to December 2016. We included 985 women, of which 45.6% (n = 449) had normal karyotype and were considered as a control group; 37.2% (n = 366) were carriers of a polymorphism; and 17.3% (n = 170) showed the common polymorphic inversion for chromosome 9. All women underwent a fresh autologous ICSI cycle. Statistical analysis was performed by ANOVA and Chi-square where applicable.

Participants/materials, setting, methods: The cytogenetic study was performed by culture of peripheral blood lymphocytes stimulated with phytohemagglutinin and subsequent staining with trypsin-Giemsa (GTG bands). 15 metaphases were evaluated for each case and the banding resolution was 400–550 bands per haploid set. All cases were carried out according to the International System for Human Cytogenetic Nomenclature Guidelines.

Main results and the role of chance: Polymorphic variants for chromosomes 1 (46,XX,1qh+), 9 (46,XX,9qh+), 13 (46,XX,13 ps+), 14 (46,XX,14 ps +), 15 (46,XX,15 ps+), 16 (46, XX,16qh+), 21 (46,XX,21 ps+) and 22 (46, XX,22 ps+) were included, as well as the most frequent inversion of chromosome 9, 46, XX, inv(9)(p11q13). Basal data showed no differences among the three groups for the female ages, infertility years, days of stimulation, number of oocytes retrieved, number of metaphase II oocytes and number of transferred embryos. However, we observed statistical differences in antral follicle count between control group (3.2 ± 0.7), polymorphism carriers (4.6 ± 0.7) and chromosome 9 inversions (3.7 ± 1.0), p = 0.008. And for the implantation rate being the results as follows 34.7%, 31.6% and 26.0%, p = 0.048 for the control, polymorphism and inversion 9, respectively.

Focusing on chromosome 21 because its greater clinical relevance (n = 53), we found that female characteristics were similar compared to the control group, and despite demonstrating a similar response to stimulation, significant differences were noted in implantation rate (35.3% vs. 44.4%, p = 0.036); pregnancy rate (44.8% vs. 60.0%, p = 0.008) and miscarriage rate (22.5% vs. 53.3%, p = 0.005) between women with normal versus 21 ps+ polymorphism karyotype, suggesting that the higher miscarriage rate coud be related to higher embryo aneuploidy rate in these patients.

Limitations, reasons for caution: Despite the advantages that our data set confer the analysis, limitations still remain. One consequence of a retrospective study is that not all pertinent risk factors are likely to have been identified and subsequently recorded. Therefore, only association, and not causation, can be inferred from the results.

Wider implications of the findings: Although the female carriers of the polymorphism on chromosome 21 have better implantation and pregnancy rates than women with normal karyotypes, the high miscarriage rates suggest a female aneuploid factor to be taken into account in women who are seeking pregnancy.

Trial registration number: It does not apply.

P-600   mitochondrial DNA Levels in Euploid Blastocysts and Pregnancy Outcome

H. Gomaa[1], R. Baydoun[1], I. Lapana[1], S. Soliman[2]

[1]Newlife Fertility Center, Embryology, Mississauga, Canada
[2]NewLife Fertility Center, REI, Mississauga-, Canada

Study question: To evaluate the relation between mtDNA level and pregnancy outcome.

Summary answer: No correlation between mtDNA levels and pregnancy rate.

What is known already: Aneuploidy is one of the most important factors of implantation failure and early miscarriage, especially in old age females. Preimplantation genetic screening (PGS) is recommended to improve the pregnancy outcome by screening embryos for aneuploidy and selecting only euploid blastocysts for transfer. Mitochondria are the generator of the energy in the cell. Mitochondrial DNA (mtDNA) is located in the mitochondrial matrix. Some studies showed that, there is a correlation between high mtDNA level in the blastocysts and failure of implantation.

Study design, size, duration: This is a retrospective study conducted at the private New Life Fertility clinic. We have identified and reviewed health record of 78 patients who underwent FET in 2016. In which, preimplantation genetic screening was performed and all of embryos transferred were euploid blastocysts.

Participants/materials, setting, methods: We divided the cycles into two groups based on BHCG results, Group A: +ve BHCG, Group B: -ve BHCG. We analyzed clinical data, including demographic information, medical history, quality and number of embryos transferred, the ratio of mtDNA to nuclear DNA in each embryo, endometrial preparation protocol and pregnancy outcome. The primary outcome measures were the pregnancy rate and mtDNA level. Secondary outcome is viable ongoing pregnancy.

Main results and the role of chance: A total of 81 FET cycles for 94 euploid good quality blastocysts.

Group A: 56 FET cycles, Group B: 25 FET cycles. No significant difference between both groups regarding the age: 36.75 ± 3.70 vs 37.76 ± 2.84 (P = 0.227), endometrial thickness: 10.13 ± 1.89 vs 9.46 ± 1.50 (P = 0.254) or BMI: 25.71 ± 5.59 vs 24.50 ± 3.38 (P = 0.433).

Pregnancy rate: (56/81) [69.13%], clinical pregnancy rate: (43/81) [53%], Implantation rate:

(48/94) [51%] and ectopic pregnancy: 1.

Our results, showed that no difference in mtDNA level in both groups.

Limitations, reasons for caution: The sample size in the present study was limited. Retrospective nature of the study.

Wider implications of the findings: No impact of mt DNA level in blastocyst on pregnancy outcome.

Trial registration number: A retrospective study, no trial registration number.

P-601   Successful Polar Body-based Preimplantation genetic diagnosis for Fragile-X syndrome and Gaucher Disease

M. Bellavia[1], S. Cuomo[2], E. Crugnola[3], M. Jemec[1], L. Risch[4], G. FILIPPINI-CATTANEO[3]

[1]Procrea, Fertility center, Lugano, Switzerland
[2]ProCrea, IVF Laboratory, Lugano, Switzerland
[3]Procrealab SA, Molecular genetics laboratory, Lugano, Switzerland
[4]Labormedizinisches zentrum Dr Risch AG-, Medizinische und chemische Labordiagnostik, Bern-Liebefeld, Switzerland

Study question: Do oocyte polar bodies (PB) provide a valid and effective alternative to blastocyst biopsy for PGD for maternally-transmitted monogenic disease? A proof of concept on Fragile-X and Gaucher Disease.

Summary answer: PGD with PB biopsy can be considered to allow the selection and transfer of healthy embryos during IVF treatments of women carrying genetic disease.

What is known already: PGD is used worldwide to test embryos for specific genetic diseases; its main advantage is that it provides an alternative to selective pregnancy termination. PGD can be performed on different embryonic cells or on polar bodies.

Study design, size, duration: We present our experience of PB-PGD for two female patients carrying different genetic disorders; Gaucher disease (case 1) and fragile X syndrome (FRAX, case 2).

Participants/materials, setting, methods: A 35-year-old woman and a 37-year-old woman underwent ART treatment in our clinic. The first underwent ICSI with PB biopsy for PGD for Gaucher disease (GBA gene). The second woman underwent ICSI with PB biopsy for PGD for fragile X syndrome (FMR1-premutation). Analysis of the first and second PB were performed by multiplex PCR of 6 informative STRs flanking the gene (distal and proximal); for Gaucher Disease, the mutation was also directly tested using SNaPshot.

Main results and the role of chance: In these case reports, we describe two live births in Switzerland after PB biopsy and PGD. In case 1 (Gaucher), 14 MII oocytes underwent sequential first (day 0) and second (day 1) PB biopsy and 11 cleavage embryos were cryopreserved. The PGD analysis resulted in 7 embryos without the maternal mutation. A fresh-embryo transfer of two embryos was performed at day 2 and a healthy baby was delivered (39 weeks, male, 3460 g, 53 cm). In case 2 (FRAX), 8 MII oocytes underwent sequential first (day 0) and second (day 1) PB biopsy and 8 cleavage embryos were cryopreserved. Genetic analysis identified 3 embryos carrying the normal maternal FMR1 allele. After endometrial priming, a first frozen-thawed single embryo transfer (FET) was performed at day 3, followed by a negative bHCG test. A second FET was performed with the same protocol and a healthy baby was delivered after caesarean section (38 weeks, male, 3600 g, 50 cm).

Limitations, reasons for caution: By its nature, PB-PGD can only detect maternally-transmitted mutations. This is not a disadvantage in X-linked disorders but could lead to lower numbers of embryos for transfer in autosomal-recessive diseases. PB biopsy is also sometimes considered more technically demanding for the embryologist.

Wider implications of the findings: PB-PGD is a valuable tool for diagnosis of maternally-transmitted genetic diseases and transfer of healthy embryos. PB-PGD has two major advantages compared to trophectoderm testing: 1) shorter time of the embryos in culture, and 2) earlier testing leaving plenty of time for genetic analysis while allowing fresh embryo transfer.

Trial registration number: None.

P-602   young poor responders: should we screen for FMR1 mutations and cytogenetic aberrations?

M.W. Christensen[1], V. Poulsen[2], K. Kirkegaard[3], U.B. Jensen[4], H.J. Ingerslev[5]

[1]Aarhus University, Clinical Medicine, Aarhus N, Denmark
[2]Aarhus University, Health, Aarhus, Denmark
[3]Horsens Hospital, Gynecology and Obstetrics, Horsens, Denmark
[4]Aarhus University Hospital, Clinical Genetics, Aarhus, Denmark
[5]Aarhus University, Clinical Medicine, Aarhus, Denmark

Study question: Do young women with a reduced ovarian response have an increased risk of cytogenetic aberrations and mutations in the FMR1?

Summary answer: We found a markedly increased prevalence of FMR1 mutations and X chromosome mosaicism in young poor responders compared with known prevalence in the background population.

What is known already: Poor response to FSH stimulation (POR) is a reliable indicator for reduced ovarian reserve in young women indicating an increased risk of premature menopause. Women with premature menopause

are known to have an increased incidence of mutations in *FMR1* and of cytogenetic changes. Thus, younger women with POR may also have an increased risk of cytogenetic changes and mutations in *FMR1*, both with possible risk for the offspring.

Study design, size, duration: Retrospective cohort study based on 43 young idiopathic poor responders identified in a retrospective database search comprising a total of 13.431 women attending ART in three Danish fertility clinics between 2006 and 2016.

Participants/materials, setting, methods: 239 women fulfilled criteria for inclusion (age ≤37 years at oocyte pick-up, ≤5 oocytes harvested in >2 cycles, FSH dose (>225 IU), no previous ovarian surgery, chemotherapy, or irradiation). Only 43 accepted to participate. *FMR1* mutations were analysed by PCR (FragilEase™ kit, Perkin-Elmer). Karyotyping was performed on peripheral lymphocytes (Q-band staining). Two metaphases were analysed in a digital karyotyping system (Icarus). Abnormal cases were analysed by fluorescence in situ hybridization (FISH) (50 cells).

Main results and the role of chance: 13 out of 43 (30.2%) had an X-chromosome mosaicism. One patient (2%) had a *FMR1* premutation (> 55 repeats), and 7 (16%) had a so-called grey zone repeat number (41-54 repeats). *FMR1*-premutations are found in 0.004 % (1/250) in the general female population and grey zone alleles in 1.7 %. No structural chromosome aberrations were identified. X-chromosome mosaicism was found in 16 women (37.2%), in most cases of low grade, but in two cases (5%) with 16 and 18% mosaicism. Similarly Lakhal et al (2010) found X-chromosome mosaicism in 6.2% of 1000 women with premature ovarian failure. The prevalence of X chromosome mosaicism in the general population is increasing by age reaching a maximum of 0,4% at the age of 70 years.

Limitations, reasons for caution: The number of participants is relative small given the study period of 10 years. Nevertheless, the finding of both *FMR1* abnormalities and X-chromosome mosaicism in our study was far higher than in the general population.

Wider implications of the findings: The present results indicate that young patients with idiopathic POR share similarities with women undergoing premature menopause, and indicate that POR patients should be screened for *FRM1* aberrations since abnormal repeat lengths in the mother can expand to the next generation with a risk of Fragile-X syndrome in the offspring.

Trial registration number: Not applicable.

P-603   Actual levels of mosaicism detection by construct reference curves

Y. Qiu, D. Chen, P. Liu, J. Xia, Q. Shi, L. Xie, Z. Zhu, F. Chen, H. Jiang

BGI, R&D, Shenzhen, China

Study question: The problem of whether the low levels of mosaic embryos can be transferred has always existed.

Summary answer: And different levels of mosaicism have different clinical phenotypes.

What is known already: Mosaic embryos which are characterized by the presence of a mixture of diploid and aneuploid cells, are not usually transferred because they are deemed to be abnormal. And the phenotypic manifestations of the mosaicism embryos are dependent on mosaicism level, the chromosome involved, and tissue distribution. PGDIS suggested that mosaic embryos for trisomies capable of liveborn viability (chromosomes 13/18/21) are of lowest priority when mosaic embryo is being considered for transfer. And suggest cut-off point for definition of mosaicism is 20-80% (aneuploid-euploid mosaics). Recently, array CGH and NGS that have accurately measured mosaicism level by quantifying the copy number change

Study design, size, duration: Here, 5 cell lines were purchased from https://catalog.coriell.org/ with known karyotype (47, XX, +18; 47, XX, +21; 47, XY, +13; 46, XY and 46, XX). DNA that extracted from these cell lines were constructed libraries and sequenced on BGISEQ-500, and the karyotypes of sequencing were matched with the expected.

Participants/materials, setting, methods: The study involved mixing experiments with different ratios of aneuploid and euploid samples lines under micromanipulation, including 0:8, 1:7, 2:6, 3:5, 4:4, 5:3, 6:2, 7:1, 8:0,

respectively, each was prepared in triplicate. Experiments of a total of 81 samples were performed and these samples were amplified using the single cell SurePlex amplification kit (SurePlex, Rubicon) according to the manufacturer's protocol. After that these amplified DNA were constructed libraries and sequenced on BGISEQ-500.

Main results and the role of chance: As result, copy number ratios for each chromosome were calculated for the different mimic experiments and expressed as average $\pm$ SD. We obtain 0%, 12.5%, 25%, 37.5%, 50%, 62.5%, 75%, 87.5%, and 100% mosaicism level, including chromosome 13, 18, 21, each level were triplicate. The copy number ratio of chromosome 13 were 0.96 ± 0.15 (0%), 1.02 ± 0.004 (12.5%), 1.06 ± 0.008 (25%), 1.10 ± 0.033 (37.5%), 1.15 ± 0.025 (50%), 1.25 ± 0.026 (62.5%), 1.27 ± 0.01 (62.5%), 1.34 ± 0.04 (75%), 1.36 ± 0.03 (100%) respectively. The linear relation of chromosome 13 between copy number ratio and mosaicism level is $y=0.4199x +0.959$, $R^2 = 0.9488$. $y=0.4676x+1.0151$, $R^2 = 0.9138$ and $y=0.3071x +1.0027$, $R^2 = 0.8581$ were linear relations of chromosome 18 and 21. Each linear relation is independent and applicable to mosaicism level detection of corresponding chromosome.

Limitations, reasons for caution: These three reference curve were just applicable to corresponding chromosome mosaicism level detection. Mimic mosaic samples have been validated by these curves. And we are collecting clinic samples to do validation by fluorescence in situ hybridization (FISH) methods.

Wider implications of the findings: Based on these mimic mosaic cell lines, the results showed that a new method to detect mosaic level of embryo.

Trial registration number: no.

P-604   clinical outcomes after transfer of embryos with low-level chromosomal mosaicism

C. Jiramongkolrat[1], W. Suksalak[1], S. Martkamchan[1], S. Nabu[1], S. Suwannasing[1], K. Maneewas[2], S. Chanchamroen[2], W. Quangkananurug[3]

[1]*Next generation genomic, Laboratory, Bangkok, Thailand*
[2]*Safe fertility center, Laboratory, Bangkok, Thailand*
[3]*Safe fertility center, clinician, Bangkok, Thailand*

Study question: Can low-level mosaic embryos be transferred? Does the presence of chromosomal mosaicism affect clinical outcomes?

Summary answer: Transfer of mosaic embryo showed a significant lower pregnancy rate but it can improve the success rate for couples with no euploid embryos for transfer.

What is known already: Mosaic embryo is defined as the presence of more than one population of cells with different genotypes within the same embryo. The recent advances in comprehensive chromosome analysis using Next generation sequencing (NGS) provides the greatest dynamic range for detection of chromosomal mosaicism. Therefore, mosaic embryo has been classified and reported in many laboratories worldwide. However, the criteria for calling mosaic embryo may be different between laboratories and clinical outcomes of mosaic embryos are not fully understood.

Study design, size, duration: This retrospective observational study was performed in one private fertility clinic in Thailand between September 2015 and September 2016. Clinical outcomes obtained from 443 PGS cycles that transfer a single euploid or mosaic embryo were evaluated.

Participants/materials, setting, methods: The trophectoderm samples were subjected to whole genome amplification followed by comprehensive chromosome analysis using NGS method. Low-level chromosomal mosaicism was defined as the percentage of mosaicism between 20-50%. Genetic counseling regarding the risks and consequences of transferring a mosaic embryo was provided for all patients who elected to transfer mosaic embryos. The clinical outcomes, i.e. clinical pregnancy and biological pregnancy rate were followed. Statistical analysis was evaluated using the Fisher's exact statistical test.

Main results and the role of chance: There were a total of 406 cycles of single euploid embryo transfers (mean age 34.9 years, range 24-52) and 37 cycles of single mosaic embryo transfers (mean age 36.1 years, range 26-49). The clinical pregnancy rate, as confirmed by an intrauterine gestational sac with fetal heartbeat visualized by ultrasound examination, of transferring low level

mosaic embryos was significant lower than those of euploid embryos (37.8% vs. 56.4%; *p = 0.0377*). Among cycles with transferring of a mosaic embryo, 14 (37.8%) were clinical pregnancy, 5 (13.5%) were biochemical pregnancy rate and 18 (48.6%) were not pregnant. Clinical pregnancy rate was not significant different between embryos with 30% and 40% mosaicism (44.4% vs. 38.8%). The number of chromosomal mosaicism was evaluated in pregnancy group and found that 11 (78.6%) were from embryos with one chromosomal mosaicism and 3 (21.4%) were from embryos with two or more chromosomal mosaicisms.

Limitations, reasons for caution: Due to the limited number of samples, more data and additional clinical data including prenatal diagnosis and live birth are required.

Wider implications of the findings: This study demonstrated that transfer of embryos with low-level mosaic slightly decreased the pregnancy outcome. However, it may potentially improve IVF success rate for couples with no euploid embryo available for transfer. The classification of mosaic embryo can improve embryo selection and clinical management strategies to optimize the reproductive outcome.

Trial registration number: Not applicable.

P-605   Pre-implantation genetic testing (PGT) is particularly more cost-effective in 41-42 yr-old women: A cost-effectiveness analysis of PGT in women with advanced maternal age

M. Polat[1], G. Bozdag[2], I. Yarali[3], S. Mumusoglu[2], L. Karakoc Sokmensuer[4], H. Yarali[2]

[1]Anatolia Tup Bekek Ve Kadin Sagligi Merkezi, Ankara, Turkey
[2]Hacettepe University- School of Medicine, Obstetrics and Gynecology, Ankara, Turkey
[3]Anatolia IVF and Woman Health Center, Histology and embryology, Ankara, Turkey
[4]Hacettepe University- School of Medicine, Histology and Embryology, Ankara, Turkey

Study question: Is pre-implantation genetic testing (PGT) more cost-effective to achieve live birth compared to standard in-vitro fertilization (IVF) in patients with advanced maternal age (AMA)?

Summary answer: Compared to standard IVF, PGT is more cost-effective to achieve live birth particularly in the 41-42-yr-old female age subgroup.

What is known already: Aneuploidy is the main contributor to implantation failure and increased risk of miscarriage in IVF, particularly in women with AMA. Instead of performing sequential and unscreened IVF cycles, PGT by trophectoderm biopsy and comprehensive chromosome screening might be undertaken to optimize results. Regarding PGT in AMA cases, other than the lack of randomized controlled trials (RCT) supporting efficacy, financial burden due to increased cost can be a limiting factor. There is paucity of data on the cost-effectiveness analysis of performing PGT in AMA cases, stratified by female age and number of blastocysts available to be biopsied.

Study design, size, duration: In AMA cases, a decision-analysis model was developed to compare cost per live birth of PGT (with freeze-all approach) versus standard IVF. All possible outcomes from ovarian stimulation up to embryo transfer from single started stimulation cycle were entered into the model. In PGT arm, up to 2 frozen single euploid embryo replacement (FSEER) cycles and in standard IVF, up to one fresh and one frozen embryo transfer were entered into the model.

Participants/materials, setting, methods: Data were derived from our database of 228 consecutive AMA patients undergoing PGT and 1107 consecutive AMA patients undergoing standard IVF. Blastocyst biopsy (Day5/6) and array-comprehensive genomic hybridization for 24 chromosomes were employed. Couples undergoing PGT due to genetic disorders or translocations were excluded. Patients were stratified according to female age as 38-40, 41-42 and 43-45. The main outcome was cost to achieve live birth exceeding 24 weeks of gestation. Sensitivity analysis was performed.

Main results and the role of chance: Overall, the live birth per one stimulation cycle along with up to two FSEER cycles was 14.4% in the PGT arm; the miscarriage, multiple and preterm birth rates were 12.7%, 0% and 8.6%. The respective figures were 11.6%, 28.2%, 28.2%, and 23.4% in the standard IVF arm. In all age subgroups, the costs per live birth were $13.119 and $13.960 in

the PGT and standard IVF arms, respectively. When stratified by female age, in women 38-40-yr old, the cost per live birth was $11,045 and $10,789 in PGT and standard IVF arms. In women 41-42-yr old, cost to achieve live birth was $11,933 and $21,023 in PGT and standard IVF arms. Lastly, in women 43-45-yr old, these figures were $46,205 and $43,421 in PGT and standard IVF arms, respectively.

Limitations, reasons for caution: The analysis may vary with differences in pricing in different countries. Hidden additional costs of unscreened IVF arm, including i) increased time out-of-work, emotional burden and potential endometrial injury associated with miscarriage and curettage; ii) long-term morbidity associated with preterm birth due to multiple pregnancy have not been assessed.

Wider implications of the findings: In AMA cases, when compared with standard IVF, performing PGT is more cost-effective, only in the 41-42-yr old female age subgroup, but not in 38-40 and 43-45 yr-old subgroups. Decrease in miscarriage and multiple pregnancy rates remain to be the other main two advantages of PGT.

Trial registration number: None.

P-606   Preimplantation genetic screening 2.0: which indications can benefit? zygote number, female age and medical history are analyzed

C. Lagalla[1], N. Tarozzi[1], M. Nadalini[1], M. Di Santo[1], F. Pennetta[1], M.A. Bonu[1], A. Borini[2]

[1]9.Baby Family and Fertility Center, Reproductive medicine IVF Laboratory Unit, Bologna, Italy
[2]9.baby Family and Fertility Center, Reproductive Medicine Clinical Unit, Bologna, Italy

Study question: Which indications to follow for recruitment of patients in a Preimplantation Genetic Screening (PGS) program? Which is the limit not to overstep to have benefits?

Summary answer: There is a limit over that PGS has no benefit on patients. Indications, age and number of fertilized oocytes clarify which patients should be recruited.

What is known already: It is recognized that there is a new generation of PGS, the so-called PGS 2.0, identified by biopsy at blastocyst stage, comprehensive chromosome screening (CCS) and elective single embryo transfer (eSET) after vitrification and thawing. However, debate is still open regarding which patients can really benefit from this newest approach.

Study design, size, duration: Retrospective observational study carried out between May 2013 and December 2016 on 277 PGS cycles. The average female age was 40.4 years, ranging from 26 to 48. Cycles with complete PGS diagnosis were 166, 103 of which had embryo transfer. The performance of different groups of PGS patients was evaluated.

Participants/materials, setting, methods: Trophectoderm biopsy was performed on Day 5-6, followed by array-CGH and eSET.

The performance of PGS patients was evaluated in terms of eSET cycles per started cycles and main outcome measures.

Patients were assessed according to: 1) PGS indications: 218 AMA (advanced maternal age) patients; 45 RIF (repeated implantation failure) patients; 22 RM (recurrent miscarriage) patients; 18 SMF (severe male factor) patients; 40 patients without indication); 2) female age; 3) number of fertilized oocytes.

Main results and the role of chance:

- Regarding indications, the best outcome was obtained in SMF patients (ongoing pregnancy rate: 53.8%), while the worst, surprisingly/noteworthy, in patients with no specific indication (ongoing pregnancy rate: 17.9%), despite their significantly lower mean age (P < 0.01).
- According to female age, no significant difference in terms of ongoing pregnancy rate was found in the different age groups, although, as expected, younger patients had significantly higher cumulative pregnancy rate (68.2%) compared to the oldest ones (37.8%), (P = 0.02). Of interest is that all patients over 44 years old never reached embryo transfer: 76.2% of them because their embryos did not reach blastocyst stage and the remaining 23.8% because they did not produce euploid blastocysts.

- If considering the number of fertilized oocytes, when it was ≤2, the eSET cycles per started cycles were only 17%, with a low cumulative pregnancy rate (12.5%).
- Finally, wondering how many fertilized oocytes would be necessary to obtain at least one euploid blastocyst, data showed 3.6 in women <38 years old, 5.4 in 38-40 years old women, 13 in 41-42 years old women and, remarkably, 55.9 in patients over 42 years old.

Limitations, reasons for caution: The study is referred to patients attending our Fertility Center, therefore it might not reflect the clinical scenario offered in other Centers worldwide. The low number of cases of different study groups represents another limitation. So it would be interesting to perform the analysis in a multicentric, large-scale study.

Wider implications of the findings: The study sheds light on specific biological parameters and clinical features which may help clinicians in the selection and management of patients for a PGS program.

Trial registration number: None.

P-607   Does the low-grade mosaicism detected by next-generation sequencing affect the live birth rate?

R. Morales Sabater[1], B. Lledó Bosch[1], J.A. Ortiz Salcedo[1], J. Ten Morro[2], J. Llácer Aparicio[3], R. Bernabeu Pérez[3]

[1]Instituto Bernabeu, Biotech, Alicante, Spain
[2]Instituto Bernabeu, Reproductive Biology, Alicante, Spain
[3]Instituto Bernabeu, Reproductive Medicine, Alicante, Spain

Study question: Is the preimplantation genetic screening (PGS) by Next- generation sequencing (NGS) able to improve the birth rate compared with the array comparative genomic hybridization (aCGH)?

Summary answer: The NGS is able to detect low-grade mosaics undetected by aCGH, however the transfer of these embryos does not modify the live birth rate significantly.

What is known already: Chromosomal aneuploidy is highly prevalent in human embryos. It is a reason for the relatively low success rates of IVF cycles. PGS by aCGH has been used to identify euploid embryos in order to improve the clinical outcome of IVF treatments. However a percentage of morphologically normal euploid blastocysts fail to implant or result in a pregnancy loss. The chromosomal mosaicism, which consists of a mixture of diploid and aneuploid cells, has been considered as a feasible explanation for some failures after the transfer of euploid embryos. The incorporation of NGS to PGS has improved the mosaicism detection compared with aCGH.

Study design, size, duration: We reanalyzed by NGS trophoectoderm biopsies of day 5 and 6 blastocysts previously analyzed by aCGH (from February 2014 to March 2016). We included 85 euploid blastocysts analyzed by aCGH from patients who didn't achieve pregnancy (n = 46) and patients who resulted in live birth (n = 39). In all cases only one embryo was transferred. We considered a mosaic embryo by NGS when the estimated percentage of aneuploid cells was between 20% and 80%.

Participants/materials, setting, methods: The amplified genomic DNA from trophoectoderm biopsies (stored at -80°C) was reanalyzed by NGS. Next-generation sequencing was performed using the Veri-Seq protocol and MiSeq sequencer (Illumina). The analysis was performed using the BlueFuse Multi software (Illumina). The patients who didn't achieve pregnancy had β-hCG levels lower than 2 mUI/ml 14 days after the oocyte retrieval. The differences between the groups were evaluated using Pearson chi-square and t-student statistical tests (SPSSv20.0).

Main results and the role of chance: The DNA samples from trophoectoderm biopsies of day 5 and 6 euploid blastocysts analysed by aCGH (n = 85) were reanalysed by NGS. We detected chromosomal mosaicism in 24 blastocysts (28.2%). In all cases the percentage of aneuploid cells was between 20% and 40% (low-grade mosaicism). Within the group of euploid embryos that didn't achieve pregnancy (n = 46) we detected chromosomal mosaicism in 15 cases (32.6%), and we detected 9 mosaic embryos (23.1%) in the group of live births (n = 39). The percentage of low-grade mosaic embryos seems to be higher among the patients that didn't achieve pregnancy than in those who resulting in live births (32.6% vs 23.1%), however the difference was not statistically significant (p = 0.33).

There were no significant differences between the groups (no pregnancy vs live birth) with respect to maternal age (29.5 vs 29.31, p = 0.89), paternal age (41.8 vs 39.5, p = 0.07), MII oocytes retrieved (10.9 vs 10.7, p = 0.79) and percentage of top and good quality embryos transferred (p = 0.16).

Limitations, reasons for caution: This study was limited by the small sample size. Larger study is needed to stablish if the low-grade mosaicism detected by NGS could affect the live birth rate. In general, more data are needed to conclude the effect of the mosaicism in the embryo development.

Wider implications of the findings: The NGS is more efficient to detect mosaicism than aCGH. However, the transfer of low-grade mosaics detected by NGS does not affect the live birth rate, according to our data. Therefore, the transfer of these embryos should not be avoided until more data is obtained.

Trial registration number: not applicable.

P-608   Detection limit of partial insertions and deletions for PGS in terms of NGS by analyzing 242 embryos of couples with Robertsonian or reciprocal translocations

H. Blanca[1], S. González-Reig[1], V. Penacho[2], N. Castejón-Fernández[3], D. Amorós[3], F. Galán[4], L.A. Alcaraz[5]

[1]Bioarray, PGD/PGS, ELCHE ALICANTE, Spain
[2]Bioarray, R&D&i, Elche Alicante, Spain
[3]Bioarray, Bioinformatics, Elche Alicante, Spain
[4]Bioarray, Medical diagnosis, Elche Alicante, Spain
[5]Bioarray, Technical Direction, Elche Alicante, Spain

Study question: What is the detection limit of next-generation sequencing (NGS) along with low-pass whole genome sequencing in the determination of partial insertion and deletions?

Summary answer: Up to 242 embryos from couples following IVF treatment due to altered karyotype were analyzed by using NGS Ion-Torrent™ PGM platform.

What is known already: Balanced translocations have a significantly impact in fertility and miscarriage risk. Preimplantation genetic screening (PGS) involves the genetic study of the embryo's genome in order to determine its chromosomal arrangement, prior to selection of euploid embryos and desired successful implantation rate in IVF. Initial attempts at preimplantation genetic diagnosis were limited by the inability to simultaneously evaluate aneuploidy and unbalanced translocations in all 24 chromosomes. Missdiagnosis reached up to 70% of aneuploidy in chromosomes unrelated to the rearrangement. Contemporary platforms are more accurate and less susceptible to technical errors.

Study design, size, duration: This retrospective trial involved genetic testing with NGS of 242 embryos from 47 patients with Robertsonian (17) or reciprocal (30) translocations recruited from January 2016 to December 2016. Aberrations with different sizes and most affected chromosomes (all but chromosomes 16, 19, 20 and X and Y) were analyzed.

Participants/materials, setting, methods: After human oocyte insemination, 242 embryo single-cell or trophoectodermal biopsy was performed on day 3 or 5. Whole genome DNA was amplified by Ion SingleSeq™ Kit. Copy Number Variation (CNV) analysis was performed with Ion Reporter™ Software 5.2., which determined the ploidy status with less than 0.01X read coverage.

Main results and the role of chance: As a result of the analysis, we obtained that 179 of the total embryos analyzed (242) were aneuploid: 25 of 179 (14%) presented trisomies, 28 (15.6%) monosomies, 35 (19.6%) full gain and losses and 91 (50.8%) had partial imbalances; 58 (63.7%) of them presented the same imbalance than respective balanced translocation carriers and 33 of them (36.27%) presented others different. A total of 63/242 were euploid and suitable for embryo transfer. The implantation rate was 80 % and ongoing pregnancy rate at 20weeks gestation was 60 %. The smallest aberration detected by the software was 10 Mb in size. By manual inspection, we were able to identify aberrations as small as 5 Mb. We found differences depending on the chromosome analyzed.

Limitations, reasons for caution: Although reliability of NGS Ion-Torrent™ PGM platform along with low-pass whole genome sequencing for both aneuploidy and unbalanced translocations detection, the smallest fragment detected by NGS was 5 Mb.

Wider implications of the findings: PGS coupled to NGS is able to simultaneously identify aneuploidy events and unbalanced translocations, and increases

the chances of obtaining a healthy newborn. It's also important to determine the detection limit of this technique, to identify not only the aberration arising from a balanced translocation, but also segmental chromosomal aberrations.

Trial registration number: None.

P-609   Expression of genes for PPAR-γ, COX-2 and pro-inflammatory cytokines in granulosa cells from women with polycystic ovary syndrome

S. Ryu[1], J.Y. Lee[2], S.H. Kim[3], S.G. Lee[4]

[1]Seoul, Korea- South,
[2]Hamchoon Women's Clinic, OB & GYN, Seoul, Korea- South
[3]Seoul National University College of Medicine, OB & GYN, Seoul, Korea- South
[4]Maria Hospital, Republic of Korea,

Study question: Is there the difference in expression of genes for PPAR-γ, COX-2 and proinflammatory cytokines (IL-6 and TNF-α) in granulosa cells from polycystic ovarian syndrome patients undergoing ICSI?

Summary answer: PPAR-γ and COX-2 mRNA were significantly down-regulated in the granulosa cells of PCOS women, but expression of IL-6 and TNF-α did not show significant differences.

What is known already: Although the etiology of PCOS is still obscure, granulosa cells dysregulation may affect ovarian follicular environment, which may be associated with poorer reproductive outcomes observed in PCOS patients. The existing literature has shown that there is a controversy about expression level of PPAR-γ and few studies on COX-2 expression in PCOS have been found in the literature. Infertile women with PCOS were found to have higher serum and folicular fluid concentrations of TNF-α and IL-6 than control women, suggesting that granulosa cells produce both cytokines.

Study design, size, duration: This was a prospective study in which 15 granulosal cell samples were obtained on the day of oocyte retrieval. Granulosa cells were collected from pooled follicular fluid and extracted mRNAs were frozen at -80°C till analysis.

Participants/materials, setting, methods: Nine patients with PCOS and 6 controls were enrolled for this study. Total mRNAs were extracted from granulosa cells. Reverse transcription was performed and quantification of gene expression levels was achieved by real-time quantitative PCR. Mann-Whitney test was used to compare the mean values of mRNA. Correlation between expressions of the different parameters was tested by nonparametric Spearman's correlation.

Main results and the role of chance: There were no significant differences in age, body mass index and total dose of gonadotropin except for LH/FSH ratio between PCOS and control group. PPAR-γ and COX-2 mRNA were significantly down-regulated in the GCs of PCOS women compared with controls ($p = 0.034$, 0.018, respectively), but expression of IL-6 and TNF-α mRNA did not show significant differences. No significant correlation was detected between expression of these mRNA and clinical characteristics, the number of retrieved oocytes, oocyte maturity, cleavage, or good-embryo rate. There was positive correlation between PPAR-γ, COX-2, IL-6 or TNF-α mRNA levels.

Limitations, reasons for caution: It should be noted that the results of this study were derived after analyzing a relatively small number of cases and PCOS study group did not contain various PCOS phenotypes.

Wider implications of the findings: Resulting data may provide novel clues for ovarian granulosa cells dysfunction in PCOS and indirectly provide evidence that the effect of PPAR-γ agonist in PCOS might come from altered ovarian follicular environment. Further studies with a larger sample size are required to confirm these.

Trial registration number: not applicable.

P-610   National reference materials of preimplantation genetic aneuploid screening based on next generation sequencing

J. Huang[1], P. Liu[2], F. Chen[2], H. Jiang[2], Y. Qiu[2], D.Y. Chen[2], J. Xia[2], L. Xie[2], Z. Zhu[2], Q.Y. Shi[2]

[1]National Institutes for Food and Drug Control, National Institutes for Food and Drug Control, Beijing, China
[2]BGI-SHENZHEN, R&D, ShenZhen, China

Study question: We want to establish one set of national reference materials which can effectively evaluate the effectiveness of PGS detection technology based on next generation sequencing(NGS)

Summary answer: Our reference materials have been verified by BGISEQ-500 platform and can be used for evaluating the accuracy of the PGS based on NGS.

What is known already: Developing with the maturity of NGS technology, due to its characteristics of high accuracy, high throughput, low cost and easy operation, PGS detection technology based on NGS has been more and more used in clinical practice. At present the main NGS platforms include Illumina, Life and BGI-SHENZHEN's BGISEQ series, and different companies based on these platforms developed a variety of PGS detection technologies, how to evaluate the accuracy of these PGS detection technologies becomes an urgent problem needed to solve.

Study design, size, duration: The set of national reference materials consists of 89 strains normal tarotype, CNVs(at least 1 M) and aneuploid cell lines, which includes 67 different CNVs cell lines, 1 data QC cell line, 9 normal karotype people's cell lines, 6 different sizes CNVs mixes mosaic cell lines and 6 trisomic embryo stem cell lines. All these cell lines were collected and validated from May 2015 to September 2016.

Participants/materials, setting, methods: All of the 89 strains cell lines with known karyotype bought from Coriell Institute or hospital and sorted into 0.2 ul PCR tube with 3-5 cells every tube by flow cytometry. We used EmbryoSeq kit, its software and BGISEQ-500 to verify this set of national reference materials. We used EmbryoSeq kit to construct libaries according to the manufacturer's protocol, send them to sequence on BGISEQ-500 and analyse sequencing data with automatic EmbryoSeq software.

Main results and the role of chance: 9 sets of this reference material were detected by BGISEQ-500, all of >4 M CNVs, aneuploid and normal cell lines can be detected correctly, the results were same with known karotype, and there are 15 strains 1-4 M CNVs and 80% of them can be also detected correctly. These results achieved reference materails'technical requirements. After BGISEQ-500 sequencer, other NGS platform also verify this reference materials, that have same serults with BGISEQ-500.

Limitations, reasons for caution: Due to the time and some cell lines were difficult to culture, this set of reference materials doesn't contain all of 24 chromosome aneuploid and CNVs, so those chromosome perhaps don't meet this set of reference materials' technical requirements if they don't be included in this set of reference.

Wider implications of the findings: Although this set of reference materials are validated only on several NGS platform now, but it can also be used for other new developed NGS sequencer, even maybe it can apply to the third generation sequencer or micro array platform.

Trial registration number: NO.

P-611   Does blastocyst biopsy technique effect aneuploidy rates?

J.B. Whitney[1], R. Anderson[2], C. Rios[3], N. Nugent[1], S. Zozula[1], F. Garner[4], M.C. Schiewe[1]

[1]Ovation Fertility, ART Lab, Newport Beach- CA, U.S.A.
[2]Southern California Center for Reproductive Medicine, Clinic, Newport Beach- CA, U.S.A.
[3]Ovation Genetics, Genetics Lab, Henderson- NV, U.S.A.
[4]Fertility Center of Las Vegas, Research, Las Vegas- NV, U.S.A.

Study question: Do the inherent variables associated with the blastocyst biopsy procedure influence aneuploidy rates? Does the blastocyst biopsy technique produce equivalent results independent of mechanical variables?

Summary answer: Optimal trophectoderm biopsying involves minimal laser pulses and intact biopsy pieces free of appreciable cell lysis. Deviation from this ideal more often produces aneuploid results.

What is known already: Preimplantation Genetic Screening (PGS) offers patients the ability to know the ploidy status of embryos before implantation. The efficacy and invasive nature of this embryo procedure has made the use of PGS questionable in the past. Current technologies, such as trophectoderm biopsy, have been successfully applied to facilitate a complete chromosomal ploidy diagnosis. The blastocyst biopsy procedure has proven to not increase

any known birth defects, appears to not damage embryo competence and is viewed as an improved method for obtaining embryo genetic material.

Study design, size, duration: Using a prospective, observational cohort design, 1204 blastocysts were biopsied between July 2015 through January 2016 from 220 cycles (average age: 37.2). Multivariate logistic regression was applied to derive models which predicted ploidy. Variables were selected for the model and analyzed using forward selection and backward elimination, with $p<0.05$ required to remain in the model. Pearson's chi-square test was then used to assess the association of nominal variables with observed embryo ploidy.

Participants/materials, setting, methods: Patient embryos were cultured in Life Global media with LGPS under tri-gas incubation conditions, and biopsied at or beyond the full blastocyst stage. Each embryologist self-reported biopsy parameter variables, including embryo quality, day of development, # of laser pulses applied (≤4, 5-9, ≥10 pulses), biopsy sample size (≤3 or ≥4 cells) and if the resulted biopsy sample appeared primarily lysed. For comparative analysis purposes, each blastocyst was classified as having an ideal or difficult biopsy.

Main results and the role of chance: 85% of all biopsies performed were classified as ideal, while only 175 blastocyst biopsies were considered difficult. Biopsy modelling variables revealed significance for age, embryo grade and the day of blastulation. The derived model also uniquely identified significant mechanical parameters including number of laser pulses and increased cell lysis as predictors of aneuploidy. A second model based only on biopsy mechanics identified cell lysis and the number of resulting biopsy pieces as significant predictors of ploidy. Comparing ideal to difficult biopsies, higher ($p<0.05$) aneuploidy rates occurred when biopsies were difficult. Embryo quality and day of development showed no significance for producing a difficult biopsy. Additionally, no difference was observed among the 5 technicians. An implantation rate of 72% was achieved for women ≤37 years old and 73% for women ≥38 years old following vitrified single euploid embryo transfers. The implantation potential of embryos derived from patients with difficult biopsies was not determined due to an insufficient sample size, however multiple pregnancies are ongoing. Spontaneous abortions were 5% across all age groups and no chromosomal errors were reported.

Limitations, reasons for caution: This study highlights an objective, observational analysis, but cannot delineate if aneuploid embryos are more susceptible to yielding a difficult biopsy. No differences in aneuploidy or prevalence of difficult biopsy parameters was observed between technicians, indicating that the embryo is the probable source of difficulty, not the technician micromanipulating.

Wider implications of the findings: The model derived in this study revealed independent mechanical variables that increased aneuploidy rates. We suggest that the variables identified by these models, describe a specific style of biopsy questioning if technique affects or is predictive of genetic outcomes. These variables appear to be linked and generally occur simultaneously.

Trial registration number: None.

P-612   Lessons learned from over 1,100 preimplantation genetic screening (PGS) cycles: blastocyst development and aneuploidy outcome analysis

R. Anderson[1], J.B. Whitney[2], M.C. Schiewe[2]

[1]Southern California Center for Reproductive Medicine, ART Lab, Newport Beach-CA, U.S.A.
[2]Ovation Fertility, ART Lab, Newport Beach- CA, U.S.A.

Study question: What are the relevant clinical outcome percentages for blastulation and aneuploidy in women using PGS in conjunction with their ART cycle?

Summary answer: Significant data was generated providing generalized aneuploidy percentages and cycle yield outcomes. With optimized embryology laboratory practices, most cycles achieve a euploid embryo.

What is known already: PGS offers patients the ability to know the ploidy status of embryos before implantation. Current technologies, such as trophectoderm biopsy, have been successfully applied to facilitate a complete chromosomal ploidy diagnosis. NextGen sequencing results are thought to correlate directly with the ICM status and subsequent pregnancy ploidy, but a conclusive link remains unattainable. The error rate of a PGS euploid embryo resulting in a chromosomally abnormal pregnancy remains extremely low, but the alternative of an aneuploid embryo resulting in a normal fetus is unknown. PGS testing has improved blastocyst utilization by facilitating single euploid embryo transfers.

Study design, size, duration: Retrospective analysis from a single center's 5 year (October 2011 to December 2016) PGS/Blastocyst biopsy program resulting in 1,087 autologous cycles, 88 donor cycles and 6234 embryos tested. Each cycle reported eggs retrieved, maturity, fertilization, usable blastocysts and aneuploidy results. All ICSI/PGS cycles achieving an oocyte retrieval cultured all embryos to blastocyst stage and were included in this analysis. No cycles were excluded for any reason.

Participants/materials, setting, methods: Patient embryos were cultured in Life Global media with LGPS under tri-gas incubation conditions, and biopsied at or beyond the full blastocyst stage. All embryos were biopsied on either day 5,6,7 and sent for array CGH (2011-2014) or NextGen sequencing (2015-2016). All patients were treated by a single physician and followed standard ART stimulation protocols. All cycles were cryo-all, with emphasis on subsequent single vitrified/thawed euploid embryo transfer.

Main results and the role of chance: The average patient (mean age=37.01) produced 15.1 eggs, with an 84.4% maturity rate and 76.4% normal 2PN fertilization. These cycles averaged 5.1 biopsied blastocysts per cycle and yielded 2.5 euploid embryos. Cycles generating blastocysts and resulting in at least one normal embryo occurred 89% of the time for patients ≤37 years old, and 59% for patients ≥38 years old. Blastocyst production rate was 56.1% for patients ≤37 years old and 50.1% for patients 38-42 years old. Blastocyst euploidy rates were 54.6% for patients ≤37 years old and 29.1% for patients ≥38 years old. Embryos made from donor oocytes achieved a 68.6% blastulation rate and euploidy rates of 66.1%. Blastocyst generation decreased and aneuploidy rates increased significantly with age. Top quality day 5 embryos yielded an average euploid rate of 54% compared to 42% on day 6 and 27% on day 7. Top quality day 5 donor oocyte embryos achieved a 72% euploidy rate. No donor cycles failed to achieve a euploid blastocyst.

Limitations, reasons for caution: Aneuploidy rates are greatly influenced by patient selection and embryology biopsy criteria. Our center chose to perform no patient selection and enrolled all patients into a PGS cycle with modest biopsy requirements. The data in this analysis is necessary for further regression modeling to establish predictive parameters.

Wider implications of the findings: This study generated insightful data using a standardized approach to accurately report IVF derived embryo aneuploidy rates. Further validation is needed to determine whether each PGS tested embryo reflects an accurate diagnosis, however the donor data supports historic ART outcomes and provides significant predictive value.

Trial registration number: none.

P-613   Advanced maternal age (AMA) and preimplantation genetic screening (PGS) outcome after FET – controlled retrospective study

D. Lorenzi, M. Bilinski, A. Quinteiro Retamar, F. Nodar, S. Kopelman, S. Papier, C. Alvarez Sedo

CEGYR Reproductive Medicine and Genetics, Reproductive Biology and Genetics, Buenos Aires, Argentina

Study question: Which is the benefit of PGS in patients with advanced maternal age (AMA) in compare to a similar group of patients that did not performed it?

Summary answer: The main benefit to perform PGS in AMA group is to increase the pregnancy and implantation rate/transfer, and reduce the miscarriage rate.

What is known already: Recent studies indicate that between 60% - 90% of miscarriages in the first trimester may be the result of chromosomal aneuploidy. Evidences suggest that aneuploidy rate increases with maternal age. For this reason, PGS may be a reasonable choice in order to improve efficiency in the selection of euploid embryos (chromosomally normal). At the present, the 22 autosomal pairs of chromosomes and the sexual pair can be evaluated by

aCGH (Comparative Genomic Hybridization) or NGS (Next Generation Sequencing).

Study design, size, duration: It is a retrospective controlled study. Nighty three PGS cycles corresponding to AMA patients (A) were performed between 2013 and 2016. One hundred and thirty cycles were considered as a control group (B) between the same years.

Participants/materials, setting, methods: PGS was performed by aCGH and NGS at blastocyst stage (D5 or D6). All the patients performed IVF (ICSI) procedure at the same center. Delayed frozen embryo transfers were performed in both groups (at blastocyst stage). All patients had > 37 y/o. T-test and Chi square were performed for statistical analysis.

Main results and the role of chance: The overall average age was 40.5 ± 1.8 (A) and 40.0 ± 1.7 (B) (p>0.05). The average number of MII oocytes were similar 7.7 (A) vs. 6.9 (B). The fertilization rate and blastulation rate were also comparable 79.5% (A) vs. 79.6% (B), 42.4% (A) vs. 43.1% (B), respectively. In group A, the euploid blastocyst rate was 28.9% and embryo transfer cancellation rate was 57%. Comparing both groups, a significantly increased in the clinical pregnancy rate (51% vs. 34%) and implantation rate (53% vs. 23%) was seen (p < 0.05). Miscarriage rate was 7% in group A and 29% in group B (p<0-05).

Moreover, 3% of the embryos in AMA group had a single aneuploidy for chromosome 13, 18 and 21.

Limitations, reasons for caution: This is a retrospective study and all the clinical outcomes are per ET and not cumulative.

Wider implications of the findings: The overall rate of euploid blastocysts in PGS population is about 50%, this significantly decreased in AMA group, confirming that oocyte aging is the main cause of aneuploidies. ET cancellation is higher in AMA group. However, when a euploid blastocyst is selected the chance of pregancy and implantation is higher.

Trial registration number: None.

P-614 Preimplantation genetic diagnosis (PGD): the number of matures oocytes is determinant for Reciprocal but not for Robertsonian translocations

A. Mayeur[1], L. Hesters[2], N. Ahdad[3], S. Brisset[4], J. Steffan[5], G. Tachdjian[4], S. Romana[6], N. Achour-Frydman[2]

[1]Antoine Béclère Hospital, Unit of reproductive biology, Clamart Cedex, France
[2]Antoine Béclère Hospital, Unit of reproductive biology, Clamart, France
[3]Antoine Béclère Hospital, Unit of reproductive medicine, Clamart, France
[4]Antoine Béclère Hospital, Unit of Cytogenetic, Clamart, France
[5]Necker-Enfants Malades Hospital, Unit of genetic, Paris, France
[6]Necker-Enfants Malades Hospital, Unit of Cytogenetic, Paris, France

Study question: The number of balanced embryos is the main limiting factor to obtain pregnancies after PGD. Is there a link with ovarian response?

Summary answer: An adequate ovarian response should be obtained for Reciprocal translocations but not for RT. For RCT below 12 mature oocytes, PGD outcomes are very poor.

What is known already: Previous studies showed that the unbalanced embryos rate after PGD is more elevated in RCT (almost 75%) compared to RT (almost 50%), consequently the chance to reach embryo transfer for a couple is lower in case of RCT. It is well established that the ovarian response to controlled ovarian stimulation (COS) was not impaired by the presence of a balanced translocation in women.

Study design, size, duration: This study was conducted retrospectively. We included an overall of 264 couples that benefited from a preimplantation genetic diagnosis (PGD) for a male or female balanced chromosomal translocation (172 couples for RCT and 92 for RT) between 2006 and 2015. We analyze the characteristics of 555 PGD attempts (201 for RT and 354 for RCT).

Participants/materials, setting, methods: The aim of the present study was to determine, for RT and RCT, if the ovarian response may have a predictive value on the number of unbalanced embryos. After a correlation study (Logiciel stat), we have compared, for RT and RCT, the PGD outcomes of three quartiles representing the number of mature oocytes (>25th percentile, [25-75] percentile, >75th percentile).

Main results and the role of chance: The unbalanced embryo rates were significantly increased in case of RCT compared to RT (77.3 % vs 54.0%, $P < 0.0001$). Of note we found a significant increase of unbalanced embryo rates in female RT carriers compared to male (61.9% vs 49.8% $P = 0.002$). The number of mature oocytes was strongly correlated with the number of embryos biopsied and balanced embryos, regardless of the type of translocation. The quartile study for RCT couples showed that when more than 12 mature oocytes were available for PGD, the pregnancy rates obtained per pick-up and per embryo transfer were 26.3% and 37.3% respectively. Theses rates were significantly higher when compared to the 25th quartile (less than 6 matures oocytes, 6.7% per pick up and 14.8% per embryo transfer). For RT, the number of mature oocytes does not impact PGD outcomes and pregnancy rates remain not different even if less than 7 mature oocytes are available (25th quartile).

Limitations, reasons for caution: According to French low, genetic analysis was performed by fluorescent in situ hybridization with DNA probes targeting chromosomes involved in the translocation. Inter-chromosomal effect could not be assessed.

Wider implications of the findings: This study indicates that the management of COS for RT and RCT should not be the same in PGD. A real caution of ovarian reserve is necessary for RCT and oocytes pooling should be discussed when less than 6 matures oocytes are available for PGD procedure.

Trial registration number: NA.

P-615 A genetic predisposition for ovarian hyperstimulation syndrome? In-depth analysis of four non-PCOS cases

K. Stouffs[1], S. Santos-Ribeiro[2], S. Daeleman[2], A.S. Gürbüz[3], A. Gheldof[1], S. Seneca[1], H. Tournaye[2], C. Blockeel[2]

[1]UZ Brussel- Vrije Universiteit Brussel, Center for Medical Genetics- Reproduction and Genetics, Brussels, Belgium
[2]UZ Brussel- Vrije Universiteit Brussel, Center for Reproductive Medicine- Reproduction and Genetics, Brussels, Belgium
[3]Private Novafertil, IVF Centre, Konya, Turkey

Study question: Is there a genetic predisposition in non-PCOS women who developed the ovarian hyperstimulation syndrome after GnRH antagonist protocol with GnRH agonist trigger and freeze-all approach?

Summary answer: Whole exome sequencing (WES) of four non-PCOS patients with ovarian hyperstimulation syndrome (OHSS) showed the absence of a common genetic background.

What is known already: OHSS is an exaggerated response to ovarian stimulation, characterised by cyst enlargement of the ovaries, abdominal distention and pain, fluid shift from the intravascular space to the third space, which can result in ascites, pericardial and pleural infusions, and generalised oedema. This may lead to hypovolaemia, haemoconcentration, electrolyte imbalances and coagulation disorders and haemorrhage from ovarian rupture, ARDS, thromboembolism and renal failure. Reports on a total of only 7 patients who developed OHSS after GnRH agonist trigger and freeze-all approach have been published.

Study design, size, duration: Worldwide blood samples of 4 of the 7 previously published cases of OHSS after GnRH agonist trigger and a freeze-all strategy were gathered. These samples were analysed through WES, searching for (1) known causes of OHSS were investigated and (2) new causes present in at least two individuals.

Participants/materials, setting, methods: DNA samples of patients were collected after written consent. WES studies were performed according to standard procedures with an average sequencing depth of 75x. Further filtering, based on population frequencies (<1%) and type of alteration (only protein-changing mutation were selected) was performed by a scientist experienced in gene panel analysis.

Main results and the role of chance: In a first part of the study, we looked at the presence of mutations in genes already known to be involved in OHSS (i.e. FSHR, LHR/LHCGR, CYP11A1, CYP19A1, ESR1, ESR2, PGR, VEGFR1, VEGFR2, VEGF, AMH, AMHR, GDF9, BMP15, SOD2, SHBG, FOLR1, MTHFR, TP53, PAI and TNFalfa). In PGR and TP53 a heterozygous alteration was detected, each in one individual. PGR is predicted to be involved in progesterone resistance with a recessive inheritance pattern and was therefore not

considered as being causal. TP53 is especially involved in cancer development. The detected alteration has a very low population frequency (~1/40000), but the functional consequences of the detected variant remain unknown.

In part 2 of the study, we looked at variants in genes previously not linked to OHSS. We especially focussed on genes with variants present in ≥ 2 patients. Although no evident link with OHSS was detected among the genes with variants in multiple patients, we have composed a list of genes which potentially contribute to OHSS. Among these are genes involved in oocytes maturation or genes expressed in ovaries.

Limitations, reasons for caution: Since OHSS after GnRH agonist trigger and freeze-all is an exceptionally rare disorder with only 7 patients reported so far; it is impossible to study large patient groups. Future functional studies are essential to define a more precise involvement of the detected variant in the development of OHSS.

Wider implications of the findings: Defining a genetic predisposition for OHSS is essential in view of prevention. If a common (risk) genetic factor is involved, preliminary screening could be offered.

Trial registration number: n/a.

P-616   Anti-Mullerian hormone (AMH) levels in the follicular fluid – a predictive marker of human blastocysts ploidy status

J. Liss[1], M. Liss[2], E. Gorniak[3], K. Kretek[4], E. Pastuszek[2], I. Malinowska[2], K. Lukaszuk[2]

[1]INVICTA, Fertility and Reproductive Centre, Gdansk, Poland
[2]INVICTA, Fertility and Reproductive Center, Gdansk, Poland
[3]INVICTA, Fertility and Reproductive Center, Warsaw, Poland
[4]INVICTA, Fertility and Reproductive Center, Wroclaw, Poland

Study question: To correlate AMH levels in follicular fluid (FF) with ploidy status of blastocysts in preimplantation genetic screening (PGS) cycles.

Summary answer: High level of AMH in the follicular fluid may be a good predictor of the development of euploid embryo.

What is known already: Follicular fluid is a product of secretory activity of granulosa and thecal cells and provides a very important microenvironment for the development of oocytes. Some biochemical substances found in the FF surrounding the oocyte may play a critical role in determining oocyte quality and consequently the capacity of fertilization and embryo development. Studies of the follicular fluid AMH levels have shown a more direct role of AMH as a regulator of human folliculogenesis. FF AMH levels are positively associated with embryo implantation, although direct and indirect effects FF AMH levels on in vitro fertilization (IVF) have not been clarified yet.

Study design, size, duration: Our study was planned as a prospective cohort research and consisted of 43 women (median age 36 years, range 33-40) with the diagnosis of infertility who were undergoing IVF treatment with PGS between August 2016 and December 2016 at INVICTA Fertility Centre, Poland.

Participants/materials, setting, methods: The follicular fluid sample was obtained from preovulatory follicle sized ≥ 18 mm of diameter from each ovary. AMH level in serum and FF was measured on day of pick-up by VIDAS® AMH assay (bioMérieux). A total of 87 blastocysts were evaluated with the NGS protocol. Ion Torrent Suite Software and Invicta Bioinformatics Team Script were used for chromosome copy number variation analysis.

Main results and the role of chance: All embryos were cultured separately to blastocysts stage. The trophectoderm biopsy was performed on day 5 or day 6 development. Among the 87 blastocysts, 39 (44.8%) were euploid, while 48 (55.2%) were aneuploid. The average level of follicular fluid AMH in normal embryos was $3{,}69 \pm 3.1$ ng/ml. The FF AMH levels were significantly higher (p<0.03) in euploid embryos compared to aneuploid, where the average level of FF AMH was 2.52 ± 2.4 ng/ml. The area under the curve (AUC) of FF AMH for prediction of euploid blastocysts was 0.63 (p = 0.05, 95% CI 0.506-0.749). A threshold of 2.75 ng/ml of FF AMH had a sensitivity of 58%, specificity of 72%. No significant differences were observed with respect to age of patients. There was also no significant differences in BMI, FSH, LH, baseline level of AMH in serum, measured on third day of menstrual cycle. No correlation were observed between serum AMH levels on the day of pick-up and ploidy status of embryos.

Limitations, reasons for caution: The study is limited by sample size. A higher sample size could be used in future studies to corroborate the current findings.

Wider implications of the findings: The present study revealed correlation between FF AMH and ploidy status of blastocysts. FF AMH might be a predictive marker for prognosis of genetic status of embryos created from oocytes from follicles with elevated FF AMH level.

Trial registration number: not applicable.

P-617   Clinical implementation of next-generation sequencing (NGS) for preimplantation genetic screening (PGS) improves pregnancy outcomes

J. Friedenthal[1], S. Maxwell[2], S. Munné[2], Y. Kramer[2], C. McCaffrey[2], J. Grifo[2]

[1]New York University Langone Medical Center, Obstetrics and Gynecology, New York, U.S.A.
[2]New York University Langone Fertility Center, Obstetrics and Gynecology, New York, U.S.A.

Study question: Does NGS for PGS improve pregnancy outcomes as compared to array comparative genomic hybridization (aCGH)?

Summary answer: NGS improves implantation and ongoing pregnancy rates/live birth rates compared to aCGH among patients undergoing in vitro fertilization (IVF) with PGS.

What is known already: Array CGH is widely used for IVF with PGS. NGS, a new platform for PGS, may be able to detect more cases of mosaicism and triploidy (69XXY) than aCGH. Genetic abnormalities detected by NGS are significantly higher among pregnancies resulting in miscarriage than live birth.

Study design, size, duration: This was a retrospective study of 1015 patients undergoing IVF with PGS followed by single thawed euploid embryo transfer (STEET) from 1/2014 to 12/2016 at a single university medical center.

Participants/materials, setting, methods: All IVF cycles with PGS and STEET were included. Oocyte thaws for biopsy, double embryo transfers (ET), mosaic ET, or cycles with incomplete outcome data were excluded. Primary outcomes: implantation rate (IR), spontaneous abortion rate (SABR), and ongoing pregnancy rate/live birth rate (OPR/LBR). Demographic data included age, gravidity, parity, number of prior IVF cycles, ovarian reserve testing, and infertility diagnosis. Student's t-test and Fisher's exact test were used for statistical analysis with P < 0.05 considered significant.

Main results and the role of chance: 424 patients underwent PGS with aCGH, and 591 patients underwent PGS with NGS. 18 patients were excluded from the NGS group for incomplete outcome data (11) or mosaic ET (7). There was no difference in baseline demographics between groups. The mean age of patients was 35.7 years. IR was significantly higher in the NGS group compared to the aCGH group (71.7% vs. 65.1%, p = 0.027). The OPR/LBR was also significantly higher in the NGS group (62.3% vs. 55.0%, p = 0.023). The SABR was decreased in the NGS group compared to the aCGH group, but this was not statistically significant (11.9% vs. 12.7%., p = 0.813).

Limitations, reasons for caution: This study was limited by its retrospective design. Prospective data on the outcomes of mosaic embryo transfers is needed to determine their true implantation potential.

Wider implications of the findings: PGS using NGS significantly improves pregnancy outcomes over PGS using aCGH. Mosaic embryos may have reduced implantation potential. Therefore, the exclusion of mosaic embryos with NGS may explain these results.

Trial registration number: N/A.

P-618   The price of a euploid embryo identified from preimplantation genetic testing for aneuploidy (PGT-A): A cost analysis

R. Goldman[1], C. Racowsky[1], J. Fox[1], S. Munne[2], L. Ribustello[2], E. Ginsburg[1]

[1]Brigham and Women's Hospital and Harvard Medical School, Obstetrics-Gynecology and Reproductive Biology, Boston, U.S.A.
[2]Reprogenetics, Clinical, Livingston, U.S.A.

Study question: To determine the expected age-related costs of undergoing IVF with PGT-A to obtain a 90% likelihood of having at least one euploid blastocyst.

Summary answer: The estimated cost to obtain a 90% chance of a euploid blastocyst increases with age, most substantially after 37y, and again after the age 40y.

What is known already: Many patients undergoing IVF for infertility treatment elect to undergo PGT-A hoping to optimize their chance of having a live birth and a reduced risk of miscarriage by selecting a euploid embryo for transfer. Oocyte aneuploidy increases with age, while the embryo yield per cycle tends to decrease with age. To minimize overall cost, some patients choose to undergo additional stimulation cycles and bank blastocysts prior to running PGT-A. The optimal number of blastocysts to bank, the number of cycles needed, and the cost of having a high likelihood of a euploid embryo are important issues for patient counseling.

Study design, size, duration: A retrospective analysis of 520 first, fresh, autologous IVF/ICSI cycles from women with normal ovarian reserve, treated from 1/2011-3/2015, was conducted. Age-specific probabilities of euploidy were estimated from 14,500 PGT-A results from an external testing laboratory. The expected number of blastocysts per cycle was calculated, and a cost analysis was performed to estimate the price of IVF/ICSI/PGT-A needed to achieve a 90% chance of having at least one euploid blastocyst, stratified by patient age.

Participants/materials, setting, methods: The expected number of blastocysts per cycle was calculated for patient age by yearly increments beginning at 34y using data from our University-based IVF center in the United States (US). Assuming an average cost of $12,500 USD for an IVF/ICSI cycle with biopsy, and $2,500 USD for PGT-A testing, the expected cost of treatment to obtain a 90% chance of having at least one euploid blastocyst was calculated.

Main results and the role of chance: To achieve a 90% chance of having one euploid blastocyst with PGT-A, a patient who is 34-36y would need 3 blastocysts, a 37-39-year-old would need 4 blastocysts, and a 40-year-old would need 5 blastocysts. Provided there is at least one blastocyst obtained following a cycle, a 34-year-old should expect to pay, on average, $19,500 US dollars (USD), while a 37-year-old should expect to pay $22,500 USD. The cost increases more significantly above the age of 37y. While a 37-year-old and 38-year-old both need 4 blastocysts to have a 90% chance that one is euploid, the 38-year-old would have to undergo more IVF/ICSI cycles, on average, to obtain 4 blastocysts, and should expect to pay approximately $30,000 USD; a 40-year-old who needs 5 blastocysts should expect to pay $44,000 USD.

Limitations, reasons for caution: The population used for this analysis includes only women with normal ovarian reserve, and the sample size is smaller for older women. This cost analysis is designed for patients who have at least one blastocyst following an IVF/ICSI cycle, though many do not. IVF/PGT-A costs vary greatly across clinics.

Wider implications of the findings: Our model should be useful when counseling patients presenting to infertility clinics for IVF/ICSI with PGT-A regarding the estimated number of blastocysts needed, the number of cycles to undergo, and the overall approximate cost of having a euploid embryo for transfer.

Trial registration number: Not applicable.

P-619   The association between thrombophilic gene mutations and recurrent pregnancy loss in Middle Eastern women

M. Al Halabi[1], S. Alsamawi[2], H. Deroubi[2], A. Taha[2], R. Doghouz[2], A. Alkhatib[3], A. Alhussaini[4]

[1]Faculty of Medicine of Damascus University, Embryology- Reproductive Medicine and Genetics, Damascus, Syria
[2]Orient Hospital, Assisted Reproduction Unit, Damascus, Syria
[3]Orient Hospital, Molecular Genetics Unit, Damascus, Syria
[4]Faculty of medicine of Baqubah University, Obstetrics and Gynecology, Baqubah, Iraq

Study question: Our objective is to evaluate the prevalence of thrombophilic gene mutations in Middle Eastern women with recurrent pregnancy loss (RPL) compared with women who had uneventful pregnancies.

Summary answer: Thrombophilia accompanied with Factor V Leiden (FVL) may plays a role in pathophysiology of RPL, suggesting that patients with RPL should be screened for FVL.

What is known already: RPL is a multifactorial condition, defined as two or more consecutive pregnancy losses and affecting 1-5% of reproductive-age woman. After chromosome abnormality, thrombophilia is one of the most important genetic factors that could cause RPL. However, the etiology of RPL remains unknown in ~50% of cases. Although numerous studies are available in literature, thrombophilia rate seems to vary from study to another due to different selection criteria and ethnicity of patients.

Study design, size, duration: A total of 300 Middle Eastern women were recruited in this case-control multicenter study between October 2012 and October 2015. Patients group included 200 women with RPL and the control group included 100 women from the same ethnic background and with at least one successful pregnancies and no history of pregnancy loss, which matched by age with patients.

Participants/materials, setting, methods: 200 women with RPL (who have two or more pregnancy losses) were recruited in this study, compared with 100 women without adverse pregnancy outcome, at Orient hospital, faculty of medicine of Damascus University and faculty of medicine of Baqubah University.

Genotyping of thrombophilic gene mutations were carried out by amplification Refractory Mutation System- PCR (ARMS-PCR) method after DNA extraction.

Main results and the role of chance: This study has shown that Factor V Leiden (FVL) is significantly associated with RPL (56/200)28% compared with controls (9/100) 9%, (p-values was 0.0036). And there were no statistically significant differences in the prevalence of methylenetetrahydrofolate reductase MTHFR (C677T and A1298C), prothrombin (G20210A) mutation and other mutations between RPL patients and controls. It is of interest to note that FVL constitutes a major risk factor if RPL is considered in comparison with controls [Odds Ratio were 4.13 (CI:1.43-5.85)].

Limitations, reasons for caution: We could not study some rare gene mutations as: factor XIII (V34L), β-fibrinogen (455 G → A), plasminogen activator inhibitor-1 (4 G/5 G) and human platelet antigen-1 (a/b9L33P).

Wider implications of the findings: Our results agree with Mitraui et al.; Finan et al.; and Mahjoub et al. and disagree with by Zahed et al.; Alfirevic et al.; and Howard et al., who found no correlation between FVL mutation and RPL. Moreover, FVL mutation prevalence was similar in patients and controls (Pauer et al).

Trial registration number: none.

P-620   PGS2.0 significantly decreases the miscarriage rate while maintaining similar live birth rate per oocyte retrieval cycle compared to conventional IVF/ICSI among women aged above 36

H. He[1,2,3], K. Luo[1,2], Y. Peng[2], S. Zhang[1,2], C.H. Lu[1,2], F. Gong[1,2], G. Lu[1,2,3], G. Lin[1,2,3]

[1]Institute of Reproductive & Stem Cell Engineering- School of basic medicine- Central south university, Reproductive department, Changsha, China
[2]Reproductive & Genetic Hospital of CITIC-XIANGYA, Clinical department, Changsha, China
[3]Key laboratory of Reproductive & Stem Cell Engineering- Ministry of Health, Central laboratory, Changsha, China

Study question: Whether women with advanced maternal age (AMA) could benefit from preimplantation genetic screening (PGS) 2.0 treatment?

Summary answer: PGS 2.0 treatment could significantly decrease the miscarriage rate while not reduce the live birth rate per oocyte retrieval cycle (OCC) among women with AMA.

What is known already: It was well established that the miscarriage risks increased with maternal age, and embryo aneuploidy was the leading reasons of it. PGS 2.0 was widely used nowadays combined blastocyst biopsy and comprehensive chromosomal analysis to examine the complete chromosomes before embryo transfer to improve the pregnancy outcomes. Until now, numerous studies had reported that PGS 2.0 could decrease the miscarriage rate and increase the live birth rate among women with AMA. However, some

researchers also argued that 'intent-to-treat" analysis was not adopted in these studies and patients not reaching transfer were neglected for evaluating the efficiency of new PGS strategy.

Study design, size, duration: This is a retrospective study comparing the pregnancy outcomes of women with AMA who underwent PGS treatment (n = 177) or conventional IVF/ICSI (n = 177) between November 2011 and April 2015 at the Reproductive and Genetic Hospital of CITIC-XIANGYA. Intent-to-treat analysis were applied in this study.

Participants/materials, setting, methods: Only patients whose age ≥ 36 and number of retrieved oocytes ≥1 were included in this study. The chromosome karyotype of the couples should both be normal and had no adverse pregnancy history. Patients using testicular or epididymal sperm were excluded, and those whose embryos were biopsied for twice or using donated oocytes or sperms were also excluded. Propensity score matching were applied to select proper controls with the ratio of 1:1

Main results and the role of chance: 105 (59.3%) OCCs were cancelled in PGS group, significantly higher than 26 (14.7%) in IVF/ICSI group (P < 0.001). No formed blastocyst and no euploid embryos after genetic testing were the main reasons of cycle cancellation in PGS group. After intent-to-treat analysis, the clinical pregnancy rate (CPR) and live birth rate (LBR) per OCC in PGS patients was comparable with IVF/ICSI patients (CPR: 20.3% vs. 27.7%, P = 0.087; LBR: 17.5% vs. 16.9%, P = 1.000). And the accumulative CPR was significantly lower in PGS patients (23.2% vs 36.2%, P = 0.006) but the accumulative LBR was not significantly different from IVF/ICSI patients (19.8% vs 23.7%, P = 0.450). However, the CPR and LBR per embryo transfer cycle (ETC) in PGS patients were higher (CPR: 47.6% vs. 34.7%, P = 0.043; LBR: 42.7% vs. 21.1%, P < 0.001), and miscarriage rate (MR) was lower (10.3% vs 39.1%, P = 0.001) when compared to IVF/ICSI patients, which was in accordance with previous studies.

Limitations, reasons for caution: This study was limited by the small sample size and retrospective design, a randomized double-blinded controlled trial was demanded to confirm this conclusion.

Wider implications of the findings: This study was limited by the small sample size and retrospective design, a randomized double-blinded controlled trial was demanded to confirm this conclusion.

Trial registration number: None.

P-621　Risk assessment for three way translocation (TWT) carriers

E. Armenti[1], T. Escudero[2], S. Munne[3]

[1]Reprogenetics, Genetic Counseling, Livingston, U.S.A.
[2]Reprogenetics, Laboratory, Livingston, U.S.A.
[3]Reprogenetics, Chief Scientific Officer, Livingston, U.S.A.

Study question: Are the proportion of unbalanced embryos and the pregnancy risks of three way translocation (TWT) patients comparable to those of reciprocal translocation (RT) patients?

Summary answer: The proportion of unbalanced embryos and the pregnancy risk for TWT cases is similar to simple reciprocal translocation (RT) cases.

What is known already: Patients carrying structural chromosome abnormalities have a variety of reproductive problems, e.g. increase in spontaneous abortions and unbalanced offspring. The most common is the RT, carried by 0.2% of the population, with an estimated 70% imbalance rate in embryos. An RT is the interchange of genomic material between two chromosomes. Complex chromosome rearrangement (CCR) cases are more intricate. The most common CCR is the TWT: interchange of material between three chromosomes. Although the most common CCR, TWTs are poorly studied due to their rarity, though assumed to have poorer prognoses, as meiotic segregation possibilities are more complex and numerous.

Study design, size, duration: Three patients are included in this study. Case A is carrier of 46,XY,t(7;9;12)(p21;q22;p12.2), partner 33 years old (yo). Case B has a a 46,XX,t(1;2;3)(p3;p11.2;q27), 33 yo. Case C is carrier of 46,XY,t (5;16;10)(q33;q23;q24.1), partner 37 yo. All karyotypes were identified via evaluation for mut

The RT group had an average maternal age of 33 yo.

Participants/materials, setting, methods: Risk assessment obtained via pregnancy and family history. Embryos from cases A, B, and C underwent aCGH PGD. The proportion of 'normal/balanced" embryos was obtained, generating the probability of success for TWTs. Case A produced 17 embryos in two cycles; Case B produced 5 embryos and Case C produced 22 embryos, each in one cycle.

To compare successful PGD rates between TWT and RT, 162 embryos from 25 RT cases were reviewed.

Main results and the role of chance: All cases had histories of first trimester pregnancy loss (SAB); two had recurrent pregnancy loss. Two cases had pregnancies that were normal/balanced for the TWT; one with a healthy child, one with an aneuploid SAB. No additional fertility problems were reported

Case A produced 4 normal/balanced, 12 unbalanced and 1 aneuploid embryo. In Case B, all 5 embryos were unbalanced. Case C produced 3 normal /balanced, 14 unbalanced and 4 embryos with aneuploidy unrelated to the translocation and 1 no-result embryo.

Table 1 shows the diagnoses of TWT cases, RT cases and statistical differences. The only significant difference is the percentage of unbalanced embryos.

Diagnosis	TWT (%)	RT (%)	p
Normal/Balanced	7(15.9%)	38(23.5%)	n.s.
Aneuploid	5(11.4%)	27(16.7%)	n.s.
Unbalanced	31(70.5%)	85(52.5%)	0.05
No Result	1(2.3%)	12(7.4%)	n.s.
Total	44(100.0%)	162(100.0%)	

In comparing TWT and RT, no significant differences were found in the proportion of normal/balanced embryos.

It is assumed that TWTs have poorer outcomes due to the increase in unbalanced gamete possibilities (64 vs. 16). This shows the proportion of transferable embryos is similar to RT cases. Scriven et al, 2014 found the proportion of alternate segregates was 27.6%, paralleled by this study, with 27.3% identified (5.9% normal/balanced, 11.4% aneuploid).

Limitations, reasons for caution: The low number of participants in the TWT group as well as the low number of their embryos limited to some extent the accuracy of the statistical comparison with the RT group. More cases should be included in order to asses a proper success rate for these PGD cases.

Wider implications of the findings: TWT meiosis likely generates a hexavalent ring, a stabilizing factor promoting alternate and adjacent 1 segregations. These aren't different segregations, but rather recombination events transforming one into another, together comprising 55.3% of PGD embryos. The success of TWT PGD may depend on recombinations in hexavalent critical regions, favoring alternate segregation.

Trial registration number: NA.

P-622　A validated approach to detect balanced chromosome abnormality based next generation sequencing at single cell level

Y. Xie[1], J. Xia[2], P. Liu[2], F. Xu[2], X. Zhao[2], J. Xu[2], Q. Li[2], Q. Shi[2], Y. Qiu[2], D. Chen[2], Z. Zhu[2], L. Xie[2], F. Chen[2]

[1]BGI Education Center, University of Chinese Academy of Science, Shenzhen 518083, China
[2]BGI-SHENZHEN, R&D, SHENZHEN, China

Study question: To establish an approach based next generation sequencing to detect balanced chromosome abnormality in preimplantation human embryos.

Summary answer: The results show that our approach can accurately detect BCA events at single cell level.

What is known already: Balanced chromosome abnormality(BCA) is a common chromosomal structural variation. The past most commonly used detection methods are based on cytogenetics. Current years, next generation

sequencing has been reported to detect BCA-associated breakpoints. Preimplantation genetic diagnosis (PGD) is widely applied in BCA carriers to increase the chance for a successful live birth. However, Previous methods can only be used to detect BCA for couples had multiple abortions and need assisted reproductive, BCA carrier embryos were seldom discriminated from the normal ones mainly due to the technique restriction. we provide a next generation sequencing approach to detect BCA in Preimplantation human embryos.

Study design, size, duration: Six cell lines samples containing BCAs validated by karyotyping were cultured to get enough cells. Single cell from cell lines isolated by mouth control pipette, and amplified with QIAGEN REPLI-g Single Cell Kit. Genomic DNA from cell lines was extracted with the QIAamp DNA blood mini kit.

Participants/materials, setting, methods: Six single cell whole genome amplification DNA and genomic DNA were sheared into ~3000 bp fragments with a HydroShear DNA Shearing Device, and mate-pair libraries were constructed by an established protocol. Each DNA library was then sequenced on BGISEQ-500 as paired-end 50-bp reads. By clustering anomalous read pairs and filtering out the false-positive results with a control cohort and the concomitant mapping information.

Main results and the role of chance: By clustering anomalous read pairs and filtering out the false-positive results. BCA events in all six single cell samples could be detected with ~100 million reads pairs per sample, and corresponding genomic DNA samples from same cell lines also detect concordant BCA events. The BCA detection results of these samples were concordant with karyotyping, showing 100% accuracy. Our results suggest that our approach can accurately detect BCA events, even in single cell. Our approach advances the application of next generation sequencing for BCA detection, especially for evaluating the genetic risk of BCA carriers and carrier screen in later PGD treatment.

Limitations, reasons for caution: This approach need further validated using amount of clinical PGD samples that contained BCAs.

Wider implications of the findings: This approach can become a clinical applicable approach to detect precise breakpoint of balance chromosome abnormality and to further distinguish normal embryos in PGD.

Trial registration number: NO.

P-623 Genetical analysis of extra X in Klinefelter Syndrome:47XXY

A. Tanaka[1], M. Nagayoshi[1], T. Yamaguchi[1], T. Ichiyama[1], M. Ohno[1], S. Watanabe[2]

[1]Saint Mother Hospital, Department of Obstetrics and Gynecology, Kitakyushu, Japan
[2]Hirosaki University Graduate school of Medicine, Department of Anatomical Science, Hirosaki, Japan

Study question: Does the extra X in Klinefelter Syndrome (KS) patients originate only paternally?

Summary answer: There might be a possible mechanism of production of extra X from disomic XX oocyte which would associate with low risk of KS after ICSI.

What is known already: It has been reported that the incidence of sperms with abnormal sex chromosome is higher in the testis tissue smear of KS patients and these sperms are the cause of KS.

Study design, size, duration: Blood samples from 12 KS patients were used for X-chromosome short tandem repeats (STR) analysis. The STR analysis also included data of the parents of the KS patients (8: both parents, 4: mother only, 0: father only) from January 2015 to December 2016. This study was conducted with the informed consent of all participating patients and approved by The Institutional Review Boards of the Saint Mother Obstetrics and Gynecology Clinic.

Participants/materials, setting, methods: Blood samples of 12 KS patients and one or both of their parents were used to determine the origin of the extra X chromosome using X-chromosome haplotype markers (short tandem repeats of 12 loci), according to the method by Shrivastava et al. With DNA extracted from the samples, multiplexed PCR amplifications of the 12 X-STR loci and AMELOGENIN were conducted using an Investigator Argus X-12 QS Kit (Quigen, Germany).

Main results and the role of chance: X-chromosomal STR DNA profiles were compared among KS patient and their parents. In 7 of the 12 KS patients, both two X chromosomes were maternal origin, showing that an extra X chromosome was left in an oocyte as a result of chromosomal non-disjunction at the 1st (4/7) or 2nd (3/7) meiotic division. In 5 patients, X-chromosomes were inherited from parents, suggesting that fertilization of XY-sperm is the cause of KS.

Limitations, reasons for caution: Further investigation with more X-STR is needed. It might be premature to draw conclusions about the origin of the extra X.

Wider implications of the findings: Although the sample number applied for X-chromosomal STR DNA profiling is not enough, the present data may indicate that contribution of XX oocyte to the production of XXY embryos is greater than XY sperm. Namely, a XX oocyte penetration by a Y sperm is the main cause of KS.

Trial registration number: UMIN Clinical Trials Registry: UMIN000024542.

P-624 Why do euploid embryos miscarry? A study analysing the factors of euploid embryo transfer(ET) diagnosed with comprehensive chromosome screening(CCS) that resulted miscarriage or ongoing pregnancy

F.K. Boynukalin[1], M. Gultomruk[2], N. Findikli[3], M. Bahceci[1]

[1]Bahceci Health Group, IVF Department, Istanbul, Turkey
[2]Bahceci Health Group, Research and Development, Istanbul, Turkey
[3]Bahceci Health Group, Embryology Laboratory, Istanbul, Turkey

Study question: It is estimated that more than 50% of miscarriages are due to aneuploidy. This study investigates possible factors affecting the miscarriage after euploid embryo transfer.

Summary answer: Our study indicates that endometrial thickness and serum progesterone (P4) levels before progesterone replacement can play a significant role in miscarriages after CCS.

What is known already: CCS-based trophectoderm (TE) biopsy has been demonstrated to be a safe, accurate and reproducible approach. Also CCS for aneuploidy assessment has been shown to exert a beneficial effect on clinical outcomes; it increases the chance or implantation, decreases high order multiple gestation and decreases the likelihood of miscarriage associated with aneuploidy. Although CCS decreases the miscarriage rate, it can never eliminates it. Due to its highly unknown and multidimensional nature, miscarriages after euploid embryo transfers can create a more complex clinical environment for patients and clinicians that is need to be elegantly managed.

Study design, size, duration: This retrospective study compiled 363 controlled ovarian stimulation(COH) cycles of 247 patients undergoing preimplantation genetic screening(PGS) between October 2015 to October 2016. Next generation sequencing(NGS) was performed for CCS and clinical indications for PGS included recurrent implantation failure and advanced maternal age. A total of 2024 embryos were analysed and 886(43.8%) of these were euploid. Of these 363 cycles, 132(36.4%) were cancelled due to all-aneuploid results. In 193 patients, 200 ET cycles were further evaluated.

Participants/materials, setting, methods: All patients underwent COH with GnRH antagonist and rFSH or hMG. TE biopsy was performed on day 5 or 6. Blastocysts were cryopreserved using vitrification.Endometrial preparation was performed as artificial hormone replacement therapy. Single euploid embryos were transferred in frozen-thaw cycles. A clinical pregnancy was defined as the presence of a gestational sac within the uterus. Ongoing pregnancy was defined as confirmed fetal heart beat by ultrasonography and continued at least 12 weeks of pregnancy.

Main results and the role of chance: Following transfer of 200 single euploid embryos in 193 women, 155 had positive hCG levels (77.5%/ET) leading to 140 had clinically confirmed and 119 ongoing pregnancies (70%/ET and 59.5%/ET respectively). In 21 women, pregnancies ended up miscarriage (15%). Outcomes were compared between cycles with ongoing pregnancies and miscarriages. There were no statistical differences between ongoing pregnancies and miscarriages regarding female age(35,1 ± 4,5 and 34,5 ± 4,9 years, respectively), female BMI (23,6 ± 3,8 kg/m^2 and 23,5 ± 4,1 kg/m^2 respectively), antral follicle count (11,6 ± 6,7 and 13,6 ± 5,9 respectively), previous IVF attempt (2,9 ± 1,8 and 3,2 ± 3,1 respectively), day of stimulation(9.5 ± 0.73 and 9.7 ± 0.65 days,

respectively), peak E2(1819 ± 1279.4 and 2032 ± 1100 pg/ml, respectively), and peak P4(0.87 ± 0.52 and 0.91 ± 0.48 ng/ml, respectively). The two groups were also similar in terms of the number of oocyte retrieved, and injected MII oocytes. A significantly higher peak endometrial thickness and lower P4 levels before progesterone replacement was observed in ongoing pregnancy group (9,0 ± 1,3 mm, 0,25 ± 0,26 ng/ml respectively) compared to miscarriage group (8,3 ± 1,1 mm, 0,54 ± 0,58 ng/ml; p: 0.026, p: 0.034 respectively). The two groups mean mitoscore levels, distribution morphological grading of embryos and day of blastocysts (day 5 or day 6) were also similar. Regression logistic analysis showed that endometrial thickness and P4 levels were the significant parameters that can predict ongoing pregnancy rates.

Limitations, reasons for caution: The study is limited by its retrospective nature. A higher sample size or a prospective design can be used in future studies to corroborate the current findings.

Wider implications of the findings: Our results suggest that endometrial preparation for frozen ET may have a significant role for prevention of miscarriages. Review of cut-off values for endometrial thickness and P4 levels in large groups may be useful.

Trial registration number: None.

P-625 single cell rapid testing technique for preimplantation genetic screening on the BGISEQ-50

Q. Shi, F. Chen, P. Liu, D. Chen, Y. Qiu, J. Xia, Z. Zhu, L. Xie

BGI-Shenzhen, R&D, Shenzhen, China

Study question: A rapid PGS (preimplantation genetic screening) technique, targeting at single cell, needs be developed on the BGISEQ platform.

Summary answer: A single cell rapid testing technique for PGS (rapid PGS) within 18 hours on BGISEQ-50 was successfully built.

What is known already: The controversy between fresh embryo transfer and frozen embryo transfer always existed. In some areas, doctors prefer fresh embryo transfer in IVF cycles. According to this situation, PGS would be better completed within 24 hours. BGISEQ-50 was published in the 11th ICG conference, on November 5, 2016. BGISEQ-50, which is powered by combinatorial Probe-Anchor Synthesis (cPAS) and improved DNA Nanoballs (DNB) technology, has fewer replication mistakes, and the whole process including sample preparation can be completed in 18 hours.

Study design, size, duration: Single cells of 67 different cell lines with known karyotypes, including 43 cell lines with different CNVs sizes (>4 M), 15 aneuploid cell lines, and 9 negative cell lines, were performed WGA (whole genome amplification). The library construction of above WGA products would use our new single cell rapid PGS method, and sequenced on BGISEQ-50. The results of the BGISEQ-50 sequencing would be compared with the known karyotypes.

Participants/materials, setting, methods: All the above cell lines purchased from the website https://catalog.coriell.org/. Single cell of different cell lines was picked up using micromanipulation. The picked 67 samples were amplified with the PicoPLEX® WGA Kit (Rubicon Genomics, Ann Arbor, MI, USA), according to the manufacturer's protocol. Then, we constructed the libraries using our new rapid method, the input of the WGA products could change from 1 ng to 100 ng. Finally, we sequenced these libraries on BGISEQ-50.

Main results and the role of chance: The yield of the WGA products was about 3 microgram, 50 ng DNA was inputted to perform subsequent experiments. The sequence data produced on BGISEQ-50 conformed to its quality control standard. In our test, we referred to perform windows selection, GC bias correction and copy number analysis on the sequencing reads. The whole process, including WGA, library construction, sequencing, and analysis, could be finished in 18 hours. The 43 cell lines with different CNVs sizes (>4 M), along with 15 aneuploid cell lines, and 9 negative cell lines could be all detected successfully on the BGISEQ-50. Our new <18 hours single cell rapid PGS technique could realize fresh embryo transfer.

Limitations, reasons for caution: For now, the throughput of BGISEQ-50 could sequence 16 samples in one run, which needs further optimization.

Wider implications of the findings: In the future, we will perform this single cell rapid PGS method in clinical utilization for fresh embryo transfer, after testing more samples.

Trial registration number: not applicable.

P-626 Inconclusive PGS results: go for a second biopsy!

M. Parriego[1], L. Coll[1], M. Boada[1], F. Vidal[2], S. Mateo[1], B. Coroleu[1], A. Veiga[1]

[1]*Hospital Universitari Dexeus, Department of Obstetrics- Gynaecology and Reproduction, BARCELONA, Spain*
[2]*Universitat Autònoma de Barcelona, Departament de Biologia Cel.lular- Fisiologia i Immunologia, Bellaterra, Spain*

Study question: Is blastocyst re-biopsy and re-vitrification a reasonable and safe procedure to be applied in cases of inconclusive or no results after a PGS analysis?

Summary answer: Our preliminary results show that blastocyst re-biopsy and re-vitrification is a good approach that ultimately allows the transfer of euploid embryos and good clinical outcomes.

What is known already: One of the advantages of trophectoderm biopsy is the significant decrease in the percentage of undiagnosed embryos (from around 10% with blastomere biopsy to less than 5% with trophectoderm biopsy). However, patients with few or no euploid embryos can be specially affected by this residual percentage of diagnostic failure. Moreover, blastocyst vitrification has been reported to have a limited impact on embryo viability even in cases when blastocysts are re-vitrified.

Study design, size, duration: Embryos from PGS cycles were vitrified shortly after the biopsy procedure before the genetic diagnosis was achieved. From January 2015 to December 2016, PGS patients having embryos with inconclusive or no results were offered the possibility of warming such embryos and perform a second biopsy and vitrification.

Participants/materials, setting, methods: Twenty seven patients agreed to the warming of 29 blastocysts to perform a second biopsy. After warming, surviving blastocysts were cultured until re-expansion. Embryos not re-expanded on day 7 were discarded. Trophectoderm cells from re-expanding blastocysts were biopsied using laser thermolysis. Biopsied blastocysts were vitrified for the second time while waiting for the results. The genetic analysis was performed by aCGH using the kits and protocols provided by the manufacturer (Illumina, USA).

Main results and the role of chance: The survival rate after warming was 86.2% (25/29) although only 72.4% of the embryos re-expanded (21/29) and could be re-biopsied. After the second biopsy and analysis, 95.2% (20/21) of the embryos could be successfully diagnosed. The euploidy rate was 65% (13/20). Embryos with failed amplification after the first biopsy showed a 50% of euploidy rate (7/14). On the other hand, all embryos with inconclusive results that could be diagnosed (6/7) turned out to be euploid.

To date, 6 re-biopsied euploid embryos have been warmed for transfer in 6 patients with a 100% survival and re-expansion rate. Four clinical pregnancies have been achieved with 2 ongoing pregnancies and 2 miscarriages.

Limitations, reasons for caution: To date, few transfers of re-biopsied blastocyst have been performed. As data grows, the results obtained should be monitored.

There are more sensitive techniques than a-CGH that might have allowed to obtain diagnosis in some of the undiagnosed embryos without the need of performing a second biopsy.

Wider implications of the findings: Blastocysts with inconclusive diagnosis show suboptimal results regarding survival and re-expansion rates. This fact should be informed to patients. When the second biopsy can be performed, euploid re-biopsied re-vitrified blastocysts have a high implantation potential. Re-biopsy allows the rescue of euploid embryos thus enhancing the cumulative pregnancy rate per cycle.

Trial registration number: not applicable.

P-627 A systematic comparison on the bacterial colonization of paired endometrial tissue and fluid samples: Implication on endometrial microbiome studies in the future

Y. Liu[1], K.K.W. Wong[1], J. Huang[1], S.K.W. Tsui[2,3], S.S.C. Chim[1], T.C. Li[1]

[1]*The Chinese University of Hong Kong, Dept of Obstetrics and Gynaecology- Faculty of Medicine, Hong Kong, Hong Kong*

[2]The Chinese University of Hong Kong, School of Biomedical Sciences- Faculty of Medicine, Hong Kong, Hong Kong
[3]The Chinese University of Hong Kong, Hong Kong Bioinformatics Centre, Hong Kong, Hong Kong

Study question: Are the profiles of bacteria (microbiomes) in endometrial fluid reflecting those in the endometrial biopsied tissue?

Summary answer: No, the kinds and abundance of the bacterial taxa (plural of taxon, i.e. species/genus) in endometrial biopsies are different from their corresponding endometrial fluid samples.

What is known already: Contrary to widely-held belief, the endometrium and endometrial fluid are not sterile but harbor bacteria. IVF patients with endometrial fluid not dominated by Lactobacillus are associated with significantly lower implantation rate (61% vs 23%), pregnancy rate (71% vs 33%), ongoing pregnancy rate (59% vs 13%) and live birth rate (59% vs 7%).

Study design, size, duration: This is a non-interventional observational study on 102 bacterial taxa in endometrial tissue sample and its paired endometrial fluid sample collected from three reproductive-age women.

Participants/materials, setting, methods: Endometrial biopsied tissue and its corresponding endometrial fluid were collected from the same participant attending our Assisted Reproductive Technology Unit. Genomic DNA was extracted, PCR-amplified of the 16 S ribosomal RNA gene, which is universally possessed by all bacteria, but not by human, and sequenced on the MiSeq-200 (Illumina) sequencing platform. Similar sequencing reads (>97% nucleotide identity) were clustered as one bacterial taxon (genus/species, plural: taxa.). Read counts were normalized across different samples before comparison.

Main results and the role of chance: We have sequenced endometrial biopsied tissue and their corresponding endometrial fluid samples from three women at a median depth of 29,597 reads (interquartile range, 7,106 reads to 84,166 reads) per sample.

We detected 40, 63 and 43 bacterial taxa in participants A, B and C, respectively. Of these, only 35 taxa (24% of 146 taxa) were detected in both the endometrial tissue and fluid samples. Sixty-nine taxa (47%) were detected only in the tissue samples. Interestingly, 42 taxa (29%) were detected only in the fluid samples. The most abundant taxon in the tissue samples was a Bifidobacterium, while that in the fluid samples was a Lactobacillus.

Further, the Pearson product-moment correlation coefficients between the abundance values of taxa in the tissue samples and those in the fluid samples were 0.64, 0.13 and -0.24, and the p-values were $<1\times10^{-4}$, 0.31 and 0.12, respectively, for participants A, B and C.

Hence, among >100 bacterial taxa detected in this study, there were no correlation between their abundance values in the endometrial fluid and the endometrial tissue in two of the three participants. There was only a moderate correlation in one participant.

Limitations, reasons for caution: The limitation on this pilot study is that it involved only three patients and two samples from each of them, albeit each sample was sequenced at moderately high read depth.

Wider implications of the findings: The endometrial tissue harbors bacterial taxa not detectable in endometrial fluid and vice versa. The abundance values of taxa detected in the two endometrial samples are weakly correlated. Additional qualitative and quantitative information can be acquired in microbiome analysis of both the endometrial and fluid samples from the same woman.

Trial registration number: Not applicable for this basic science study.

P-628   Mosaic embryos: is it worth re-biopsying them?

L. Coll[1], M. Parriego[1], M. Boada[1], F. Vidal[2], M. Tresanchez[1], B. Coroleu[1], A. Veiga[1]

[1]Hospital Universitari Dexeus, Department of Obstetrics- Gynaecology and Reproduction, Barcelona, Spain
[2]Universitat Autònoma de Barcelona, Departament de Biologia Cel·lular- Fisiologia i Immunologia, Bellaterra, Spain

Study question: Is the performance of a second biopsy and analysis useful and efficient in mosaic embryos?

Summary answer: Performing a second analysis in mosaic embryos provides additional information for decision making and counseling about the possible transfer of such embryos.

What is known already: Trophectoderm biopsy allows the detection of certain levels of mosaicism. However, its clinical significance is yet to be determined although healthy live births have been generated by the transfer of mosaic euploid-aneuploid embryos. The decision to transfer euploid-aneuploid mosaic blastocysts should be taken considering the chromosomal anomaly and chromosomes involved.

Study design, size, duration: In our Preimplantation Genetic Screening (PGS) program, biopsied blastocysts are vitrified until diagnosis is performed. From January 2015 to December 2016, PGS patients with mosaic embryos were offered the possibility of warming such embryos and perform a second biopsy to obtain more information about their chromosomal constitution and better assess their possible use for transfer.

Participants/materials, setting, methods: Seventeen patients agreed to the warming of 20 mosaic blastocysts to perform a second biopsy. After warming, surviving blastocysts were cultured until re-expansion. Embryos not re-expanded on day 7 were discarded. Trophectoderm cells from re-expanding blastocysts were biopsied using laser thermolysis. The analysis was performed by aCGH using the kits and protocols provided by the manufacturer (Illumina, USA).

Main results and the role of chance: The survival rate after warming was 100% (20/20) although only 85.7% of the embryos re-expanded (18/20) and could be re-biopsied. After the second biopsy and analysis all the embryos could be diagnosed and mosaicism was confirmed in 8/18 blastocysts.

The first analysis in those 18 blastocysts showed that 11 had whole chromosome mosaicism and 7 had been diagnosed as segmental mosaics. Seven out of 11 embryos presenting whole chromosome mosaicism were confirmed to be mosaic after the second analysis. Three embryos showed a euploid result. One was mosaic for a different chromosome.

Regarding embryos with segmental mosaicism, its presence was only confirmed in 1/7 embryos. The rest showed a euploid profile after the second analysis.

Even based in a limited number of cases, our results show that segmental mosaicism is less confirmed than whole chromosome anomalies after a second biopsy.

Embryos with segmental mosaicism should be those first selected in cases of considering a transfer of a mosaic embryo.

Limitations, reasons for caution: Small sample size.

Array CGH is not an optimal tool for low degree mosaicism detection.

Embryos firstly diagnosed as mosaic that resulted euploid after a second biopsy should still be considered as mosaic. Patients' decision to transfer them must be taken after proper genetic counseling.

Wider implications of the findings: More sensitive analysis techniques are leading to the detection of more mosaic embryos in PGS programs, thus increasing the difficulty to decide embryo eligibility for transfer. It is of importance to collect as much information as possible about the actual chromosomal constitution of these embryos and the significance of mosaicism.

Trial registration number: Not applicable.

P-629   Higher incidence of chromosome 11 abnormalities associated with male embryos in cycles undergoing oocyte donation

M. Serdarogullari[1], O. Coban[2], E.M. Bilgin[3], Z. Onar Sekerci[3]

[1]British Cyprus IVF Center, Embryology, Gazi Magusa, Cyprus
[2]British Cyprus IVF Center, Embryology, Famagusta, Cyprus
[3]British Cyprus IVF Center, Gynecology & Obstetrics, Famagusta, Cyprus

Study question: Are there any gender-specific differences in distribution of chromosomal abnormalities between female and male embryos obtained in cycles undergoing oocyte donation?

Summary answer: Chromosomal distribution between female and male embryos shows similar pattern except chromosome 11, which showed a significantly higher abnormality rate towards male gender.

What is known already: It is known that oocyte donation programs yield high pregnancy and take home baby rates. Although it is generally believed that such high rates are mainly due to superior gamete quality, recent studies have reported a high rate of chromosomal abnormality in donor cycles. However, studies in which the incidence and distribution of genetic abnormalities in

embryos have been assessed and documented according to the gender of the embryo is scarce. To the best our knowledge this study is the first study to investigate distribution of genetic abnormalities in male and female embryos generated from donor oocytes

Study design, size, duration: This retrospective study was performed in British Cyprus IVF Centre between January and October 2016

Participants/materials, setting, methods: In this study, a total of 62 cycles of 62 patients that had undergone oocyte donation and comprehensive chromosomal screening (CCS) cycles for gender selection were included. All male partners showed normal semen parameters according to World Health Organisation. Mean age of oocyte donors was (24.5 ± 2.4). From 365 biopsied blastocyst-stage human embryos, 319 were analysed and 312 were efficiently diagnosed.

Main results and the role of chance: Of these 312 embryos diagnosed, 133 were found to be chromosomally abnormal (42.6%). Due to complex aneuploidy, gender of 11 embryos has not been reported (21%) hence excluded from the analysis. In total 3504 chromosomes in female embryos and 3744 in male embryos were assessed. Of female embryos, 0.66% were found to carry monosomy; 0.60% were trisomic and 0.31% had segmental imbalances. On the other hand, 0.69% of male embryos had monosomy; 0.77% displayed trisomy and 0.43% had segmental imbalances. There was not any difference between male and female embryos with respect to the incidence of monosomy, trisomy and segmental imbalances ($p = 0.739$, $p = 0.103$, and $p = 0.151$, respectively). A chromosome-specific analysis revealed more abnormalities in chromosome 11 in male (5.9%) than female (0.7%) embryos ($P = 0.020$).

Limitations, reasons for caution: This investigation is a retrospective study and due to the limited number of samples, further data with larger sample sizes should be evaluated in order to confirm our findings.

Wider implications of the findings: Chromosome 11 carries very important genes associated with epigenetic/imprinting disorders and its full or partial loses/gains can be very important in reproductive genetics. If confirmed in prospective studies with larger sample sizes, our results may indicate the novel yet unknown pathway for gender-specific early demise of male embryos before implantation.

Trial registration number: non applicable.

P-630 Validation of a high throughput, low cost NGS PGS assay: impact of library preparation and read length on resolution

K. Warren[1], P. Wang[2], W. Parker[2], B. Hodgson[1], M. Jasper[1]

[1]Reproductive Health Science Ltd, TechInSA Incubator, Thebarton, Australia
[2]ACRF Cancer Genomics Facility, Centre for Cancer Biology, Adelaide, Australia

Study question: With the aim of developing a high throughput, low cost PGS NGS assay, we evaluated the impact of library preparation kit and read length on single cell and 5-cell inputs.

Summary answer: The quantity and quality of sequencing data is highly dependent on multiplexing, library preparation method and read length. Their optimization makes PGS highly scalable.

What is known already: Limited WGA technologies suitable for copy number detection are commercially available. DOPlify[TM] (Reproductive Health Science Ltd) has been specifically developed for Next Generation Sequencing (NGS). The time and financial efficiencies offered by NGS of clinical samples is mediated by multiplexing, with the cost per sample decreasing as more samples are multiplexed. However, this can also negatively impact the test resolution and quality of results. When limited source material for genome wide evaluation is available, effective fragmentation, highly efficient adapter ligation and optimal read length is imperative to maximize the reads per sample available for interrogation.

Study design, size, duration: The aim of this study was to compare NGS run and sequencing read metrics from a range of library preparation kits as models for a PGS workflow. Using a common input DOPlify[TM] WGA product, kits from Kapa Biosystems, Illumina and Bioo Scientific were used in parallel according to manufacturers' instructions. The prepared libraries were sequenced together to eliminate any inter-sequencing variability.

Participants/materials, setting, methods: Individually sorted single cell and 5-cell aliquots from four aneuploid cell lines (Coriell Institute for Medical

Research) were used as test material. DNA libraries were prepared from four individual DOPlify[TM] WGA DNA samples that were created from a pool of eight individual WGA reactions to create a uniform input template. The libraries were subsequently sequenced (paired-end) using a NextSeq (n = 16; 150 bp) platform according to standard protocol (Illumina).

Main results and the role of chance: More than 12,250,000 reads per sample were generated using this workflow. Random downsampling to approximately 300,000 reads per sample was performed to mimic low pass NGS and sequencing data was bioinformatically aligned to hg19, before mapping rates and mapping quality were determined for single-end reads truncated to 36, 50, 75 and 150 bp. In addition, the generation of artificial aneuploidy samples with whole chromosome gains or losses, and segmental duplications or deletions were used to bioinformatically determine the resolution of the pipeline. The number of mappable reads increased as the read length was extended from approximately 64% for 36 bp to 70%, 78% and >80% for 50, 75 and 150 bp length reads respectively for Kapa HyperPlus kit samples. At a read length of 36 bp, Covaris shearing resulted in an approximate 40% increase in the number of unmappable reads compared to enzymatic fragmentation. Bioinformatic modelling using artificial copy number variations (CNVs) demonstrated a 5Mbp detection limit with binning 300,000 reads into 1Mbp bins. It was also demonstrated that increasing the limit of detection to 2Mbp was possible when 600,000 reads were binned into 500kbp bins. Kapa HyperPlus NGS genomic coverage was x0.01; 96 sample run (1×75 bp) and increased to x0.05; 48 samples (1×150 bp).

Limitations, reasons for caution: This data has been generated from limited NGS runs, and therefore increasing the number of sequencing runs is necessary to increase the number of samples per sequencing parameter/condition and to confirm intra-sequencing results.

Wider implications of the findings: Differences in resolution were evident with choice of library preparation kit and read length. By selecting RHS DOPlify[TM] and Kapa HyperPlus kits, we have validated a protocol that multiplexes 48-96 samples per PGS MiSeq NGS run and provides sensitivity down to 2 Mb using longer read lengths.

Trial registration number: not applicable.

P-631 Identification of novel mutations in PLCZ1 in two patients with fertilization failure after ICSI

R.R. Guggilla[1], M. Ferrer-Buitrago[2], S.N. Amdani[3], D. Bonte[2], C. Jones[2], K. Coward[3], P. Coucke[4], P. De Sutter[2], K. Coward[3], B. Heindryckx[2]

[1]Ghent University Hospital- Ghent Fertility and Stem cell Team, Reproductive Medicine, Gent, Belgium
[2]Ghent University Hospital- Ghent Fertility and Stem Cell Team, Reproductive Medicine, Ghent, Belgium
[3]University of Oxford, Nuffield department of obstetrics and gynaecology, Oxford, United Kingdom
[4]Ghent University Hospital, Center for Medical Genetics, Ghent, Belgium

Study question: Are abnormalities in the phospholipase C zeta (PLCZ1) gene responsible for failed fertilization after ICSI?

Summary answer: PLCZ1 mutational screening in patients with a history of failed or low fertilization after ICSI resulted in the identification of three mutations in two patients.

What is known already: In mammals, sperm-oocyte fusion leads to the oocyte activation process, which is initiated by calcium oscillations in the oocyte cytoplasm. A sperm specific phospholipase C zeta (PLCZ1) is known to induce this series of specific calcium oscillations, which hallmarks the start of oocyte activation. Loss of PLCZ1 function is known to cause oocyte activation failure. To date, there are only three missense mutations reported in two patients with fertilization failure.To obtain more insight in the role of PLCzeta in fertilization, a larger screening of the gene in patients experiencing failed or low fertilization after ICSI is warranted.

Study design, size, duration: Patients (n = 25) with previously low or total failed fertilization after routine ICSI were enrolled in the study after written consent. The genomic DNA was sequenced in these patients to check for abnormalities in the PLCzeta gene. In addition, RT-PCR was performed on the sperm

of a patient with splice mutation to see the effect of splice mutation at transcriptional level. The patients also underwent Assisted Oocyte Activation (AOA) after ICSI to obtain fertilization and pregnancy.

Participants/materials, setting, methods: Genomic DNA was extracted from the patient saliva samples. PCR was performed using primers designed to amplify all the 15 coding exons and the exon-intronic boundaries. The amplified PCR products were sequenced using illumine MiSeq. RNA from one patient was isolated using Picopure RNA isolation kit, cDNA synthesis was performed using iscript and RT-PCR with primers spanning exon 3 and 5. For AOA, sperm was injected together with calcium followed by a double ionomycin exposure.

Main results and the role of chance: PCR amplification and Illumina sequencing of the PLCZ1 gene revealed a known missense mutation c.698 A>T; H233L and a novel truncating mutation c.964 A>T; K322* in a compound heterozygous state in one patient.

In a second patient, a rare heterozygous variant c.422 G>A; R141H was found.

Finally, we detected a novel heterozygous invariant splice mutation c.136-1 G>C in a third patient.

The 136-1 G>C substitution is predicted to lead to loss of splice acceptor site by three different splice prediction programmes. The loss of splice acceptor site leads to loss of exon4. To analyze the effect of this mutation at transcriptional level, we extracted RNA from the sperm sample of the patient. RT-PCR on the patient cDNA confirmed the loss of exon4.

AOA was performed during ICSI on all the three patients oocytes to restore fertilization. This resulted in 80% fertilization rate and a successful live birth in the patient with the splice mutation

The second patient with compound heterozygous mutations had 5 cycles of AOA with a mean fertilization rate of 24.63% and a live birth was obtained.

The third patient with a rare variant had two cycles of AOA, which resulted in 33.33% fertilization but no pregnancy could be established yet

Limitations, reasons for caution: We still need to verify further the functional effect of these mutations by making recombinant protein of these mutations and injecting them into oocytes to verify its effect on activation rate, calcium pattern and embryonic developmental potential.

Wider implications of the findings: Identification of mutations in two patients with failed fertilization after ICSI confirms the crucial role of the PLCZ1 protein in the fertilization process. Screening of more patients with failed fertilization after ICSI will give us more insight of the frequency of PLCZ1 mutations in these patients.

Trial registration number: not applicable.

P-632   From prenatal diagnosis of fetal abnormality to preimplantation genetic diagnosis (PGD) by using next-generation sequencing (NGS) technologies: A case study for skeletal dysplasia PGD

D. Amoros[1], S. González-Reig[2], F. Galán[3], V. Penacho[4], H. Blanca[5], N. Castejón[6], L.A. Alcaraz[7]

Study question: Couple with two abortions due skeletal dysplasia, from initial diagnostic to complete preimplantational study. A reliable method to avoid malformation in subsequent pregnancies is needed.

Summary answer: We applied Trio whole exome sequencing (Trio-WES), involving both parents and fetus, combined with PGS/PGD and informativity testing in order to obtain healthy embryos.

What is known already: Skeletal malformations and dysplasias involve more than 300 syndromic and non-syndromic disorders, characterized by considerable phenotypic and genetic heterogeneity (recessive, X-linked disorders, or spontaneous mutations). If chromosomal abnormalities are not detected, a powerful technique for genetic testing of gene mutations associated with those

observed abnormalities is needed, where Trio-WES is indicated. After that, if causative point mutations are detected, PGD coupled with informativity testing is mandatory before in vitro fertilization (IVF) in order to transfer disease-free embryos successfully.

Study design, size, duration: A couple with two consecutive abortions due to skeletal dysplasia came to our laboratory for genetic counseling. Since there was no previous medical history in the family for this pathology, we applied Trio-WES to the couple as to the fetus. We found that both members were genetic carriers of Jeune syndrome. After that, two IVF cycles were performed combining PGS and PGD (August-October 2016). A total of 2 euploid disease-free embryos were selected to transfer.

Participants/materials, setting, methods: Trio-WES study was performed on DNA isolated from both the second abortion material and parental blood samples. Targeted-WES was performed using Ion-AmpliSeq™ Exome Kit on Ion Proton™ platform. Two mutations were detected in compound heterozygosity state in DYNC2H1 gene (pathogenic p.(Thr2106fs*7), and likely pathogenic p.(Asp3015Gly)). After oocyte insemination and day-5 biopsy, DNA whole genome amplification was followed by PGS/PGD/informativity testing in all embryos. SNPs detected through exome sequencing were used for the informativity test.

Main results and the role of chance: We present the case study of a healthy couple, with a previous history of two abortions due to undiagnosed skeletal dysplasia. A protocol for preconception assessment based on genetic diagnosis of an affected abortion was developed, in order to prevent inheritance diseases in subsequent pregnancies. In the set-up phase, we performed genetic diagnosis on malformed abortion by Trio-WES using Ion-AmpliSeq™ Exome Kit on Ion-Proton™ platform. After 5-day embryo biopsy, a combined PGD/PGS cycle was carried out. Along informativity testing, SNP-genotyping linked to gene regions involved by mutations was performed according to original Trio-WES data, giving us an accurate genetic profiling of embryos before implantation. A total of 65 informative SNP markers were selected in 2000 Kb flanking region on both sides of DYNC2H1 gene and Ion-AmpliSeq™ primer pools were designed. Targeted next-generation sequencing on Ion-PGM™ System along with Ion-AmpliSeq™ and Ion-ReproSeq™ workflow was performed. After IVF, among the seven embryos analyzed, 2 were euploid and 5 aneuploid. Both euploid ones were also healthy carriers for only one mutation, therefore they were suitable for transfer. This has not been performed yet due to gynecological issues in the patient. Presented framework will improve whole PGD/PGS in terms of turnaround-time, reliability and cost-effectiveness.

Limitations, reasons for caution: Limited to couples with an affected child or previous abortions due to genetic disease. Even a more accurate genetic diagnosis is required; a truthful one can only be achieved if the gene was previously implicated in a similar condition. The diagnostic yield from Trio-WES is reported to be approx. 15-30%.

Wider implications of the findings: Couples with undiagnosed pathologies could be benefited from this combined Trio-WES-PGD assay. We decided to couple the most powerful genetics tools available, with the aim of offering a very reliable and cost-effective method for those patients without previous clinical history reported.

Trial registration number: This is not a clinical trial so it is not linked to a trial registration number.

P-633   Accurate detection of small segmental aneuploidy using next generation screening in preimplantation genetic diagnose and screening (PGD/PGS)

Z. Shuang[1], X. Pingyuan[2], C. Dehua[3], O. Qi[4], L. Ge[5]

[2]China and National Engineering and Research Center of Human Stem Cell, research department, Changsha, China
[3]Institute of Reproduction and Stem Cell Engineering- Central South University, research department, Changsha, China
[4]Reproductive and Genetic Hospital of Citic-Xiangya, Research department, Changsha, China
[5]Central South University, Institute of Reproduction and Stem Cell Engineering, Changsha, China

Study question: To identify whether genome amplification (WGA) method combined with next generation sequencing (NGS) could efficiently detect segmental aneuploidy less than 16 Mb in blastocysts from PGD/PGS?

Summary answer: The PCR-based WGA methods are superior than the multiple displacement amplification (MDA) to detect the small segmental aneuploidy in sequencing depth of 0.1× data.

What is known already: Previous studies have indicated the NGS-based method for PGS/PGD could accurately detect segmental aneuploidy above 16 Mb. The small segmental aneuploidy, may inherited from a carrier of structural abnormality or can be generated de-novo in preimplantation development, could lead to miscarriage or born chromosomally abnormal fetus with micro-deletion and micro-duplication syndrome. Reliable and accurate PGD/PGS by NGS is dependent on efficient whole genome amplification of a representative biopsied sample. But currently, there is no available data to show which WGA method and to what extent the sequencing depth is required to efficiently detect segmental aneuploidy less than 16 Mb.

Study design, size, duration: This study was designed to evaluate three commercially available methods of WGA (Sureplex, DOP-PCR and MDA) in TE biopsies. Totally twenty blastocysts and ten genomic DNA samples with known small segmental abnormalities were used. The study was approved by the ethics committee (LL-SC-SG-2014-011), and all blastocysts with small segmental aneuploidy were donated for research with informed consent from the couples.

Participants/materials, setting, methods: Twenty blastocysts and with the small segmental aneuploidy which related to translocation were thawed and re-biopsied. Three TE biopsies were collected from each single blastocyst and subject to DOP-PCR, MDA and Sureplex amplification and then detecting the small segmental aneuploidy by NGS, respectively. Then, ten genomic DNA samples harbouring known chromosome disease CNVs (range of 1.49 - 5.79 Mb) identified by SNP array were subjected to Sureplex amplification and for NGS analysis for further validation.

Main results and the role of chance: Twenty blastocysts with variable CNVs sized between 1.29 Mb to 10.5 Mb were thawed and subjected to three amplification methods (DOP-PCR, SurePlex and MDA) respectively. The chromosome mapping of the unique reads were 50%, 60% and 50% respectively. Both PCR-based WGA methods (Sureplex and DOP-PCR) exhibited more uniformity and potentially less regional amplification bias than the MDA-based WGA system. Also, the PCR-based WGA products detected all the CNVs with sizes and map intervals similar to those detected in FISH. In contrast, from the MDA products, NGS only identified the three larger CNVs (10.5, 8.63 and 6.28 Mb) and failed to completely detect the remain smaller CNVs. Furthermore, a number of false positive results were present in the MDA products. Since the two PCR-based WGA methods applied to TE biopsies provided a more sensitive and specific detection of CNV, we further evaluate the reproducibility of Sureplex with variably sized (1.8, 2.2, 1.74, 1.67, 1.5, 1.49, 2.8, 4.8, 3.75 and 5.79 Mb) as the test CNV. All this CNVs was detected from all three replicate Sureplex WGA products with the correct copy number.

Limitations, reasons for caution: Nonetheless, further validation studies using blinded samples and different sequencing depths are warranted to determine the sensitivity and specificity of NGS for detection of a wider range of pathogenic CNV that can arise in embryos in different locations of the genome.

Wider implications of the findings: When NGS was applied to TE biopies WGA products derived by either Sureplex or DOP-PCR amplification, we showed that known disease CNVs in the range of 1-16 Mb could be reliably and accurately detected at the correct genomic positions. But the MDA methods may lack the capacity.

Trial registration number: not applicable.

P-634 The likelihood of transferring a euploid embryo after PGD-Aneuploidy cycles depends not only on female age but also on the number of biopsied blastocysts

M. Cetinkaya[1], M.A. Tufekçi[1], C. Cinar Yapan[1], C. Pirkevi[1], S. Kahraman[1]

[1]Istanbul Memorial Hospital, Assisted Reproductive Technologies and Reproductive Genetics Center, Istanbul, Turkey

Study question: Could the number of biopsied blastocysts compensate for the age effect in cycles with aneuploidy screening?

Summary answer: Until 40 years of age a good ovarian reserve providing a higher number of biopsied blastocysts can compensate for the age effect leading to aneuploidy.

What is known already: Aneuploidy is the most common type of chromosome abnormality and the leading cause of implantation failure, miscarriage and congenital abnormalities. Three RCTs have already demonstrated higher clinical pregnancy rates in young good prognosis patients with single embryo transfer, but investigations in other groups are limited to observational studies. Although scientific principles of comprehensive aneuploidy screening are widely accepted, controversy remains about the clinical and, particularly, economic effectiveness of this approach (Lee et al., 2014). Thus, patients and especially advanced maternal age cases need to be informed properly regarding their realistic chances of producing euploid embryos in different clinical scenarios.

Study design, size, duration: This retrospective study comprised a period between August 2011 and December 2016. A total of 1154 patients were subjected to aneuploidy screening, due to advanced maternal age (≥38), recurrent pregnancy loss (≥2) and repeated implantation failure (≥3).

Participants/materials, setting, methods: Patients were grouped according to female age (<35: n = 208; 35-37: n = 138; 38-40: n = 320; 41-42: n = 299 and ≥43: n = 189). They were also analyzed regarding the number of biopsied blastocysts (1: n = 273; 2-3: n = 456; 4-5: n = 276; ≥6: n = 149). Trophectoderm biopsy samples were analyzed with array CGH.

Main results and the role of chance: Regression and multivariate analyses performed designated female age and the number of biopsied blastocysts (BB) as being the most significantly correlated with the likelihood of finding at least one euploid blastocyst (LFLOEB) (p<0.0001). Mainly, five groups and the highest probability is found for females <35 and between 35-37 years of age for 4-5 and ≥6BB (90.5%, 94.4%, 90.0%, 93.3% respectively), but also for the 38-40 age category with ≥6BB (92.3%). LFLOEB is elevated for patients <35 with 2-3BB and females between 38-40 with 4-5BB, but also for patients between 41-42 years of age with ≥6BB (78.7%, 74%, 73.9%, respectively). Likewise, the LFLOEB is similar for females <35 with only 1BB, for patients between 38-40 years of age with 2-3BB, or 41-42 with 4-5BB and ≥43 with ≥6BB (57.9%, 56.6%, 57.6%, 61.1%). A diminished LFLOEB is obtained for females between 35-37 years of age with 1BB, for patients between 41-42 with 2-3BB, for the 38-40 age category with 1BB and for ≥43 with 4-5BB (33.3%, 34.6%, 41.7% and 46.7%, respectively). The worst scenario is for patients of 41-42 years of age with 1BB and for those ≥43 with 1 or 2-3BB (14.4%, 12.9% and 16.5%, respectively).

Limitations, reasons for caution: Results were obtained in an IVF program aiming prolonged culture and blastocyst transfer to select viable embryos. Cancellation rates of patients aiming at PGD-Aneuploidy but not reaching the blastocyst stage were not addressed in this study.

Wider implications of the findings: When counselling patients for PGD-Aneuploidy, maternal age and ovarian reserve should be considered together to inform them about their realistic chances of achieving a viable pregnancy. The couple should be well aware of the medical and psychological aspects of miscarriages and of terminations due to chromosomal aneuploidies.

Trial registration number: Not applicable.

P-635 Patient characteristics influence the outcome of embryo aneuploidy testing cycles

G. Cutts[1], M. Simpkins[1], K. Spath[1], N. Kubikova[1], S. Alfarawati[1], D. Wells[1], E. Fragouli[1]

[1]Reprogenetics UK, Institute of Reproductive Sciences, Oxford, United Kingdom

Study question: Do patient characteristics influence outcomes of aneuploidy testing cycles? Is there a particular patient group who might benefit more from preimplantation testing for aneuploidy (PGT-A)?

Summary answer: Patient characteristics influence embryo aneuploidy. Given consistently elevated aneuploidy rates, women of advanced reproductive age (ARA), irrespective of additional indications, may benefit most from PGT-A.

What is known already: PGT-A aims to assist couples that have experienced repeated implantation failure, or recurrent miscarriages, or women of

advanced reproductive age to achieve pregnancies and healthy births. Various methodologies are used, but the most widely applied examine the entire chromosome complement of trophectoderm (TE) samples biopsied from blastocysts. Randomised controlled trials (RCTs) have suggested that PGT-A via comprehensive chromosome screening is associated with positive outcomes. However, these studies have been criticised due to the patient groups included (generally good prognosis). We aimed to assess whether aneuploidy rates are influenced by PGT-A indications, and determine which patient group might benefit the most.

Study design, size, duration: This was a retrospective analysis of the chromosome constitution of TE samples removed from 1966 of embryos. These embryos were generated by 323 couples undergoing 366 PGT-A cycles. 149 of these couples were referred for advanced female reproductive age (ARA, average age 40.8 years), 61 for recurrent miscarriage (RM, average age 38 years), and 113 for repetitive IVF failure (RIF, 36.3 years). The corresponding data was collected from 2015 to 2016.

Participants/materials, setting, methods: All TE samples initially underwent whole genome amplification. Cytogenetic assessment took place by next generation sequencing (NGS). NGS has greater sensitivity and dynamic range, compared to other comprehensive cytogenetic methods. It can therefore reliably detect euploid embryos, as well as those with aneuploidies present in all of the TE cells (non-mosaic), and those with chromosome errors present in some TE cells (mosaic). Statistical analysis took place with ANOVA and Fisher's exact test.

Main results and the role of chance: 433 (22%) blastocysts were euploid, with the remaining 1,533 (78%) carrying different abnormalities. Of the aneuploid TE samples, 516 (26%) had errors present in all of the TE (non-mosaic), 486 (25%) had errors present in part of the TE (mosaic), and 531 (27%) had a combination of mosaic and non-mosaic abnormalities. There were significant differences (P = 0.015) in the euploidy rate among the referral groups with ARA generating the fewest (19%, vs. 24% in RM and RIF). ARA also generated significantly more (P < 0.0001) blastocysts with non-mosaic aneuploidy, compared to RIF (62% vs. 45%), but not when compared to RM (P = 0.7, 62% vs. 50%). The RIF and RM groups generated significantly more embryos with chromosome mosaicism, compared to the ARA group (P = 0.0106, 48% vs. 54%). Irrespective of PGT-A indication, the abnormality rate significantly increased with advancing female age (P < 0.0001, 67% for women of 36 years or younger vs. 83% for women of 37 years or older). Moreover, the no transfer rate for the younger patient group (≤36) was 11.6%. For those patients ≥37 the no transfer rate was 41%.

Limitations, reasons for caution: Cytogenetic characterisation of blastocysts was based upon NGS results of a single TE sample. As not all cells in the embryo are tested, some mosaic embryos will inevitably be classified incorrectly. However, any error is likely to be evenly spread across all groups and have little impact on the conclusions.

Wider implications of the findings: Differences in euploidy and aneuploidy rates were observed among the patient groups investigated. This suggests that patient characteristics influence embryonic chromosome constitution. PGT-A would likely be of most benefit for reproductively older women, irrespective of indication, due to the large number of abnormal blastocysts they tend to produce.

Trial registration number: Not applicable.

P-636 Embryo asymmetry on day 2 is associated with blastocyst mosaicism after trophectoderm biopsy

A. Rodríguez-Arnedo[1], J. Ten[1], M.C. Díaz-Martinez[1], L. Martí-Ferri[1], I. Ochando[2], J.A. Ortiz[3], J. Guerrero[1], L. Cascales[1], J. Llácer[4], R. Bernabeu[4]

[1]Instituto Bernabeu, Embryology Dept., Alicante, Spain
[2]Instituto Bernabeu, Embryology Dept., Albacete, Spain
[3]Instituto Bernabeu Biotech, Molecular Biology Dept., Alicante, Spain
[4]Instituto Bernabeu, Reproductive Medicine, Alicante, Spain

Study question: What is the relationship between embryo quality parameters at cleavage stage and the appearance of mosaicism after trophectoderm biopsy?

Summary answer: The presence of blastomeric asymmetry on day 2 increased the rate of embryo mosaicism at the blastocyst stage.

What is known already: Anaphase lagging is the main process by which mosaicism arises in the preimplantation embryo. We know that mosaicism is increased in the cleavage divisions compared to the blastocyst stage, where it is still prevalent despite the variability in results. It seems that mosaicism and aneuploidies are routine during the first cleavage divisions in human embryos (Taylor et al., 2014). Moreover, the greater sensitivity of the techniques of genetic diagnosis makes the detection of mosaic embryos possible. Therefore, it would be important to know at what point of the embryo development begins to generate cellular lines with different chromosome copy number.

Study design, size, duration: Retrospective analysis of 1039 day 5/6 blastocysts biopsied in our institution from January 2014 since December 2016.

Participants/materials, setting, methods: Before trophoectoderm biopsy, we registered some morphological parameters at the cleavage stage (day 2/3): number of cells, asymmetry and fragmentation degree. The quality of the embryos was graded as A, B, C or D (ASEBIR criteria). An embryo was considered as asymmetric when a difference of 20% in blastomeric size was found between the biggest and the smallest one. Data were analyzed and related to chromosomal diagnosis, obtained by array-CGH in our PGS program.

Main results and the role of chance: The embryo quality on day 2 and day 3 was not associated with the presence of mosaic blastocysts (p = 0.504 and p = 0.544, respectively). The degree of embryo fragmentation at day 2 and 3, also did not reveal a relationship with mosaicism (p = 0.769 and p = 0.804, respectively).

Regarding assymetry we stablished 3 groups: group A: symmetric, group B; slightly asymmetric (a difference less than 20% in blastomeric sizes), and group C: asymmetric. On day 2, the percentages of mosaic embryos in each group were 12.2%, 5%, and 25%, respectively, with statistical significance (p = 0.004). However, on day 3, the percentages of mosaic embryos in each group were not statistically significant (12.8%, 11.5%, and 8.6%, respectively, p = 0.748). Finally, non-statistical differences were observed in the number of cells on day 2 or 3 and the presence of mosaic embryos.

Limitations, reasons for caution: The main limitation is that this is a retrospective study.

Wider implications of the findings: Morphokinetics could be related to chromosomal haplotype in preimplantation embryos. There are many parameters that could influence in different cell lines during embryo development, but probably asymmetry could seriously affect the final result of chromosomal status. The way in which the first divisions occur could determine a future mosaic embryo.

Trial registration number: No trial registration.

P-637 Combined preimplantation genetic diagnosis, informativity testing and aneuploidy screening with human leukocyte antigen (HLA)-Matching by a novel single nucleotide polymorphism-genotyping in terms of Next-Generation Sequencing

V. Penacho[1], S. González-Reig[2], H. Blanca[2], D. Amoros[3], N. Castejón-Fernández[3], F. Galán[4], A. Aguilar[5], L.A. Alcaraz[6]

[1]Bioarray S.L., R&D+i, Elche Alicante, Spain
[2]Bioarray S.L., PGS/PGD, Elche Alicante, Spain
[3]Bioarray S.L., Bioinformatics, Elche Alicante, Spain
[4]Bioarray- S.L., Medical Counselling, Elche Alicante, Spain
[5]SanaGen- S.L., Reproduction, Seville, Spain
[6]Bioarray S.L., Technical Direction, Elche Alicante, Spain

Study question: Is our NGS strategy coupled to HLA-allele prediction from SNP-genotyping reliable to achieve successful birth of genetically suitable donor-baby(ies) and hematopoietic stem cell transplantation (HSCT)?

Summary answer: We've implemented a novel methodology for predicting HLA-alleles from SNP-genotyping combined with Ion-AmpliSeq™ sequencing for the PGD of β-thalassemia in order to ensure sufficient informativity.

What is known already: The major histocompatibility complex (MHC) containing the classical HLA system is among the most polymorphic and diverse regions in the human genome. Combination of in vitro fertilization (IVF), PGD for haemoglobinopathies, and HLA-typing, allows the birth of healthy children

who are potential donors of stem cells for their affected siblings through HSCT. Nowadays, multiplex short tandem repeat polymerase chain reaction (STR-PCR) within both the HLA and β-globin loci is routinely performed in PGD-HLA. Analysis of HLA-SNPs and SNPs linked to β-globin gene mutations with NGS technology enables an all-in-one informativity testing, PGS and PGD shortly after embryo biopsy.

Study design, size, duration: A thalassemia trait couple with an affected child was referred for thalassemia-HLA PGD. A preclinical set-up study was first conducted after written informed consent from parents about whole procedure and its outcomes. Complete study comprised two IVF-cycles with PGS/PGD (May-December 2016). Mother carried a common β-globin gene (HBB) mutation, known as hemoglobin (Hb) Lepore-Washington-Boston (g.63632_71046del). Father carried other frequent HBB mutation (g.70842 C>T, Cd39C> T). Affected child was therefore double heterozygous for both parental gene mutations.

Participants/materials, setting, methods: Imputation from HLA-SNP genotyping was predicted from family blood samples within 9 HLA-antigen loci (Class I {-A|-B|-C }; Class-II {-DPA1|-DPB1|-DQA1|-DQB1|-DRB1|-DRA}) using SNP2HLA software. In parallel, informativity testing for β-globin locus was performed. Haploview provided SNPs-linkage disequilibrium. Potentially informative SNPs up to 200Kb flanking regions were used for Ion-AmpliSeq™ primer-design and subsequent targeted-NGS on Ion PGM™ platform. After oocyte insemination and day-5 biopsy, DNA-whole genome amplification was followed by PGS/PGD/informativity testing in embryos.

Main results and the role of chance: A single-custom set of 160 SNPs typed across HLA and HBB loci has been studied in order to ensure a sufficient informativity. Genotype data for all SNPs with European ancestry was found in The International HapMap Project. SNPs were only selected for four-digit prediction accuracy ≥90% at each locus in HLA-typing. Mismatch in SNP-haplotype and recombination rate between informative flanking markers was estimated in less than 5% and 0.05%, respectively. Around 17% of SNPs studied were fully informative in order to select mutation-free and HLA-matched embryos. Along two β-thalassemia/HLA-PGD cycles, a total of 16 embryos resulted. NGS-Ion PGM™ System along with Ion-ReproSeq™ workflow determined that 8 were euploid, 5 aneuploid and 3 presented a chaotic arrangement. No amplification failures, neither false positives nor negatives were detected. The overall ADO rate was ≤3%. Finally, PGD/SNP informativity testing in euploid embryos showed 3 mutation-free ones and 1 was found to be both healthy and HLA-compatible with the affected sibling. To date, embryo transfer is pending. Following the ESHRE-PGD recommendations about covering 5 HLA regions together with at least 2 markers linked to HBB locus, 20 different STRs on both HLA and HBB loci ensuring enough informativity were used to validate SNP-based approach.

Limitations, reasons for caution: Number of HLA-PGD studies is limited to couples with affected children by genetic or acquired immune system diseases. Also, some SNPs within HLA-region can show strong LD to particular alleles. Improving the HLA-allele prediction algorithm would optimize the selection of informative SNPs based upon maximizing the predictability of SNP haplotypes.

Wider implications of the findings: This SNP approach is extremely useful regarding to time-consuming and cost-effectiveness along PGD-HLA cycles, against laborious, expensive and case-specific STR-PCR protocols. Also, HLA-SNPs genotyping combined with Ion-AmpliSeq™ NGS-technology could be applicable for preimplantation-HLA selection alone or in combination with genetic diseases or acquired immune system disorders, only curable by HSCT.

Trial registration number: This is not a clinical trial so it is not linked to a trial registration number.

P-638   The quality of the inner cell mass and trophectoderm is correlated with mosaicism

L. Martí Ferri[1], J. Ten[1], M.C. Díaz[1], A. Rodríguez-Arnedo[1], J. Guerrero[2], L. Cascales[1], B. Lledó[3], J. Llácer[4], R. Bernabeu[4]

[1]Instituto Bernabeu, Embryology, ALICANTE, Spain
[2]Instituto Bernabeu, Oocyte Donation, ALICANTE, Spain
[3]Instituto Bernabeu Biotech, Molecular Biology and Genetics, ALICANTE, Spain
[4]Instituto Bernabeu, Reproductive Medicine, ALICANTE, Spain

Study question: Is there any association between the quality of the embryo and the position of the inner cell mass (ICM) with the appearance of mosaic blastocysts?

Summary answer: We found a relationship between the quality of the blastocyst and the diagnosis of mosaicism.

What is known already: Anaphase lagging is the main process by which mosaicism arises in the preimplantation embryo. In the blastocyst stage, this phenomenon is still prevalent despite the variability in results (Taylor et al., 2014). Moreover, the greater sensitivity of genetic diagnosis techniques makes possible the detection of mosaic embryos. These embryos may have a lower implantation rate and a greater risk of genetic abnormalities, so the detection of mosaic embryos prior to transfer is important. Although a correlation between different morphokinetic parameters and embryo ploidy has been observed, we do not find any study evaluating mosaicism.

Study design, size, duration: This is a retrospective study evaluating 663 blastocyst biopsied on day 5 or 6 from January 2014 since March 2016.

Participants/materials, setting, methods: The quality of the trophectoderm (1-3) and the ICM (1-3) was assessed independently, according to Gardner's criteria prior to embryo biopsy. The position of the ICM at the moment of biopsy (outside, inside or in the herniation) was also evaluated. Data were analyzed and related to chromosomal diagnosis, obtained by array-CGH in our PGS program.

Main results and the role of chance: The quality of the ICM and the trophectoderm was associated statistically with the appearance of mosaic embryos. The rate of mosaicism for the ICM quality was: 8.3% (grade 1), 17.2% (grade 2) and 23.1% (grade 3) (p = 0.001). The appearance of mosaicism for the trophectoderm quality was: 6.1% (grade 1), 17.8% (grade 2) and 13.9% (grade 3) (p = 0.0001). So, blastocysts with high quality (grade 1 ICM and grade 1 trophectoderm) had the best options not to be mosaics. We do not found statistical differences in relation to the position of the ICM and the diagnosis of mosaic embryos (11.9%, outside; 12.8%, inside; 8.2% herniation; p = 0.705).

Limitations, reasons for caution: The main limitation is the retrospective nature of the study. We also have to consider that the assisted hatching procedure performed on day 3 makes that the blastocyst morphology, mainly the trophectoderm, could be slightly different, so the blastocyst assessment could differ from the standard blastocyst classification.

Wider implications of the findings: The quality of the ICM and trophectoderm may be a marker of mosaicism. To our knowledge this is the first work evaluating blastocyst quality and mosaicism.

Trial registration number: Not applicable.

P-639   The effect of complete ban of comprehensive chromosome screening on the outcome of in vitro fertilization of patients with advanced maternal age in Hungary

A. Vereczkey[1], G. Teglas[2], L. Nanassy[2]

[1]Human Reproduction Institute Versys Clinics, Surgery, Budapest, Hungary
[2]Human Reproduction Institute Versys Clinics, Embryology, Budapest, Hungary

Study question: How does prohibition of comprehensive chromosome screening affect clinical outcomes of patients with advanced maternal age (AMA)?

Summary answer: Based on our results using CCS increases sustained implantation rates while reduces miscarriage and multiple pregnancy rates and the number of unnecessary embryo transfers.

What is known already: In 2015, due to a legislative change in Hungary, classification of CCS from recommended for patients with AMA changed to experimental, that led to its complete ban. Since then several meta-analyses showed that comprehensive chromosome screening is a useful tool to select embryos that results in a higher implantation and a reduced miscarriage rates. The aim of this longitudinal retrospective analysis is to investigate the effect of embryos selection on clinical outcomes using CCS or conventional morphology-based selection.

Study design, size, duration: Data were collected from all stimulated, autologous cycles where female patients had an advanced maternal age (37-42) between January of 2013 and May of 2016 at our clinic. Patients with known

chromosome rearrangements were excluded from the analysis. Retrospectively two groups were formed based on the type of embryo selection.

Participants/materials, setting, methods: In the CCS group the transferred embryo(s) were all euploid (array-CGH, day-3 biopsy), while in MBS group only conventional morphology-based selection was applied. In the CCS group 52 fresh embryo transfers were carried out with 64 embryos and in MBS group 102 embryos were transferred in 70 fresh cycles. We analyzed only one cycle from all patients to ensure the independence of observations.

Main results and the role of chance: The mean maternal age did not differ in the two groups (39,00 ± 1,833 in CCS group, 39,16 ± 1,603 in MBS group) while the mean number of embryos transferred was significantly higher in MBS group (1,46 ± 0,440 vs. 1,25 ± 0,582; p = 0,0393). Despite the difference in the number of transferred embryos, clinical pregnancy rates did not differ (40,00% (28/70) in MBS vs. 49,02% (25/51) in CCS group). We found a significantly higher miscarriage rate in MBS group (40,63% (13/32) vs. 15,39% (4/26), p = 0,0455). These embryos had a 4,54-fold risk (95%CI=1,1193-18,4123, p = 0,0342) for miscarriage after a detected heart-beat compared to the euploid embryos. The sustained implantation rate were significantly higher in the CCS group (40,63% (26/64) vs. 20,59%(21/102), p = 0,0077). We did not find a significant difference in case of ongoing pregnancy rates (43,14%(22/51) in MBS vs. 27,14%(19/70), p = 0,0812). Furthermore, in the MBS group one pregnancy were terminated due to a trisomy on chromosome 21.

Limitations, reasons for caution: This analysis is partially longitudinal meaning after the ban of CCS only conventional methods were used. Also, despite of analyzing more than 3 consecutive years of data, the number of observation lower than expected.

Wider implications of the findings: Our results demonstrate that CCS is a more effective technique to select embryos for transfers than conventional morphology-based selection for patients with AMA. Using CCS, less patients experience miscarriage that is considered a major benefit compared to conventional IVF/ICSI treatments.

Trial registration number: None.

P-640   Concordance rates between single blastomere day-3 (D3) and trophectoderm biopsies (D5) using Next Generation Sequencing (NGS)

A. Liñán Tegedor[1], A. Bayram[1], A. Arnanz[1], C. Rubio[2], R. Chopra[3], I. Elkhatib[1], C. Simón[4], H. Fatemi[5]

[4]Igenomix Foundation, Department of Obstetrics & Gynecology. University of Valencia- INCLIVA. Research Department- Igenomix, Valencia, Spain
[5]IVI Middle East Fertility Clinic LLC, IVI Fertility Clinics LLC, ABU DHABI, United Arab Emirates

Study question: To evaluate the concordance rates of NGS findings by analyzing the same, non-transferred embryos, after day 3 and day 5 biopsies.

Summary answer: NGS results on D3 and D5 embryo biopsies, showed concordance rates of 92.4% for whole-chromosome aneuploidies and 94.9% for segmental aneuploidies. In total 87.3% concordances.

What is known already: Previous publications, using array-CGH and comparing D3 versus trophectoderm biopsies to full analysis of aneuploid embryos, showed similar high concordance rates per embryo diagnosis for D3 biopsies (98 %) and trophectoderm biopsies (96.6 %). This blinded study was conducted to re-analyse 109 embryos previously diagnosed as aneuploidy. PGS was performed using array-CGH on D3 (n = 50) or D5 (n = 59) biopsies. After the two biopsy strategies, reanalysis of whole blastocysts was carried out with same array-CGH protocol (Mir ,2016).

Capalbo et al using aCGH found that the sensitivity of D3 biopsy predicting the blastocyst chromosomal constitution was 86.4% and specificity was 95%

Study design, size, duration: Observational study, including 35 patients (118 embryos) undergoing PGS at IVI Abu Dhabi from August 2016 to January 2017, to validate the chromosomal status of D5 embryos previously diagnosed on D3 with NGS technology. Double biopsies (D3 and D5) were performed to all embryos, reaching blastocyst stage on D5 and not being selected for transfer

(including surplus euploid embryos, that could not be vitrified according to the country law).

Participants/materials, setting, methods: Infertile patients with normal karyotype undergoing PGS with fresh oocytes, with more than four embryos to biopsy on D3, women aged between 18 and 45 years old, with a body mass index between 19 and 30. For the cases of D3 embryo biopsy, only embryos with five or more nucleated blastomeres and less than 25 % fragmentation were biopsied and for blastocyst biopsy, only hatching blastocyst were biopsied. NGS was performed after whole genome amplification.

Main results and the role of chance: Concordance rates for segmental and whole chromosome aneuploidies, determined on D3 and D5 biopsies were blindly evaluate. We calculated two types of concordance rates: the concordance rate per analyzed chromosome, where we considered the total number of chromosomes independently if they were called as euploid or aneuploidy (24 chromosomes per embryo); and the concordance rate per embryo diagnosis, where we considered discrepancies in the embryo diagnosis as euploid or aneuploid.

The overall concordance rate per analyzed chromosome (24 chromosomes x 118 embryos) was 98.4% (2787/2832 analyzed chromosomes). For whole-chromosome aneuploidy, the concordance rate was 99.0% (2803/2832) and for segmental aneuploidies was 99.3% (2813/2832).

The concordance rates per embryo diagnosis were 92.4% (108/118) for whole-chromosome aneuploidies and 94.9% (112/118) for segmental aneuploidies. Therefore, false positive rate per D3 embryo diagnosis (euploid/aneuploid) was 11.9% (14 out of 118 embryos). From which 6.8% (8/118) were whole-chromosome discrepancies between D3 and D5, and 5.1% (6/118) were segmental aneuploidies. False negative rate per embryo diagnosis (aneuploid/euploid) was 0.8% (1 out of 118).

The concordance rates per embryo diagnosis for aneuploid/aneuploid embryos were 83.1% (98/118), representing embryos aneuploid at both biopsy stages, but with and additional aneuploidy either on D3 or D5.

Limitations, reasons for caution: The difficulty to discriminate the origin of the discrepancies, that could be attributed to D3 or D5 mosaicism, or to technical artefacts. Single cell genetic technologies are still biased by amplification artefacts. Further inner cell mass analysis could also identify discrepancies with trophectoderm and bring additional information.

Wider implications of the findings: Is important to know the limitation of D3 and D5 biopsies from biological and technical point of view to consider the proper stage of embryo biopsy. The reported mosaicism incidence in preimplantation embryos is wide (between 4 and 90%). Further studies are needed to elucidate the real rate of mosaicism.

Trial registration number: not applicable.

P-641   New algorithm for a precise determination of the level of mosaicism in Preimplantation Genetic Screening (PGS) with next-generation sequencing (NGS)

N. Castejon Fernandez[1], D. Amoros[2], S. Gonzalez-Reig[3], H. Blanca[3], V. Penacho[4], F. Galan[5], L.A. Alcaraz[6]

[1]Bioarray, Bioinformatic, ELCHE ALICANTE, Spain
[2]Bioarray SL., Bioinformatics, Elche, Spain
[3]Bioarray SL., PGD/PGS, Elche, Spain
[4]Bioarray SL., R&D&i, Elche, Spain
[5]Bioarray SL., Medical diagnosis, Elche, Spain
[6]Bioarray SL., Technical Direction, Elche, Spain

Study question: Are we capable to improve the accuracy identifying genome-wide aneuploidies based on NGS, using a new filter-duplicates and a copy number variation (CNV) calling algorithms?

Summary answer: Our algorithm can accurately identify percentage of aneuploidy for embryo-biopsies, improving confidence-value and reducing risk of misdiagnosis. Less reads are required enabling high-level multiplexing.

What is known already: With the advent of NGS for PGS purpose, bioinformatics has become a key area of development. Filtering PCR-artifacts, normalization and aberrations calling are common tasks implemented in any software designed for analyzing NGS data. However, most of the algorithms implemented to date have been developed for post-natal diagnosis, where NGS has recently become a useful but not fully compatible approach for PGS. Previous methods based on whole-

genome sequencing (WGS) require high-depth coverage on the whole genome scale and are not cost-efficient. Moreover, they do not determine precisely the level of mosaicism, because this is very uncommon in post-natal diagnosis.

Study design, size, duration: *In-silico* and *in-vitro* approaches were achieved in order to evaluate the percentage of mosaicism. Firstly, *in silico* mosaic-embryos were designed controlling the percentage of mosaicism from sequencing alignment data of 25 euploid/aneuploid embryos. *In vitro* mosaic-embryos were mimetized from DNA of cell-culture.

To determinate minimum reads number per embryo required for a correct PGS forecast, a random sequence selection within these embryos was carried out to perform *in silico* embryos from 100,000 to 5000 reads.

Participants/materials, setting, methods: Sequencing data from previous biopsied day-3 and day-5 euploid/aneuploid embryos was used to perform *in silico* sets. DNA was isolated from aneuploid lymphocyte cell-culture lines showing trisomy18, Turner syndrome and euploid and mixed to create *in vitro* set.

Biopsied and *in vitro* embryos were sequenced on Ion-PGM™ platform and analyzed using Ion-ReproSeq™ workflow and our own-designed algorithm.

MAPD quality values and ploidy stage per embryo were thoughtfully evaluated.

Main results and the role of chance: While Ion-ReproSeq™ workflow needs at least 100.000 reads per embryo for a successful analysis, our algorithm accurately predicted the ploidy stage of submitted embryos with only 10.000 reads per embryo. Also, Ion-ReproSeq™ workflow was able to detect the mosaicism stage when it was greater than 40% of aneuploidy, and to diagnose embryos as aneuploid; otherwise aneuploidy was hidden and undetected. Our algorithm has been able not only to detect the whole mosaicism spectrum (from 90 to 10%), but also to indicate the exact percentage of aneuploidy in an analyzed mosaic cell. This has allowed us to be more consistent with the final diagnosis of the embryos submitted. Moreover, our approach would provide the possibility to discover the biological significance of mosaic embryos along IVF cycles and to discuss the convenience of transfer according to its mosaic state. Finally, we can assert that our algorithm is reliable regarding to accuracy improvement, time-consuming and cost-efficiency, which enhances PGS service and allows us to offer it specifically for every couple and cycle. Even, it is limited not only to discover variations within exons, but also on whole genome.

Limitations, reasons for caution: MAPD-quality values greater than 0.4 can difficult diagnosis, by modifying the percentage of mosaicism showed by our algorithm. However, mosaic embryos never could be wrongly identified as euploids. This limitation is semi-controlled by applying the filter-duplicates algorithm that decreases reads-variability while quality of copy number calls increases.

Wider implications of the findings: Our algorithm is more accurate than Ion-ReproSeq™ workflow one. It shows the exact ploidy-rate in mosaic-embryos, enabling detection even at very-low mosaicism. This approach could improve implantation chances, giving us a deep-knowledge about the developmental potential of mosaic embryos generated by *in vitro* fertilization-cycles and biological-implications derived from transferring themselves.

Trial registration number: None.

P-642　Quantitative polymerase chain reaction (qPCR)-based patterns consistent with mosaicism/partial aneuploidies(PA) indicate blastocysts with slightly lower reproductive competence: preliminary results from a non-selection study

D. Cimadomo[1], C. Patassini[2], A. Giancani[1], E. Scepi[1], L. Dovere[1], S. Romano[1], G. Orlando[1], L. Rienzi[1], F.M. Ubaldi[1], A. Capalbo[2]

[1]*CLINICA VALLE GIULIA, Genera- Reproductive Medicine Center, Roma, Italy*
[2]*GENETYX, Molecular Biology Laboratory, Marostica VI, Italy*

Study question: Can we set qPCR parameters and thresholds to infer mosaicism and/or large PA in blastocysts on trophectoderm-based analysis' patterns and predict embryos' reproductive competence?

Summary answer: The developed criteria for qPCR data analysis may indicate mosaicism and/or large PA in trophectoderm biopsies and identify blastocysts with a slightly lower reproductive competence.

What is known already: Mosaic blastocysts are made of cells with different karyotypes. Recently, targeted-qPCR has been reported to inherently identify whole chromosome mosaicism in cell-mixture models of trophectoderm biopsies with a considerable sensitivity and specificity. PA are imbalances involving a portion

of a chromosome, which targeted-qPCR may also identify when the imbalance involves a large chromosomal region. In this study, we tested whether specific parameters and thresholds compatible with mosaicism and PA applied to clinical blastocyst stage preimplantation genetic diagnosis for aneuploidies (PGD-A) cycles can be valuable to identify embryos with lower reproductive potential.

Study design, size, duration: Prospective non-selection study involving 369 vitrified euploid single blastocyst transfers between March 2015 and September 2016. Aneuploidy testing performed through qPCR on trophectoderm biopsies according to a previously published method. Euploid blastocysts to be transferred were chosen independently from putative mosaicism/PA.

Participants/materials, setting, methods: Only euploid blastocysts whose qPCR profile plot showed an overall concurrence ≤ 0.3 and an inter-chromosome standard deviation ≤ 0.32 and ≤ 0.18 for male and female embryos, respectively, were considered as a first inclusion criteria. Putative mosaicism was defined as copy number (CN) ≤ 1.65 or ≥ 2.35 and an intra-chromosome assays' concurrence ≤ 0.25. Putative PA were defined as two consecutive assays on a chromosome arm with a CN ≤ 1.65 or ≥ 2.35 and an intra-chromosome assays' concurrence ≥ 0.4.

Main results and the role of chance: 3.5%(n = 13/369) and 28.2% (n = 104/369) of the transferred blastocysts were not included due to an overall concurrence and inter-chromosome standard deviation above the defined thresholds, respectively. 78.6% of the blastocysts included in the study showed a qPCR profile not compatible with mosaic and/or PA(n = 198/252;95% CI=73.0%-83.5%), and 21.4% were classified as "putative mosaic" and/or "putative PA" for at least one chromosome(n = 54/252,95%CI=16.5%-27.0%). Specifically, 15.1% "putative mosaic"(n = 38/252;95%CI=10.9%-20.1%), 6.3% "putative PA"(n = 16/252; 95%CI=0.4%-10.1%) and 0.4% both (n = 1/252;95%CI=0%-2.2%.). No correlation was found between blastocyst morphology and qPCR profiles compatible with mosaicism/PA (p = 0.4).

The positive pregnancy rates per SET were 52.6%(n = 20/38;95%CI=35.8%-69.0%) and 43.8%(n = 7/16;95%CI=19.8%-70.1%) for "putative mosaic" and "putative PA", respectively. The biochemical pregnancy loss rates were 10.0%(n = 2/20;95%CI=1.2%-31.7%) and 14.3%(n = 1/7;95%CI=0.4%-57.9%). The miscarriage rates were 22.2%(n = 4/18;95%CI=6.4-47.6%) and 16.6%(n = 1/6;95%CI=0.4%-64.1%). The ongoing pregnancy rates (>12 gestational weeks) per SET were 36.8% (n = 14/38;95%CI=21.8%-54.0%) and 31.3%(n = 5/16;95%CI=11.0%-58.7%).

When combining "putative mosaic" with "putative PA" and comparing the clinical outcomes with non-mosaic/PA, the positive pregnancy test rate per SET were 50.0%(n = 27/54;95%CI=36.1%-63.9%) and 60.6%(n = 120/198;95%CI=53.4%-67.5%), respectively. The biochemical pregnancy loss rates were 11.1%(n = 3/27,95%CI=0.2%-29.2%) and 8.3%(n = 10/120;95% CI=0.4%-14.8%). The miscarriage rates were 20.8%(n = 5/24;95%CI=7.1%-42.2%) and 9.1%(n = 10/110; 95%CI=4.5%-16.1%). At last, the ongoing implantation rate per SET was significantly lower for "putative mosaic/PA" blastocysts versus non-mosaic/PA ones (p = 0.05): 35.2%(n = 19/54; 95% CI=22.7%-49.4%) and 50.5%(n = 100/198;95%CI=43.3%-57.7%).

Limitations, reasons for caution: Mosaicism on trophectoderm biopsies does not predict mosaicism in the whole blastocyst due to an unavoidable sampling bias. Putative mosaicism/PA were not confirmed on products of conceptions or ongoing pregnancies. Additional biological and technical issues can produce CN profiles resembling mosaicism and have not been tested in this study.

Wider implications of the findings: These preliminary outcomes highlighted a slightly lower reproductive potential for embryos showing an intermediate CN consistent with mosaicism/PA. These data need to be corroborated in a higher sample size to define whether the newly developed bioinformatic algorithm can be incorporated in the clinical management of qPCR-based PGD-A cycles.

Trial registration number: none.

P-643　Detection of segmental aneuploidy and mosaicism in the human preimplantation embryo by next generation sequencing (NGS) methodologies

A. Biricik[1], E. Cotroneo[1], M. Surdo[1], S. Bono[1], M.G. Minasi[2], E. Cursio[2], E. Greco[2], F. Fiorentino[1], F. Spinella[1]

[1]*Genoma Group, Molecular Genetics laboratory, Rome, Italy*
[2]*European Hospital, Reproductive Medicine, Rome, Italy*

Study question: Can MiSeq-based (Veriseq) and personal genome machine (Reproseq)–based next-generation sequencing (NGS) accurately detect segmental aneuploidy and embryonic mosaicism in trophectoderm biopsies?

Summary answer: Segmental imbalances as little as 4.5 Mb and 10 Mb, and chromosomal mosaicism ≥20% and ≥30% were reliably detected with the Veriseq and Reproseq-based NGS, respectively.

What is known already: Preimplantation genetic screening (PGS), specifically with NGS, for aneuploidy testing on embryos has become a common practice to improve outcomes in patients undergoing treatment for infertility through in vitro fertilization. As technology has evolved, detection of segmental aneuploidy and embryonic mosaicism has become possible. Although possible to diagnose, the limits of detection for segmental aneuploidies and mosaicism between different NGS platforms has not been examined.

Study design, size, duration: This study evaluates the ability to detect segmental aneuploidy and mosaicism between two NGS platforms. Samples composed of specific euploid/aneuploidy cells ratio (10–90% mosaicism) of 10 (n = 54) and 100 (n = 54) total cells were obtained and analysed with both platforms. In addition euploid (n = 6) and aneuploid (n = 6) cell lines were used as control. Duplicates of eight cell lines with different structural abnormalities (from 4.5 Mb to 17 Mb) were used for segmental aneuploidy assessment.

Participants/materials, setting, methods: Female euploid/male trisomy 21 cell line were used for one set, and a male euploid with either female trisomy 18 or a female trisomy 21 cell line were used for another. Sensitivity and specificity of aneuploidy detection at each level of mosaicism was determined and compared between platforms. CNV analysis was accomplished by current version of BlueFuse software (Veriseq) or IonReporter Software(ReproSeq). Benefit in terms of time, and user-friendliness were determined and compared between platforms

Main results and the role of chance: In total, 120 samples were assessed for mosaicism detection, 108 chromosomal mosaics (true positive) and 12 aneuploid or euploid (true negative) samples. Sensitivity was 90% (95% confidence interval [95% CI]: 83.18% to 94.73%) and 81.82% (95% confidence interval [95% CI]: 74.17% to 87.99%) for Veriseq and Reproseq, respectively. The 12 false negative results obtained with VeriSeq were from samples with 10% mosaicism. The 24 false negative results obtained with ReproSeq were from the samples with <30% mosaicism. Specificity was 100% (95% confidence interval [95% CI]: 73.54% to 100.00%) for both platforms. These studies indicated a different limit of detection for mosaicism detection with a limit of detection (LOD) of 20% and 30% for VeriSeq and ReproSeq, respectively. Analysis of segmental aneuploidy in the cell lines demonstrated that ReproSeq could identify a segmental imbalance as small as 10 Mb in size, while VeriSeq, using a manual call, identify microdeletion as little as 4.5 Mb. No additional segmental imbalances were identified. ReproSeq protocol was more rapid (<15 h) compared to VeriSeq. VeriSeq was judged by our operators to be more user-friendly than ReproSeq.

Limitations, reasons for caution: Further data and broad-based clinical application are required to confirm the limit of detection for mosaicism level and segmental aneuploidies of NGS platforms.

Wider implications of the findings: These findings demonstrate that VeriSeq-based NGS platform has a much higher resolution for segmental aneuploidies and a higher level of accuracy at a lower level of mosaicism compared to ReproSeq.

Trial registration number: none.

P-644 Embryo selection of euploid embryos by an automated time-lapse prediction is superior to conventional morphological analysis: a retrospective study

E. Rocafort[1], M. Enciso[2], A. Leza[1], J. Sarasa[2], J. Aizpurua[3]

[1]IVF Spain, IVF Lab, Alicante, Spain
[2]iGLS, Genetics, Alicante, Spain
[3]IVF Spain, Reproductive Medicine, Alicante, Spain

Study question: Is the time-lapse prediction useful in a Preimplantation Genetic Screening (PGS) program to select among euploid embryos the one with the highest implantation potential?

Summary answer: The automated time-lapse prediction provides valuable information for embryo selection, significantly increasing the chances of pregnancy and accurately predicting the implantation potential of euploid embryos.

What is known already: Previous studies confirmed that genetic screening of human blastocysts significantly improves pregnancy rates per transfer diminishing the likelihood of miscarriage. Unfortunately, there is still a considerable number of euploid embryos that fail to implant. New embryo selection markers to improve ART-outcomes have been developed. Time-lapse imaging (TLI) has emerged as an interesting non-invasive tool to identify competent embryos. No conclusive data about this technology utility for chromosome abnormalities determination is available. In the present study we investigate if combined TLI and PGS embryo selection may be a valuable strategy to identify those embryos with the best chances of success.

Study design, size, duration: This unicentric and retrospective study included 81 patients seeking PGS-cycles with autologous oocytes and 163 with donated eggs between September 2013 and July 2016. The control group (*PGS-only*) comprised cycles in which embryos had been selected for transfer following euploidy criteria only. The study group (*PGS+Eeva*) comprised cycles in which embryo selection for transfer was based on combined PGS and Eeva predictions.

Participants/materials, setting, methods: All embryos were cultured, biopsied, and vitrified at the blastocyst stage. Genetic analyses of trophectoderm biopsies were performed by NGS. Single euploid blastocyst transfers were performed in all cases. Transfers were differed and under HRT. Within the control *PGS-only* group, the best morphological euploid embryo available was transferred. Within the *PGS+Eeva* group, the euploid blastocyst with the highest Eeva-prediction available was prioritized for transfer. Ongoing pregnancy rates of study groups were statistically compared.

Main results and the role of chance: Clinical characteristics were comparable between groups. There were no significant differences in terms of MII, fertilized eggs, blastocyst rate, high quality blastocyst rate and euploidy rate between groups. However, significant differences (*p*<0.05) were found when comparing ongoing pregnancy rates of the *PGS*-only and *PGS+Eeva* groups independently in both autologous oocytes and egg donation cycles. Significantly higher pregnancy rate was achieved in the PGS+Eeva group in transfers were *high* Eeva prediction in addition to PGS were used as criteria for embryo selection compared to the PGS-only group after the transfer of the best morphological quality euploid embryo available in both autologous oocytes cycles (75% vs 35,1%, *p*<0.05) and egg-donation cycles (67.2% vs 50% *p*<0.05)]. These results show that Eeva Test provides valuable information for euploid embryo selection, significantly increasing the chances of pregnancy in cycles where chromosomally normal embryos predicted by Eeva as *high* are prioritized for transfer. An improvement by selecting *high*-Eeva-classified euploid embryos was also observed when only high morphological quality embryo transfers (AA, BB or BA or BB according to Gardner's criteria) were analysed. The TLI+PGS combined selection of embryos strategy rendered 2x pregnancy rates compared to the ones obtained by the selection of high morphological quality euploids.

Limitations, reasons for caution: The unicentric and retrospective design of this study may be a reason for caution. Further data regarding follow up outcomes must be included to confirm the predictive value of the analysed parameters.

Wider implications of the findings: This analysis reveals the ability of early cleavage time-lapse parameters to predict embryo implantation potential and suggests that normal chromosome status determination is not enough to guarantee a viable pregnancy. Other biomarkers such as automated time-lapse-based parameters can add valuable information to embryo selection strategies.

Trial registration number: A trial registration number was not required due to the retrospective study design.

P-645 'Batching' of multiple IVF cycles combined with preimplantation genetic testing for aneuploidy: how does the number of cycles undertaken affect outcomes?

N. Kubikova[1], K. Spath[1], D. Babariya[1], M. Simpkins[2], G. Cutts[2], S. Alfarawati[2], E. Fragouli[2], D. Wells[1]

[1]University of Oxford, Nuffield Department of Obstetrics and Gynaecology, Oxford, United Kingdom
[2]Reprogenetics UK, Institute of Reproductive Sciences, Oxford, United Kingdom

Study question: When undertaking several sequential IVF-PGS cycles, what outcomes are anticipated? Is there a threshold number of embryos beyond which additional cycles are of no benefit?

Summary answer: Having multiple IVF-PGS cycles significantly increases the likelihood that a euploid embryo will be identified. Undergoing two cycles may represent the most cost-effective strategy.

What is known already: Patients and clinics sometimes choose to batch embryos from several IVF cycles. This can potentially reduce the costs of genetic testing and increase the likelihood of finding a euploid embryo for transfer. The strategy also allows production of multiple embryos in a relatively short space of time, an important consideration if the patient is of declining fertility due to age. Batching of embryos has become a routine practice in many clinics. Nonetheless, it is not clear how many cycles are optimal for maximising the desired outcome of identifying a euploid embryo, leading to transfer, and ultimately a healthy live birth.

Study design, size, duration: We investigated the effect of female age, referring clinic, and IVF indications on embryo outcomes in patients who have undergone at least two IVF cycles in combination with preimplantation genetic testing for aneuploidy (PGT-A) via next generation sequencing (NGS). A comparative analysis of cycles was carried out in order to determine the proportion of euploid embryos, aneuploidy, and mosaicism rate present in trophectoderm biopsies. Patients were referred by 8 European IVF clinics.

Participants/materials, setting, methods: In total, 635 embryos generated by 61 patients in 141 cycles were analysed. These patients underwent 2 (n = 49), 3 (n = 6), 4 (n = 5), or 5 (n = 1) IVF/PGT-A treatments. The trophectoderm samples were subjected to comprehensive chromosome screening using NGS. Maternal age ranged from 29-47 years (mean 39.8) and patients' reasons for referral included advanced maternal age, recurrent implantation failure, and recurrent miscarriage, with the average of 2.7 months between the first and second IVF treatments.

Main results and the role of chance: As expected, aneuploidy significantly increased with advancing maternal age (P = 0.001). No euploid embryos were found in women aged 44 or over regardless of IVF cycle number (0/35 blastocysts in total). Female age had a strong influence on aneuploidy rate, but the incidence of mosaic abnormalities was not associated with age. Statistical assessment of the first two cycles (n = 61) suggested a significant increase in the proportion of euploid embryos in the second cycle (12.4% and 20.1%, in cycles 1 and 2, respectively, P = 0.03). This difference may be due, in part, to the production of greater numbers of embryos, perhaps a consequence of tweaks to the stimulation protocol during the second cycle. In the 40 patients with no euploid embryos in cycle 1, 50% had at least one euploid embryo in cycle 2. Of the 21 patients who had at least one euploid embryo in the first cycle, 13 produced at least one additional euploid embryo in cycle 2 (4 patients produced two euploid embryos, 2 patients produced three and 1 patient produced four euploid embryos). No association was observed between the proportion of euploid embryos and reason for referral or the clinic treating the patient.

Limitations, reasons for caution: This study looked at the incidence of aneuploidy and the likelihood of identifying euploid embryos after sequential IVF cycles. However, clinical outcomes of PGS, including pregnancy rates per cycle, implantation and miscarriage rates, were not considered. Those outcomes should ideally be evaluated as part of a randomised control trial.

Wider implications of the findings: While all cycles contribute to the probability of finding a chromosomally normal embryo, most patients who will ultimately produce a euploid blastocyst have done so after the two cycles. The findings have potential implications for optimisation and management of batching procedures and consideration of costs versus benefit of such strategies.

Trial registration number: not applicable.

P-646   Comparing rates of blastomere and trophectoderm cells biopsies for Preimplantation Genetic Diagnosis using the array-CGH technique

M. Gkountakou[1], Y. Panagiotidis[1], A. Papatheodorou[1], P. Vanderzwalmen[2], T. Pavlidou[1], A. Gkountis[1], K. Ravanos[1], N. Prapas[1], Y. Prapas[1,3]

[1]Iakentro, Fertility Centre, Thessaloniki, Greece
[2]Centers Prof. Zech, IVF, Bregenz, Austria
[3]Institut Médical de Champel, IVF Unit, Geneve, Switzerland

Study question: Purpose of this study was to compare rates after blastomere and trophectoderm biopsy using the same (array-CGH) technology, which has reliability, precision and permits determination of all chromosomes numerical abnormalities.

Summary answer: Both types of biopsies showed similar high pregnancy rates, as well as high ongoing pregnancy rates between the two groups.

What is known already: Preimplantation genetic screening (PGS) is a method to detect aneuploidies in preimplantation embryos. Those embryos diagnosed as chromosomally normal embryos will be candidates for transfer to the maternal uterus. The technique most commonly used for PGS is array-comparative genomic hybridization (CGH) Currently, blastomere and trophectoderm biopsies are the two main approaches used for PGS, but there is a trend towards trophectoderm biopsies, because the biopsy of trophectoderm cells would not adversely affect embryo development.

Study design, size, duration: A retrospective study was performed at a private clinic (Iakentro, Thessaloniki, Greece) during a period of 3 years (January 2014 to December 2016), conducted to analyze 479 embryos of 95 infertile couples. Preimplantation genetic screening (PGS) was performed using array-CGH. Embryo biopsy was performed either on day 3 or day 5. Only whole chromosome aneuploidies were considered.

Participants/materials, setting, methods: A mean number of 10-12 oocytes were fertilized by partner's sperm. Embryos were cultured in single step culture medium (Sage, 1-step) and the blastocysts developed on day5. Embryo biopsy was performed either on day 3 (44 patients, mean female age of 34.6) or day 5 (51 patients, mean female age of 32.9).All patients included in the study signed a consent form that includes all the possible pitfalls that may happen in PGS analysis

Main results and the role of chance: Pregnancy rate (40.9% vs 41.2%) and ongoing pregnancy rate (77.7% vs 80.9%) were similar in two groups. The PGS result was confirmed in the whole blastocyst in (a) 53/233 (22.7 %) normal embryos after day-3 biopsy and (b) 84/246 (34.1 %) normal embryos after trophectoderm biopsy. Concordance rates for both biopsy strategies and for individual chromosomes were evaluated by Fisher's exact test and showed no significant differences.

Limitations, reasons for caution: This study includes couples having repetitive implantation failures (RIF). The results of this study should not be extrapolated to any other group.

Wider implications of the findings: According to the results shown, both types of embryo biopsy are suitable approaches that can be used if required in a PGS program. Therefore, both types of embryo biopsies can coexist in the same PGS program and the patient's treatment can be customized according to the individual patient's requirements.

Trial registration number: The study was approved by the Institutional Review Board (Ref. no. 3/2015, granted 7 January 2015).

P-647   Unraveling the role of seminal fluid exosomes within the male reproductive tract

A. Clement[1], N. Pereira[1], Z. Rosenwaks[1], D. Lyden[2], A. Hoshino[2], G. Palermo[1]

[1]Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.
[2]Weill Cornell Medicine, Children's Cancer and Blood Foundation Laboratories-Departments of Pediatrics and Cell and Developmental Biology- Drukier Institute for Children's Health- Meyer Cancer Center, New York, U.S.A.

Study question: To identify exosomes in the male reproductive tract and suggest putative signaling mechanisms in human ejaculates, epididymal and testicular tissue.

Summary answer: Exosomal vesicles are produced at different levels in the male genital tract and appear to control the seminiferous tubules' spermatogenic function.

What is known already: Exosomes are small membrane vesicles containing functional biomolecules such as proteins, lipids, RNA and DNA. They are shed from most cells and are present in various body fluids. Although they have been previously identified in seminal fluid, their precise source or role in the male reproductive tract remains puzzling. It is known that exosomes can mediate

immunomodulatory influences on recipient cells and may indeed exert an effect on the female reproductive organs during the conception and implantation period. Exosomes may also play a role in the communication between Sertoli cells among seminiferous tubules and be responsible for modulating spermatogenic waves.

Study design, size, duration: From January to December 2016, 85 consenting men screened for infertility donated their 99 ejaculated, 2 testicular and 1 epididymal tissue specimens. Epididymal and testicular tissue specimens were surgically retrieved from men with obstructive azoospermia (OA) or non-obstructive azoospermia (NOA). Sperm samples were centrifuged 500xg for 10 min followed by 3,000xg for 20 min on the supernatant to remove cell debris. The supernatant was preserved at 4° C until exosome isolation.

Participants/materials, setting, methods: Seminal fluid was centrifuged at 12,000xg for 20 min to ensure removal of residual debris. The resulting supernatant was centrifuged at 100,000xg for 70 min for exosomal isolation. Exosomes were washed in 3 ml PBS and pelleted again by ultracentrifugation. The final exosome pellet was re-suspended in PBS and protein concentration was measured by BCA. The NanoSight LM10 nanoparticle analysis system was used for characterization of exosomes.

Main results and the role of chance: A total of 99 semen samples in 74 men had the following semen parameters: $69.6 \pm 22 \times 10^6$/mL (concentration) and $46.1 \pm 5\%$ (motility). The number of seminal fluid exosomes isolated was $4.1 \pm 3 \times 10^8$/ μL, with a mean size of 171 ± 16 nm in the samples that went through NanoSight analysis. The exosome protein content of the 100 μL seminal fluid sample was 96.8 ± 119 μg. The exosome protein content in the ejaculate of men showed a negative correlation of exosome protein per spermatozoon (R^2 0.14; $P < 0.001$) and exosome protein per motile spermatozoon (R^2 0.13; $P < 0.001$) in relation to the sperm concentration in the initial ejaculate. However, the exosome protein content in the ejaculate of oligoasthenozoospermic men (101.9 μg per 100 μL) was comparable to normozoospermic men (111.9 μg per 100 μL). Interestingly, men with OA due to vasectomy retained some exosome protein content, while men with congenital absence of the vas deferens (CBAVD) did not. Exosomal protein content in epididymal tissue of men with OA was 1.29 μg/100 μL and in testicular tissue of men with NOA was 25.0 μg/100 μL, possibly representing a proportional sourcing of exosomes from the different levels of the male genital tract.

Limitations, reasons for caution: The proportional contribution of exosomes in the testis, epididymis and seminal fluid in the same individual was not assessed. The current study only included men undergoing infertility screening. Thus, whether the profile in exosomal number, size, and protein content is comparable to normozoospermic men with proven fertility remains unanswered.

Wider implications of the findings: Analysis of seminal fluid exosomes may elucidate their role in immunomodulation within the genital tract during the peri-conception period. Exosomes may be involved in ordaining waves of spermatogenesis within the seminiferous tubule network. Exosomes are differentially produced at various levels of the male genital tract.

Trial registration number: Not applicable.

P-648   Identification of circular RNAs in human spermatozoa

A. Alteri[1], G. Del Vecchio[2], G. Fabozzi[3], M.G. Amendola[3], C. Piscitelli[3], A. Colicchia[3], C. Presutti[2], P. Giannini[3]

[1]IRCCS- San Raffaele Scientific Institute, Obstetrics and Gynaecology Unit, Milan, Italy
[2]Sapienza- University of Rome, Biology and Biotechnology "Charles Darwin" Department, Rome, Italy
[3]Casa di Cura Villa Margherita, FertiClinic, Rome, Italy

Study question: Are circRNAs (circRNAs) expressed in human spermatozoa?

Summary answer: We have identified a novel class of non-coding RNA, circRNAs that were expressed in human spermatozoa

What is known already: The RNA population carried by sperm is large, heterogeneous, and rich in non-coding RNAs (ncRNAs). However, for most of the thousands of transcripts carried by sperm, functions are completely unknown. Recently, a novel class of ncRNAs called circRNAs have been described, as

produced in eukaryotic cells during post-transcriptional processes. They are ~100 nucleotide-long single-stranded RNA molecules forming a circle through covalent binding. A large number of circRNAs has been identified but their function awaits further investigations

Study design, size, duration: Spermatozoa were isolated from the semen specimen of a healthy fertile man by centrifugation and swim-up method. RNA extraction was carried out from 80×10^6 cells

Participants/materials, setting, methods: Total RNA was isolated using a spin column-based commercial kit. cDNA libraries were generated according to the Illumina TruSeq RNA-seq protocol and sequenced on Illumina HiSeq 2000 with 100 bp paired end reads. Only circRNAs with two or more supporting reads within single samples were kept. Furthermore, Real-Time PCR was performed to confirm results obtained, using primers designed as convergent primers to detect circular junctions, and to cross the backsplice junction

Main results and the role of chance: We performed a RNA-seq experiment on a normal semen sample (WHO 2010) from healthy, fertile patient. We mapped all the RNA-seq reads to the genome using Bowtie in single-end mode, allowing ≤2 mismatches. We extracted back-spliced ordering reads from the reads unmapped to the HG19 reference genome and ciRcus was used for circRNAs annotation and analysis. Three thousand possible circRNAs were predicted by at least two supporting reads. This represents a surprising number compared with those obtained for other types of cells and tissues. Based on the potential function in the reproductive process, we considered four of the most conserved circRNAs circ-nr2f1, circ-gigyf2, circ-insig1, circ-rmst, for the subsequent validation. We validated the authenticity of the identified circRNAs by two independent methods. Firstly, compared with linear RNAs, circRNAs are endowed with a strong resistance to exonuclease RNAse R. Thus, we quantified the RNAse R resistance of these candidate circRNAs and all of them showed > 5 times higher stability than the linear transcripts following RNase R treatment. Secondly, Real-Time PCR was performed with divergent primers detecting the circRNA junction and linear isoforms. We found that expression patterns of the four circRNAs considered were consistent with the RNA-seq data

Limitations, reasons for caution: This study must be confirmed in a larger cohort of patients

Wider implications of the findings: The nucleus of mature spermatozoa contains a complex population of RNAs despite its transcriptionally inert state that are thought to contribute extra-genomically to early embryonic development. The circRNAs seem to be the best candidates for a potential role of spermatozoal RNA content in embryogenesis activation

Trial registration number: N/A.

P-649   Effect of a severe male factor condition on chromosome segregation in spermatozoa from reciprocal translocation carriers

A.D. Crippa, B. Gurrieri, C. Tabanelli, A.P. Ferraretti, M.C. Magli, L. Gianaroli

S.I.S.Me.R., Reproductive Medicine Unit, Bologna, Italy

Study question: Does the frequency of unbalanced segregation modes in spermatozoa from reciprocal translocation carriers change with the severity of the male factor condition?

Summary answer: There is no correlation between the occurrence of specific segregation modes and sperm indices.

What is known already: Carriers of reciprocal translocations have an increased risk of pregnancy loss or transmitting chromosomal abnormalities to their offspring because of the production of a higher number of unbalanced spermatozoa. They mainly result from two events: the unbalanced segregation during meiosis of the chromosomes involved in the translocation and the occurrence of additional aneuploidy events.

Study design, size, duration: From 2005, 45 sperm samples from carriers of reciprocal translocation were analyzed by Fluorescence In Situ Hybridization (FISH) to investigate the mode of segregation for the chromosomes involved in the translocation (2:2 alternate, 2:2 adjacent-I, 2:2 adjacent-II, 3:1 and 4:0). The distribution of frequencies of the segregation patterns was evaluated using the Kolmogorov-Smirnov test. In 29 samples, aneuploidy for 9 chromosomes was also tested.

Participants/materials, setting, methods: When classified according top WHO criteria, 14 samples were normozoospermic, and 31 were oligoastheno-teratozoospermic (19 moderate-OAT, $\geq$5 million spermatozoa/ml and 12 were severe-OAT, < 5 million spermatozoa/ml). A combination of specific probes was used to determine the segregation mode in each rearrangement. In 29 carriers, multicolour FISH with probes specific for X, Y, 13, 15, 16, 17, 18, 21 and 22 was used to estimate the incidence of aneuploidy for chromosomes not involved in the translocation.

Main results and the role of chance: The frequency of unbalanced gametes was comparable in the two groups (63.6% $\pm$ 19.4 in normozoospermic and 58.9% $\pm$ 21.9 in OAT). Frequencies and dispersion of the five segregation modes were respectively 36.7% $\pm$ 19.4, 29.4% $\pm$ 15.9, 9.3% $\pm$ 7.9, 24% $\pm$ 12.8, 0.6% $\pm$ 1.0 in normozoospermic and 41.1% $\pm$ 21.9, 21.9% $\pm$ 14.3, 12.9% $\pm$ 13.1, 23.1% $\pm$ 33.2, 1.0% $\pm$ 1.5 in OAT.

In both patients' groups, the frequency of 2:2 alternate was significant higher than 2:2 adjacent-II ($P < 0.001$), and the frequency of 2:2 adjacent-I was significant higher than 2:2 adjacent-II ($P < 0.02$). The 2:2 adjacent-I pattern occurred at the same frequency than the 3:1, whereas the 2:2 adjacent-II was less frequent than the 3:1 ($P < 0.03$). The 4:0 segregation mode was by far the most rare segregation mode ($P < 0.001$).

In the OAT group, additional differences were found with the 2:2 alternate segregation occurring more frequently than the 2:2 adjacent-I ($P = 0.0022$) and 3:1 ($P = 0.014$).

Regarding aneuploidy events for the chromosomes not involved in the translocation, the frequency of aneuploidy in OAT patients (5.7% $\pm$ 4.0) was significantly higher when compared to normozoospermic patients (2.7% $\pm$ 1.6; $P = 0.028$).

Limitations, reasons for caution: This study included a restricted number of samples. Additional data would be necessary to corroborate our findings.

Wider implications of the findings: In translocation carriers, the frequency of unbalanced gametes is not affected by sperm indices, although segregation patterns may have different frequencies. As a male factor condition is associated with a higher incidence of aneuploidy, semen parameters in translocation carriers help estimating the global risk of forming chromosomally abnormal spermatozoa.

Trial registration number: none.

P-650   Analysis of PGD Uptake after Expanded Carrier Screening: Attitudes and Reproductive Decisions of High-Risk Couples

S. Sehnert[1], S. Yarnall[1], S. Rodriguez[1], J. Miller[2], S. Munne[3], S.H. Chen[4], N. Kumar[1]

[1]CooperGenomics, Medical Affairs, NEW YORK, U.S.A.
[2]CooperGenomics, Bioinformatics, New York, U.S.A.
[3]CooperGenomics, Bioinformatics, Livingston, U.S.A.
[4]IRMS, Reproductive Endocrinology, Short Hills, U.S.A.

Study question: For couples who were identified as "high-risk" through expanded carrier screening (ECS), what was the uptake of PGD and what factors influenced this decision?

Summary answer: 40% of "high-risk" couples pursued preimplantation genetic diagnosis (PGD); of those who did not pursue PGD, cost was the most influential factor.

What is known already: ECS assesses carrier status and reproductive risk for monogenic autosomal recessive and X-linked diseases. Couples in which both partners carry the same autosomal recessive disease, or couples in which the female partner carries an X-linked disease, are considered to be at high reproductive risk. 2.20% of couples who undergo ECS are identified as high-risk. ECS can afford high-risk individuals additional reproductive options, including the option to pursue preimplantation genetic diagnosis (PGD). While significant research has been conducted on PGD technologies, the patient-facing side of PGD, including the decision-making process and the emotional impact, remains largely unexplored.

Study design, size, duration: This retrospective study was conducted via an online survey. The survey contained questions regarding participants' family planning journey prior to ECS, their emotional reactions after ECS, their reproductive decisions after ECS, and the factors which drove those decisions.

Patients identified as high-risk through the carrier screening laboratory within the last four years (2012-2016) were eligible for participation. A total of 127 participant responses were collected and included in analysis.

Participants/materials, setting, methods: The study population consisted of patients identified as high-risk through ECS. Eligible couples were contacted via phone and email to alert them of the study and invite their participation. Those wishing to participate completed an online survey. Responses were analyzed and statistical analyses were performed. Informed consent was obtained.

Main results and the role of chance: 40.4% of couples identified as high-risk through ECS pursued PGD, which demonstrates the significant clinical impact of ECS on high-risk couples' reproductive decisions. Of those who did not pursue PGD, 48.5% reported pursuing prenatal testing such as amniocentesis or CVS— procedures which carry a risk of miscarriage and may not be indicated had carrier status not been known, further speaking to the impact of ECS on high-risk couples' approach to clinical care. Cost was cited as the most influential factor in the decision not to pursue PGD; as cost declines, PGD may become an increasingly popular option. Additionally, analysis showed that 78.9% of respondents reported sometimes or often feeling relieved they had ECS. 81.4% of respondents reported never or rarely having difficulty making reproductive decisions after ECS.

Limitations, reasons for caution: The majority of patients included in this analysis reported having a high level of education (94.4% with a university degree or higher), and 80.6% of respondents reported an income of greater than $100,000. Uptake and awareness of PGD may be lower among patients from a different demographic.

Wider implications of the findings: Patients expressed satisfaction and relief after undergoing ECS. As ECS becomes an increasingly integral component of reproductive medicine, we should continue to investigate its utility and consider recommendations for ECS as routine care within and beyond the fertility clinic. Genetic counselors can play an important role in providing these services.

Trial registration number: NA.

P-651   Investigating the role of sperm-specific RNA to screen men with unexplained infertility

V. Gunnala, N. Pereira, S. Cheung, J. Lekovich, Z. Rosenwaks, G. Palermo

Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.

Study question: To identify the compartmentalization of candidate gene clusters within the human spermatozoon that contribute to spermatozoal fertilization capacity and embryo developmental competence.

Summary answer: Functional assessment of gene clusters localized in various components of the spermatozoon may identify concealed reasons of unexplained infertility in men with normal semen parameters.

What is known already: Semen analyses are routinely used to investigate male infertility. However, they rarely predict spermatozoal function or reproductive outcomes. Men with seemingly normal semen parameters can therefore be infertile, suggesting the presence of an otherwise unknown or concealed genetic male factor. Querying spermatozoal RNAs has emerged as a novel technique, which enables identification and classification of sperm-specific RNAs. By quantifying vital RNA transcripts within the components of the spermatozoon, we can assess their contribution to male gamete competence, as well as the delivery of such RNA transcripts to the oocyte and subsequent embryonic development.

Study design, size, duration: In this prospective study, 31 consenting men screened for infertility donated their ejaculated semen samples during a 15-month period. Three men with proven fertility (natural conception) served as controls. Following RNA extraction from semen samples, differentially expressed RNA transcripts were identified and classified into gene clusters based on sperm-specific components i.e., the acrosome, nucleus, mid-piece, and flagellum. The expression of these transcripts were compared with standard semen parameters, and between the study and control groups.

Participants/materials, setting, methods: RNA was isolated from 25×10^6 human spermatozoa using a commercially available spin column kit. Spermatozoal

RNA concentration was subsequently assessed. Illumina stranded RNA sequencing (RNA-Seq) library preparation was used to construct paired-end libraries. Pilot sequencing was expanded to 50-60 M reads at 2×76 bp. RNA expression was calculated in fragments per kilobase of transcript per million mapped reads (FPKM). Functional assessment and classification of genes was performed via the Database for Annotation, Visualization and Integrated Discovery (DAVID).

Main results and the role of chance: Thirty-one men with a mean age of 39.6 ± 5 years had the following semen parameters: 46.3 ± 19 x 10^6/mL concentration and 44.8 ± 14% motility. The age of the female partner in the study and control groups was comparable. None of the couples in the study population conceived naturally or with intrauterine insemination. The expression of *APLF, CYUB5R4, ERCC4,* and *TNFRSF21* was found to be higher in men <40 years (47.2 ± 15 FPKM) compared to those >40 years (13 ± 9 FPKM; $P = 0.02$). On plotting the RNA transcript expression against semen parameters, a positive correlation between *AKAP4* and motility was noted (R^2 0.40; $P = 0.01$). Differentially expressed RNA transcripts between the study and control groups were identified and grouped into gene clusters based on the following sperm-specific components: *DPY19L2* and *ATP6V1E2* (acrosomal); *APLF, CYUB5R4, ERCC4, MORC1, PIWIL1, TNFRSF21, TSSK6* and *H1FNT* (nucleus); *ADCY10, SMCP, PLK4* and *AGPAT2* (mid-piece); and, *AKAP4* and *CATSPER1* (flagellum). There was a strong correlation between the expression of *ATP6V1E2* and fertilization rates (R^2 0.63; $P < 0.001$) in men who underwent ICSI. The gene cluster localized to the nucleus, which is known to regulate DNA repair mechanisms throughout spermatogenesis, was significantly under-expressed in the study group when compared to the control group ($P < 0.001$).

Limitations, reasons for caution: While these preliminary results are encouraging, prospective data in a larger cohort are required to elucidate the epigenetic mechanisms involved in male infertility and male gamete competence. Differential expression of RNA transcripts should be confirmed in more than a single ejaculated semen sample from each participant in the study group.

Wider implications of the findings: Functional assessment of the gene cluster specific to certain compartments of the human spermatozoon may supplement standard semen analysis and serve as a vital tool in the diagnosis of unexplained infertility. This may further facilitate tailoring of assisted fertility treatments, thereby reducing the time to pregnancy.

Trial registration number: Not Applicable.

P-652 The Impact of Genetic Ethnicity on Clinical Practice: A Comparison of American and European Fertility Patients

S. Yarnall[1], S. Rodriguez[2], R. Shraga[3], N. Kumar[2], I.B. Carlsson[2]

[1]Recombine, Product, New York- N.Y., U.S.A.
[2]CooperGenomics, Medical Affairs, New York, U.S.A.
[3]Phosphorus, Bioinformatics, New York, U.S.A.

Study question: Do we see differences in the genetically-predicted ethnicities of patients from European fertility clinics as compared to patients from United States (US) clinics?

Summary answer: We found that the genetically predicted ancestries of European and American fertility patients did not significantly differ, which may impact carrier screening recommendations.

What is known already: Genetic carrier screening is routinely offered to patients in US fertility clinics. While offerings were initially based upon patients' reported ethnicities, the recognition of increased genetic admixture and technological advances caused a shift to broader acceptance of expanded carrier screening (ECS) panels. Such panels are pan-ethnic and screen for over 200 diseases. ECS has not been widely accepted across Europe. The resistance is partially due to a belief that the US is genetically diverse from years of admixture while the European population is genetically homogeneous, making pan-ethnic screening unnecessary. We sought to determine if a difference in admixture was present.

Study design, size, duration: Our retrospective analysis examined genomic data from an ECS panel run on more than 10,000 patients over the past three years. Documented informed consent was obtained to use genotype information in a de-identified manner. Data was analyzed from a total of 7544 participants, 6297 from US clinics and 1247 from European clinics. A previously-validated genetic ancestry admixture analysis was run on all samples.

Participants/materials, setting, methods: Carrier screening for all samples was performed on the Illumina Infinium HD Custom Genotyping platform. Genetic ancestral origin was predicted by a statistical model based on 672 SNPs validated using samples from the 1000 Genomes Project, and admixture proportions were calculated for 6 ancestral populations (European, Oceania Native, Native American, East Asian, Sub-Saharan African, and South Asian). A comparison of predicted admixture proportions was made between patients in Europe against patients in the US.

Main results and the role of chance: For comparison, the European and American patients were further subdivided into four groups, based upon which ethnicity they self-reported on test requisition forms: European, Mediterranean, Latin American, or African. Across all four comparison groups, our results showed similar average admixture proportions. For example, European patients who self-identified as Mediterranean were genetically predicted to be an average of 86% European, and 5% Sub-Saharan African. American patients who self-identified as Mediterranean were genetically predicted to be an average of 81% European and also 5% Sub-Saharan African. European patients who self-identified as African were predicted to be an average of 78% African and 16% European, which was strikingly similar to the predictions for American patients who self-identified as African (78% African and 12% European). This similarity in admixture proportions was also seen between European and American patients who self-identified as European and Latin American. These results demonstrate that on a genetic level, both European and American patients demonstrate equal degrees of admixture. The European patient population may not be as genetically homogenous as previously believed. Pan-ethnic carrier screening panels could prove to be effective at identifying carriers in a European population, who would otherwise be missed.

Limitations, reasons for caution: Future studies with larger patient populations may strengthen the above findings. Additionally, more in depth details regarding ancestral origin could be obtained from comparison between a higher number of SNPs.

Wider implications of the findings: Our findings indicate that both European and American patients who identify as one specific ethnicity experience equal amounts of genetic admixture. Thus, pan-ethnic expanded carrier screening among reproductive patients may be more beneficial to European patients than previously believed.

Trial registration number: NA.

P-653 Mitochondrial DNA (mDNA) detection from blastocoelic fluid: a potential indication of blastocyst viability

C. Albanese[1], A. Pomante[1], G. Romeo[2], D. Luiselli[3], S. De Fanti[3], A.P. Ferraretti[1], M.C. Magli[1], L. Gianaroli[1]

[1]S.I.S.Me.R., Reproductive Medicine Unit, Bologna, Italy
[2]European School of Genetic Medicine, Genetic Medicine, Bologna, Italy
[3]Alma Mater Studiorum- Bologna, Biological- Geological and Environmental Science, Bologna, Italy

Study question: Could the blastocoelic fluid represent a source of embryonic mtDNA?

Summary answer: mtDNA can be isolated from blastocoelic fluid and the D-loop region can be sequenced

What is known already: The mtDNA copy number in blastocysts, as assessed by trophectoderm (TE) biopsy, has been associated with the potentiality of the embryo to implant. Several studies have shown that embryos with a content of mtDNA above a certain cut-off level rarely give rise to a term pregnancy. Other scientific works have demonstrated the presence of DNA in the blastocoelic fluid (BF). This DNA can be analyzed to provide information on the genetic status of the corresponding blastocyst

Study design, size, duration: To assess the presence of mtDNA in BF samples, qualitative analysis of mtDNA was performed on 10 BFs from expanded blastocysts on which aCGH analysis had already been completed on TE cells in our PGS program

Participants/materials, setting, methods: BFs was extracted by 10 aneuploid blastocysts from 10 couples with an age between 37 and 41 years. Patients had previously signed an informed consent to this additional procedure. The samples were amplified by WGA to test aneuploidy on BFs. An aliquot

of the amplified product was processed to amplify the D-loop region by an operator blind to source of DNA

Main results and the role of chance: mtDNA was found in all tested BF with amplification bands specific for the tested region of the D-loop. Following sequencing, the prediction of the haplogroup was possible in all samples (mean probability of 84.35 ± 0.18%, range 50-100%)

Limitations, reasons for caution: This is a preliminary approach with a small number of samples to verify the presence of mtDNA in the BF. No quantitative analysis was performed, and only non-transferred embryos were tested

Wider implications of the findings: Blastocentesis can be a non-invasive method to evaluate not only the chromosome condition of the blastocyst, but also its competence. After proving the presence of mtDNA in the BF, we are now performing a quantitative analysis that would allow us to establish a possible correlation with implantation

Trial registration number: Not applicable.

P-654   Identification of High-Risk Carrier Couples With Limited versus Expanded Carrier Screening Panels

S. Rodriguez[1], S. Yarnall[2], N. Kumar[2]

[1]Recombine, Product, New York- N.Y., U.S.A.
[2]CooperGenomics, Medical Affairs, New York, U.S.A.

Study question: Our aim was to determine the effectiveness of expanded carrier screening panels in a clinical setting.

Summary answer: Testing with only a limited panel of conditions missed 22% of carriers of high-impact conditions.

What is known already: Recent statements by United States professional societies have provided guidance on appropriate approaches to the clinical implementation of expanded carrier screening panels. However, formal recommendations from the same professional societies remain limited to a select few conditions based upon the patient's reported ethnic background. With such a large difference between guidelines and formal recommendations, and an increased awareness of genetic admixture across the globe, we sought to examine the effectiveness of expanded carrier screening to capture high-risk carrier couples by comparing the percentage of carriers identified on 3 panels of increasing scope.

Study design, size, duration: The retrospective analysis included data from more than 10000 patients who underwent carrier screening within the past five years. Carrier counts were tallied for each disease screened, and overall number of carriers was analyzed for 3 disease panels of increasing scope: (1) diseases currently recommended for screening by professional society guidelines; (2) diseases considered to be high-impact for reproductive decision making; and (3) a broad panel of 200+ diseases that range in severity.

Participants/materials, setting, methods: Documented informed consent was obtained to use de-identified genetic data from expanded carrier screening tests. Individuals were screened for over 200 recessive genetic diseases using Illumina's Infinium HD Genotyping Platform.

Main results and the role of chance: On the most limiting panel, which only screened for diseases currently included in professional society guidelines, 12% of patients were identified as carriers. When compared to a larger panel inclusive of 188 high impact diseases, our results indicated that limited screening failed to identify 22% of carriers in our patient population. An additional 10% of patients were identified as carriers when the panel was expanded further to include a total of over 200 diseases of varying impact. Expanded carrier panels are more effective at identifying patients at risk of having children with genetic conditions who thus may benefit from increased reproductive options.

Limitations, reasons for caution: Analysis among a larger population of patients, or with a greater number of SNPs for ethnic admixture analysis, may reveal different degrees of admixture than reported here; however, such differences are not expected to be significant.

Wider implications of the findings: Data from our ethnically diverse patient population demonstrate that screening for only traditionally recommended diseases failed to identify over a quarter of carriers. Such oversight might contribute to decreased detection of carrier couples, and thus the inability for patients to make fully informed reproductive decisions.

Trial registration number: NA.

P-655   DNA methylation at imprinted genes varies with infertility diagnosis in infertile men

R. Ng[1], S. Pitigalaarachchige[1], A. Pradhan[1], K. Poon[1], V. Chow[1], S. Ma[1]

[1]University of British Columbia, Vancouver- BC, Canada

Study question: Are there DNA methylation abnormalities in different diagnoses of infertile men and are these abnormalities similar?

Summary answer: There are DNA methylation errors at imprinted genes in men diagnosed with oligozoospermia. Errors were not found in more severe forms of infertility (azoospermia).

What is known already: Previous studies have shown that men with oligozoospermia may show more DNA methylation errors at imprinted genes.

Study design, size, duration: Our case control study includes a total of 121 patients, which includes 20 fertile control men and 21 vasectomy reversal men to be used as controls for azoospermic men. The remaining 80 patients were divided into four categories based on infertility diagnosis: 24 with oligozoospermia (5-15 million sperm/ml), 33 with severe oligozoospermia (< 5 million sperm/ml), 15 with obstructive azoospermia, and 8 with non-obstructive azoospermia.

Participants/materials, setting, methods: We examined the methylation status of four imprinted genes (H19, IG-GTL2, MEST, and LIT1) and globally in the sperm of reproductive age men using bisulfite pyrosequencing. DNA fragmentation and MTHFR genotype were also examined.

Main results and the role of chance: For oligozoospermic men, DNA methylation was significantly different in the MEST gene compared to fertile control men ($P = 0.00046$). Similarly, for severe oligozoospermic men, DNA methylation was found to be significantly different in the H19, IG-GTL2, and MEST genes compared to fertile control men ($P = 0.0036$, $P = 0.037$, $P = 0.000086$; respectively). DNA fragmentation was also found to be significantly different in severe oligozoospermic men compared to fertile control men ($P = 0.0041$). Differences in MTHFR genotype were not found to be significantly different.

Limitations, reasons for caution: The number of patients in some subcategories may not be sufficient. There may be potentially significant findings in the other comparisons if the sample sizes were similar.

Wider implications of the findings: Our results provide further evidence of methylation defects at imprinted genes in the sperm of infertile men.

Trial registration number: Not applicable.

P-656   Importance of the Aging Male Gamete on ART Outcome

P. Xie, S. Cheung, Z. Rosenwaks, G. Palermo

Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.

Study question: To assess the effects of paternal age on the occurrence of sperm chromosomal aneuploidy and its relevance in pregnancy outcome.

Summary answer: Advancing paternal age affects spermatogenic meiosis of most autosomes, affecting the ability of the male gamete to fertilize and generate competent embryos.

What is known already: As we recognize the relevance of maternal age, the effect of aging on the male gamete has only recently been recognized. Aging men have a higher concentration of spermatozoa with fragmented chromatin and may be prone to meiotic error capable of affecting the conceptus' health.

Study design, size, duration: Cytogenetic analysis for chromosome X, Y, 13, 15, 16, 17, 18, 21, and 22 was performed on human spermatozoa from consenting men whose partners underwent at least one ICSI cycle. These men were categorized into one of 7 age ranges, and the rates of disomy and diploidy were recorded. ICSI outcomes and aneuploidy rates for each age group were compared.

Participants/materials, setting, methods: Paternal ages were grouped according to the following ranges: 25-30, 31-35, 36-40, 41-45, 46-50, 51-55, and > 55. Semen samples were prepared and processed for sperm aneuploidy

by 9 chromosome FISH. The diploidy and disomy occurrences were recorded, as well as ICSI fertilization rates and pregnancy characteristics.

Main results and the role of chance: FISH assay was carried out on semen samples from a total of 87 men. We found that the average aneuploidy rate was highest for men in the >55 age group (9.6%). When comparing autosomal disomy rates among all age groups, we found that men in the 25-30 age group had the highest average disomy for chromosome 21 (1.2%). However, men in the >55 age group had the highest average disomy specifically for chromosomes 17 (1.2%) and 18 (1.3%), in addition to highest overall aneuploidy. Individual gonosomal aneuploidy was also assessed, in which disomy YY was found to be highest in the 51-55 age group (0.9%), disomy XX highest in the 46-50 age group (0.3%), and disomy XY highest in the >55 age group once again (1.2%).

A total of 157 ICSI cycles were also assessed and grouped according to paternal age. The fertilization rate of 87.7% in the youngest age group decreased to 46.0% in the >55 age group. Similarly, the clinical pregnancy rate was highest in the 25-30 age group (80.0%), but absent in the >55 age group. Furthermore, the rate of pregnancy loss was characterized by a steadily increasing trend, highest in the 51-55 age group (50.0%).

Limitations, reasons for caution: As it may be expected but not undeniably documented, advancing paternal age affected spermatogenic meiosis almost exclusively non-disjunction. While we could not fully control for an eventual female factor, increasing spermatogenic meiotic errors in aging men adversely affect their ability to fertilize and achieve a successful implantation.

Wider implications of the findings: Paternal age contributes to the functional health of the male gamete. With respect to male aging and chromatin integrity, we confirmed aging affects meiosis and increases aneuploidy except for chromosome 21, reported most in younger men. Men aging through the effect on autosomal aneuploidy, affects the success of ART outcome.

Trial registration number: Not applicable.

P-657   Is more better? A higher oocyte yield is independently associated with more day-3 euploid embryos

ABSTRACT UNDER PRESS EMBARGO

P-658   Alterations in endocrine and paracrine regulation of oocyte maturation and folliculogenesis underlie the etiology of primary ovarian insufficiency

D.E. Parfitt, T. Hu-Seliger, C. Clementi, A. Oromendia, P. Yurttas Beim

Celmatix Inc, Research and Development, New York, U.S.A.

Study question: We aimed to uncover the biological functions most often implicated in primary ovarian insufficiency (POI) through a systematic literature review and statistical validation analysis.

Summary answer: Genetic variants with the strongest effect-size across published studies for POI are implicated in endocrine and paracrine regulation of oocyte maturation and folliculogenesis.

What is known already: POI is thought to be a heterogeneous condition characterized by cessation of ovarian function before the age of 40. By the time of diagnosis, gonadotrophin levels in POI patients are close to the menopausal range, greatly limiting fertility treatment options. As with natural menopause, overt POI is preceded by a period of reduced fecundity coupled with reduced ovarian reserve. Although hundreds of studies have associated several genetic regions and biological processes with POI, a comprehensive literature review and statistical meta-analysis has not been performed across the entire body of work.

Study design, size, duration: Natural language processing algorithms were used to identify articles in NCBI PubMed pertaining to genetics and POI. Of the 3,259 articles identified algorithmically, 387 were found to be true positives after manual evaluation, which also uncovered articles cited in the references that were not identified algorithmically. Reported gene associations were ranked using the Clinical Genome Gene-Disease Clinical Validity Classification Framework. An in-house annotation database was used to assign a biological function to each gene.

Participants/materials, setting, methods: Pathogenic variants residing in genes that met the criteria for "strong" evidence of clinical association with POI were statistically validated using random effects model meta-analyses using PRISMA guidelines. Variants were excluded from analysis if there were <2 published studies or overlapping cohorts, or if an article's presentation of information precluded the determination of the risk allele. Q value distribution was used to establish a false-discovery rate-adjusted p-value of 0.05.

Main results and the role of chance: Our analysis revealed that 14 genes currently satisfy ClinGen criteria for strong evidence of association with POI. These genes have well-established roles in hormone regulation, immune response regulation, steroidogenesis, ovarian follicle development, tissue remodeling, cell proliferation/differentiation, and glucose homeostasis. 28 variants within these genes have been studied across 80 case–control experiments, however, only 3 variants (within 3 of the 14 genes) were found to be significantly associated with POI across studies (p<0.05). Two of the variants that survived statistical validation across studies lie within genes involved in paracrine regulation of oocyte maturation and folliculogenesis (odds ratio (OR)=4.40, p = 0.015 and OR=1.54, p = 0.002, respectively). A third variant that demonstrated statistical significance after meta-analysis lies within a gene related to endocrine regulation of these same processes (OR of 4.01, p = 0.027). Genetic variants related to other biological processes implicated in POI do not yet demonstrate adequate clinical evidence across multiple studies.

Limitations, reasons for caution: This study relied upon study-specific aggregate data, not individual patient data, which may introduce bias from heterogeneity inherent in the study cohorts. The random-effects models, however, do take into account heterogeneity as one function of defining statistical significance.

Wider implications of the findings: Our analysis reveals three genetic variants strongly associated with POI. These variants implicate endocrine and paracrine ovarian factors not routinely assayed for in traditional fertility workups. Clinical use of these genetic markers may enable early identification of women at high risk for diminished ovarian reserve and POI.

Trial registration number: Not applicable.

P-659 A multivariate genome-wide DNA methylation analysis of placental villi from assisted reproductive technology and naturally conceived pregnancies

K. Louie, E. Chan Wong, S. Ma

University of British Columbia, Obstetrics and Gynaecology, Vancouver, Canada

Study question: Are genes differentially DNA methylated in the placenta between assisted reproductive technology and naturally conceived pregnancies?

Summary answer: A multivariate linear regression model identified no genes with significantly altered DNA methylation in the placenta that is associated with mode of conception.

What is known already: ART newborns are at a higher risk of being born intrauterine growth restricted, small for gestational age, and preterm. They are also at a higher risk for imprinting disorders and later life chronic diseases including diabetes and cancer, yet the causes and mechanisms are yet to be determined. Multiple studies have previously identified DNA methylation differences in the placenta associated with newborns conceived via ART, including in vitro fertilization (IVF) and intracytoplasmic sperm injection (ICSI), compared to NC newborns; however, these studies focused on few genes or are small in sample size with little clinical information about the cohort.

Study design, size, duration: Cross-sectional case-control study: 16 NC, 16 IVF, and 16 ICSI pregnancies. ART pregnancies were recruited from fertility clinics, while NC pregnancies were recruited from hospitals across Vancouver, Canada. Consent was obtained by physicians and nurses prior to sample collection. Ethics was approved by the University of British Columbia ethics committee.

Participants/materials, setting, methods: Placentas were stored at 4 C for up to 2 days. Villi samples were stored at -80 C until DNA extraction and bisulfite conversion. Bisulfite converted DNA was sent to The Centre of Applied Genomics (Toronto, Canada) for the application of the Illumina Golden Gate Cancer Panel I. Raw idat files containing signal intensities for 1505

probes per sample were imported and analyzed in R (3.3.2). Clinical information was extracted from pregnancy outcome forms and self-reported questionnaires.

Main results and the role of chance: A total of 49 probes were excluded due to poor signal detection. There was significant clustering by sex, therefore an addition 82 probes targeting the X chromosome were excluded. A single sample was removed due to clustering uniquely from other samples due to > 5% of its probes having poor detection signal; this sample was excluded. Principal Variance Component Analysis (PVCA) revealed that the only known covariate associated with the top 5 principal components was batch (3% of the total variance). There were no significant differences in maternal age, gestational age, sex, mode of delivery, birth weight, placental weight and dimensions, and Apgar scores between conception modes (P > 0.05, ANOVA/Kruskal-Wallis/Fisher's exact test). Incidence of twins was significantly higher among ICSI newborns (7 ICSI, 3 IVF, 0 NC; P = 0.002). Using an empirical Bayes method in a univariate linear model, we identified 26 significant (adjusted P < 0.05) CpG sites with altered DNA methylation between IVF and ICSI pregnancies, where 3 CpG sites had a > 15% difference in DNA methylation between ICSI and IVF (22.9% TUCS3, 18.5% HOXA5, -15.6% HOXA11). A multivariate model adjusting for the batch effect and twin status identified no significant DNA methylation alterations.

Limitations, reasons for caution: The microarray only targets a small portion of the methylome; more CpG sites will need to be investigated in conjunction with more complete clinical information. Further inclusion of ART newborns with adverse neonatal outcomes will be needed to produce more accurate predictive models.

Wider implications of the findings: Our results suggest that adverse neonatal outcomes among ART pregnancies may not be associated with DNA methylation alterations in the placenta. It is also possible that DNA methylation alterations may not be linearly related to these adverse outcomes, suggesting that future studies should focus on poor outcome cases.

Trial registration number: not applicable.

P-660 Differences in aneuploidy survival to first trimester of aneuploid embryos

P. Colls[1], T. Escudero[2], S. Munne[2]

[1]Reprogenetics, Livingston- New Jersey, U.S.A.
[2]Reprogenetics- A CooperSurgical Company, Research, Livingston- New Jersey, U.S.A.

Study question: Do different chromosome trisomies detected at blastocyst stage reach first trimester at different rates?

Summary answer: Most aneuploidies do not reach first trimester clinical detection, and those that do, survive at very different rates.

What is known already: Different chromosome susceptibilities to aneuploidy were observed from clinically recognized pregnancies and from embryos and gametes in FISH studies. POC studies are limited to those aneuplodies surviving to first trimester, FISH studies of embryos were limited in sample size and number of chromosomes analyzed. Those studies showed that some chromosomes are either more susceptible to aneuploidy or that are more likely to survive to first trimester. With the advent of comprehensive chromosome screening techniques such as next generation sequencing (NGS) and much higher use of PGS in clinical practice, all chromosomes and large sample size of embryos are being analyzed.

Study design, size, duration: This is a retrospective study of 5,238 cycles from over 100 fertility centers from January 2016 to December 2016 are included in this study involving 26,915 embryos sequenced by Next Generation Sequencing (NGS).

Participants/materials, setting, methods: All blastocyst stage embryos were biopsied and the samples were processed according to Illumina protocol for NGS. Embryos were classified as aneuploid, polyploid, complex abnormal, or mosaic. Mosaic samples were those that contained the equivalent of 20-80% abnormal cells. For this study single trisomies and monosomy X rates at blastocyst stage were compared with published POC data to determine the frequency of blastocyst aneuplodies that reach first trimester

Main results and the role of chance: The results are summarized in table 1:

Chromosome	Trisomy in blastocyst stage embryos (%)*	Aneuploidies in spontaneous abortions in the 1st trimester**	Embryo Loss (%)
XY tris	1.85%	0.43%	76.76%
XY mono	1.72%	1.46%	15.12%
1	2.00%	0.00%	100.00%
2	2.03%	0.19%	90.64%
3	1.87%	0.04%	97.86%
4	1.97%	0.11%	94.42%
5	2.01%	0.01%	99.50%
6	2.00%	0.02%	99.00%
7	1.93%	0.15%	92.23%
8	2.00%	0.13%	93.50%
9	2.56%	0.12%	95.31%
10	1.79%	0.06%	96.65%
11	2.10%	0.01%	99.52%
12	2.02%	0.03%	98.51%
13	2.49%	0.18%	92.77%
14	2.48%	0.14%	94.35%
15	3.51%	0.29%	91.74%
16	4.90%	1.24%	74.69%
17	1.73%	0.03%	98.27%
18	2.20%	0.20%	90.91%
19	2.21%	0.00%	100.00%
20	2.28%	0.10%	95.61%
21	3.62%	0.36%	90.06%
22	4.36%	0.38%	91.28%

Limitations, reasons for caution: It is unknown if blastocyst mosaicism detected by NGS will result in clinically recognized first trimester full trisomies or even mosaicism, and if so if they should have been included in the first column.

Wider implications of the findings: Most trisomies are lost at a 90% rate, but only a 75% is lost for chromosome 16, and 15% for monosomy X. Therefore, even though trisomy 22 is more common than trisomy 16 in blastocyst, it seems that trisomy 16 and monosomy X survives to first trimester in higher proportions.

Trial registration number: N/A.

P-661   Preimplantation Genetic Diagnosis (PGD) for Multiple Indications: Patient Outcomes

D. Goldberg-Strassler[1], R. Prates[2], M. Konstantinidis[2], R. Cabey[1], J. Gay[3], A. Jordan[1], E. Armenti[1]

[1]Reprogenetics, Genetic Counseling, Livingston, U.S.A.
[2]Reprogenetics, Molecular, Livingston, U.S.A.
[3]Reprogenetics, Genetic Counseling, Livginston, U.S.A.

Study question: Do patients who pursue PGD for multiple indications undergo more IVF cycles, banking cycles, and have fewer embryos to transfer?

Summary answer: There is an increase in number of embryos available for transfer when couples pursue PGD for multiple indications undergo banking cycles.

What is known already: PGD testing for single gene disorders is performed effectively with linkage analysis via Karyomapping (Illumina, USA), a single nucleotide polymorphism (SNP) array technology. Comprehensive chromosome screening (CCS) using array comparative genomic hybridization (aCGH) (24sure, Illumina) or next generation sequencing (NGS) (VeriSeq, Illumina) are validated technologies utilized in PGD testing for translocations. With a troph-ectoderm biopsy, PGD testing for multiple indications, such as multiple single gene disorders, may opt to include CCS.

Study design, size, duration: This study documents outcomes from 1153 patients between 2014 through 2016 and identified 15 patients who pursued PGD for multiple indications. These indications include both a translocation and a single gene disorder or at least two single gene disorders; both dominant, both recessive, both X-linked, one dominant and one X-linked, one dominant and one recessive, one X-linked and one recessive.

Participants/materials, setting, methods: Patients must have undergone PGD testing for multiple indications; including two ore more single gene conditions or a single gene condition and translocation. PGD testing for the single gene disorder(s) for these cases was performed via Karyomapping. International patients were excluded from this study.

Main results and the role of chance: From January 2014 through December 2016, PGD testing for single gene conditions was performed for 1153 patients. Of these, 32 patients expressed interested in pursuing PGD for multiple indications and 15 underwent at least 1 in vitro fertilization (IVF) cycle with subsequent PGD results. These patients account for 1.3% (15/1153) of those pursuing PGD for single gene disorders. Of these patients, 20% (3/15) reported an underlying fertility issue. These 15 patients underwent 27 IVF cycles, which yielded 21 PGD reports. The majority, 95% (20/21), of these PGD reports included CCS via aCGH or NGS. Additionally, 5/15 (33%) of patients banked biopsied samples to pursue another IVF cycle prior to PGD testing. The percent of embryos available for transfer per the total number of embryos tested was 13/115 (11%). As a comparison, patients pursuing PGD for one single gene condition had 2129/7058 (30%) of the embryos available for transfer; which is not statistically significant.

Limitations, reasons for caution: This population is a small sample size compared to the total number of patients who pursue PGD for single gene disorders. As such, it demonstrates a strong indication of the expectations for cycles from these patients, but more data is needed to assess statistical significance.

Wider implications of the findings: With the increase in expanded carrier screening and patient awareness regarding availability of PGD, there may be an increase in patients wishing to pursue PGD for multiple indications. As such, this patient population may benefit from banking while undergoing multiple IVF cycles in order to increase their success rate.

Trial registration number: not applicable.

P-662   Incidental identification of copy number variations (CNV) in patients during preimplantation genetic diagnosis (PGD) – clinical implications and counseling issues when encountering secondary findings

R. Cabey[1], D. Goldberg-Strassler[2], E. Armenti[2], A. Jordan[2], J. Gay[2], M. Konstantinidis[3], R. Prates[4], S. Munne[5]

[1]Reprogenetics, genetic counseling, Livingston- New Jersey, U.S.A.
[2]Reprogenetics, genetic counseling, Livingston- NJ, U.S.A.
[3]Reprogenetics, molecular, Livingston- NJ, U.S.A.
[4]Reprogenetics, molecular, Miami- FL, U.S.A.
[5]Reprogenetics, genomics research, Livingston- NJ, U.S.A.

Study question: What is the clinical significance and implications of microdeletions and microduplications which are incidentally identified during test preparation for PGD via Karyomapping (Illumina, USA)?

Summary answer: Incidental findings identified during PGD can have clinical significance; awareness and implementation of standard procedures for reporting such findings to physicians/patients is of great importance.

What is known already: Karyomapping is found to provide comprehensive assessment of the region of interest and it has been proven to be an effective method of PGD for single gene disorders. The methodology utilizes a single

nucleotide polymorphism (SNP) array which includes ~300,000 SNPs spread across the entire human genome. This allows for an advanced, genome-wide view of samples assessed which, similarly to other advanced methodologies utilized in the field of genetics, increases the chances for detection of incidental findings. Incidental findings are characterized as additional findings identified during a protocol in which the test is not designed to detect.

Study design, size, duration: This study records the incidence and significance of incidental findings identified among 624 couples undergoing PGD for gene disorders using Karyomapping. The findings were identified and reported during a 19 month period from July 2015 to January 2017.

Participants/materials, setting, methods: All PGD cases were prepared through utilization of Karyomapping SNP arrays. DNA samples were obtained from couples and family members for test preparation purposes. During evaluation of sample quality, review of the SNP array profiles was completed and revealed 17 CNVs; both, microduplications and microdeletions. All incidental findings were reported to the physician and patient and recommendation for follow-up chromosomal microarray testing via an outside diagnostic laboratory was provided.

Main results and the role of chance: The 17 incidental findings involved 9 unique chromosomes and consisted of 15 microduplications and 2 microdeletions. The size of microduplications detected ranged from 0.18 megabases (Mb) to 6 Mb. One microdeletion identified (located on chromosome X) was determined to be of considerable size at 28 Mb, potentially associated with health implications in the carrier female. Follow-up microarray analysis was pursued in 12 cases (60%), as 5 of the patients declined further evaluation. All microarray analyses confirmed the presence of the CNV identified via Karyomapping; however the significance of each varied. One CNV was classified as "possibly pathogenic" and another as a "possible susceptibility region". Five of the CNVs were reported as variants of uncertain significance (VUS) and 4 were reported as normal population variants. Results are pending on 1 case. Interestingly, 2 patients were found to have almost identical microduplications and follow-up microarray via 2 different labs revealed discordant classifications for the clinical significance. One patient elected to include their microduplication (classified as a VUS) in her PGD testing and results from 2 PGD cycles revealed 1 embryo available for transfer. This patient was expected to deliver in January 2017.

Limitations, reasons for caution: A few hundred couples were assessed as part of this study; 2.7% of these identified with incidental findings. Although this study provides a substantial view into the matter, a larger population needs to be assessed in order to definitively determine the general incidence, clinical implications and significance of such findings.

Wider implications of the findings: Incidental findings can potentially have significant health implications to the patient, other family members and/or future children. It is imperative to recognize this issue in the clinical laboratory setting and a standard procedure should be implemented to address cases in which these incidental findings are identified.

Trial registration number: not applicable.

P-663   Day of trophectoderm biopsy influences implantation and ongoing pregnancy rates of similarly-graded euploid blastocysts

M. Irani, C. O'Neill, G. Palermo, G. Vinay, C. Zhang, X. Qin, K. Xu, N. Zaninovic, Z. Rosenwaks

Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.

Study question: Does the day of trophectoderm biopsy (day 5 versus day 6) affect implantation rate (IR) and ongoing pregnancy rate (OPR) of similarly-graded euploid blastocysts?

Summary answer: Similarly-graded euploid blastocysts biopsied on day 5 are associated with a significantly higher IR and OPR compared to those biopsied on day 6.

What is known already: Trophectoderm biopsy for aneuploidy assessment is performed on embryos after reaching blastocyst stage, which preferentially occurs on day 5 or day 6 after fertilization. Studies have shown that transfer of day 5 blastocyst in a fresh IVF cycle is associated with a higher IR compared to day 6, which is attributed to a higher synchrony with the endometrium.

However, there are inconsistent data on the IR of frozen/thawed embryos. Therefore, assessing for euploidy and controlling for the day of trophectoderm biopsy and blastocyst grading prior to biopsy may help identify the best embryos to replace.

Study design, size, duration: It is a retrospective cohort study at an academic medical center. All frozen/thawed embryo transfer (FET) cycles in which only euploid blastocysts were transferred between January 2013 and December 2016 were reviewed. Patients who had transfer of two blastocysts of different grading or timing of biopsy were excluded. A total of 779 FET cycles (972 embryos) were included. Preimplantation genetic screening was performed using array comparative genomic hybridization.

Participants/materials, setting, methods: Cycles were divided into two groups based on the day of trophectoderm biopsy: day 5 (n = 405) and day 6 (n = 374). The morphological grading of blastocysts was assessed immediately prior to trophectoderm biopsy allocating embryos into the following four groups: excellent (^{3}3AA), good (3-6AB, 3-6BA, 1-2AA), average (3-6BB, 3-6AC, 3-6CA, 1-2AB, 1-2BA), and poor (1-6BC, 1-6CB, 1-6CC, 1-2BB). χ^2, Fisher's exact test, odds ratio (OR) with 95% confidence intervals were calculated and adjusted for confounding factors.

Main results and the role of chance: Cycles in which blastocysts were biopsied on day 5 were associated with a significantly higher OPR compared to those biopsied on day 6 (60.9% vs. 46.7%; p = 0.009). The odds ratio remained significant after controlling for blastocyst grading prior to biopsy, number of available euploid embryos, age, type of FET cycle (natural vs. programmed), and peak endometrial thickness (aOR=1.5; 95%CI=0.9-1.1). Euploid blastocysts that were biopsied on day 5 were associated with a significantly higher IR compared to those biopsied on day 6 (64.8% vs. 49.7%; p<0.001). There was no significant difference in the SAB rate between the two groups (9.5% vs. 9.7%; p>0.05).

Within embryos biopsied on day 5, excellent-quality blastocysts (n = 49) were associated with a significantly higher IR (83.6%) compared to average-quality (n = 290) (63.1%; p = 0.007) and poor-quality (n = 78) (50%, p<0.001) blastocysts. The IR of good-quality blastocysts (n = 86) (73.2%) was significantly higher compared to poor-quality (50%, p = 0.002) counterparts. Similarly, within embryos biopsied on day 6, poor-quality blastocysts were associated with a significantly lower IR (39.4%) compared to excellent-quality (70.5%), good-quality (57.5%), and average-quality (52.5%) cohort. The odds ratios remained significant after adjusting for age, type of FET cycle, peak endometrial thickness, and number of available euploid embryos for each patient.

Limitations, reasons for caution: Although the large number of cycles in this study clearly demonstrates that the pace of embryo development significantly influences the outcomes of similarly-graded euploid blastocysts, it is limited by its retrospective nature. A prospective study would be valuable to confirm our findings.

Wider implications of the findings: In spite of the aneuploidy assessment, the day of trophectoderm biopsy and the evaluation of blastocyst morphometric parameters, which reflect the metabolic health of the blastocyst, are paramount to select the best embryo.

Trial registration number: N/A.

P-664   PGS is most beneficial for older women with many embryos

E. Fedorova[1], S. Shlykova[2], K. Shunkina[1], O. Zaitceva[3], E. Lapina[4], T. Yanchuk[4], A. Kalugina[4]

[1]AVA-PETER Ltd., Genetics, Saint-Petersburg, Russia C.I.S.
[2]AVA-PETER Ltd., Embryology, Saint-Petersburg, Russia C.I.S.
[3]AVA-PETER Ltd., Reproductology, Saint-Petersburg, Russia C.I.S.
[4]AVA-PETER, Reproductology, Saint-Petersburg, Russia C.I.S.

Study question: Which strategy is better for AMA women with many embryos: eSET after PGS or freeze all embryos and transfer them one by one?

Summary answer: For this group, eSET after PGS resulted in 0.65 clinical pregnancy rate while the calculated chance to choose a euploid embryo for transfer is 0.23.

What is known already: Currently there are two opinions regarding PGS: a) It is beneficial because eSET after PGS improves the clinical pregnancy rate and reduces chances of twin pregnancy and miscarriage; b) It is harmful because

some embryos are falsely diagnosed as aneuploid and rejected, thus reducing the chance of pregnancy, and it is better to freeze all embryos and transfer them one by one in consecutive cycles. When women of advanced maternal age have a choice of several blastocysts available for transfer, it is not clear which strategy is better.

Study design, size, duration: This is a retrospective cohort study of patients undergoing IVF coupled with frozen embryo transfer after PGS in a single clinic from October 2012 to July 2016. Calculated and actual rates for clinical pregnancy and live birth are compared for three groups of patients with different proportion of euploid embryos.

Participants/materials, setting, methods: The study cohort consisted of 169 women aged 25 to 46, implanted with thawed autologous embryos after PGS-aCGH. Total of 861 embryos were analyzed, and patients were divided into 3 groups by proportion of euploid embryos: 0.1-0.29 (n = 31, mean age 36.9), 0.3-0.57 (n = 77, mean age 35.3), 0.6-1.0 (n = 61, mean age 33.45). Real clinical pregnancy (CP) rates were compared to theoretical chance of picking the euploid embryo ('right choice') for transfer in the first cycle.

Main results and the role of chance: In the 0.1-0.29 group there were from 4 to 15 embryos (mean of 6 embryos) per patient, with average 1.38 euploid embryo per patient. Mean calculated "right choice" chance was 0.23, and the real CP rate for the first cycle was 0.65 (p<0.05), live birth (LB) rate 0.55. The majority of these patients had AMA as indication for PGS. In the 0.3-0.57 group there were from 2 to 16 embryos (mean of 5,6 embryos) per patient with average 2.5 euploid embryo per patient. Calculated chance and actual CP rate were equal, comprising 0.4, with 0.34 LB rate. For the 0.6-1.0 group there were from 1 to 10 embryos (mean of 3.9 embryos) per patient, with average 3 euploid embryo per patient. Real CP rate at 0.51 was lower than calculated chance of 0.82 (p<0.05). Since this is the youngest group, it is likely that outcomes of IVF cycles were influenced by uterine factors, in contrast to the first group where the success depended on the genetic component.

Limitations, reasons for caution: This study was performed on a relatively small number of patients, and the chance of picking the euploid embryo for the first transfer was calculated purely on a probability basis, while in clinical practice, of course, choice of non-screened embryos for transfer is based on their morphology.

Wider implications of the findings: Our results suggest that when AMA patients have a choice of blastocysts for transfer, PGS followed by eSET gives them a much higher chance of clinical pregnancy and live birth already after the first cycle than consecutive transfer of all available embryos.

Trial registration number: not applicable.

P-665 Intermediate number of CGG repeats in patients with Fragile X premutation is associated with poorer ovarian reserve

J. Lekovic[1], L. Man[2], N. Pereira[2], K.P. Xu[2], Z. Rosenwaks[2], J. Gerhardt[2]

[1]Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine- Weill Cornell Medicine, Obstetrics and Gynecology, New York City- NY, U.S.A.
[2]Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine- Weill Cornell Medicine, Obstetrics and Gynecology, New York, U.S.A.

Study question: Do Fragile X premutation carriers with intermediate number of CGG repeats have a lower ovarian reserve than those with lower and higher number of repeats?

Summary answer: Fragile X premutation carriers with intermediate number (70-90) of CGG repeats have lower ovarian reserve than those with lower and higher number of repeats

What is known already: FMR1 premutation carriers (56-200 CGG repeats within FMR1 gene on X chromosome) have diminished ovarian reserve and higher incidence of premature ovarian insufficiency [POI] when compared to healthy controls. One of the proposed mechanisms is gonadotoxicity of the transcription/translation product of the mutated gene. Patients with intermediate number of repeats (70-90) have a higher risk of POI then those with less (<70) and more (>90) repeats. Possible explanation is lower concentration of the gonadotoxic mRNA/protein in the lower repeat group, and decreased transcription of the FMR1 gene caused by epigenetic changes with the higher number of CGG repeats.

Study design, size, duration: Retrospective cohort study including all FMR1 premutation carriers who underwent controlled ovarian hyperstimulation [COH]and preimplantation genetic diagnosis [PGD] for FMR1 gene mutation in a 5-year period at one academic center. Man Whitney U was used for comparison of continuous variables and P value < 0.05 was considered statistically significant

Participants/materials, setting, methods: The electronic medical record system was searched for all patients undergoing COH and PGD for FMR1 gene mutation during the study period where the number of CGG repeats was available. Thirty-one patients were included. None had prior ovarian surgery. Primary outcomes included the Anti-mullerian hormone level [AMH] (ng/mL), antral follicle count [AFC] and the number of oocytes retrieved. If a patient had multiple COH cycles, the mean AFC and number of oocytes retrieved were used.

Main results and the role of chance: There were 12 patients with intermediate (70-90) number of CGG repeats (study group) and 19 patients with lower and higher (<70 and >90) number of CGG repeats (control group). All patients underwent antagonist protocol and were matched for body mass index. Even though the patients in the study group were younger (median age 32.5 vs. 34.5 years, P = 0.04), their median AMH levels were lower (0.5 (IQR 0.3-0.9) vs 0.8 (IQR 0.6-1.75) ng/mL, P = 0.05) as well as their median AFC (6 (IQR 4-8) vs 9 (IQR 6-13, P = 0.03). Number of retrieved oocytes was also significantly lower in the study group (6 (IQR 3-8) vs. 8 (IQR 6-14), P = 0.03).

Limitations, reasons for caution: Main limitations of our study represent its retrospective nature, small sample size and inability to control for possible cofounders.

Wider implications of the findings: Current study suggests that FMR1 gene premutation carriers with intermediate number of repeats have poorer ovarian reserve which should be taken into account when counseling such patients and setting expectations for COH outcome.

Trial registration number: N/A.

P-666 Refining embryo transfer strategies after PGD for translocations using comprehensive chromosome testing

E. Coonen[1,2], C. Van Uum[1], Engelen. J.[1], M. Meijer-Hoogeveen[3], R. Van Golde[2], J. Derhaag[2], A. Van Montfoort[1], M. Pieters[3], M. Goddijn[4], J. Brink-van der Vlugt[5], S. Repping[4], C. De Die-Smulders[1], S. Mastenbroek[4]

[1]Department of Clinical Genetics, GROW School for Oncology and Developmental Biology Maastricht University Medical Center+, Maastricht, The Netherlands
[2]Center for Reproductive Medicine, GROW School for Oncology and Developmental Biology, Maastricht University Medical Centre+
[3]Department of Reproductive Medicine, University Medical Center Utrecht, Utrecht, The Netherlands
[4]Center for Reproductive Medicine, Academic Medical Centre, University of Amsterdam
[5]Center for Reproductive Medicine, University Medical Center Groningen, Groningen, The Netherlands

Study question: Does the genome-wide ploidy profile of PGD translocation embryos inferred from the blastomere status (balanced/euploid vs. balanced/aneuploid) predict implantation potential?

Summary answer: PGD translocation embryos with an inferred balanced/aneuploid genotype have a lower, but not zero implantation potential compared to embryos with a balanced/euploid genotype

What is known already: The scientific validity of comprehensive chromosome testing in preimplantation embryos to improve the live birth rate and reduce the miscarriage rate in IVF patients is still under debate. Healthy live births have recently been reported after transfer of blastocysts with an inferred mosaic aneuploid genotype, yet live birth rates seem to be lower and miscarriage rates higher compared to transfer of euploid blastocysts.

The use of NGS and array technology in couples undergoing PGD for chromosomal or monogenic disorders allows for simultaneous genome-wide ploidy analysis of all embryos. Whether this data can be used to optimise PGD treatment is unknown.

Study design, size, duration: Observational, prospectively designed, multi-centre study covering a 3-year period (2014-2016) during which 117 couples underwent 171 PGD cycles for structural chromosomal abnormalities.

The multicentre structure encompassed three IVF laboratories that had biopsied material tested by one and the same genetic centre. Comprehensive chromosome testing was performed by array CGH. The included study cohort comprised first attempt PGD cycles with day 3 single blastomere biopsy and fresh single embryo transfer (n = 73).

Participants/materials, setting, methods: In all three centres only embryos with a balanced karyotype for the chromosomes comprising the PGD indication were eligible for transfer. Two of the three centres received no ploidy information for non-indication chromosomes and ranked eligible embryos for transfer solely based on morphology. The third centre did receive this information and ranked embryos based on both chromosomal constitution and morphology, prioritising the balanced/euploid ones.

Main results and the role of chance: In all, 73 embryo transfers met the inclusion criteria. There were 38 transfers in the two centres that did not use ploidy information, resulting in 20 ongoing pregnancies. Twenty-seven transfers involved a balanced/euploid embryo, resulting in 19 ongoing pregnancies (70%), and 11 transfers involved a balanced/aneuploid embryo, resulting in one ongoing pregnancy (9%). There were 35 transfers in the center that did use ploidy status to rank embryos, resulting in 8 ongoing pregnanies. Twenty-seven transfers involved a balanced/euploid embryo, resulting in 7 ongoing pregnancies (26%), and 8 transfers involved a balanced/aneuploid embryo, resulting in one ongoing pregnancy (13%). All transfers in all centres taken together, 54 transfers involved a balanced/euploid embryo, resulting in 26 ongoing pregnancies (48%), and 19 transfers involved a balanced/aneuploid embryo, resulting in two ongoing pregnancies (11%) (p = 0.004). Aneuploidy of non-indication chromosomes involved a trisomy 19 and a trisomy X. Miscarriage rates, here defined as the percentage of cycles where a biochemical pregnancy did not result in an ongoing pregnancy, were 4% for balanced/euploid and 50% for balanced/aneuploid embryos.

Limitations, reasons for caution: The observed difference in implantation rate between balanced/euploid and balanced/aneuploid embryos is statistically different, but the number of cases is still small. To appraise the clinical effectiveness of both embryo transfer strategies, the cumulative live birth rate (result of fresh and cryo transfers) per woman should be assessed.

Wider implications of the findings: The biopsied blastomere-inferred embryo genotype of the non-indication chromosomes is predictive of the implantation potential. Whether ranking embryos for transfer accordingly improves PGD treatment outcome should be further investigated.

REPRODUCTIVE ENDOCRINOLOGY

P-667   Involvement of local ovarian interleukin-1beta in insulin-resistance of granulosa cells in women with polycystic ovarian syndrome

G. Sun, Q. Zhu, Y. Sun

Ren Ji Hospital- School of Medicine- Shanghai Jiao Tong University, Center for Reproductive Medicine, Shanghai, China

Study question: Does increased interleukin-1β abundance in the ovary play a role in local ovarian insulin resistance in PCOS women?

Summary answer: The increased abundance of Interleukin-1β abundance in PCOS ovary decreases insulin sensitivity by impairing its receptor-coupled signaling pathway in granulosa cells.

What is known already: The polycystic ovary syndrome (PCOS) is the most common disorder in women of reproductive age. Women with PCOS is more likely to develop insulin resistance (IR). However, the underlying cause of IR remains largely unknown. Low-grade inflammation is associated with IR in several major insulin-target tissues. We studied whether interlukin-1β (IL-1β), the best-studied pleiotropic proinflammatory cytokine, was increased in granulosa cells and follicular fluid in PCOS with IR, and whether these increases were associated with IR in PCOS women. The mechanism of IL-1β-induced IR in granulosa cells was also investigated.

Study design, size, duration: Ovarian granulosa cells and follicular fluid were collected from PCOS patients with IR (n = 21) or without IR (n = 23), who underwent in vitro fertilization (IVF) or intracytoplasmic sperm injection (ICSI). IR status was determined according to the homeostasis model of assessment for insulin resistance index (HOMA-IR) or fasting insulin level. Women of normal body mass index without IR but with tubal factor as the only cause of infertility were enrolled as control (n = 21).

Participants/materials, setting, methods: Follicular fluid and granulosa cells were collected. IL-1β abundance in the follicular fluid was determined with ELISA and IL-1β mRNA in the granulosa cells was measured with quantitative real time PCR. Cultured granulosa cells were used to study whether IL-1β treatment cause IR and to explore the underlying mechanism.

Main results and the role of chance: Higher IL-1β concentration in the follicular fluid and increased IL-1β mRNA abundance in the granulosa cells were detected in PCOS with IR than PCOS without IR or non-PCOS patients. The level of IL-1β was positively correlated with fasting insulin level and HOMA-IR, but negatively related with lactate concentration in the follicular fluid. Meanwhile, mRNA of phosphatase and tensin homolog deleted on chromosome 10 (PTEN), a lipid phosphatase which antagonizes the activity of PI3K thereby inhibiting Akt phosphorylation resulting in impaired insulin sensitivity, in granulosa cells was significantly elevated in PCOS with IR, and positively correlated with IL-1β concentration in the follicular fluid. IL-1β treatment of cultured granulosa cells up-regulated PTEN mRNA and protein abundance in a dose-dependent manner. Pretreatment with IL-1β attenuated not only Akt phosphorylation by insulin but also the shift of GLUT4 from cytoplasm to cell membrane. These data suggest that elevated IL-1β concentration in PCOS ovary is a causative factor of IR in granulosa cells.

Limitations, reasons for caution: IL-1β is only one of the factors that contribute to the development of IR in the PCOS ovary. Other contributing factors await to be identified.

Wider implications of the findings: Alleviation of the inflammatory process may ameliorate IR in the ovary so that the ovarian functions may be improved.

Trial registration number: Not applicable.

P-668   Effect of ovarian hyper-stimulation with follicular phase of progesterone on ovarian microenvironment in mice

X. Wen[1], Y. Kuang[2], L. Zhou[2], B. Yu[3], H. Long[4], Z. Yan[2], Q. Lyu[2], J. Xie[3], W. Chai[2]

[1]*Shanghai ninth hospital, Department of Assisted Reproduction, Shanghai, China*
[2]*Shanghai Ninth People's Hospital, Department of Assisted Reproduction, Shanghai, China*
[3]*Shanxi Medical University, Department of Biochemistry and Molecular Biology, Taiyuan, China*
[4]*Shanghai Ninth People's Hospital, Department of Assisted Reproduction, Shnghai, China*

Study question: To investigate the effect of different doses of medroxyprogesterone acetate (MPA) combined with Human Menopausal Gonadotropin (HMG) on ovarian microenvironment during follicular phase in mice.

Summary answer: Administration of MPA and HMG achieved the double effect of promoting multiple follicular development and inhibiting premature luteinizing hormone (LH) surge in the follicular phase.

What is known already: Studies found that early administration of progesterone (P) in the follicle made endogenous ovarian LH could not be synthesized and secreted so as to achieve the purpose of controlling premature LH surge. Meanwhile, the production of endogenous P is not affected by exogenous P. And our clinical outcome suggested that a high retrieved oocyte number and clinical pregnancy rate achievedin the progestin primed ovarian stimulation (PPOS) protocol compared with short-term protocol.

Study design, size, duration: The BALB/C female mice were randomly divided into four groups: 1) control group: sodium carboxymethylcellulose

(CMC-Na), HMG and MPA (4/10/20/40 mg/d) as control group; 2) study group: HMG+MPA (4/10/20/40 mg/d). Meanwhile, 3 week female mice were divided into 3 groups: CMC-Na, HMG and HMG+MPA groups. All animals were treated for 5 successive days.

Participants/materials, setting, methods: Vaginal smear was used to observe the sexual cycle, the levels of sex hormone were determined by enzyme-linked immunosorbent assay (ELISA) and the ovarian morphology and follicular development were observed by hematoxylin eosin (HE) staining. The expression of ovarian hormone receptor were observeed by immunohisto-chemistry, and the expression of PI3K/Akt/mTOR protein in follicular develop-mental signal pathway was determined by western blotting.

Main results and the role of chance: The ovary weight index in the HMG +MPA group was higher than that of control group. The levels of serum Follicle-Stimulating Hormone (FSH), Follicle Stimulating Hormone Receptor (FSHR) and the percentage of antral follicles in HMG and HMG+MPA groups were significantly higher than those in CMC-Na group and MPA group (p<0.05) while reduced levels of LH and LHR were observed. Western blotting showed that phosphorylation of PI3K/Akt/mTOR protein in the experimental group was lower than that in the HMG group and higher than in the MPA and CMC-Na groups.

Limitations, reasons for caution: The mechanism of PPOS protocol remain to be further explored and this study shown only in one species.

Wider implications of the findings: This animal study can provide guidance for optimizing clinical PPOS protocol.

Trial registration number: This study was registered with the Chinese Clinical Trial Registry (ChiCTR-ONRC-14004419).

P-669   Early serum oestradiol rise during ovulation induction in WHO Group II anovulatory infertility predicts the development of > 3 mature follicles

M.P. Lauritsen[1], A. Pinborg[2], A. Loft[3], A. Nyboe Andersen[4]

[1]Copenhagen, Denmark
[2]Copenhagen University Hospital Hvidovre, Department of Clinical Medicine., Kettegård Allé 30- 2650 Hvidovre-, Denmark
[3]Copenhagen University Hospital Rigshospitalet-, The Fertility Clinic- Section 4071-, 2100 Copenhagen-, Denmark
[4]Copenhagen University Hospital Rigshospitalet-, The Fertility Clinic- Section 4071-, 2100 Copenhagen, Denmark

Study question: Can the increments in serum oestradiol (E_2) levels during ovulation induction with gonadotrophins in WHO Group II anovulatory infertil-ity predict the development of >3 mature follicles and thus cancellation of the cycle?

Summary answer: E_2 increments from stimulation Day 1 to stimulation Day 5 significantly predicted the development of an excessive response with >3 mature follicles.

What is known already: The prediction of hypo- or hyper-response to gonadotrophin stimulation during ovulation induction for anovulatory infertility is a clinical challenge. It has previously been shown that the number of inter-mediate follicles and the levels of E_2 on the day of human chorionic gonado-trophin (hCG) are correlated with high-order pregnancy rates in ovulation induction with gonadotrophins. However, parameters measured at this stage of stimulation may support the decision of withholding hCG but do not contribute to an individualised initial treatment approach.

Study design, size, duration: This prospective, clinical study performed between 2010 and 2012 included 71 normogonadotrophic, anovulatory women who were consecutively treated with an individualised, nomogram-based starting dose of highly purified human menopausal gonadotrophin (HP-hMG) (Nyboe Andersen et al, 2008). All women underwent one ovulation induction cycle according to a flexible, low-dose step-up regimen where it was also allowed to step-down in order to control for multiple follicular development.

Participants/materials, setting, methods: Serum levels of E_2 and follicle development were assessed at baseline, on stimulation Day 5, on the day of dominance, and on the day of hCG administration. Receiver operating

characteristics (ROC) curves were used to evaluate the E_2 increments during stimulation as a predictor of the outcome of treatment.

Main results and the role of chance: E_2 increased significantly between all four time points ($P < 0.001$). On stimulation Day 5, a significantly higher E_2 increment was observed in women who developed > 3 mature follicles com-pared with the group of monofollicular development or 2–3 follicles (534.6%, 95% CI: 233.3–1227.4% and 237.1%, 95% CI: 184.5–304.1%, respectively, $P = 0.005$). The E_2 increment from stimulation Day 1 –5 could predict the develop-ment of > 3 mature follicles with an area under the curve (AUC) of 0.76 (95% CI: 0.60–0.92). Thus, a woman with more than at two-fold increase in E_2 from stimulation Day 1—5 had a 33% risk of developing >3 mature follicles. A woman with *less* than a two-fold increase in E_2 from stimulation Day 1 to stimu-lation Day 5 had an 88% chance of developing ≤3 mature follicles and fulfilling the hCG criteria.

Limitations, reasons for caution: The relatively small sample size of the study may reduce the power of the results.

Wider implications of the findings: Ultrasonography has to a large extent replaced E_2 measurements in the monitoring of follicular response to stimula-tion. However, our study underlines the fact that E_2 measurements may be valuable in the prediction of multifollicular growth that may not be immediately observed on ultrasound.

Trial registration number: EudraCT-number 2010-021459-16. ClinicalTrials. gov Identifier: NCT01250821.

P-670   Progesterone at baseline and during stimulation predict live birth rate after IVF and should be evaluated before and during ovarian stimulation

A. Guivarc'h Leveque[1], P. Arvis[1], P.L. Broux[1], M. Bidet[1], S. Fromentin[1], F. Jaffre[1], N. Lucas[1], L. Moy[1], G. Priou[1], P. Lehert[2]

[1]Clinique la Sagesse, AMP, Rennes, France
[2]Université Louvain, statistics, Louvain, Belgium

Study question: Can progesterone at baseline of controlled ovarian stimula-tion and during stimulation anticipate progesterone at HCG day and predict Live birth (LB).

Summary answer: Progesterone history since baseline impacts LB rate fol-lowing a non linear effect admitting an optimal value and decreasing at lower and higher values.

What is known already: Progesterone Elevation(PE) at HCG day (P_{HCG}) negatively impacts live birth. Previous studies suggest that baseline proges-terone level P_b and during stimulation may predict PE. The double relation-ship $P_b \rightarrow P_{hcg} \rightarrow LB$ allows us hypothesizing a direct impact of P_b on LB. However, previous results are not consistent between studies and were not based on the continuous values of P_{hcg} but dichotomized following the threshold 1.5 ng/ml. Besides, no studies provided evidence of the direct effect of P_b on LB.

Study design, size, duration: Non-interventional, retrospective, observa-tional, single-centre cohort study. No inclusion or exclusion criteria were applied. A sample size of 4300 cycles was calculated to provide a power of 90% to detect an odds ratio (OR) on LB as large as .6/Log(P_b) at $P < .001$ level (type-1 correction for multiple testing). Due to the expected correlation between cycles on the same patient, the analysis was conducted on the last recent 5447 IVF/ICSI cycles performed on 2192 patients during 2009-2015.

Participants/materials, setting, methods: Patients (median age 34y [IQ=31-37], BMI= 22.8 ± 4.8) underwent controlled ovarian stimulation (rFSH ± LH, HP-HMG) with either agonist or antagonist protocols. The effect of P_b on P_{hcg} was tested by a linear mixed model assessing the non linear effect of the log-transformed progesterone value at baseline and day 6 of stimulation on PE by polynomial regression. The effect of P_b on LB was tested by a non lin-ear mixed model admitting the same factors and covariables.

Main results and the role of chance: Progesterone as baseline P_b was con-firmed as the main predictor of PE(ratio RG of the geometric mean P_{hcg}/P_b RG= 1.58, (95%CI [1.55-1.62], $P < .001$, determination R^2=.29), followed by the total dose of gonadotropin FSH_{tot} (RG=1.11 per 10^3.iu/L [1.01,1.22], p=.023). A highly significant non-linear effect of P_b on LB was constituted by a

linear (odds ratio OR=.86 [.61,.99], p=.04) and quadratic (OR=.22, [.10,.49], P < .001) components, resulting in an optimal LB value at .65 ng/ml ([.59,.75], bootstrapping) and decreasing LB rate for both lower values and higher values. According to our model, a mean decrease in LB of 28% (OR=.82, .68-.98) was found for patients out of the P_b interval [.20,.85] ng/ml (21.7% of the sample). Progesterone at day 6 of stimulation (P_6) was found more predictive than P_b with a similar non linear variation on LB admitting a maximum LB at P_6= .64 ng/ml [.5,.69], with a mean LB decrease of 24% (OR=.76, .63-.93) was found for patients out of the P_6 interval [.2,.9] ng/ml (18.7% of the sample).

Limitations, reasons for caution: Our results derive from a retrospective single-center study; the exact identification of the optimum value and its confidence interval is likely to depend of the lack of uniformity of progesterone assay kits.

Wider implications of the findings: Compared with progesterone measured at HCG, progesterone at baseline and day 6 also predict live birth. Measuring progesterone at baseline and during the stimulation are recommended. An optimal interval of progesterone value at baseline and day 6 is recommended for both fresh or differed embryo transfer.

Trial registration number: NA.

P-671 The effect of oil and water-soluble contrast medium in hysterosalpingography on thyroid function

S. So[1], W. Yamaguchi[1], H. Tajima[1], T. Nakayama[2], N. Tamura[3], N. Kanayama[3], F. Tawara[1]

[1]Tawara IVF clinic, Medical office, Shizuoka, Japan
[2]Shizuoka Kosei Hospital, Department of Gynecology & Obstetrics, Shizuoka, Japan
[3]Hamamatsu University School of Medicine, Department of Obstetrics and Gynaecology, Hamamatsu, Japan

Study question: Is there a difference in thyroid function (thyroid stimulating hormone: TSH and free-T4: FT4) after hysterosalpingography (HSG) with an oil-soluble contrast medium (OSCM) and a water-soluble contrast medium (WSCM)?

Summary answer: Approximately 25% of the women in the OSCM-group developed subclinical hypothyroidism (SCH). Conversely, patients in the WSCM-group did not show a change in thyroid function.

What is known already: Several studies have already shown an adverse effect of OSCM on thyroid function after HSG. However, it is unknown whether WSCM also depresses thyroid function after HSG.

Study design, size, duration: This was a retrospective study. Thirty-one patients who underwent HSG with OSCM and 58 patients who had HSG with WSCM were included in this analysis, which took place between March 2013 and August 2014.

Participants/materials, setting, methods: The patients had undergone a thyroid function test at our clinic less than three months before HSG and all showed normal thyroid function. The subjects' thyroid function also was checked at least once following HSG. HSG was performed using the oil-soluble contrast medium Lipiodol® (an iodized poppy seed oil; Terumo, Japan) and the non-ionic water soluble contrast medium Isovist® (iotrolan, Bayer Schering Pharma AG Berlin, Germany).

Main results and the role of chance: TSH and FT4 levels did not differ between the patients before HSG with OSCM and WSCM (TSH: 1.46 ± 0.63 mIU/L in the OSCM group vs. 1.42 ± 0.65 mIU/L in the WSCM group; FT4: 1.20 ± 0.14 ng/dL in the OSCM group vs. 1.21 ± 0.14 ng/dL in the WSCM group). After HSG, TSH levels were significantly higher in the OSCM group (2.43 ± 0.94 mIU/L) compared to that of the WSCM group (1.64 ± 1.01 mIU/L). Patients in both the OSCM and WSCM groups showed unchanged FT4 levels after HSG. Some 22.5% of patients who underwent HSG with OSCM developed SCH within one month of the test. On the other hand, some patients who underwent HSG with WSCM also developed SCH (9.5%). In an interval-matched comparison, the proportion of SCH development following HSG was significantly higher in patients who underwent the test with OSCM than in those in which it was administered using WSCM.

Limitations, reasons for caution: The retrospective design is the limitation.

Wider implications of the findings: Our data clearly indicates that WSCM is safe for thyroid function in women who plan to get pregnant. SCH during pregnancy is a known risk factor for miscarriage. Therefore, we recommend that WSCM initially be used to detect tubal patency.

Trial registration number: none.

P-672 Endocrinological evidence why humans can hardly live above around 5.000 m altitude

M. Von Wolff[1], C.T. Nakas[2], D. Keenan[3], V. J.D.[4], T. Merz[5], A.R. Huber[6], J. Pichler Hefti[7]

[4]Mayo Clinic, Endocrine Research Unit- Dept. of Internal Medicine- Mayo School of Graduate Medical Education- Center for Translational Science Activities-, Rochester- MN 55905, U.S.A.
[5]Inselspital- University Hospital Berne, Division of Intensive Care Medicine-, Berne, Switzerland
[6]Cantonal Hospital Aarau, Center for Laboratory Medicine-, Aarau, Switzerland
[7]Inselspital- University Hospital, Division of Pneumology, Berne, Switzerland

Study question: Is there any endocrinological evidence why humans can hardly live above around 5.000 m altitude?

Summary answer: Activation of stress axes and inhibition of reproductive axis at altitude above 5.000 m probably contribute to the incapability of humans to live at extreme altitudes.

What is known already: Humans cannot live for a long time above around 5.000 m altitude for reasons which have not been completely understood and which are not restricted to cardiorespiratory changes alone. Previous studies analysing the hormone system at high altitude were based on small study groups, limited to men, were only carried out at altitudes of up to 5.000 m or the study design was not ideal because the studies were carried out during mountaineering expeditions.

Study design, size, duration: The prospective observational cohort field study was performed in the context of the Swiss High Altitude Medical Research Expedition 2013 to Mount Himlung Himal (7126 m). 40 healthy subjects (21 male, 19 female) aged between 18 and 70 years had been included in the trial. Hormonal concentrations of all hypothalamus pituitary axes were measured between 550 and 7.050 altitude. No supplementary oxygen was used during the climb.

Participants/materials, setting, methods: Basal hormone concentrations (cortisol, TSH, fT3, fT4, LH, total testosterone, prolactin and GH) were analysed the next day in the morning after reaching the next altitude step at 550, 4.800, 6.025 and 7.025 m. Hormone concentrations were also measured after acclimatization at 4.800 m. Pulsatility of selected hormones (cortisol, TSH, prolactin, GH) was analysed following blood collections every 10-20 minutes over 8 hours in 8 females at 550, 4.800 and 6.025 m. Additionally cardiorespiratory parameters were evaluated.

Main results and the role of chance: Overall: Changes of hormonal concentrations correlated with altitude but not with oxygen saturation. Stress axes were activated and reproductive axes were inhibited at high altitude.

In detail: Cortisol and prolactin concentrations in males and females decreased at ascent to 4.800 m and then increased at 6.025 m and 7.050 m. Cortisol decrease at 4.800 m was normalized after acclimatization. fT4 increased with increasing altitude, increase at 4.800 m was also normalized after acclimatization. LH decreased in males with increasing altitude.

Pulsatility analysis: The increase of hormone concentrations such as cortisol and prolactin was due to an increase of pulse rate. Mass per pulse however decreased.

Limitations, reasons for caution: Effect of acclimatization was only analysed on 4.800 m altitude but not at higher altitudes.

Wider implications of the findings: Activation of stress axes at high altitude and decrease of LH secretion might affect early and late pregnancy in women at high altitude. However, this negative effect might not be relevant in case of slow ascent allowing sufficient acclimatization.

Trial registration number: Clinicaltrials.gov: NCT01953198.

P-673   A randomised, assessor-blind, AMH-stratified, dose-response trial in Japanese IVF/ICSI patients undergoing controlled ovarian stimulation with follitropin delta

O. Ishihara[1], J.C. Arce[2], #. Japanese Follitropin Delta Phase 2 Study Group[3]

[1]Saitama Medical University, Department of Obstetrics & Gynaecology, Iruma-gun-Saitama, Japan
[2]Ferring Pharmaceuticals, US Development, Parsippany, U.S.A.
[3]On behalf of participating sites, Fertility clinics, Japan, Japan

Study question: To establish the relationship between follitropin delta dose (FE 999049; recombinant FSH produced from the human cell line PER.C6®) and ovarian response in Japanese IVF/ICSI patients.

Summary answer: A significant dose-response relationship was established between follitropin delta and number of oocytes retrieved in Japanese IVF/ICSI patients.

What is known already: A significant dose-response relationship has been established for follitropin delta with respect to number of oocytes retrieved as well as serum concentrations of estradiol, inhibin B, inhibin A and progesterone in a clinical trial conducted in European IVF/ICSI patients of whom 98% were Caucasians (Arce et al, Fertil Steril, 2014).

Study design, size, duration: Randomised, controlled, assessor-blind, multi-centre, dose-response trial in 158 Japanese IVF/ICSI patients, 20-39 years (mean age 33.7 years), undergoing controlled ovarian stimulation with three dose levels of follitropin delta (Ferring Pharmaceuticals) and with follitropin beta (Follistim, MSD) included as a reference group for validity purposes. A single blastocyst was transferred in the fresh cycle. Clinical pregnancy was defined as a gestational sac.

Participants/materials, setting, methods: Patients were randomised to fixed doses of 6, 9 or 12 μg/day follitropin delta (N = 117) or 150 IU/day follitropin beta (N = 41). Randomisation was stratified by serum AMH (low: 5.0-14.9 pmol/L, high: 15.0-44.9 pmol/L; Elecsys® AMH, Roche Diagnostics). Gonadotropin dosing was initiated on day 2-3 of the menstrual cycle, ganirelix 0.25 mg/day added from day 6 of stimulation and triggering of final maturation done when observing ≥3 follicles ≥17 mm. OHSS was assessed using Golan's classification.

Main results and the role of chance: A significant (p < 0.001) dose-response relation between follitropin delta and number of oocytes retrieved was observed for the overall trial population (p<0.001), the high AMH stratum (p<0.001) and the low AMH stratum (p = 0.004). An average of 53% more oocytes were retrieved in the high AMH stratum compared to the low AMH stratum (6 μg: 7.9 vs 5.3; 9 μg: 11.2 vs 5.6; 12 μg: 12.9 vs 9.5; follitropin beta: 11.8 vs 9.3). Significant (p<0.05) dose-responses were also observed for serum estradiol, progesterone, inhibin B and inhibin A on day 6 and/or at end of stimulation with follitropin delta. The proportion of patients with excessive response (≥15 oocytes) after stimulation with follitropin delta increased from 6% with 6 μg to 15% with 9 μg and 28% with 12 μg, while it was 20% with follitropin beta. The rate of early moderate/severe OHSS for follitropin delta was 8% for 6 μg, 8% for 9 μg and 13% for 12 μg, and 20% for follitropin beta, with most cases (84%) in the high AMH stratum. The clinical pregnancy rate per started cycle with follitropin delta was 24% for 6 μg, 20% for 9 μg and 33% for 12 μg, and 20% for follitropin beta.

Limitations, reasons for caution: Patients with very low (<5 pmol/L) or very high (>45 pmol/L) AMH were not included in this dose-response trial.

Wider implications of the findings: The findings from this trial confirm the dose-response relationship of follitropin delta in Japanese IVF/ICSI patients in relation to number of oocytes retrieved and other pharmacodynamic parameters, and reinforce the concept that the gonadotropin dose should be guided by an ovarian marker such as initial serum levels of AMH.

Trial registration number: NCT02309671.

P-674   Telomere length is short in PCOS and oral contraceptive does not affect the telomerase activity of granulosa cells in patients with PCOS

Y. Li[1], B. Deng[2], M. Mai[1], K. Dai[1], R. Li[1], W. Wang[1,3]

[1]Sun Yat-sen Memorial Hospital, Department of Obstetrics and Gynaecology, Guangzhou, China
[2]Xia Men Maternity and Child Care Centers, Department of Reproductive Medicine, Xia Men, China
[3]Corresponding Author, /, China

Study question: Are telomerase activity(TA) and telomere length(TL) associated with IVF outcome of PCOS patients? Does oral contraceptive affect the TA and TL in patients with PCOS?

Summary answer: Shorter TL was found in PCOS patients. No effect of oral contraceptive pill(OCP) pretreatment on the TA and TL either.

What is known already: Telomerase is the critical enzyme for maintaining TL. TA positively correlates with the proliferation activity of GCs. Our previous study showed that the TA of GCs in non-PCOS patients positively correlated with the pregnancy outcome of IVF. OCP could reduce the basal luteinizing hormone and androgen levels and improve IVF outcomes in PCOS patients.

Study design, size, duration: 163 infertile women were enrolled and divided into a PCOS group(n = 65) and a non-PCOS group(n = 98). The PCOS group were further divided into a TA<0.070 group(n = 34) and a TA≥0.070 group(n = 31), a TL<1 group(n = 41) and a TL≥1 group(n = 24), an OCP pretreatment group(n = 35) and a non-OCP pretreatment group(n = 30), respectively.

Participants/materials, setting, methods: The TA of GCs was determined using the telomeric repeat amplification protocol enzyme-linked immunosorbent assay(TRAP-ELISA). The TL was analyzed using real-time fluorescence quantitative PCR.

Main results and the role of chance: No obvious differences were observed in TA between these groups. The TL was 0.971 in PCOS group and 1.118 in non-PCOS group(P = 0.005). The patients with TL≥1 accounted for 36.9%(24/65) in PCOS group and 54.1%(53/98) in non-PCOS group ($\chi^2 = 0.441$, P = 0.032). The infertility duration of PCOS patients was 5 years in TA<0.070 group and 4 years in TA≥0.070 group(P = 0.038), 5 years in TL<1 group and 3 years in TL≥1 group(P = 0.006), respectively. No obvious differences were observed in IVF outcome between these groups. No obvious differences were observed in TA, TL and IVF outcome between OCP pretreatment group and non-OCP pretreatment group in PCOS patients.

Limitations, reasons for caution: Whether extension of the OCP pretreatment time affects the TA and TL of GCs in PCOS patients still needs further exploration.

Wider implications of the findings: These findings suggest that impaired TL is associated with PCOS. PCOS patients with a lower TA and shorter telomeres have an earlier onset of infertility symptoms. OCP does not affect the TA of granulose cells in patients with PCOS.

Trial registration number: N/A.

P-675   increased follicular expression of growth differentiation factor 8 and its receptors in PCOS ovaries

T.T. Lin[1], H.M. Chang[2], P.C.K. Leung[2], Y.M. Zhu[1]

[1]Women's hospital- School of Medicine- Zhejiang University, Department of Reproductive endocrinology, Hangzhou, China
[2]BC Children's Hospital Research Institute-University of British Columbia, Department of Obstetrics and Gynecology, Vancouver, Canada

Study question: Do human ovarian cells express growth differentiation factor 8 (GDF8)?

Summary answer: GDF8 and its functional receptors are expressed in human ovarian tissues and with an increased follicular expression in PCOS ovaries than normal ovaries.

What is known already: Our recent studies have shown that GDF8 plays a critical role in the regulation of ovarian functions, including steroidogenesis,

gonadotropin responsiveness, cell proliferation, lysyl oxidase activity and cumulus expansion.

Study design, size, duration: This is a laboratory study conducted over a 1-year period, and 48 samples was included.

Participants/materials, setting, methods: A total of 34 normal menstrual cycle women and 14 PCOS patients undergoing ovariectomy or partial ovariectomy were recruited at a University hospital. Immunohistochemical staining of ovarian tissue sections using microscopic evaluation to assess the presence, distribution, and cellular localization of GDF8 and its functional receptors.

Main results and the role of chance: The immunostaining of GDF8, ACVR2A, ACVR2B and ALK5 was detected in a few granulosa cells (GCs) of primary follicles, but not in primordial follicles in normal and PCOS ovaries. The antigens for these proteins were expressed in the oocytes regardless of the developmental stage. Additionally, all these proteins were localized in the GCs and thecal cells (TCs) of different sizes (0-2, 2-5 and 5-10 mm) of antral follicles in normal and PCOS ovaries with a progressively increasing expression pattern (P < 0.05). A significantly higher expression of GDF8 was detected in the GCs than in the matched TCs of 2-5 mm (P < 0.01) and 5-10 mm (P < 0.01) antral follicles in normal and PCOS ovaries. Furthermore, these proteins were also expressed in the luteal cells of the corpus luteum of normal ovaries, with a higher expression in the large luteal cells (P < 0.05). Compared to the normal ovaries, the GCs and TCs of large antral follicles (2-5 mm and 5-10 mm) in PCOS ovaries display a higher expression of GDF8, ACVR2A, ACVR2B and ALK5 (P < 0.05).

Limitations, reasons for caution: This was mainly a descriptive study with no functional studies on the target proteins found.

Wider implications of the findings: The distinct expression of GDF8 and its functional receptors in human ovarian tissues suggest their roles in the growth of oocytes, GCs, TCs and luteal cells. The different expression of GDF8 in antral follicle cells between normal and PCOS ovaries suggest the possible involvement ofGDF8 in the pathogenesis of PCOS.

Trial registration number: null.

P-676　Epiregulin (EPI) promotes the maturation of human denuded germinal vesicle (GV) stage oocyte taken from ≥38 aged women undergoing IVF

S.J. Lee[1], H.C. Kwon[2], G. Yi[1], J.H. Park[1], J.H. Han[1], Y.P. Cheon[1]

[1]Miraewaheemang hospital, IVF clinic, Seoul, Korea- South
[2]Miraewaheemang IVF lab, Ob-gyn, SEOUL, Korea- South

Study question: Epiregulin was known as mediator of LH action for oocyte maturation. Can epiregulin practically trigger maturation of human denuded oocyte?

Summary answer: mRNA levels of epiregulin were 5 times higher in cumulus-cells of young-age-women than old-age-women. Addition of epiregulin in IVM could significantly increase maturation-rate of denuded-oocytes

What is known already: Epiregulin is a recently described member of the EGF family, which also includes amphiregulin (AR), epiregulin (EPI), and betacellulin (BTC). In animal models, epiregulin show higher expression in younger ovary and matured COC than older ovary and immature COC. EGFs including EPI are paracrine mediators that propagate the LH signal throughout the follicles. EGSs promote oocyte maturation by signaling through the EGFR. EGFR are expressed in granulosa ell, cumulus cell, 8 cell embryos, and blastocyst as well as oocyte.

Study design, size, duration: A total of 1224 human germinal vesicle (GV) oocytes obtained from 411 IVF patients were investigated in this study between January 1, 2016 and January 10, 2017. The spontaneous nuclear maturation and cytoplasmic maturation in IVM was investigated in two groups [young-age-group (YG); ≤ 35 years old and old-age-group (OG); ≥ 38 years old)]. Individual healthy GV oocytes were randomly divided into two epiregulin treatment groups (10 ng/ml group and 20 ng/ml group)

Participants/materials, setting, methods: Epiregulin mRNA expression in cumulus cells was investigated by real-time RT-PCR. The epiregulin protein was localized by immunohistochemistry of human ovarian tissues. The cumulus cells

were totally removed for confirming of the presence of GV and nuclear maturation (NM) was determined by examining the oocytes at 24 h for GVBD and polar body extrusion. Oocytes reaching into MII stage were fertilized by ICSI for examining cytoplasmic maturation (CM).

Main results and the role of chance: Epiregulin protein was founded to be localized in the granulosa cells of primary follicles, secondary follicles and preovulatory follicles. mRNA levels of epiregulin were 5 times higher in cumulus cells of younger aged women than cumulus cells of older aged women. When comparing maturation rates from results of younger and older group, higher maturation rate was observed in younger group than older group [nuclear maturation rate(NMR); 37.79% vs 23.99%, cytoplasmic maturation rate (CMR) 55.5% vs 49.2%, p<0.01]]. When comparing maturation rates in studies treated with 20 ng/ml concentration, more GV oocytes could reach to MII oocytes and then could be fertilized in both of younger and older group than no treatment control [NMR (younger control vs younger treatment: 37.79% vs 51.82% and older control vs older treatment: 23.99% vs 51.3%), CMR (younger control vs younger treatment: 55.5% vs 60.2% and older control vs older treatment: 49.2% vs 67.2%).

	control	10 ng/ml	20 ng/ml
Young-age-group			
NMR (%)	37.79	41.67	51.82
Old-age-group			
NMR (%)	23.99	48.92	51.30
Young-age-group			
CMR (%)	55.51	60.00	60.22
Old-age-group			
CMR (%)	55.51	61.20	72.02

Limitations, reasons for caution: Our study was restricted to patients treated by GnRH antagonist protocol. After fertilization, the quality of the embryo was not confirmed.

Wider implications of the findings: Epiregulin mediated oocyte maturation may be important in disorder of androgen excess, such as polycystic ovarian syndrome which is characterized by anovulation, unregulated follicle growth, and the absence of dominant follicles.

Trial registration number: none.

P-677　Prospective randomized study comparing two short IVF protocols for low ovarian reserve

L. Blasco, C. Villas, R. Crecas, I. Pons, S. Fernández-Shaw
URH García del Real, Human Reproduction, Madrid, Spain

Study question: Differences in the effectiveness of short GnRH antagonist cycles with corifollitropin alfa and GnRH agonist cycles with follitropin alfa in low ovarian reserve.

Summary answer: The number of MII, good quality and frozen embryos, and pregnancy rate are slightly higher with GnRH antagonist and corifollitropin alfa. Differences aren't statistically significant.

What is known already: Low ovarian reserve is one of the most difficult challenges in reproduction, related to the poor prognosis and the increasing number of patients with this condition. The combination of GnRH antagonist and corifollitropin alfa is a patient friendly and efficient treatment due to corifollitropin alfa´s extended half-life of 7 days. There is still little literature comparing the efficacy of this protocol against the short agonist protocol with follitropin alpha in patients with low ovarian reserve.

Study design, size, duration: This is a prospective randomized study between September 2015 and January 2017 in patients undergoing their first IVF cycle after their diagnosis of low ovarian reserve (Bologna criteria). All

patients were treated with estradiol valerate and norgestrel (Progyluton®) for a month before ovarian stimulation. Patients (82) were then randomized for treatment with GnRH antagonist (Orgalutran®) with corifollitropin alfa 150 mcg (Elonva®) (group A) or GnRH agonist (Synarel®) with follitropin alfa 300 IU/day (Gonal®) (group B).

Participants/materials, setting, methods: IVF patients in a private clinic were randomized in group A (43) or group B (39). Ovarian stimulation started on day 3. HMG (HMG Lepori®) was added when needed after day 8. Primary endpoint was the number of MII obtained. Secondary variables were days of stimulation, dose of additional HMG, endometrial thickness, number of follicles>13 mm, total oocytes, developing, top quality and frozen embryos, pregnancy rate per cycle and transfer, and cumulative pregnancy rate.

Main results and the role of chance: There were no differences in demographic characteristics of both groups. Mean age was 38.8, BMI 22.4, antral follicle count 6.95, baseline FSH 3.22 mUI/ml and basal estradiol 57.63 pg/ml.

The stimulation in group A lasted 7.85 days vs. 7.28 in B. Additional dose of HMG required was 382.84 UI in group A vs 215.38 IU in B. Two cycles were cancelled in group B (low response) and none in A. The number of follicles>13 mm was 6.19 in group A vs 5.51 in B. Total number of oocytes and MII retrieved was 5.7 and 4.72 in group A vs. 5.05 and 3.66 in B respectively. Number of developing embryos was 2.04 vs 1.49 in group A and B respectively. Top quality embryos (A and B) on day +3 were 0.53 and 0.63 in group A vs. 0.33 and 0.43 in group B respectively. The number of frozen embryos was 0.79 in group A and 0.66 in group B. Pregnancy rate per cycle and per transfer was 25.9% in group A vs. 17.9% and 19.9% in group B. Cumulative pregnancy rate (fresh plus frozen embryo transfers) were 27.9% in group A vs. 20.5% in group B. Differences were not statistically significant.

Limitations, reasons for caution: The sample size of this study limits the conclusions. Studies with larger sample of patients are needed to reach consolidated conclusions in this area.

Wider implications of the findings: Stimulation with GnRH antagonist and corifollitropin alfa might increase the number of mature oocytes, developing embryos, good quality embryos (A/B), frozen embryos and pregnancy rate. Differences found with the use of GnRH agonist and follitropin alpha were not statistically significant, but might be clinically important.

Trial registration number: Pending.

P-678   Circulating irisin and GIP, but not asprosin, underscore the manifestation of polycystic ovary syndrome

T.H. Chin, S.Y. Huang, Y.C. Hsu, Y.K. Soong, C.L. Chang

Chang Gung Memorial Hospital, OB/GYN, Taoyuan, Taiwan R.O.C.

Study question: We hypothesized the newly identified white adipose tissue-derived hepatic glucose release hormone, asprosin, may play a role in the manifestation of polycystic ovary syndrome (PCOS).

Summary answer: PCOS patients have an overtly elevated irisin and glucose-dependent insulinotropic polypeptide (GIP) levels; however, serum asprosin level is not associated with the risk of PCOS.

What is known already: PCOS is characterized by oligo/anovulation, polycystic ovary, and hyperandrogenism. In addition, we have recently reported that aberrant regulation of the muscle-derived irisin and gut-derived GIP is associated with the risk of PCOS, and hyperinsulinism/dyslipidemia in PCOS patients. Asprosin is a glucogenic adipokine derived from the C-terminus of profibrillin, and its level is elevated in humans and animals with insulin resistance. On the other hand, the blockage of asprosin functions has a profound glucose- and insulin-lowering effect. However, its role in the development of PCOS remains to be investigated.

Study design, size, duration: A total of 792 patients diagnosed with PCOS according to the Rotterdam criteria and 138 healthy women were recruited in a period of 4 years.

Participants/materials, setting, methods: Healthy women and PCOS patients were recruited for a metabolic syndrome test at a teaching hospital. Serum levels of asprosin, irisin, GIP, androgens, lipids, insulin, and glucose were measured. HOMA-IR, beta cell function, QUICKI, and ISI Matsuda were calculated to measure insulin sensitivity and insulin resistance.

Main results and the role of chance: As a group, PCOS patients exhibited hyperandrogenism, glucose intolerance, hyperinsulinism, and dyslipidemia. Levels of asprosin, irisin, and GIP were significantly correlated with levels of steroid hormones, glucose, insulin, and lipids in patients ($p < .01$). As reported earlier, we found that serum irisin and GIP levels were significantly elevated in PCOS patients when compared with control women ($p < .001$). However, the serum level of asprosin in PCOS patients was similar to that of healthy volunteers (p = 0.959). This finding hinted that PCOS can be partly attributed to abnormal irisin and GIP metabolism, whereas the asprosin-mediated glucose metabolism does not contribute to the risk of PCOS or the presentation of PCOS-associated metabolic syndrome.

Limitations, reasons for caution: Although we did not observe an aberrant regulation of asprosin in PCOS patients, a role of asprosin in the development of glucose intolerance in select PCOS patients cannot be ruled out.

Wider implications of the findings: While serum levels of the white adipose tissue-derived asprosin correlated with a variety of metabolic biomarkers, asprosin's glucogenic action does not play a critical role in the development of PCOS, or the manifestation of hyperandrogenism, glucose intolerance, hyperinsulinism, and dyslipidemia in PCOS patients.

Trial registration number: Not applicable.

P-679   Agonist trigger is associated with defective progesterone production and decreased LH receptor and VEGF expression in luteal granulosa cells that are partially reversed by hCG

N. Akin[1], G. Bildik[1], A. Seyhan[2], B. Balaban[2], B. Urman[2,3], O. Oktem[2,3]

[1]*Koc University School of Medicine- Graduate School of Health Sciences, Reproductive Biology, Istanbul, Turkey*
[2]*American Hospital, Women's Health Center- Assisted Reproduction Unit, Istanbul, Turkey*
[3]*Koc University School of Medicine, Department of Obstetrics and Gynecology - the division of reproductive endocrinology and infertility, Istanbul, Turkey*

Study question: Is there any difference in luteal function of the granulosa cells of the antagonist IVF cycles triggered with a GnRH agonist vs. hCG?

Summary answer: Yes. Luteal function is defective and luteolysis is enhanced in the granulosa cells of IVF cycles triggered with a GnRH agonist.

What is known already: Pregnancy rate declines in antagonist IVF cycles when ovulation is triggered with a GnRH agonist without hCG support and fresh embryo transfer is performed. But it is understudied at molecular level if luteal function is defective that can explain lower pregnancy rates in these IVF cycles and if hCG administration improves it. We therefore analyzed and compared molecular characteristics of the luteal granulosa cells obtained from good responder patients undergoing antagonist IVF cycles triggered with a GnRH agonist vs. hCG.

Study design, size, duration: A translation research study utilizing ex vivo models of human luteal granulosa cells obtained during oocyte retrieval procedure from IVF patients (IRB approval #: 2016.262.IRB2.123).

Participants/materials, setting, methods: Luteal granulosa cells were obtained from 42 antagonist IVF cycles triggered with recombinant hCG (n = 24) or GnRH agonist leuprolide acetate (n = 18). Steroidogenic enzyme and receptor expressions were analyzed by qRT-PCR. Autophagy, the predominant form of granulosa cell death during luteolysis was investigated with specific markers (LC3B-I/II) on western blot. A subset of the cells from agonist triggered cycles were treated with recombinant hCG (10 IU/mL) to investigate if hCG administration improves their luteal function.

Main results and the role of chance: There was a significant reduction in the viability (56% vs. 94% respectively, p<0.001) along with increased autophagic death of the luteal granulosa cells of agonist triggered IVF cycles compared to hCG triggered ones. The expression of LH receptor, 3β-HSD, progesterone receptor, VEGF-A/B/C and E2/P productions were significantly lower in these cells compared to hCG triggered ones. hCG (10 IU/mL) treatment for 24 h partially reversed these findings and improved progesterone production from these cells compared to their counterparts not treated with hCG.

IVF characteristics

	hCG trigger	Agonist trigger	P	Molecular luteal characteristics	hCG trigger (reference)	Agonist trigger before hCG treatment	Agonist trigger after hCG treatment
Age	33.7 ± 2.5	33.4 ± 1.8	0.32	LH receptor	1[a,c]	0.43 ± 0.01[a,b]	0.81 ± 0.04[b,c]
FSH day3	6.7 ± 1.4	5.8 ± 1.7	0.33	P receptor	1[a,c]	0.51 ± 0.02[a,b]	0.91 ± 0.05[b,c]
E2 day 3	47.7 ± 14	51.3 ± 12	0.27	3b-HSD	1[a,c]	0.34 ± 0.01[a,b]	0.88 ± 0.05[b,c]
E2 hCG day	2082 ± 730	3783 ± 1177	**0.0014**	Aromatase	1[a,c]	0.67 ± 0.04[a,b]	0.28 ± 0.03[b,c]
P hCG day	0.8 ± 0.3	1.2 ± 0.5	**0.03**	VEGF	1[a,c]	0.2 ± 0.01[a,b]	0.6 ± 0.03[b,c]
Total oocyte number	10.2 ± 4.2	15.6 ± 3.2	**0.0012**	In vitro P production (ng/mL)	1581 ± 186[a,c]	164 ± 16[a,b]	466 ± 35[b,c]
Mature oocyte number	8.7 ± 2.6	12.6 ± 2.3	**0.0056**	In vitro E2 production (pg/mL)	2328 ± 147[a,c]	1477 ± 106[a,b]	978 ± 106[b,c]

a:p<0.05, b:p<0.01, c:p<0.01 for aromatase.
a:p<0.001, b:p<0.01, c:p<0.05 for LH and P receptor,3β-HSD, VEGF, in vitro P and E2.

Limitations, reasons for caution: Reduced IVF success after agonist trigger may not be solely attributed to defective luteal function as some other mechanisms might be involved in the process.

Wider implications of the findings: Increased luteolysis along with reduced VEGF expression and in vitro estradiol and progesterone production in luteal granulosa cells after agonist trigger not only provide molecular evidence for lower pregnancy rates in these cycles but also explain why this strategy should be adopted to reduce the risk of OHSS in hyper-responders.

Trial registration number: None

P-680 The usage of Daphaston and hMG protocol in normalovulatory women undergoing controlled ovarian hyperstimulation during IVF/ICSI treatments in combination with embryo cryopreservation

X. Zhu[1], H. Ye[2], Y. Fu[1]

[1]Shanghai Ninth People's Hospital, Department of Assisted Reproduction, Shanghai, China
[2]Shanghai Ninth People's Hospital, Department of Assisted Reproduction-, Shanghai, China

Study question: Was the delivery of dydrogestrone (Daphaston) from the early-follicular phase feasible to suppress the premature luteinizing hormone (LH) surge in normalovulatory women undergoing in vitro fertilization(IVF)/intracytoplasmic sperm injection(ICSI) treatments?

Summary answer: Daphaston can effectively block the premature LH surge in normalovulatory women undergoing controlled ovarian hyperstimulation (COH).

What is known already: Thanks to vitrification techniques, the concept of progesterone blocking estrogen(E$_2$) -induced positive feedback was recently extended to the the early follicular phase. It was known that the bioavailability and the clinical effects differ with different types of progesterone formulation. Hitherto, there has been no investigation evaluating the efficacy of dydrogesterone (brand name: Daphaston), a kind of synthetic progesterone, for the inhibition of premature LH surge during COH.

Study design, size, duration: 250 women were recruited from October 2015 to July 2016 in this prospective trial and participants were allocated randomly to the Daphaston group and the Utrogestan group.

Participants/materials, setting, methods: Normalovulatory patients with 25-40years old were enrolled. Daphaston 20 mg per day or Utrogestan 100 mg per day was taken orally from cycle day3 until the trigger day, with hMG 150/225IU was injected alternatively. When the dominant follicles reached mature, GnRH-a 0.1 mg was used for trigger. Viable embryos were cryopreserved in both protocols for later transfer. The hormone profile, embryo results and pregnant outcomes were analysed exhaustively to discriminate the differences between the two groups.

Main results and the role of chance: Consistent LH suppression was achieved during COH in most patients, none of the participants experienced a premature LH surge. No significant between-group differences were observed in the number of oocytes retrieved (8.22 ± 5.46 vs. 8.8 ± 5.62, P > 0.05), mature oocytes (7.2 ± 4.72 vs. 6.98 ± 4.68, P > 0.05), fertilized oocytes (6.16 ± 4.34 vs. 6.32 ± 4.23, P > 0.05), viable embryos (2.96 ± 2.22 vs. 3.4 ± 2.54, P > 0.05). Furthermore, the clinical pregnancy rate(53.04% vs. 51.7%, P > 0.05), early miscarriage rate(8.2% vs. 11.84%, P > 0.05), implantation rate(38.68% vs. 35.71%, P > 0.05) and cumulative pregnancy rate per woman(66.67% vs. 69.47%, P > 0.05)were also comparable.

Limitations, reasons for caution: A major limitation of our study is the limited number of participants enrolled. In addition, the unfinished FET cycles as well as the limited data on neonatal outcomes also contribute to decrease the power of the study.

Wider implications of the findings: Our findings corroborated the validity of Daphaston in the prevention of premature LH surges. It is of great significance not only in the application, optimization and popularization of progesterone protocol, but also in the establishment of a more patient-friendly stimulation protocol in combination with embryo cryopreservation.

Trial registration number: The trial was registered with the Chinese Clinical Trial Registry (ChiCTR-IOR-15007265).

P-681 Ontogeny of newly described hypo-androgenic PCOS phenotype in infertile women from younger through older ages

D. Albertini[1], V. Kushnir[2,3], S. Darmon[2], Q. Wang[2], L. Zhang[2], D. Barad[2,4], N. Gleicher[2,4,5,6]

[6]Rockefeller University, Stem Cell and Molecular Embryology Laboratory, New York-NY, U.S.A.

Study question: What is the ontogeny over advancing age of women with hypoandrogenic polycystic ovary syndrome (hPCOS)?

Summary answer: hPCOS can already be identified in young women in age-stratum <35 years, and changes in phenotype with age.

What is known already: hPCOS is a surprisingly frequent PCOS phenotype in older infertile women, characterized by disproportionally high anti-Müllerian hormone (AMH) for age and/or follicle stimulating hormone (FSH) levels. It if

further characterized by age-specific hypo-androgenism of adrenal origin and is strongly associated with autoimmunity, especially anti-thyroid autoimmunity.

Study design, size, duration: We extracted data on 708 consecutive infertility patients, and separated them into three age-strata, <35, 36-42, and >42 years. In each stratum, we investigated how levels of AMH and testosterone (T) interrelate between high-AMH (AMH $\geq 75^{th}$ quantile) and normal AMH (25th - 75th quantile) and low-T (total testosterone $\leq$ 19.0 ng/dL), normal-T (19.0-29.0 ng/dL) and high-T (>29.0 ng/dL).

Participants/materials, setting, methods: Routine in vitro fertilization (IVF) cycle outcomes and clinical phenotypes of patients were then compared between groups with AMH and T as variables.

Main results and the role of chance: The hPCOS phenotype already exists in age stratum <35 years. It likely arises from a lean, initially hyper-androgenic PCOS phenotype that develops autoimmune-induced insufficiency of the adrenal zona reticularis (low-T and low-DHEAS) as well as zona fasciculata (low-C) in comparison to controls. Adrenal insufficiency in these patients, thus, concomitantly affects adrenal androgen and glucocorticoid production (mineralocorticoid were not investigated).

Limitations, reasons for caution: Data are based on a relatively small cohort of patients treated at a single fertility center.

Wider implications of the findings: At least partially, this phenotype represents under Rotterdam Criteria PCOS Phenotype-D. The ontogeny of at least some Phenotype-Ds at young ages is, therefore, likely driven by adrenal autoimmunity, supporting the Androgen Excess and PCOS Society which claims that Phenotype-D varies in etiology from classical hyper-androgenic PCOS.

Trial registration number: n/a.

P-682 Inositol treatment of anovulation in women with polycystic ovary syndrome: a meta-analysis of randomised trials

J. Pundir[1], D. Psaroudakis[2], P. Savnur[2], P. Bhide[3], L. Sabatini[2], H. Teede[4], A. Coomarasamy[5], K. Khan[6], S. Thangaratinam[6]

[1]St Bartholomew's Hospital, Centre of Reproductive Medicine, London, United Kingdom

[3]Homerton University Hospital, Fertility and Assisted Reproduction, London, United Kingdom
[4]Monash University, Monash Centre for Health Research and Implementation, Melbourne, Australia
[5]University of Birmingham, Tommy's National Centre for Miscarriage Research, Birmingham, United Kingdom
[6]Barts and The London School of Medicine and Dentistry, Women's Health Research Unit, London, United Kingdom

Study question: Is inositol, a nutritional supplement, associated with improved ovulation, clinical pregnancy and live birth in women with polycystic ovary syndrome?

Summary answer: Inositol is associated with significantly improved ovulation rate and regularised menstrual cycles; however data is limited on clinical pregnancy and no data on live birth.

What is known already: Polycystic ovary syndrome is a common cause of anovulation and infertility, and a risk factor for development of metabolic syndrome and endometrial cancer. Inositol has been reported to improve glycaemic and hormonal factors in women with PCOS.

Study design, size, duration: Systematic review and meta-analysis of randomised controlled trials that evaluated the effects of inositol as an ovulation-induction agent.

Participants/materials, setting, methods: We searched MEDLINE, EMBASE, Cochrane library, ISI conference proceedings, Randomised Controlled Trial Number, Register and Meta-register for RCTs and WHO trials' search portal for relevant studies. We included studies that compared inositol with placebo or other ovulation induction agents. Quality of studies was assessed for risk of bias. We pooled the results using random effects meta-analysis and reported the findings as relative risk (RR) for dichotomous variables, and standardized mean differences (SMD) for continuous estimates.

Main results and the role of chance: We included 10 randomised trials which enrolled a total of 601 women; 8 studies compared myo-inositol or di-chiro-inositol with placebo, one study compared Myo-inositol with Di-chiro-inositol with placebo, one study compared Myo-inositol with metformin, and none compared myo-inositol with clomiphene.

Inositol was associated with significantly improved ovulation rate (RR 2.3; 95% CI 1.1, 4.7; I^2 = 75%) and regularised menstrual cycles (RR 6.8; 95% CI 2.8, 16.6; I^2 = 0%) compared with placebo. Only one study reported on clinical pregnancy rate with inositol compared with placebo (RR 3.3; 95% CI 0.4, 27.1), and one study compared with metformin (RR 1.5; 95% CI 0.7, 3.1). No studies evaluated live birth rates and miscarriage rates as an outcome.

There was a significant reduction in levels of biomarkers such as total androgens, total testosterone, free testosterone and serum DHEA levels with inositol than placebo. The glycaemic parameters of serum fasting insulin, fasting glucose, HOMA and insulin area under the curve and Glucose/Insulin ratio were significantly improved with inositol.

Limitations, reasons for caution: Data on clinical pregnancy rate is limited to only one study. There is no data available on live birth and miscarriage rate. There is a lack of data on long term outcomes.

Wider implications of the findings: Inositol appears to regulate menstrual cycles, improve ovulation and induce metabolic changes in PCOS. If found to be effective with well-designed multicentre trial, inositol supplementation, alongside lifestyle advice could become a first line treatment to improve fertility, and reduce the burden of endometrial hyperplasia and malignancy in women with PCOS.

Trial registration number: NA.

P-683 Krüppel-like factor12 induced granulosa cell apoptosis by repressing SPHK1 expression

C. Zhang, Y. Jiang, C. Huang, M. Zhang, Q. Yan, Z. Diao, L. Ding, H. Sun, G. Yan

The Affiliated Drum Tower Hospital- Medical School of Nanjing University, Reproductive Medicine Center, Nanjing, China

Study question: Does KLF12 regulate granulosa cell apoptosis and follicular atresia?

Summary answer: KLF12 induces granulosa cell apoptosis by transcriptionally repressing SPHK1, which decreases S1P production and the post-translational modification of FOXO1.

What is known already: S1P, formed by the phosphorylation of the sphingisine catalyzed by sphingosine kinase, significantly inhibits granulosa cell apoptosis via PI3K/AKT signaling pathway. Forkhead box Os (FOXOs), a subfamily of forkhead box transcriptional factors, are well known to play essential roles in many cellular processes, including proliferation, differentiation, and apoptosis. It has been reported that oxidative stress induces FOXO1 nuclear translocation and activation in granulosa cells, resulting in increased atretic follicles in mouse ovaries.

Study design, size, duration: KGN and mouse granulosa cells (mGCs) were used to investigate the molecular mechanisms in vitro. We further address the mechanism of granulosa cell apoptosis and follicular atresia through KLF12-mediated SPHK1/S1P pathway in Klf12 knock-in mice model. This is an experiment study lasted one year.

Participants/materials, setting, methods: KGN and mGCs were used as study models. Western blotting, quantitative PCR, cell death detection assay and human S1P ELISA were used to determine the mechanism of granulosa cell apoptosis induced by KLF12.

Main results and the role of chance: We found that the pro-apoptotic stimuli H_2O_2 efficiently promoted KLF12 expressioninKGN cells.KLF12 significantly induced granulosa cell apoptosis and caspase-3 activation. Moreover, Western Blot analysis revealed that the levels of AKT(S473) and FOXO1(S256) phosphorylation decreased and FOXO1 acetylation increased in KLF12-overexpressingKGN cells.In addition, the expression of SPHK1 and the intracellular levels of pro-survival S1Pwere negatively regulated by H_2O_2 and KLF12 in KGN cells.Furthermore, FOXO1 acetylation and pro-apoptotic gene activation induced by H_2O_2 and KLF12 were also reversed by SPHK1 overexpression in KGN cells.

Limitations, reasons for caution: This is an in vitro study utilizing KGN and mGCs. The relationship between KLF12 and SPHK1 should be further evaluated. Furthermore, the results obtained should be confirmed by using ovarian granulosa cell conditional Klf12 knock-in mice in vivo.

Wider implications of the findings: This is an in vitro study utilizing KGN and mGCs. The relationship between KLF12 and SPHK1 should be further evaluated. Furthermore, the results obtained should be confirmed by using ovarian granulosa cell conditional Klf12 knock-in mice in vivo.

Trial registration number: None.

P-684   Study of Foxo3a, FoxL2, p27 and PTEN gene expression in ovarian tissue in women with premature ovarian insufficiency (POI) and polycystic ovary syndrome (PCOS)

N. Thanatsis, V. Koika, N. Georgopoulos, G. Decavalas, A. Kaponis

Patras University School of Medicine, Obstetrics & Gynaecology Department, Patras, Greece

Study question: Is the expression of Foxo3a, FoxL2, p27 and PTEN altered in ovarian tissue in women with premature ovarian insufficiency (POI) and polycystic ovary syndrome (PCOS)?

Summary answer: Foxo3a and FoxL2 are under-expressed in ovarian tissue in women with POI compared to controls; however, no such pattern was identified in women with PCOS.

What is known already: Studies in mutant mouse models have revealed that loss of Foxo3a, FoxL2, p27 and PTEN (suppressors of follicular activation) function may cause global activation of the primordial follicle pool and depletion of the follicle reserve, resulting in POI. Likewise, alterations of follicle function in PCOS ovaries include increased primordial follicle activation, suggesting a possible similar genetic background for these disorders. FoxL2 is the only one of the four investigated genes, whose mutations is linked with POI in humans (Blepharophimosis-ptosis-epicanthus syndrome and cases of non-syndromic POI).

Study design, size, duration: The expression of Foxo3a, FoxL2, p27, PTEN genes was studied in ovarian tissue obtained from women diagnosed with POI, versus women with PCOS and versus healthy control women with normal menstruation. The patients were recruited in the Gynaecology Department of Patras University Hospital between the years 2014 and 2016 (the study is ongoing). The ovarian biopsy was performed during planned or acute laparoscopic pelvic surgery for benign disorders. All participants gave written informed consent.

Participants/materials, setting, methods: Ovarian tissue was obtained from five women with POI, three women with PCOS and six age matched healthy controls. The gene expression of Foxo3a, FoxL2, p27, PTEN and beta-Actin (housekeeping gene) was studied using reverse transcription PCR and real time PCR. The quality of the PCR reactions was confirmed by melting curve analysis and the $2^{-\Delta\Delta Ct}$ algorithm was used to analyze the relative expression of the target genes in comparison to the housekeeping gene beta-Actin.

Main results and the role of chance: The preliminary results of our study revealed a statistically significant 2.66-fold decrease in FoxL2 gene expression in ovarian tissue in women with POI compared to healthy controls (p = 0.029). Moreover, statistically significant under-expression of Foxo3a was demonstrated in the POI group compared to both PCOS patients (p = 0.0436) and controls (p = 0.0131). Our study did not identify a statistically significant difference in FoxL2 and Foxo3a expression between PCOS patients and controls (p >0.05 for both). As far as PTEN and p27 gene expression is concerned, no statistically significant difference between POI patients and control patients was shown; however, a statistically significant decrease in PTEN and p27 gene expression was revealed in POI patients compared to PCOS patients (p = 0.0286 and p = 0.0083 for PTEN and p27 expression respectively).

Limitations, reasons for caution: Although we managed to achieve a ratio of POI patients and healthy controls of nearby 1/1, the study size was small. The current presentation contains preliminary data, as the study is still ongoing.

Wider implications of the findings: Our findings support literature data regarding the role of FoxL2 and Foxo3a in pathogenesis of POI not only in mice but also in humans. As suppressors of primordial follicle activation and genetic causes of POI, FoxL2 and Foxo3a may prove to be of great diagnostic-therapeutic value in the future.

Trial registration number: Not Applicable.

P-685   L-carnitine supplementation increases the expression of SDHA gene in granulosa cells and improves oocyte maturation and embryo quality in aging women undergoing IVF

C.H. Kim[1], Y. Jeung[2], J.W. Moon[3], S.H. Kim[1], H.D. Chae[1], B.M. Kang[1]

[1]*Asan Medical Center- University of Ulsan Medical College, Obstetrics and Gynecology, Seoul, Korea- South*
[2]*Asan Medical Center, Obstetrics and Gynecology, Seoul, Korea- South*
[3]*M Fertility Center, Obstetrics and Gynecology, Seoul, Korea- South*

Study question: Could the supplementation of L-carnitine improve controlled ovarian stimulation (COS) and IVF results and mitochondrial function in granulosa cells in aging women undergoing IVF?

Summary answer: The supplementation of L-carnitine Increases the numbers of mature oocytes and good quality embryos and *SDHA* expression in granulosa cells in aging women undergoing IVF.

What is known already: Female fertility decreases rapidly after age 37. Diminished ovarian reserve is the major contributing factor for infertility with aging. Ovarian aging has shown to be accompanied by mitochondrial dysfunction. The processes of oocyte maturation require energy, which is provided by mitochondria. Carnitine plays a critical role in energy production. It transports fatty acids into the mitochondria so they are oxidized to produce energy.

Study design, size, duration: This retrospective cohort study included 102 consecutive IVF/ICSI cycles in 102 infertile patients over 37 years who were given L-carnitine at a dose of 330 mg twice a day orally for 60-90 days before and during COS period (study group, n = 53) or were not given L-carnitine (control group, n = 49) in our center between January 2015 and March 2016.

Participants/materials, setting, methods: If patients underwent two or more cycles of IVF/ICSI during the study period, charts corresponding to the 1st IVF/ICSI cycle were reviewed and data of other IVF/ICSI cycles except 1st cycle were excluded from this analysis. The expression of *SDHA* mRNA in granulosa cells obtained during oocyte pick-up was analyzed by realtime RT-PCR. Chi-square test and Fisher's exact test were used to compare fraction. Statistical significance was defined as P < 0.05.

Main results and the role of chance: There were no significant differences in patient's characteristics between the study and control groups. Total dose and days of gonadotropins used for COS were similar between the two groups. The number of oocytes retrieved was also comparable. However, the numbers of mature oocytes, fertilized oocytes and grade I or II embryos were significantly higher in the study (p < 0.001, p < 0.001, p = 0.003, respectively). Relative amount of *SDHA* mRNA in the ganulosa cells was significantly higher in the study group of 9.44 ± 3.94 compared with 4.10 ± 2.36 in the control group (p < 0.001). Clinical pregnancy rate seemed to be higher in the study, but the difference did not achieve the statistical significance.

Limitations, reasons for caution: This study may have a limitation to assess the efficacy of L-carnitine due to a small number of sample available and its retrospective nature. In addition, no study has been conducted on the appropriate dose of L-carnitine for infertile women with advanced age.

Wider implications of the findings: L-carnitine supplementation before and during COS period is a feasible and effective adjuvant treatment to improve the oocyte and embryo quality through the mitochondrial activation in aging women undergoing IVF.

Trial registration number: None.

P-686   Deficiency of adrenomedullin 2/intermedin (ADM2/IMD) in oocytes leads to reduced fertility in mice

C.L. Chang, T.H. Lee, S.Y. Huang, Y.C. Hsu, T.H. Chin , Y.K. Soong

Chang Gung Memorial Hospital, OB/GYN, Kweishan Taoyuan, Taiwan R.O.C.

Study question: We hypothesized that oocyte-derived adrenomedullin 2/ intermedin (ADM2 or IMD) could play a critical role in the regulation of ovarian folliculogenesis and fertility.

Summary answer: Although oocyte-specific knockout of *Adm2* significantly increased ovulated oocytes after superovulation treatment, ADM2 deficiency led to significant reduction of fertility.

What is known already: ADM2 and related adrenomedullin (ADM) peptides signal through the heterodimeric CLR/RAMP1, 2, and 3 receptors. These peptides have been shown to play a role in the maintenance of uterine blood flow and cardiovascular adaptation during pregnancy. In addition, ADM is essential for normal embryo implantation and embryogenesis. On the other hand, ADM2 has been shown to represent an oocyte-derived ligand that regulates cell interactions in cumulus-oocyte complexes (COCs), and the suppression of ADM2 signaling in rat ovaries *in vivo* leads to oocyte atresia and aberrant cell cycle progression in follicular cells.

Study design, size, duration: To test the hypothesis that ADM2 plays a role in the regulation of ovarian folliculogenesis and fertility, we generated mice with oocyte-specific knockout of *Adm2*. These mice were generated by crossing mice carry a LoxP-flanked *Adm2* exon 3 transgene cassette and mice with a zona pellucida 3 (Zp3) promoter-Cre recombinase transgene. The Zp3-Cre transgene allows specific deletion of *Adm2* exon 3 in growing oocytes prior to the completion of the first meiotic division.

Participants/materials, setting, methods: Mice were bred to generate animals that have heterozygous or homozygous deletion of the *Adm2* gene in oocytes. The expression of *Adm2* transcript was determined by quantitative PCR. Female mice with wild-type, heterozygous, or homozygous genotypes were stimulated with gonadotropins at 28 days of age to induce synchronized ovulation. The number of fertilized and unfertilized oocytes in oviducts was determined after manual dissection.

Main results and the role of chance: The heterozygous female mice are fertile and appear to have no reproductive abnormality. On the other hand, mice with homozygous deletion have significantly reduced fertility, perhaps due to aberrant embryogenesis ($p < .01$). Stimulation with gonadotropins led to superovulation in all genotypes of animals. Interestingly, the number of ovulated oocytes from heterozygous and homozygous animals was significantly higher than that of wild-type littermates ($p < .01$), and this increase appeared to be gene copy-dependent. In addition, we found that a large fraction of fertilized eggs from homozygous animals were arrested at early stages of development.

Limitations, reasons for caution: Although mice with ADM2 deficiency in oocytes have increased number of ovulated oocytes following superovulation, they actually have reduced fertility. Therefore, the exact roles of oocyte-derived ADM2 in the process of folliculogenesis and embryogenesis remain to be fully vetted.

Wider implications of the findings: Our data strongly implicate that, in addition to functioning as an anti-apoptosis factor in COCs, ADM2 may play a follicular compartment-specific regulatory role in the regulation of follicle recruitment, and act as a survival factor during early embryo development.

Trial registration number: Not applicable.

P-687   Coasting revisited: Duration and drop in Estradiol levels affects IVF outcome

L. Ugwumadu, E. Charalambous, P. Nick, E. Kalu

Kingston Hospital NHS Trust, Assisted Conception Unit, Kingston, United Kingdom

Study question: To assess the effect of percentage drop in Estradiol (E_2) level and duration of coasting on IVF outcomes.

Summary answer: The overall LBR was 44%. However, this is compromised when coasting is prolonged (>7days) and the percentage of E2 drops is >60%.

What is known already: Ovarian hyperstimulation syndrome (OHSS) is a complication of fertility treatment with varying severity. The combined incidence of moderate or severe OHSS ranges from 3.1 to 8%. Serum estradiol (E2) measurement remains an integral part of cycle monitoring in most IVF treatments.The pattern of rise in E2 is a useful tool in the identification of both women at risk of OHSS and poor responders. Coasting is a strategy to minimise severe OHSS. It involves withdrawing exogenous gonadotrophins and withholding the hCG trigger until the serum estradiol level decreases to a 'safer' level.

Study design, size, duration: Data was collected prospectively on 97 IVF cycles where coasting occurred for 2 or more days between February 2010 to March 2016. The decision to coast was based on E2 levels,and the hCG trigger was administered when the serum E_2 level was <15000 pmol/l. Data was analysed based on the numbers of days of coasting and the percentage drop in E_2 levels. The primary outcome was Live Birth Rate (LBR).

Participants/materials, setting, methods: 97 coasted cycles were analysed. The primary outcome measure was Live birth rate and secondary outcomes were the mean number of oocytes retrieved, fertilised embryos, overall fertilisation and implantation rate. Outcome measures were analysed based on the number of days of coasting and the percentage drop in E_2 levels.Statistical analysis was performed using Microsoft Excel. Mann-Whitney test and Fisher exact test or chi-squared test were used for analysis of effect respectively.

Main results and the role of chance: The mean age, E_2 at coasting, peak E_2 and E_2 at HCG trigger were 34.82 ± 3.79, 18722 ± 6406 pmol/l, 26071 ± 7582 pmol/l and 13299 ± 4750 pmol/l respectively.Coasting ranged between 2-11 days(mean 3.64 ± 1.68). The mean number of oocytes retrieved, fertilised embryos, overall fertilisation, implantation and LBR were 10.62 ± 5.53, 6.80 ± 4.47, 94%, 56% and 44% respectively. Coasting days divided into three groups: group I (n = 54) –coasting <3 days only, group II (n = 37) coasting ≥4–6 days and group III (n = 6) ≥7 days. LBR in group I, II and III were 51.85%, 37.82% and 16.67% (P = 0.04) respectively. Data was further analysed to determine the effect of percentage change in E_2. Group A (1-50%), Group B (51-60%), Group C(>61%). LBR were 47.06%, 53.33% and 35.48% respectively (P = 0.02).

Limitations, reasons for caution: None

Wider implications of the findings: Several papers have suggested a significant compromise with duration of coasting beyond 2.6 days. However, these studies are limited by the varying methods and outcome measure. Our findings are in keeping with an earlier retrospective study which showed that coasting for up to 8 days did not affect LBR.

Trial registration number: Not applicable.

P-688   Existence and physiological significance of osteopontin in human follicular fluid and blood during the in vitro fertilization cycle

Y. Kuwabara, S. Ono, K. Watanabe, M. Yonezawa, T. Ichikawa, S. Akira, T. Takeshita

Nippon Medical School, Obstetrics and Gynecology, Tokyo, Japan

Study question: This study was aimed at investigating the presence and physiological significance of osteopontin (OPN) in follicular fluid and blood in the human ovarian cycle.

Summary answer: The blood OPN concentration was positively correlated with OPN and VEGF concentration in follicular fluid irrespective of the blood sampling period.

What is known already: OPN is a secreted glycosylated phosphoprotein that is distributed in a wide variety of tissues and involved in various physiological and pathological processes. Recently, we have reported that Opn expression is markedly upregulated in mouse ovarian granulosa cells (GCs) in response to a gonadotropin surge through epidermal growth factor receptor signaling. By using cultured GCs, we further demonstrated experimental evidence showing that OPN promotes progesterone synthesis and VEGF production through PI3K/AKT signaling during the early luteal phase (Kuwabara et al., Journal of Endocrinology, 2015).

Study design, size, duration: Twenty-two women undergoing in vitro fertilization with a minimal stimulation protocol with clomiphene from February to May 2016 participated in this study. Sample collection was performed on the third day of withdrawal bleeding (a), 2 days before oocyte retrieval (b), and on the day of oocyte retrieval (c).

Participants/materials, setting, methods: Blood was collected in Spitz tubes containing EDTA and centrifuged at 2500 rpm for 15 min. The supernatant was transferred to a separate container and stored at -70°C until measurement. The follicular fluid collected during oocyte retrieval was also prepared in the same way. The OPN concentration in each specimen and the VEGF concentration in follicular fluid were measured by using ELISA, and the statistical correlation between each specimen was examined.

Main results and the role of chance: The plasma OPN concentrations were as follows: (a) 372.3 ± 69.3 ng/mL (median: 287.9 ng/mL), (b) 357.2 ± 63.0 ng/mL (median: 288.5 ng/mL), and (c) 381.5 ± 73.3 ng/mL (median: 278.4 ng/mL), with no significant difference between groups. The OPN concentration in follicular fluid was 106.2 ± 13.4 ng/mL (median: 70.94 ng/mL), and a positive correlation was found between plasma samples

(a: r = 0.48 p < 0.01, b: r = 0.51 p<0.02, c: r = 0.49 p<0.05). No correlation was found between VEGF concentration in follicular fluid and predictive factors of ovarian hyperstimulation syndrome (OHSS), including anti-Müllerian hormone, estradiol, and luteinizing hormone/follicle-stimulating hormone in serum; however, the follicular fluid VEGF concentration was positively correlated with the plasma OPN concentration (a: r = 0.65 p<0.01, b: r = 0.79 p<0.01, c: r = 0.77 p<0.01).

Limitations, reasons for caution: Because the sample size of this study is small, further investigation with more patients is necessary to confirm our preliminary findings.

Wider implications of the findings: OPN is considered to be involved in ovarian VEGF production, as suggested by the mouse experiment. Because the serum OPN concentration showed a positive correlation with the follicular fluid VEGF concentration at oocyte retrieval, OPN is suggested to be an independent clinical marker for evaluating the risk of OHSS.

Trial registration number: Not appliacable.

P-689   Ovarian reserve, as assessed by measuring serum anti-Müllerian hormone levels, declines more rapidly than expected in a longitudinal cohort of rheumatoid arthritis patients

J. Brouwer[1,2], R. Dolhain[2], J. Hazes[2], N. Erler[3], J. Visser[4], J. Laven[5]

[1]Erasmus MC- University Medical Center Rotterdam, Division of Reproductive Medicine - Department of Obstetrics & Gynaecology, Rotterdam, The Netherlands
[2]Erasmus MC- University Medical Center Rotterdam, Department of Rheumatology, Rotterdam, The Netherlands
[3]Erasmus MC- University Medical Center Rotterdam, Department of Biostatistics, Rotterdam, The Netherlands
[4]Erasmus MC- University Medical Center Rotterdam, Department of Internal Medicine, Rotterdam, The Netherlands
[5]Erasmus MC- University Medical Center Rotterdam, Division of Reproductive Medicine- Department of Obstetrics & Gynaecology, Rotterdam, The Netherlands

Study question: Does ovarian function, as measured longitudinally by serum anti-Müllerian hormone (AMH) levels, show a faster decline in women with chronic inflammation, like rheumatoid arthritis (RA)?

Summary answer: In RA, serum AMH levels declined faster over time than in controls, indicating that chronic inflammation compromises the ovarian function.

What is known already: A compromised ovarian function has been described in patients with type II diabetes mellitus and in young girls with cancer, suggesting that an unhealthy soma results in an early decline of ovarian reserve. It is unknown whether the same holds true for chronic inflammation. RA is an example of a chronic inflammatory disease, which is known to compromise fertility, and often affects women in their fertile age. Serum AMH levels are a proxy for the size of the ovarian follicle pool, and as such are the most reliable predictor of the age at which menopause sets in.

Study design, size, duration: In a prospective nationwide cohort on reproduction in RA (PARA study, 2002 – 2008, N = 297), 128 (43%) women were re-assessed in 2015-2016, 10.7 ± 1.8 years after the first study visit. From the original PARA study only serum samples from the preconception period and 6 months postpartum were used.

Participants/materials, setting, methods: All women had established RA according to the 1987 revised American College for Rheumatology (ACR) criteria. Serum AMH levels were measured using the pico AMH assay (provided by Ansh Labs, Texas, USA). AMH levels were compared to a cross-sectional healthy control group (n = 554) (Lie Fong 2012). A linear mixed model was built to assess the effect of RA related clinical factors on the decline of serum AMH levels over time.

Main results and the role of chance: 128 women were re-assessed at a mean age of 42.6 ± 4.4 years, with a median disease duration of 15.8 (IQR 12.7 – 21.5) years. The mean age at baseline was 31.8 ± 3.8 years. The participants appeared to be a more fertile selection of the original PARA cohort, with less participants (4.7%) than non-participants (22%) being nulliparous at the end of the original PARA study, and less smokers in participants (7%) than in non-participants (17%). Nonetheless, at follow-up, more patients had AMH levels below the 10th percentile of controls (39%; 95%CI 31–48%), compared to their

AMH levels at baseline (16% (95%CI 9.3–22%) under the 10th percentile of controls). The linear mixed model showed a significant effect of age, but no significant effect of RA related factors on the decline of serum AMH levels over time.

Limitations, reasons for caution: This study was performed in a selected population (response rate 43%). Since participants appeared to be more fertile, the steeper AMH decline may be even more pronounced in the total RA population. The use of a conversion factor for AMH levels in the healthy control group should be interpreted cautiously.

Wider implications of the findings: The findings in this study support the idea that also in chronic inflammatory conditions, the body is less fit for reproduction, resulting in a faster decline of ovarian function and probably an earlier age at menopause. Optimal treatment of chronic inflammation in an early phase may improve long-term women's health.

Trial registration number: NA.

P-690   The effect of 6 months weight -loss/maintenance on anthropometric, biochemical and psychological profile in Lebanese PCOS women: A prospective randomised control study

C. Hmedeh[1], G. Ghazeeri[2], L. Tinworth[1], I. Tewfik[1]

[1]University of Westminster, Human Nutrition, London, United Kingdom
[2]American University of Beirut Medical Center, Obstetrics and Gynecology, Beirut, Lebanon

Study question: Does a 6 months weight -loss/maintenance improves anthropometric, biochemical and psychological profile in Lebanese PCOS women?

Summary answer: Conclusion: A 6-month hypo-caloric weight-loss/maintenance program has shown to be effective in Lebanese PCOS women by decreasing their weight and improving their health status.

What is known already: Polycystic ovarian syndrome (PCOS), the most common cause of anovulatory infertility, is a disorder of the endocrine system affecting 5-10% worldwide of women in their reproductive age. Nowadays, PCOS is a major public health concern accompanied with different metabolic and endocrine abnormalities. Obesity usually co-exists with PCOS and leads to complications such as increased androgen level, hirsutism, infertility, anovulation, type 2 diabetes, and cardiovascular diseases. Research for possible treatments and intervention options leading to disease improvement can be beneficial to treat these complications.

Study design, size, duration: A randomized prospective public health nutrition intervention was conducted. Seventy eight PCOS patients were subject to food frequency, physical and psychological activity (BDI-II and GAD-7) questionnaires, two 24-hour-recalls on weekdays and weekends, and biochemical analysis at baseline, 3 and 6 months from baseline. The duration for this study is 6 months.

Participants/materials, setting, methods: Setting: Patients were recruited from obstetrics and gynecology clinics at the American University of Beirut Medical Center (AUB-MC), Lebanon. **Subjects:** PCOS women grouped as: Group1: overweight/obese PCOS patients receiving weight-loss program and lifestyle modification, Group2: overweight/obese PCOS controls, Group3: Lean PCOS controls and Group4: lean PCOS patients receiving weight maintenance nutritional program and lifestyle modification.

Main results and the role of chance: After six months, 7% weight-loss was achieved in overweight/obese intervention groups and weight maintenance in lean intervention groups. There was a significant reduction in waist (-4.2 cm (±5.6)) and hip circumference (-3.1 cm (±3.5)) with P< 0.001.There was no significant (P > 0.001) improvement in biochemical analysis (fasting blood sugar, CRP (C-reactive protein), LDL-C (Low density lipoprotein cholesterol), HDL-C(High density lipoprotein cholesterol), TG (Triglycerides), total cholesterol, fasting insulin, total testosterone, Vitamin D). Physical activity increased (3.1 hours/week (±1.5)). Anxiety and depression scores decreased (BDI-II (Beck depression inventory) and GAD-7 (Generalized anxiety disorder assessment)); -0.8 (±0.8) and -0.7 (±0.7) with P < 0,001 compared to controls.

Limitations, reasons for caution: This is a single centered (one medical center as a setting of the study) study done at the capital of Lebanon, which does not cover patients with different socio-economic and cultural status.

Wider implications of the findings: Those who significantly lost weight demonstrated improvement in their reproductive and psychological abnormalities. The weight loss in this study Intervention groups depicted a deviation to a healthy lifestyle that affected their PCOS features. All PCOS patients should seek nutritional intervention in order to prevent further metabolic and reproductive complications.

Trial registration number: N/A.

P-691　New additional biomarker proposal for the diagnosis of polycystic ovary syndrome through serum midkine cut-off value with anti-Müllerian hormone in Turkish population: A prospective study

M. Erguven[1], T. Irez[2], S. Kahraman[3], C. Pirkevi[3], G. Dundar[2], A. Bilir[4]

[1]İstanbul Aydın University- Faculty of Medicine, Department of Medical Biochemistry, İstanbul, Turkey
[2]Biruni University- Faculty of Medicine, Department of Histology and Embryology, İstanbul, Turkey
[3]İstanbul Memorial Hospital, Assisted Reproductive Techniques and Reproductive Genetics Center, İstanbul, Turkey
[4]İstanbul Aydın University- Faculty of Medicine, Department of Histology and Embryology, İstanbul, Turkey

Study question: Can midkine (MK) be used as a new additional biomarker with an old conventional biomarker anti-Müllerian hormone (AMH) for the diagnosis of polycystic ovary syndrome in Turkish population?

Summary answer: MK levels were increased in concomitant with AMH levels at the PCOS cases, thus it can be a accepted as a new additional biomarker.

What is known already: The abnormally elevated AMH levels in serum and follicle fluid of PCOS patients participate in the major steps of the anovulation, and are related to pathogenesis and pathophysiological characteristic of PCOS. MK, a heparin-binding growth factor/cytokine, promotes growth, survival, migration and gene expression of various target cells and play roles in many diseases. In normal adult tissues, MK expression is highly restricted. MK has a mitogenic effect on primordial germ cells and retionic acid promotes cytoplasmic maturation of oocytes through MK promoter in vivo models. The role of MK in infertility is still understudied.

Study design, size, duration: A prospective study of 220 women suffered from PCOS who were scheduled for intracytoplasmic sperm injection (ICSI) at hospital infertilityclinic during 2011-2016.

Participants/materials, setting, methods: This study included 130 PCOS patients and 90 proven fertile women aged 24-41 years. Serum levels of folicule stimulating hormone (FSH) and luteinizing hormone (LH) with the radioimmunoassay, estrodiol 2 (E2), prolactin (PRL) with the immunoradiometric test, AMH and MK levels with the enzyme-linked immunosorbent assay (ELISA) on cycle day 3 and body mass index (BMI), MII oocyte and fertilisation rates were all evaluated by using

ANOVA test and p<0.05 was considered statistically significant.

Main results and the role of chance: Mean values of hormone and MK levels for the control group (fertile women) were FSH 5.7 mIU/ml, LH 3.2 mIU/ml, E2 39.1 pg/ml, PRL 15.67 ng/ml, AMH 3 ng/ml and MK 250 pg/ml. For the PCOS group, these were FSH 5.4 mIU/ml (p<0.05), LH 5.6 mIU/ml (p<0.0001), E2 41.9 pg/ml (p<0.05), PRL 15.44 ng/ml (p>0.05), AMH 5.83 ng/ml (p<0.00001) and MK 420 pg/ml (p<0.000001). These data can be summarized as follows that LH, E2, AMH and MK levels were increased at the PCOS group, but FSH and PRL levels were found decreased. Consequently, the serum MK cut-off value was determined as 420 pg/ml for PCOS. BMI was similar between groups as 26.8 kg/m^2 and 27.3 kg/m2 for the control group and the PCOS group, respectively (p>0.05). MII oocyte rate was lower at the PCOS group (45 %) than at the control group (74 %) (p< <0.00001). The lowest fertilisation rate was determined at the PCOS group as 50 %, where it was 93 % at the control group (p<0.000001).

Limitations, reasons for caution: Only patients enrolled for ICSI were included in this study and the number of the study participants were also low. These may limit the generalizability of these findings.

Wider implications of the findings: The results of this study are in agreement with most previously published studies about the PCOS and AMH. No study was found about the role of MK in PCOS cases as well as its' mechanism of action with AMH. This data can be used in clinical practice internationally.

Trial registration number: This study with a trial registration number of 3/2011 was approved by ethical committee of Istanbul University, Cerrahpasa Faculty of Medicine.

P-692　FP receptor antagonist, OBE002, inhibits both PGF2α- and OT-induced contractions of human pregnant myometrium in vitro

S.H. Kim[1], L. Riaposova[1], O. Pohl[2], A. Chollet[2], J.P. Gotteland[2], A. Hanyaloglu[3], P. Bennett[1], V. Terzidou[1]

[1]Imperial College London, Surgery and Cancer- Parturition Research Group, London, United Kingdom
[2]ObsEva SA, Chemin des Aulx 12- CH-1228 Plan-les-Ouates, Geneva, Switzerland
[3]Imperial College London, Surgery and Cancer- GPCR Research Group, London, United Kingdom

Study question: To demonstrate the effect of the FP receptor antagonist, OBE002, on suppressing $PGF_{2\alpha}$-induced myometrial contractions, and to investigate its potential effect on OT-induced contractions.

Summary answer: OBE002 showed significant, dose-dependent inhibition of both $PGF_{2\alpha}$- and OT-induced contractions of human myometrium. These findings suggest a possible interaction between FP and OT receptors.

What is known already: Prostaglandins play key roles in the onset of labour. $PGF_{2\alpha}$ has been shown to exert uterotonic effect via the FP receptor, and the contractile effects of OT have been reported to be partially regulated by $PGF_{2\alpha}$ by augmenting receptor expression. Antagonism of FP has been suggested to inhibit contractions in isolated sheep and human myometrium and to open BK Ca^{2+} channels. To demonstrate the tocolytic ability of OBE002, a novel FP receptor antagonist, it is critical to evaluate its effects in vitro.

Study design, size, duration: The inhibitory effects of OBE002 in both $PGF_{2\alpha}$- and OT-induced myometrial contractions were investigated in human pregnant myometrial strips. Myometrial tissues from 6 different patients were used for each experimental condition. All experiments were performed within 24 hours of tissue collection to ensure tissue viability.

Participants/materials, setting, methods: Myometrial strips were obtained from non-labouring women undergoing caesarean section at term. Baseline measurement of contraction frequency, peak, duration, work per contraction and total work were made using a DMT Myograph 800 MS. OBE002 was added (6, 60, 600 or 6000 nM) and effects upon spontaneous contractility measured in the next 10 min. Then agonists ($PGF_{2\alpha}$/OT) were added at 10, 100, and 1000 nM or 1, 10, and 100 nM, respectively, at 10 min intervals and contractility was recorded.

Main results and the role of chance: OBE002 suppressed the effect of $PGF_{2\alpha}$ on myometrial contraction ratio and peak amplitude in a dose-dependent manner and had a significant overall effect on the total work done at 600 nM (p<0.05 vs DMSO, ANOVA) and 6000 nM (p<0.01 vs DMSO, ANOVA). OBE002 also exerted a dose-dependent uterorelaxant effect on OT-induced contractions, affecting the contraction ratio and peak amplitude. A significant relaxant effect on OT-induced contractility was observed on addition of 6000 nM OBE002 (p<0.05 vs DMSO, ANOVA). Spontaneous myometrial contractility was reduced in presence of OBE002, however, this did not reach significance.

Limitations, reasons for caution: The mechanisms involved in the inhibition of $PGF_{2\alpha}$-induced myometrial contractions by OBE002 remains to be determined. In order to elucidate the exact link between FP and OT receptors, further experiments are required.

Wider implications of the findings: These studies confirm the effect of OBE002 as an FP antagonist in human tissues and provide evidence for receptor crosstalk between OT and FP receptors. Our findings raise a potential combinational therapeutic target for the management of term and preterm labour via the manipulation of the differential GPCR interactions/crosstalk.

Trial registration number: N/A.

P-693 GnRH agonist (GnRHa) trigger for final oocyte maturation in fresh embryo transfer IVF/ICSI cycles – a systematic PRISMA review and meta-analysis

P. Humaidan[1], S. Esteves[2], T. Haahr[1], M. Roque[3]

[1]The Fertility Clinic - Skive Regional Hospital Faculty of Health- Aarhus University, The Fertility Clinic Skive- Skive Regional Hospital- Department of Clinical Medicine- Health- Aarhus University, Skive, Denmark
[2]Androfert- Andrology and Human Reproduction Clinic- 13075-460 Campinas- SP- Brazil, Department of Surgery- University of Campinas UNICAMP- Campinas- SP- Brazil, Campinas, Brazil
[3]ORIGEN, ORIGEN – Center for Reproductive Medicine- Rio de Janeiro- RJ- Brazil, Rio de Janeiro, Brazil

Study question: Compared to hCG trigger, does GnRHa trigger and modified luteal LH activity support (LLS) reduce live birth rate (LBR) in IVF patients undergoing fresh transfer?

Summary answer: There was no significant difference in LBR when GnRHa trigger followed by modified LLS was compared to hCG trigger in fresh transfer cycles.

What is known already: The use of GnRHa as a final oocyte maturation trigger in oocyte donation and elective frozen embryo transfer cycles is well established due to lower OHSS rates than hCG trigger. Notwithstanding, a recent Cochrane meta-analysis concluded that GnRHa trigger is associated with reduced LBRs and increased miscarriage rates in fresh autologous IVF cycles compared to hCG. However, the evidence is not unequivocal, and some studies have found promising reproductive outcomes among couples undergoing GnRHa trigger and LLS. Due to the clinical implications of such intervention, the role of GnRHa trigger and LLS in fresh IVF cycles needs to be clarified.

Study design, size, duration: We conducted a systematic review and meta-analysis of randomized clinical studies published in English, as of December 14th 2016. An electronic search was performed within the PubMed and EMBASE databases, including a search within the references of relevant articles. The PRISMA statements for systematic reviews and meta-analysis were followed. We used the Grading of Recommendations Assessment, Development and Evaluation (GRADE) for assessing the quality of the evidence of all outcome measures.

Participants/materials, setting, methods: Participants were patients submitted to IVF/ICSI cycles using GnRH antagonist co-treatment undergoing fresh embryo transfer. The intervention was GnRH agonist trigger followed by modified LLS. The comparator was hCG trigger. The primary outcome measures were LBR and OHSS rate. The secondary outcome measures included the number of oocytes retrieved, M2 oocytes, the number of good quality embryos, clinical and ongoing pregnancy rates, and miscarriage rates. We conducted a thorough bias evaluation of the included studies.

Main results and the role of chance: A total of five publications met the selection criteria and were included in the qualitative / quantitative analysis, with a total of 859 patients. There was no statistically difference in live birth rate when comparing GnRHa to hCG group (Odds Ratio [OR] 0.77, 95% confidence interval [CI] 0.56, 1.05). Both ongoing and clinical pregnancy rates were close to unity, with an OR 0.96 (95% CI 0.64, 1.34; I^2 = 50%) and OR 0.98 (95% CI 0.73, 1.30; I^2 = 25%), respectively. OHSS were seen in a total of 4/413 cases in the GnRHa group compared to 7/413 in the hCG group (OR 0.48, 95% CI 0.15, 1.60). For miscarriage rate, a non-significant difference was observed between groups (OR 1.28; 95% CI 0.73-2.22). No significant differences were seen regarding number of oocytes retrieved, M2 oocytes and number of good quality embryos.

Limitations, reasons for caution: GRADE evidence was low regarding OHSS and very low regarding LBR. Caution should be applied when examining studies concerning LLS after GnRHa trigger in fresh transfer cycles. While earlier studies were designed as 'proof of concept', recent trials have optimized the method, albeit not adequately powered to draw firm conclusions

Wider implications of the findings: The GnRHa trigger group seems to have a slight, albeit non-significant reduction in the ORs for LBR; however, the most recent RCTs show ORs close to unity as regards the LBRs. The evidence suggests that GnRHa trigger is non-inferior to hCG regarding reproductive outcomes in fresh transfer antagonist co-treated cycles.

Trial registration number: Prospero registration number: CRD42016051091

P-694 Serum testosterone level is not a marker of ovarian reserve nor ART outcome for poor ovarian responders

T. Inoue[1], N. Nakayama[2], K. Remi[1], Y. Asai[1], T. Himeno[1], Y. Morimoto[1]

[1]HORAC Grand Front Osaka clinic, medical, Osaka, Japan
[2]HORAC Grand Front Osaka clinic, laboratory, Osaka, Japan

Study question: Is there a correlation between serum testosterone level and ovarian reserve tests, or assisted reproductive technology (ART) outcomes for poor ovarian responders?

Summary answer: No significant correlation was recognized between serum testosterone level and ovarian reserve tests, nor ART outcomes for poor ovarian responders.

What is known already: Testosterone, an androgen, has been shown to play an important role in follicular recruitment or development. In a recent meta-analysis, testosterone pretreatment during ART cycle resulted in an increased number of retrieved oocytes. Some researchers suggested an increased chance of live birth with testosterone supplementation, however more supporting data is still required to make such a conclusion. If supplementation of testosterone improves the outcome of ART and contributes to successful implantation, serum testosterone level would have a positive correlation with the number of retrieved oocytes and pregnancy rate in ART cycles.

Study design, size, duration: The present prospective control study is designed to identify correlation between serum testosterone level and ART outcome. Four hundred and forty-one women had blood test in order to record testosterone and anti-mullerian hormone (AMH) from January 2015 until December 2016. One hundred and fourteen poor responders fulfilled Bologna criteria, and they had IVF-ETs with ovarian stimulation in the same period.

Participants/materials, setting, methods: This study was performed at a private ART clinic located in Japanese urban area. Hormone data was available from all infertile women with various causes after written informed consent. Hormone testing methods were electro-chemiluminescence immunoassay for testosterone, and enzyme-linked immunosorbent assay for AMH gen II. The ART data was collected from medical records on the women who had IVF-ET with conventional or mild ovarian stimulation.

Main results and the role of chance: The average age of the participants was 39.2 (SD = 4.51, 25-49). The average testosterone was 0.16 ng/mL (SD = 0.12, 0-2.25). Testosterone from 151 women (34.2%) showed a below normal limit (0.11 ng/mL), and that of 46 women (10.4%) was below a detection sensitivity limit (<0.03 ng/mL). The coefficient of determination were R2 = 0.0036 (vs. age) and 0.047 (vs. AMH). The numbers of poor responders with lower testosterone (group A) and those with normal to high testosterone (group B) were 38 and 76, respectively. The profiles of the two groups on age and AMH were identical. The average number of retrieved oocytes in group A was 3.27 ± 2.29, and 3.21 ± 2.39 in group B. The clinical pregnancy rate (PR) in group A was 36.8%, and 25.0% in group B. The miscarriage rate (MR) in group A was 14.2%, and 26.3% in group B. There were no significant difference in the number of retrieved oocytes (p = 0.45), PR (p = 0.07) or MR (p = 0.67).

Limitations, reasons for caution: Small sample size, possible dispersion of the cause of their infertility or the patients' back ground.

Wider implications of the findings: One third of infertile women showed decreased serum testosterone level. Testosterone is independent from ovarian reserve markers. ART outcomes such as the number of retrieved oocytes, pregnancy rate and miscarriage rate are identical despite testosterone levels. The findings raise questions regarding the effect of testosterone supplementation on ART treatment.

Trial registration number: none.

P-695 GnRH agonist compared with hCG trigger for the induction of final oocyte maturation results in decreased oocyte competence in women aged 35-40 years

S. Tannus[1], R. Turki[2], Y. Cohen[2], W.Y. Son[2], H.M. Dahan[2]

[1]McGill Universoity Health Center, MUHC Reproductive Center, Montreal- QC, Canada
[2]McGill University, Obstetrics and Gynecology, montreal, Canada

Study question: Does the use of gonadotropin releasing hormone agonist (GnRHa) to trigger final oocyte maturation results in decreased oocyte and/or embryo competence compared with human chorionic gonadotropin (hCG)?

Summary answer: The results of this study suggest that GnRHa when used in hyper-responder women, aged 35-40 years, has a negative effect on oocyte and embryo competence.

What is known already: A single bolus of GnRHa can stimulate the release of LH and FSH that mimic the natural mid-cycle surge required for final oocyte maturation. However, this gonadotropin release is of shorter duration and results in significantly reduced amounts of gonadotropins released from the pituitary gland compared with natural surge. This results in limited exposure of the cumulus-oocyte-complex to endogenous gonadotropins. LH surge is important in keeping the activity of the gap junctions between the oocyte and granulosa cells in the final oocyte maturation stage. Whether the limited LH exposure following GnRHa trigger result in suboptimal oocyte maturation is still unknown.

Study design, size, duration: 272 hyper-responder women aged 35-40 years who underwent GnRH antagonist IVF cycles in which final oocyte maturation was achieved either by GnRHa (n = 168) or hCG (n = 104), and freeze-all embryos was performed due to increased risk of ovarian hyperstimulation syndrome (OHSS), from 2012-2014 were studied retrospectively. Embryo transfer was performed in subsequent warming cycles (n = 542). All the warming cycles per woman were included in the analysis until a live birth was achieved.

Participants/materials, setting, methods: Increased risk for OHSS was considered when peaked stimulated E2 levels >12000 pmol/l or the presence of >15 follicles of 12 mm in diameter. In these cases, cycle segmentation with freezing all embryos at the blastocyst stage was performed. Exclusion criteria included: cycles in which subsequent warming cycles was not performed and cycles in which embryo culture was not extended to the blastocyst stage. The primary outcome was the cumulative live birth rate.

Main results and the role of chance: Maternal age was similar (median 37 years, p = 0.88). Women in the GnRHa group required lower total gonadotropin dose (1795 vs. 2318 IU, p < 0.001), had a higher level of stimulated E_2 (13674 vs. 11499 pmol/l, p = 0.001), had a higher number of oocytes retrieved (22 vs. 21, p = 0.002) and a higher proportion of MII oocytes (78 vs. 74%, p = 0.045). Despite higher number of MII oocytes available in the GnRHa group, the number of 2pn embryos and the number of cryopreserved blastocysts (Median of 5 blastocysts in both groups) were similar. The GnRHa group underwent 370 frozen blastocyst transfer (FBT) cycles and the hCG group underwent 172 FBT cycles. The number of cycles per woman (2.2 vs. 1.65, p < 0.001) and the proportion of transferred blastocysts (68 vs. 53%, p = 0.01) were higher in the GnRHa group. When comparing the clinical outcomes, the hCG group had a higher implantation rate (48 vs. 39%, p = 0.008), needed a lower number of cycles to achieve live birth (1.32 vs. 2.12, p < 0.001) and the proportion of embryos thawed and transferred was significantly lower (33 vs. 57%, p < 0.001). The cumulative live birth rate was similar between the groups (48.15 vs. 48.08%, p = 0.90).

Limitations, reasons for caution: The retrospective nature of the study was a major limitation, the study included women aged 35-40 years and studies examining this effect in younger patients are needed.

Wider implications of the findings: Although the GnRHa induced surge is sufficient to yield adequate number of mature oocytes, the limited exposure of the cumulus-oocyte-complex result in suboptimal development which manifest in limited embryo formation and decreased implantation rates. The use of GnRHa should be limited to cases where increased risk of OHSS is present.

Trial registration number: N/A.

P-696   Clinical utility of the novel automated AMH assay as a diagnostic test for PCOS in women of Indian origin

P.R. Jirge[1], S. Iliodromiti[2], S.M. Chougule[3], S. Yelburga[1], R. Shah[1], S. Nelson[4]

[1]Sushrut Assisted Conception clinic, Reproductive Medicine, Kolhapur, India
[2]School of Medicine- University of Glasgow, Department of Obstetrics and Gynaecology, - Glasgow, United Kingdom
[3]Sushrut Assisted Conception Clinic, Department of Reproductive Medicine, Kolhapur, India
[4]University of Glasgow, Reproductive and Maternal Medicine, Glasgow, United Kingdom

Study question: Can Anti-müllerian hormone (AMH) facilitate the diagnosis of PCOS in women of Indian origin?

Summary answer: AMH can facilitate the diagnosis of PCOS in women of Indian descent, with adequate sensitivity and specificity to enable its routine clinical use.

What is known already: Women of white descent with PCOS have higher serum AMH level than non-PCOS women. AMH has been proposed as a diagnostic test for PCOS in white women.

Study design, size, duration: This is a single centered prospective study of 441 Indian women undergoing infertility evaluation from January 2016 to January 2017.

Participants/materials, setting, methods: The study included women with polycystic ovarian morphology (PCOM) who met the Rotterdam criteria for PCOS (n = 75), women with PCOM only (n = 72) and controls (n = 294). AMH was measured with the Elecsys automated assay. We estimated the performance characteristics of AMH (sensitivity, specificity, optimal cut-off and area under the ROC (AUROC) for diagnosing PCOS.

Main results and the role of chance: Women with PCOS had substantially higher AMH (7.4 (IQR: 5.2 to 10.8) ng/ml) than women with PCOM (4.7 (IQR: 3.2 to 7.2) ng/ml) or women without PCOS (1.6 (IQR: 0.9 to 2.7) ng/ml) (p < 0.001). AMH greater than 4.3 ng/ml can discriminate women with PCOS from women without (controls and PCOM) with a sensitivity of 88% and specificity of 82% (AUROC of 0.92). Sensitivity analysis where we compared PCOS with women with non-PCOS male factor infertility (non-infertile) did not materially change this cut-off. AMH greater than 6.9 ng/ml discriminates PCOS from PCOM with a sensitivity of 60% and specificity of 74% (AUROC of 0.73).

Limitations, reasons for caution: Single centre study that used the Rotterdam Consensus PCOS criteria, alternative PCOS diagnostic criteria may require differential threshold values.

Wider implications of the findings: A serum AMH > 4.3 ng/ml is very sensitive to diagnose PCOS on women of Indian origin. This can facilitate diagnosis of PCOS in primary care when sonography is not available.

Trial registration number: N/A.

P-697   Prediction models for ovulation, conception, pregnancy and live birth in infertile women with polycystic ovary syndrome

Y. Deng[1], L. Xie[1], X.K. Wu[1], E.H. Ng[2], E.S. Victorin[3], H. Zhang[4], R.S. Legro[5], B.W. Mol[6]

[1]Heilongjiang University of Chinese Medicine, Department of Obstetrics and Gynecology, Harbin, China
[2]The University of Hong Kong, Department of Obstetrics and Gynecology, Hong Kong, China
[3]Karolinska Institutet, Department of Physiology and Pharmacology, Stockholm, Sweden
[4]Yale University School of Public Health, Department of Biostatistics, New Haven, U.S.A.
[5]Pennsylvania State University, Department of Obstetrics and Gynecology, Hershey, U.S.A.
[6]University of Adelaide, School of Pediatrics and Reproductive Health, Adelaide, Australia

Study question: Can we predict ovulation, conception, pregnancy and pregnancy outcome in Chinese women with WHO type II anovulatory infertility?

Summary answer: In Chinese women with WHO type II, ovulation, pregnancy and live birth could be predicted from demographic, clinical and biochemical variables.

What is known already: Prediction models for pregnancy outcomes in infertile women with PCOS have been reported. And there are some models with good predictive performance that can be used reliably as a guide for making decisions about fertility treatment, in patients similar to the development population. However, there are no papers on prediction models for pregnancy in

Chinese women with PCOS, in particular with the different stages of pregnancy.

Study design, size, duration: From July 2012 to October 2015 we performed a multicenter randomized clinical trial in 1000 Chinese women with PCOS (Rotterdam criteria). In a factorial design women were randomized to active/control acupuncture and clomiphene citrate (CC)/placebo up to four months. Here, we evaluate whether ovulation, pregnancy and live birth could be predicted.

Participants/materials, setting, methods: We used multivariate logistic regression analysis using significance level of 0.10 among 43 candidate variables. Interaction between selected variable and treatment were assessed. We constructed receiver operating characteristic (ROC) curves and calculated the areas under them (AUC) to assess the predictive power of models.

Main results and the role of chance: Among the 1000 women, 780 ovulated, 320 conceived, 218 were pregnant, of which 205 resulted in a live birth. Previous conception (OR = 1.70, 95%CI = 1.07-2.69) increased the probability of ovulation, while high free androgen index (FAI) level (OR = 0.94, 95% CI = 0.90-0.98) anti-Mullerian hormone level (OR = 0.95, 95%CI = 0.91-0.98), a longer menstrual cycle (OR = 0.99, 95%CI = 0.99-1.00) and smoking (OR = 0.38, 95%CI = 0.16-0.89) decreased ovulation chances. Among women who ovulated, higher difference between systolic and diastolic blood pressure (OR = 1.03, 95%CI = 1.00-1.06), E2 level (OR = 1.001, 95%CI=1.000-1.001) and previous pregnancy loss (OR=1.86, 95%CI=1.29-2.76) were predictors for conception. Among women who conceived, CC treatment (OR=0.53, 95% CI=0.27-1.00), higher sex hormone-binding globulin (SHBG) level (OR=0.99, 95%CI=0.98-1.00), FAI level (OR=0.85, 95%CI=0.77-0.94) and cholesterol level (OR=0.70, 95%CI=0.51-0.95) were predictive of lower chances of pregnancy. Among women who were pregnant, acupuncture treatment (OR=0.10, 95%CI=0.01-0.75), lower low density lipoprotein (OR=4.78, 95% CI=1.32-17.37), higher mean arterial pressure (OR=0.66, 95%CI=0.51-0.85), previous pregnancy loss (OR=0.08, 95%CI=0.01 = 0.61), and concurrent diagnosis of metabolic syndrome (OR=0.10, 95%CI=0.01-1.00) were significantly negatively associated with live birth. AUCs were 0.81 (95%CI=0.77-0.85) for the ovulation model, 0.66 (95%CI=0.61-0.71) for the conception model, 0.69 (95% CI=0.61-0.76) for the pregnancy model.

Limitations, reasons for caution: There are limitations to the generalizability of our findings to clinical practice and other populations. Our participants were all anovulatory and our interventions only included CC and acupuncture. Our collection of information may not include potential predictors that could impact on clinical outcome.

Wider implications of the findings: Overall, most of our predictors overlap with those found in other studies. Expected predictors such as age and BMI were not statistically significant in our assessment. The proposed models could be applied to anovulatory patients with PCOS after confirmation through a further validation study.

Trial registration number: The trial was registered at clinicaltrials.gov (NCT-01573858) and Chinese clinical trial registry (ChiCTR-TRC-12002081).

P-698   Brain-derived neurotrophic factor promotes human granulosa-like tumor cell steroidogenesis through activating FSH receptor-mediated signaling pathway

M. Xie[1], M. Li[1], X. Ding[1], Y. Shao[1], J. Jing[1], Y. Liu[2], B. Yao[1]

[1]Nanjing Jinling Hospital, Center of Reproductive Medicine, Nanjing, China
[2]Nanjing Jinling Hospital, Department of Medical Statistics, Nanjing, China

Study question: How brain-derived neurotrophic factor (BDNF) promotes steroidogenesis and proliferation of human granulosa-like tumor cell (KGN cell)?

Summary answer: BDNF treatment can regulate FSH receptor expression and modifications and activate FSHR-mediated signaling pathway in KGN cell.

What is known already: BDNF and FSH receptor are expressed in ovarian granulosa cells, and play important roles in regulating ovarian development and functions. BDNF functions as a regulator in follicle growth, oocyte maturation, accelerating the extrusion of polar bodies and maintaining the corpus luteum. FSHR plays essential roles in the regulation of steroidogenesis and follicle proliferation during ovary maturation. FSHR-induced signaling is involved in the modulation of nuclear events in granulosa cells. Studies have linked the BDNF-associated signaling pathway to FSHR mRNA expression in the regulation of follicle development, suggesting that BDNF may potentially affect granulosa cells through FSHR.

Study design, size, duration: This study was designed to investigate the steroidogenesis in human granulosa-like tumor cell line KGN treated by BDNF and the underlying mechanism.

Participants/materials, setting, methods: KGN cells were exposed to different treatments: FSH (100 ng/ml), BDNF (5 ng/ml) and combined FSH (100 ng/ml) and BDNF (5 ng/ml). Steroidogenesis (estradiol and progesterone) were determined on a chemiluminescent immunoassay system. Cell proliferation was assessed with EdU assay. BDNF and cAMP levels, and PKA kinase activity were analyzed by ELISA. FSHR, CREB and phospho-CREB levels were determined by Western blotting. Phosphorylation and ubiquitination of FSHR was examined by immunofluorescence and immunoprecipitation.

Main results and the role of chance: KGN cells products and secrets BDNF. After exposing to different treatment, the secretion of estradiol ($p < 0.01$) and progesterone ($p < 0.01$) were stimulated in KGN cells by combination of BDNF and FSH, also the cell proliferation ($p < 0.01$). BDNF plus FSH treatment decreased BDNF level and enhanced FSHR phosphorylation and ubiquitination. Combined treatment also increased the cAMP level, and PKA and CREB activity, suggesting the activated cAMP/PKA/CREB signaling pathway. Moreover, inhibition of BDNF expression by siRNA markedly reduced the estradiol secretion and down-regulated FSHR, aromatase and phosphorylated CREB; meanwhile, FSH treatment partly alleviated the effects of BDNF siRNA on KGN cells. These findings suggested that BDNF modulates graunlosa cell functions and the action probably mediated by FSHR-coupled signaling pathway, to affect aromatase-mediated steroidogenesis.

Limitations, reasons for caution: Although KGN cells have common characteristics and are functionally similar to primary human ovarian granulosa cells and widely used to study the steroidogenesis of granulosa cell in vitro, there are many different between the primary granulosa cell and KGN cell such as karyotype and the response to the stimulating factors.

Wider implications of the findings: The present study has established a molecular link between BDNF and FSHR function, partly revealing the mechanisms by which neurotrophic factors modulate hormone secretion in granulosa cells. Overall, these findings concerning in KGN cells may be applied for a further understanding of the functional regulation of granulosa cells.

Trial registration number: None.

P-699   A pharmacogenetic approach to improve low ovarian response by androgens pre-treatment

B. Lledo[1], J.A. Ortiz[1], R. Morales[1], B. Martinez[1], A. Turienzo[1], J. Llacer[2], R. Bernabeu[2]

[1]Instituto Bernabeu, Molecular Biology, Alicante, Spain
[2]Instituto Bernabeu, Reproductive Medicine, Alicante, Spain

Study question: Does the length in the polymorphism of androgen receptor (AR) gene affect the ovarian response when using androgen in a previous cycle?

Summary answer: Androgen receptor genotyping could help us to identify poor ovarian responder (POR) patients that will be benefited of transdermal testosterone pre-treatment.

What is known already: Androgens and their receptors have been shown to play an important role in ovarian physiology. Recently, clinicians have attempted to improve the ovarian response in POR by using androgens or androgen modulators prior to IVF treatment. However, there is still some controversy about the evidence that pre-treatment with transdermal testosterone may improve the clinical outcomes for POR. The human androgen receptor (AR) gene contains a highly polymorphic CAG repeat. The aim of this work was to investigate if AR polymorphism could be used for selection patients that they will benefit of androgen treatment in previous cycle.

Study design, size, duration: A retrospective study was performed. We included 88 ovarian stimulation cycles performed by 44 patients diagnosed as POR and genotyped for AR polymorphism. All patients carried out two cycles: one without androgens pre-treatment and the second one with androgen

preparation. We compare the results in pair from each. The main outcomes were the number of retrieved oocytes and MII.

Participants/materials, setting, methods: We included 44 patients diagnosed as POR according to the Bologna criteria. All patients were genotyped for AR polymorphism using fluorescent PCR. For androgen pre-treatment 25 mg testosterone were applied for 28 days in the cycle preceding the ovarian stimulation. The ovarian stimulation protocol was adjusted according to patient characteristics.

Main results and the role of chance: No significant differences were reported when we compared the cycles for each patient in total according to oocyte yield, MII, days of stimulation and gonadotrophin dosages. However, according to AR polymorphism statistical differences were shown in oocyte yield and MII. Patients that carried CAG repeats in AR gene between 22 and 24 showed an increased in the number of oocytes when they were pre-treated with androgens, from 2.61 oocytes yielded in the cycle without androgens to 5.11 in the cycle with androgens (p<0.05). For the patients that carried a number repeats lower than 22 and higher than 24 no significance differences were reported in the number of oocytes obtained in the cycle with or without androgens (2.94 vs 2.56; p = 0.876). Similar result was obtained for mature oocytes. More MII oocytes were obtained in the pre-treated cycle in patients that carry a number of CAG repeats between 22 and 24 (1.86 vs 4.04; p<0.05). No significant differences in the number of MII oocytes were found in patients that get out of 22 and 24 repeats between the two cycles (2.31 vs 2.13; p = 0.878).

Limitations, reasons for caution: The study is limited by its retrospective nature. A higher sample size or a prospective randomized design should be used in future studies to corroborate the current findings. In addition, research into the contribution of the effect of the polymorphism in the AR function will be of a great interest.

Wider implications of the findings: The use of androgens as strategy to increase the number of retrieved oocyte in POR remains controversial. Our data suggest that the AR genotype could clarify the effectiveness of the androgen pre-treatment. Androgen receptor genotyping could help us to identify POR patients that will be benefited of transdermal testosterone pre-treatment.

Trial registration number: No trial.

P-700 The potential mechanisms involved in the intervention of Electro-acupuncture on decreasing the progression of OHSS in a rat model

X. Huang, L. Chen, B. Yao

Nanjing Jinling Hospital, reproductive medical center, Nanjing, China

Study question: How electroacupuncture (EA) improve the characteristics of ovarian hyperstimulation syndrome (OHSS) in rats?

Summary answer: EA reduce ovarian size and serum hormones of OHSS, manifested by negative regulation of ovarian corpus luteum formation and ovarian enzymes expression of steroidogenesis.

What is known already: OHSS is a potentially life-threatening complication of ART, characterized by enlarged ovarian size of a large number of corpus luteum, high sex hormones synthesized and released. However, there was no direct evidence implicating the modulators during the occurrence. Recently, we have shown that EA, as a treatment can efficiently reduce the ovarian size and decline serum sex hormones level of OHSS rats, which signified the signs of OHSS were improved. However, the underlying mechanisms of EA on changing ovarian structure and steroidogenesis of OHSS still unknown, in this study we will explore that in a rat model.

Study design, size, duration: OHSS was induced in 22 days (D22) female Sprague–Dawley rats by four consecutive daily injections of 50IU PMSG from D25 to D28, sacrificed 48 h later by 150IU hCG at D29; regular-stimulation with 10IU PMSG at D27 and 10IU hCG at D29; control rats injected with saline (n = 8 per group); EA (Sanyinjiao (SP6) and Guanyuan (CV4), 15 min/day, 2/ 15 Hz) applied for OHSS rats from D22 to D31; Serum and ovary were collected for further experiments.

Participants/materials, setting, methods: Ovarian sections with HE staining to assess the histomorphology changes, modulators in serum and ovarian that PGE2, PGF2α detected by ELISA. Serum E2, P, T and FSH, LH measured by chemiluminescence or ELISA. Expressions of crucial ovarian steroidogenesis enzymes and upstream PKA pathway were examined by Western blot and qPCR. Neuropeptide Y (NPY), target of EA, and its regulated cell proliferation-related molecules PCNA evaluated to interpret the original control of EA on OHSS.

Main results and the role of chance: The ovary/body weight ratio in EAO rats was significantly lower than that in OHSS (p<0.01), the average number of corpus luteum (p<0.05) and expressions of luteotrophic regulator PGE2 in ovary and serum (both p<0.001) were synchronous reduced in EAO rats compared with OHSS, EA increased the ovarian luteolytic factor PGE2α expression (p<0.05) than OHSS, but not serum. In addition to serum sex hormones, the gonadotropins FSH, LH also declined after EA intervention. Ovarian steroidogenesis enzymes StAR, Cyp11a1, 3β-HSD, 17β-HSD, aromatase Cyp19 mRNA and protein expression were all down regulated in EAO group, the upstream FSHR, LHR and they actived PKA/CREB pathway were attenuated consistently with the enzymes expression. NPY expression in EAO ovary was up-regulated, which can inhibit the ovarian cell proliferation, we found that ovarian PCNA was reduced but cell cycle inhibit molecule P27 and phosphorylated P27 were enhanced. Immunohistochemical staining of ovarian sections also showed that PCNA in EAO rats was weaker than in OHSS.

Limitations, reasons for caution: The *in vivo* experiments were performed in a rat model.

Wider implications of the findings: Our findings provide underlying mechanisms of electroacupuncture on OHSS treatment: EA can efficiently alleviate the signs of OHSS by reducing the corpus luteum formation and attenuating the steroid hormone synthesis pathway. Clarifying the inner properties of EA could open new therapeutic avenues for OHSS patients in ART.

Trial registration number: None.

P-701 Non-equivalence of anti-müllerian hormone automated assays - clinical implications for use as a companion diagnostic for individualised gonadotrophin dosing

S. Iliodromiti[1], B. Salje[1], D. Dewailly[2], C. Fairburn[3], R. Fanchin[4], M. Gaudoin[3], H.W.R. Li[5], K. Lukaszuk[6], E.H.Y. Ng[5], P. Pigny[7], T. Tadros[4], S.M. Nelson[1]

[7]*Centre de Biologie Pathologie- Centre Hospitalier Regional Universitaire de Lille, Laboratoire de Biochimie et Hormonologie, Lille, France*

Study question: Do Anti-müllerian hormone automated immunoassays (Elecsys® and Access) exhibit similar performance and can they be used interchangeably as a companion diagnostic for individualisation of follitropin delta dosing?

Summary answer: The Access assay gives systematically higher AMH values than the Elecsys® assay. This discordance misclassifies over 49% of women to an inappropriate follitropin delta dose.

What is known already: Personalised medicine encompasses in-vitro companion diagnostics for the safe and effective use of a corresponding therapeutic product. The use of a companion diagnostic with a particular therapeutic product is stipulated in the instructions for use in the labelling of both the diagnostic device and the corresponding therapeutic product. Follitropin delta is the first gonadotrophin to be licenced with a companion diagnostic, the Roche Elecsys® AMH Plus assay. Alternative automated AMH assays including the Beckman Coulter Access immunoassay are considered to provide similar results, but clarification of their suitability as an off licence companion diagnostic for follitropin delta is required.

Study design, size, duration: We systematically searched the existing literature for studies that had measured AMH using both automated assays in the

same cohort of women. Individual paired patient data were acquired from each author and combined with unpublished data.

Participants/materials, setting, methods: We identified 5 eligible prospective published studies and one additional unpublished study. 100% response from the authors was achieved. We collected paired AMH data on 848 women. Passing-Bablok regression and Bland-Altman plots were used to compare the analytical performance of the two assays. The degree of misclassification to different treatment categories was estimated should the Access AMH be used as a companion diagnostic instead of the Elecsys AMH in determining the dosing of follitropin delta.

Main results and the role of chance: The Passing-Bablok regression shows a linear relationship (Access = -0.05 + 1.10*Elecsys). The Access assay systematically gave higher values by an average of 10% compared with the Elecsys assay (slope =1.10, 95% CI: 1.09 to 1.12). The average bias between the two assays was 2.7 pmol/L. The 95% limits of agreement were -11.7 to 6.0. A substantial proportion of women (ranging from 49 to 90% depending on the AMH category) would receive a lower dose of follitropin delta based on the Access AMH assay. Up to 10% (ranging from 2.5 to 10%) of women with high ovarian reserve would have been misclassified to a greater dose of follitropin delta based on the Access AMH assay.

Limitations, reasons for caution: We compared the values of the two principal automated assays, extrapolation of our findings to other automated AMH assays would require replication.

Wider implications of the findings: An international standard for the calibration of the automated AMH assays is warranted to facilitate efficient use of AMH as a companion diagnostic. For optimal performance of the follitropin delta dosing algorithm it should be used in conjunction with its licensed companion diagnostic the Elecsys® AMH Plus immunoassay.

Trial registration number: N/A.

P-702 Ovarian volume as a surrogate marker of ovarian recovery following ovarian stimulation with different triggers of oocyte maturation: kisspeptin, GnRH agonist and human chorionic gonadotropin

R. Islam[1], A. Abbara[2], S. Clarke[2], G. Christopoulos[1], A. Comninos[3], R. Salim[1], S. Lavery[1], G. Trew[1], W. Dhillo[3]

[1]Imperial College NHS Healthcare Trust, Reproductive medicine, London, United Kingdom
[2]Imperial College London-, Investigative medicine, London, United Kingdom
[3]Imperial College London, Investigative medicine, London, United Kingdom

Study question: Is ovarian volume at early OHSS screening (day 2-5 following oocyte retrieval) altered when using different triggers of oocyte maturation (human chorionic gonadotropin(hCG), gonadotropin-releasing hormone (GnRH) agonist or kisspeptin)?

Summary answer: *Ovaries recovered most rapidly following kisspeptin triggering:* Mean ovarian volume (± SD) was 192 ± 97mls following hCG, 53 ± 37mls following GnRH agonist and 9 ± 4mls following kisspeptin; P < 0.0001.

What is known already: Ovarian hyperstimulation syndrome (OHSS) is a serious iatrogenic condition that is predominantly related to the mode of triggering oocyte maturation during IVF treatment. Kisspeptin is a novel trigger which stimulates the physiological release of GnRH from the hypothalamus. Kisspeptin has recently been shown to safely trigger oocyte maturation in a population at high risk of OHSS, but has yet to be directly compared with other triggers. Ovarian volume and ascitic fluid are commonly used to categorise the severity of OHSS in diagnostic guidelines.

Study design, size, duration: Women at high risk of OHSS (antral follicle count ≥23), aged <35yrs, BMI <30 kg/m^2 with both ovaries intact, were screened sonographically and for OHSS symptoms during early OHSS screening (2-5 days following oocyte retrieval) at Hammersmith Hospital, London, UK (2013-2016).

Participants/materials, setting, methods: Ovarian volume on ultrasound, ascitic volume and OHSS symptoms were determined when patients were triggered with (hCG) (n = 29), GnRH agonist (GnRHa) (n = 94) or kisspeptin (n = 115) at time of early OHSS screening. Statistical analysis was performed using One-way ANOVA with post-hoc Bonferroni correction.

Main results and the role of chance: Mean ovarian volume (MOV) (±SD) following GnRH agonist trigger (53 ± 37mls) was significantly lower than in patients triggered with hCG (192 ± 97mls; p <0.0001). MOV following kisspeptin trigger (9 ± 4mls) was significantly lower still when compared with GnRH agonist trigger (p <0.0001). Compared to baseline ovarian volumes prior to commencing ovarian stimulation, ovarian volumes at early OHSS screening remained enlarged 28-fold following hCG, 10-fold following GnRH agonist and 5.8-fold following kisspeptin triggering. Mean total ascitic volumes were lower after GnRH agonist (5.8 ± 22mls) and kisspeptin (4.6 ± 7.8mls) when compared with hCG (102 ± 150mls; p<0.0001).

Symptoms of OHSS were more frequently reported following GnRH agonist use than kisspeptin and more frequently still following hCG:

Abdominal pain was reported in 80% following hCG, 22% following GnRH agonist and 12% following kisspeptin. Abdominal bloating was reported in 90% following hCG, 30% following GnRH agonist and 11% following kisspeptin. Nausea was reported in 43% following hCG, 14% following GnRH agonist and 2% following kisspeptin. Vomiting was reported in 10% following hCG, 5% following GnRH agonist and 1% following kisspeptin.

Limitations, reasons for caution: Further research studies are warranted to directly compare kisspeptin to more established triggers of oocyte maturation in prospective randomized controlled trials.

Wider implications of the findings: Kisspeptin may present a safer alternative to GnRHa or hCG triggering in patient at high risk of OHSS undergoing IVF treatment.

Trial registration number: Clinical Trials Registration Number: NCT01667406

P-703 A modified natural protocol for frozen-thawed embryo transfer – Don't mind the LH surge (It's the progesterone that matters). A proof of concept study

A. Weiss[1,2], S. Baram[1,2], R. Beck-Fruchter[1], S. Goldman[1], Y. Geslevich[1]

[1]Emek Medical Center, Obstetrics and Gynecology, Afula, Israel
[2]Technion - Israel Institute of Technology, Rappaport Faculty of Medicine, Haifa, Israel

Study question: Does a FET protocol where progesterone is started during the late follicular phase disregarding the LH surge for scheduling embryo transfer provide satisfactory results?

Summary answer: The tested protocol is simple to implement, flexible and can potentially increase the clinical pregnancy rate after FET for ovulating women.

What is known already: The best protocol for FET cycles has yet to be determined. Natural cycle and modified natural cycle FET protocols achieve synchronization between endometrium development and embryo age by timing the embryo transfer relative to the LH surge or an exogenous hCG injection. The former requires meticulous monitoring of the cycle and requires the IVF unit to be available daily for transfer, while the latter has yielded conflicting results.

Study design, size, duration: Candidates for FET with a history of regular menstrual cycles were recruited for the study prospectively. This proof of concept trial was approved by the local ethics committee and the Ministry of Health for 20 patients completing the protocol. The patients were recruited from May to December 2016. Results were compared retrospectively to a cohort of 40 patients with similar clinical attributes with an artificial cycle protocol.

Participants/materials, setting, methods: Good prognosis patients scheduled for FET with 48 hour embryos were included. Endometrial thickness, follicle size and estradiol, progesterone and LH levels were monitored during the follicular phase. Progesterone suppositories were started 48 hours prior to scheduled embryo transfer regardless of the timing of the LH surge provided there was a leading follicle, endometrial thickness of at least 7 mm and any elevated progesterone began no sooner than 72 hours before transfer.

Main results and the role of chance: Twenty patients completed the study protocol. Baseline parameters between the study group and the control group were similar. There were 12/20 (60%) clinical pregnancies in the study group versus 8/40 (20%, p<0.01) clinical pregnancies in the control group. The

implantation rate was 45% and 13.24% respectively (p<0.001). The multifetal pregnancy rate was 33% versus 12.5% (NS). The differences in pregnancy rates were more pronounced when considering only those cycles where at least one high quality embryo was available for transfer: 12/15 (80%) clinical pregnancies versus 7/33 (21%, p<0.001) and an implantation rate of 56% versus 13.8% respectively (p<0.0001). Most of the cycles in the study group required two visits before the transfer, a baseline visit during menstruation and one monitoring visit during the late follicular phase. Weekend transfers were completely avoided.

Limitations, reasons for caution: The sample size is small and the groups were not randomly selected. The results should be analyzed in the context of being a proof of concept trial. Larger prospective trials should be conducted.

Wider implications of the findings: Progesterone administered during the late follicular phase does not hinder the chances of a clinical pregnancy. Synchronization of endometrium and embryo by controlling the timing of progesterone administration is attained. By disconnecting the process from the LH surge, cycle monitoring is simplified with more flexibility in transfer scheduling.

Trial registration number: NCT02749344.

P-704   Effect on endometrial histology and pharmacokinetics of different dose regimens of progesterone vaginal pessaries, in comparison with progesterone vaginal gel and placebo

I. Duijkers[1], I. Klingmann[2], M. Wargenau[3], R. Prinz[3], S. Hrafnsdottir[4], T. Magnusdottir[4], R. Levy-Toledano[5], C. Klipping[1]

[1]dinox BV, Dept: not applicable, Groningen, The Netherlands
[2]Pharmaplex bvba, Dept: not applicable, Wezembeek-Oppem, Belgium
[3]M.A.R.C.O. GmbH & Co, Dept: not applicable, Düsseldorf, Germany
[4]Actavis Group PTC ehf, Dept: not applicable, Hafnarfjordur, Iceland
[5]Teva Pharmaceutical Europe BV, Dept: not applicable, Amsterdam, The Netherlands

Study question: Which progesterone vaginal pessary (Cyclogest®) dose regimen induces adequate secretory transformation of the endometrium, in comparison with progesterone vaginal gel (Crinone®) and placebo?

Summary answer: The most adequate secretory transformation of the endometrium was observed during treatment with 400 mg progesterone vaginal pessaries, administered twice daily.

What is known already: In clinical practice, progesterone via the vaginal route is widely used for luteal phase support in assisted reproduction technique (ART) cycles. Although few studies have investigated the endometrial effect of vaginal progesterone, no clinical trials have been performed yet to determine the optimal dose of progesterone pessaries in this indication.

Study design, size, duration: The study consisted of two randomized, observer-blind crossover parts. Part 1 (3-way crossover) investigated 200 mg progesterone vaginal pessaries twice daily (bid), 400 mg pessaries bid, and 90 mg progesterone vaginal gel once daily (od) including 61 treated subjects. Part 2 investigated 100 mg pessaries bid and 400 mg pessaries od in a 2-way crossover including 64 treated subjects. Of these, 22 subjects additionally received placebo vaginal pessaries bid in a third study period.

Participants/materials, setting, methods: The study was performed in healthy female volunteers of reproductive age. The subjects used 2 mg estradiol bid for 24 days in each treatment cycle. Progesterone or placebo was administered vaginally from cycle day 15 onwards during 10 days. An endometrial biopsy for histological evaluation was performed on cycle day 23. Pharmacokinetic parameters were determined after the first progesterone dose on day 15 and after the last dose on day 24.

Main results and the role of chance: Frequencies of secretory transformation of the endometrium, i.e. adequate responses, during treatment with Cyclogest® 200 mg and 400 mg bid were comparable with those during Crinone® treatment (90-94%), whereas lower secretory transformation rates were observed during treatment with 100 mg bid and 400 mg vaginal pessaries od (64% and 75% respectively). No adequate response was observed after placebo demonstrating the assay sensitivity of the trial concept. The late secretory state of the endometrium, which is physiologically closer to the endometrium receptivity conditions on cycle day 23 than the early secretory state, was

observed in 90%, 82% and 78% with Cyclogest® 400 mg bid, Crinone® od and Cyclogest® 200 mg bid respectively. Pharmacokinetic parameters after multiple dosing of progesterone vaginal pessaries showed a dose-dependent, but not dose-proportional, increase of plasma progesterone levels, with 400 mg bid presenting a consistently higher progesterone plasma level over the full dosing period in comparison to the vaginal gel and all other pessary dose regimens. The lowest incidence of bleeding and spotting was reported during treatment with 400 mg vaginal pessaries bid. Progesterone treatments were safe and well tolerated. Drug-related adverse events were not dependent on the absolute amount of progesterone administered.

Limitations, reasons for caution: The primary outcome parameter, endometrial histology, is a surrogate for the actual clinical endpoint, endometrial receptivity, which is investigated in a subsequent efficacy study in patients undergoing assisted reproduction treatment.

Wider implications of the findings: Based on the results of this study, the 400 mg bid vaginal pessary seems to be optimal for luteal phase support and as effective as 90 mg vaginal gel od to induce adequate endometrial transformation. The efficacy of this dose regimen is confirmed by evaluating pregnancy rates in ART cycles.

Trial registration number: EudraCT number 2012-001726-95

P-705   Effects of TSH levels on pregnancy outcomes and neonatal birth weights for patients undergoing IVF in China

Y. Guo[1], X. Du[2], F. Zhang[2], J. Sun[2], X. Yang[3]

[1]The First Affiliated Hospital of Zhengzhou University, Reproductive Medicine Center, Zhengzhou-Henan, China
[2]The First Affiliated Hospital of Zhengzhou University, Reproductive Medicine Center, Zhengzhou, China
[3]The First Affiliated Hospital of Zhengzhou University-, Reproductive Medicine Center, Zhengzhou, China

Study question: The objective of the investigation was to study the effects of TSH levels on pregnancy outcomes of IVF and the clinical characteristics of their neonates.

Summary answer: Pregnancy outcomes and neonatal birth weights in IVF patients appear to have no relation to TSH levels.

What is known already: The upper limit of normal TSH has been revised from 5 mIU/L to 2.5 mIU/L for pregnant women. The ideal thyroid-stimulating hormone (TSH) range for infertile women undergoing IVF has not been determined.

Study design, size, duration: Design: Retrospective cohort study.

Setting: University-affiliated reproductive medicine center.

Patient(s): A total of 10259 first fresh IVF cycles with autologous oocytes from June 2011 to June 2015.

Participants/materials, setting, methods: All the patients were divided into polycystic ovary syndrome (PCOS) group and non-PCOS group, and then according to TSH levels, each group was subdivided into 5 subgroups[(0–0.5), [0.5–2.5), [2.5–3.5), [3.5-4.5)and [4.5-12] mIU/L]. The live birth rates, miscarriage rates and neonatal birth weights among the TSH groups were compared.

Main results and the role of chance: There were no difference in live birth rates and miscarriage rates between TSH groups. Live birth rates and miscarriage rates were not associated with TSH level after adjusting for age. No significant differences were observed in the NBWs and premature birth conceived via IVF cycles between TSH groups.

Limitations, reasons for caution: Owing to the limited sample size in our center, the sample size of neonates was small, especially in groups 1 and 5. Additionally, there is little research on the relationship between NBW and TSH levels in ART at present. Therefore, more NBW studies must be performed in the future.

Wider implications of the findings: There is a lack of evidence that revised the upper limit of normal TSH from 5 mIU/L to 2.5 mIU/L is beneficial. Pregnancy outcomes and neonatal birth weights in IVF patients appear to have no relation to TSH levels.

Trial registration number: not applicable.

P-706 The effect of storage conditions on stability of AMH measurement in serum and blood using the automated AMH assay

J.Y. Lee[1], B.C. Jee[2], S.H. Kim[3], W.D. Lee[4], S.K. Kim[5], Y.C. Lee[6], H. Kim[3]

[1]Hamchoon Women's Clinic, Seoul, Korea- South
[2]Seoul National University Bundang Hospital, Department of Obstetrics and Gynecology, Seongnam, Korea- South
[3]Seoul National University College of Medicine, Department of Obstetrics and Gynecology, Seoul, Korea- South
[4]Maria Infertility Hospital, Department of Obstetrics and Gynecology, Seoul, Korea- South
[5]Seoul National University Bundang Hospital, Obstetrics and Gynecology, Seongnam, Korea- South
[6]Maria Infertility Hospital, Department of Obstetrics and Gynecology, Busan, Korea-South

Study question: Does the automated AMH assay acquire the validation concerning time-dependent stability in serum, and the stability of AMH values after exposure and storage in whole-blood?

Summary answer: The automated AMH assay exhibits very high reproducibility and stability in serum and whole blood for a week, comparable to the revised Gen II assay.

What is known already: Recent studies suggested that AMH measurement may be prone to preanalytical instability depending on sample storage conditions. In clinical setting, blood samples are not processed within the recommended time scales. The original Gen II assay provided time-dependent reduced AMH value of serum samples, but provided significantly increased AMH values when measured in whole-blood samples storaged at room temperature subsequently separated serum.

Study design, size, duration: This was a prospective study in which 386 samples from volunteers were stored at three different temperatures and assayed for AMH at times 0, 48 hours and 1 week after collection using the automated AMH (Access) and revised Gen II assay.

Participants/materials, setting, methods: Volunteers (n = 76) were healthy non-pregnant women aged 25–45 years. We divided Serum group 1(centrifuged within 2 hours of collection and stored at fridge temperature), Serum group 2(centrifuged within 2 hours of collection and stored at -20°C) and Whole-blood group (stored at room temperature before centrifugation and assay). Samples were evaluated simultaneously with the revised Gen II and Access assay. Comparisons of sample concentrations at each time point were undertaken as paired t-tests.

Main results and the role of chance: AMH concentrations measured using the Access assay remained unchanged in serum for up to 1 week at fridge temperature and -20°C (correlation coefficient > 0.99). The time-dependent stability of Access assay in stored serum was comparable to that of the revised Gen II assay (correlation coefficient > 0.99). The concordance between log-transformed values measured using the Access and Gen II assay was rho = 0.92 (95% CI 0.84–0.95). The Passing–Bablok regression equation was y (Access assay in ng/ml) = 0.82 × Gen II (correlation coefficient = 0.99, p-value < 0.01). Testing the effects of storage in whole-blood samples at room temperature showed a consistent AMH values for up to 1 week with both the Access and revised Gen II assay (correlation coefficient > 0.99).

Limitations, reasons for caution: The reproducibility and stability may vary depending on basal AMH levels. The observed stability of AMH in stored serum and whole-blood samples requires further larger investigations.

Wider implications of the findings: In clinical setting, protracted storage of whole-blood at room temperature has little impact on the AMH concentration measured using the automated AMH assay. The results indicate that minor variations of AMH levels due to storage issues in the automated AMH assay will have little impact on the clinical decision.

Trial registration number: not applicable.

P-707 Growth differentiation factor-8: A new clinical biomarker and treatment target for the improvement of pregnancy outcome for polycystic ovary syndrome patients

L. Fang, Y. Yu, R. Zhang, J. He, Y. Sun

The First Affiliated Hospital of Zhengzhou University, Reproductive Medical Center, Zhengzhou, China

Study question: To evaluate the expression pattern and predictive value of serum growth differentiation factor-8 (GDF-8) for the pregnancy outcome in polycystic ovary syndrome (PCOS) patients

Summary answer: Serum GDF-8 levels are dysregulated during the process of controlled ovarian hyperstimulation (COH) and affect the pregnancy outcome in PCOS patients.

What is known already: We have shown that GDF-8 down-regulates StAR expression and decreases progesterone production in human granulosa cells. In addition, in non-PCOS patients, serum GDF-8 level on the hCG administration day and the level of GDF-8 decrease from hCG administration day to oocyte pick-up (OPU) day are valuable predictors of pregnancy during IVF/ICSI-ET treatment. Our findings suggest that before hCG administration day, higher serum GDF-8 may be a beneficial factor for pregnancy by keeping a lower progesterone level. After hCG administration, decrease of GDF-8 level may be critical for early embryo implantation and successful pregnancy by maintaining the high level of progesterone.

Study design, size, duration: Human serum and follicular fluid samples were obtained from 24 control and 20 PCOS patients (pregnant: n = 9 and non-pregnant: n = 11) undergoing IVF/ICSI-ET at the Reproductive Medicine Center of the First Affiliated Hospital of Zhengzhou University in China. Informed consent was obtained from all patients. The diagnosis of PCOS was based on the Rotterdam-PCOS criteria in which at least two of the following features were present: oligo/amenorrhea, clinical or biochemical hyperandrogenism, and polycystic ovaries on ultrasonography.

Participants/materials, setting, methods: All patients were treated with a standard long GnRH-agonist protocol. Blood samples were obtained by venipuncture at GnRH-agonist day, gonadotropin day, hCG administration day, 12 h after hCG administration, OPU day, 48 h after OPU and 14 days after ET. Serum GDF-8 levels were measured by ELISA at different time points and were correlated with the pregnancy results. GDF-8 levels in the follicular fluid were also measured. RT-qPCR was used to measure mRNA level.

Main results and the role of chance: Serum GDF-8 levels on gonadotropin day and OPU day were significantly higher in the PCOS patients than that in the non-PCOS patients (7.0 ± 4.0 vs 4.5 ± 1.3, p = 0.007; 2.8 ± 1.5 vs 1.9 ± 0.8, p = 0.035). GDF-8 levels in follicle fluid were also significantly higher in PCOS patients than that in non-PCOS patients (2.2 ± 1.6 vs 1.2 ± 0.8, p < 0.001). Interestingly, unlike the results that obtained from control patients, serum GDF-8 levels at all the time points during the COH procedure as well as follicular fluid GDF-8 levels of PCOS patients were significantly lower in the pregnant group than in non-pregnant group. RT-qPCR analyses showed that the basal mRNA levels of GDF-8 receptor, ALK5 (also known as TGFβR1), in the primary culture of granulosa cells did not vary significantly between control and PCOS patients. Interestingly, treatment with hCG up-regulated ALK5 mRNA levels in the granulosa cells of PCOS patients, while this effect did not observed in the granulosa cells of control patients. In addition, treatment granulosa cells of PCOS patients with human recombinant GDF-8 increased aromatase and FSH receptor mRNA levels but decreased StAR and LH receptor mRNA levels. Moreover, the regulatory effects of GDF-8 on these genes were similar in between granulosa cells of PCOS and control patients.

Limitations, reasons for caution: Despite the interesting results that serum and follicular fluid GDF-8 levels were lower in the pregnant than non-pregnant of PCOS patients, the underlying mechanisms remain unknown and need to be further defined. In addition, further studies using more clinical samples to confirm the current findings are warranted.

Wider implications of the findings: This work, for the first time, demonstrated the GDF-8 expression pattern in PCOS patients during COH procedure which increased our understanding of the roles of GDF-8 in the pathogenesis of PCOS and unraveled that maybe GDF-8 can be therapeutic targeted to improve the pregnancy rate for PCOS patients.

Trial registration number: Not applicable.

P-708 Pregnancy Outcomes Study in euthyroid women with Thyroid Autoimmunity after Levothyroxine intervention—an open labelled RCT study (The POSTAL study)

H. Wang[1], H. Chi[2], H. Gao[1], R. Li[3], L.I. Zeng[4], B.W. Mol[5], T. Hong[1], J. Qiao[6]

[5]The Robinson Research Institute- University of Adelaide and The South Australian Health and Medical Research Institute- Adelaide- 5000 SA- Australia- The South Australian Health and Medical Research Institute-, School of Pediatrics and Reproductive H,
[6]Peking University Third Hospital-, Center of Reproductive Medicine- Department of Obstetrics and Gynecology-, Beijing, China

Study question: What is in euthyroid infertile women with thyroid auto-immunity (TAI) undergoing IVF-ET, the effect of levothyroxine treatment on pregnant outcomes.

Summary answer: Among euthyroid TAI infertile women undergoing IVF levothyroxine treatment does not improve the pregnant outcomes.

What is known already: It is known that TAI is associated with spontaneous pregnancy loss and poor pregnancy outcomes. In an IVF program, women with thyroid autoantibodies had lower fertilization, implantation and pregnancy rates, but higher abortion rates than women without such antibodies. Whether to give adjuvant therapy to regulate TAI before and during IVF is still controversial. Here, we investigate whether suppletion with levothyroxine in women with TAI undergoing IVF improves outcomes.

Study design, size, duration: The POSTAL study is a randomized, open-labelled, parallel two-group, single-centered clinical trial (ChiCTR-TRC-13004097). After informed consent, participating women were randomly assigned (1:1) to the levothyroxine (25-50ug/d) treatment group or the non-treatment controls. Levothyroxine treatment started two weeks before the IVF cycle. In women who conceived, levothyroxine was continued till delivery. We planned to recruit 600 women. A subgroup analyses was planned for women with TSH <2.5 or ≥2.5 mIU/L.

Participants/materials, setting, methods: Eligible women were euthyroid women with thyroid antibodies (Ab) (thyroperoxidase (TPO) and/or thyroglobulin (TG) Ab positive), aged 23-40 years, who were scheduled for their 1st or 2nd IVF cycle with fresh embryo transfer. Women with autoimmune diseases other than TAI, recurrent spontaneous miscarriage, diabetes mellitus or diagnosed endocrinological diseases were excluded. The primary endpoint was miscarriage rate. Secondary endpoints were, among others, clinical pregnancy rate and the live birth rate.

Main results and the role of chance: Between July 1st, 2012, and Nov 30th, 2016, 600 women were randomized, 300 to the levothyroxine group and 300 to controls. Baseline TSH levels were higher in the levothyroxine group than in the control group (2.891.02 vs. 2.210.99 mIU/L). Other baseline characteristics were comparable. In the levothyroxine group, 282 women had a fresh transfer, 15 did not complete their cycle, and 3 did not start their IVF cycles. In the control group, 285 women has a fresh transfer, 11 did not complete their cycle, and 4 did not start their IVF cycle.

In the intervention group, the average levothyroxine dosage during COH was 30.012.2 ug/d. The miscarriage rate was not different between the levothyroxine group and the controls (9.1% vs. 9.1%, P = 0.81). The clinical pregnancy rates (44% vs. 48.7%, P = 0.38) and live birth rates (36.9% vs. 37.6%, P = 0.94) were also both not different between the groups. Comparing the pregnant outcomes between individuals with TSH < 2.5 mIU/L and TSH ≥2.5 mIU/L, no significant difference were found between the groups and within the groups.

Limitations, reasons for caution: Thus was an open labelled RCT which might have confounded our findings effects. The lower levothyroxine dosage in the study might also minimize the effect of levothyroxine on pregnant outcomes to some extent. The trial was registered 12 months after start of the study.

Wider implications of the findings: In euthyroid infertile women undergoing IVF with TAI, levothyroxine treatment did neither decrease miscarriage rates, nor improve clinical pregnancy and live birth rates.

Trial registration number: The trial is registered at http://chictr.org.cn, the trial number ChiCTR-TRC-13004097.

P-709 Effectiveness and safety of follitropin alfa in infertile women using assisted reproductive technology in real-world clinical practice: a multicenter, prospective, open, non-interventional study

P. Sydow[1], R. Schneidereit[2], K. Pribbernow[3], C. Keck[4], I. Wiegratz[5]

[1]VivaNeo Praxisklinik Sydow Berlin, Private Practice, Berlin, Germany
[2]Teva GmbH, Medical Affairs- Business Unit Specialty Medicines, Berlin, Germany
[3]Kinderwunschzentrum Magdeburg, Private Practice, Magdeburg, Germany
[4]Endokrinologikum Hamburg, Private Practice, Hamburg, Germany
[5]VivaNeo Kinderwunschzentrum Wiesbaden, Private Practice, Wiesbaden, Germany

Study question: To examine number of oocytes retrieved and clinical pregnancy rate following controlled ovarian stimulation therapy with Ovaleap® in infertile women treated in real-world clinical practice.

Summary answer: Effectiveness and safety of controlled ovarian stimulation with Ovaleap® were supported during real-world assisted reproductive technology treatment using a gonadotropin releasing hormone (GnRH) antagonist protocol.

What is known already: Ovaleap® (follitropin alfa), a recombinant human follicle-stimulating hormone authorized by the European Medicines Agency in 2013, showed therapeutic equivalence in efficacy and safety to Gonal-f® for stimulation of follicular development in a multinational, multicenter, randomized, active-controlled, assessor-blind, comparative study of infertile women using assisted reproductive technology (ART). Using a GnRH agonist protocol, number of retrieved oocytes following controlled ovarian stimulation (COS) was equivalent in Ovaleap® and Gonal-f® patients. Safety of Ovaleap® treatment was further demonstrated in an open-label, uncontrolled, follow-up study of these patients with up to 2 additional Ovaleap® treatment cycles.

Study design, size, duration: 400 participants are planned for this multicenter, prospective, non-interventional study of women undergoing in vitro fertilization (IVF)/intracytoplasmic sperm injection (ICSI) following COS using Ovaleap® in a GnRH antagonist protocol during routine ART in approximately 40 specialized reproductive medicine centers in Germany. Study enrollment began in March 2016, with participant recruitment planned for 1 year. This planned interim analysis examined women who received ≥1 Ovaleap® dose and had Visit 3 (clinical pregnancy evaluation) data.

Participants/materials, setting, methods: Eligible women were 18-40 years old, undergoing first COS for IVF/ICSI, and were treated with Ovaleap® using a GnRH antagonist protocol. Study visits included baseline, Visit 2 (embryo transfer day), and Visit 3 (clinical pregnancy examination). Ovaleap® treatment duration was 1 stimulation cycle. Primary endpoints included number of oocytes retrieved and clinical pregnancy rate. Safety was examined by frequency and intensity (mild, moderate, severe) of adverse drug reactions (ADRs) and serious ADRs.

Main results and the role of chance: Of 192 patients who screened eligible, the 155 included in this interim analysis received ≥1 Ovaleap® dose and had Visit 3 data. Patient mean age was 32.8 ± 4.1 years, mean body mass index was 23.5 ± 3.2 kg/m^2, and mean anti-Müllerian hormone level was 3.6 ± 2.5 µg/L. Mean duration of the GnRH antagonist administration was 5.7 ± 1.9 (median = 6.0) days. Mean duration of Ovaleap® administration was 9.8 ± 1.7 (median = 10.0) days, and mean total Ovaleap® dose was 1752.7 ± 539.0 (median = 1650.0) IU. In women with oocyte retrieval (n = 152), mean number of retrieved oocytes was 11.7 ± 8.0 (median = 10.0; range 1-61). Oocyte retrieval was cancelled in 3 women due to low follicle number (1), premature increase in progesterone level and bleeding (1), and not reported (1). The overall clinical pregnancy rate was 33.5% (52/155) and by embryo transfer (n = 132; 1 excluded due to missing day of embryo transfer) was 39.4% (52/132). Of the 13 patients (8.4%) reporting ≥1 ADR, 9 (5.8%) reported ovarian hyperstimulation syndrome (OHSS), including 5 rated mild, 3 moderate, and 1 severe and 2 patients (1.3%) reported miscarriage. Six ADRs were rated serious (4=OHSS, 2=miscarriage). Of the 9 OHSS ADRs, 3 (including the severe OHSS) occurred during pregnancy (Week 5, late-onset OHSS) and 3 (all mild) resulted in egg/embryo freezing.

Limitations, reasons for caution: This study presents the planned interim analysis of the ongoing multicenter, prospective, open, non-interventional study. Caution should be used in the interpretation of results pending final analysis of the completed study.

Wider implications of the findings: The effectiveness (number of oocytes retrieved, clinical pregnancy rate) and safety of controlled ovarian stimulation with Ovaleap® appear to extend to real-world ART clinical practice, including IVF and ICSI treatment using a GnRH antagonist protocol. These interim real-world outcomes are consistent with those previously reported in randomized controlled clinical trials.

Trial registration number: Not applicable.

P-710 Ovulation induction (OI) or intrauterine insemination (IUI) with gonadotropins in patients with polycystic ovary syndrome (PCOS): description of patients and triggering rates. The GLOBALE-SOPK study

V. Isnard[1], P. Sagot[2], M. Pasquier[3], S. Frantz-Blancpain[4], S. Paillet[5]

[1]CHU de Nice Hôpital l'Arche II, Nice Cedex 3, France
[2]ART Department, Dijon Hospital, Dijon, France
[3]ART Department, Créteil Hospital, Créteil, France
[4]ART Department, Bordeaux Hospital, Bordeaux, France
[5]Medical Affairs Department, Merck, Lyon, France

Study question: Describe the triggering rates, the profiles and the management of PCOS patients undergoing OI/IUI having been prescribed follitropin alfa in a second gonadotropin stimulation attempt

Summary answer: The study highlights the great wealth of PCOS symptoms.

Real trigger rate is 93.3% [89.8; 96.8] with most patients (84.3%) receiving human chorionic gonadotropin alpha injection.

What is known already: PCOS is the most common endocrine disorder in infertile women (15-20% of prevalence), leading to anovulation and fertility disorders.

The diagnosis is complicated due to the multiplicity of criteria which are all rarely present in a single patient.

By consensus, PCOS is defined by the presence of at least two of the following criteria:

(1) Oligo and/or anovulation,
(2) Clinical and/or biochemical hyperandrogenism,
(3) Polycystic ovaries;

Treatment of infertility due to PCOS is in first-line clomiphene citrate. In case of failure or resistance, a personalized treatment by gonadotropins is recommended.

The mean triggering rate in literature is 74.1% in PCOS patients.

Study design, size, duration: It was a longitudinal observational national multicenter study with a maximum of 14 weeks follow-up. PCOS adult patients receiving follitropin alpha in a second stimulation attempt according to usual medical practices were included.

To demonstrate a triggering rate ≥ 70%, providing a maximum error of 5%, inclusion of 320 patients in 64 centers was needed. Participating physicians were asked to include the first 7-15 patients meeting inclusion/exclusion criteria and agreeing to participate in the study.

Participants/materials, setting, methods: Physicians were selected from an exhaustive listing and randomized until obtaining 64 French active participants. Their data were recorded using a registry.

Patients were selected at first or second attempt, but included only during the second attempt. Inclusion took place at the first monitoring visit (about one week after initiation of stimulation).

Follow-up was based on usual clinical practices until the 12th week of amenorrhea if pregnancy was achieved.

CRFs were completed by participating physicians.

Main results and the role of chance: Out of 172 selected physicians, 51 were active and recruited 202 patients. The sample was characterized by a mean age of 29.9 ± 4.3 years, mean infertility duration of 2.9 ± 1.7 years and mean BMI of 23.9 ± 4.4 kg/m2. Cycles averaged ≥ 35 days in 52.2% of patients (amenorrhea in 19.4%). Mean number of follicles was 40.8 ± 18.6.

35.1% of patients presented hyperandrogenism. Although NIH and Rotterdam definitions were not inclusion criteria, patients' disease matched with those definitions in 38.9% and 46.4% respectively.

72.8% of patients were previously treated by clomiphene citrate during an average of 3.8 ± 1.2 cycles at a mean dose of 93.5 ± 33.9 mg/day.

At second attempt, mean starting dose of FSH was 61.5 ± 23.7 UI, increased or stabilized since first attempt in 34.5% and 60.5% respectively. Mean stimulation duration was 9 ± 6.4 days with 55.7% of patients managed by OI (44.3% by IUI). Real triggering rate was 93.3% [89.8; 96.8] with most patients (84.3%) receiving a human chorionic gonadotropin alpha injection. B-hCG test revealed pregnancy in 25.9% of patients following triggering while periods occurred in 70.9%. Clinical pregnancy (mainly single) was confirmed in 20.1% of patients.

Limitations, reasons for caution: This study demonstrates the difficulty of finding a real definition for PCOS patients given the heterogeneity of patient profiles due to various criteria.

No triggering factors were identified because of the limited number of patients without a trigger not allowing the comparison based on the presence or absence of trigger.

Wider implications of the findings: A broad description of PCOS population was provided in this study but the great wealth of PCOS symptoms was also highlighted. However the real triggering rate reported at the second cycle of stimulation cycle by gonadotropins in those patients was high: 93.3% [89.8; 96.8] compared to the literature (74.1%).

Trial registration number: NA.

P-711 Effectiveness of a monoclonal antibody against human chorionic gonadotropin (hCG) to prevent reproductive and metabolic dysfunctions in transgenic female mice

C.A. Marcial Lopez[1], L. Ratner[1], J. Gupta[2], K. Nand[2], R. Calandra[1], G. Talwar[2], S. Rulli[1]

[1]Instituto de Biología y Medicina Experimental, CONICET, Buenos Aires, Argentina
[2]Talwar Research Foundation, Talwar Research Foundation, New Delhi, India

Study question: Is the monoclonal antibody against human chorionic gonadotropin (hCG) effective in preventing the phenotypic alterations of transgenic mice hypersecreting hCG?

Summary answer: The treatment was more effective in reversing the phenotype of transgenic female mice when it was administered at the juvenil stage as compared to adulthood

What is known already: hCG is involved in many functions during placentation and fetal development. Its levels are increased during pregnancy and postmenopause, and in pathological conditions, such as trophoblastic and non-trophoblastic tumors. Our previous studies demonstrated that transgenic female mice overexpressing the hCGβ-subunit (hCGβ+ mice) are infertile, exhibit increased levels of hCG, prolactin, progesterone and testosterone. Later in life, they develop prolactinomas and mammary gland tumors. In addition, these animals present insulin resistance and glucose intolerance. A monoclonal antibody developed by Dr. Talwar's group has high affinity for the hCG β-subunit, without cross-reaction with pituitary hormones.

Study design, size, duration: hCGβ+ females were injected i.p. with the monoclonal antibody (300 µg/mouse/dose) at 5 weeks (hCGβ+ mAB5w: every other day for one week, followed by one dose weekly; n = 10) and 16 weeks of age (hCGβ+ mAB16w: one dose weekly; n = 4) during two months. These were compared with females hCGβ+ injected with vehicle as controls (n = 5). Fertility studies, body weight, carbohydrate metabolism and the presence of tumors at 3-6 months of age were conducted.

Participants/materials, setting, methods: For fertility studies, hCGβ+ treated females were mated with wild type males two days after the last injection. Body weight was registered for 12 days. Blood glucose was measured in fasted female mice at 0, 30, 60 and 90 min after glucose administration (2 g/kg; i.p) for intraperitoneal glucose tolerance test (IGTT). The same procedure was used for insulin tolerance test (ITT; 0,75 IU/kg of insulin).

Main results and the role of chance: The effectiveness of the treatment would depend on the stage in which it is administered. During the juvenil stage, (hCGβ+ mAB5w) female mice normalized the estrous cycle and recovered fertility, but not at adulthood (hCGβ+ mAB16w). No differences in body weight between the groups were observed. The glucose tolerance test was normalized in both treated groups (p<0.05). All groups maintained the insulin resistance (p<0.05). Pituitary tumor development was prevented in the hCGβ+ mAB5w group.

Limitations, reasons for caution: Complementary studies will be needed for a better understanding of the mechanisms involved during the treatment with the monoclonal antibody against hCG. Other doses should be tested in order to get all the phenotypic alterations normalized.

Wider implications of the findings: This treatment was able to immuno-neutralize the effects of hCG, which could be a useful tool for therapies related with cancer and reproduction/infertility.

Trial registration number: not applicable.

P-712 Are there differences in Anti-Müllerian Hormone (AMH) values between populations? Usefulness of AMH reference values in a large Spanish population to predict ovarian reserve

J. Sunol Sala[1], M. Junyent[1], A. Garcia-Faura[1], M.J. Miravitlles[1], B. Fernandez-Forner[2], F. Echevarne[2], M. Lopez-Teijon[1]

[1]Institut Marques, Reproductive Medicine Service, Barcelona, Spain
[2]Laboratorios Echevarne, Provença- 312- 08037, BARCELONA, Spain

Study question: Are there differences in the distribution of AMH values in Spanish women compared with other studied populations?

Summary answer: AMH values in Spain are higher than those reported for other European countries and the USA, but lower than those reported for China.

What is known already: There is evidence in the world medical literature that infertility is a growing phenomenon; prevention and treatment strategies are therefore needed. One of the most reliable tests of a woman's ovarian reserve and her potential fertility is the Anti-Müllerian Hormone level. To date, the distribution of AMH values has not been reported for Spanish women. The aim in this study was therefore to define normality data of AMH by age and age groups in Spanish women, and to compare these results with those from other studied populations.

Study design, size, duration: This is a cross-sectional study with 10443 healthy women aged between 20 and 45 years from eleven different communities in Spain. We determined AMH values for each age and in groups of 5 years. Linear regression analyses were used to calculate ovarian age.

Participants/materials, setting, methods: All AMH values were assessed using an ELISA assay (AMH Gen II ELISA assay; Beckman Coulter, Brea, CA, USA). All samples were processed in the same central laboratory.

Main results and the role of chance: The mean age of the women was 36.6 years ± 4.3 years. Reference values for AMH, expressed as 25th, 50th, and 75th centiles by age and five year groups, were obtained. There were significant differences in AMH values between groups of women aged 30-<35 years, 35-<40 years, and 40-45 years. No significant differences were observed in AMH values in the first two age groups (20-<25 years, and 25-<30 years). The 50th centiles of mean AMH ranged from 3.45 to 0.72 ng/ml. AMH values were found to be significantly, and inversely, correlated to age (r= 0.35; p<0.001). From the regression equation, the estimated yearly decrease in AMH was 0.2 ng/ml. The range of AMH values in Spanish women were higher than those reported for other European countries and the USA, and lower than those reported for China.

Limitations, reasons for caution: The weakness of our study is the use of cross-sectional data, making it difficult to distinguish the behaviour of different variables over time. Thus, longitudinal values are needed to validate our nomogram. A further limitation is that it was not possible to correlate clinical data with the AMH values.

Wider implications of the findings: Each population may use its AMH reference values to define the ovarian reserve in addition to the patient's chronological age. AMH values in Spain are different from those reported for other populations.

Trial registration number: Not applicable.

P-713 Comparison of pretreatments with leupron stop, oral contraceptive, estrogen priming and estrogen primed antagonist in short antagonist ivf cycles

K. Ulker, Y. Sahin, S. Kahraman

Istanbul Memorial Hospital, In vitro fertilization and genetic diagnosis, Istanbul, Turkey

Study question: Do pretreatments pretreatments with leupron stop, oral contraceptive, estrogen priming and estrogen primed antagonist have difference in the outcome of short antagonist ivf cycles?

Summary answer: Collected and fertilized oocyte numbers, and live birth rates are lower with estrogen priming in comparison with leupron stop, oral contraceptive and estrogen primed antagonist.

What is known already: Non-homogenous follicular growth is one of the frequent problems of short antagonist ivf cycles and leads less mature and fertilized oocyte rates among the collected cumulus oophorus complexes (COC), thus it decreases the IVF success rates. Pretreatments aiming to lower pre and early follicular FSH levels are used to develop follicles with homogenous sizes during the initial phase of controlled ovarian stimulation. Although, there are numerous studies suggesting the benefits of the modalities, a through comparison of the efficacy of them with each other is lacking.

Study design, size, duration: Our retrospective, case controlled study included 655 short antagonist protocol ivf cycles between 2011 and 2015 in İstanbul Memorial Hospital. Following age, body mass index and Anti-Müllerian Hormone (AMH) level matching, four pretreatment modality groups including leupron stop (LS; n = 128), oral contraceptive (OC; n = 228), estrogen priming (EP; n = 128) and estrogen primed antagonist (EPA; n = 171) were formed.

Participants/materials, setting, methods: Infertile women with previous multiple unsuccessful IVF cycles with non-homogenous follicular growth were included. Ivf trial number, infertility duration, oocyte pick up characteristics including cumulus oophorus complex, mature oocyte and fertilized oocyte numbers; and ivf outcome measures including biochemical, clinical and ongoing pregnancy rates and live birth rates of the four groups were compared using one way analysis of variance and Bonferroni correction tests. A p value <0.05 was considered significant.

Main results and the role of chance: Daily and total dose of used gonadotropins and stimulation length in EP and OC groups were significantly lower than LS and EPA groups (p<0.05). Lack of FSH suppression after the last dose of OC till the follicular phase and mild suppression of FSH with EP may be the explanation. Long stop group, because of the most powerful suppression, had the longest stimulation period.

Cumulus oophorus, mature oocyte and fertilized oocyte numbers of EP group (6.8 ± 4.9, 5.2 ± 3.8, 4.1 ± 2.9, respectively) were significantly lower than LS (10.0 ± 6, 8.0 ± 4.8, 6.8 ± 4.1, respectively), OC (8.7 ± 6.8, 6.7 ± 5.2, 6.0 ± 4.6, respectively) and EPA (8.8 ± 6.0, 6.0 ± 4.9, 5.9 ± 4.4, respectively) groups' (p<0.05). Higher estrogen levels with EP may suppress some follicles at the recruitment stage.

Although, biochemical, clinical and ongoing pregnancy rates did not differ among groups (p > 0.05), live birth rate of EP group (17%) was significantly lower than LS (30%), OC (32%) and EPA (31%) groups' (p<0.05).

Used daily/total gonadotropin dose was significantly lower in OC group (p<0.05) and followed by estrogen priming group.

Estrogen priming group with the least oocytes, mature oocytes and fertilized oocytes had the lowest live birth rates (p<0.05), although the biochemical, clinical and ongoing pregnancy rates did not differ among groups (p>0.05).

Limitations, reasons for caution: The study was retrospective and presented the results of age, BMI and AMH matched cases. In clinical practice, presence of endometriosis, adenomyosis and cysts may urge to select certain pretreatment modality. Doses were adjusted depending the experience and preferences of the clinicians and randomization lacked.

Wider implications of the findings: Pretreatment modalities may be more effective in clearly defined specific groups. Higher gonadotropin doses in EP may improve the group specific IVF outcomes. However, until more definitive results EP should not be the first choice pretreatment modality to constitute homogenous follicular growth.

Trial registration number: None.

P-714 Fetal sex affects the maternal level of plasma anti-Mullerian hormone during pregnancy in cattle

A. Stojsin-Carter[1], N. Costa[2], R. De Morais[2], T. De Bem[3], M. Costa[2], D. Gillis[4], T. Carter[5], M. Neal[6], M. Miranda[2], O. Ohashi[2], L. Favetta[5], A. King[5]

[1]University of Guelph, Biomedical Sciences, Guelph- ON, Canada
[2]Universidade Federal do Pará, Instituto de Ciências Biológicas, Belem, Brazil
[3]Universidade de São Paulo, Departamento de Medicina Veterinária, Sao Paulo, Brazil
[4]University of Guelph, School of Computer Science, Guelph, Canada
[5]University of Guelph, Biomedical Sciences, Guelph, Canada
[6]ONE Fertility, IVF lab, Burlington, Canada

Study question: The aim of this study was to investigate the association between the plasma anti-Mullerian hormone (Pl AMH) levels in cows carrying male vs. female fetuses.

Summary answer: Cows carrying a male compared to a female fetus showed a significantly different change in Pl AMH between day 35 and 135 of pregnancy.

What is known already: AMH has recently gained attention as a potential early pregnancy sex-determining marker due to its markedly different expression in male vs. female fetuses. Only a few studies to date have investigated human maternal levels of AMH during gestation, with only one having reference to fetal sex. All of these studies showed a decline of maternal AMH levels during pregnancy, presumably due to inactivation of follicle growth, except of the single study in humans considering the impact of fetal sex on maternal AMH revealed a significantly higher Pl AMH levels in mothers carrying a male fetus.

Study design, size, duration: Pl AMH was measured in cows (n = 8) carrying female and male fetuses throughout gestation day 0, 35, 135 and 275 for each animal, as well as measured at single time points in the period between 85 and 155 days of gestation in cows (n = 21) and their fetuses. Expression of AMH receptor 2 (AMHR2) was measured in the placenta membranes and cotyledons of male and female fetus pregnancies (n = 13) between 38 and 80 days of gestation.

Participants/materials, setting, methods: Cows were subjected to peripheral or post-mortem blood collection coupled with a matching fetal blood collected via heart puncture in EDTA tubes and centrifuged at 1.400 rpm. The top plasma layer was aspirated and the Bovine AMH ELISA kit AL-114 was used to measure concentration of Pl AMH. Fetal sex was determined by the measurement of the anogenital distance. Cotyledon and placenta membranes from each reproductive tract were used to measure AMHR2 mRNA expression via qPCR.

Main results and the role of chance: Pl AMH in the multiple time point experiment between cows carrying a male vs. a female fetus between day 35 and 135 was significantly different, (p = 0.036; 255.4 ± 178.5 pg/ml vs. -181.3 ± 146.1 pg/ml, respectively); however, Pl AMH between days 135 and 275 was not significantly different (p = 0.786; 87.6 ± 161.2 pg/ml vs. 59.5 ± 54.3 pg/ml, respectively). Pl AMH in the single time point experiment in cows carrying a male or female fetus for the period of 85 to 155 days of gestation was not significantly different (p = 0.557; 947.3 ± 146.6 pg/ml vs. 809.4 ± 180.5 pg/ml, respectively). Significant differences were also observed between the average male and female fetus Pl AMH (p<0.05; 175,309.9 ± 16,903.7 pg/ml vs. 154.1 ± 22.3 pg/ml, respectively), and between Pl AMH of pregnant cows and their corresponding fetuses of both sexes (p<0.05). AMHR2 mRNA expression in cotyledon and placenta membrane samples were evaluated and found not to be significantly different in opposite sex fetuses (p = 0.553, and p = 0.660 respectively). When comparing within each sex samples, results were not significantly different for the male (p = 0.381), or the female (p = 0.927). The relative AMHR2 mRNA expression average in male cotyledon and placenta were 0.015 ± 0.004 and 0.050 ± 0.030 respectively, and in female cotyledon and placenta were 0.017 ± 0.001 and 0.081 ± 0.060 respectively.

Limitations, reasons for caution: Larger studies with additional sampling time points should be completed to verify these findings.

Wider implications of the findings: The evidence of thousand times higher fetal Pl AMH levels in male vs. female fetuses and a linked significant increase in the maternal Pl AMH levels between day 35 and 135 supports the hypothesis that ovarian function and maternal physiology can be affected by the sex of the fetus.

Trial registration number: 0.

P-715   Severe vitamin D deficiency is negatively associated with antral follicle count in infertile women

J. Bosdou[1], E. Kolibianakis[1], C. Venetis[2], G. Mintziori[1], D. Goulis[1], T. Tarlatzi[3], K. Karastefanou[4], L. Kyriazi[4], N. Konstantinidou[4], D. Savaidou[1], B. Tarlatzis[1]

[1]Aristotle University of Thessaloniki- Medical School, Unit for Human Reproduction- 1st Department of Obstetrics and Gynecology, Thessaloniki, Greece
[2]University of New South Wales-, Dept. of Women's and Children's Health- St George Hospital- School of Women's and Children's Health, Kogarah, Australia
[3]Hôpital Erasme - ULB, Fertility Clinic- Department of Obstetrics and Gynecology, Brussels, Belgium
[4]Biogenesis, Assisted Reproduction Unit, Thessaloniki, Greece

Study question: Is severe vitamin D deficiency associated with anti-Mullerian Hormone (AMH) and antral follicle count (AFC) in infertile patients?

Summary answer: Severe vitamin D deficiency is negatively associated with antral follicle count in infertile women.

What is known already: Vitamin D receptor has been identified in many reproductive tissues, while vitamin D serum levels have been negatively associated with female infertility. However, it remains unclear what levels of vitamin D are normal and what levels indicate severe deficiency in infertile women. Moreover, it is not known what are the implications of severe vitamin D deficiency regarding female reproductive potential, although there is evidence to support an association between vitamin D and ovarian reserve, as assessed by AMH and AFC.

Study design, size, duration: This is a prospective, cross-sectional study, performed between January 2016 and January 2017, in 157 consecutive Caucasian women, attending an IVF Unit. Cause of infertility varied among women and was due to age, endometriosis, fibroids, tubal factor or was idiopathic. Ovarian reserve was evaluated by assessment of serum AMH and AFC.

Participants/materials, setting, methods: AMH and vitamin D were assessed in the same blood sample using the automated Elecsys-AMH and Elecsys-Vitamin D total assay (Roche-Diagnostics), respectively. Severe vitamin D deficiency was defined as serum vitamin D <10 ng/mL. The time of blood samples collection was recorded to account for seasonal variation of vitamin D levels. Statistical analysis was performed using bivariate and multivariable logistic regression. Continuous variables are presented as mean (95% CI) and binary variables as proportion (95% CI).

Main results and the role of chance: Female age was 38.5 (37.7-39.2) years, BMI was 25.1 (24.5-25.8) kg/m^2 and infertility duration was 5.1 (4.6-5.6) years. Baseline serum FSH and AMH levels were 10.9 (9.8-12.2) IU/mL and 12.5 (10.4-14.5) pmol/L, respectively. AFC was 11.7 (10.4-12.9), while serum vitamin D levels were 19.5 (17.9-21.2) ng/mL. Out of the 157 patients analysed, 31 (19.6%, 13.7-26.7) had severe vitamin D deficiency. No significant association was present in bivariate analyses between severe vitamin D deficiency and age (coefficient: +0.04, 95%CI: -0.05 to +0.12), BMI (coefficient: +0.04, 95%CI: -0.04 to +0.12), duration of infertility (coefficient: +0.03, 95% CI: -0.08 to +0.14), AMH (coefficient: -0.03, 95%CI: -0.07 to +0.02), FSH (coefficient: +0.01, 95%CI: -0.04 to +0.06) and smoking (odds ratio: 1.28, 95% CI: 0.57 to 2.89). On the other hand, a significant negative association was present between severe vitamin D deficiency and AFC (coefficient: -0.07, 95%CI: -0.14 to -0.01, p = 0.03). This negative association remained significant (p = 0.04) in multivariable logistic regression analysis, controlling for age, BMI, smoking, duration of infertility, AMH, FSH and seasonal variation of vitamin D levels. AFC was significantly lower in patients with (mean: 8.58, 95%CI: 6.73 to 10.43) as compared to those without (mean: 12.41, 95%CI: 11.28 to 13.53) severe vitamin D deficiency.

Limitations, reasons for caution: The sample size in the current study might have limited the establishment of a significant association between severe vitamin D deficiency and AMH. Moreover, the results presented do not necessarily imply the presence of a causative association between severe vitamin D deficiency and AFC.

Wider implications of the findings: Confirmation of the present results in further prospective studies may justify the conduction of clinical trials evaluating vitamin D supplementation in infertile patients with severe vitamin D deficiency.

Trial registration number: -.

P-716   Differential incorporation of estrogen receptor β (ERβ) into promoter regions and its relevence to aromatase gene expression in women with polycystic ovary syndrome

E. Hosseini[1], F. Mehraein[2], M. Shahhoseini[3], L. Karimian[4], M. Ashrafi[5], P. Afsharian[3], R. Aflatoonian[5]

[1]Department of Obstetrics and Gynecology-, Shahrekord University of Medical Sciences, Shahrekord, Iran

[3]Department of Genetics- Reproductive Biomedicine Research Center-, Royan Institute for Reproductive Biomedicine- ACECR-, Tehran, Iran

[4]Department of Embryology- Reproductive Biomedicine Research Center-, Royan Institute for Reproductive Biomedicine- ACECR-, Tehran, Iran
[5]Department of Endocrinology and Female Infertility- Reproductive Biomedicine Research Center-, Royan Institute for Reproductive Biomedicine- ACECR-, Tehran, Iran

Study question: Is there any correlation between differential binding of ERβ into promoter regions of *CYP19A1* and its gene expression in cumulus cell of PCOS?

Summary answer: Differential occupancy of regulatory promoters of *CYP19A1* gene with ERβ protein was observed in cumulus cells (CCs) of PCOS patients compared to non-PCOS women.

What is known already: Estrogen biosynthesis by aromatase coding gene (*CYP19A1*) expression is a hallmark of several aspects of human reproductive health, ovarian functions and is also implicated in the development or progression of numerous diseases, including PCOS. Human ovarian cell aromatase is controlled by locally produced estradiol hormone through its receptor (i.e., Estrogen Receptor β). ER β is a transcription factor which directs the expression of the aromatase gene in cumulus cells. Our previous study showed that epigenetic alterations could change the aromatase gene expression in CCs, which may play a key role in the abnormal folliculogenesis and ovarian function in PCOS.

Study design, size, duration: Cross-sectional study was conducted on 24 patients (12 PCOS patients and 12 women with normal cycling ovaries as control group). Cumulus cells were obtained from women aged 18–36 year old, who underwent ovarian stimulation with antagonist protocol for intracytoplasmic sperm injection between November 2014 to April 2015. Informed consents were obtained from the participants.

Participants/materials, setting, methods: Cumulus oocyte complexes (COC) were obtained from follicles during ovarian puncture. Shortly before ICSI, CCs were stripped from the COC with hyaluronidase. Only cumulus cells with metaphase II oocytes (characterized by the presence of the first polar body) were selected for this study. Gene expression levels of *ERβ* were quantified using Q-PCR. Incorporation levels of ERβ protein to three promoter regions of *CYP19A1* gene (PII, PI.3 and PI.4) were evaluated by Chromatin Immunoprecipitation (ChIP) assay.

Main results and the role of chance: PCOS cumulus cells showed significant up-regulation of *ERβ* gene compared to the control group. Also, ChIP-qPCR analysis of ERβ binding into the three analyzed promoter regions of *CYP19A1* gene showed an increased occupancy of the PII and PI.4 promoters with the ERβ protein in CCs of PCOS patients ($P = 0.01$ and $P = 0.02$, respectively). In contrast, the incorporation of ERβ into promoters PI.3 in these patients is comparable to the control group.

Limitations, reasons for caution: Further studies are necessary to evaluate the interactions of other transcription factors with ERβ and to clarify the detailed mechanisms involved in the *CYP19A1* gene expression in PCOS patient.

Wider implications of the findings: Regarding the importance of the regulatory role of ERβ on the expression of aromatase gene, an augmented ovarian cells reaction in PCOS patients undergoing ovarian stimulation, relevant to aromatase expression, may be described by increased gene expression along with incorporation of the ERβ protein to its promoters.

Trial registration number: not applicable.

P-717   The effect of positive TPO-Ab on pregnancy outcomes of euthyroid IVF women

M. Cao[1], Z. Liu[2], D. Yang[3]

[1]Sun Yat-sen Memorial Hospital, Obstetrics & Gynecology, Guangzhou, China
[2]Nanfang Hospital, Department of Ultrasound, Guangzhou, China
[3]Sun Yat-sen Memorial Hospital, Department of Obstetrics & Gynecology, Guangzhou, China

Study question: It is still controversial if positive thyroid autoimmunity will affect the pregnancy outcomes of euthyroid women, especially women undergo in vitro fertilization (IVF).

Summary answer: Anti-thyroperoxidase antibody (TPO-Ab) is an independent risk factor of biochemical pregnancy and miscarriage of euthyroid women underwent IVF.

What is known already: Thyroid disease is the second most common endocrine condition in women at childbearing age. Thyroid hormones are involved in control of menstrual cycle and fertility by regulating the actions of follicle-stimulating hormone and luteinizing hormone on steroid biosynthesis by specific triiodothyronine sites on oocytes. Abnormal thyroid function cause adverse effects on maternal and fetal outcomes, for instance, pregnancy loss, gestational hypertension, or pre-eclampsia, pre-term delivery. Thyroid autoimmunity refers to the positive state of antithyroid antibodies, TPO-Ab and/or antithyroglobulin antibody (TG-Ab). Whether positive thyroid autoimmunity will affect the pregnancy outcomes of euthyroid women underwent IVF treatment was not clearly elucidated.

Study design, size, duration: A retrospective cohort study comparing pregnancy outcomes of women underwent IVF with positive or negative TPO-Ab were conducted. This study reviewed 6321 infertility women who received IVF treatment at Reproductive center, Sun Yat-sen Memorial Hospital, Sun Yat-sen University between January 2014 to October 2016.

Participants/materials, setting, methods: Women met the following criteria were included in this study, 1) aged 20-35 years old, 2) with normal thyroid hormone levels, 3) not received treatment against thyroid dysfunction, 4) not complicated with other autoimmunity diseases, 5) did not take any hormones or anti-coagulation medications in recent 3 months. Women with TPO-Ab more than 60IU/L were defined as antibody positive cases. Clinical data and pregnancy outcomes of women with positive and negative TPO-Ab were compared.

Main results and the role of chance: Euthyroid women underwent IVF with positive or negative TPO-Ab showed no differences in age, body mass index, duration of infertility, causes of infertility, basal FSH, LH, AMH, AFC, TSH levels. No significant differences of endometrial thickness, number of oocytes retrieved, number of embryos transferred, implantation rate, clinical pregnancy rate, and ectopic pregnancy rate were detected between euthyroid women with or without TPO-Ab. However, biochemical pregnancy rate and miscarriage rate of euthyroid women with positive TPO-Ab were much higher than those with negative TPO-Ab (biochemical pregnancy rate, 10.5% vs. 5.9%; miscarriage rate, 15.0% vs. 8.7%, $P < 0.05$). Logistic regression analysis showed that TPO-Ab is an independent risk factor of both biochemical pregnancy (adjusted OR 2.53, 95% CI 1.37-2.97, $P < 0.05$) and miscarriage (adjusted OR 3.02, 95% CI 1.62-3.87, $P < 0.01$) of euthyroid women underwent IVF.

Limitations, reasons for caution: This study recruited patients from single center, which might have selection bias, and may not represent other population from China.

Wider implications of the findings: It is necessary to screen thyroid autoimmunity of women undergo IVF, especially those with repeated miscarriage.

Trial registration number: NA.

P-718   Increased proportion of mature oocytes with sustained-releasing growth hormone treatment in poor responders: a randomized controlled study

Y.S. Kim[1], T.K. Yoon[2], J.W. Kim[3], M.J. Kim[2], J. Kim[2], S.A. Choe[2], D.R. Lee[4]

[1]CHA Medical School, Seoul, Korea- South
[2]CHA Fertility Center- Seoul Station, Obstetrics and Gynecology, Seoul, Korea- South
[3]Fertility Center of CHA Gangnam Medical Center, Obstetrics and Gynecology, Seoul, Korea- South
[4]CHA University, Biomedical Science, Seongnam, Korea- South

Study question: Does sustained-release human growth hormone (GH) supplement in poor responders undergoing in-vitro fertilization using GnRH antagonist protocol improve ovarian response?

Summary answer: Supplementation of sustained-release GH before and during controlled ovarian stimulation would improve ovarian response with more mature oocytes in poor responders.

What is known already: Use of growth hormone in poor responders has been found to show a significant improvement in ovarian response.

Study design, size, duration: This study was a single center, randomized, open label, parallel study. Infertile women who were diagnosed with decreased ovarian reserve were recruited from March 2014 to September 2015. With power 90% and significant level of 5%, sample size was calculated in reference to result from previous study. To detect significant difference in serum estradiol level of 150 pg/mL on hCG day, 62 samples were required in each group assuming 10% of lost-to-follow-up.

Participants/materials, setting, methods: Study eligibility was determined in reference to the Bologna criteria.The eligible participants were randomized into recombinant growth hormone treatment group and control. Women in the treatment group received sustained-release human growth hormone (Eutropin Plus® 20 mg, LG Life Sciences) three times before and during COS (Mid-luteal, late luteal and menstrual cycle day 2). The basal characteristics and IVF outcomes were compared between the two groups.

Main results and the role of chance: A total of 127 patients were included in the final analysis. The mean age of study population was 39.6 years and mean AMH was 0.6. Mean body mass index, medians of age, duration of infertility and previous number of IVF cycles were not different between GH treatment group (N = 62) and control (N = 65). There was no significant difference in the basal characteristics between the two groups. On hCG triggering day, GH group showed higher serum level of IGF-I and number of follicles (> 14 mm) than control (3.1 ± 2.3 vs 2.4 ± 1.6, P = 0.043). Higher proportion of MII oocytes in total retrieved oocytes (67.5 vs 52.3, P = 0.030) were observed in GH group. There were no significant differences in total dose of gonadotropin, endometrial thickness, fertilization rate and number of transferred total/good embryos. The proportion of clinical and ongoing pregnancy and miscarriage were not different between the two groups. In the multivariable linear regression models which controlled for the effect of confounders (i.e. age group, AMH, BMI, infertility duration, previous number of IVF cycles, endometrial thickness, progesterone on hCG and total number of retrieved oocytes), the probability of ongoing pregnancy was not different between the two group.

Limitations, reasons for caution: First, there was no comparison group with daily injection of recombinant GH. Further studies using control group with daily injection of recombinant GH would be needed. Second, we did not measured IGF-I and IGFBP-3 in follicular fluid. Serum level of those may reflect the local IGF-I and IGFBP-3 level.

Wider implications of the findings: The sustained-release form of recombinant GH would benefit wide range of poor responders undergoing fresh IVF-ET cycles. Since pregnancy rate in the poor responder group were generally low, larger sample would be needed to detect subsequent improvement in pregnancy rate.

Trial registration number: None.

P-719   GnRH-antagonist and agonist/antagonist conversion based ovarian stimulation protocols did not alter developmental outcomes and the embryonic ploidy

Z. Beyhan[1], D. Tortoriello[2], J. Wang[2], L. Keskintepe[1]

[1]Sher Institute for Reproductive Medicine-Las Vegas, Embryology, Las Vegas, U.S.A.
[2]Sher Institute for Reproductive Medicine-New York, Reproductive Endocrinology and Infertility, New York, U.S.A.

Study question: Do ovarian stimulation protocols based on GnRH-antagonist and agonist/antagonist conversion affect developmental outcomes and the embryonic ploidy during IVF cycles?

Summary answer: GnRH-antagonist and agonist/antagonist conversion based ovarian stimulation protocols did not alter developmental outcomes and the embryonic ploidy during IVF cycles.

What is known already: Potential adverse effects of gonadotropin analogs employed for ovarian stimulation on embryo development and quality have been a concern during controlled ovarian stimulation treatments. Though controversial, several studies indicated an association between stimulation protocols (gonadotropin type, dosage and duration) and ploidy status of embryos. Proponents of this idea suggest that the ovarian response to the hormonal stimulation affects the ability of recruited follicles to support oocyte growth and maturation, thus altering the competency of resulting oocytes and embryos.

Study design, size, duration: Retrospective cohort study. A total of 170 patients who underwent ovarian stimulation cycles followed by trophectoderm biopsy with array comparative genomic hybridization in a single center in 2014.

Participants/materials, setting, methods: Two different types of controlled ovarian stimulation protocols with gonadotropin-releasing hormone [GnRH] -antagonist, or agonist/antagonist conversion were used to treat 170 patients (antagonist protocol: 114 and conversion protocol: 56). A total of 542 blastocysts were biopsied and screened for aneuploidy using array genomic hybridization. Main outcome measures were frequencies of fertilization, blastocyst conversion and ploidy status of resulting embryos.

Main results and the role of chance: Fertilization and blastocyst conversion rates did not differ between stimulation protocols (% 86 and % 89 fertilization, % 43 and % 48 blastocyst conversion). There was no change in the rate of euploid embryos with different stimulation protocols for antagonist and conversion protocols (%38 and %35 respectively). Although it did not reach a statistical significance, patients who were < 35 yrs old tend to produce more euploid embryos with antagonist protocol than those with conversion protocol (%52 and % 34 respectively). When patients were classified based on their cycle day 3 FSH levels (FSH<8mIU/ml vs FSH>8 mIU/ml), no outcome measure of the study was different between stimulation protocols

Although it is plausible that controlled ovarian stimulation protocols affect the quality of preimplantation stage embryos, our results did not suggest any significant difference between two commonly used current stimulation protocols, in terms of embryo development and ploidy status.

Limitations, reasons for caution: Retrospective analysis with a relatively modest sample size in a single center setting.

Wider implications of the findings: Data presented here adds the growing body of data about possible relationship between ovarian stimulation protocols and embryo competency/characteristics.

Trial registration number: NA.

P-720   Close relationship of hirsutism to hyperandrogenemia in women with polycystic ovary syndrome - with LC-MS/MS measurements

Z. Xiaomiao[1], Y. Yang[2], N. Di[2], A. Ricardo[3], D. Yang[2]

[1]SunYat-Sen Memorial Hospital- Sun Yat-Sen University, Obstetrics and Gynecology, Guangzhou, China
[2]Sun Yat-sen Memorial Hospital of Sun Yat-sen University, Obstetrics and Gynecology, Guangzhou, China
[3]the Medical College of Georgia- Augusta University, Obstetrics and Gynecology- and Medicin, Augusta, U.S.A.

Study question: There were little overlaps between hirsutism and hyperandrogenemia although they were both representatives of the clinical and biochemical aspects of androgen excess. Is it true or because the unaccurate evaluation?

Summary answer: The incidence of hirsutism assessed by modified Ferriman-Gallwey (mFG) and simpified FG, was 80.2% and 86.6%, in patients deemed hyperandrogenemic by LC-MS/MS (P < 0.001).

What is known already: Hyperandrogenism is critically important for the diagnosis and management of PCOS, and can be determined clinically, usually by hirsutism, or biochemically, through the level and total testosterone (TT) or, better still, free testosterone (FT). However, there were little overlaps between hirsutism and hyperandrogenemia found in published reports. We have published that the improved clinical evaluation of hirsutim had a much closed relationship with TT level, with the measurement of liquid chromatography and tandem mass spectrometry assay (LC-MS/MS). Here we hypothesized that TT measured by LC-MS/MS would predict the extent of unwanted hair growth well in Asian PCOS subjects.

Study design, size, duration: Study designed: A cohort study in an academic hospital for one year. Size and duration: A total of 332 consecutive women with PCOS aged 18 to 44 years were recruited at Sun Yat-sen Memorial Hospital from September 21, 2014 to October 10, 2015.

Participants/materials, setting, methods: All subjects were screened using a standard tool to collect clinical data, undergo a physical examination and blood sampling The relationship between hirsutism and TT and its corresponding FAI

values measured by LC-MS/MS versus chemiluminescent immunoassay (CLIA). The concordance and the deviation of TT and the mFG and sFG (solely including the scores of the upper lip, lower back, lower abdomen, and thigh) scoring system for diagnosing hyperandrogenism were further analyzed.

Main results and the role of chance: The incidence of hirsutism assessed by mFG and sFG, was 80.2% and 86.6%, in patients deemed hyperandrogenemic by LC-MS/MS (P < 0.001), compared to 56.6% and 67.5% of those determined hyperandrogenemic by CLIA, respectively. Rank correlation coefficient between TT level determined by LC-MS/MS and mFG scores was 0.642 (95% CI: 0.571, 0.703, P < 0.001); while that between TT by CLIA and mFG scores was 0.045 (95% CI: - 0.067, 0.156, P = 0.420). Likewise, TT by LC-MS/MS was positively correlated with sFG scores, with a R = 0.780 (95% CI: 0.730, 0.817). FAI estimated from LC-MS/MS TT values was positive related to mFG and sFG scores, with a R = 0.261 and 0.204, respectively (P < 0.01). There were 80.2% women with increased mFG scores who were also hyperandrogenemic defined by increased TT level measured by LC-MS/MS.Furthermore, the cluster analysis demonstrated that TT level measured by LC-MS/MS clustered with mFG score; these two parameters could explain 84.7% of variance. Logistic regression analysis indicated that the risks of increased TT level measured by LC-MS/MS for those with increased mFG score (mFG score ≥ 5) (OR) was 13.485 (p < 0.0001).

Limitations, reasons for caution: The free testosterone level could not be measured by accurate method of LC-MS/MS yet.

Wider implications of the findings: Hirsutism has close relationship with TT measured by LC-MS/MS in Mongoloid Chinese women with PCOS, suggesting that the evaluation of facial and body terminal hair growth should be the first line examination to predict hyperandrogenism.

Trial registration number: ChiCTR-DDT-14005186

P-721   Comparison of fresh versus frozen embryo transfer in women with Polycystic Ovary Syndrome

R.A. Gupta, K.D. Nayar, M. Gupta, M. Singh, G. Kant, N. Sharma, D. Nayar

Akanksha IVF Centre, Mata Chanan Devi Hospital, New Delhi, India

Study question: Is frozen embryo transfer in subsequent cycle better than fresh transfer in women with polycystic ovary syndrome (PCOS) when human chorionic gonadotropin (hCG) is used as trigger in antagonist cycles.

Summary answer: Clinical pregnancy rates and live birth rates are better with freezing and transfer in subsequent cycle compared to fresh embryo transfer in women with PCOS

What is known already: Transfer of fresh embryos is a usual practice but in women at risk of ovarian hyper stimulation due to excess follicle development, elective cryopreservation of all embryos and transfer in subsequent cycle is preferred. Fresh cycles have supra physiological steroid levels which may alter the endometrial receptivity and probably affect placentation adversely whereas frozen embryo transfer is done to the uterus after a programmed physiologic cycle of hormone replacement to prepare the endometrium.

Study design, size, duration: A prospective cohort study. Infertile women less than 35 years with the polycystic ovary syndrome diagnosed by Rotterdam criteria who were undergoing their first IVF cycle from 1st Jan 2015 to 28th Feb 2016 were included. Cycles complicated by ovarian hyper-stimulation syndrome (OHSS) were excluded.

Participants/materials, setting, methods: Women (N = 126) with terminal estradiol levels below 2500 pg/ml were triggered with recombinant hCG and based on the number of retrieved oocytes were divided into two groups, Group A- < 15 oocytes retrieved had fresh embryo transfer and Group B where > 15 oocytes were retrieved, all embryos were frozen on day 3 and transferred in subsequent cycle. Primary outcomes were clinical pregnancy rates and live birth rates. Secondary outcome were fertilisation, implantation and miscarriage rates.

Main results and the role of chance: Group A had 73 fresh transfer and Group B had 53 frozen embryo transfer. Both groups were comparable regarding age, body mass index (BMI), basal follicular stimulating hormone (FSH), Antimullerian hormone (AMH) and antral follicle count (AFC). Categorical data was represented as frequency and percentages, differences in these measures between the groups were compared using chi-square tests and quantitative data by student t test. Clinical pregnancy rates (Group A-38.4% versus Group B- 41.5%, p = 0.88), Live Birth Rate (Group A: 26.0% versus Group B: 33.9% p = 0.25) were slightly higher in Group B though not statistically significant. The misscarriage rate in both the groups were comparable. (Group A 15.1 % and Group B 15.1 %, p = 0.8).

Limitations, reasons for caution: Due to the small sample size the study lacks power, which is the main limitation.

Wider implications of the findings: Performing frozen embryo transfer in PCOS women with average estradiol levels yet higher number of recovered oocytes is better than fresh transfer, implying adopting practice of routine elective freezing of embryos and transfer in subsequent cycle for better reproductive outcomes even in hCG triggered cycles in PCOS women.

Trial registration number: MCDH/2014/27.

P-722   Pre-hCG serum progesterone elevation in consecutive 762 IVF cycles: There is a cycle to cycle variation in ovarian response and progesterone levels

S. Yildiz Oguz[1], K. Yakin[1,2], A. Isiklar[2], B. Balaban[2], B. Urman[1,2], O. Oktem[1,2]

[1]Koc University School of Medicine, Department of Obstetrics and Gynecology- the Division of Reproductive Endocrinology and Infertility, Istanbul, Turkey
[2]American Hospital, Women's Health Center- Assisted Reproduction Unit, Istanbul, Turkey

Study question: Should we expect to see similar pre-hCG progesterone (P) levels in two consecutive IVF cycles comparable for gonadotropins, GnRH analog used, and duration of stimulation?

Summary answer: Serum P level at ovulation trigger in the subsequent IVF cycle may change unpredictably and disproportionately with P and ovarian response of a previous cycle.

What is known already: It is well-documented that serum P level at the time of hCG administration is significantly correlated with the magnitude of ovarian response to stimulation (the number of pre-ovulatory follicle≥14 mm, E_2 on hCG day, total and mature oocyte numbers). However, it is largely unknown whether serum P levels and ovarian response change proportionally in two consecutive IVF cycles stimulated with the same protocol and FSH given at a similar dose and duration.

Study design, size, duration: A non-interventional, retrospective cohort data of from single center

Participants/materials, setting, methods: A total of 381 patients (age:31.2 ± 3.2) undergoing two consecutive ovarian stimulation cycles (n = 762) with GnRH agonist long protocol were analyzed. Total FSH dose (2887 ± 1022 vs. 2856 ± 1034 IU respectively, p = 0.42) and duration of stimulation (10.3 ± 1.3 vs. 10.4 ± 1.6 days respectively, p = 0.72) were comparable between the cycles. The mean interval between the cycles was 6.7 ± 3.5 months. Paired t-test or Wilcoxon matched-pairs signed rank test were used to compare P levels and ovarian response parameters between the cycles.

Main results and the role of chance: Serum P level on hCG day was significantly increased (≥ 50%;≥ +1 SD) in the second IVF cycle in 95 of 381 patients compared to the first cycles values of P (2.06 ± 0.4 vs. 1.03 ± 0.3 ng/mL respectively, p < 0.01). Ovarian response (preovulatory follicles≥14 mm, E2 on the day of hCG, and total and mature oocyte numbers) significantly increased along with P in the second IVF cycle in only 45 (47.3%) while it did not change significantly in 11 (11.5%); and significantly decreased in the remaining 39 (41.2%) of the 95 patients compared to their first IVF cycle. In another 41 of these 381 patients serum P level significantly decreased by ≥ 50% (≥ +1 SD) in the second vs. first IVF cycle (0.64 ± 0.3 vs. 2.1 ± 0.5 respectively, p<0.001). Despite the decline in P level ovarian response significantly increased in the second cycle in 13 (31.7%); did not change significantly in 7 (17%), and significantly decreased in the remaining 21 patients (51.3%) compared to their first cycle. In the remaining 245 patients (64.3%) serum P level at ovulation trigger, ovarian response and oocyte yield were completely comparable between the first and second IVF cycles.

Limitations, reasons for caution: Retrospective nature of data.

Wider implications of the findings: These findings indicate that serum P may change in the next IVF cycle unpredictably and disproportionately with P and ovarian response of previous cycle suggesting that growth characteristics and steroidogenic activities of antral cohorts that produce P before ovulation in response to FSH may exhibit considerable cycle to cycle variations.

Trial registration number: None.

P-723 Outcomes of in vitro fertilization in poor responders of ≤ 40 years of age using either daily gonadotropin stimulation or long acting FSH stimulation

M. Chawla[1], M. Fakih[2], P. Devroey[3], O. Qasim[4], A. Shunnar[5], G. Emerson[6], V. Perumal[7]

[1]Fakih IVF Fertility Centre, IVF, Abu Dhabi, United Arab Emirates
[2]FAKIH IVF Fertility Center, IVF, Abu Dhabi, United Arab Emirates
[3]FAKIH IVF Fertility Center, IVF, Abu Dhabi, United Arab Emirates
[4]FAKIH IVF Fertility Center, embryology, Abu Dhabi, United Arab Emirates
[5]FAKIH IVF Fertility Center, ivf, abudhabi, United Arab Emirates
[6]FAKIH IVF Fertility Center, Embryology, Abu dhabi, United Arab Emirates
[7]AIIMS, Clinical Statistics, New Delhi, India

Study question: Evaluation of outcomes of in vitro fertilization in poor responders in two stimulation regimens, daily gonadotropins (HMG-HP) and long acting FSH stimulation protocol.

Summary answer: The primary and secondary outcomes in poor responders showed no significant difference in the various clinical and embryological parameters in the two groups studied.

What is known already: Long acting FSH is a novel recombinant FSH analog which can be administered in the follicular phase and sustains the follicular development for the first week unlike other gonadotropins. Cochrane review concluded its efficacy in normoresponders and was comparable to daily recombinant FSH. Poor responders were excluded from these studies. Due to its two fold longer half life and sustained pharmacological FSH activity, it has a critical role to play in initial spurt of follicular growth in poor responders. Previous studies have been small and retrospective with no difference in results between two regimens.

Study design, size, duration: This study was conducted as prospective observational study from Jan 2016- September 2016 at FakihIVF Fertility center, UAE.

One hundred and thirty three women, ≤40 years of age undergoing in vitro fertilization with fresh cycle transfers were included.

Inclusion criteria – Women with previous poor response (< 4 COCs after maximal stimulation), FSH ≤ 20 IU/L, BMI ≤ 32 kg/sq m.

Exclusion criteria – Women > 40 years.

Participants/materials, setting, methods: Using Antagonist protocol.

Group A – Long acting FSH in a single dose of 150 microgram on day 2 and followed by HMG from day 7 in a dose of 225 units.

Group B – HMG-HP 300 IU daily from day 2 of the cycle.

Primary outcome was ongoing pregnancy rate.

The secondary outcome measures were length of stimulation protocol, number of eggs retrieved, number of embryos transferred, number of cancelled cycles.

Main results and the role of chance: The two groups did not differ in mean age, AMH levels, number of stimulation days, number of eggs retrieved and number of embryos transferred.

The ongoing pregnancy rates per cycle in Group A were 36.7% (11/30) and in Group B were 34.2% (25/73). The difference was not statistically significant (P = 0.815). The pregnancy rate per embryo transferred was 23.9 % (Group A) and 21.4 % (Group B) respectively. The implantation rates were Group A (30.4%) and Group B (23.9%) (p = 0.0.39) respectively. The cancellation rates (no embryos transferred) were lower in Group A (14.3%) than Group B (25.5%) but the difference was not found statistically significant. ROC analysis indicates that AMH is not a significant predictor of cumulative pregnancy status as evidenced by Area Under Curve (AUC), which shows 0.646 for Antagonist group and 0.553 for Long acting FSH group.

Limitations, reasons for caution: Large randomised studies are needed to prove the efficacy of Long Acting FSH in poor responders.

Wider implications of the findings: Long acting FSH may provide a reduction in the daily burden of injections for poor responders with comparable results to conventional regimens. This can improve the drop out rates for in vitro fertilization in poor responders where multiple cycles are needed to achieve success.

Trial registration number: The study was approved by the local ethical committee and Institutional review board.

P-724 The role of pigment epithelium-derived factor (PEDF) in the pathogenesis and treatment of polycystic ovary syndrome (PCOS)

I. Miller[1], D. Chuderland[1], R. Rol-El[2], R. Shalgi[1], I. Ben-Ami[2]

[1]Tel-Aviv University, Department of Cell and Developmental Biology- Sackler Faculty of Medicine, Tel-Aviv, Israel
[2]Assaf Harofeh Medical Center- affiliated with Sackler Faculty of Medicine Tel-Aviv University, IVF and Infertility Unit Department of Obstetrics and Gynecology, Tel-Aviv, Israel

Study question: Does pigment epithelium-derived factor (PEDF) play a role in the pathogenesis and treatment of polycystic ovary syndrome (PCOS)?

Summary answer: Androgen-induced low PEDF level enables increase of VEGF and IL6/8 expression. Treatment with rPEDF reduces VEGF and IL6/8 levels, alleviating the angiogenic and inflammatory imbalances.

What is known already: PCOS is the most common endocrine disorder in women. Whereas the etiology of PCOS remains elusive, there is compelling evidence that chronic, systemic inflammation is a significant component of this disorder. However, the relationship between inflammation and hyperandrogenism, the hallmark of PCOS, is not well understood. PCOS patients commonly have increased expression of ovarian VEGF and cytokines (such as IL6/8). This overproduction of VEGF and IL6/8 is associated with ovarian hyperstimulation syndrome (OHSS). We showed that PEDF, a potent anti-angiogenic and anti-inflammatory factor, which counteracts VEGF and IL6/8, plays fundamental role in the pathogenesis and treatment of OHSS.

Study design, size, duration: In-vitro studies included cultures of human primary granulosa cells (hpGCs) from follicular fluids aspirated from women undergoing IVF treatments. Primary cells were allowed to reach quiescence after 5 days of culture in hormone-free medium. In-vivo studies included PCOS mice model: pregnant ICR mice were administered once daily with dihydrotestosterone (DHT) or with oil, as control, on days 16–19 of pregnancy. Female offspring were allowed to grow to reproductive age (8 weeks).

Participants/materials, setting, methods: We used a mouse PCOS model and cultured hpGC. Changes in the levels of PEDF, VEGF and IL6/IL8 were measured by qPCR, Western blot and ELISA.

Main results and the role of chance: Stimulation of hpGCs with DHT (10 ng/ml) resulted in significant downregulation of PEDF mRNA expression (~70%, P < 0.001), concomitantly with significant increase of IL6 and IL8 mRNA expression (P < 0.05). Co-stimulation with DHT (10 ng/ml) and rPEDF (5 nM), restrained the increase in the expression of IL6 and IL8 mRNA (P < 0.05). Stimulation of hpGCs with IL8 increased the expression of VEGF and decreased that of PEDF mRNA; whereas co-stimulation with IL8 and rPEDF restrained VEGF upregulation (P < 0.04). Finally, we found in the PCOS mice model an increase in the level of ovarian VEGF concomitant with a decrease in the level of PEDF mRNA (P < 0.05).

Limitations, reasons for caution: The in-vivo experiments were performed in a mouse model.

Wider implications of the findings: Our findings suggest a novel role of PEDF in PCOS pathogenesis and treatment. Hyperandrogenism reduces ovarian PEDF level, enabling high VEGF and IL6/8 levels. This angiogenic and inflammatory imbalance can be restored by rPEDF treatment. Further studies of PEDF role in the ovary could reveal new fertility therapeutic avenues.

Trial registration number: Not relevant.

P-725 The lower serum Anti-Müllerian Hormone (S-AMH) threshold measured by the Elecsys assay that predicts development of three mature follicles for In-Vitro Fertilization (IVF)

F. Pilsgaard[1], A.G.A. Grynnerup[2], K. Løssl[1], A. Zedeler[1], J.W. Bogstad[1], L. Praetorius[1], L. Bungum[3], A. Nyboe Andersen[4], A. Pinborg[1]

[1]University Hospital of Copenhagen Hvidovre Hospital- The Fertility Clinic, Department of Obstetrics and Gynecology-, Hvidovre, Denmark
[2]University Hospital of Copenhagen Hvidovre Hospital, Department of Clinical Biochemistry, Hvidovre, Denmark

[3]University Hospital of Copenhagen Herlev Hospital- The Fertility Clinic, Department of Obstetrics and Gynecology-, Herlev, Denmark
[4]University Hospital of Copenhagen Rigshospitalet- The Fertility Clinic, Department of Obstetrics and Gynecology-, Copenhagen Ø, Denmark

Study question: Can serum AMH predict the patients with low ovarian reserve that reach the classical hCG criteria of three mature follicles after ovarian stimulation?

Summary answer: The S-AMH threshold giving the most accurate prediction was 4.15 pmol/L for reaching the hCG criteria and 4.3 pmol/L for positive pregnancy test.

What is known already: AMH is a marker of the ovarian reserve and the response to ovarian stimulation. The classical criteria for hCG-administration is ≥ 3 follicles ≥ 17 mm after controlled ovarian stimulation. S-AMH has shown to predict the ovarian response to gonadotrophin stimulation. Few studies have investigated the optimal S-AMH threshold predicting who will reach the classical hCG criteria among women with low ovarian reserve. A new fully automated assay is able to detect very low values of AMH.

Study design, size, duration: Prospective cohort study of 80 women with an AMH ≤ 12 pmol/L referred for IVF/ICSI. AMH was measured using the Elecsys assay on cycle day 2-3. Patients were treated in a short GnRH-antagonist protocol with a fixed dose of 300 IE HP-hMG. Follicular development was followed by ultrasound. Triggering ovulation with hCG was given when there was at least 1 follicle ≥ 17 mm. S-hCG ≥ 5 IE/L two weeks after embryo transfer defined positive hCG.

Participants/materials, setting, methods: Participants were women ≤ 40 years of age with a regular menstrual cycle and a low to limited ovarian reserve defined as AMH levels ≤ 12 pmol/L. Three out of 80 cycles (3.8%) were cancelled due to no follicular development. Embryo transfer was performed in 53/80 women (66.3%). Receiver operator curve (ROC)-analysis was used to identify the optimal AMH threshold for reaching the hCG criteria and for positive hCG. Analyses were performed using SAS 9.3.

Main results and the role of chance: The median age was 36.0 (range 26; 39) years, median cycle length was 26.0 (range 17; 34) days. Median AMH was 5.0 (range 0.41; 12.0) pmol/L. Twenty-one women (26.3%) reached the hCG criteria and 19 women (26.3%) had a positive hCG test. The lowest AMH-value observed in the group with positive hCG was 0.98 pmol/L. ROC-analysis showed that an AMH threshold of 4.15 pmol/L predicted those patients that reached the hCG criteria with 90.5% sensitivity and 44.1% specificity, area under curve (AUC) = 0.69 (95% CI; 0.57-0.81). Using AFC as predictor the AUC was 0.70, (95% CI; 0.57-0.82). Including both predictors in the model AUC was 0.70, (95% CI; 0.58-0.82).

As a predictor of positive hCG, AMH ≥ 4.3 pmol/L had the optimal performance with 78.9% sensitivity and 42.6% specificity, AUC was 0.63, (95% CI; 0.48-0.78). AFC was less accurate, AUC = 0.50, (95% CI; 0.34-0.66). When predicting positive hCG the best performance was achieved with the combined test with an AUC of 0.65, (95% CI; 0.51-0.79). Both regarding the classical hCG criteria and positive hCG test a combination of AMH and AFC had the best screen performance.

Limitations, reasons for caution: The study has a limited sample size and only one cycle per woman was included. The optimal would be to analyse AMH in relation to cumulative birth rates.

Wider implications of the findings: In women with lower ovarian reserve S-AMH is unable as a single marker to predict women that reach the hCG criteria or achieve pregnancy after ovarian stimulation as specificity is low. S-AMH cannot be used to allocate women to either IVF or oocyte donation prior to their first stimulation cycle.

Trial registration number: NA.

P-726 Melatonin treatment is able to restore menstrual cyclicity in PCOS women: a pilot study

V. Immediata, V. Tagliaferri, S. De Cicco, E. Scarinci,
C. Di Florio, C.M. Santarsiero, A. Tropea, R. Apa, A. Lanzone,
D. Romualdi

Gynaecology and Obstetrics, Università Cattolica del Sacro Cuore, Roma, Italy

Study question: Does a six month treatment with melatonin improve the clinical, hormonal and metabolic features of normal-weight women affected by polycystic ovary syndrome (PCOS)?

Summary answer: Treatment with melatonin may improve menstrual irregularities and biochemical hyperandrogenism in normal-weight PCOS women.

What is known already: Melatonin seems to regulate steroidogenesis, folliculogenesis and oocyte maturation within the ovary, to protect follicles against oxidative stress and to rescue them from atresia. Melatonin may also play a role in the regulation of gonadotropin release hormone - gonadotropin axis. The reduction of melatonin levels due to pinealectomy induces the development of PCOS in rats. Melatonin supplementation is able to reduce long term body weight gain in animals. In addition, lower levels of this hormone have been detected in the ovarian follicles of PCOS women and this finding has been related to the anovulation that characterize the syndrome.

Study design, size, duration: Prospective cohort study including forty normal-weight PCOS women between January 2016 and September 2016 in an academic research environment.

Participants/materials, setting, methods: Forty normal-weight PCOS women (mean BMI 22.7, 18 – 35 years) were enrolled. Ultrasonographic pelvic exams, hirsutism score evaluation, hormonal profile assays (Antimullerian Hormone, Thyroid stimulating hormone, Follicle Stimulating Hormone, Luteinizing Hormone, Estradiol, Prolactin, Testosterone, Androstenedione, 17hydroxyprogesterone, Sex Hormone Binding Globulin and Dehydroepiandrosterone Sulfate), oral glucose tolerance test (OGTT) with the determination of insulin and glucose levels and lipid profile at baseline and after 6 months of melatonin treatment were performed.

Main results and the role of chance: Almost 95% of subjects experienced an amelioration of menstrual cycles during the treatment with melatonin with a significant increase in the number of cycles/six months (P < 0.01). A slight, yet significant, decrease in body weight (P< 0,01) and, consequently, in BMI (P < 0.01) was observed. A significant decrease in androgens levels occurred (Free Androgen Index: p<0.05; Testosterone: p<0.01; 17hydroxyProgesterone: p<0.01). FSH levels significantly raised (p<0.01) and AMH serum levels significantly dropped (p<0.01). After therapy, we did not observe a significant modification in the insulin secretion during the OGTT and the treatment did not affect peripheral insulin sensitivity in our group of patients. All patients had a normal lipid profile at baseline; total cholesterol, HDL and triglycerides plasma levels remained unvaried after six months of treatment, whereas LDL-cholesterol plasma concentrations showed a significant reduction.

Limitations, reasons for caution: The lack of a placebo group and the small sample size represent limitations of this pilot study. Future randomized controlled trials on this topic are needed to confirm our findings.

Wider implications of the findings: This is the first study focused on the effects of exogenous melatonin in PCOS patients. Melatonin seems to improve menstrual irregularities and biochemical hyperandrogenism independently of effects on insulin metabolism, Based on our results, melatonin could be considered a potential future therapeutic agent for women affected by PCOS.

Trial registration number: NCT02663570.

P-727 Is the performance of commercial progesterone assays suitable for determining fresh-cycle embryo transfer or freeze policy?

J. Lyon[1], C. Fairbairn[1], M. Gaudoin[2], R. Fleming[1]

[1]GCRM Ltd, Biochemistry, Glasgow, United Kingdom
[2]GCRM Ltd, Clinical, Glasgow, United Kingdom

Study question: Can commercially available progesterone assays be used to guide a policy of fresh embryo transfer versus segmentation if the progesterone concentration is deemed too high?

Summary answer: Commercially available progesterone assays show progressively greater inter-laboratory and inter-assay variability as progesterone concentrations decrease (Variance of >15% at <8.0 nmol/L).

What is known already: An early rise in progesterone concentration during ART stimulation is associated with asynchronicity between endometrial development and the subsequent embryo development, resulting in reduced implantation rates. Previous research states that if the progesterone concentration is > 4.5 nmol/L on day of trigger, it may be expedient to vitrify all suitable embryos (segmentation). This increases the risk of losing viable embryos. There

are uncertainties about the precision of commercially available progesterone assays at low concentrations. We aimed to assess performance over an extended time-scale across multiple laboratories, to determine suitability for guiding a policy of fresh embryo transfer versus segmentation.

Study design, size, duration: Objective multicentre comparative cohort study. Sixteen successive monthly distributions of 80 serum samples were sent to contributing laboratories running one of five different progesterone assay systems (Abbott Architect®, Beckman Coulter Access 2®, Roche Elecsys®, Siemens Centaur® and Siemens Immulite®) through the NEQAS quality control system. The mean and percentage coefficient of variation (%CV) of the progesterone concentrations (as published by UK NEQAS) were compared.

Participants/materials, setting, methods: The absolute progesterone concentrations and inter-laboratory variance were assessed for sample values from the 80 samples analysed in 16 distributions for five different assay formats. A recovery test at follicular phase concentrations was also effected for one commercial platform (Beckman Coulter Access 2®).

Main results and the role of chance: At a mid-luteal progesterone concentration of 40 nmol/L the mean %CV was 8%. As the progesterone concentration decreased, the %CV increased. At progesterone concentrations between 8 and 10 nmol/L, the %CV was 14%. Variance at concentrations lower than this increased markedly.

The recovery test at approximately 5 nmol/L showed a variance of 20%.

The data are strong evidence questioning the reliability of commercial assays at follicular phase levels.

These statistical analyses undermine the potential role for these tests.

Limitations, reasons for caution: Recovery tests should be performed in all of the methods to confirm that the test weaknesses are universal.

Wider implications of the findings: Commercially available progesterone assays show progressively greater inter-laboratory and inter-assay variability as progesterone concentrations decrease. This increased variability could result in inappropriate decisions when deciding to proceed with a fresh embryo transfer or to employ segmentation and should be taken in to consideration by ART clinics.

Trial registration number: not applicable.

P-728   Change in endocrine, metabolic and body composition profiles of lean women with polycystic ovary syndrome after 1-year treatment with oral contraceptives

Y.J. Kim[1], S.H. Yoon[2], K.R. Hwang[3], D.H. Lee[4], S.M. Lee[1], K.W. Yi[1], H.T. Park[1], J.H. Shin[1], T. Kim[1], J.Y. Hur[1]

[1]Korea University Medical Center, Department of Obstetrics and Gynecology, Seoul, Korea- South

[2]Graduate School of Medicine- Dongguk University, Department of Obstetrics and Gynecology, Seoul, Korea- South

[3]Seoul National University Boramae Medical Center, Departments of Obstetrics and Gynecology, Seoul, Korea- South

[4]Department of Obstetrics and Gynecology, Daejeon Maria fertility Hospital, Daejeon, Korea South

Study question: Do 1-year treatment with oral contraceptives (OC) change endocrine, metabolic and body composition profiles of lean women with polycystic ovary syndrome (PCOS)?

Summary answer: Treatment with OC for 1 year could change not only endocrine and metabolic profiles, but also body composition profiles of lean women with PCOS.

What is known already: Body composition profile is a useful clinical predictive marker for development of PCOS, a common reproductive endocrine and metabolic disease with ethnic variation. Although OC is commonly used to manage the symptoms of menstrual irregularity and a- or oligo-menorrhea with PCOS, most previous studies of its effect on endocrine, metabolic and body composition profiles have been cross-sectional, retrospective or case–control.

Study design, size, duration: One hundred and forty of women with BMI<25 Kg/m^2 and PCOS diagnosed by Rotterdam criteria were recruited to check endocrine, metabolic and body composition profiles with 1-year OC use and annual follow-up in this cohort study.

Participants/materials, setting, methods: Before and after 1-year OC use, endocrine and metabolic profiles were analyzed by serum sample and body composition profiles were checked using multi-frequency bioelectrical impedance analysis. Data were analyzed by Paired t-test and McNemar test where appropriate.

Main results and the role of chance: Among endocrine profiles, SHBG (100.6 ± 95.6 nmol/L vs. 171.5 ± 52.1 nmol/L, P = 0.002) and DHEAs (192.3 ± 88.4 μg/dL vs. 228.8 ± 110.6 μg/dL, P = 0.002) were increased, and testosterone (0.9 ± 0.5 ng/mL vs. 0.6 ± 0.4 ng/mL, P < 0.001), 17-α-OHP (2.3 ± 1.6 ng/mL vs. 1.2 ± 0.7 ng/mL, P < 0.001) and AMH (12.5 ± 10.0 ng/mL vs. 10.8 ± 8.5 ng/mL, P = 0.011) were decreased after 1-year OC use. In metabolic profiles, total cholesterol (195.2 ± 33.5 mg/dL vs. 201.8 ± 32.5 mg/dL, P = 0.007) and 25-OH vitamin D (16.2 ± 9.5 ng/mL vs. 21.6 ± 14.8 ng/mL, P = 0.039) were increased by 1-year OC use. For body composition profiles, protein mass (10.3 ± 1.1 Kg vs. 10.1 ± 1.1 Kg, P = 0.004), mineral mass (2.4 ± 0.2 Kg vs. 2.3 ± 0.2 Kg, P = 0.004), muscle mass (38.5 ± 4.0 Kg vs. 37.7 ± 4.1 Kg, P = 0.004), fat free mass (40.8 ± 4.2 Kg vs. 40.1 ± 4.3 Kg, P = 0.006) and basal metabolic rate (1364.5 ± 102.0 Kcal vs. 1330.9 ± 107.0 Kcal, P < 0.001) were decreased with 1-year OC use. Before and after 1-year OC use, women with abnormal free androgen index (≥5) were 48.6% and 21.4% (P < 0.001), women with abnormal HOMA-IR (> 2) were 52.9% and 57.1% (P = 0.282), and women with abnormal percent body fat (>28%) were 34.3% and 31.4% (P = 0.703).

Limitations, reasons for caution: Further study should be necessary with larger sample size and longer follow-up.

Wider implications of the findings: One-year OC use could change androgen activity, lipid profiles and body composition of muscle and fat in lean women with PCOS.

Trial registration number: N/A.

P-729   Prediction of metabolically unhealthy phenotype by the visceral adiposity index, lipid accumulation product and triglyceride-glucose index in Chinese women with polycystic ovary syndrome

H.W.R. Li[1], K.S.L. Lam[2], S. Tam[3], W.K.E. Wong[3], V.C.Y. Lee[1], P.T. Cheung[4], P.C. Ho[1], E.H.Y. Ng[1]

[1]The University of Hong Kong- Queen Mary Hospital, Department of Obstetrics and Gynaecology, Pokfulam, Hong Kong

[2]The University of Hong Kong- Queen Mary Hospital, Department of Medicine, Pokfulam, Hong Kong

[3]The University of Hong Kong- Queen Mary Hospital, Department of Pathology and Clinical Biochemistry, Pokfulam, Hong Kong

[4]The University of Hong Kong- Queen Mary Hospital, Department of Paediatrics and Adolescent Medicine, Pokfulam, Hong Kong

Study question: Can visceral adiposity index (VAI), lipid accumulation product (LAP) and triglyceride-glucose (TyG) index predict metabolic unhealthiness in Chinese women with polycystic ovary syndrome (PCOS)?

Summary answer: Chinese-VAI (CVAI) and LAP are the best predictors of metabolic unhealthiness encompassing metabolic syndrome (MetS), insulin resistance (IR) and dysglycaemia in Chinese women with PCOS.

What is known already: Women with PCOS, both obese and non-obese, are at increased risks of metabolic derangements compared with the general population. VAI, LAP and TyG are established composite indices derived from some components of the MetS, and have been validated by previous studies as effective markers of metabolic unhealthiness as defined by the presence of MetS, IR and/or dysglycaemia. CVAI is the Chinese version of VAI calculated as -187.32+1.71*Age + 4.23*body mass index + 1.12*waist circumference + 39.76*log$_{10}$[triglycerides] – 11.66*[HDL-C] (Xia et al, 2016); it has been shown to be more accurate than the original VAI in reflecting metabolic health in Chinese.

Study design, size, duration: This cross-sectional observational study was based on metabolic data obtained from 459 women diagnosed with PCOS according to the Rotterdam criteria. These subjects were prospectively recruited in the Hong Kong Chinese population between 2010 and 2013. A cohort of 253 ovulatory and age-matched healthy women in the same population served as controls.

Participants/materials, setting, methods: Subjects were recruited from a university hospital or community family planning clinics. Blood was taken after 8-hour fasting for metabolic assessment. MetS was defined according to the joint interim statement (Alberti et al, 2009); IR was defined by the upper quartile of the homeostasis model assessment of insulin resistance (HOMA-IR), and dysglycaemia was defined by the American Diabetes Association criteria. Prediction on metabolic unhealthiness by CVAI, VAI, LAP and TyG was analysed by ROC curve.

Main results and the role of chance: The prevalence of MetS was 71 (15.5%) out of 459 PCOS subjects, compared to 3 (1.2%) out of 253 controls. We defined metabolic unhealthiness by the combined criteria as the presence of either MetS, IR and/or dysglycaemia. The prevalence of metabolic unhealthiness was 229 (49.9%) in PCOS subjects versus 68 (26.9%) in controls. For the prediction of MetS, the areas under the ROC curve (AUROC) were higher for LAP (0.945) and CVAI (0.936) compared to VAI (0.919) and TyG (0.892) (p<0.05). For prediction of IR, the AUROC were significantly higher for LAP (0.846) and CVAI (0.841) compared to VAI (0.777) and TyG (0.770) (p<0.05). For prediction of dysglycaemia, the AUROC were not significantly different among LAP (0.828), CVAI (0.821), VAI (0.812) and TyG (0.831). For prediction of metabolic unhealthiness by our combined criteria, the AUROC were significantly higher for LAP (0.860; sensitivity 70.3% and specificity 90.0% at best cut-off of 16.8) and CVAI (0.854; sensitivity 70.3% and specificity 88.7% at best cut-off of 29.2) compared to VAI (0.790; sensitivity 81.7% and specificity 62.2% at best cut-off of 0.88) and TyG (0.779; sensitivity 69.9% and specificity 74.4% at best cut-off of 8.03) (p<0.05).

Limitations, reasons for caution: The cross-sectional nature of this analysis did not allow the validation of the studied metabolic indices in predicting long term cardio-metabolic morbidity, which would worth further exploration by longitudinal follow-up of the study cohort. This study was targeted at the Chinese population, and generalisability to other ethnicities needs further exploration.

Wider implications of the findings: Using the MetS criteria alone will miss a number of metabolic problems like IR or dyglycaemia in women with PCOS. CVAI and LAP are simple composite metabolic indices which serve as accurate surrogate markers of the metabolically unhealthy phenotypes including MetS, IR and dysglycaemia in women with PCOS.

Trial registration number: Nil.

P-730 Can likelihood of natural pregnancy be predicted from demographics and LH surge characteristics?

S. Weddell[1], J. Schiffer[2], C. Gnoth[3], S. Johnson[4]

[1]SPD Development Company Ltd, Scientific and Medical Affairs, Bedford, United Kingdom
[2]Heinrich-Heine-University Düsseldorf, Mathematical Institute, Dusseldorf, Germany
[3]green-ivf- Grevenbroich Endocrinology and IVF-Center, Department of Gynecology and Obstetrics- University of Cologne, Grevenbroich, Germany
[4]SPD Development Company Ltd, Clinical and Regulatory Affairs, Bedford, United Kingdom

Study question: Predicting likelihood of conceiving naturally could help those considering whether to attempt IVF. This analysis examined whether demographics and LH surge characteristics can predict success?

Summary answer: Predictors of pregnancy were length of time trying to conceive, other well-known demographic factors, lower basal LH levels and steeper LH rise during the surge.

What is known already: There are many factors already known to influence the probability of conceiving naturally, such as age, BMI, smoking and previous obstetric history. Fertility declines during the perimenopause, but onset of the perimenopause is not currently predictable and often not recognisable. In addition, conditions such as PCOS may influence fertility. These conditions can manifest in disturbances in the LH surge profile. Therefore, it is possible that characterisation of the LH surge, along with basic demographic information, could provide important information on the chances of natural conception.

Study design, size, duration: This was a home based observational study. Volunteers seeking to conceive naturally (>18 years old) were recruited via internet advertisements from across the UK. Demographic data was self-

reported. Volunteers collected daily urine samples for 1 entire menstrual cycle. Cycles from 185 women who achieved pregnancy and 200 women who failed to become pregnant were included in the analysis.

Participants/materials, setting, methods: Urinary luteinising hormone was measured using AutoDELFIA (Perkin Elmer, Waltham, MA, USA) across the whole cycle. The surges were characterised to examine baseline levels, surge day, peak day, peak concentration and magnitude of surge. The best description of baseline levels was found to be square root of (LH concentration on cycle day 6 - 15)^2, and description of magnitude was (LH on peak day - LH on surge day)/LH on surge day.

Main results and the role of chance: Mean age (SD) of those who achieved pregnancy was 30.55 (5.05) compared to 30.75 (5.14) who did not conceive. Those who failed to conceive had higher BMI (27.91 compared to 26.90) and were more likely to be current smokers. An extremely significant predictor of pregnancy was number of months trying to conceive; mean of 7.72 months for those that became pregnant versus 17.75 for those that did not. Number of previous livebirth was also significantly different (mean of 0.92 for pregnant group versus 0.66 for not pregnant group). Both self-reported endometriosis and PCOS was more prevalent in the group that failed to conceive.

Volunteers who conceived had slightly shorter self-reported menstrual cycle characteristics (average cycle, shortest cycle, longest cycle), but this finding was not significant. In the study cycle, surge day or concentration was not significantly different between groups (day 16.21 Pregnant, 16.61 Not Pregnant; 54.84mIU/ml Pregnant, 58.22mIU/ml Not Pregnant). However, volunteers who conceived had a lower basal LH level, which was significantly different on day 6. The surge profile was also steeper in the group that became pregnant. This indicates that LH cycle profiles may assist in predicting pregnancy success.

Limitations, reasons for caution: The study was for one menstrual cycle, thus intra-individual cycle variation was not considered. Demographic and pre-study cycle length characteristics were self-reported, but as they were reported prior to study conduct, inaccuracies are likely to be equal between the two groups. Male factors were not considered.

Wider implications of the findings: Providing robust information on chances of natural conception can provide realistic expectations on likelihood of success and whether to seek IVF treatment earlier or later. This may be valuable to women who wish to try for natural conception to enable them to make objective decisions on their path to pregnancy.

Trial registration number: NCT01577147.

P-731 The assessment of follicular fluid metabolite profile in poor and high responder patients undergoing intracytoplasmic sperm injection

D. Montani[1], D. Moriyama[1], D. Braga[2], A. Rodrigues-Oliveira[3], D. Oliveira-Silva[3], E. Borges Jr.[4], R. Fraietta[1], E. Lo Turco[1]

[1]Sao Paulo Federal University, Department of Surgery- Division of Urology- Human Reproduction Section, Sao Paulo, Brazil
[2]Fertility Medical Group, Research, Sao Paulo, Brazil
[3]Sao Paulo Federal University, Institute of Environmental- Chemical and Pharmaceutical Sciences, Diadema, Brazil
[4]Fertility Medical Group, Clinic department, Sao Paulo, Brazil

Study question: Is the metabolite composition of follicular fluid (FF) associated with the response to controlled ovarian stimulation (COS) for IVF?

Summary answer: The metabolite composition of FF is associated with the response to COS.

What is known already: Bidirectional communication between the oocyte and surrounding cumulus cells is essential for the acquisition of oocyte competence, and due to their close connection, cumulus cells and FF may retain a footprint of the follicular conditions experienced by the oocyte. Therefore, this may be a valuable tool to understand ovarian physiology. Low-responder young patients have reduced oocyte viability, perhaps as a consequence of altered ovarian microenvironment. On the other hand, the overproduction of oocytes, in high-responders, can cause considerable patient discomfort, and important short-term complications including ovarian hyperstimulation syndrome, high incidence of multiple pregnancies and ethical/legal implications of embryo storage.

Study design, size, duration: For this prospective study, 69 samples of FF were collected from patients undergoing routine ICSI cycles in an University-affiliated assisted reproduction centre, from October/2015 to June/2016. Samples were split into three groups according to the response to COS: Low responder, when ≤ 4 oocytes were retrieved (LR, n = 11, 33.2y-old), normal responder when >4 and < 15 oocytes were retrieved (NR, n = 47, 33.1y-old), and hyper responder patients, when ≥ 15 oocytes were retrieved (HR, n = 11, 32.8y-old).

Participants/materials, setting, methods: Patients received rFSH for COS and GnRH-antagonist for pituitary blockage. Metabolites were extracted using Bligh and Dyer protocol and individually analysed by electrospray ionization mass spectrometry in the positive ionization mode. Data for NR group were compared with other groups. Principal Component and Partial Least Square Discriminant analyses were used to perceive general clustering and to confirm the discriminatory metabolites, respectively. These were based on the VIP metabolites hiperrepresented in each group.

Main results and the role of chance: Dithienyl disulphate was hiperrepresented in the LR group, which was associated with the cellular oxidant detoxification, oxidoreductase and glutathione peroxidase activity pathways. Sulfonic acid was increased in the HR group, which was associated with gamma glutamyltransferase activity and glutamate metabolic process. Those pathways and metabolic processes were obtained through enrichment analysis using the CytoScape 3.4.0.

Limitations, reasons for caution: Although these results may add to the general knowledge of ovarian biology and its response to COS, these must be investigated in plasma, favouring the implementation of individualized COS protocols.

Wider implications of the findings: Our data suggest that identification of metabolites correlated with ovarian response to COS may support the implementation of individualized COS protocols, offering a valuable opportunity for achieving the treatment success with reduced discomfort, emotional and financial costs for the patients.

Trial registration number: N/A.

P-732 Administration of FSH 8 hours post-triggering of final oocyte maturation with hCG does not improve oocyte maturation rate in normal responders undergoing ICSI

I. Sfontouris[1], G. Lainas‘[1], T. Lainas[1], C. Venetis[2], G. Petsas[1], I. Zorzovilis[1], B. Tarlatzis[3], E. Kolibianakis[3]

[1]Eugonia, Assisted Reproduction Unit, Athens, Greece
[2]University of New South Wales, School of Women's and Children's Health, Sydney, Australia
[3]Aristotle University of Thessaloniki, 1st Dept of Obstetrics and Gynecology, Thessaloniki, Greece

Study question: Does FSH administration 8 hours post-triggering of final oocyte maturation with hCG increase oocyte maturation rate as compared to hCG-only in normal responders undergoing ICSI?

Summary answer: Oocyte maturation rate is similar following FSH administration 8 hours post-triggering final oocyte maturation with hCG as compared to hCG-only in normal responders undergoing ICSI.

What is known already: In IVF programs, the most common form for triggering final oocyte maturation involves administration of hCG that mimics LH surge. However, there is evidence to suggest that, similarly to spontaneous ovulation or GnRH agonist trigger, an FSH surge around the time of triggering final oocyte maturation may have biological importance for the recovery of a fully mature and developmentally competent oocyte. During standard ovarian stimulation protocols, the last dose of FSH may be administered usually 1 day before and rarely on the day of hCG triggering, allowing serum FSH levels to decline prior to the time of final oocyte maturation.

Study design, size, duration: Retrospective cohort study of 229 patients undergoing ovarian stimulation for ICSI. In order to induce final oocyte maturation, patients were administered 250 mcg rec-hCG followed by a single dose of 50 IU of rec-FSH 8 hrs later (FSH/hCG group, n = 57) or rec-hCG only (hCG group, n = 172). The primary outcome measure was oocyte maturation

rate, defined as the proportion of MIIs/COCs. The study was conducted from January 2015 until September 2016 at a private IVF Unit.

Participants/materials, setting, methods: Eligible patients were ≤42 years old, were treated with GnRH antagonist protocol and had 5-18 follicles ≥11 mm on the day of triggering. Patients undergoing oocyte donation, PGD, those who had GnRH agonist triggering for final oocyte maturation, and patients with poor (<5 follicles) or excessive ovarian response (>18 follicles) were excluded. Patients were included in the study only once. Continuous variables are expressed as median (interquartile range) and binary variables as proportion and 95% CI.

Main results and the role of chance: Baseline characteristics were similar in the two groups, except for a higher baseline oestradiol in the FSH/hCG compared to the hCG group [46.0 (21.9) vs. 37.5 (19.8), p = 0.020]. There were no significant differences between the FSH/hCG and hCG groups regarding the total gonadotrophin dose [1762.5 (762.5) vs. 1650 (650) IU, p = 0.209], oestradiol [1607 (1517) vs. 1731 (1320.8) pg/ml, p = 0.279] and progesterone levels [0.9 (0.6) vs. 0.8 (0.5) ng/ml, p = 0.316] on the day of triggering, days of stimulation [11 (3) vs. 10 (2), p = 0.407], number of follicles developed [12 (12) vs. 11 (7), p = 0.233], number of oocytes retrieved [10 (10) vs. 10 (7), p = 0.312], number of metaphase-II oocytes [8 (8) vs. 7 (6), p = 0.360], number of 2PN oocytes [5 (6) vs. 5 (5), p = 0.816], number of embryos transferred [2(1) vs. 2(2), p = 0.533] and number of embryos cryopreserved [2.5 (2) vs. 3 (2), p = 0.176], respectively. No differences were also present between the FSH/hCG and the hCG groups regarding clinical pregnancy rate (47.4%; 95% CI:34.0-60.7 vs. 54.1%; 95%CI:46.5-61.6, p = 0.445). Oocyte maturation rate did not differ between FSH/hCG and hCG groups [80% (17.1) vs. 82.4% (22.8), p = 0.710]. No difference was present in maturation rates between the two groups in multivariable analysis controlling for baseline estradiol.

Limitations, reasons for caution: This is a retrospective study and although a multivariable analysis was performed controlling for confounders, some form of unknown bias cannot be excluded. Thus the present findings should be confirmed by relevant RCTs Moreover, the optimal timing and dosage of FSH administration might need to be further explored.

Wider implications of the findings: Although FSH surge accompanies LH surge during spontaneous ovulation, the simulation of this event by administration of 50 IU of FSH 8 h following hCG administration does not appear to be beneficial for enhancing oocyte maturation rate in normal responders undergoing ovarian stimulation for ICSI.

Trial registration number: Not applicable.

P-733 Short-time effect of N-acetyl-L-cysteine (NAC) against natural follicular depletion in pre-pubertal and adult mice – A randomized study

A. Anastácio[1], S. Alonso de Mena[1,2], R. Kuiper[3], M. Saghafian[4], M. Hassan[5,6], K.A. Rodriguez-Wallberg[1,2]

[1]Karolinska Institutet, Department of Oncology and Pathology, Stockholm, Sweden

[3]Karolinska Institutet, Core facility for morphologic phenotype analysis FENO-Department of Laboratory Medicine, Stockholm, Sweden
[4]Karolinska Institutet, Department of Biosciences and Nutrition BioNut, Stockholm, Sweden
[5]Karolinska Institutet, Division of Experimental Cancer Medicine ECM- Department of Laboratory Medicine LABMED, Stockholm, Sweden
[6]Karolinska University Hospital Huddinge, Clinical Research Center KFC, Stockholm, Sweden

Study question: Can antioxidant substances, such as N-acetyl-L-cysteine (NAC), be used to reduce the natural steady-state follicle depletion in pre-pubertal or adult mice?

Summary answer: Our preliminary data indicates that intraperitoneal administration of NAC could reduce the natural programmed ovarian follicle depletion in pre-pubertal mice but not in adult mice.

What is known already: Follicular depletion starts early in life, with a massive loss of small follicles before puberty. Thereafter, cyclical follicle recruiting occurs throughout the reproductive lifespan until exhaustion and menopause onset. Oxidative stress by reactive oxygen species (ROS) contributes to somatic aging

in general, and also has been implicated in reproductive aging. NAC is an anti-oxidant substance that has been shown to effectively rescue oocytes and embryos from ROS-induced telomere shortening and apoptosis. NAC is also a highly soluble substance that diffuses easily in biological tissues, it is non toxic and can be used for parenteral treatment.

Study design, size, duration: Randomized controlled study. Thirty four C57BL/6 N mice, 16 pre-pubertal (3 weeks) and 18 adults (8-10 weeks), were randomly assigned to intraperitoneal NAC injection or to control (pre-pubertal N = 8; adult N = 9 in each group). The animals were sacrificed 3 or 7 days after the first day of NAC treatment and the ovaries dissected for histological analysis. Follicle density of small size follicles was calculated. The study was approved by the regional ethics committee for animal experiments.

Participants/materials, setting, methods: Intraperitoneal NAC injection (150 mg/Kg) was administered on two consecutive days. Ovarian sections (5 μm) were H&E stained and scanned (3Dhisthech®). Follicles were counted by two independent observers according to Pedersen & Peters (1968). Follicle density was calculated as the total number of small follicles divided by the area of ovarian tissue examined.

Main results and the role of chance: We found 3 and 7 days after the treatment with NAC a higher follicle density in the ovaries of pre-pubertal mice that received NAC ($13.0/mm^2 \pm 4.7$) than in the control group ($10.2/mm^2 \pm 4.4$). However, this was not observed in adult mice that received NAC ($7.8/mm^{2 \pm} 3.1$) when compared to adult controls ($7.2/mm^{2 \pm} 2.7$).

The effect of NAC was statistically significantly different between pre-pubertal and adult mice ($p = 0.01$) with a higher follicle density in pre-pubertal mice ($13.0/mm^{2 \pm} 4.7$) compared with adult mice treated with NAC ($7.8/mm^{2 \pm} 3.1$). This difference was not observed in the control groups.

Limitations, reasons for caution: We estimated effects on follicle density after a short-time experimental treatment with NAC. Although we observed a differential effect between pre-pubertal and adult mice, a transitory effect also in the ovary of adult mice that was not persistent at the point of estimates several days later cannot be ruled out.

Wider implications of the findings: Our results suggest that antioxidant substances such as NAC might reduce natural ovarian reserve depletion, according to our findings using pre-pubertal mice. The absence of effect in the ovaries of adult mice might indicate that the mechanisms of programmed ovarian follicle depletion are different between adult and pre-pubertal mice.

Trial registration number: not applicable.

P-734 Ovarian reserve testing- Antral follicle count (AFC) remains the single best predictor in comparison to AMH and FSH

P. Selvaraj[1], K. Selvaraj[2]

[1]Fertility Research Centre- GG Hospital, Obstetrics and Gynaecology, Chennai, India
[2]G G Hospital, Fertility Research Centre, Chennai, India

Study question: The aim of the study was to determine the single best predictor of ovarian reserve and response in patients undergoing an ART program.

Summary answer: In our study, AFC emerged as an independent predictor of response and pregnancy rates.

What is known already: Age is strongly correlated with ovarian response and anti mullerian hormone (AMH) has been emerging as an effective predictor. Comparisons have been made between the value of antral follicle count versus follicle stimulating hormone and AMH with variable conclusions.

Study design, size, duration: A prospective study was conducted from January 2015 - Dec 2016 with the sample size of 369 women undergoing assisted reproduction. The mean age of women is 31.33 years.

Participants/materials, setting, methods: The mean AFC, AMH and FSH values were determined based on the age group < 30 years and > 30 years. The oocyte retrieval rates and pregnancy rates were determined based on the three key fertility predictors as mentioned above. Data's were analyzed using the SPSS version 16.0 for statistical significance.

Main results and the role of chance: The Mean values of AFC, FSH and AMH in women <30 years (A) was $10.49 \pm 5.46, 7.44 \pm 3.49$ and 5.59 ± 3.63 respectively. The Mean AFC, FSH and AMH in women > 30 years (B) was $8.46 \pm 4.69, 7.78 \pm 3.11$, and 4.33 ± 3.34. The oocyte retrieval rates were correlated with age and the corresponding AFC, AMH and FSH as mentioned above. The mean numbers of oocytes in women in-group A was 10.36 ± 5.75 and for group B 7.89 ± 5.36. Pregnancy rates for these women in group A was 58% and for group B was 47.7%.

The mean serum levels of AMH as well as the total number of oocytes retrieved and AFC were significantly higher in the women in-group A. However, there was no significant difference in pregnancy rates between groups (A and B). No significant difference was observed between groups (A and B) with respect to FSH levels. The maximum numbers of oocytes was retrieved at high AMH values (>5) with a mean age of 30.33 years. The total number of AFC was positively and significantly correlated ($p = 0.01$) with pregnancy rates.

Limitations, reasons for caution: Only fresh embryo transfers were considered in this study with exclusion of donor programs. AMH values may correlate with age and response but not conclusively with pregnancy rates in comparison to a more valuable indicator such as AFC

Wider implications of the findings: FSH values do not seem to add significance to response or pregnancy rates as much as the AMH or AFC. In our study, AFC emerged as an independent predictor of response and pregnancy rates.

Trial registration number: not applicable.

P-735 Elevated progesterone levels negatively influence cumulative live birth rates by affecting both endometrial receptivity and embryonic competence

A. Racca[1], S. Santos-Ribeiro[2], N. De Munck[2], S. Mackens[2], I. Mateizel[2], M. Camus[2], G. Verheyen[2], H. Tournaye[2], C. Blockeel[2]

[1]UZ Brussel, Centre for Reproductive Medicine, Brussels, Belgium
[2]UZ Brussel, Centre for Reproductive Medicine, Brussel, Belgium

Study question: Could late follicular phase serum progesterone (P) concentrations be associated with embryonic competence?

Summary answer: Embryo quality and cumulative pregnancy rates in women with high P levels are decreased. High P affects fertilization rates after IVF but not after ICSI.

What is known already: The success of IVF depends intrinsically on two important factors: embryo quality and endometrial receptivity. It is still a matter of much debate whether among ART patients high or low levels of late-follicular-phase P negatively affects the oocytes or the endometrium, since both are simultaneously subjected to the influence of P. Both oocyte donation and embryo cryopreservation models are the best clinical tools to distinguish the effects of high serum P levels on oocytes from those on the endometrium.

Study design, size, duration: A single-centre retrospective cohort analysis of 3350 gonadotropin-releasing hormone (GnRH) antagonist down-regulated cycles with a fresh embryo transfer was performed between 2010 and 2014. The sample was categorized according to the following P levels on the day of ovulation triggering: < 0.5 ng/mL, 0.5-1.5 ng/mL and >1.5 ng/mL. Embryo development and live birth rates (LBR) after the fresh and subsequent frozen embryo transfers were compared among these groups, followed by pairwise group comparisons whenever significant.

Participants/materials, setting, methods: Cycles using pre-implantation genetic diagnosis, in-vitro maturation and donor oocytes were excluded. We performed multivariable generalized estimating equation (GEE) regression analysis accounting for the following potential confounders: female age, cycle rank, total dose of exogenous follicle-stimulating hormone (FSH), the late-follicular-phase estradiol (E2) levels, the number of oocytes/embryos produced and the number, stage and grade of the embryos transferred. The frozen embryo transfer (FET) took place either in a natural or an artificial cycle.

Main results and the role of chance: Comparing the < 0.5 ng/mL, 0.5-1.5 ng/mL and >1.5 ng/mL, as late-follicular-serum P levels increased, female age decreased significantly (median age 34, 33 and 31 years/old, respectively; $p = 0.002$). Conversely, the total dose of exogenous FSH consumed, late-follicular E2 levels and the number of oocytes retrieved (median 7, 9 and 12, respectively; $p < 0.001$) increased with increasing trigger P levels. Regarding oocyte and embryo quality, fertilization rates following IVF decreased significantly with increasing P levels (65.8%, 59.5% and 46.5%, respectively; $p = 0.0051$). Importantly, even after disregarding the oocytes that did not

fertilize, women in the P > 1.5 ng/mL group had a significantly lower number of embryos of sufficient quality to transfer or cryopreserve at both cleavage and blastocyst stage (49.6%, 48.0% and 43.1% of all fertilized oocytes were useable at blastocyst stage, respectively; p = 0.029). In the multivariable GEE regression models for live birth, fresh LBR varied significantly (29.3%, 34.3% and 25.5%, respectively; p = 0.0029) among the groups. Most importantly, while both women with P < 0.5 and >1.5 ng/mL had similarly low cumulative LBR (38.8%, 43.9% and 38.3%, respectively; p = 0.0211), only the difference between the women with P levels between 0.5-1.5 ng/mL and >1.5 ng/mL remained significant after pairwise comparison.

Limitations, reasons for caution: The main limitation of the study was its retrospective nature. Furthermore, the analysis was restricted to patients under GnRH antagonist pituitary suppression and some potential confounding factors such as female smoking could not be accounted for.

Wider implications of the findings: Our results are in contrast with previous studies suggesting that high P is not associated with reduced embryo quality or cumulative LBR. The knowledge that high P levels may hinder oocyte/ embryo competence and, ultimately, diminish cumulative LBR could play an important role in how we perform ovarian stimulation henceforth.

Trial registration number: not applicable.

P-736   Alteration in gastrointestinal health and dysbiosis of gut microbiota in women with Polycystic Ovary Syndrome

D. Romualdi, S. De Cicco, C. Di Florio, V. Immediata, V. Tagliaferri, C.M. Santarsiero, V. Versace, A. Tropea, A. Lanzone, R. Apa

Università Cattolica del Sacro Cuore, Obstetrics and Gynaecology, Roma, Italy

Study question: Do women with Polycystic Ovary Syndrome (PCOS) present a dysbiosis of gut microbiota and an increase in gastrointestinal symptoms?

Summary answer: PCOS women report a high rate of functional gastrointestinal symptoms (abdominal discomfort, bloating, flatulence, constipation), which are presumably associated with a dysbiosis of gut microbiota.

What is known already: Polycystic ovary syndrome (PCOS) is a common endocrine disorder affecting women in reproductive age. The clinical expression of the syndrome is characterized by the combination of menstrual irregularities, anovulation and hyperandrogenism. It is now well established that PCOS is associated with a chronic state of inflammation and insulin resistance, though the underlying triggers for these two key imbalances still remain unknown. Changes in gut microbiota composition have been associated with different metabolic disorders, including obesity and diabetes; the gut microbiota may play a role in the development of obesity, inflammation and insulin resistance that represent the hallmarks of PCOS.

Study design, size, duration: Here we present the preliminary results of an ongoing observational prospective pilot study comprises 23 women with PCOS and 10 healthy controls from 18 to 35 years, recruited in an academic research environment from January to September 2016.

Participants/materials, setting, methods: 23 PCOS women diagnosed according to the Rotterdam Criteria (19 – 33 years, mean BMI 26) and 10 healthy women (19 – 33 years, mean BMI 21) were enrolled. Gynecological evaluation included anthropometric characteristics, hirsutism score, ultrasound ovarian features, and hormonal parameters. Each participant also underwent an oral glucose tolerance test (OGTT). The evaluation of the gastrointestinal health consisted of Bristol stool charge, Gastrointestinal Symptoms rating Scale (GSRS), psychometric tests, and lactulose/mannitol breath test.

Main results and the role of chance: PCOS participants were affected by oligo-amenorrhea, hirsutism, accompanied by elevated free testosterone and AMH levels. An increased Body mass index (BMI) was also observed in PCOS subjects. The lipid profile and the insulin secretion during the OGTT did not significantly differ between PCOS women and controls. The prevalence of altered Bristol stool scale (constipated or inflammation) was significantly higher in the PCOS group (P < 0,05). On examining individual gastrointestinal symptoms, GSRS was higher compared with control group (P < 0,05). Specifically, abdominal discomfort, borborygmus, bloating, increased flatus and constipation were more frequently observed in PCOS subjects. Severity of the symptoms was not correlated with the androgen levels and the AUC insulin at the Spearman test.

Psychometric tests showed no significantly differences in anxiety, depression and vitality; the perception of quality of life was lower in PCOS, in according with literature. PCOS women presented a good resilience evaluated with CD risk and Self Efficacy questionnaires. At lactulose/mannitol breath test PCOS group displayed a significant alteration of intestinal transit and an estimated dysbiosis was present in more PCOS patients than controls. The direct evaluation of gut barrier dysfunction with urine analysis after lactulose/mannitol breath test and of the inflammatory status is now being carried out.

Limitations, reasons for caution: The small sample size represents a limitation. The recruitment is ongoing.

Wider implications of the findings: The finding of a dysbiosis or microbial imbalance in the gut microbiota of PCOS women creates opportunities for potential treatments (probiotics/ prebiotics) and adds a new player in the physiopathologic picture of the syndrome.

Trial registration number: N/A.

P-737   Baseline AMH is associated with ovulation induction dose and ovulatory response and predicts ovulation rate in women with Polycystic Ovary Syndrome

Q. Wu[1], J. Li[2], X.K. Wu[2], L. Xie[2], E.H. Ng[3], B.W. Mol[4], R.C.C. Wang[5]

[1]The Chinese University of Hong Kong, Department of Obstetrics and Gynecology- Prince of Wales Hospital, Hong Kong, China
[2]Heilongjiang University of Chinese Medicine, Department of Obstetrics and Gynecology- First Affiliated Hospital, Harbin, China
[3]The University of Hong Kong, Department of Obstetrics and Gynaecology, Hong Kong, China
[4]School of Pediatrics and Reproductive Health- University of Adelaide, Department of Obstetrics and Gynecology, Adelaide, Australia
[5]The Chinese University of Hong Kong, Department of Obstetrics and Gynecology- Prince of Wales Hospital-Reproduction and Development Laboratory- Li KaShing Institute of Health Sciences, Hong Kong, China

Study question: To investigate association between baseline AMH levels, ovulatory response to ovulation induction dose among women enrolled in the Polycystic Ovary Syndrome Acupuncture and Clomiphene Trial (PCOSAct).

Summary answer: Higher baseline AMH is negatively associated with lower ovulatory response and requires higher ovulation induction dose to achieve ovulation in women with PCOS.

What is known already: AMH plays an inhibitory role in follicular development and recruitment, contributing to follicular arrest.AMH also reduces aromatase activity and sensitivity of follicles to FSH stimulation. Therefore, elevated serum AMH may have higher threshold response to ovulation induction and affect pregnancy outcome in women with PCOS.

Study design, size, duration: A secondary analysis of the Polycystic Ovary Syndrome Acupuncture and Clomiphene Trial (PCOSAct), a large-sample, multi-center, randomized placebo-controlled clinical trial conducted from 2012 to 2015 in mainland China.1000 PCOS women were randomly assigned in a 1:1:1:1 ratio, to receive true acupuncture or control acupuncture integrated with clomiphene or placebo clomiphene for up to four cycles treatment. Baseline serum AMH concentrations were measured by AnshLabs AL-105-I Ultra-Sensitive AMH/MIS ELISA kits.

Participants/materials, setting, methods: Logistic regression models to test association of demographic, metabolic and biochemical profiles with ovulation, conception, pregnancy and live birth adjusted by the interventions.OR and 95% CI to compare ovulation induction dose and ovulatory response according to the logistic models. ROC to confirm prediction values of AMH for ovulation. Kaplan–Meier curve to compare time to ovulation in the four quartiles.

Main results and the role of chance: Age, BMI(body mass index), WHR (whist to hip ratio),duration of infertility,baseline AMH,progesterone, total testosterone, E2(estradiol), SHBG (sex hormone-binding globulin)and glucose were significantly associated with ovulation, but not conception, pregnancy and live birth. AMH levels were significantly higher among women who did not achieved ovulation than those women who achieved ovulation both overall and within intervention groups (P < .0001) and required higher ovulation induction dose to achieve ovulation. Baseline AMH significantly predicted ovulation

(AUC0.60, P < .001) and lower baseline AMH has higher chance of ovulation (87.0%vs 71.1%) and shorter duration to ovulate (23 days vs 58 days for 50% ovulation).

Limitations, reasons for caution: The significant association of baseline AMH with ovulation in PCOS requires prospective study to validate.

Wider implications of the findings: This is the first large-scale trial to show the association of baseline AMH with ovulatory response to ovulation induction dose and the prediction values of baseline AMH on ovulation. AMH should be measured prior to infertility treatment in PCOS women.

Trial registration number: The PCOSAct Chinese Clinical Trial Registry: ChiCTR-TRC-12002081.

P-738   Ovarian response to controlled ovarian hyperstimulation: what does serum FSH say?

S. Oudshoorn[1], C. Van Tilborg[2], O. Hamdine[3], H. Torrance[4], M. Eijkemans[5], E. Lentjes[6], C. Lambalk[7], F. Broekmans[2]

[1]University Medical Center Utrecht, Reproductive Medicine and Gynecology, Utrecht, The Netherlands
[2]University Medical Centre Utrecht, Reproductive Medicine and Gynaecology, Utrecht, The Netherlands
[3]Radboud University Medical Centre Nijmegen, Reproductive Medicine, Nijmegen, The Netherlands
[4]University Medical Centre Utrecht, Reproductive Medicine and Gynaeoclogy, Utrecht, The Netherlands
[5]University Medical Centre Utrecht, Julyus Centre for Health Sciences and Primary Care, Utrecht, The Netherlands
[6]University Medical Centre Utrecht, Clinical Chemistry and Haematology, Utrecht, The Netherlands
[7]VU Medical Centre, Obstetrics and Gynaecology, Amsterdam, The Netherlands

Study question: Do serum follicle stimulating hormone (FSH) levels on the day of human chorionic gonadotropin (hCG)-trigger differ between women with a poor, normal or hyperresponse to 150 IU recombinant FSH (rFSH)?

Summary answer: Hyperresponders showed slightly higher serum FSH levels on day of hCG-trigger as compared to poor responders. Poor or hyperresponders did not differ from normal responders.

What is known already: When ovarian response to stimulation for in vitro fertilization (IVF) or intracytoplasmic sperm injection (ICSI) is suboptimal, the FSH dose is often adjusted in a subsequent cycle. This is based on the assumption that serum FSH levels were inadequate for optimal stimulation and a suboptimal response will be averted in the new cycle by choosing a different rFSH dose.

Study design, size, duration: Nested cohort study within a randomized controlled trial conducted at the University Medical Centre Utrecht (CETRO trial). Blood was drawn from 124 women on cycle day 2 and on day of hCG triggering. Expecting a difference in serum FSH on day of hCG of 2 IU/L, a sample size of 64 women (16 poor, 32 normal and 16 hyperresponders) would provide 80% power to detect this difference (standard deviation (SD) of 2 and alpha 0.05).

Participants/materials, setting, methods: Women aged ≤ 39 years with a regular cycle and fixed FSH dose of 150 IU. Exclusion criteria: BMI > 32 kg/m^2 and > 2 previous unsuccessful IVF/ICSI cycles. The primary outcome measure was serum FSH level on day of hCG-triggering. Serum FSH levels were determined by the Beckman-Coulter Unicel DXi800 chemiluminescence assay. The interassay coefficient of variation varies from 5.7% to 6.6% for the concentration range of 7-46 IU/L.

Main results and the role of chance: Median [range] age was 32.5 [28-38], 33.0 [22-39] and 28.0 [22-37] for poor (n = 16), normal (n = 94) and hyperresponders (n = 17), respectively. Age differed significantly between poor and normal vs. hyperresponders (p = 0.024 and p = 0.024). Median bodyweight was 70.0 kg [55- 86], 68.0 kg [52-94] and 60.6 kg [51-78] respectively and differed significantly between normal vs. hyperresponders (p = 0.036). Mean (SD) serum FSH levels on day of triggering were 9.5 IU/L (2.4) in poor, 10.4 IU/L (2.3) in normal and 11.5 IU/L (2.2) in hyperresponders. Serum FSH levels in the poor responders differed significantly as compared to those in hyperresponders

(p = 0.03). There was a weak, but significant correlation between serum FSH level on day of hCG and the number of obtained oocytes (correlation r = 0.203, p = 0.024, r^2 = 0.041). The multivariable model including age, body weight, basal serum FSH, basal anti-Mullerian hormone (AMH) and serum FSH level on the day of hCG showed a standardized regression coefficient of 0.151 (p = 0.063) for the number of retrieved oocytes.

Limitations, reasons for caution: The number of retrieved oocytes was only slightly determined by serum FSH level on the day of hCG trigger. After correction for age, body weight, basal serum FSH and basal AMH the correlation between serum FSH level on the day of hCG and ovarian response disappeared.

Wider implications of the findings: The current study shows that a poor response is not related to inadequate serum FSH levels. Therefore, increasing the rFSH dose in poor responders is probably meaningless. In hyperresponders however, lowering the dose in a subsequent cycle may lead to lower serum FSH levels thereby moderating ovarian response.

Trial registration number: NCT00866034 (CETRO trial).

P-739   Prediction of IVF outcome based on the follicular output rate

J. Ruman[1], V. Teal[2], G. Griesinger[3]

[1]Merck & Co.- Inc., Women's Health, Kenilworth NJ, U.S.A.
[2]Merck & Co.- Inc., Statistics, Kenilworth NJ, U.S.A.
[3]Medizinische Universitaet zu Luebeck, Department of Obstetrics and Gynecology, Luebeck, Germany

Study question: Does the follicular output rate (FORT) differ between recombinant FSH (rFSH) and corifollitropin alpha (CFA) during controlled ovarian stimulation in a GnRH antagonist IVF protocol?

Summary answer: FORT was significantly higher in CFA-stimulated cycles and accurately predicted oocyte output and metaphase II oocyte number; however, the relationship to pregnancy outcomes was uncertain.

What is known already: The FORT, defined as the number of pre-ovulatory follicles in response to FSH administration divided by the pre-existing antral follicle count (AFC), may be a better and more immediate measure of the efficacy of ovarian stimulation than mean oocyte numbers retrieved. The responsiveness of antral follicles to FSH may predict their reproductive competence, such that patients with a larger proportion of FSH-responsive antral follicles may be more likely to become pregnant after assisted reproductive technologies.

Study design, size, duration: Retrospective analysis comparing the FORT between women treated with CFA or rFSH from three randomized controlled trials, Pursue (N = 1388), Engage (N = 1476) and Ensure (N = 395). Women underwent controlled ovarian stimulation in a GnRH antagonist protocol followed by hCG trigger prior to IVF.

Participants/materials, setting, methods: Women received 150 µg CFA or 300 IU rFSH in Pursue (ages 35-42, ≥50 kg), 150 µg CFA or 200 IU rFSH in Engage (ages 18-36, >60 kg), and 100 µg CFA or 150 IU rFSH in Ensure (ages 18-36, ≤60 kg). AFC (<11 mm) and pre-ovulatory follicle count (>15 mm) were used for FORT, defined as pre-ovulatory follicles/AFCx100.

Main results and the role of chance: CFA elicited the growth of more preovulatory follicles from the existing AFC versus rFSH. For CFA and rFSH, respectively, the mean FORT values (adjusted for trial and age) were 85.0 versus 76.8 (p<0.001) for the combined cohort, and 74.1 versus 71.2 in Pursue (p = 0.180), 86.0 versus 75.0 in Engage (p<0.001), and 96.2 versus 79.2 in Ensure (p = 0.070). For CFA and rFSH, respectively, the overall mean oocyte output values (oocytes retrieved/AFCx100, adjusted for age) were 100.6 versus 98.1 in Pursue (p = 0.463), 121.9 versus 107.3 in Engage (p = 0.001), and 133.5 versus 102.3 in Ensure (p<0.001). FORT and oocyte output were consistent with the number of metaphase II oocytes for CFA and rFSH: 7.5 versus 7.2 in Pursue (p = 0.37), 10.4 versus 8.8 in Engage (p<0.001), and 10.3 versus 7.6 in Ensure (p<0.001). Significant increases in FORT with CFA compared to rFSH were observed in the younger cohorts of women from Engage and Ensure, but not in the older cohort in Pursue. No differences in pregnancy rates based on FORT were observed in any study. As this analysis only included pregnancy outcomes from fresh embryo transfers, future studies utilizing cumulative

pregnancy rates are needed to further evaluate the correlation between FORT and IVF outcomes.

Limitations, reasons for caution: This was a retrospective analysis. Measurement of antral follicles by transvaginal ultrasound was not standardized across study centers or observers. A larger study sample may be necessary to discern clinically meaningful differences in pregnancy outcomes based on FORT.

Wider implications of the findings: The association between oocyte output and antral follicles that effectively respond to FSH suggests that FORT may be a qualitative indicator of differences in ovarian response and oocyte competence based on type of gonadotropin used during stimulation. Additional research regarding the correlation between FORT and IVF pregnancy outcomes is warranted.

Trial registration number: NCT01144416, NCT00696800, NCT00702845.

P-740 Vitamin D and live birth rate after IVF

V. Seifert-Klauss[1], A. Ritzinger[2], B. Lesoine[3], F.D. Berg[3], M. Schmidmayr[4]

[1]Klinikum rechts der Isar, München, Germany
[2]Klinik und Poliklinik für Frauenheilkunde der TU München, Gynäkologische Poliklinik, Munich, Germany
[3]A.R.T. Bogenhausen GmbH, IVF, Munich, Germany
[4]Klinik und Poliklinik für Frauenheilkunde, Kinderwunsch-Sprechstunde, Munich, Germany

Study question: How do Vitamin D levels prior to IVF treatment differ between women with unsuccessful IVF-outcome and those with a live birth?

Summary answer: A cut-off of 16,5 ng/ml discriminated best between women with and without a live birth with good sensitivity, but poor specificity.

What is known already: Vitamin D regulates 3% of the human genome and specifically target genes of the Vitamin D Receptor (VDR) involved in cell-proliferation and differentiation, oxidative stress and apoptosis, membrane transport, and cell adhesion. Weather conditions during the month before IVF treatment have been found to have an impact on live birth rate, but in women undergoing euploid embryo transfer, vitamin D status was unrelated to pregnancy outcomes (not including live birth rate). A recent meta-analysis found lower vitamin D Status (< 20 ng/ml vs. >/= 20 ng/ml) was associated with a lower live birth rate (RR 0.76, 95 % CI 0.61-0.93).

Study design, size, duration: This prospective observational cohort pilot-study included 83 patients scheduled for IVF treatment in a university-affiliated IVF-Center. Participants had a serum dermination of their vitamin D and calcium levels prior to downregulation and stimulation. Follow-up included the pregnancy outcome until live birth.

Participants/materials, setting, methods: The relationship between Vitamin D and IVF outcome was modelled by multiple regression analysis. Age, serum-cacium, BMI and Vitamin D were the independent confounders, IVF outcome was the dependant variable. The association was further studied using receiver operating characteristics (ROC) modelling.

In order to find the cut-off, which would best discriminate between patients with a later live birth and those without, Youden's J Index (sensitivity - (1- specificity)) and a tree diagram were performed.

Main results and the role of chance: Average participant age was 37,6 (± 3,37) years, average BMI was 22,95 (± 4,2), serum calcium was 2,4 (± 0,09) and Vitamin D 19,64 (± 9,1). Median Vitamin D values were 21 ng/ml (average 23) in women with ongoing pregnancy, and 17 ng/ml (average 19) im women aborting or not becoming pregnant.

Multiple regression analysis revealed no significant influence of Vitamin D on birth rate. The ROC area under the curve was 0,67, not sufficient to predict IVF success from a vitamin D determination. However, the results hint at some connections which could be relevant, if validated in a larger cohort:

no patient with a vitamin D value below 13,5 ng/ml had a live birth, the birth rate of all women over 13,5 ng/ml was 15%, while women with values over 29,5 ng/ml had a birth rate of 27,3%. A cut-off of 16,5 ng/ml showed a sensitivity of 0,889 and a specificity of 0,446.

Limitations, reasons for caution: This analysis did not take into account all factors related to IVF outcome, such as male factor, prior pregnancy, or

therapeutic regime. Also, the small sample size precludes any generalization for clinical practice at this time. Also, there is no proof of a therapeutic value of giving exogenous vitamin D.

Wider implications of the findings: These findings may serve to plan a prospective trial on the value of giving Vitamin D to Vitamin D- insufficient infertilitiy patients.

Trial registration number: not applicable.

P-741 Polycystic ovary syndrome (PCOS): markers of responsiveness to Metformin therapy

V. Galiano[1], E. Garzia[2], G. Murru[1], C. Lepadatu[2], A.M. Marconi[3]

[1]Ospedale San Paolo- Polo Universitario - ASST Santi Paolo e Carlo, Clinica Ostetrica e Ginecologica- Procreazione Medicalmente Assistita, Milano, Italy
[2]Ospedale San Paolo- Polo Universitario - ASST Santi Paolo e Carlo, Procreazione medicalmente assistita, Milano, Italy
[3]Ospedale San Paolo, Clinica Ostetrica e Ginecologica, Milano, Italy

Study question: Is it possible to identify reliable predictors of response and compliance of Metformin therapy in PCOS patients, also studying the proper duration of treatment?

Summary answer: Baseline insulin resistance, BMI, androgenemia and LH/FSH ratio are strictly related to the success of therapy in restoration of ovulatory cycles and reduction of hyper-androgenemia

What is known already: PCOS diagnosis is based on the presence of chronic anovulation, polycystic ovaries and hyperandrogenism. Insulin-resistance is a common even not mandatory feature of the syndrome. The insulin-sensitizing Metformin, currently one of the treatment of choice in PCOS patients, has been shown to improve metabolic abnormalities, decrease androgen levels and improve menstrual pattern and ovulatory function. Nevertheless the extensive use of this medication is contained by the highly variable compliance and response rate

Study design, size, duration: In this prospective not randomized cohort study were analyzed 105 PCOS consecutive patients of reproductive age treated with Metformin 1500 mg/daily by the Gynecological Endocrinology outpatient clinic of the Reproductive Medicine Unit, San Paolo Hospital – University of Milan, Italy. Metformin outcomes were considered: the recovery of regular menstrual cycles, the BMI reduction in overweight patients, the decrease of hyperandrogenemia and hyperandrogenism, the insulin-resistance mitigation, the lipid profile normalization

Participants/materials, setting, methods: All patients met the ESHRE/ASRM 2003 Rotterdam criteria. At inclusion, before treatment, they underwent to a complete clinical evaluation, to an endocrine/metabolic laboratory assessment and to a transvaginal ultrasonography. Later were carried out semestral checks of all parameters. Therapy outcomes were compared to baseline data in order to notice the degree of variation of every single output and to eventually identify reliable markers of compliance and response to the therapy

Main results and the role of chance: The Metformin treatment resulted in a clear improvement of the glucose metabolism in all the treated patients. Nevertheless a great level of baseline insulin resistance do not automatically means improvement of all therapy outcomes. Insulin-resistance, obesity, hyperandrogenemia and also high LH/FSH ratio are singularly markers of treatment efficacy in terms of restoration of regular ovulatory cycles and of reduction of hyperandrogenemia. The predictive value of these markers significatively increase when they are combined. A lower baseline insulin resistance as much as regular androgenemia, irrespectively of the basal BMI, correlates to an easier weight and visceral adiposity containment as a result of treatment.In our population we have not observed severe side effects of Metformin therapy. The drop-out rate was mainly due to mild gastro-intestinal symptoms and to inadequate motivation. Comparing the data of this group of patients (n: 27) with the group who carried out at least six months of therapy (n: 74), the first showed lower endocrine-metabolic impairment. The comparison of the results obtained after 6, 12 and 18 months of treatment leads for optimal duration of therapy of 12 months because of generally achieving in this time the great part of clinical and endocrine-metabolic positive effects

Limitations, reasons for caution: During this study no specific alimentary regimen has been recommended. Patient's lifestyle and eating habits during the study could potentially interfere with the syndrome expressions.

Wider implications of the findings: Metformin is effective in the treatment of PCOS. The different sensitivity to therapy may lie in the heterogeneity of PCOS population. Greater efforts have to be done to develop a clinically useful predictive model of Metformin treatment response, in order to reduce the poor/null response and the drop out rate

Trial registration number: Not applicable.

P-742 Maternal anti-mullerian hormone (AMH) as a predictor of embryo aneuploidy in young patients undergoing in vitro fertilization with preimplantation genetic diagnosis (PGD)

M. Piccolomini[1], T. Bonetti[2], J.R. Alegretti[3], P. Serafini[4], E. Motta[5]

[1]Huntington Medicine Reproduction, São Paulo- SP, Brazil
[2]Huntington Medicina Reprodutiva / Universidade Federal de Sao Paulo, Scientific Director / Gynecology Endocrinology Discipline. Gynecology Department, Sao Paulo, Brazil
[3]Huntington Medicina Reprodutiva, Embryology Director, Sao Paulo, Brazil
[4]Huntington Medicina Reprodutiva / Universidade de Sao Paulo, Clinical Director / Gynecology Discipline. Obstetrics and Gynecology Department, Sao Paulo, Brazil
[5]Huntington Medicina Reprodutiva / Universidade Federal de Sao Paulo, Clinical Director / Gynecology Endocrinology Discipline. Gynecology Department, Sao Paulo, Brazil

Study question: Is the low ovarian reserve determined by AMH serum levels associated to the incidence of blastocyst aneuploidy in young patients submitted to in vitro fertilization (IVF)?

Summary answer: Low AMH levels isn't a predictor of blastocyst aneuploidy in young patients, suggesting the low ovarian reserve in <37yrs-old patients isn't an indication to PGD.

What is known already: The AMH, produced by granulosa cells, is postulated to be associated with both ovarian reserve and function. Serum AMH declines with age and ovarian reserve reducing, and it has the advantage of stability, keeping constant levels throughout the menstrual cycle and is not influenced by other hormones or oral contraceptives. Then, it has been considered a better predictor of ovarian reserve. The ovarian reserve declining by ageing is associated with oocyte quality, which in turns affect the embryo quality. Nevertheless, the relationship between low ovarian reserve and oocyte/embryo qualities in young patients has not been clearly stablished.

Study design, size, duration: This is a retrospective study including 236 IVF cycles with embryo biopsy for PGD between February 2014 and May 2015. Patients had serum AMH measured to evaluate ovarian reserve, and underwent a standard ovarian stimulation and IVF protocols. A total of 562 embryos were biopsied and analyzed by comparative genomic hybridization array (CGHa) in a reference genetic laboratory.

Participants/materials, setting, methods: The embryos were cultured until the fifth day of development, when the trofectoderm biopsies were performed according to standard procedures. Embryos were cryopreserved for future transfers as routine using standard protocols. After CGHa analysis, the embryos were classified as euploid or aneuploid. Also, the patients were categorized by ages subgroups: ≤37 yrs-old (n = 77) and >37 yrs-old (n = 159), and the association of AMH and aneuploidy rates were analyzed for each subgroup.

Main results and the role of chance: The indication for CGHa in patients included in the study were advanced maternal age (67.4%), recurrent miscarriage (8.9%), implantation failure (9.3%), severe male factor (4.2%), genetic factor (2.5%) and screening for patient choice (7.6%). Women ages varied from 30 to 49 yrs-old (39.3 ± 3.4), and had mean AMH levels of 1.9 ± 2.1 ng/ml. In general, the patients had 9.7 ± 6.6 oocytes recovered, 2.4 ± 1.6 blastocysts biopsied and the aneuploidy embryos rate was 68.5%. The comparison between subgroups showed similar mean number of embryos biopsied (≤37yrs-old: 2.4 ± 1.5 and >37yrs-old: 2.4 ± 1.6; p = 0.746). As expected, younger patients had a higher levels of AMH (≤37yrs-old: 2.5 ± 2.7 and >37yrs-old: 1.7 ± 1.8; p = 0.005) and lower aneuploidy embryos rate (≤37yrs-old: 54.7% and >37yrs-old: 75.2%; p<0.001). The levels of AMH were inversely correlated to age in both subgroups of patients (Pearson correlation: ≤37yrs-old: r = -0.256; p = 0.025 and >37yrs-old: r = -0.215; p = 0.007). However,

there was not association between AMH measurements and eneuploidy embryos rate for ≤37yrs-old (Pearson correlation: r = 0.034; p = 0.766) or >37yrs-old (Pearson correlation: r=-0.083; p = 0.301) subgroups. Finally, we compared the aneuploidy rates of ≤37yrs-old patients between those presenting AMH < 1.0 ng/ml (55.2%) or AMH≥1.0 ng/ml (54.5%; p = 0.943) and >37yrs-old (AMH < 1.0 ng/ml: 76.1%, AMH≥1.0 ng/ml 74.2%; p = 0.725).

Limitations, reasons for caution: Besides the retrospective design of this study, it is known the AMH measurements methods presents a high variation between laboratories, which can be considered limitations of this study. A higher number of patients should be included in the analysis in order to minimize those biases.

Wider implications of the findings: Our findings confirmed the association between ageing and aneuploidy. However, low ovarian reserve represented by AMH is not associated to aneuploidy rates, regardless of patient age. It suggest that oocytes quality is preserved in young patients presenting low ovarian reserve, and there is no indication for PGD in those cases.

Trial registration number: not applied.

P-743 Telomere content is not altered in girls with Idiopathic Central Precocious Puberty treated with GnRH analogue: a preliminary study

C. Furtado[1], R. Iannetta[2], D. Cristina Chielli Pedroso[1],
A.C. C. J. S Rosa e Silva[3], R. Alberto Ferriani[1], R. Tocantins Calado[4],
R. Maria dos Reis[1]

[1]Ribeirao Preto Medical School- University of Sao Paulo, Obstetrics and Gynaecology, Ribeirao Preto, Brazil
[2]Ribeirao Preto Medical School- University of Sao Paulo, Obstetrics and Gynaecology, Ribeirão Preto, Brazil
[3]Ribeirao Preto Medical School- University of Sao Paulo, Obstetrics and Gynaecology, Ribeiro Preto, Brazil
[4]Ribeirao Preto Medical School- University of Sao Paulo, Internal Medicine, Ribeirao Preto, Brazil

Study question: What are the implications of idiopathic central precocious puberty (ICPP) on telomere content in girls treated with gonadotropin releasing hormone analogue (GnRHa)?

Summary answer: Telomere Content is not altered in girls with ICPP and metabolic and endocrinology aspects were not correlated with telomere.

What is known already: The ICPP is related to the appearance of physical and hormonal signs of pubertal before eight years old. It is observed an increase in growth velocity, disproportionate advancement of bone age and maturation, metabolical and endocrinological alterations. Polycystic Ovarian Syndrome (PCOS) seems to be common in patients with ICPP treated with gonadotropin releasing hormone analogue (GnRHa). The suppressive therapy with GnRHa is related to suppression of oestrogen and excessive exposure to androgenic hormones, with clinical and/or laboratory hyperandrogenism. Metabolic alterations and hyperandrogenism associated with ICPP is related to changes in telomere biology and maybe an important feature of this disease.

Study design, size, duration: Observational case-control study, in which 45 patients with a history of treatment of ICPP with GnRHa and 40 controls (CO) were included

Participants/materials, setting, methods: Patients with ICPP previously treated with leuprolide acetate (3.75 mg per month) at least six months and healthy control women were included. Height, age, weight, body mass index (BMI) were measured. Insulin, triglycerides and testosterone were evaluated. Insulin resistance was predicted by HOMA (Homeostasis Model Assessment). Telomere content was measured using quantitative real-time PCR (qPCR). Statistical analyses were determined by Wilcoxon test and Spearman correlation was carried out.

Main results and the role of chance: Age mean was 15.96 (±2.73) in ICPP and 16.08 (±3.98) in controls. The variables weight (p=.0001) and BMI (p=.0001) was increased in IPP group. Insulin (p = 0.0048) and HOMA (p = 0.0144) was higher in IPP than in CO. Triglycerides were not different between the groups (p = 0.46). Telomere content was not different between ICPP (1.35 ± 0.30) and control (1.30 ± 0.56) (p = 0.2919). We did not observe any correlation between telomere and testosterone, BMI and weight in the subjects analysed. Only a negative correlation was observed between telomere and age (r2=- -0.39, p = 0.01).

Limitations, reasons for caution: Limited number of cases of the study group. An increase of sample size is recommended to make the data more robust and confirm the results.

Wider implications of the findings: Telomere content was not different in ICPP and control women and no correlations were observed in metabolic and endocrinology variables analysed.

Trial registration number: N/A.

P-744 Low anti-Müllerian hormone resulted in reduced pregnancy rates within two years of fertility treatment irrespective of female age; a prospective cohort-study of 546 infertile women

H. Hvidman[1], L.L. Thuesen[1], M.P. Lauritsen[1], J.G. Bentzen[1], R. Sylvest[1], A. Loft[1], A. Pinborg[2], A. Nyboe Andersen[1]

[1]Rigshospitalet- Copenhagen University Hospital, The Fertility Clinic, Copenhagen, Denmark
[2]Hvidovre Hospital- Copenhagen University Hospital, Dept. of Obstetrics & Gynaecology, Hvidovre, Denmark

Study question: Can serum-AMH predict long-term success rates in infertile women aged below 40 initiating fertility treatment?

Summary answer: Low AMH was associated with a reduced chance of conceiving within two years after start of fertility treatment in women below 40 years of age.

What is known already: AMH is a well-established predictor of the ovarian response to controlled ovarian stimulation, but a weak predictor of pregnancy and live-birth rates after assisted reproduction.

Study design, size, duration: A prospective cohort study of 546 infertile women aged 20–40 years initiating fertility treatment at a tertiary centre during 2011–2013 with a two-year follow-up on treatment outcome. Oocyte recipients were excluded.

Participants/materials, setting, methods: All women underwent a throughout examination at cycle day 2–5 before initiating their first treatment cycle. Examination included blood sampling (AMH, LH, FSH and thyroid hormones) and ovarian sonography (antral follicle count, pathology). Data on reproductive outcome within two years of the examination was based on the clinic's register.

Main results and the role of chance: Women with a mean age 32.3 ± 4.0 were stratified in low AMH (1st quintile), median (range) pmol/l: 7.8 (< 3;12), intermediate AMH (2nd–4th quintiles, reference): 25 (13;49), and high AMH (5th quintile): 66 (50;417). The proportion of women having achieved a pregnancy within two years of fertility treatment was reduced in women with low AMH: 66.7%, 81.5%, and 76.4%, respectively (p = 0.03). Even after age-adjustment, the chance of having achieved a pregnancy within two years was halved in women with low AMH compared with the reference group (aOR 0.5; 95% CI: 0.3;0.8), whereas no difference in pregnancy rates was observed between the intermediate and high AMH groups (aOR 0.7, 95% CI: 0.4;1.2). The cumulative pregnancy rates were independent of female age; 80.7% in age group 20–29, 78.5% in age group 30–34, and 73.0% in age group 35-39 (p = 0.2). Nine women had an undetectable serum-AMH (<3 pmol/l) at inclusion of whom 3 (33%) achieved a pregnancy during the two-year follow-up period.

Limitations, reasons for caution: The presented data are preliminary. Further analysis including competing risk survival analysis will be conducted. Data were not adjusted for sperm quality.

Wider implications of the findings: The presented results indicate that AMH may be used to predict not only the response to controlled ovarian stimulation but also to advice women on their cumulative chance to achieve a pregnancy.

Trial registration number: Not applicable.

P-745 Thyroid status and prevalence of Thyroperoxidase Antibodies (TPO-Ab) in women referred to a Danish University Fertility Clinic

D. Grove-Laugesen[1], E. Ebbehøj[1], U.B. Knudsen[2]

[1]Aarhus University hospital, Department of Endocrinology and Internal Medicine, Aarhus C, Denmark
[2]Aarhus University, Institute of Clinical Medicine, Aarhus C, Denmark

Study question: How does thyroid status and Thyroperoxidase Antibodies (TPO-Abs) differ in infertile women compared to fertile women and how do they affect success of in vitro fertilization (IVF)?

Summary answer: Level of thyrotropin and frequency of TPO-Abs did not differ between infertile and fertile women and did not affect success of IVF

What is known already: Thyroid hormones are vital for a woman's fertility. TPO-Abs increase the risk of developing hypothyroidism, also during assisted reproduction and pregnancy. In many studies, infertility is associated with increased risk of thyroid autoimmunity such as TPO-Abs. Recent data from observational studies have questioned the importance of TPO-Abs on results of fertilization treatment. Level of thyrotropin and frequency of TPO-Ab in Danish women seeking fertility treatment is unknown, and a possible effect on success of fertilization treatment has not previously been investigated.

Study design, size, duration:

(1) The cohort consists of women referred for fertility treatment at Aarhus University Hospital, Denmark, January 1st 2012 until March 31th 2014. Here we present preliminary data from 2012 (n = 558). In a cross sectional study, level of thyrotropin and frequency of TPO-Abs were compared between infertile and fertile women. In a prospective cohort study (N = 281) we investigated the effect of these parameters and of grouping on success of IVF.

Participants/materials, setting, methods: Single women treated with donor semen and women with male infertility as primary diagnosis were considered fertile, others infertile (57 %). Biochemistry was obtained as part of infertility work-up. Body mass index(BMI), smoking, details on fertilization treatment, and outcome of each treatment cycle was collected prospectively in a treatment database.

Main results and the role of chance: 559 women were referred for treatment. 41 were excluded from the study due to co-morbidity, mainly cancer. Known or newly diagnosed thyroid diseases were comparable between groups. These women were excluded from analysis. 317 women were infertile (57 %). Thyrotropin level was 1.63 (95%CI 1.52;1.74) among the infertile women and did not differ from the fertile women (1.60 (95%CI 1.48;1.73)) p = 0.76. Frequency of TPO-Abs was 15.18 % among infertile and 14.94% among fertile (chi square test for difference, P = 0.96). Age at referral, BMI, and smoking were comparable between groups.

276 women were treated with IVF. In this sub cohort, infertile women were 1.58 (95%CI 0.53;2.63) years older (p = 0.003) but groups were otherwise comparable. Success of first IVF (positive human chorion gonadotropin (hcg), loss of embryo, and child birth (overall 32.6 %) did not differ between groups. Increasing age significantly reduced chance of biochemical and clinical pregnancy and chance of child birth, whereas level of thyrotropin, TPO-Abs, smoking, and BMI did not. Only 30 women had TPO-Abs. They did not differ from TPO-Ab-negative women and TPO-Abs did not predict chance of IVF.

Limitations, reasons for caution: Level of thyrotropin and TPO-Abs were only available for 448 and 199 respectively, however women without available biochemistry were comparable in terms of demographics. We were not able to look separately at success of ICSI.

Wider implications of the findings: To our knowledge this is the first study describing thyroid status with thyrotropin and TPO-Abs in Danish women seeking fertility treatment. Findings do not differ from similar populations. Our data adds to the ongoing debate regarding the impact of thyroid autoimmunity on fertility treatment. Larger studies are warranted.

Trial registration number: This study was approved by the Danish Dataprotection Agency (1-16-02-487-13) and by the Danish Health and Medicines Authority (3-3013-495).

P-746 Sonographic measures of bone density and markers of bone turnover during pregnancy and lactation

B. Seeber[1], B. Böttcher[2], G. Goebel[3], E. Nadia[2], S. Ziehr[2], W. Ludwig[2]

[1]UFK Innsbruck, Gynecologic Endocrinology and Reproductive Medicine, Innsbruck, Austria
[2]Medical University of Innsbruck, Gynecologic Endocrinology and Reproductive Medicine, Innsbruck, Austria
[3]Medical University of Innsbruck, Biostatistics, Innsbruck, Austria

Study question: Does bone mineral density during pregnancy and lactation measured with ultrasonometry (QUS) correlate to serum markers of bone turnover?

Summary answer: Serial measurements of BMD showed no significant change during pregnancy and lactation and did not correlate to observed changes in markers of bone turnover.

What is known already: A high bone turnover during pregnancy has been shown using biochemical markers of bone resorption and formation and also reflected in a decrease in BMD during pregnancy. To our knowledge, no study has thus far compared these assessment techniques in the same cohort to test for a possible correlation and to evaluate the use of a simple hand ultrasound-based screening method during pregnancy.

Study design, size, duration: This prospective longitudinal 2-year study was designed with 50 female patients followed during pregnancy, in the puerperium, and the lactation period. Measurements of bone mineral density and laboratory markers of bone turnover were repeated at five different time points (once each trimester, 6-8 weeks post-partum, and once during lactation.)

Participants/materials, setting, methods: 51 female pregnant patients were included in this study after obtaining written consent. Quantitative ultrasonometry to assess BMD was performed at the distal metaphyses of the proximal phalanxes II-V in the outpatient department of a university hospital. Biochemical markers of bone remodeling, osteoprotective factors, and serological markers of bone turnover were measured. Statistical analyses evaluated percentage of change in BMD over time and correlated measures of BMD with serum markers for potential use for screening.

Main results and the role of chance: BMD of the proximal phalanxes assessed by AD-SoS and UDPI showed no significant change from baseline during pregnancy ($p = 0.16$ and $p = 0.7$, respectively).

Correlation analyses showed a significant association between AD-SoS and UDPI, $\rho = 0.52$ and 0.63 ($p < 0.01$, respectively).

Markers of bone turnover showed significant changes throughout time (Friedman's test). Biochemical markers of bone turnover increased over the time of pregnancy ($p < 0.001$). Markers of bone resorption (TRAP-5b, ß-Croßlaps) rose and peaked in the puerperium. Markers of bone formation, namely OC, rose significantly ($p < 0.001$) after having decreased in the second trimester and peaked during lactation.

However, no statistically significant correlations between changes in BMD measures and serum parameters of bone turnover and remodeling were found.

Limitations, reasons for caution: No non- pregnant control group was analyzed during the same period. The cohort is too small to analyze subgroups based on parity, BMI, diet or age. The patients in this cohort may not be representative of all pregnant women, especially those with risk factors for bone loss.

Wider implications of the findings: Our results contradict those of previous studies which show a decline in bone density during pregnancy. It is possible that the ultrasonometry used was not sensitive enough to detect subtle changes in BMD. It is possible that the proximal phalanx is not a location of high bone turnover during pregnancy.

Trial registration number: UN 3641277/ 4.3 at study institution.

P-747   A prospective randomised controlled study (RCT) evaluating the effect of early hcg trigger on pregnancy rates in patients undergoing IVF-ICSI cycles using GNRH- antagonists

A. Jindal[1], R. Singh[2], M. Singh[3], P.C. Jindal[4]

[1]Bhopal Test Tube Baby Centre, Infertility, Bhopal, India
[2]Bttb Centre & Ln Medical College-, Infertility, Bhopal, India
[3]Bttb Centre & L N Medical College, Infertility, Bhopal, India
[4]Bttb Centre, Infertility, Bhopal, India

Study question: Does an early Administration Of Human Chorionic Gonadotropin (hCG) Improve Pregnancy rates In IVF-ICSI Cycles With GnRH Antagonists?

Summary answer: Yes: Early HCG-triggering of final oocyte maturation result in an improved probability of pregnancy by leading to a less deranged and more receptive endometrium.

What is known already: The criteria used for hCG administration in GnRH - Antagonist cycles (hCG triggering for the final oocyte maturation as soon as ≥ 3

follicles ≥ 17 mm) have not been evidence-based, and their importance for the probability of pregnancy was unknown until recently. Studies have shown that delaying hCG administration is associated with a decreased probability of ongoing pregnancy because of premature closure of the Implantation-Window.

Early HCG-triggering is expected to result in lower progesterone levels on the day of hCG and this intervention might result in an improved pregnancy rates by leading to less deranged and more receptive endometrium.

Study design, size, duration: The purpose of this randomized controlled trial of 416 infertile patients between 2006 to 2016, below 42 yrs of age, was to evaluate whether triggering of final oocyte maturation as soon as ≥ 3 follicles ≥ 16 mm present on ultrasound or one/two day later affects the probability of pregnancy in patients stimulated with GnRH-antagonists in IVF-ICSI-cycles.

PRIMARY OUTCOME: pregnancy rate

SECONDARY OUTCOME: number of MII oocytes, endometrial-thickness, progesterone levels and complications like OHSS

Participants/materials, setting, methods: Patients were randomized by a computer-generated list and after proper consent were divided into two groups of 208 patients each (group one - Early HCG and group two - Late HCG).

Main results and the role of chance: Significant differences were observed between the group One(early-hCG) and group Two (the late-hCG group) regarding -

Pregnancy Rates (33% Vs 21%, respectively) and

Progesterone Levels (0. 7 ± 0. 5 Vs 1. 1 ± 0. 4 ng/mL, respectively) on the day of hCG administration and

Endometrial Thickness (10. 8 +/- 2. 3 mm Vs 7. 3 +/- 2. 5 mm) on day of embryo transfer.

the number of Metaphase II Oocytes (6. 1 ± 4. 1 Vs 9. 1 ± 4. 8, respectively). and

less Complications like OHSS (3 % Vs 7%)

More similar multicentric trials are needed to assess its potential in improving the implantation chances in IVF-ICSI cycles, thereby improving pregnancy rates and reducing the complications of ART.

Limitations, reasons for caution: Why delaying HCG administration leads to an increased incidence of endometrial advancement is not clear?

The adverse effect of Progesterone elevation on the day of hCG is explained by the induction of differences at the histological level and gene expression level between endometrial samples exposed to high concentrations of progesterone.

Wider implications of the findings: Our study suggests that prolongation of follicular phase is associated with a higher incidence of premature secretory changes of the endometrium due to Progesterone elevation and supraphysiological E2 levels in late-hCG group.

Since earlier hcg- triggering results in lower progesterone levels, such an intervention might give better pregnancy rates.

P-748   Changes in Assisted Reproductive Technology Use After Large Increases in Patient Cost-sharing: Is Something Amiss in Denmark?

J. Hsu[1], M. Price[1], M. Schiotz[2], V. Seo[1], P. Rinaudo[3], A. Frolich[4]

[1]Massachusetts General Hospital, Mongan Institute Health Policy Center, Boston-MA, U.S.A.
[2]Bispebjerg Hospital- Copenhagen University Hospital, Department of Integrated Care, Region Hovedstaden, Denmark
[3]University of California San Francisco, Obstetrics- Gynecology & Reproductive Science, San Francisco- CA, U.S.A.
[4]Bispebjerg and Frederiksberg Hospitals- Copenhagen University Hospital, Research Unit for Chronic Conditions, Region Hovedstaden, Denmark

Study question: How did the large increase in patient cost-sharing for Assisted Reproductive Technology (ART) in Denmark impact its use?

Summary answer: After patient cost-sharing increased to 50% of ART costs in 2011, ART use dropped by 23% when compared to use between 2007-10.

What is known already: Recent advancements in assisted reproductive technology (ART) have improved birth rates and reduced complications; however, ART treatment remains expensive and often requires multiple treatments before a live birth. Many countries increasingly are limiting use of expensive treatments in an effort to reduce spending growth. Several countries have limited ART use by requiring patient cost-sharing, e.g., coinsurance. In general, cost-sharing for medical care has been an effective means for reducing use and spending, but often can have undesirable or unintended clinical consequences. There have been few studies examining the impact of a sudden increase in ART cost-sharing.

Study design, size, duration: We examine the impact of a large cost-sharing increase on ART use within a historical population cohort, i.e., a pre-post longitudinal design focused on within-clinic effects. In Denmark, ART coverage had been generous and use levels amongst the highest in the world. In 2010, Denmark announced plans to require substantial cost-sharing starting in 2011, i.e., a 50% coinsurance (from <10%). The policy was expected to reduce ART treatment use, and thus reduce national expenditures.

Participants/materials, setting, methods: Eligible subjects were Danish women who received publicly-financed ART between 2007-2013. We obtained data from public datasets, e.g., Danish ART and birth registries. To assess changes in the number of ART uses, we used linear models with clinic-level fixed effects. We examined the percent of treatments that had a live birth within six to ten months after ART treatment, using logistic regression and adjusting for maternal age and clinic.

Main results and the role of chance: In 2010, 10,718 women received 24,681 treatments with ART (mean = 2.3 treatments/person-year); and, among women receiving ART in 2010, 52% had a live birth within 6-10 months after treatment. In 2011, after the policy change, both the number of women receiving ART and the number of treatments per woman dropped (8,565 women, 18,986 treatments, mean = 2.2 treatments/person-years); among women receiving ART in 2011, 53% had a live birth within 6-10 months after treatment. Use dropped in each subsequent year from 2011-13; moreover, use initially increased in 2010 (the year of the policy announcement but before implementation), when compared to use in 2007-09. In analyses examining ART use between 2007-13, the 2011 coinsurance introduction was associated with a 23% decrease in ART use (mean of 181 fewer treatments per clinic per year; 95%CI: 93-270 fewer treatments). The odds of a live birth after treatment increased slightly for those treated in 2011, compared with those treated in 2007-2010 (OR=1.13; 95%CI: 1.09-1.18).

Limitations, reasons for caution: The pre-post design does not address any potential secular changes in ART use, though any such alternative explanations would need to coincide with the cost-sharing policy announcement and introduction.

Wider implications of the findings: There are growing financial barriers to ART use; fewer women are seeking treatment, and those that do have fewer treatments. Some women might have initiated ART earlier in anticipation of the policy implementation. Overall, the findings help explain the drop in all live births within Denmark, starting in 2011.

Trial registration number: Not applicable.

P-749 A comparison of cost - effectiveness of freeze - all protocol and fresh embryo transfer in women undergoing IVF - ICSI

L.D. Khoa[1], V.T.N. Lan[2], H.M. Tuong[3], D.Q. Vinh[1], P.D. Toan[1], T.N. Quang[4], R.J. Norman[5], B.W. Mol[6]

[1]My Duc Hospital, IVFMD, Ho Chi Minh, Vietnam
[2]University of Medicine and Pharmacy at Ho Chi Minh City, Obstetrics and Gynaecology, Ho Chi Minh, Vietnam
[3]Research Center for Genetics and Reproductive Health, School of Medicine, Ho Chi Minh, Vietnam
[4]University of Medicine and Pharmacy at Ho Chi Minh City, Public Health, Ho Chi Minh, Vietnam
[5]The Robinson Research Institute, Reproductive Endocrine and Medicine, Adelaide, Australia
[6]The Robinson Research Institute, Evidence Based Women's Health Care, Adelaide, Australia

Study question: What is the cost-effectiveness of a freeze-all versus fresh embryo transfer in women undergoing IVF/ICSI?

Summary answer: In women undergoing IVF/ICSI, the use of fresh embryo transfer protocol is cost-effective as compared to a freeze-all protocol.

What is known already: Conventionally, IVF embryos are transferred in the same cycle in which oocytes are collected, while remaining embryos are frozen and stored. Although recent data suggest that pregnancy outcomes could be improved after frozen compared with fresh embryo transfer, the immediate cost of freezing all embryos are higher than a policy in which the first transfer is done in a fresh cycle. The cost-effectiveness of both policies has not been compared.

Study design, size, duration: We performed a cost-effectiveness analysis (CEA) from a patient perspective alongside a RCT comparing freeze-all versus fresh transfer in non-PCOS women undergoing IVF. Cost data were calculated from used resources and prices based on micro–costing per patient. Data were collected from chart review and from patient questionnaires.

Participants/materials, setting, methods: For all patients, we measured direct medical costs relating to treatment (IVF, pregnancy follow-up, delivery), and indirect costs (travel, accommodation, income lost). We evaluated the cost-effectiveness of the Freeze-all and fresh Embryo transfer and then calculated an incremental cost-effectiveness ratio (ICER). One-way sensitivity Analysis (PSA) was used to explore the robustness of our findings.

Main results and the role of chance: Between June 2015 and April 2016, we randomized 782 women. Cost data were based on 704 women who returned questionnaires. The live birth rates after the first cycle were 33.8% for freeze-all versus 31.5% for fresh transfer (P = 0.542). The cost per live birth was 7,456 EUR for a freeze-all transfer, versus 5,699 EUR for the fresh transfer. The incremental cost of one live birth gained by freeze-all compared to fresh embryo transfer was 28,928 EUR. One–way sensitive analysis indicates live birth rate and IVF laboratory cost are factors that have largest effects on ICER.

Limitations, reasons for caution: This was a single IVF center study limited to the first embryo transfer cycle only. To make firm conclusions on the economic impact of freeze-all and fresh embryo transfer on pregnancy outcomes (live birth rate, complications), a cost-effectiveness analysis study based on all cycles is needed.

Wider implications of the findings: In non-PCOS couples undergoing IVF/ICSI, a freeze-all strategy is not cost-effective over a fresh embryo strategy.

Trial registration number: NCT02471573.

P-750 Assisted reproductive technology treatment and risk of breast cancer and gynecological cancers in women

D. Vassard[1], C.H. Glazer[2], J. Lyng Forman[3], M. Kamper-Jørgensen[4], A. Pinborg[5], L. Schmidt[4]

[1]University of Copenhagen- Institute of Public Health, Department of Public Health-Section of Social Medicine, København S, Denmark
[2]Bispebjerg University Hospital, Department of Occupational and Environmental Medicine, Copenhagen, Denmark
[3]University of Copenhagen- Institute of Public Health, Department of Public Health-Section of Biostatistics, Copenhagen, Denmark
[4]University of Copenhagen- Institute of Public Health, Department of Public Health-Section of Social Medicine, Copenhagen, Denmark
[5]Copenhagen University Hospital, Department of Obstetrics/Gynaecology- Hvidovre Hospital-, Copenhagen, Denmark

Study question: Is assisted reproductive technology (ART) treatment associated with risk of breast cancer or gynecological cancers during 16 years of follow-up?

Summary answer: Ovarian cancer risk was increased after initiated ART treatment. Breast cancer risk increased after 10 years. Risk of endometrial and cervical cancer were decreased.

What is known already: Concern has been raised about the potential adverse effects of ovarian stimulation hormones in ART treatment, and previous findings on the impact on breast cancer incidence and incidence of

gynecological cancers have been conflicting. Parity and type of hormones used have been shown to influence cancer risk, and a long-term elevated risk of breast cancer has been suggested. Risk of ovarian cancer has been shown to be elevated among ART-treated. Endometriosis, which also causes infertility, is associated with increased risk of ovarian cancer.

Study design, size, duration: The Danish National ART-Couple (DANAC) cohort includes all ART-treated Danish women during 1994-2009. After relevant exclusions, the population consisted of 42,510 ART-treated women identified from the Danish IVF Register and 202,595 age-matched controls from the background population with no previous history of ART treatment. The total study population of 245,105 women with no previously diagnosed cancer were followed in population-based registers until ultimo 2010. Cancer diagnoses were retrieved from the Danish Cancer Registry.

Participants/materials, setting, methods: Up to three fresh ART treatment cycles were accessible free of charge to heterosexual couples during 1994-2007 and also for homosexual female couples and single women during 2007-2009. Hazard ratios (HR) and 95 % confidence intervals (95% CI) were estimated in cox proportional hazards regression adjusted for age, calendar year, time since initiation of treatment, educational level, parity and partnership status as time-dependent variables.

Main results and the role of chance: During follow-up, the number of women diagnosed with cancer of the cervix were 589 (80 among ART-treated), endometrium 177 (22 among ART-treated), breast 2,304 (427 among ART-treated) and ovary 192 (56 among ART-treated). For the overall follow-up period there was an increased risk of ovarian cancer among ART-treated women (HR 1.52, 95 % CI 1.36-1.69), and the increased risk was accentuated during the first six years after initiated ART treatment. The highest incidence of ovarian cancer was found 2-4 years after initiated ART treatment (HR 1.81, 95 % CI 1.46-2.24). No overall increased risk of breast cancer was found (HR 1.01, 95 % CI 0.98-1.5), although hazard ratios tended to increase towards the end of follow-up at 10-12 years (HR 1.26, 95 % CI 0.97-1.62) and 12-14 years after initiated ART treatment (HR 1.21, 95 % CI 0.83-1.75). An overall lower risk among ART-treated women was found for cancer of the cervix (HR 0.70, 95 % CI 0.64-0.77) and insignificantly lower for endometrial cancer (HR 0.92, 95 % CI 0.80-1.06). Endometrial cancer risk appeared to be elevated among ART-treated 12-14 years after initiated ART (HR 1.89, 95 % CI 0.90-3.98), although this result was insignificant.

Limitations, reasons for caution: An increased risk of ovarian cancer in the years after initiated ART treatment probably reflects detection bias. A low number of women followed as long as 10-16 years after ART treatment limited the statistical strength of estimates during this period. Endometriosis could explain the elevated ovarian cancer risk among ART-treated.

Wider implications of the findings: Monitoring and longer follow-up in large cohorts could clarify whether long-term breast and endometrial cancer risk is elevated in ART-treated women. The short-term elevated ovarian cancer risk is important to address in studies taking cause of infertility into account, as well as risk of detection bias linked to ART treatment.

Trial registration number: Not relevant.

P-751 Knowledge, perceptions and acceptability of IVF treatment among women in an urban West African city

M. Achiaa[1], M.B. Yakass[2,3], B. Woodward[4]

[1]Lister Hospital & Fertility Centre, Department of Nursing Services, Accra, Ghana
[2]University of Ghana, Department of Biochemistry- Cell & Molecular Biology, Accra, Ghana
[3]Lister Hospital & Fertility Centre, Assisted Conception Unit, Accra, Ghana
[4]X&Y Fertility, Assisted Conception Unit, Leicester, United Kingdom

Study question: In a society where childbearing is almost mandatory and a third of couples experiencing infertility, what is the knowledge and perceptions on in-vitro fertilisation (IVF)?

Summary answer: Religious beliefs still pose a barrier to the perceptions and acceptability of IVF treatment by religiously-entrenched women, but it is acceptable to more educated women.

What is known already: IVF treatment is a widely accepted option for assisted conception in the developed world. In developing countries, where

couples have difficulty getting pregnant, a visit to a fertility clinic may not be a top priority. Rather, many preferentially visit a religious leader (e.g. pastors, imams) or try out some local herbal preparations claimed to offer help to women to conceive. For some. IVF treatment is still perceived as a new phenomenon, mainly due to lack of awareness and general acceptability. The cost implications of medical assisted conception are also prohibitive for many people in developing countries.

Study design, size, duration: This was a prospective study performed between September - December 2016. Open-ended questionnaire was administered via interviews to 150 women in the study area to gain information on their knowledge and acceptability of IVF treatment. Five healthcare professionals were also sampled purposively for their views on IVF practice. Participant responses were reviewed and grouped and when a theme/concept became apparent, codes were assigned. The chi-square test was used to analyze statistical difference in the data.

Participants/materials, setting, methods: One hundred and fifty (150) respondents aged between 18 – 50 years were recruited from the general population. The study area was an urban harbour city (Accra, Ghana) and can be described as a mix of middle to high and low-income families. Interview responses were transcribed, coded and analysed in SPSS software quantitatively and qualitatively.

Main results and the role of chance: When respondents were grouped according to age, only about half of younger respondents (≤25 years) were aware of IVF treatment, whereas all older respondents (≥46 years) had a basic knowledge of the IVF procedure. Those with secondary (high school) and tertiary (university) education had a significantly better knowledge of IVF treatment than their counterparts with basic or no formal education at all (p = 0.011). The internet served as the major source of information (72.3%) for those who had knowledge of IVF. On attitude, a good number of respondents accepted IVF treatment as a reliable means to conceive, but to them this will only be an option when 'all else has failed". Many stated cost was the main reason why IVF treatment would not be on their top priority when they are faced with infertility and that such treatment was 'for the rich". Others also viewed IVF treatment 'as sinful and against their religious belief". Such opinions came from Christians and Muslims alike. Others also perceived IVF as 'unnatural and had the propensity to make people lose faith in God". Some respondents had the perception that children born as a result of IVF were 'not normal and unhealthy".

Limitations, reasons for caution: The low number of study respondents should be considered when drawing conclusions based on this study.

Wider implications of the findings: With increasing education and public awareness through social media and other internet based approaches, knowledge of IVF treatment should become more widespread, and make the technique more acceptable in religiously-entrenched societies in developing countries

Trial registration number: N/A.

P-752 Increased rate of inferior neonatal outcomes among twins following assisted reproductive technology

Y.A. Wang[1], N. Safi[1], F. Ali[2], K. Lui[2], Z. Li[1], M. Umstad[3], E. Sullivan[1]

[1]University of Technology Sydney, Faculty of Health, Ultimo, Australia
[2]University of New South Wales, School of Women's and Children's Health, Sydney, Australia
[3]Royal Women's Hospital, Royal Women's Hospital, Parkville, Australia

Study question: Do twins born following assisted reproductive technology (ART) have higher rates of inferior neonatal outcomes compared to non-ART twins?

Summary answer: ART twins have higher rates of preterm birth, low birthweight, need for resuscitation, admission to Neonatal Intensive Care Unit (NICU), and prolonged hospital stay.

What is known already: Twin pregnancies have a higher risk of maternal and neonatal complications than singleton pregnancies. The higher incidence of twin pregnancy following ART results in higher rates of adverse maternal and perinatal outcomes compared to non-ART pregnancies. It remains unclear whether ART twins have similar perinatal outcomes compared to non-ART twins.

Study design, size, duration: A retrospective population study using the Australian National Perinatal Data Collections (NPDC). The study included 19,662 twins of ≥ 20 weeks gestational age or ≥ 400 grams birthweight born in Australia between 2007 and 2011. The analysis included 2290 (23.3%) ART twin sets and 7541 (76.7%) non-ART twin sets.

Participants/materials, setting, methods: The rates of stillbirth, preterm birth, low birthweight, low Apgar score, need for resuscitation, admission to NICU, prolong hospital stay, and neonatal death were compared between ART and non-ART twins. Generalized Estimating Equations was used to assess the likelihood of any neonatal outcomes following ART, with adjusted odds ratio (AOR) and 95% confidence intervals (CI) presented. Weinberg's differential rule was used to estimate the rate of monozygotic twins.

Main results and the role of chance: ART mothers were 3.3 years older than non-ART mothers. Compared to non-ART mothers, higher proportions of ART mothers were primiparous, non-smoking, with normal body mass index and with private health insurance. The rates of pregnancy-induced hypertension and gestational diabetes were significantly higher for ART mothers than non-ART mothers (12.2% vs. 8.4%, p < 0.01) and (9.7% vs. 7.5%, p<0.01) respectively. The incidence of monozygotic twins was 2.0% for ART twins and 1.1% for non-ART twins. Compared with non-ART twins, ART twins had higher rates of preterm birth (AOR: 1.13, 95% CI: 1.05-1.22), low birth weight (AOR: 1.13, 95% CI: 1.05-1.22), and need for resuscitation (AOR: 1.26, 95% CI: 1.17-1.36). In contrast, ART twins had significantly higher live birth rate than non-ART twins (98.6% vs. 97.7%; P < 0.01). Liveborn ART twins had 28% (AOR 1.28, 95% CI 1.09-1.50) increased odds of having any adverse neonatal outcome compared to liveborn non-ART twins, especially for opposite-sex ART twins (AOR 1.42 95% CI 1.11-1.82).

Limitations, reasons for caution: Since there is no information on ART procedures in the NPDC, we were unable to investigate the impact of single versus multiple embryo transfer on outcomes. The large proportion of mothers with missing data on body mass index and smoking during pregnancy may impact the validity of the comparison.

Wider implications of the findings: As ART twins had higher rates of adverse outcome, special antenatal care is recommended for them. Couples access ART should be fully informed the risk of adverse outcome of twin pregnancies. Single embryo transfer should be continued encouraged to reduce the rate of ART twin pregnancies.

Trial registration number: N/A.

P-753   Summary of 3 years of Polish state-founded in-vitro fertilization infertility treatment program for years 2013-2016. Results after 3 years

I. Martynowicz[1,2], P. Kuć[2,3], A. Kuczyńska[2,4], R. Milewski[5], M. Tarasiewicz[2,3], W. Kuczyński[2,3]

[1]Medical University of Białystok, Department of Gynecology and Gynecological Oncology, Białystok, Poland
[2]Centre for Reproductive Medicine, KRIOBANK, Białystok, Poland
[3]Medical University of Białystok, Department of Perinatology, Białystok, Poland
[4]Medical University of Białystok, Department of Reproduction and Gynaecological Endocrinology, Białystok, Poland
[5]Medical University of Białystok, Department of Statistics and Medical Informatics, Białystok, Poland

Study question: What are the results of Polish state-founded *in-vitro* fertilization infertility treatment program for years 2013-2016 in June 2016 when program was terminated?

Summary answer: Results are comparable with data collected by ESHRE from European registers despite limitation of fertilized eggs to six.

What is known already: This was the first time Polish government conducted *in vitro* fertilization (IVF) programme financed from public funds. Due to infertility treatment regulations being developed by the Polish government at the time programme started, some limits in number of fertilized eggs (only six) and transferred embryos (only one) for women under 35 years of age were introduced.

Study design, size, duration: 3 IVF procedures were available for women aged <40 with FSH<15 mU/mL on beginning of a cycle or AMH>0.7 ng/mL.

For women aged <35 number of fertilized eggs was limited to six and single embryo transfer (SET) was obligatory. For women >35 years of age there were no limitations in number of fertilized eggs and double embryo transfer (DET) was approved. Presented results contain data from 3 years of programme.

Participants/materials, setting, methods: Participants: In 17990 patients 27650 controlled ovarian stimulation in various protocols were initialized. Settings: 34 clinics realizing the IVF programme were obligated to report every procedure within 2 weeks. Methods: retrospective analysis of treatment outcomes including clinical and embryological data.

Main results and the role of chance: Cumulative pregnancy rate per cycle was 44.93%. Clinical pregnancy rate per cycle was 30% and 33.7% per transfer. The pregnancy rate by thawing in frozen embryo transfer (FET) was 29.73% and per SET and DET was 28.03% and 37.59% respectively. In the group of women under 35 years clinical pregnancy rate per fresh embryo transfer was 33.31% and multiple pregnancy rate was 4.61%. Clinical pregnancy rate per fresh embryo transfer in group of women between 35 and 40 years was 34.11% and multiple pregnancy rate was 14.12%. Miscarriage rate was 10.11% and single pregnancy was 92.94%. Ovarian hyperstymulation syndrome (OHSS) rate was 2.37%. High numbers of analyzed cycles limit the impact of chance in the presented data.

Limitations, reasons for caution: This presentation contains data form June 2013 to June 2016, while procedures were financed from public funds. When all live-birth data will be submitted and analyzed the result will be complete and final.

Wider implications of the findings: Despite limiting factors, pregnancy rates of the programme were relatively high. This may have impact on future public funded IVF programs.

Trial registration number: N/A.

P-754   Prevalence and impact of elective gender selection in oocyte donor recipient cycles in the United States 2005-2013

D. Barad[1,2], V. Kushnir[3,4], D. Albertini[3], S. Darmon[3], N. Gleicher[2,3,5,6]

[1]The Center for Human Reproduction, n/a, New York- NY, U.S.A.
[2]Foundation for Reproductive Medicine, n/a, New York- NY, U.S.A.
[3]Center for Human Reproduction, n/a, New York- NY, U.S.A.
[4]Wake Forest School of Medicine, Obstetrics & Gynecology, Winston-Salem- NC, U.S.A.
[5]Medical University Vienna, Obstetrics & Gynecology, Vienna, Austria
[6]Rockefeller University, Stem Cell and Molecular Embryology Laboratory, New York- NY, U.S.A.

Study question: What is the prevalence and impact of elective gender selection (eGS) in oocyte donor recipient cycles?

Summary answer: Elective gender selection reduced the odds of live birth in oocyte donor recipient cycles.

What is known already: Elective gender selection has been criticized for possible 'gender bias, social harm, and the diversion of medical resources from genuine medical need". Cleavage stage as well as trophectoderm biopsy have previously been associated with decreased embryo viability.

Study design, size, duration: Utilizing data between 2005-2013 from the national Assisted Reproductive Technology Database of the Society for Assisted Reproductive Technology (SART), we report on the prevalence of eGS and its effect on birth outcomes in first fresh oocyte donor-recipient cycles (ODRCs) and their subsequent frozen-thawed embryo cycles. Statistical models adjusted for patient and donor ages, number of embryos transferred, race, and cycle year were created to compare outcomes in eGS cycles relative to and non-eGS cycles.

Participants/materials, setting, methods: 33,756 patients initiated a first ODRC, among which 570 (1.68%) underwent eGS for assessment.

Main results and the role of chance: Live birth rates were significantly lower for eGS than non-eGS cycles (48.1 vs. 55.7%, P = 0.04). Adjusted for patient and donor ages, oocytes retrieved, embryos transferred, race and reporting year, the odds of live birth in cycles with eGS were reduced by 30% (OR 0. 70 95% CI 0. 59 to 0.84; P < 0.001) in comparison to non-eGS cycles. While Asian

women represented only 7.2% of the overall ODRC population they were 19.1% of the population choosing to undergo eGS.

Limitations, reasons for caution: Techniques for embryo biopsy have changed over the study period so findings in this analysis may not be generalizable to current practice.

Wider implications of the findings: Like other forms of preimplantation diagnosis, elective gender selection can have a significant negative impact of cycles outcomes in oocyte donor recipient cycles. Patietns should be appropriately counseled before choosing to have such elective procedures.

Trial registration number: n/a.

P-755   Assisted reproductive technology treatment and risk of death in women

L. Schmidt[1], D. Vassard[1], M. Kamper-Jørgensen[1], G.L. Pedersen[1], J. Lyng Forman[2], C.H. Glazer[3], I. Hageman[4], A. Pinborg[5]

[1]University of Copenhagen, Department of Public Health- Section of Social Medicine, Copenhagen K, Denmark
[2]University of Copenhagen- Department of Public Health- Section of Biostatistics, Copenhagen, Denmark
[3]Bispebjerg University Hospital, Department of Occupational and Environmental Medicine, Copenhagen NV, Denmark
[4]Copenhagen University Hospital- Rigshospitalet, Psychiatric Center Copenhagen, Copenhagen, Denmark
[5]Copenhagen University Hospital, Department of Obstetrics/Gynaecology- Hvidovre Hospital, Copenhagen, Denmark

Study question: Is assisted reproductive technology (ART) treatment associated with risk of death during a 16 year follow-up period?

Summary answer: ART-treated women had a lower risk of death short-term, although the risk was similar to untreated women from 10 years after ART treatment initiation.

What is known already: Previous studies have shown decreased risk of death among ART-treated women compared to women in the background population. Because reasonably good health is a prerequisite for initiating ART treatment, the association may reflect selection of healthy women into ART treatment. This process is known as the 'healthy patient effect'. To the best of our knowledge, this 'healthy patient effect' has not been directly addressed in prior investigations on this subject. ART implies delayed or obstructed parenthood for women in treatment, and factors such as childlessness, older age at first childbirth and non-marital status are associated with increased risk of death.

Study design, size, duration: The Danish National ART-Couple (DANAC) cohort includes all ART-treated Danish women during the years 1994-2009. After relevant exclusions, the population consisted of 42,897 ART-treated women identified from the Danish IVF Register and 204,514 age-matched comparison women from the background population with no previous history of ART treatment. The total study population was made up of 247,411 women, who were followed in population-based registers until ultimo 2010.

Participants/materials, setting, methods: Up to three ART treatment cycles were accessible free of charge for heterosexual couples during 1994-2007 and also for homosexual female couples and single women during 2007-2009. Associations between ART treatment and death were estimated using Cox proportional hazards regression adjusted for age, educational level, parity, time since ART treatment initiation and partnership status as time-dependent variables and prior comorbidity as a fixed variable. Hazard ratios (HR) with 95% confidence intervals (95% CI) were estimated.

Main results and the role of chance: In total 2,041 women died, 235 among ART treated (0.6 %) and 1,806 among the untreated women (0.9 %). An initial lower risk of death among ART treated women persisted with adjustment for socio-demographic factors and comorbidity prior to treatment (1-2 year HR 0.84, 95 % CI 0.75-0.94), but within 10 years after treatment initiation the risk of death among ART-treated and untreated was similar (10-11 year HR 1.01, 95 % CI 0.71-1.45). When incorporating reproductive status before and during the follow-up period, differences between ART-treated and untreated women were minor and/or insignificant. Risk of death was highest among childless women regardless of ART treatment status, particularly death caused by

cancer, psychiatric factors and suicide. Among women with children, having children during observation was associated with lower risk of death compared to those who only had children prior to observation, regardless of ART treatment status.

Limitations, reasons for caution: Number of deaths was insufficient to investigate separate causes of death. Measurement of comorbidity was based on hospital in- and outpatient diagnoses, other minor conditions could be relevant.

Wider implications of the findings: ART-treated women have a transient decreased risk of death, which diminishes with increased time since ART treatment initiation. ART-treated women are not necessarily healthier than an untreated comparison group, but the initial lower risk of death may also be caused by pregnancy planning, pregnancy and shorter duration since achieved parenthood.

Trial registration number: Not relevant.

P-756   Anxiety and ART: should we be anxious about it?

C. Harrison[3], L. Corda[1], H. Ockhuijsen[2], O. Stidston[1], N. Macklon[1], J. Boivin[3]

[1]Complete Fertility Unit- Princess Anne Hospital- Southampton, Reproductive Medicine, Southampton, United Kingdom
[2]University of Utrecht- Netherlands, Reproductive Medicine, Utrecht, The Netherlands
[3]University of Cardiff- Wales, School of Psychology, Cardiff, United Kingdom

Study question: Can patients at risk of anxiety after embryo transfer (i.e, during the waiting period) be identified and reassured about the impact of anxiety on outcome?

Summary answer: Pre-existing anxiety is the primary determinant of anxiety during the waiting period, but pre-treatment and waiting period anxiety do not significantly impact clinical outcome.

What is known already: Dealing with subfertility and its treatment is reported as being a stressful life experience for couples. Stress and anxiety are known to affect the experience of ART, and have been suggested to influence pregnancy rates. It has been proposed that emotional response to treatment results, and possibly compliance to treatment, is conditioned by demographic and clinical factors, as well as level of pre-existing anxiety. However, it has not yet been established to what extent these factors are responsible for stress during the waiting period of treatment. Coping interventions have been suggested to reduce stress in the time after embryo transfer.

Study design, size, duration: Archival data from the routine care control arm of a randomized controlled trial, examining the effects of a coping intervention, were used in the present study ($n = 124$) (Ockhuijsen et al. 2014). Participants completed the hospital anxiety and depression scale (HADS) just prior to the first scan during stimulation (T1), on Day 10 of the 14-day waiting period (T2), and 6 weeks after the start of the waiting period (T3, about 4 weeks post treatment results).

Participants/materials, setting, methods: Respondents were recruited over two years from a Dutch University Hospital fertility clinic and composed of Dutch-speaking women undergoing ART. Self-reporting and medical records yielded demographic (e.g., age, education) and clinical data (e.g., number of previous cycles, fresh or frozen cycle), as well as outcome of treatment. Multiple regression analyses were used to examine whether demographic and clinical factors were associated with anxiety at T2 and T3, whilst controlling for anxiety at T1.

Main results and the role of chance: Most of the respondents (mean age 34.8 years), had received higher education ($n = 77$, 63%), were nulliparous ($n = 85$, 69%), had been infertile for three years or more ($M = 3.13$, $SD=2.27$), and were undergoing a fresh stimulated IVF/ICSI cycle ($n = 96$, 77.4%). A total of 28 (24.8%) participants achieved a positive pregnancy test and 18 (14.2%) achieved a live birth with treatment. Levels of anxiety were significantly higher at T2, compared to T1 and T3 ($p < .001$). The mean difference in anxiety between T1 and T2 was 2.02 (95% CI 7.94 - 5.92). Greater age was associated with significantly less anxiety at T2 ($P < .01$) but none of the other demographic or clinical variables were associated with anxiety at T2 and T3. Pre-existing anxiety levels at T1 were significantly and positively associated with anxiety at T2 and T3 ($P < .001$), as was anxiety at T2 with anxiety at T3 ($P < .001$). There

was no evidence to support a relationship between overall anxiety and success of treatment.

Limitations, reasons for caution: Sample size was small and there was possible bias of relying on self-report measures of anxiety in an RCT. Moreover, the majority of the sample had higher educational attainment, meaning that the results may not necessarily apply to other educational groups, and from which socio-economic status cannot be reliably inferred.

Wider implications of the findings: Pre-treatment assessment of anxiety may identify those that could benefit from earlier intervention before embryo transfer. While younger women may be seen as 'having time', they may be at greater risk of increased anxiety. Interventions to reduce anxiety may include reassurance about the impact of anxiety on outcome.

Trial registration number: Not applicable.

P-757   Twelve years of the first "Embryo adoption" program worldwide

V. Moens, A. Garcia-Faura, M. Lopez-Teijon

Institut Marques, Reproductive Medicine Service, Barcelona, Spain

Study question: Is Embyo Adoption (EA) an alterantive to international child adoption? Is it the best choice for thousands of embryos that accumulate on IVF laboratories worldwide?

Summary answer: Almost 1.000 newborns, since we created the concept of « Embryo Adoption » in 2004, to give a chance to our IVF laboratory abandoned embryos.

What is known already: Abandonment of frozen embryos in treatment centres is a common phenomenon. Adopting these embryos offers them a chance of life, and the recipient the opportunity to carry a child.

Embryos available for recipients come from donation (where progenitors specify they would like to give their embryos to other couples) or adoption (where progenitors fail to respond to letters from the treatment centre for over 4 years, and, by spanish law, the centre takes over their legal custody). Thus the difference between EA and donation is simply a legal one. No official adoption papers are necessary.

Study design, size, duration: Retrospective descriptive study including 1.728 patients that underwent EA between 2004 and 2016. Approximately 50% of patients from 124 different countries chose EA for reasons common throughout reproductive medicine (ovarian factor or severe male infertility, previous failed IVF alternative treatments), but the remainder chose EA primarily for social reasons: women without a male partner who wanted to have a child and couples or single women who were on the waiting list for standard adoption.

Participants/materials, setting, methods: The embryos offered for adoption all came from young healthy parents: women under 35 years for whom we had a complete medical and family history, and also information regarding children born.

To avoid the possibility of future consanguinity, sibling embryos were distributed to recipients living in different regions or countries. Racial matching was respected, but there was no matching of specific physical characteristics or blood groups.

Recipient patients underwent hormonal replacement treatment for cryotransfer

Main results and the role of chance: In our study only 3% of the patients donated their frozen embryos to other couples; almost 55% of the patients didn't answer to the requirement on how they wished to destine their frozen embryos, although spanish law gives them all options (donation to other couples, to science or destruction).

Between January 2004 and December 2016, 2.656 embryo transfers took place, with an average number of 2,2 embryos transferred, that has decreased to 1,3 during the last 3 years. We observed a pregnancy rate/transfer of 43%, with a miscarriage rate of 12%. To date 972 children have been born in our EA program following this treatment.

Limitations, reasons for caution: The main reason for caution in our study is the heterogenicity of the patients that came for EA treatment: half of them were healthy and didn't correspond to patients with previous fertility problems.

Wider implications of the findings: Embryo adoption is an effective IVF treatment, and offers the possibility of life to frozen embryos. Worried about our responsibility towards these cyopreserved embryos, that accumulate, in 2004 we inaugurated the first Embryo Adoption program worldwide; After 12 years, almost 1.000 babies have been born.

Trial registration number: Not applicable.

P-758   National Italian ART register, eleven years (2005-2015) of data collection with 3 different legislation changes

R. De Luca, G. Scaravelli, R. Spoletini, V. Vigiliano, S. Bolli, S. Fiaccavento, L. Speziale

National Health Institute, National Centre for Disease Prevention and Health Promotion, Rome, Italy

Study question: Analyze and compare the trends of eleven years of ART application in Italy (from 2005 to 2015) through four radical changes in the law governing these procedures

Summary answer: The law changes reflected in the application of ART treatments, have positively affected the results and the achievement of the best practices in infertility treatments

What is known already: In Italy a severe law has regulated the application of ART. Banning embryo cryopreservation, genetic preimplantation screening and diagnosis, gametes donation, obliging to the transfer of all the embryos created for a maximum of three. For five years Italy has had one of the highest triplet pregnancy and delivery rate (3.3% and 2.7 % respectively) and a quite low pregnancy and delivery rate in all cycles. The Constitutional Court, has radically changed the law

Study design, size, duration: Retrospective evaluation of eleven years of ART application through the analysis of the data collected by the Italian National ART Register (IARTR) since 2005. 611,941 ART Cycles were collected altogether, including 532,347 homologous fresh (FRESH), 49,766 frozen embryo (FER) and 27,342 frozen/thawed oocytes (FO), plus 2,496 donation cycles

Participants/materials, setting, methods: About 179 clinics per year participated to the study (range 169 to 185). Among those clinics about 53% were private settings 37% were public and 10% were private payed by NHS. The records were kept in the archive of IARTR. The analysis has been performed utilizing SPSS 22.0

Main results and the role of chance: Number of total cycles reported was 609,445 including 532,347 homologous fresh (FRESH), 27,342 frozen/thawed oocytes(FO) and 49,766 frozen embryo (FER) plus 2,287 donation cycles. Pregnancy rates per transfer change overtime with respect to FRESH, FO and FER treatments from 24.5% to 26.5%, from 11.4% to 20.8% and from 16.3% to 28,5% respectively. Delivery rate per cycle with at least one live birth change from 8.0% to 11.7%, from 4.9% to 11.1% and from 7.8% to 18.6% respectively. Twin and 'triplet or more" birth rate per delivery for fresh cycles changed from 21.6% to 17.3% and from 2.7% to 0.8%. During the study period 93,414 ART infants were born, corresponding to the 0.7% of all the national births in the beginning and to the 2.2% in 2015

Limitations, reasons for caution: Since the national ART Register collect only summary data more deep analysis could not be performed. The donation cycles, has been permitted in Italy only at the end of 2014, so the implementation of this procedure was not yet complete in 2015

Wider implications of the findings: The analysis of the Italian situation during these years, has demonstrated how Countries specific legislations could affect the results and outcomes of these procedures, and how the application of a restrictive law in the field of human reproduction has contributed to offer to the patients a suboptimal kind of treatment

Trial registration number: not applicable.

P-759   A randomised controlled trial comparing the Cost-effectiveness of blastocyst (Day 5/6) versus cleavage stage (Day 3) embryo transfers in IVF-ICSI Cycles in developing countries

R. Singh[1], M. SINGH[2], A. JINDAL[2], P. JINDAL[2]

[1]*Bhopal Test-Tube-Baby Centre & International Infertility Institute, Infertility, Bhopal, India*
[2]*BTTB CENTRE, INFERTILITY, Bhopal, India*

Study question: To determine whether blastocyst stage (day 5 / 6) embryo transfer is cost-effectiveness in improving the pregnancy rate, and other outcomes, compared with cleavage stage (day 3) embryo transfer?

Summary answer: Cleavage stage-day 3 transfers with top quality embryos, are more cost-effective and do not compromise the pregnancy outcome, compared with day 5/6 Transfers

What is known already: There are only a few studies comparing the cost-effectiveness of Day 2/3 Vs 5/6 embryo transfer outcomes.

Embryos from IVF-ICSI are commonly transferred into a woman's uterus at either the cleavage stage (day 2 / 3) or blastocyst stage (day 5 / 6).

Until recently, most ART cycles transferred embryos at cleavage stage, however there has been a trend to transferring embryos at the blastocyst stage as this timing is about the same as natural cycle embryos moving into the uterus.

Advances in cell culture media have led to a shift in IVF-ICSI from cleavage stage to the costly blastocyst transfer.

Study design, size, duration: The rationale for blastocyst transfer is to improve uterine and embryonic synchronicity.

As we practice in a developing country, it has become necessary to perform more economical Day 3 transfer in order to reduce the cost of extended Day 5/6-blastocyst culture.

Day 3 transfers were assessed to determine if the outcome was comparable with that obtained following Day 5/6 blastocyst transfer.

This RCT is conducted at our centre between 2007 and 2016 for patients below 40 years.

Participants/materials, setting, methods: If more than 06 oocytes were retrieved and three top quality embryos (6-8 blastomeres & less than 20% fragmentation without multinucleation) were observed at day 2,couples were included in the study.

Total 438 patients were assigned to Day-3 or Day-5/6 transfer by computer generated randomised list after proper consent.

Primary outcomes: pregnancy-rates and cost of cycle

Secondary outcome: multiple pregnancy, miscarriage rates, cumulative pregnancy rates, failure to transfer embryos, and embryo freezing

Main results and the role of chance: Pregnancy rates were 31% for Day- 3 Cleavage stage transfers and 34% for Day- 5/6 Blastocyst transfers, the difference being not statistically significant.

Failure to transfer any embryos was higher in the Day-5/6 blastocyst transfer group and more embryos were available for freezing in the Cleavage stage transfer group.

Although more Abortions and Multiple pregnancies were seen in the Cleavage stage Day-3 transfer as compared to the Blastocyst Day-5/6 transfer, the difference is not statistically significant.

Our data show clearly that for IVF-ICSI for women under 40 years at day -2 with three top quality embryos, the pregnancy outcome are similar after embryo transfer at cleavage stage (Day-3) or blastocyst stage (Day 5/6).

These preliminary results have shown that Day -3 Cleavage stage transfers with top quality embryos having the highest implantation potential, do not compromise pregnancy outcome as compared to the costlier Day -5/6 blastocyst transfers.

Limitations, reasons for caution: Thus, although there is no benefit favouring blastocyst transfer it remains unclear whether the day of transfer impacts on cumulative pregnancy rates.

Future more studies should report cumulative live birth rates to enable couples to make decisions on the best cost-effectiveness treatment option available in poor & developing countries.

Wider implications of the findings: Our results have shown that day 3 transfers do not compromise pregnancy outcome compared to day 5/6.

Day 3 transfer has also provided a unique opportunity to study day 3 morphology critically and avoid costly extended blastocyst culture, therefore be a feasible low-cost alternative to expensive day 5/6 blastocyst culture.

Trial registration number: NONE.

P-760   A prospective randomised contolled study comparing a low-cost antagonist-protocol using oral ovulation inducing agents in ivf-icsi-cycles with a standard agonist long protocol in developing country

P.C. Jindal[1], R. SINGH[2], M. SINGH[3], A. JINDAL[4]

[1]Bhopal Test Tube Baby Centre, Infertility, Bhopal, India
[2]BTTB Centre & L N Medical College- Bhopal, Infertility, Bhopal, India
[3]BTTB Centre & L N Medical College- Bhopal, Infertility, Bhopal, India
[4]BTTB Centre, Infertility, Bhopal, India

Study question: To compare the cost-effectiveness of a low cost antagonist protocol using oral ovulation induction agents (Clomiphine Citrate or Aromatase Inhibitors) with a standard long GnRH-Agonist-Protocol in IVF-ICSI -Cycles in developing-countries?

Summary answer: GnRH-Antagonist in combination with oral-ovulation-inducing-drugs offers the advantage of an economical method of stimulation in IVF-ICSI-Cycles, as compared to the agonist-protocol, with a similar pregnancy-rate.

What is known already: Infertility affects 10 - 20% of couples trying to conceive in whom IVF-ICSI has improved chances of achieving pregnancy. In standard IVF method with controlled-ovarian-hyperstimulation (COH), development of multiple follicles is stimulated by using gonadotrophins, combined with a gonadotrophin-releasing hormone (GnRH) - Agonist or Antagonist. It is expensive with many adverse effects.

The objective of this prospective randomised controlled study is to compare the cost-effectiveness of a low-cost antagonist protocol using oral ovulation induction agents (Clomiphine Citrate or Aromatase Inhibitors) with a standard long GnRH agonist protocol in IVF-ICSI cycles in developing countries, where IVF is self financed.

Study design, size, duration: This prospective randomised controlled study is to compare the cost-effectiveness of a low cost antagonist protocol using oral ovulation induction agents (Clomiphine Citrate) with a standard long GnRH agonist protocol in IVF-ICSI cycles.

The patients in the study underwent a long GnRH-Agonist or an Antagonist protocol with randomisation using a computer generated list, after proper consent.

A total of 378 IVF-ICSI cycles were prospectivly studied in patients below 40 years of age.

Participants/materials, setting, methods: A total of 378 IVF-ICSI patients below 40 years of age (2010-2016) were randomised into two groups using a computer generated list.

The agonist-group underwent the standard-long-GnRH-analogue-protocol.

The antagonist-group received oral-ovulation-inducing drugs (Clomiphene Citrate / Aromatase-Inhibitor) for the first five days of cycle followed by gonadotropins and 0.25 mg antagonist (Cetrorelix) injection daily till the day of hCG, using a flexible antagonist start approach.

Primary-outcome: Pregnancy-Rate and Cycle-Cost

Secondary-outcome: Gonadotropins-used, number of Mature-Oocytes and Embryos

Main results and the role of chance: There was a significant difference in the gonadotropin usage between the two groups.

As a result, the cost of the oral ovulation inducing drugs (Clomiphene Citrate / Aromatase- Inhibitor) - gonadotropin - antagonist cycle was significantly lower than the standard long GnRH agonist - gonadotropin protocol. (600 - 800 USD Vs 1000 - 1500 USD)

Though the mean number of Mature -Oocytes retrieved was higher in the long protocol group (M2: 6. 1 Vs 11. 6),

yet the clinical pregnancy rate per transfer was similar in both groups (31 % Vs 34 %)

The oral-ovulogen-antagonist cycles were more cost-effective and more patient friendly.

The group of patients who were treated with oral-ovulogen-gonadotropins-antagonist, had lesser injections, fewer visits, and significantly reduced cycle cost with comparable pregnancy rates.

Therefore, it is advisable to use this less expensive option of oral ovulation inducing agents with flexible antagonist protocol for IVF-ICSI in developing countries.

Limitations, reasons for caution: In ART, different stimulation protocols are used, including natural cycle IVF, modified natural cycle IVF, and standard IVF with controlled ovarian hyperstimulation(COH).

Our study is to assess the cost-effectiveness of the oral-ovulation-inducing-drugs(Clomiphene-Citrate / Aromatase- Inhibitor) -Antagonist-cycle compared with standard -long-GnRH-Agonist-protocol and similar multicentric RCTs are required

Wider implications of the findings: Usage of GnRH antagonist in combination with oral-ovulation-inducing-drugs offers the advantage of an economical

method of stimulation in IVF-ICSI-cycles, as compared to the standard long-agonist protocol, with a similar pregnancy rate in poor and developing countries where ART is self-financed and hence cost is a major factor to be considered.

Trial registration number: NONE.

P-761 The hurdles to parenthood: Exploring Chinese lesbians' opinions towards the use of assisted reproductive technologies

I.P.Y. Lo[1], C.H.Y. Chan[2]

[1]The University of Oxford, Sociology, Oxford, United Kingdom
[2]The University of Hong Kong, Social Work and Social Administration, Hong Kong, Hong Kong

Study question: What are the prospect of childbearing and perceived difficulties in achieving parenthood through the use of assisted reproductive technologies (ART) among Chinese lesbians?

Summary answer: Participants expressed hesitation in childbearing due to concerns over the lack of genetic connection of the child with both mothers, inter-generational discrimination, and financial burden.

What is known already: A growing body of literature has emerged in the past two decades concerning the process of decision-making and transitioning to parenthood among lesbian couples in the West. Despite the fact that parenthood is generally considered an essential life goal and fulfilment of filial piety in Chinese societies, Chinese lesbians' aspirations for reproduction and family formation have rarely been paid attention in a predominantly heterosexist environment where access to ART is restricted to heterosexual couples and same-sex marriage is not legally recognized.

Study design, size, duration: Semi-structured interviews were conducted with 12 lesbian-identified Chinese women who aged between 18 and 35 and resided in Hong Kong in 2015. Participants were recruited through local lesbian, gay, bisexual, and transgender (LGBT) organizations, a university in Hong Kong, and personal networks.

Participants/materials, setting, methods: A list of open-ended questions was used to guide the discussion and allow respondents to articulate their attitudes towards the use of ART, childbearing, and family formation. Each interview lasted around 90 minutes and was audio-recorded and transcribed. Data was analyzed with the assistance of NVivo which is a qualitative data analysis software. Based on Grounded theory, coding (namely open coding, axial coding and selective coding) and categorizing were the major techniques employed.

Main results and the role of chance: All lesbian participants in this study expressed hesitation in childbearing. Some participants claimed that the use of ART was not worth the effort due to the lack of genetic connection of the child with both mothers. The internalized stigma also urged some of them to worry that their children born as a result of ART would face discrimination due to their non-normative family formation and structure. All participants expressed the need to accumulate financial resources so that they might have the capital not to worry about the negative costs of coming out or/and to emigrate to Western countries where same-sex marriage was legally recognized or/and ART was provided. Traditional Chinese belief about family plays a key role in our participants' attitudes towards ART and fertility plans. Most of them felt reluctant to disclose their sexual orientation particularly to their parents since being homosexual would be considered a shame to the family of origin. Lesbian parenthood would mean that they had to come out to family, relatives, and even the public.

Limitations, reasons for caution: With a small sample size, this qualitative research cannot be considered representative of the Chinese lesbian population. Meanwhile, there has been neither census data identifying lesbian individuals nor research based on a random sample of this subgroup. Further quantitative and qualitative studies are needed to understand Chinese lesbians' reproductive health.

Wider implications of the findings: The nature of childlessness among Chinese lesbians is not only a medical issue but also a psychosocial issue which is linked with gender and sexual norms. This research sensitizes healthcare professionals to the alternative needs, wants, and psychosocial burden of Chinese lesbians in relation to fertility plan.

[7]the second hospital affiliated to Shandong University of traditional Chinese medicine, Reproductive medicine center, jinan, China
[8]Wuxi shenpingxintai Medical Technology Co.- Ltd., Wuxi shenpingxintai Medical Technology Co.- Ltd., wuxi, China

Study question: To study the effect of transcutaneous electrical acupoint stimulation (TEAS) of pain-relieving in women undergoing transvaginal ultrasound-guided oocyte aspiration.

Summary answer: Oocyte retrieval causes pain and discomfort. TEAS suppressed the pain and also alleviated nausea and vomiting associated with the operation.

What is known already: Transvaginal ultrasound-guided oocyte aspiration is a standard procedure in the process of in vitro fertilization and embryo transfer (IVF-ET). In many clinics, conventional medical analgesia (CMA) during OPU includes sedative pre-medication with benzodiazepine, local analgesics administered as a paracervical block (PCB) and intravenous administration of fast-acting opiates during OPU. But CMA is known to produce a number of side effects such as nausea, tiredness and confusion.Acupuncture has demonstrated its pain-relieving effect both intra-operatively and post-operatively. Transcutaneous electric acupoint stimulation (TEAS), increase the reproducibility of this acupuncture-like technique and to reduce invasiveness, an user-friendly technique, instead of using manual needling or electro-acupuncture.

Study design, size, duration: Participants were20-45ages individually randomly assigned (in a 1:1 ratio) to receive either TEAS or Mock TEAS. Specifically, randomization numbers were produced by SAS 9.13 software and were put in sealed random envelopes.Patients were divided into two groups according to the order in which the subjects were enrolled in the group. Mock TEAS (group I, n = 194) and TEAS (group II, n = 196). The study was completed between May 2013 and May 2015.

Participants/materials, setting, methods: A total of 390 women undergoing oocyte retrieval,was completed at four reproductive centers: Peking University People's Hospital; Peking University Third Hospital; Beijing Obstetrics and Gynecology Hospital; Second Affiliated Hospital of Shandong University of Traditional Chinese Medicine.The levels of pain, nausea and vomiting associated with oocyte retrieval were evaluated immediately and one hour after operation using visual analog scale (VAS)Serum concentrations of β-endorphin were measured by commercially available original auxiliary reagent for humanβendorphin ELISA Kit.

Main results and the role of chance: In 390 subjects, pain levels evaluated with VAS instantly (18.63 versus 24.39 P < 0.01) and 1 hour after oocyte aspiration (4.64 versus 6.77, P < 0.05) were both lower in TEAS group than mock TEAS group. Nausea assessment revealed a significant decrease instantly (2.9 ± 0.66 versus 1.24 ± 0.40, P = 0.033) but not 1 hour (0.10 ± 0.1 versus 0.21 ± 0.16, P = 0.59) after oocyte aspiration. Furthermore, serum β-endorphin level was higher in TEAS group after the oocyte retrieving procedure than mock TEAS group (11.41 versus 9. 14, P < 0.001).The present study substantiated the efficacy of 2/100 Hz TEAS in ameliorating the pain induced by ovum pick up(OPU), without paying the intention of comparing the efficacy between fixed frequency and mixed frequency.Several underlying mechanisms have been proposed for the EA/TEAS-induced reduction of postoperative nausea and vomiting.TEAS seems to be a safe and effective method to reduce pain, nausea and vomiting associated with OPU.

Limitations, reasons for caution: Considering the characters of TEAS procedure, the operator of TEAS stimulation is not blinded, only the patients and doctors to evaluate the degree of pain, nausea and vomiting were blinded.

Wider implications of the findings: TEAS seems to be a safe and effective method to reduce pain, nausea and vomiting associated with OPU.we hope It can be widely applied to around the world.

Trial registration number: The project was registered at Chinese Clinical Trial Registry, a World Health Organization International Clinical Trial Registration Platform (http://www.chictr.org.cn; Registration No. ChiCTR-TRC-13003952).

P-763   Final report of clinical efficacy of modified adenomyomectomy in infertile women with adenomyosis

S.H. Yoon[1], K.R. Hwang[2], Y.J. Kim[3]

[1]Dongguk University ILSAN Hospital, Obstetrics and Gynecology, Goyang city-Gyeong Gi Do, Korea- South
[2]Seoul National University Boramae Medical Center, Obstetrics and Gynecology, Seoul, Korea- South
[3]College of Medicine- Korea University, Obstetrics and Gynaecology, Seoul, Korea-South

Study question: Does reduction surgery of adenomyosis have clinical efficacy in infertile women?

Summary answer: Modified adenomyomectomy as a uterus-sparing surgery could be an effective method for increasing pregnancy rate and conservation of fertility potential in infertile women with adenomyosis.

What is known already: The relation between infertility and uterine adenomyosis is controversial, but it appears to affect endometrial receptivity and increase abortion rate. In infertility where uterine conservation is paramount, the treatment of adenomyosis is often complicated, that is to say, medical treatment is often transient and hysterectomy for eradication could not preserve their fertility. At this stage, there is no agreement on the most appropriate therapeutic methods on fertility outcome in infertility patients with adenomyosis. Regarding surgical removal of adenomyosis, including laparoscopic reduction, uterus-sparing surgery appears to be satisfactory and reduced the need for hysterectomy, but needs well designed prospective study.

Study design, size, duration: Prospective clinical trial was conducted. The subjects consisted of 50 infertile patients with adenomyosis and were enrolled after the failure of In Vitro Fertilization (IVF) for pregnancy from December 2007 to September 2016.

Participants/materials, setting, methods: All cases were classified as having unexplained infertility, adenomyosis with severe periodic dysmenorrhea and occasional menorrhagia. This newly designed operative procedure included pediatric foley insertion into the uterine cavity, injection of diluted vasopressin along the uterine incision, T- or transverse H-incision on the adenomyotic wall, careful excision of adenomyosis tissue using argon laser under intra-operative ultrasonography. After debulking surgery, patients underwent follow up examination for symptom relief, reduction of adenomyosis by MRI and pregnancy rate.

Main results and the role of chance: The mean age and the duration of infertility were 35.60 ± 3.37 years and 55.48 ± 48.24 months, respectively. The mean volume of excised specimens of adenomyosis was 94.15 ± 56.63 g. The

relief of dysmenorrhea was observed clearly in all patients at 6 months after operation (NRS; 7.28 ± 2.29 vs. 1.56 ± 1.29, p < 0.001). The amount of menstrual blood was also significantly decreased (140.44 ± 91.68 vs. 66.33 ± 65.85, p = 0.009). The CA 125 level was significantly decreased at the time of 6 months after operation (187.75 ± 229.52 vs. 20.36 ± 19.19, p = 0.026). Postoperational complication occurred in four patients (subfascial hematoma, ureter fistula, shrinkage of uterus and premature ovarian insufficiency). Five patients were lost in the follow-up. Of 33 patients who attempted pregnancy, 18 patients conceived by natural or IVF or thawing ET after the operation (18 of 33; 54.5%). However, miscarriage occurred in five patients, ectopic pregnancy in three patient, preterm delivery in two patient and eight patients (8 of 33; 24.2%) delivered by cesarean section at term. The rest of the patients have been trying to conceive by IVF-ET or natural course.

Limitations, reasons for caution: The sample size is small, so further study with larger number of patients will be helpful to investigate the possibility of this result.

Wider implications of the findings: This modified adenomyomectomy was related to symptom relief of dysmenorrhea, menorrhagia and increasing pregnancy rate, implying that reduction surgery could be considered as a successful method for infertile women with adenomyosis who need fertility preservation. This is the first report on the clinical pregnancy outcome of uterus-sparing surgery in adenomyosis.

Trial registration number: N/A.

P-764   Combination treatment of preoperative embryo cryopreservation and endoscopic surgery (surgery- assisted reproductive technology hybrid therapy) in infertile women of late reproductive age with uterine tumour

K. Kuroda[1], M. Kitade[1], J. Kumakiri[1], M. Jinushi[1], Y. Ujihira[1], R. Ozaki[1], Y. Ikemoto[1], K. Nakagawa[2], R. Sugiyama[2], S. Takeda[1]

[1]Juntendo University- Faculty of Medicine, Department of Obstetrics and Gynaecology, Tokyo, Japan
[2]Sugiyama Ladies Clinic, Division of Reproductive Medicine, Tokyo, Japan

Study question: What are the factors of successful combination treatment of preoperative embryo cryopreservation and endoscopic surgery in infertile women of late reproductive age with uterine tumours?

Summary answer: Sufficient preoperative frozen embryos are needed for a successful 'surgery-assisted reproductive technology (ART) hybrid therapy'.

What is known already: Endoscopic surgery is gold standard for infertile women with uterine tumours, but a waiting time for preoperative GnRH agonist administration and postoperative contraception period is required. Ageing is the most important factor in infertility treatment due to a decrease in the quality and number of eggs and an elevated miscarriage rate. It is debatable whether infertility treatment or surgery should be the first choice for women of late reproductive age with uterine tumours. In 2009, we first reported successful cases of a combination of ART for embryo cryopreservation and surgery (surgery-ART hybrid therapy) in infertile advance-aged women with multiple myomas.

Study design, size, duration: This study was approved by the Local Ethics Committee. Women of late reproductive age with uterine myomas underwent ART for embryo cryopreservation preoperatively and reproductive surgery from 2014 to 2015. One warmed embryo was transferred into the uterus after the postoperative contraceptive interval.

Participants/materials, setting, methods: A total of 18 women underwent surgery-ART hybrid therapy in Juntendo University Hospital. One woman acquired no embryo and gave up conceiving. Out of 17 women, 4 were in postoperative contraceptive period and 13 underwent embryo transfer. Three women delivered babies and 3 women had ongoing pregnancy. Seven women had implantation failure or miscarriage. A comparison was made between 6 women who conceived babies (success group) and 7 women of hybrid therapy failure (failure group).

Main results and the role of chance: The women in the success and failure groups were 40.0 ± 1.4 and 42.0 ± 1.1 years (p = 0.026) of age and 3.3 ± 4.5 and 5.3 ± 5.9 years of the duration of infertility (NS), and had 2.2 ± 1.9 ng/ml

and 1.6 ± 1.7 ng/ml of serum AMH levels (NS), respectively. The numbers of preoperative frozen embryos were 4.8 ± 1.3 in the success group and 2.0 ± 0.9 in the failure group (p<0.001). The success and failure groups had 9.5 ± 8.5 and 9.7 ± 12.4 uterine myomas (NS) with a diameter of 5.8 ± 3.3 and 7.2 ± 2.9 cm (NS), respectively. The 6 women who had a successful surgery-ART hybrid therapy were significantly younger and had a larger number of cryo-preserved embryos than the 7 women who had hybrid therapy failure.

Limitations, reasons for caution: The limitation of this study is that it is a retrospective study.

Wider implications of the findings: Surgery-ART hybrid therapy should be considered as one of the infertility treatments for women of late reproductive age or diminished ovarian reserve with uterine tumours as well as ovarian endometrioma.

Trial registration number: None.

P-765   Laparascopic strassman metroplasty for bicornuate uterus

S.S. Sattari Nejad[1], H. Asefjah[2]

[1]Golsar Hospital, Rasht, Iran
[2]Laleh Hospital, Tehran, Iran

Study question: is laparascopic metroplasty feasible for unification of bicornuate uterous

Summary answer: laparascopic strassman metroplasty is a good alternative for bicournuate uterous

What is known already: Laparoscopic strassman metroplasty is feasible, it depends on sugeons skill of suturing, second look laparoscopy hysteroscopy is mandatory to evaluate strength of suture line

Study design, size, duration: Laparoscopic Strassman metroplasty were done in five patients with bicornuate uterus with history of at least two second trimester abortion with triple puncture technique, after transverse fundal hysteratomy incision including fundal cleft, unification of uterus was done with intracorporeal sutures in two layers, after three months of sequential hormone therapy HSG repeated,

Three patients got pregnant, delivered at 37 − 3 8 wks of gestation, there was no defect or dehesence in incision line

Participants/materials, setting, methods: Case report, five cases were operated within two years duration, three patients conceived, two patients lost their follow up,they received hormone replacement therapy for three months post operatively,then second look laparoscopy and hysteroscopy done,then they were allowed for conception,three patient got pregnant and cesarian section done on thirty eight weeks of gestation.there was no adhesion at suture line

Main results and the role of chance: normal full term pregnancy outcome with no definite adhesion formation as seen in conventional laparatomy method of strassman metroplasty

Limitations, reasons for caution: normal full term pregnancy outcome with no definite adhesion formation as seen in conventional laparatomy method of strassman metroplasty

Wider implications of the findings: This issue is not related to my presentation and cases

There in not enough literiture, this surgery has not been reported laparoscopicaly from USA or Canada yet, there is one report from India by Sinha

in video clip this technique for llaparascopic strassman metroplasty will be displayed

Trial registration number: 1967.

P-766   Differentiating tissues and organs in endoscopic images using a convolutional neural network

P. Török[1], R. Lampé[1], B. Harangi[2], J. Lorincz[1]

[1]University of Debrecen, Department of Obstetrics and Gynecology, Debrecen, Hungary
[2]University of Debrecen, Faculty of Informatics, Debrecen, Hungary

Study question: Is it possible to identify different tissues and organs during endoscopy supported by a software.

Summary answer: During the learning curve of laparoscopy trainees can get help in differentiating tissues by an automated digital image processing based decision support system

What is known already: Endoscopy surgery is the part of everyday work of surgeon. In an experienced hand provides less postoperative morbidity, complications and the time periods of hospital stay and returning to normal activity, so it has a lot of advantages compared to the laparotomy.Opposing to open-surgery, the recognition of organs is rather difficult in laparoscopy because of the lack of the tactile information. Knowing detailed anatomy, having experience letting us to recognize structures in the abdominal cavity. Because of the anatomical variations, tissue identification is not always sure relying on the visual information.

Study design, size, duration: Our dataset has been collected retrospectively during 35 different gynecological endoscopic operations at the Department of Obstetrics and Gynecology of the University of Debrecen. The videos have been recorded by a high definition 1-MOS endoscopic camera at 30 frames/sec rate and resolution of 1920×1080 pixels.

Participants/materials, setting, methods: Data of patients scheduled for gynecological endoscopic operations are analyzed. The medical expert or an assistant should manually mark the region of interest. Then, the maximum number of sub-images of size 224×224 pixels are cut off along the axis from the video frame. Finally, the classification problem is solved automatically using a convolutional neural network with the resulted labels are pinned on the corresponding organs in the video frame.

Main results and the role of chance: We have presented an approach to develop an application, which helps medical experts with performing endoscopic surgeries. Our effort primarily addressed the drawback of losing tactile information during key-hole surgery in the recognition of different organs. To address this problem, we have developed a semi-automatic tool, which requires a manual annotation regarding the axis of the interested organs first. Then, several sub-images covering the selected organs are extracted and classified by a fine-tuned GoogLeNet convolutional neural network.The classification performance of the fine-tuned GoogLeNet model on our test dataset considering the top-1 error rate is 0.193 at sub-image level. That is, 403 out of the 500 test images have been classified correctly. However, notice that these sub-images are only small, non-overlapping segments of the interested organs. That is, it is reasonable to fuse these label information for recognizing the corresponding organ. To do so, we have applied the simple majority-voting rule on the 4-5 labels supplied by the sub-images for the same organ. In this way, our proposed approach has reached 94.2% final accuracy regarding this binary classification task.

Limitations, reasons for caution: Our collected dataset is relatively small with containing insufficient number of images to train a complex neural network, so we should extend the size of our dataset.

Wider implications of the findings: Using the software made by the results of the study, accuracy of the tissue/organ recognition could be increased during training laparoscopic technique, or for the experts as well.

Trial registration number:

P-767   Neck scarf of ureter and bulldog of the uterine vessel in Da Vinci Robotic deep infiltrative endometriosis excision

Y.C. Chuang, H.F. Lu, F.S. Peng, W.H. Ting

Far Eastern Memorial Hospital, OBS&GYN, New Taipei City, Taiwan R.O.C.

Study question: How to improve the safety of the ureters during Deep infiltrative endometriosis which is one of the most challenging gynecologic operation?

Summary answer: We could always check the ureters safety during difficult dissection with the help of

neck scarf on the ureters

What is known already: Deep infiltrative endometriosis is one of the most challenging gynecologic operation due to the distorted anatomy by the fibrosis of endometriosis gland.

The major surgical procedure including the following

(1) The bilateral ovarian chocolate cyst decompression and then suspension with a suture to abdominal wall as external traction.

(2) The ureterolysis by trace the ureter course from pelvic brim to crossing with uterine vessels

(3) Dissection of the origin of uterine vessels from the origin of the internal iliac artery and block it with bulldog temporally

(4) 4.Develop the pararectal space, and expose the Cul-de-sac by using the vaginal and rectal probe

Study design, size, duration: Here we present our technique by using the yellow rubber band to collar the ureter as neck- scarf, when using Da Vinci Si robot system with four arms (included robotic laparoscopy), the stable third arm as an assistant of the surgeon to traction the neck scarf to prevent ureter injury when dissection.

Participants/materials, setting, methods: 20 consecutive patients with deep infiltrative endometriosis were safely operated without fistula, ureter injury, laceration.

Main results and the role of chance: We could always check the ureter safety during difficult dissection, especially during the long surgery the surgeon was fatigue and had less concentration while using the energy source.

Limitations, reasons for caution: technical limitation for those who are not very familiar with the anatomy of the ureters course and the uterine vessels crossing with ureters

Wider implications of the findings: it is also feasible to use the technique in laparoscopic hysterectomy for uterine myoma or adenomyosis

Trial registration number: no.

P-768   Outcomes of laparoscopic peritoneal vaginoplasty operation in patients with mullerian agenesis

G. Uncu[1], **A. Orhan**[1], **K. Aslan**[1], **I. Kasapoglu**[1], **M.A. Atalay**[1], **B. Ata**[2], **K. Ozerkan**[1]

[1]Uludag University School of Medicine, Obstetrics and Gynecology, Bursa, Turkey
[2]Koc University School of Medicine, Obstetrics and Gynecology, Istanbul, Turkey

Study question: To assess the postoperative outcomes and complications of peritoneal vaginoplasty operation.

Summary answer: Laparoscopic peritoneal vaginoplasty is a good alternative beyond the other techniques.

What is known already: RKMH is a very rare syndrome with mullerian agenesis. Its incidence is 1 in 5.000-10.000 women. The major complaints of these patients are infertility and sexual inability. There are numerous surgical and non-surgical approaches for vaginal reconstruction for better satisfactory results. But there is no consensus whether on which approach is the best.

Study design, size, duration: Retrospective cohort study, consisting 25 women with Rokitansky-Kustner-Hauser-Mayer (RKMH) syndrome between the years 2010-2016

Participants/materials, setting, methods: Women with a surgical history of RKMH syndrome were detected when the operation database of the years 2010-2016 were screened. Patients' age, diagnose time, operation type, peri-operative and postoperative complications, postoperative vaginal depth, and sexual comfort of patients were analyzed.

Main results and the role of chance: Total of 25 patients with RKMH were detected. Mean age at diagnose was 27,6 years (+/- 5.1). All the patients successfully underwent laparoscopic peritoneal vaginoplasty by the three surgeons (GU, KO, BA) There were two complications.

The first one was bladder injury during peritoneal dissection and it was repaired laparoscopically. The second one was postoperative complication. It was rectovaginal fistula. The patient admitted with vaginal defecation after three months of surgery and general surgeons operated her. After one year of surgery she successfully recovered. One patient did not apply appropriate mold exercises and than vagina collapsed. All the patients scored their sexual comfort from 0 to 10 points. The mean score result was 8.17 (+/- 1.9).

Limitations, reasons for caution: Retrospective study desgin, Small sample size.

Wider implications of the findings: Laparoscopic peritoneal vaginoplasty is a good alternative beyond the other techniques. This technique has satisfactory functional outcomes and lower complication rates and could be safely applied to patients with mullerian agenesis.

Trial registration number: not applicable.

P-769   An acute presentation of a Müllerian duct abnormality

M. Rimmer[1], **V. Kandavel**[2], **T. Ghobara**[2], **S. Keay**[2]

[1]University Hospital Coventry & Warwickshire, Obstetrics & Gynaecology, WARWICK, United Kingdom
[2]University Hospital Coventry & Warwickshire, Obstetrics & Gynaecology, Coventry, United Kingdom

Study question: Case report describing acute on chronic pelvic pain due to a Müllerian duct abnormality.

Summary answer: A rudimentary right uterine horn and absent right kidney and ureter were noted on MRI and removed laparoscopically, resolving the patients abdominal pain.

What is known already: Congenital malformations of the female reproductive tract are common miscellaneous deviations from normal anatomy with a range of reproductive outcomes. Gonadal differentiation occurs between the 6th and 8th week of gestation, a lack of SRY protein results in the pluripotenial gonads developing into ovaries. This results in Wolffaian duct degeneration and persistence of the Müllerian ducts. Following organogenesis the Müllerian ducts fuse to form the fallopian tubes, uterus, cervix and upper two thirds of the vagina. Should the two ducts fail to fuse correctly a range of uterine abnormalities can occur. One such abnormality is a rudimentary uterine horn.

Study design, size, duration: Patient was admitted under the general surgeons with abdominal pain and at laparoscopy referred to Gynecology after observing a dilated right fallopian tube.

Participants/materials, setting, methods: Case report – patient consent obtained.

Main results and the role of chance: 23 year-old nulliparous female presented with menorrhagia and pelvic pain localized to the right iliac fossa for 3 months duration. She was admitted under the surgeons with raised inflammatory markers, appendicitis, urinary tract infection and ovarian cyst rupture or tortiontorsion was suspected. Pelvic and abdominal ultrasound identified an inflammatory, possibly bowel related, mass surrounding the right ovary. At diagnostic laparoscopy hemorrhagic fluid was seen in the pelvis and paracolic gutter; a normal appendix; right hydrosalpinx and a small uterus were identified. A Gynecologicical opinion was sought and a diagnosis of pelvic inflammatory disease and right hydrosalpinx was made. At gynecology follow-up, a repeat transvaginal ultrasound demonstrated a mass (25 × 25 mm) superior to the right ovary adjacent to the right iliac vein and artery. It was oval in shape with increased echogenicity. A uterine abnormality was suspected and an MRI pelvis requested. MRI confirmed a rudimentary right uterine horn which haematometra, right hydrosalpinx and absent right kidney. The rudimentary horn was removed and right salpingectomy undertaken laparoscopically which resulted in complete resolution of her pelvic pain. At laparoscopy minimal endometriosis was noted which was ablated. Series have indicated around 3% of women with congenital uterine abnormalities have endometriosis.

Limitations, reasons for caution: Not applicable.

Wider implications of the findings: Using ESHRE/ESGE consensus on classification of female genital tract abnormalities this case is classified as Class IV, subsection A abnormality – rudimentary horn with cavity.

- Anatomy is the foundation for systematic classification of uterine anomalies.
- Variations deriving from the same embryological origin form the basis of the classes.

Trial registration number: Not applicable.

POSTER VIEWING SESSION
SAFETY AND QUALITY OF ART THERAPIES

P-770   Risk evaluation for pronuclear transfer using for preventing the transmisson of mitochondrial disease: a mouse model

L. Tianjie

Peking University Third Hospital, OB/GYN, Beijing, China

Study question: Is it safe to prevent transmission of mitochondrial disease using pronuclear transfer as a mitochondrial replacement technology?

Summary answer: There is a potential risk associated with metabolism in pronuclear transfer offspring

What is known already: Pathogenic mitochondria DNA (mtDNA) mutation is closely linked with many mitochondria diseases that usually lead to fatal results such as premature death. MtDNA is transmitted maternally within oocyte cytoplasm. Management of mitochondrial disease is limited due to its characteristic inheritance. Pronuclear transfer is considered to be effective in preventing the transmission of pathogenic mtDNA from mother to offspring.

Study design, size, duration: Pronuclear transfer technology were performed between zygotes of CD-1 mice to obtain constructed zygotes and offspring. We preformed 263 zygotes to assess embyoes development and 40 PNT offsprings to evaluate risk of PNT procedure.

Participants/materials, setting, methods: The constructed zygotes produced by PNT was fused by electrofusion. By testing mitochondria DNA copy number, the ratio of donor mitochondria was calculated. The cell number of balstocyst was counted and gene expression profiling was identified by NGS technique. Then PNT blastocyst were transferd to pesodu-pregnant mice. For PNT offspring, the body weight, ratio of fat/weight and energy expenditure were measured. The reproductive function was also assessed both in female and male PNT offspring.

Main results and the role of chance: The development efficiency was significantly decreased in PNT embryos compared with normal control embryos. Compared with normal fertilized embryos, total cell numbers of the blastocysts from PNT technology were decreased significantly, and a large amount of genes showed the abnormal expression levels. But there were no significant differences between neonatal body weight and plancenta weight. the ratio of donor mitochondria was no more than five percent. However, the quality of PNT blastocysts was declined. Compared with control blastocysts, implantation rate and birthrate in PNT blastocysts were all impaired. For PNT offspring, compared to the controls, the body weight, ratio of fat/weight, energy expenditure, blood pressure and glucose tolerance showed no difference both in female and male pronuclear transfer mice. Estrous cycle, histical analysis of ovary and fertility were normal in female pronuclear transfer mice, so were the testicular morphology, sperm concentration and fertility in male pronuclear transfer mice. However, a considerable of genes were differentially expressed between pronuclear mice and control group.In tissues where mebabolism were more vigorous like brain, heart, liver and muscle, an abundant of genes showed the abnormal expression levels. Differentially expressed genes were highly related in metabolism, which suggest a potential risk of pronuclear transfer offspring.

Limitations, reasons for caution: The ratio of donor mitochondria was not assessed in all tissues of PNT offspring during the whole life cycle. In addition, the F2 mice of PNT mice were not evaluated throughout the whole life.

Wider implications of the findings: The result not only emphasize the potential risk associated with metabolism of PNT procedure using to prevent transmission of mitochondrial disease but also facilitate a better understand of the effects of PNT procedure on development of offspring and enhancing the awareness of improving the outcome of PNT procedure.

Trial registration number: not clinical trial.

P-771 Monozygotic twinning following assisted reproduction: a six-year experience base on a large cohort of pregnancy

S. Bing, W. Zhaolian, H. Xiaojin, X. Xiaofeng, C. Yunxia

The First Affiliated Hospital of Anhui Medical University, Reproductive Medicine Center, Hefei, China

Study question: To characterize the incidence and risk factors for monozygotic twinning (MZT) after assisted reproductive technologies

Summary answer: There is a pretty higher prevalence rate of monochorionic-diamniotic(MC-DA) MZT after ART. Both maternal age and blastocyst transfer are risk factors of monozygotic pregnancy independently.

What is known already: MZT pregnancies are associated with an increased risk of both fetal and maternal complications. Although an elevated rate of MZT after ART has been previously reported, but the risk factors of the high incidence in the ART procedures are full of much controversy.

Study design, size, duration: All clinical pregnancies after embryo transfer carried out in our center between 2011 and 2016 (n = 8860) were

retrospectively analyzed for the incidence of MZT. The effect of different clinical data and laboratory procedures on the incidence of MZT was evaluated.

Participants/materials, setting, methods: The following ART risk factors were assessed: maternal age, type of ET (fresh versus frozen), ICSI, embryo stage at time of ET (cleavage or blastocyst)

Main results and the role of chance: The overall MZT rate was 2.55% (226/8860). Eighty one MZTs occurred in the fresh cycles and 145 MZTs followed in the frozen cycles (2.67% vs. 2.49%). MZT incidence did not differ significantly whether or not ICSI was performed (2.79% vs. 2.44%). The MZT rate that resulted from single embryo transfer (SET) cycles (1.99%) was slightly lower than multiple embryo transfer cycles (2.61%),but with non-significance. However, women <35 years displayed a higher rate (2.81%) than women ≥35 years old (1.16%). Blastocyst transfer was associated with a significantly increase in MZT incidence than cleavage-stage embryos transfer (2.79% VS 2.02%, P = 0.008). In the logistic regression analysis of subgroups, blastocyst transfer is a major risk factor of MZT in the fresh cycles (P = 0.044), while maternal age plays a more important role in the frozen cycles (P = 0.004).

Limitations, reasons for caution: This study is limited by its retrospective nature. Many parameters could not be assessed as the relatively uncommon occurrence of MZT during ART procedures.

Wider implications of the findings: We should pay more attention to the potential risk of maternal age and blastocyst transfer to increase MZT. More studies are needed to reveal the exact mechanism.

Trial registration number: The study was approved by the Ethical Committee of Anhui Medical University.(ECAMU No 2008035).

P-772 Congenital malformations in offspring of women after IVF treatment with or without a previous maternal malignancy

Z. Sabeti Rad[1], B. Friberg[2], E. Henic[2], L. Rylander[3], O. Ståhl[4], B. Källén[5], G. Lingman[6]

[1]*Malmö, Sweden,*
[2]*Skånes University Hospital, Centre of Reproductive medicine, Malmö, Sweden*
[3]*Lund University, Division of Occupational and Environmental medicine, Lund, Sweden*
[4]*Skånes University Hospital, Department of Oncology, Lund, Sweden*
[5]*Tornblad Institute, Lund University, Lund, Sweden*
[6]*Skånes University Hospital, Department of Obstetrics and Gynecology, Lund, Sweden*

Study question: Is there an increased risk for congenital malformations after a maternal history of malignancy and use of IVF?

Summary answer: No increased risk was seen after only a history of maternal malignancy. An increased risk was seen after use of IVF and IVF+ maternal malignancy.

What is known already: Survival after malignancy has increased and the question of risks, including risk for congenital malformations for the offspring of these women has become important. Data on congenital malformations in such offspring are limited.

Study design, size, duration: We compared congenital malformations in offspring, born in Sweden 1994-2011 to women with a history of malignancy (at least one year before delivery) with all other offspring. The study comprises 1 773 926 live born infants, among them 71 954 were identified with malformation diagnoses (4.1%), among which 47 081 were relatively severe (2.7% of total material).

Participants/materials, setting, methods: Data were obtained by linkage between five Swedish national health registers. Adjustment for confounders was mainly made by Mantel-Haenszel methodology.

Main results and the role of chance: We identified 71 954 (4.1%) infants with congenital malformation, of which 47 081 (2.7%) were relatively severe (roughly corresponding to major malformation). Among 7284 infants to women with a history of malignancy 204 relatively severe malformations were found (2.8%, OR = 1.04, 95% CI 0.91-1.20). After IVF (In vitro Fertilization), the risk of a relatively severe malformation was significantly increased in women without a history of malignancy (OR =1.31, 95% CI 1.24-1.38) and still more in women with such a history (RR = 1.85, 95% CI 1.08-2.97). However,

there were no significant differences neither, for any malformations (OR 1.04, 95% CI 0.92-1.16) nor for relatively severe malformations (OR 1.04, 95% CI 0.91-1.20), when comparing offspring only after maternal history of malignancy.

Limitations, reasons for caution: One limitation is that fetuses with prenatally identified malformations that were selectively aborted are not included. Such events are reported to the Swedish Birth Defect Register but (in accordance with Swedish law) without maternal identification which makes linkage with the cancer register impossible.

Wider implications of the findings: No general increase in malformation rate was found in infants born to women with a history of malignancy. A previously known increased risk after IVF was verified and it is possible that this risk is further augmented among infants born of women with a history of malignancy.

Trial registration number: Not applicable.

P-773 Is a double-embryo transfer detrimental to a patient's chances of pregnancy?

S. Lai[1], B. Vollenhoven[1,2,3], M. Healey[3,4,5], T. Osianlis[1]

[1]Monash University, Department of Obstetrics and Gynaecology, Clayton, Australia
[2]Monash Health, Department of Obstetrics and Gynaecology, Clayton, Australia
[3]Monash IVF, N/A, Richmond, Australia
[4]Royal Women's Hospital, Department of Obstetrics and Gynaecology, Parkville, Australia
[5]University of Melbourne, Department of Obstetrics and Gynaecology, Parkville, Australia

Study question: How do pregnancy and birth outcomes differ between single (SET)- and double-embryo transfers (DET) when considering blastocyst quality?

Summary answer: A high-quality embryo in a single transfer has better outcomes than in a double-embryo transfer with another embryo of any quality.

What is known already: The transfer of multiple embryos in in-vitro fertilisation (IVF) was originally utilized to maximise rates of implantation and pregnancy; however, its use has subsequently led to a high risk of multiple pregnancy and its associated complications. It is also accepted that SET results in healthier babies. Although SET is typically preferred, a variety of factors may influence the decision to concurrently transfer a second embryo. The quality of embryos is one such factor, and it remains unclear how this may affect pregnancy outcomes.

Study design, size, duration: This was a retrospective cohort study of 4275 single-embryo transfers and 881 double-embryo transfers in the blastocyst stage that occurred between 2005 and 2015. All SETs and DETs during this period were eligible for inclusion in the study (n = 72,867). Exclusion criteria included cases with missing data points (n = 10,564), duplicate transfers (n = 41,721), and transfers not utilising day-5 embryos (n = 8,715). Cases were also excluded where the quality of embryos was not adequate for our analysis (n = 6711)

Participants/materials, setting, methods: Data was extracted from private IVF clinic database. To keep data independent, embryo transfers included in the study were limited to one per woman. An internal embryo quality grading system was used – Grade A (very good) to D (poor). Grade A SETs were compared with DETs with at least one Grade A embryo. Chi-square test used and crude odds ratios quoted. Logistic regression was performed with adjusted odds ratios, controlling for number of factors.

Main results and the role of chance: We found that implantation, clinical pregnancy and live birth rates were higher with single Grade A embryo transfers than DET involving at least one Grade A embryo. The absolute event rate (AER) for implantation was 0.49 for SET and 0.29 for DET with at least one high quality embryo, with a relative risk reduction (RRR) of 41% (p<0.001). For clinical pregnancy, the AER was 0.52 for SET and 0.45 for DET, with a RRR of 14% (p<0.001). For clinical pregnancy loss, the AER was 0.13 for SET and 0.15 for DET, with a relative risk increase (RRI) of 15% (p = 0.29). For live birth, the AER was 0.45 for SET and 0.38 for DET, with a RRR of 16% (p<0.001). For multiple pregnancy, the AER was 0.01 for SET and 0.15 for DET, with a RRI of 977% (p<0.001).

Limitations, reasons for caution: Although adjustment for all available confounders using statistical analysis was attempted, there will be factors not available or included in analysis that may have biased our results.

Wider implications of the findings: Our results contradict the historical precedent that transferring multiple embryos may compensate for low implantation and pregnancy rates; and suggest that to do so may cause harm.

Trial registration number: The local trial registration number is 15172 M.

P-774 Systematic review of the clinical efficacy of vaginal progesterone for luteal phase support in assisted reproductive technology cycles

T. Child[1], S. Leonard[2], J.S. Evans[2], A. Lass[3]

[1]University of Oxford, Nuffield Department of Obstetrics and Gynaecology, Oxford, United Kingdom
[2]Costello Medical Consulting Ltd, Evidence Development, Cambridge, United Kingdom
[3]Besins Healthcare UK Ltd., TBC, London, United Kingdom

Study question: What is the comparative efficacy and safety of vaginal progesterone (VP) preparations licensed for use in the UK for luteal phase support (LPS) in assisted reproductive technology (ART) cycles?

Summary answer: No studies reported statistically significant differences in efficacy or safety between Utrogestan Vaginal (UV) and Crinone, Crinone and Lutigest or Lutigest and Cyclogest.

What is known already: A variety of progesterone preparations are available for LPS including intramuscular injection, oral, rectal and vaginal administration. The comparative efficacy and safety of these preparations have been well reported in the literature, with oral preparations having lower progesterone concentrations in the endometrium and intramuscular routes complicated with injection-site reactions. VP has similar efficacy to other routes with the advantage of rapid absorption and so is the most common form used for LPS in Europe. Despite this wide use of VP, limited data are available on the comparative efficacy and safety of the different VP products available.

Study design, size, duration: A systematic literature review (SLR) was conducted using the MEDLINE, EMBASE and Cochrane Library Databases on 30th June 2016 with no date limit.

Participants/materials, setting, methods: Randomised controlled trials (RCTs) investigating the comparative efficacy or safety of at least two VP preparations (UV, Crinone, Cyclogest or Lutigest) for LPS in ART cycles were eligible. Bibliographies of identified SLRs and major conference proceedings were also hand-searched for further publications. Abstracts and full-texts were screened for eligibility by two independent reviewers. Extraction of data from relevant studies and quality assessment was performed by one individual with verification by another.

Main results and the role of chance: 1,914 records were screened for relevance with 17 studies included in the SLR. Seven studies compared UV with Crinone, one compared Lutigest with Crinone, one compared Lutigest with Cyclogest and another compared Cyclogest with Crinone. Variations in timing or dosage of UV were investigated in seven studies. The most common primary outcome measure was ongoing pregnancy rate (OPR; seven studies), followed by clinical pregnancy rate (CPR; six studies), patient-reported outcomes (PRO; two studies) and delivery (DR) and expected live birth rates (ELBR; one study each). Adverse events (AEs) were reported in five studies. No significant difference in CPR or ELBR was identified in any comparison of UV with Crinone whilst UV and Lutigest were found to be non-inferior to Crinone in OPR comparisons. Differences in PROs for Crinone and Lutigest were found not to be significantly different to Cyclogest.

Limitations, reasons for caution: Due to the nature of comparisons between different formulations of VP eg. gel versus tablet, true double-blinding of the studies was not possible; however, one study implemented assessor blinding. Furthermore, the time points and definitions of outcome measures differed between studies making comparisons across studies inappropriate.

Wider implications of the findings: The results of this SLR suggest that UV, Crinone, Cyclogest and Lutigest each represent valid, equally safe and effective choices of VP preparation for LPS in ART cycles.

Trial registration number: N/A.

P-775 Cardiovascular health of 9-year-old IVF offspring is not associated with IVF but with parental subfertility

D. Kuiper[1], A. Hoek[2], S. La Bastide-van Gemert[3], J. Seggers[1], M.J. Heineman[4], M. Hadders-Algra[1]

[1]University Medical Center Groningen, Institute of Developmental Neurology, Groningen, The Netherlands
[2]University Medical Center Groningen, Department of Obstetrics and Gynaecology, Groningen, The Netherlands
[3]University Medical Center Groningen, Department of Epidemiology, Groningen, The Netherlands
[4]Academic Medical Center, Department of Obstetrics and Gynaecology, Amsterdam, The Netherlands

Study question: Does the *in vitro* procedure, ovarian hyperstimulation or subfertility affect blood pressure (BP) of 9-year-old IVF children born to subfertile couples?

Summary answer: Our study demonstrates that the higher BP in 9-year-old children born to subfertile couples is not due to IVF-procedures but is associated with couples' subfertility.

What is known already: Possible long-term effects of IVF on child health and development have been studied relatively little. This is surprising, as it is known that environmental conditions may influence embryonic and fetal development which may result in health related problems in later life. Some studies suggested that IVF adversely affects BP at school age. Yet, it is unclear which component of IVF attributes to this potentially less favourable BP.

Study design, size, duration: A prospective assessor blinded study of two groups of children followed from birth onwards: the Groningen Assisted Reproductive Technology (ART) cohort-study and the Long-Chain PolyUnsaturated Fatty Acids (LCPUFA) study. In total 449 children were assessed at the age of 9.

Participants/materials, setting, methods: We evaluated cardiovascular health, focusing on BP (in mmHg and percentiles), and heartrate on 57 children born following controlled ovarian hyperstimulation-IVF (COH-IVF); 47 children born after modified natural cycle-IVF (MNC-IVF); and 65 children who were conceived naturally to subfertile couples. Cardiovascular parameters were measured multiple times on one day. Similar data of a reference group (n = 279) of children born to fertile couples of the LCPUFA-study were available.

Main results and the role of chance: BP was similar in the COH-IVF, MNC-IVF and Sub-NC groups. This allowed us to pool the groups to form a subfertile group (n = 169). The subfertile group had a higher systolic blood pressure percentile (SBP, mean [σ]: 60.7 [19.2]), diastolic blood pressure percentile (DBP, 62.5 [18.8]) and heart rate (81.5 [9.9]) than the fertile reference group: SBP (56.3 [24.5]); DBP (55.8 [23.3]) and heart rate (77.0 [9.7]). In the adjusted analyses the subfertile group still had a higher SBP percentile (adjusted B [95%CI]: 7.86 [2.16-13.55]); a higher DBP percentile (7.64 [2.20-13.08]); and a higher heart rate (7.40 [4.96-9.85]).

Limitations, reasons for caution: Larger study groups are necessary to draw firm conclusions regarding ovarian hyperstimulation and the *in vitro* procedure. Another limitation is that all blood pressure measurements were performed on one day.

Wider implications of the findings: Our findings are in line with other studies describing less favourable cardiovascular outcomes in IVF offspring. Our study suggests that the higher BP and heart rate is not due to procedures of IVF but due to parental subfertility. The findings may have important implications for the counselling of subfertile couples.

Trial registration number: -.

P-776 The effects of repeated hormonal treatments on tubo-ovarian gene expression, on ovulated oocytes and on the sex-ratio of the offspring obtained

G. Di Luigi, V. Di Nisio, G. Rossi, S. Cecconi, G. Carta

University of L'Aquila, Department of Life- Health & Environmental Sciences, L'Aquila, Italy

Study question: To understand if gonadotropins could modulate tubo-ovarian gene expression. To evaluate the number and quality of oocytes ovulated, and the sex-ratio of the offspring obtained.

Summary answer: Cyclin D1 and p53 increased after 4 cycles of stimulation in FT of treated mice. Number and quality of oocytes decreased. Sex-ratio was not subverted.

What is known already: Epidemiological data evidenced an increased risk for borderline ovarian tumors in infertile women treated with IVF and about two thirds of serous borderline ovarian tumors are characterized by kras mutations that determines a significant increase of cyclin D1 expression. Ovarian cancer would arise from the fallopian tube (FT), not from the ovarian cortex. Quality and number of oocytes decrease after repeated ovarian hyperstimulations. Sex-ratio is influenced by hormonal levels and stress factors.

Study design, size, duration: Ovaries and FT of naturally-ovulating mice and of mice undergoing 0-4-8 rounds of gonadotropin stimulations were analyzed to detect localization and expression levels of Oct-3/4, Sox-2, p53, β-catenin, cyclin D1, pChk1 and pH2AX. Ovulated oocytes were analyzed to detect meiotic spindles and chromosome alignment. Sex-ratio of the offspring obtained were analyzed and compared with control mice, evaluating two consecutive generations of offspring.

Participants/materials, setting, methods: Four (4 T) to eight (8 T) rounds of stimulations were performed with intervals of 1 week between each. Repetitive cycles of ovarian stimulation were performer according to the protocol of Van Blerkom and Davis. For each experiment, control (Ctr; N = 5) and hyperstimulated (N = 20/round, 10 4 T+10 8 T) mice were sacrificed. The experiment was replicated four times.

Main results and the role of chance: After 4 and 8 cycles of ovarian hyperstimulation with gonadotropins, ovaries and FT of control and treatment groups showed no differences in Oct-3/4, Sox-2, β-catenin intracellular localization nor in Oct-3/4, Sox-2, p53, β-catenin, pChk1 and pH2AX contents. By contrast, cyclin D1 and p53 levels increased significantly in the FT, but not in the ovarian cortex of treated mice. After 4 and 8 cycles of ovarian stimulation, the increase of cyclin D1 remained below 46%, which is the rate recorded in ovarian carcinomas. Number and quality of oocytes decreased meanwhile frequency of abnormal meiotic spindles increased with treatments. After 8 consecutive stimulations, no oocyte was retrieved. Sex-ratio was unchanged in both consecutive generations.

Limitations, reasons for caution: The significant increase of cyclin D1 and p53 levels detected in the FT needs to be further investigated.

Wider implications of the findings: We cannot reject the possibility that in a small percentage of susceptible women also a relatively low increase of cyclin D1, as that recorded in mice, could sensitize epithelial cells towards malignant transformation. It remains ethically proper to inform women at risk, about the potential consequences of infertility treatments.

Trial registration number: Not needed.

P-777 Comprehensive protocol of traceability during in vitro fertilization: the result of a multicentre failure mode and effect analysis (FMEA)

L.F. Rienzi[1], F. Bariani[2], M. Dalla Zorza[3], E. Albani[4], F. Benini[5], S. Chamayou[6], M.G. Minasi[7], L. Parmegiani[8], L. Restelli[9], G. Vizziello[10], A. Nanni Costa[11]

[10]Momo' fertiLife, IVF center, Bisceglie, Italy
[11]Italian National Institute of Health ISS, Italian National Transplant Centre CNT-, Rome, Italy

Study question: Can traceability of gametes and embryos be ensured during in vitro fertilization (IVF)?

Summary answer: A simple and comprehensive traceability system that can be applied in different settings is proposed and its capacity to minimize the risk of miss-matches shown.

What is known already: Miss-matches in IVF are very rare but unfortunately possible with dramatic consequences for both patients and health care professionals. Traceability is thus a fundamental aspect of the treatment. A clear process of patient and cell identification involving witnessing protocols has to be in place in every unit. To identify potential failures in the traceability process and to develop strategies to mitigate the risk of miss-matches, failure mode and effects analysis (FMEA) has been previously effectively used. To reduce subjectivity and to obtain a widespread comprehensive protocol of traceability, a multi-centre centrally coordinated FMEA was performed.

Study design, size, duration: Seven representative Italian centres were selected. The study had duration of 21 months and was centrally coordinated by a team of experts. After mapping the traceability process, each center identified the possible causes of mistakes in their protocol. The results of the FMEA analyses were investigated by the experts and consistent corrective measures suggested. A new FMEA analyses was performed after the recommended implementations.

Participants/materials, setting, methods: This study involved in each centre a team composed by: the laboratory director, the Quality Control & Quality Assurance responsible, Embryologist(s), Gynaecologist(s), Nurse(s) and Administrative. The FMEA analyses were performed according to the Joint Commission International (2002, 2010). For each failure a Risk Priority Number (RPN) score was calculated by multiplying the probability of occurrence (O), severity of impact on the process (S) and chance of detection (D) (RPN=OxSxD).

Main results and the role of chance: The FMEA teams identified 7 main process phases: oocyte collection, sperm collection, gametes processing, insemination, embryo culture, embryo transfer and cryopreservation. A mean of 19,29 (SD+5.8) associated process steps and 41,86 (SD+12,4) possible failure modes were recognized per centre. A RPN > 15 was calculated in a mean of 6,43 steps (range 2-12, SD+3,60). A total of 293 failure modes were centrally analysed 45 of which were considered at medium/high risk. The implementation of consistent corrective measures allowed a significant reduction in the RPNs in all centres (RPN < 15 for all steps). A simple and comprehensive traceability system was designed as the result of the seven FMEA analyses.

Limitations, reasons for caution: Specific situations such as sperm/oocyte donation, import/export and pre-implantation genetic testing were not taken into consideration. Moreover, this study is only limited to the analysis of failure modes that may lead to miss-matches, other possible procedural mistakes are not accounted.

Wider implications of the findings: The results of this study can support IVF groups in better recognizing critical steps in their treaceability protocols, understanding identification and witnessing process, and in turn enhancing safety by introducing validated corrective measures.

Trial registration number: N/A.

P-778   Intracytoplasmic morphologically selected sperm injection (IMSI) procedure affects secondary human sex ratio (SSR)

R.L.R. Baruffi[1,2], A.L. Mauri[1,2], C.G. Petersen[1,2], V.A. Comar[1], M.C. Matilla[1], L.D. Vagnini[2], A. Renzi[2], B. Petersen[2], C. Zamara[1], F. Dieamant[1,2], J.B.A. Oliveira[1,2], J.G. Franco Jr[1,2]

[1]Centre for Human Reproduction Prof. Franco Jr, Research, Ribeirao Preto, Brazil
[2]Paulista Center for Diagnosis- Research and Training, Research, Ribeirao Preto, Brazil

Study question: Does the use of the intracytoplasmic morphologically selected sperm injection (IMSI) affect the sex ratio at birth?

Summary answer: The data imply that sex selection emerges after the IMSI procedure with the sex ratio skewed towards females.

What is known already: Among the ART-associated consequences, a skewed sex ratio is an issue of concern. The secondary sex ratio (SSR), which may be defined as the proportion of live-born males out of all live births, is commonly recognized as male biased among naturally born offspring. However, according to published studies, ART methods/procedures(IVF/ICSI, blastocyst transfer, and culture media) or gamete quality may potentially affect the SSR by increasing, reducing or even reversing the ratio. With regard to IMSI, which improves the quality of sperm selected for ICSI using high magnification and MSOME criteria, virtually no information is available about its influence on SSR.

Study design, size, duration: The cohort study included children (n = 938) from pregnancies achieved through IMSI procedures that were conducted in a single fertility clinic. The children were born alive between January 2008 and September 2016. Children from fresh and frozen cycles were included, but no PGD or PGS cases were considered.

Participants/materials, setting, methods: Sperm was selected for IMSI at 15,000x magnification. The most recently available data (2008-2014) from a national demographic database were used as a control. SSR was calculated by dividing the number of live-born male babies by the number of all live-born babies. Chi-squared analysis was used to compare gender ratios. P < 0.05 was considered statistically significant.

Main results and the role of chance: Among the children born from IMSI the SSR was 47.2%. In contrast, the nationwide SSR was 51.2%, which is consistent with what is expected. There was a significant difference ($P = 0.01$) in the SSR between the IMSI population and the general population(Table 1). The reduction in the SSR remains independent of maternal and paternal age, aetiology, semen origin, type of cycle (fresh or frozen), culture medium, and embryo transfer stage and independent of whether it was a single or multiple pregnancy (Table 2).

Table 1. The sex distribution at live birth.

Population	Gender	
	Male	Female
IMSI	443	495
General	10.438.698	9.938.419

P = 0.01

Table 2. IMSI cycles and SSR distribution.

-P-1 Medium SSS(Irvine Scientific®)	43.78%(98/224)	
-IVF-Cleavage +Total-LGGT	40%(2/5)	
-IVF-Cleavage +G-1/G-2	48.0%(12/25)	
-Total-LGGT+G-1/G-2	36.4%(4/11)	
-Total-LGGT+P-1	46.2%(109/236)	
-G-1/G-2+P-1	37.5%(3/8)	
Cycle		
-Fresh	47.6%(352/739)	0.69
-Frozen	45.7%(91/199)	
Embryo stage/transfer		
-Cleavage	47.6%(383/804)	0.60
-Blastocyst	44.8%(60/134)	
Pregnancy		
-Singleton	46.3%(259/560)	
-Twins	49.7%(176/354)	0.22
-Triplets	33.3%(8/24)	

Limitations, reasons for caution: Allocation for IMSI cycles over the four media was not random. The small sample size in some subgroup populations impairs the analysis

Wider implications of the findings: It may be hypothesized that alterations in the Y chromosome may lead to morphological changes in the sperm that prevent its selection under high magnification. However, other possible causes should be considered and discussed. Additional studies with larger sample sizes to examine sex ratios after IMSI are warranted.

Trial registration number: Not applicable. The local ethics committee authorised this study.

P-779   Long-term neurological morbidity in children following in-vitro fertilization and ovulation induction pregnancies

A. Harlev[1], T. Wainstock[2], A. Walfisch[3], I. Sgal[4], S. Levin[3], E. Levitas[1], D. Landau[5], E. Sheiner[3]

[1]Soroka University Medical Center- Ben-Gurion University of the Negev, Fertility and IVF Unit- Department of Obstetrics and Gynecology, Beer Sheva, Israel
[2]Ben-Gurion University of the Negev, Faculty of Health Sciences- Department of Public Health, Beer Sheva, Israel
[3]Soroka University Medical Center- Ben-Gurion University of the Negev, Department of Obstetrics and Gynecology, Beer Sheva, Israel
[4]Ministry of Health, Ministry of Health, Jerusalem, Israel
[5]Soroka University Medical Center- Ben-Gurion University of the Negev, Department of Neonatology, Beer Sheva, Israel

Study question: To determine the risk for long-term neurological morbidity among children born after in-vitro fertilization (IVF) and ovulation induction (OI) as compared to spontaneous pregnancies.

Summary answer: Singletons conceived following IVF but not OI have an increased risk of long-term neurological morbidity

What is known already: Controversy exists regarding the association between fertility treatments and adverse neurological outcome of the children. While previous studies of children up to school-age, found no significant difference in neurodevelopmental outcome, large cohort studies that followed the participants for a longer period, up to 14 years, reported an increased risk of neurological outcome in children born following infertility treatments. Yet, another study that followed children up to 17 years indicates that children born

following fertility treatments perform above average on standardized testing and their cognitive development is normal

Study design, size, duration: A population based cohort analysis was performed, including computerized database of all singleton infants born between the years 1991-2014 in Soroka University Medical Center (SUMC). This database was linked with the computerized dataset of all pediatric hospitalizations in the same medical center. SUMC is the largest birth center in Israel, and is the only tertiary medical center in Israel's southern region, including the single IVF unit in the region.

Participants/materials, setting, methods: This study included all singleton deliveries occurring between 1991-2014 at a single tertiary medical center. Fetuses with congenital malformations were excluded. A comparison was performed between children delivered following IVF, OI and spontaneous pregnancies. Hospitalization rates up to the age of 18 years involving neurological morbidity were evaluated. A Kaplan-Meier survival curve was used to compare cumulative morbidity incidence. A Cox regression model was used to control for confounders.

Main results and the role of chance: During the study period 242,187 singleton deliveries met the inclusion criteria; 1.1% were following IVF (n = 2603), and 0.7% occurred following OI (n = 1721). Hospitalizations up to the age of 18 years involving neurological morbidity were significantly more common in children delivered following IVF (3.7%) and OI (4.1%) as compared with those following spontaneous pregnancies (3.1%; p = 0.017 using the chi-square test for trends). Attention deficit disorders (ADHD), sleep disorders, movement disorders and headaches were more common in the IVF and OI groups as compared to the spontaneous pregnancies groups. Autism, cerebral palsy, eating disorders among other evaluated complications were comparable between the study groups. The Kaplan-Meier survival curve demonstrated a significantly higher cumulative incidence of total neurological morbidity following IVF and OI (log rank p < 0.001). Using the cox regression model, controlling for multiple confounders such as maternal age, preterm delivery, maternal diabetes and hypertensive disorders in pregnancy, IVF (adjusted HR = 1.37, CI 1.12-1.67, p = 0.03), but not OI (adjusted HR = 1.15, CI 0.91-1.46, p = 0.242), was noted as an independent risk factor for long-term pediatric neurological morbidity.

Limitations, reasons for caution: This study was limited by its retrospective nature. Fertility etiology is not applicable as well as the treatment protocol used.

Wider implications of the findings: The increased rate of long term neurological pediatric complications in IVF but not OI conceived pregnancies should improve the consultation given to the patients prior to treatment. Further studies are required in order to address the underlying pathophysiology leading to these complications in IVF pregnancies in order to reduce it.

Trial registration number: N/A.

P-780   IVF is an independent risk factor for third stage of labor complications

Y. Shufaro[1,2], S. Oron[2], O. Sapir[1], G. Oron[1,2], H. Pinkas[1,2], A. Ben-Haroush[1,2], T. Shochat[3], A. Wiznitzer[2,4], B. Fisch[1,2], E. Ashwal[2,5]

[1]Beilinson Women's Hospital- Rabin Medical Center, Infertility and IVF Unit, Petach-Tikva, Israel
[2]Tel Aviv University, The Sackler Faculty of Medicine, Tel Aviv, Israel
[3]Beilinson Hospital- Rabin Medical Center, Research Authority, Petach-Tikva, Israel
[4]Beilinson Women's Hospital- Rabin Medical Center, OB & GYN, Petach-Tikva, Israel
[5]Tel-Aviv Sourasky Medical Center, Lis Maternity and Women's Hospital, Tel-Aviv, Israel

Study question: To determine if third stage of labor complications are more prevalent in term singleton vaginal deliveries following IVF gestations than in matched spontaneous control gestations.

Summary answer: Post-partum hemorrhage, manual lysis and blood transfusion requirement were significantly more prevalent following vaginal deliveries of IVF gestations than in the matched spontaneous pregnancy controls.

What is known already: IVF pregnancies are associated with a higher rate of prenatal and intra-partum complications than spontaneous gestations, even

after correction of confounding factors such as maternal age, parity and number of fetuses. Little is known about the prevalence of third stage of labor complications in IVF pregnancies, excluding a higher prevalence of placenta accreta reported in a few small studies.

Study design, size, duration: Cohort study reviewing the delivery files of all our IVF patients who vaginally delivered singletons in our hospital between 8/2011-3/2014. Two matched spontaneous pregnancy controls from our obstetrical database in the same time range were randomly selected by software based on age, gravidity, parity and week of delivery. The impact of pregnancy type on the length and complications of the third stage of labor was examined. P values were calculated using the Fisher exact test.

Participants/materials, setting, methods: The study group consisted of 242 IVF gestations, and 484 matched spontaneous pregnancy controls, who delivered vaginally. The average maternal age was 32.74 ± 5.22 years for IVF cases and 32.61 ± 5.14 years for controls. The average gravidity and parity were 2.1 ± 1.24 and 0.63 ± 0.73 for IVF, and 2.07 ± 1.13 and 0.64 ± 0.74 for controls. The delivery week was 38.69 ± 1.75 for IVF and 38.61 ± 2.46 for controls. Post-partum hemorrhage was defined when the estimated blood loss following delivery was higher than 500 mL.

Main results and the role of chance: The prevalence of diabetes, hypertensive complications and placental abruption did not differ between deliveries following IVF and controls. There was also no difference in the rate of labor inductions (26.03% following IVF and 31.2% in controls, NS) and instrumental deliveries (17.77% following IVF and 15.5% in the controls, NS). The average birthweight was 3153 ± 645 gr for IVF gestations and 3179 ± 479 for controls (NS). The 1 minute and 5 minutes Apgar scores following IVF gestations were 8.75 ± 1.13, 9.9 ± 0.62, and for controls 8.89 ± 0.67, 9.95 ± 0.48 (NS).

The average length of the third stage was similar in deliveries following IVF and controls (14.23 ± 8.89 and 13.69 ± 9.19 minutes respectively, NS). The rated of post-partum hemorrhage was 5.79% in deliveries following IVF and 1.45% in controls ($p = 0.001$). Manual lysis of the placenta was performed in 11.98% of the deliveries following IVF and in 7.02% of the controls ($p = 0.025$). Blood transfusion was required in 2.07% following IVF deliveries and 0.41% of the controls ($p = 0.032$). Abnormally adherent placenta was diagnosed in 2 deliveries following IVF (0.83%) and in none of the controls ($p = 0.045$).

Limitations, reasons for caution: Retrospective study.

Wider implications of the findings: Our results indicate that IVF is a risk factor for post-partum hemorrhage, requirement for manual lysis and blood transfusions, even after correction for confounding factors. Therefor complication anticipating management of the third stage is warranted in women delivering vaginally following IVF pregnancies, even in the absence of other risk factors.

Trial registration number: NA, the acquisition of data from the medical records for this study was approved by our IRB.

P-781   Infertility treatment affects endothelial health in early pregnancy

F. Von Versen-Höynck[1,2], R. Fleischmann[2], P. Narashiman[3], V.L. Baker[2], V.D. Winn[3]

[1]Hannover Medical School, Department of Obstetrics- Gynecology and Reproductive Sciences, Hannover, Germany
[2]Stanford University, Department of Obstetrics and Gynecology- Division of Reproductive Endocrinology and Infertility, Palo Alto, U.S.A.
[3]Stanford University, Department of Obstetrics and Gynecology- Perinatal Biology, Palo Alto, U.S.A.

Study question: Does the unphysiologic maternal milieu after assisted reproduction affects maternal endothelial function already in early pregnancy?

Summary answer: Maternal endothelial function early in pregnancy in women using assisted reproductive technologies (ART) is reduced compared to spontaneously conceived pregnancies in infertile women.

What is known already: ART is associated with an increased risk for vascular disease in pregnancy, e.g. gestational hypertension and preeclampsia. The reasons are still debated, ranging from the maternal susceptibility, hormonal milieu to embryo culture conditions. An impaired peripheral arterial tone, measured as reactive hyperemia index (RHI) is associated with an increased risk of vascular events.

Study design, size, duration: Recruitment for this ongoing prospective, observational study started in June 2014. The overall goal is a number of 45 participants finishing the study visits.

Participants/materials, setting, methods: Infertile women at 7-10 weeks gestation with a viable intrauterine pregnancy after spontaneous or ART conceptions were recruited. Cases with known disorder that affect vascular health or a recent cold were excluded. Endothelial function was evaluated using the Endo-PAT2000 system and measured as reactive hyperemia index (RHI, arbitrary units) at 11-14 weeks. Multiple comparison analysis was performed and endothelial function compared between spontaneously conceived and ART pregnancies. Data are shown as median and standard error.

Main results and the role of chance: RHI was lower in women who received infertility treatment (1.93 ± 0.06, n = 30, p = 0.009) compared to spontaneous conceptions (2.36 ± 0.26, n = 6) in infertile women. If broken down to mode of conception a significant effect on RHI was observed after stimulated intrauterine insemination and timed intercourse (1.69 ± 0.15, p = 0.005, n = 8) or fresh in vitro fertilization (IVF), (1.87 ± 0.16, p = 0.05, n = 8). Although a lower RHI has been observed in medicated frozen-thaw embryo transfer cycles (1.85 ± 0.11, p = 0.07, n = 5) this wasn't statistically significant. Interestingly, frozen-thaw embryo transfers in a natural cycle (2.0 ± 0.08, p = 0.13, n = 9) had the highest RHI in all ART groups. There were no differences in BMI, systolic or diastolic blood pressure or lipid concentrations.

Limitations, reasons for caution: Due to low numbers of participants there is a risk of chance. At this point of the study it is unclear if the observed differences in endothelial function persist throughout pregnancy and even thereafter and if they are associated with a higher risk for hypertensive disease, e.g. preeclampsia.

Wider implications of the findings: If the observed trend of impaired vascular function after ART (e.g. fresh IVF) holds up a less aggressive ovarian stimulation due to concerns about short-term effects and longer-term issues of fetal and maternal outcomes would have a high probability of driving a change in practice guidelines and standard of care.

Trial registration number: Does not apply.

P-782   Associations between embryo grading and congenital malformations in IVF/ICSI pregnancies

K. Abel[1], M. Healey[2,3], T. Osianlis[4], B. Vollenhoven[4,5]

[1]Royal Women's Hospital, Obstetrics & Gynaecology, Melbourne, Australia
[2]University of Melbourne, Department of Obstetrics and Gynaecology, Melbourne, Australia
[3]Monash IVF, Richmond, Melbourne, Australia
[4]Monash University, Department of Obstetrics and Gynaecology, Melbourne, Australia
[5]Monash IVF, Clayton, Melbourne, Australia

Study question: Does the quality of transferred embryos in a population of infants conceived by IVF and ICSI have an impact on the rate of congenital anomalies?

Summary answer: A baby conceived from a poor quality embryo may be at higher risk of congenital malformations than one from a good quality embryo.

What is known already: Multiple studies have shown that there is an association between congenital malformations and IVF/ICSI pregnancies. Other studies have investigated the role of ICSI vs. IVF, transferring fresh vs. frozen embryos, ovarian stimulation regimens, assisted hatching and transferring blastocysts vs. cleavage-stage embryos in congenital malformations. The relationship between embryo quality in implantation, clinical pregnancy and livebirth rates is well known. However, there is limited knowledge on the role of embryo quality in congenital malformations. It is thought that the malformation risk is higher in poor quality embryos, but rates of individual anomalies in good and poor embryos have not been compared.

Study design, size, duration: This study was a retrospective cohort study of 10,309 clinical pregnancies in women who underwent IVF or ICSI at a private multisite IVF clinic between January 2005 and December 2015 inclusive. Data on pregnancies were recorded in a standardised database. There were no losses to follow up due to local legislative reporting requirements.

Participants/materials, setting, methods: 10,309 single embryo transfers graded on Day 5 which resulted in clinical pregnancies were identified. One clinical pregnancy per woman was randomly selected. The type and number of congenital malformations were determined. Clinical pregnancies were further limited to those that resulted in deliveries (n = 7292). Embryos were classified as good quality (grade A or B, n = 6099) or poor quality (grade C or D, n = 1193). Malformation rates between good and poor quality embryos were compared.

Main results and the role of chance: Deliveries resulting from the transfer of poor quality embryos were more likely to have talipes (adjusted odds ratio, aOR 0.39(95% Confidence Interval 0.18-0.87), p = 0.003), birth marks (aOR 0.1(0.11-0.86), p = 0.010) and sacral dimples (aOR 0.24(0.07-0.78), p = 0.018) than births from good quality embryos. There was no significant difference in rates of major malformations between good and poor embryos.

All clinical pregnancies were also analysed to ensure that terminations and clinical pregnancy losses were captured. Comparison of demographic data were unchanged from that of deliveries. The statistically significant results in deliveries were upheld. Additionally, diaphragmatic hernia occurred more commonly in poor quality embryos (aOR 0.08 (0.007-0.95), p = 0.026), as did genetic anomalies (aOR 0.22 (0.05-0.87), p = 0.016) and hypospadias (aOR 0.32 (0.10-0.99), p = 0.11). As a result, 'all anomalies" also became statistically significant (aOR 0.75 (0.58-0.97), p = 0.008).

When all clinical pregnancies were analysed, there were less spontaneous clinical pregnancy losses in good quality embryos compared to poor quality embryos on univariate analysis, but there was no significant difference after adjusting for confounders (crude OR 0.75 (0.68-0.84), aOR 0.79 (0.61-1.03), p<0.001). There was no significant difference between the rate of terminations in good quality and poor quality embryos (aOR 0.65 (0.17-2.46), p = 0.92).

Limitations, reasons for caution: Information about anomalies was obtained from medical notes rather than a dedicated birth defects register. Subfertility and intrinsic parental factors may contribute to our results. As there are very small rate differences between good and poor embryos, studies with larger sample sizes are required to confirm or deny our findings.

Wider implications of the findings: This is the first study comparing the rates of individual congenital malformations for good and poor embryos. It assists clinicians in counselling patients about the risks of transferring poor quality embryos if there are no good embryos available. Poor grade day 5 embryos are associated with minor malformations and talipes.

Trial registration number: Not applicable.

P-783   Preliminary results on cognitive and motor development of 2-year-old IVM children

E. Buyse[1], M. Pilloy[2], M. De Vos[3], H. Tournaye[3], M. Bonduelle[1], J. Nekkebroeck[1]

[1]UZ Brussel, Centre for Medical Genetics / Reproductive Medicine, Brussels, Belgium
[2]Vrije Universiteit Brussel, Psychology, Brussels, Belgium
[3]UZ Brussel, Centre for Reproductive Medicine, VUB

Study question: Is there a difference in cognitive and motor development between children born after In vitro maturation (IVM), Intra cytoplasmatic sperm injection (ICSI) and spontaneous conceived (SC) pregnancy?

Summary answer: First results show a significant difference between IVM and SC controls for cognitive development (IVM< SC) and between IVM and ICSI for motor development (IVM<ICSI).

What is known already: Several ART follow-up studies show no significant difference in cognitive and motor development between children born after IVF and ICSI compared with SC controls. Studies that looked at children born after IVM treatment focused on medical factors. There are no more significant premature births or major birth problems after IVM compared with other modes of conception (IVF, ICSI, SC) (Buckett et al., 2007, Cha et al., 2005, Shu-Chi et al., 2006, Söderström-Antilla et al., 2006) Data of birth length- and weight of IVM-children compared with other modes of conception are inconclusive.

Study design, size, duration: A case-control study design were three groups (IVM, ICSI and SC children) were matched according to age, sex, language, ethnicity, mothers educational level, maternal age and birth order. All children are singletons, live in Belgium and have Dutch or French as mother

tongue. Recruitment ran from 2014 until 2016. Sixty-nine were invited, 53 participated.

Participants/materials, setting, methods: Seventeen IVM, 18 ICSI were invited to the UZ Brussel. Eighteen SC children were recruited in a nursery. The IVM mean age of assessment was 25 months (SD=3.47), for ICSI and SC 27 months (SD=4.22/ SD=4.63). Cognitive and motor development was investigated using the Bayley Scales of Infant Development II, Dutch version. The scales were administered yielding a mental index score and motor index score with a mean of 100 and a SD of 15.

Main results and the role of chance: The results on the B S I D- II-NL show significant differences between the three groups for cognitive and motor development. There is a significant difference on the mental index score between the IVM and de SC control group (F= 4.68, p= .014). The SC controls (M= 108.78, SD= 4.41) score higher than the IVM group (M= 101.47, SD= 9.37). There is also a significant difference on the motor index score between the IVM and the ICSI group (F= 4.26, p= .019). The ICSI group (M= 111.50, SD= 8.34) score higher than the IVM group (M= 103.89, SD= 9.92). None of the children show a delayed cognitive and motor development.

Limitations, reasons for caution: This study used multiple evaluators, giving a potential evaluators bias. Although significant differences were found, scores in all three conception groups are within a normal range. The small sample size undermines the generalizability of the results to the population. The results presented in this abstract are of a preliminary nature.

Wider implications of the findings: The IVM and ICSI treatment does not have a negative impact on the cognitive and motor development of children compared with SC controls. The small sample size and limited IVM studies require further investigation.

Trial registration number: Non-randomised study design.

P-784   Neonatal outcomes and congenital malformations in children born after treatment with progesterone primed ovarian stimulation in in vitro fertilization and vitrified embryo transfer cycles

J. Zhang, Y. Kuang

Shanghai Ninth People's Hospital-Shanghai Jiaotong University School of Medicine, Department of Assisted Reproduction, Shanghai, China

Study question: Does neonatal outcomes including congenital malformations in children born after progesterone primed ovarian stimulation (PPOS) differ from that of children born after conventional stimulations?

Summary answer: Children born after PPOS treatment do not increase the prevalence of congenital malformation and compromise the neonatal outcomes compared with conventional ovarian stimulations.

What is known already: Our previous studies demonstrated that progesterone agents such as medroxyprogesterone acetate (MPA) could prevent premature LH surges during COH in combination with a freeze-all policy, however, the safety of the children born after this new regimen remains unknown.

Study design, size, duration: A retrospective, single-center study was conducted, in which children born after PPOS treatment using exogenous gonadotropins concurrent with MPA, gonadotropin releasing hormone agonist (GnRH-a) short protocol, or mild ovarian stimulation during January 2014 to June 2016 were included.

Participants/materials, setting, methods: A total of 4596 babies were born, of which 1931 babies born after PPOS, 1658 babies born after short protocol and 1007 babies born after mild ovarian stimulation. Neonatal outcomes were anal yzed for singletons and twins separately. Multivariable logistic regression was used to evaluate the possible relationship between various ovarian stimulation methods and congenital malformations.

Main results and the role of chance: Neonatal outcomes both for singletons and twins such as mean birthweight and birthlength, gestational age, the frequency of preterm birth were comparable between groups. Rate of stillbirth, perinatal death were also similar. No differences were found in the overall incidence of congenital malformations among groups. Multivariable logistic regression indicated that children born after PPOS regimen didn't increase the prevalence of congenital malformations compared with those born after short protocol as well as mild ovarian stimulation, with adjusted odds ratio (AOR) of

1.16 (95% confidence interval (CI) 0.54–2.01) and 1.28 (95% CI 0.51–2.42), respectively, after adjusting for maternal age, BMI, parity, insemination method, cycles with Day 3 or blastocyst transfers.

Limitations, reasons for caution: This study was not a randomized controlled trial and the allocation of different ovarian stimulation treatment was not at random. Furthermore, the neonatal data were obtained by questionnaires from parents rather than access to medical records.

Wider implications of the findings: In terms of neonatal outcomes and congenital malformations, treatment with PPOS during COH is as safe as conventional ovarian stimulations.

Trial registration number: not applicable.

P-785 Improved ovarian hyperstimulation syndrome (OHSS) risk management by individualised dosing of follitropin delta based on serum anti-Müllerian hormone (AMH) and body weight

M. Fernandez Sanchez[1], H. Visnova[2], A. Yuzpe[3], B. Mirner Klein[4], B. Mannaerts[5], J.C. Arce[6], & ESTHER-1[7]

[1]IVI Sevilla, Reproductive Medicine, Sevilla, Spain
[2]IVF Cube, Reproductive Medicine, Prague, Czech Republic
[3]Olive Fertility Center, Reproductive Medicine, Vancouver, Canada
[4]Ferring Pharmaceuticals, Global Clinical R&D- Biometrics, Copenhagen, Denmark
[5]Ferring Pharmaceuticals, Science and Medicine Reproductive Health, Copenhagen, Denmark
[6]Ferring Pharmaceuticals, US Development, Parsippany, U.S.A.
[7]on behalf of the ESTHER-1 trial group, Evidence-based Stimulation Trial with Human rFSH in Europe and Rest of World, Copenhagen, Denmark

Study question: To evaluate the clinical benefits of individualised follitropin delta dosage with regard to OHSS risk management.

Summary answer: Individualised follitropin delta compared with conventional follitropin alfa reduces the need for preventive interventions for OHSS and decreases the risk of OHSS following preventive interventions.

What is known already: The risk of early OHSS increases with increasing ovarian response to gonadotropin stimulation. An individualised dosing regimen of follitropin delta (FE 999049) based on AMH (a preferred predictor of ovarian response to gonadotropins) and body weight (a determinant of systemic exposure to follitropin delta), targeting an adequate number of oocytes retrieved, significantly reduced the incidences of preventive interventions for early OHSS and preventive interventions and/or early OHSS compared to conventional follitropin alfa treatment (Nyboe Andersen and Nelson et al, Fertil Steril, 2016).

Study design, size, duration: Randomised, assessor-blind, controlled trial including 1326 patients undergoing their first IVF/ICSI cycle. Patients were randomised 1:1 to individualised follitropin delta dosing (665 patients) or conventional follitropin alfa dosing (661 patients). AMH was measured by Elecsys® AMH (Roche Diagnostics). The follitropin delta dose was fixed throughout stimulation, while the follitropin alfa dose (starting at 150 IU/day) could be adjusted upwards or downwards from day 6 of stimulation based on the individual response.

Participants/materials, setting, methods: Preventive interventions for early OHSS included cycle cancellation due to excessive ovarian response (≥25 follicles of ≥12 mm in diameter), triggering of final follicular maturation with GnRH agonist (triggering criterion 25-35 follicles ≥12 mm) and/or administration of dopamine agonist (if ≥20 follicles ≥12 mm). Early and late OHSS were defined as OHSS with onset ≤9 days and > 9 days, respectively, after triggering of final follicular maturation. OHSS was assessed using Golan's classification (1989).

Main results and the role of chance: In total, 17 and 20 cases of early OHSS were observed in the follitropin delta and follitropin alfa groups, respectively. Statistically significantly fewer patients in the follitropin delta group required preventive interventions for early OHSS compared to the follitropin alfa group (15 vs 30, p = 0.005). The type of preventive interventions employed were GnRH agonist triggering in 10 women in the follitropin delta group and 23 women in the follitropin alfa group (p = 0.019) and administration of dopamine agonist in 5 vs 10 women, respectively. Three women in the follitropin alfa group received both types of intervention. In spite of these preventive interventions, 10 patients developed early OHSS; 1 in the follitropin delta group and 9

in the follitropin alfa group. Early OHSS, 3 mild and 4 moderate cases, occurred despite triggering with GnRH agonist in 7 out of 23 women in the follitropin alfa group. The improved OHSS risk management observed with individualised follitropin delta in relation to early OHSS was also observed for late OHSS, where the number of OHSS cases were reduced to half in the follitropin delta group compared to follitropin alfa (6 vs 12 cases).

Limitations, reasons for caution: The present trial confirms that GnRH agonist triggering can reduce, but not eliminate the incidence of early OHSS. The risk of early OHSS following GnRH agonist triggering in relation to ovarian response needs to be further evaluated in prospective trials.

Wider implications of the findings: Personalised ovarian stimulation based on AMH and body weight provides clinical benefits in OHSS risk management. The lower incidence of OHSS despite preventive interventions suggests a less profound hyperstimulation associated with an individualised follitropin delta dosing regimen compared to a conventional dosing approach.

Trial registration number: NCT01956110.

P-786 Trends in utilization of cryopreserved embryos in the United States from 2004-2013: an analysis of 411,811 cycles

M.S. Christianson[1], F. Sun[2], H. Zhang[2], J.E. Stern[3], A.J. Polotsky[4]

[1]Johns Hopkins University School of Medicine, Gynecology and Obsteterics-Reproductive Endocrinology and Infertility, Baltimore- MD, U.S.A.
[2]Yale School of Public Health, Collaborative Center for Statistics in Science, New Haven- CT, U.S.A.
[3]Dartmouth Geisel School of Medicine, Obstetrics and Gynecology, Lebanon- NH, U.S.A.
[4]University of Colorado Denver, Obstetrics and Gynecology- Reproductive Endocrinology and Infertility, Denver- CO, U.S.A.

Study question: What is the quantity and utilization of embryos cryopreserved at assisted reproductive technology (ART) clinics in the United States from 2004 through 2013?

Summary answer: Embryo cryopreservation without fresh transfer has increased from 7.9% (2004) to 40.7% (2013), with 1,954,548 embryos frozen and 1,237,203 unaccounted for by embryo transfer.

What is known already: Embryo cryopreservation is inherently linked with potential ethical, legal and healthcare policy challenges. Choices regarding disposition of supernumerary embryos which survive cryopreservation involve: a potential future embryo transfer, donation for research, thaw and discard, donation to another couple, or indefinite storage. Evidence suggests that most embryos remain in storage with no specific plan for utilization. In 2003 it was estimated that at least 400,000 embryos were in storage in the United States. The trends in utilization of stored embryos in the U.S. over the past 10 years are unknown.

Study design, size, duration: Historical cohort of U.S. ART cycles reported to the Society for Assisted Reproductive Technologies Clinical Outcomes Reporting System (SART CORS) between 2004 and 2013 in which an oocyte retrieval and embryo cryopreservation took place.

Participants/materials, setting, methods: Over the 10-year period, there were a total of 411,811 autologous fresh ART retrievals from women in whom at least one embryo was cryopreserved. Cycles were categorized by year and by whether they resulted in one of the following: embryo transfer and no pregnancy, embryo transfer and clinical pregnancy, embryo transfer and live birth, or cryopreservation of all embryos with no embryo transfer.

Main results and the role of chance: Of 411,811 IVF cycles in which at least one embryo was cryopreserved, 31.5% resulted in no pregnancy, 48.6% resulted in a clinical intrauterine pregnancy, 41.5% resulted in a live birth and 19.2% had all embryos cryopreserved. The percentage of fresh cycles in which all embryos were frozen increased significantly each year after 2010 with the following percentages of freeze-all cycles: 15.6% (2010), 19.9% (2011), 30.7% (2012) and 40.7% (2013); the trend was significant with P < 0.0001. The mean number of embryos cryopreserved per cycle was 4.75. The number of embryos cryopreserved per year steadily increased from 158,383 in 2004 to 303,203 in 2013 (trend analysis significant, P < 0.0019). During the 10-year period, 1,954,548 embryos were cryopreserved and 717,345 embryos were transferred. In total, 1,237,203 embryos were cryopreserved and are potentially still

in storage, although we cannot account for embryos that were discarded, donated or did not survive the thaw.

Limitations, reasons for caution: This was a retrospective study, therefore only the available parameters could be included. SART CORS cannot account for embryos that were discarded, donated to research or donated to other couples.

Wider implications of the findings: There has been a sharp increase in the U.S. in the number of cycles in which all embryos are frozen and this may result in more embryos in storage and a subsequent increase in disposition decisions required by patients and clinics.

Trial registration number: This study was supported by the Clinical Research Scientist Training Program, Eunice Kennedy Shriver National Institute of Child Health and Human Development (R25 HD 075737).

P-787 Vitrification of cleavage stage embryos result in lower fetal birthweight than slow-freezing method: a large scale retrospective study in two centers

F. GU[1], P. Li[2], L. Guo[2], Y. Xu[2], C. Zhou[2]

[1]Sun-yat sen university, Guangzhou, China
[2]Sun Yat-sen University, Department of Obstetrics and Gynecology- Reproductive Medical Center- The First Affiliated Hospital of SunYat-senUniversity, Guangzhou, China

Study question: Does the embryo freezing method have an impact on the birthweight of newborns from thawed embryo transfer (TET) cycles?

Summary answer: The mean adjusted birthweight was lower in the vitrified group than the slow-freezing embryo transfer group.

What is known already: Vitrification has been successfully used for embryo cryopreservation and is superior to slow-freezing technique regarding the embryo survival rate and live birth rate. However, whether the vitrification method would affect fetal growth and thus the neonatal birthweight is still controversial. Most studies addressed this issue by comparing the neonatal outcome after transferring vitrified embryos with fresh embryo transfer. So far, comparative data of two cryopreservation methods with respect to the singletons' birth outcome is limited.

Study design, size, duration: The retrospective, two-center study was performed for 1797 singleton neonates born after Day 3 embryo transfer of slow frozen or vitrified embryos from January 2012 to December 2016.Each patient contributed only one cycle per group. Outcome measures was neonatal outcome including birthweight, gestational age and gender.

Participants/materials, setting, methods: All Cycles were performed in the First Affiliated Hospital of Sun Yat-sen University and Jiangmen Maternity and Child Health Care Hospital, which were two large reproductive centers in South China. Blastocyst transfer, PGD and IUI cycles were excluded. Only data from singletons born alive after the 28th week of gestation were included in the data analysis.

Main results and the role of chance: One thousand four hundred and seven singleton babies were born from vitrified group and 390 were from slow-freezing embryo transfer. The absolute birthweight was comparable between two groups (3155.5 ± 503.7 g vs. 3200.9 ± 506.4 g, $P<0.05$), but the adjusted birthweight controlled for gestational age and gender in vitrified group is lower than the slow-freezing group (z-score:0.01 ± 1.01 vs. 0.18 ± 1.08, $P<0.05$). The gestational ages were 38.6 ± 1.8 and 38.4 ± 1.7 weeks in the vitrified and slow-freezing group respectively and preterm birth occurred in 8.6% and 9.2% of these two groups without significant difference. The sex ratio (Odds ratio (OR)1.09, 95% condfidence interval (CI):0.97-1.24), rate of small for gestational age (OR:1.22, 95%,95% CI:0.87-1.71) and large for gestational age (OR: 0.82,95% CI:0.55-1.22), as well as the rate of low birthweight (OR:1.02,95% CI:0.67-1.55) and macosomia (OR:0.65,95% CI:0.40-1.06) were all comparable between the two cryopreservation method. After adjusting for numerous confounding factors, multiple linear regression analysis demonstrated that maternal weight, gestational age, embryo freezing method and infant gender were significantly related to neonatal birthweight

Limitations, reasons for caution: Although the data was from two large centers with big sample size which can represent ordinary experience of reproductive centers in South China, it was a retrospective study. Moreover,

researches for the long-term effects of vitrification method on the health of children are essential in the near future

Wider implications of the findings: Vitrified embryo transfer seemed to give rise to a decrease in neonatal birthweight when compared with the slow-freezing technique. Further studies are required to elucidate this issue with larger number of patients. The potential epigenetic changes that might cause the decrease of birthweight should be carefully concerned

Trial registration number: non-clinical trials

P-788 Influence of natural and artificial cycle on obstetric and neonatal outcomes of cryo-thawed embryo transfer: a retrospective study

S. Jing[1], L. Ge[1,2,3], G. Fei[3], L. Guangxiu[1,3], L. Changfu[1], Z. Shuoping[1]

[1]Central south university, Institute of Reproductive & Stem Cell Engineering- School of basic medicine-, Changsha, China
[2]National Health and Family Planning Commission, Key laboratory of Reproductive & Stem Cell Engineering, Changsha, China
[3]Reproductive & Genetic Hospital of CITIC-XIANGYA, Reproductive & Genetic Hospital of CITIC-XIANGYA, Changsha, China

Study question: Are pregnancy complications and neonatal outcomes after artificial cycle frozen-thawed embryo transfer(AC-FET) non-inferior to pregnancy complications and neonatal outcomes after natural cycle frozen-thawed embryo transfer (NC-FET)?

Summary answer: AC-FET is associated with a higher incidence of gestational hypertension, neonatal morbidity, preterm and low birth weight rate compared with NC-FET, especially in twins.

What is known already: Pooling prior retrospective studies of AC-FET and NC-FET results in obstetric and neonatal outcomes. Most studies were forced on live birth rates and clinical/ongoing pregnancy rates.

Study design, size, duration: This retrospective study included data from women and their neonates born after FET since January 2014 to January 2015. Patients after AC-FET and NC-FET both were 872 singletons and 206 twins. Hormone levels, the endometrial thickness before the day of embryo transfer, the obstetric and neonatal outcomes was recorded.

Participants/materials, setting, methods: The study design was a single-center, retrospective study. Pregnancies from donated gametes, surgically retrieved sperm, early miscarriage, stillbirth data and the mother who had pre-pregnancy hypertension, diabetes, intrauterine adhesions, uterine malformations, PCOS/PCO, were excluded in our study. HCG-induced/clomiphene citrate induced ovulation cycles were excluded in the study. Patients from NC-FET were randomized based on a 1:1 allocation to AC-FET for matching the BMI, age and basal endocrine level. All embryos were cryopreserved by vitrification.

Main results and the role of chance: The endometrial thickness was thinner in AC-FET than in NC-FET, [10.60 mm(9.70-11.60) vs. 11.40 mm(10.40-12.40); P < .001 in singletons and 10.55 mm(9.80-11.90) vs. 11.20 mm(10.30-12.30); P < .001 in twins]. Serum Estradiol/Progesterone/Prolactin on the day of before embryo transfer was higher in AC-FET than in NC-FET both on singletons and twins[In singletons: Estradiol: 1066miu/ml(181.7-2213.50) vs. 102.45miu/ml(74.70-142.42); P < .001 and Progesterone: 10.92miu/ml(8.30-14.68) vs. 9.64miu/ml(5.97-13.98); P < .001 and Prolactin: 28.02miu/ml (18.65-42.48) vs. 17.89miu/ml(13.63-23.16); P < .001; In twins: Estradiol: 493.3miu/ml(168.6-1907.5) vs. 93.75miu/ml(71.69-139.93); P < .001 and Progesterone: 10.30miu/ml(8.39-13.28) vs. 8.56miu/ml(5.53-13.25); P < .001 and Prolactin: 23.30miu/ml(17.09-37.06) vs. 17.24miu/ml(12.83-25.45); P < .001]. Pregnancy hypertension was higher in AC-FET than in NC-FET both in singletons(5.29% vs. 3.66%; P=.011) and twins(12.62% vs. 4.85%; P=.003). The incidence of previa was higher in AC-FET than in NC-FET both in the singletons(2.06% vs. 0.57%; P=.010) and in twins(2.43% vs. 0%; P=.061). Neonatal morbidity was higher in AC-FET compared with in NC-FET(5.50% vs. 3.67%; P = 0.067 in singletons and 6.3% vs. 2.4%; P = 0.006 in twins). For twins, pregnancy duration was longer in NC-FET compared with that in AC-FET [37.14 weeks(36.36-37.86) in NC-FET and 36.57weeks(35.14-37.43), P < .001], and the birth weight was higher in NC-FET than in AC-ET (2.65 kg

(2.40 kg-2.90 kg) in NC-FET and 2.55 kg(2.20 kg-2.85 kg) in AC-FET, P < .001). No other difference in the two groups.

Limitations, reasons for caution: The results of this study should be regarded with caution because of its limitations, mainly the retrospective design, confounding factors, and small sample size.

Wider implications of the findings: AC-FET is associated with a higher incidence of gestational hypertension and worse neonatal outcomes compared with AC-FET, especially in twins. The thinner endometrial thickness and the higher estrogen level may be the main cause for higher risk of gestational diseases in AC-FET.

Trial registration number: not applicable.

P-789 Introduction of a novel device for drug administration for ovarian stimulation

J. Guerrero[1], J. Ten[1], A. Rodríguez[1], J. Llácer[2], J. Giménez[2], P. Baviera[2], R. Bernabeu[2]

[1]Instituto Bernabeu, Biology Reproduction, Alicante, Spain
[2]Instituto Bernabeu, Reproductive Medicine, Alicante, Spain

Study question: What is the experience with an injection port for drug administration during ovarian stimulation instead of standard injections?

Summary answer: i-Port® is a well tolerated and effective alternative in terms of oocytes retrieved and gonadotropin consumption that minimizes skin punctures needed to follow the treatment.

What is known already: Ovarian stimulation involves the administration of exogenous hormones for around 9-14 days. Complaints about the number of injections required are frequents. In fact, it is estimated that at least 10% of adults have a fear of needles, which even leads in the most severe cases to avoid any medical treatment. Furthermore, the risk of misadministration is a serious matter of concern. Diabetic patients reported better tolerance to insulin administration with an injection port (i-Port®, Medtronic). We evaluate the applicability of this device in an attempt to reduce the negative impact of multiple needle sticks and increase patient satisfaction.

Study design, size, duration: Proof of concept study including 12 voluntary and healthy oocyte donors to explore the validity for ovarian stimulation with the i-Port® device, that comprises a subcutaneous soft cannula for medication delivery that is virtually painless applied with the aid of an inserter. The device must be replaced with a new one after 3 days. The study was conducted between November and December 2016.

Participants/materials, setting, methods: GnRH antagonist protocol started with an initial dose of 150-300 UI/day of urinary FSH. When lead follicle reached 13-14 mm, the antagonist was administered daily, and final ovulation was triggered with a GnRH agonist. All drugs were administered exclusively through the i-Port®. The main objective was tolerance evaluation assessed with a questionnaire focused on the comfort and the occurrence of adverse reactions. Retrieved eggs and gonadotropin consumption were also evaluated.

Main results and the role of chance: The mean age was 26.0 ± 4.1 years, being in seven cases the first time they underwent ovarian stimulation. No adverse events were reported, only in one case it was not possible to administer medication due probably to the obstruction of the cannula, which made it necessary to replace the device with a new one. The device was very well accepted taking into account that all patients stated that they would use it again and would strongly recommend it to other patients. The length of stimulation was 9.3 ± 1.2 days, with a mean gonadotropin consumption of 2131.3 ± 623.8 IU and 14.4 ± 8.1 retrieved eggs, similar to clinical efficacy that we observe in our donation program during the same period (2450.0 ± 763.1.8 IU consumed and 15.5 ± 7.1 oocytes, non significant). Considering all drugs administered, 12.5 ± 3.2 shots would have needed, that were replaced by the application of 3.3 ± 1.2 devices. No differences were observed in gonadotropin consumption or retrieved eggs in donors with previous cycles, suggesting that there is no interference in the absorption of the medication.

Limitations, reasons for caution: This was a proof of concept study with a limited number of patients oriented to validate the usability of the device. We are conducting a prospective and randomized comparative study with a higher number of cases to contrast the hypothesis of better tolerance compared with conventional injections.

Wider implications of the findings: Any patient, not only donors, could benefit from using the iPort®. Self-administration usually increases anxiety of patients not only because of needle sticks but also because a poor administration when injected may lead to suboptimal response. iPort® supports drug administration to make easier the follow up treatment.

Trial registration number: Not applicable.

P-790 The ARTHIQS joint action – EU wide institutional practice and inspection guidelines in ART

W.N. Strang[1], C. Font Sala[2], F. Merlet[3]

[1]Agence de la biomedecine, DPEGH, Saint Denis La Plaine Cedex, France
[2]Swiss Transplant, International Exchange, Bern, Switzerland
[3]Agence de la biomédecine, PEGH, Saint Denis la Plaine, France

Study question: Can heterogeneous levels of regulatory practice and the transposition of the EU Tissue and Cells Directive (EUTCD) be harmonised to levels of established good practice?

Summary answer: Working widely with the European Union (EU) ART community, ARTHIQS has analysed current practice, developed and disseminated institutional and inspection guidelines and established networks.

What is known already: The specificities of reproductive medicine are not perfectly reflected in the EUTCD. Member State legislation is also varied. This complexifies the missions of inexperienced CA and inspectors and could give rise to concerns about quality, traceability, vigilance, safety and ethics in ART cross border care.

Beyond the challenges of developing generally applicable guidelines, the major objective of the joint action is to have them adopted by the CA and modify their practices.

Study design, size, duration: An initial survey completed by 3 interactive workshops led to the development of two guidelines on institutional good practice and inspection of ART establishments. These guidelines form the basis of training and dissemination.

ARTHIQS is a 3 year EU funded Joint Action project - http://www.arthiqs.eu/

Participants/materials, setting, methods: Fifteen EU MS and nine collaborative partners elaborated surveys and guidelines through interactive authoring and technical workshops.

Training and dissemination is on-going. The EC/CHAFEA and the joint action interact with the MS CA committee to build the stakeholder network.

ESHRE provided invaluable feedback and the Council of Europe and WHO are informed of the joint action's progress and results.

A specific work,package and an External Advisory Board continuously evaluate the joint action's processes and products.

Main results and the role of chance:

- **An EU wide Survey** of the organisational and institutional status and needs of ART Competent Authorities/Delegated Bodies was carried out and analysed.
- **Institutional guidelines** were elaborated to help MS develop appropriate ART governance.
- **Inspection guidance** was produced to help guide and standardise ART establishment inspection and training. This has been completed by a Curriculum for the selection and education of inspectors.
- **Dissemination** of these guidelines is on-going through the CA-ART network and through training of CA staff and inspectors. The role of national, EU wide and international organisations in their critique and uptake is essential.
- **A Network** of ART contact points within the CAs has been established conjointly by the project and the EC. It will continue to exist after the joint action. It is expected to facilitate the implementation of the outcomes of this EU Joint Action in the MS and provide the EC with ART experts, helping to improve legislation.

Limitations, reasons for caution: Developing and disseminating EU-wide guidelines perceived as pertinent by all stakeholders is delicate. The guidelines aim to improve quality, traceability, vigilance and safety of all participants and especially mothers and children. Cross border heterogeneity and weak communications continue to make this task difficult. Dissemination is a key activity.

Wider implications of the findings: ART governance is evolving in the EU, however much remains to be done. The joint action aims at harmonising practices in CA and inspectorates. ARTHIQS feeds into on-going projects and provides the EC/CHAFEA with EU-wide resources. The joint action lays foundations for future CA cooperation.

Trial registration number: not applicable.

P-791   Risk of juvenile idiopathic arthritis among children born to women with fertility problems: a nationwide register-based cohort study

A. Jensen[1], C.D. Sperling[1], M.K. Hansen[2], M. Hargreave[1], S.K. Kjaer[1]

[1]Danish Cancer Society Research Center, Virus- Lifestyle and Genes, Copenhagen, Denmark
[2]Danish Cancer Society Research Center, Statistics and Pharmacoepidemiology, Copenhagen, Denmark

Study question: To examine whether children born to women with fertility problems have an increased risk of juvenile idiopathic arthritis (JIA) compared with children born to fertile women.

Summary answer: There was an increased JIA risk in children born to women with fertility problems; the risk in children born after fertility treatment was not increased.

What is known already: Potential long-term adverse health consequences after fertility treatment has received increasing attention. The existing studies primarily concern childhood cancer, asthma and mental disorders but it has also been suggested that mechanical manipulations of the gametes and embryos as well as the hormonal stimulation used in fertility treatment may affect the development of autoimmune diseases (e.g. diabetes mellitus type 1, hypothyroidism and JIA). However, only few studies have investigated the association between fertility treatment and risk of autoimmune diseases and only one very small study with few exposed cases and short follow-up has examined the risk of JIA after fertility treatment.

Study design, size, duration: This retrospective register-based cohort study included all 1,084,184 live-born children in Denmark between 1 January 1996 and 31 December 2012. All children were followed from date of birth until first diagnosis of JIA as diagnosed in the Danish National Patient Register, date of 16th birthday, date of emigration, date of death or date at the end of follow-up (31 December 2014), whichever occurred first.

Participants/materials, setting, methods: In total, 911,173 children were born to fertile women. 173,011 children were born to women who had ever experienced fertility problems; of these, 37,120 children were conceived after ART procedures and 52,808 children were conceived after use of fertility drugs only. Information on maternal fertility status and fertility treatment was obtained by linkage to The Danish Infertility Cohort. Cox regression models were applied to estimate hazard ratios (HRs) for JIA with adjustment for potential confounders.

Main results and the role of chance: A total of 2,237 children received a diagnosis of JIA during the follow-up period. Children born to women who had ever experienced fertility problems had a modest, but statistically significantly, increased risk of JIA (HR 1.15; 95% confidence interval (CI) 1.03-1.29) compared to children born to fertile women. However, children conceived after use of any ART (HR 1.03; 95% CI 0.81-1.30), in vitro fertilization (IVF) (HR 0.98; 95% CI 0.72-1.35), intracytoplasmic sperm injection (ICSI) (HR 0.96; 95% CI 0.63-1.46) or fertility drugs only (HR 1.13; 95% CI 0.94-1.37) were not found to be at higher risk for JIA compared with children born to fertile women. We also analysed the risk of JIA among children conceived after respectively any ART, IVF, ICSI or fertility drugs only, compared to a reference group of children born to all other women with fertility problems, but without the type of treatment analysed, in order to investigate whether there was an additional effect of fertility treatment besides the underlying infertility; however, the conclusions remained unchanged.

Limitations, reasons for caution: Even though the present study was based on data from high-quality Danish health registers, we cannot completely rule out that the exposure variables and the outcome variable might have been slightly misclassified, which would have led to a small bias of the results.

Wider implications of the findings: The results are based on national data and our findings can therefore be applied to other similar populations. However, at this point, further studies are needed to confirm our results and elucidate the explanatory factors of a potentially increased risk of JIA in children born to women with fertility problems.

Trial registration number: Not applicable.

P-792   Procoagulant properties of circulating microparticles, and subsequent intravascular coagulation, in women with ovarian hyper stimulation for in vitro fertilization

S. Cointe[1], E. Dos Santos[2], R. Lacroix[3], F. Vialard[2], J. Selva Rameix[4], S. Valérie[2], D.G. Françoise[5], R. Wainer[6], A. Fauconnier[7], F. Boitrelle[8], S. Florence[9], A. Torre[10]

[9]Faculté de Pharmacie de Marseille, VRCM- UMR-S1076-, Marseille, France
[10]Arnaud de Villeneuve Univertity hospital of Montpellier, Department of Reproductive Medicine, Montpellier, France

Study question: Can endothelial, erythrocyte, leukocyte or platelet cell microvesiculation be responsible for the procoagulant state observed after ovarian hyper stimulation for in vitro fertilization (IVF)?

Summary answer: Although no vesicular marker of cell activation quantitatively changed throughout IVF cycle, microparticles' procoagulant qualitative properties increased at ovulation triggering, followed by subsequent intravascular coagulation.

What is known already: IVF and more Ovarian Hyperstimulation Syndrome (OHSS) histories are risk factors for intravascular thrombosis during the first trimester of pregnancy. Several modifications of coagulation factors have been invoked to explain the procoagulant state following IVF; however, the involved mechanisms remain poorly understood. Recently, microparticles (MPs) have emerged as new cell-derived effectors resulting from cell activation in the vascular compartment with a key role in regulating haemostasis. We hypothesized that MPs are associated with the coagulation disturbance observed after IVF.

Study design, size, duration: Prospective cohort study, performed between the 25th of April 2012 and the 2nd of January 2015 in the Department of Reproductive Medicine of the Poissy's University Hospital.

Fifty one not smoking infertile volunteers, aged 18 to 35 years, with neither cardiovascular disease nor Lupus erythematosus related disease, and assessed from their day 3 basal hormonal assessment, at least to the ovarian triggering of their IVF cycle were included. Samples were frozen stored before being processed.

Participants/materials, setting, methods: Included women were scheduled for blood sampling at 6 different times of the IVF cycle, including day 3 basal hormonal assessments, first day of FSH stimulation, ovarian triggering day, day 2 embryo transfer, mid-luteal phase, and pregnancy test. For each sample, MP subsets from endothelial, erythrocyte, leukocyte, and platelet origins, MP functional properties (Tissue Factor-Dependent Procoagulant Activity (MP-TF), Plasmin Generation Capacity (MP-PGC)), and markers of intravascular clot formation (Fibrin monomer, D-dimer) were measured.

Main results and the role of chance: Women were 33.1 years old (95%CI 31.8-34.3). Among the 51 included women, the stimulation protocol was antagonist in 33 (64.7%), long in 10 (19.6%), and ultra-long in 8 (15.7%). Sixteen women (31.3%) were assessed at all times of their IVF cycle. Of the 6 sampling initially scheduled, women had a mean of 3.9 assessments (95%CI 3.3-4.3). The minimum number of available samples was 25 at mid-luteal phase. Endothelial-, erythrocyte-, leukocyte- and platelet-MPs showed no quantitative variation throughout IVF cycle. MP-TF showed a dramatic burst in activity, from 13.2 fM [25th-75th

percentile, 5.9-20.3 fM] to 32.5 fM [17.3-56.7 fM] (+145%), limited to the time of embryo transfer (p = 0.01). A wave of MP-PGC subsequently occurred during the luteal phase, with maximum activity of 2.8 mDO/min [1.6-4.6 mDO/min], compared to basal activity of 1.7 mDO/min [1.2-2.7 mDO/min] (+65%), shifted at mid-luteal phase (p = 0.028). This thrombolytic reaction was significantly associated with the peak of MP-TF activity (spearman r^2 = 0.63, p = 0.001). Finally, subclinical intravascular clot formation was proved by Fibrin monomer formation, from 2.4 µg/ml [1.8-3.5 µg/ml] to 3.6 µg/ml [3.3-4.8 µg/ml] (+50%, p = 0.001) and D-dimer formation from 0.28 µg/ml [0.23-0.48 µg/ml] to 1.44 µg/ml [1.0-2.1 µg/ml] (+415%, p = 0.001), both shifted at mid to late-luteal phase.

Limitations, reasons for caution: Because of the small size of our cohort and of the heterogeneity of our stimulation protocols, our results should be interpreted with caution.

Wider implications of the findings: We highlighted for the first time, a procoagulant process, occurring throughout IVF cycle, for which microparticles are mediators or markers. MP-TF could thus potentially provide a promising marker of thrombotic risk following IVF.

Trial registration number: Not applicable.

P-793   Effects of FSH vs LH stimulation on bone metabolism

M. Schmidmayr[1], A. RItzinger[2], B. Lesoine[3], D. Berg[4], V. Seifert-Klauss[5]

[1]Technische Universität München, Frauenklinik und Poliklinik- Klinikum rechts der Isar, München, Germany
[2]Technische Universität München, Frauenklinik und Poliklinik - Klinikum rechts der Isar, Munich, Germany
[3] A.R.T. Bogenhausen GmBH, A.R.T Bogenhausen GmbH, Munich, Germany
[4] A.R.T. Bogenhausen GmbH, A.R.T. Bogenhausen GmbH, Munich, Germany
[5]Technische Universität München, Frauenklinik und Poliklinik- Klinikum rechts der Isar, Munich, Germany

Study question: Does ovarian stimulation therapy affect bone metabolism – and is there any difference between rFSH and HMG stimulation?

Summary answer: Fertility treatment seems to have a protective influence on bone in short term. There was no significant difference between rFSH and HMG.

What is known already: Osteoporosis is one of the most common illnesses worldwide which causes high morbidity. Since 1947 we know about the positive effects of estrogen on bone [Reifenstein EC et al. Clin Orthop Rel Res 2011]. Since in 2006 Sun et al showed that ovarectomised rats do not lose as much bone mass after hypophysectomy than without hypophysectomy, a direct influence of FSH on osteoclasts has been discussed [Sun L et al. Cell 2006]. As FSH as well as LH/FSH combinations are used for ovarian hyperstimulation in fertility treatment, effects on bone metabolism should be investigated.

Study design, size, duration: In this prospective observational study blood samples of 95 patients were taken on four time points during 106 long protocol stimulation cycles (FSH n = 16, HMG n = 54): T1 – luteal phase of the previous cycle/start of GnRH analogues; T2 – start of stimulation; T3 – oocyte retrieval; T4 – luteal phase of stimulation cycle.

Participants/materials, setting, methods: Inclusion criteria were FSH <20mIU/ml at T1, no disease or medication with influence on bone metabolism, like anorexia or systemic glucocorticoids. At every time point bone resorption markers C-terminal telopeptide (CTX) and tartrate-resistant phosphatase (TRACP) as well as formation markers osteocalcin (OC) and bone specific alkaline phosphatase (BAP) and sex hormones follicle stimulating hormone (FSH), luteinising hormone (LH) and 17ß-estradiol (E2) were measured. At T1 calcium and vitamin D3, at T4 progesterone were additionally analysed.

Main results and the role of chance: Parameters of bone resorption CTX and TRACP as well as the bone formation marker OC were – in part significantly* – lower at T4 (CTX: 0.24 mg/ml, TRACP: 1.79U/l*, OC: 16.6 ng/ml*) than T1 (CTX: 0.26 mg/ml, TRACP: 2.09U/l*, OC: 18.5 ng/ml*). Only the bone formation marker BAP was slightly, but not significantly, higher at T4 (9.95 µg/l) than at T1 (9.75 µg/l).

Parameters of bone metabolism did not significantly differ after HMG- compared to FSH-stimulation. BAP, OC and TRACP were slightly but not significantly higher in the FSH group at T4 (FSH group: BAP 10.23 µg/l, OC 18.39 ng/ml, TRACP 2.08U/l; HMG-group: BAP 9.87 µg/l, OC 16.22 ng/ml, TRACP 1.71U/l), CTX was equal for both groups (0.24 mg/ml).

Limitations, reasons for caution: This study included a limited number of patients. Especially in the FSH subgroup data of 16 patients only were analysed. Only short term effects are investigated in this study. Further studie are needed for more evidence concerning bone safety of ovarian stimulation.

Wider implications of the findings: Ovarian hyperstimulation seems to have a beneficial effect on bone, so there is no reason not to treat patients with an elevated risk for osteoporosis.

There is no evidence for a difference between FSH and HMG. Nevertheless one should keep in mind that pregnancy itself is connected with bone loss.

Trial registration number: As this study is not an interventional study there is no trial registration number.

P-794   Morbidity and mortality associated with assisted reproduction tecniques (ART) in our hospital since 2011 to 2016

M. Urtasun Murillo[1], S. García-Francés[1], J. Barrenetxea Arrinda[1], B. Pérez Munárriz[1], N. Abián Franco[1], A. Safont Gascon[2], B. Gastón Moreno[1], I. Zabaleta Loinaz[1], M. Ruiz García[1], J. Zabaleta Jurio[1], M. Huarte Ciganda[1], G. Campo Molina[1]

[1]Complejo Hospitalario de Navarra, Obstetricia y Ginecología, Pamplona, Spain
[2]Complejo Hospitalario de Navarra, Ostetricia y ginecología, Pamplona, Spain

Study question: To analyze the morbidity and mortality associated with the techniques of fertility carried out since the start of our service in 2011 until 2016.

Summary answer: We analyzed the rates of complications including mortality in our patients in five years, and we evaluate if the data are similar to the literature

What is known already: The incidence of hemoperitoneum is 0.06-0.08% and is caused by trauma to ovarian or intrafolicullar vessels, pelvic organs (uterus, bladder, colon) or iliac vessels.

The infection is an exceptional complication, with a frequency of 0.007% according to SEGO. There are several theories to explain infection: direct inoculation from the vagina, a history of pelvic inflammatory disease or endometriosis, or puncture of an intestinal loop.

Ovarian hyperstimulation syndrome (OHSS) is an iatrogenic complication of unknown etiology, with an incidence of 0.6-10% of patients undergoing ovarian stimulation. Severe SHO occurs in 0.52% of IVF cycles and may compromise the lives of patients.

Study design, size, duration: We performed a retrospective observational study of the 8301 patients treated using assisted reproduction techniques, both through artificial insemination (AI) and in vitro fertilization (IVF) in our hospital between 2011 and 2016 and we analyzed the morbidity and mortality derived from the fertility treatments

Participants/materials, setting, methods: We analyzed a total of 8301 patients, who underwent ART during the years 2011 and 2016 in the same hospital, analyzing the rates of complications during the cycles. The morbidity analyzed were: hemoperitoneum with or without income, mild ovarian hyperstimulation syndrome (no admission) or moderate-severe (with admission), infection, embryonic reduction and other complications. We also look for cases of maternal mortality associated with ART.

Main results and the role of chance: From 2011 to 2016, a total of 8301 patients diagnosed with infertility were treated in our hospital (1,084 in 2011, 1,413 in 2012, 1,589 in 2013, 1,450 in 2014, 1,401 in 2015 and 1,364 in 2016). The complications derived from the treatments were: 11 hemoperitoneum, 9 of them (0.1%) required admission, 3 (0.2%) in 2012, 1 (0.1%) in 2013 and 4 (0.3%) in 2014. Two patients did not required admission, one in 2014 and one in 2015.

In total we had 78 cases of hyperstimulation syndrome, 34 (0.4%) were moderate and severe cases that required hospitalization, 6 cases (0.6%) in 2011, 5 (0.4%) in 2012, 7 (0.4%) in 2013, 9 (0.6%) in 2014, 5 (0.4%) in 2015 and 2 (0.1%) in 2016. 44 cases (0.5%) were mild cases with outpatient management: (0.2%) in 2011, 4 (0.3%) in 2012, 11 (0.7%) in 2013, 9 (0.6%) in both 2014, 2015 and 2016.

Both cases of infection (0,02%) required hospital treatment, one in 2013 and one in 2014.

15 patients (0,2%) requested embryo reduction, 6 (0.6%) in 2011, 2 (0.1%) in 2012 and in 2014, 1 in 2013 (0.1 %) and 4 (0.3%) in 2015

We had no mortality cases.

Limitations, reasons for caution: It should be taken into account that this is a descriptive and retrospective study to analyze the complications associated with our sample, but we do not have a comparison group. The large sample size helps us get our data.

Wider implications of the findings: The rates of complications associated with ART are similar in patients treated at our service than data published in the literature, and remain stable over the years. Fortunately, we have not mortality cases associated with these treatments.

Trial registration number: It's not a trial.

P-795   Triplet-to-twin fetal reduction may increase risk of demise in the remaining fetuses

S. Santos Ribeiro[1,2], H. Tournaye[1], N.P. Polyzos[1,3,4]

[1]Universitair Ziekenhuis Brussel, Centre for Reproductive Medicine, Brussels, Belgium
[2]Santa Maria University Hospital, Department of Obstetrics- Gynaecology and Reproductive Medicine, Lisbon, Portugal
[3]Dexeus University Hospital, Department of Reproductive Medicine, Barcelona, Spain
[4]Faculty of Health University of Aarhus, Department of Clinical Medicine, Aarhus, Denmark

Study question: Does fetal reduction (FR) improve the neonatal outcomes of the remaining twins in triplet pregnancies following ART?

Summary answer: FR was associated with a reduced risk of premature delivery <32 weeks but increased risk of subsequent fetal demise.

What is known already: ART has increased the incidence of triplet pregnancies which are associated with potentially severe obstetrical complications. Triplet-to-twin FR is frequently proposed to women with these higher-order pregnancies, in the expectation that such a technique may reduce the subsequent risks of preterm delivery and neonatal death. Nonetheless, given the scarcity of studies evaluating the benefits of this approach, the ideal management strategy of triplet pregnancies remains rather elusive.

Study design, size, duration: We performed a United Kingdom population-based retrospective analysis of all twin and triplet intrauterine pregnancies following ART cycles included in the anonymized database of the Human Fertilisation and Embryology Authority (HFEA) between 2000 and 2011. We subdivided these pregnancies in the following 3 study groups: twin (Group A), triplet-expectant-management (Group B) and triplet-to-twin (after FR, Group C) pregnancies. Pregnancies in which a fetal termination for reasons other than elective FR was performed were excluded.

Participants/materials, setting, methods: A total of 27005 intrauterine twin/triplet pregnancies were included in the analysis (26124 twin, 777 triplet-expectant-management and 104 triplet-to-twin pregnancies, respectively). Our main outcomes measures were preterm delivery <32 weeks and the number of live birth deliveries. Given the effect of female age on miscarriage rates, we performed multivariable logistic regression in all these analyses to account for this potential confounder, performing pairwise comparisons whenever warranted.

Main results and the role of chance:

	Twin	Triplet-expectant-management	Triplet-to-twin	p-value
	(Group A)	(Group B)	(Group C)	
	n = 26124	n = 777	n = 104	
Female age				<0.001
18-34	61.7%	57.9%	53.9%	
35-37	24.6%	25.5%	31.7%	
38-39	9.4%	8.9%	7.7%	
40-42	4.1%	7.3%	6.7%	
>42	0.2%	0.4%	0.0%	

Continued

Continued

	Twin	Triplet-expectant-management	Triplet-to-twin	p-value
	(Group A)	(Group B)	(Group C)	
	n = 26124	n = 777	n = 104	
Type of ART treatment				<0.001
Artificial insemination	1.4%	3.9%	8.7%	
IVF/ICSI	98.6%	96.1%	91.3%	
Preterm delivery				
<32 weeks	8.4%	24.0%	9.8%	<0.001*‡
Live birth delivery				
Of at least 1 fetus	94.9%	92.2%	90.5%	<0.001*†
Of at least 2 fetuses	82.9%	82.9%	46.8%	<0.001†‡
Of 3 fetuses	-	61.1%	-	-

*The predicted preterm and live-birth delivery rates were adjusted for female age using multivariable logistic regression; pairwise comparisons p<0.05 for the *A-versus-B, †A-versus-C and ‡B-versus-C groups, respectively.*

Twin and triplet-to-twin pregnancies had similar preterm delivery rates <32 weeks (8.4% and 9.8%, respectively), both of which were significantly lower than the risk observed in the triplet-expectant-management group (24.0%). Conversely, triplet-to-twin pregnancies had the lowest chance of delivering at least two live borns, when compared to both the twin and triplet-expectant-management groups. Specifically, women who performed FR had a 46.8% chance of delivering both of the remaining twins, which was significantly lower than the 82.9% odds of triplet-expectant-management pregnancies.

Limitations, reasons for caution: Owing to the use of this particular registry, we could not account for other potential confounding factors such as the timing and specific methods used for FR, which both may have varied substantially among the treatment centers contributing data.

Wider implications of the findings: While our results confirm that FR may indeed reduce the risk of preterm delivery, they also show that this may come at the cost of an increased risk of fetal demise. Such conclusions stress the utmost importance of considering triplet pregnancies as an ART complication to be avoided.

Trial registration number: Not applicable.

P-796   The rate of elective terminations in second trimester due to fetal malformation is similar in pregnancies conceived after assisted reproduction compared with spontaneous conception

A.K.A. Henningsen[1], C.B. Wulff[2], A. Tabor[3], A. Pinborg[4]

[1]Rigshospitalet- University Hospital of Copenhagen, Fertility Clinic, Copenhagen, Denmark
[2]Rigshospitalet- University Hospital of Copenhagen, Departmen of Fetal Medicine, Copenhagen, Denmark
[3]Rigshospitalet- University Hospital of Copenhagen, Department of Fetal Medicine, Copenhagen, Denmark
[4]Hvidovre Hospital- University Hospital of Copenhagen, Department of Obstetrics and Gynecology, Copenhagen, Denmark

Study question: Are women pregnant after assisted reproduction less likely to terminate a pregnancy after detection of a fetal malformation compared with spontaneously pregnant women?

Summary answer: We found similar rates of second trimester pregnancy terminations, regardless of mode of conception.

What is known already: Numerous studies have found an increased risk of congenital malformations among live-born children conceived after assisted reproduction compared with spontaneously conceived children. The underlying subfertility matters, as children born by couples taking a long time to conceive spontaneously also have an increased risk of congenital malformations. Still the assisted reproductive technology may also play a role. Little is known concerning the prenatal detection rate of fetal malformations in pregnancies conceived after assisted reproduction and it is unclear if women pregnant after assisted reproduction are more or less likely to terminate a pregnancy due to a fetal malformation.

Study design, size, duration: A 6-year Danish population-based cohort study including 20 723 pregnancies conceived after assisted reproduction and 280 287 spontaneously conceived pregnancies. Assisted reproduction included IVF, ICSI, frozen-embryo-transfer, intrauterine insemination and ovulation induction. All data were retrieved from the Danish Fetal Medicine Database, which includes information on combined first trimester screening for aneuploidies, anomaly scans and data on pregnancy outcome from the Danish Cytogenetic Central Register, the Danish National Patient Register and the Danish National Birth Register.

Participants/materials, setting, methods: Pregnant women who opted for the Danish National prenatal screening program from 2008 to 2013. Data on fetal malformations were based on ultrasound findings at the combined first trimester screening for aneuploidies (week 11 to 14) or at the anomaly scan (week 18 to 21). In Denmark termination of pregnancies is legal until 12 weeks of gestation. Late termination can be performed until 22 weeks of gestation but requires specific permission from the Health Authorities.

Main results and the role of chance: Fetal malformations were detected among 1.95% (n = 404) of the fetuses conceived after assisted reproduction versus 1.73% (n = 4860) of the spontaneously conceived fetuses, p = 0.02. When adjusting for known confounders such as BMI, smoking, maternal age and parity the adjusted odds ratio was 1.18 [1.03-1.35] for fetal malformations. The rate of termination after week 12 was 0.9% among women pregnant after assisted reproduction and 0.8% among spontaneously pregnant women, p = 0.02. Still, the indications for terminating the pregnancy differed between the two groups. In women pregnant after assisted reproduction 87.7% of the second trimester terminations were on fetal indications, where the fetus was diagnosed with a malformation or severe illness, compared with only 71.2% of the second trimester terminations in the group of spontaneously pregnant women, p<0.0001. As most pregnancies after assisted reproduction are planned, this explains why very few second trimester terminations were performed on other indications, than fetal malformations or severe fetal illness.

Limitations, reasons for caution: Information on mode of conception is self-reported in the Danish Fetal Medicine Database and may therefore be insufficient. Furthermore the study included only fetal malformations detected by ultrasound and were not confirmed by karyotypes or postnatal pediatric examinations.

Wider implications of the findings: The higher risk of malformations in live-born children conceived after assisted reproduction versus spontaneous conception cannot be explained by a higher tendency to continue a pregnancy despite a fetal malformation in women pregnant after assisted reproduction. Therefore a prenatal selection-bias cannot explain the increased malformations rates after assisted reproduction.

Trial registration number: Not apllicable

P-797   Effects of VEGF+ adipose tissue derived mesenchymal stem cells with platelet rich plasma on inbred rat ovarian functions in premature ovarian insufficiency model

B. Vural[1], G. Duruksu[2], F. Vural[3], M. Görguc[2], E. Karaoz[4]

[1]Kocaeli University, Department of Obstetrics and Gynecology, Kocaeli, Turkey
[2]Kocaeli University, Department of Stem Cells, Kocaeli, Turkey
[3]University of Health Sciences- Haydarpasa Numune Training and Research Hospital, Department of Obstetrics and Gynecology, Istanbul, Turkey
[4]Istinye University, Department of Histology and Embryology, Istanbul, Turkey

Study question: Does the single or co-transplantation of VEGF[+] mesenchymal stem cells (MSCs) and platelet rich plasma (PRP) improve the ovarian function of cyclophosphamide treated inbred rats?

Summary answer: MSCs supported the ovarian stroma improving the development of functional follicles by interacting with theca and granulosa cells, while PRP-treatment demonstrated anti-inflammatory and anti-apoptotic effects.

What is known already: Premature over insufficiency (POI) is an infertility problem that occurs in females under 40 years of age and is currently limited in treatment possibilities. The in vivo and in vitro studies including stem cell treatment-attempts to recover the ovarian function and fertility are at very early-stage.

Study design, size, duration: In this study, 72 inbred rats (Fisher 344) were used, which were divided in 5-groups (control, sham, VEGF[+]MSC, PRP and VEGF[+]MSC+PRP). The POI model was developed by injecting 100 mg/kg cyclophosphamide in the abdominal area of the rats. MSCs were isolated from adipose tissue of Fisher-344 rats (n = 10) and the blood was collected from the same animals to isolate PRP by serial centrifugation. MSCs were labeled with GFP and improved with VEGF by gene transfection.

Participants/materials, setting, methods: After two-months following the injection of VEGF[+]-MSCs and/or PRP, the blood samples were analyzed with respect to the AMH and Estrodiol (E_2) levels. The ovarian tissues were collected and the follicles were counted and categorized following the staining with haematoxylin-eosin. The gene expression analyses were performed to estimate the degree of inflammation and apoptosis beside the regenerative status of the tissue. The results were confirmed by immune-fluorescence staining and evaluated by blind-analyses.

Main results and the role of chance: After two months following the transplantation of cells and/or PRP into the disease model rats, the total follicle numbers of VEGF[+]MSC and VEGF[+]MSC+PRP groups were significantly improved compared to the sham-group, P < 0.01 and P < 0.01 respectively. The recovery level of follicle number for these two groups corresponded to 63% of that in control group. The fractions of primordial follicles within the total follicle count in VEGF[+]MSC and VEGF[+]MSC+PRP groups were estimated as high as those in the control. PRP-group samples showed weak recovery with high variance within itself. In all experimental groups, AMH levels were increased with respect to sham-group, and quantitatively reached to half of the control group level. The E_2 level was increased to the highest in the VEGF[+]MSC+PRP group (P:0.002, P:0.035 and P:0.014 respect to sham, VEGF[+]MSC and PRP). The BMP4, TGF-beta and IGF-1 expressions in VEGF[+]MSC+PRP group were increased 6-, 5-, 7-fold compared to control-group, and significantly higher than in sham-group. Additionally, the MSCs were localized in the stroma and around the primary, secondary, pre-antral and antral follicles. In the follicles of VEGF[+]MSC and VEGF[+]MSC+PRP groups, DDX-4 positive cells were also determined.

Limitations, reasons for caution: During the study, the number of animals in sham group was reduced to its half of initial number due to the side effect of cyclophosphamide treatment. However the remaining number of animals in this group was still sufficient for a proper statistical analysis.

Wider implications of the findings: MSCs application was shown to be important for the recovery of ovarian function and folliculogenesis. The alone-administered PRP was not sufficient for the recovery, but it was crucial for inflammation suppression. However, when MSCs and PRP were given together, the highest recovery in functional follicles was obtained on this model.

Trial registration number: none.

P-798   Estrogen enhances endothelial differentiation and angiogenic activity in rat adipose-derived stromal cells

H.J. Chiang[1], L. Steve[2]

[1]Chang Gung Memorial Hospital-Kaohsiung, Obstetrics and Gynecology, Niao - Sung Hsiang- Kaohsiung, Taiwan R.O.C.
[2]Chang Gung Memorial Hospital-Kaohsiung, Institute for Translational Research in Biomedicine, Niao - Sung Hsiang- Kaohsiung, Taiwan R.O.C.

Study question: Whether estrogen regulates endothelial differentiation of mesenchymal stem cells (MSCs), and may be helpful in cytotherapy against ischemic organ injury.

Summary answer: The endothelial differentiation of adipose-derived MSCs could be enhanced by the estrogen treatment.

What is known already: Menopause women has been reported poorer prognosis after cardiovascular event than man at the same age. The rapidly deteriorating endothelial function after menopause has been suggested the major cause. Cytotherapy with MSCs has been proved effective to recovery ischemic organ injury,however, the efficacy of cytotherapy depends on the endothelial differentiation of MSCs. To reverse the poorer prognosis of menopause women in cardiovascular event, estrogen may play an important role.

Study design, size, duration: Animal study, total 12 Sprague Dawley (SD) rats were used in this study through September to December 2016.

Participants/materials, setting, methods: Adipose-derived MSCs were isolated form abdominal adipose tissues of male SD rats and cultured in endothelial cell growth medium (EGM-2) with or without estrogen treatment (l00 nM of 17α-estradiol) for 14 days to induce endothelial differentiation. After culturing, Flow cytometric analysis, Matri-gel and trans-well examination, and immunofluorescent stainings were performed to examine the endothelial differentiation and angiogenic activity.

Main results and the role of chance: Restuls from immunofluorecent stainings showed the nuclear translocation of estrogen receptor β (ER-β) in adipose-derived MSCs after culturing with estrogen. Expression levels of endothelial progenitor cell markers (CXCR4/CD34, Sca-1/KDR, c-Kit/CD31) were increased with estrogen treatment in flow cytometric analysis. The migratory and in vitro angiogenic activity of adipose-derived MSCs were also enhanced by estrogen treatment. In addition, abundant expression level of angiogenic factors VEGF was found in adipose-derived MSCs treated with estrogen.

Limitations, reasons for caution: Our data was limited to animal study, further study will be needed to examine the regulatory mechanism and signalling pathway of estrogen in MSCs.

Wider implications of the findings: Estrogen regulating endothelial differentiation of MSCs could be applied in cytotherapy against ischemic organ injury in rats.

Trial registration number: nil.

P-799   Galectin-1 Regulates Mouse Trophoblast Stem Cell Migration and Invasion

J. You, W. Wang, M. Tang, Y. Ye, A. Liu, Y. Zhu

Women's Hospital- School of Medicine- Zhejiang University, Department of Reproductive Endocrinology, Hangzhou- Zhejiang, China

Study question: What is the role of Galectin-1 in trophoblast stem cells?

Summary answer: Galectin-1 could regulate mouse TS cell migration and invasion.

What is known already: Galectin-1 is highly expressed in mouse blastocysts and trophoblast giant cells during implantation and dysregulated Galectin-1 is associated with many pregnancy-related abnormalities. Elevated Galectin-1 contributes to certain cancer cells invasion.

Study design, size, duration: in vitro cell culture and in vivo embryo study.

Participants/materials, setting, methods: The expression of Galectin-1 in mouse oocyte, pre-implantation embryos (zygote, 2, 4, 8 cell stages, and blastocyst), and mouse TS cells were examined by RT-qPCR, Western blot, immunofluorescence. Endogenous Galectin-1 expressions in mouse TS cells were manipulated by adenoviral infection or small interfering RNA transfection, and the expressions of downstream genes were assayed by RT-qPCR and Western blot. The migratory and invasiveness of mouse TS cells were examined by transwell migration and invasion assay, respectively.

Main results and the role of chance: Galectin-1 is expressed in mouse oocyte, all stages of pre-implantation embryos, and mouse TS cells. Peak levels of Galectin-1 mRNA and protein are detected in day 4 and 5 after induction of TS cells differentiation, respectively. Overexpression of Galectin-1 increases TS cell migratory and invasive capability, and knockdown of Galectin-1 attenuates these effects. Additionally, expressions of matrix metalloproteinase (MMP) 2/9 as well as several epithelial mesenchymal transition (EMT) and TGFβ related molecules were altered after manipulating Galectin-1 expression in TS cells.

Limitations, reasons for caution: Experiments in embryos and TS cells are limited in mouse only.

Wider implications of the findings: Our study revealed the importance of Galectin-1 in trophoblast stem cell differentiation and trophoblast cell migration as well as invasion, which may provide us a better understanding of the complexity of molecular dynamics during implantation and placentation.

Trial registration number: We do not need trial registration number.

P-800   Higher restoration of liver fibrosis by stem cells derived from Menstrual Blood compared to those of Bone Marrow in mice model

M. Fathi-Kazerooni[1], M. Taghizadeh-Jahed[2], S. Khanjani[2], H. Golshahi[3], G. Tavoosidana[1], S. Kazemnejad[2]

[1]*Tehran University of Medical Sciences- School of Advanced Technologies in Medicine, Molecular medicine, Tehran, Iran*
[2]*Avicenna Research Institute, Tissue engineering, Tehran, Iran*
[3]*University of Tehran- Faculty of Veterinary Medicine, Pathology, Tehran, Iran*

Study question: Could menstrual blood stem cells (MenSCs) be considered as an appropriate substitute of bone marrow stem cells (BMSCs) for the treatment of acute liver failure?

Summary answer: Menstrual blood stem cells have the more therapeutic effect than bone marrow stem cells in the restoration of acute liver failure.

What is known already: Cell-based therapies have focused on the use of human bone marrow-derived mesenchymal stem cells for liver regeneration, but their main limitation is limited availability, invasive sample collection, and low proliferation capacity.

Menstrual blood-derived stem cells have advantages including high proliferation rate, high accessibility, renewability, and sustainability in culture without genetic abnormalities and non-ethical concerns. In previous studies, we showed the higher in vitro transdifferentiation ability of these cells into hepatocyte- like cells in comparison with BMSCs.

Study design, size, duration: After in vitro differentiation of both stem cells into hepatocyte progenitor-like (HPL) cells, MenSCs and BMSCs in undifferentiated or differentiated state were separately transplanted intravenously 48 hours after induction of liver fibrosis in Balb/C mice (each group = 5 mice). For in vivo tracking, the cells were labeled by GFP expression. All mice were sacrificed at 7 and 30 days post-transplantation to examine biochemical and molecular markers and evaluate pathological appearances.

Participants/materials, setting, methods:
- GFP transfection was done by Electroporation and tracking of GFP-transduced MenSCs was done with an in vivo imaging system.
- H&E, PAS and Masson's trichrome staining was done to evaluate liver tissue restoration, glycogen storage ability, and collagen appearance.
- The mRNA expression of hepatic markers including tyrosine aminotransferase, albumin, cytokeratin-18 and cytochrome P450 family 7 Subfamily A member 1 (CYP7A1) and inflammatory markers including IL-6 and COX-2 was examined using Real-time PCR.

Main results and the role of chance:
- Tracking of GFP-labeled MenSCs showed the migration of cells into injured areas of the liver during 1 hour after transplantation.
- MenSCs and differentiated MenSCs succeeded to engraft into the host liver.
- Transplantation of both type stem cells could improve glycogen storage ability and decrease the collagen fibers deposition in the liver sections.
- Assessment of serum parameters at day 7 exhibited significant reductions (all $P \leq 0.01$), such this downward trend continued until day 30.
- The restoration of liver biochemical markers and changes in mRNA levels of hepatic markers like albumin and CYP7A in the MenSCs treated group was more significant compared with the BMSCs treated group.
- MenSCs were more efficient than BMSCs in the suppression of mRNA expression of inflammatory markers such as interleukin-6 and cyclooxygenase-2 ($P \leq 0.01$, $P \leq 0.05$, respectively).
- HPL cells in reference to undifferentiated cells had the better effectiveness in the treatment of the acute liver injury.

Limitations, reasons for caution: The possibility of animal mortality after liver fibrosis induction: the induced animals are so susceptible due to the disorder of liver functionality.

Wider implications of the findings: MenSCs can be introduced as a new promising replacement for BMSCs for liver fibrosis treatment. The evaluation of these cells in standardized clinical trials is required to prove the future clinical application of these cells. Moreover, more studies on possible mechanisms govern on liver tissue restoration by MenSCs should be defined.

Trial registration number:

P-801   Efficient production of trophoblast lineage cells from human induced pluripotent stem cells

J. Kojima[1], A. Fukuda[2], H. Taira[3], T. Kawasaki[3], S. Takamizawa[4], T. Hasegawa[4], H. Ito[4], N. Kuji[4], K. Isaka[4], A. Umezawa[3], H. Akutsu[3]

[1]Tokyo Medical University, obstetrics and gynecology, Tokyo, Japan
[2]National Research Institute for Child Health and Development-, Center for Regenerative Medicine-, Tokyo, Japan
[3]National Research Institute for Child Health and Development, Center for Regenerative Medicine, Tokyo, Japan
[4]Tokyo Medical University, Department of Obstetrics and Gynecology, Tokyo, Japan

Study question: there may be different optimal conditions for trophoblast differentiation of human induced pluripotent stem cells (hiPSCs).

Summary answer: there are optimal conditions for BMP4 (Bone morphological protein 4) -induced trophoblast differentiation from hiPSCs.

What is known already: Embryonic stem (ES) cells and hiPSCs can differentiate into extra-embryonic cells in the presence of BMP4.

Different differentiation protocols are often used in different studies, and varying culture conditions may have resulted in conflicting observations.

Furthermore, given that the genetic background of human induced pluripotent stem cells is predominantly responsible for transcriptional and epigenetic differences.

In this study, in order to define molecular features of BMP4-mediated differentiated cells and optimal conditions for efficient production of trophoblast cells, we conducted a large-scale, high-fidelity gene expression assay following treatment of differentiated cells with various concentrations of BMP4.

Study design, size, duration: Three iPS cell lines (menstrual blood, uterine endometrium and placental artery) established in our laboratory were used in this study.

hiPSCs were subcultured 7.5×10^4 cells per well to the animal and human-drived substitues free medium, supplemented with Bone morphogenetic protein 4 (BMP4 0,5,10,20,50,100 ng/mL) up to 10 days.

Participants/materials, setting, methods: hiPS cells used in this study were established by retroviral infection of 4 reprogramming factors (OCT-3/4, SOX2, c-MYC, and KLF4), and transgene silencing was confirmed.

Samples were harvested from 1, 3, 5, 8, and 10 days for analysis of differentiation.

We analyzed population doublings (PDs), chemiluminescence enzyme immunoassay and electrochemiluminescence immunoassay of placental hormones in the culture medium, Immunofluorescence, gene expression assay, and flow cytometry.

Main results and the role of chance: The morphologic changes occurred after about 5days.

High dose of BMP4 (100 ng/mL) induce apotosis in some hiPSC.

The concentration of HCG, P4 and the expression levels of various trophoblast marker genes are upregulated by BMP4 in dose-dependent manner in all types of hiPS cells.

HCG and HLA-G positive cells were different in immunohistochemistry in day10.

High dose BMP4 differentiation formed cluster in array card analysis. However, miRNA expression states were not upregulated by BMP4.

Furthermore, single-cell analysis using flow cytometry revealed that the proportions of cells expressing HCG were increased by treatment with a high dose of BMP4, but not similar results were identified in KRT7 (cytotrophoblast marker) and HLA-G (extravilloustrophoblast marker)

It was demonstrated that hiPS cells could differnttiate to trophoblast lineages in animal and human-drived gradient free conditions, since the expression states of trophoblast-related genes and proteins were detected on BMP4 supplementation. Non-coding RNA expression states were affected by donor cell types rather than dose effect of BMP4 and single cell analysis reveal there is tendency to differentiate into syncytiotrophoblast or extravilloustrophoblast. It indicates the optimal conditions for trophoblast differentiation from hiPS cells differs among parental cell lines.

Limitations, reasons for caution: Our result indicated there are optimal conditions for trophoblast differentiation from hiPSCs.

However, We constituted only in vitro cell differentiation model.

It is difficult to reproduce early placentation, because of lacking in vivo model.

Our results will aid in the production of patient-specific trophoblast cells from hiPSCs.

Wider implications of the findings: Establishment of differentiation protocol into trophoblast lineage become powerful tool to research early human placentation.

Trial registration number: Nothing.

P-802   ChIP-seq reveals a different genomic distribution of epigenetic mark H3K27me3 at ICR/DMRs of imprinted genes induced by morphine in mouse Embryonic Stem Cells (mESCs)

I. Muñoa[1], M. Gianzo[1], J. Halsall[2], C. Ward[3], P. Garcia[3], B. Turner[2], N. Subiran[1]

[1]University of the Basque Country, Physiology Department- Faculty of Medicine and Nursery, Leioa, Spain
[2]University of Birmingham, Chromatin and Gene Expression Group- School of Cancer Sciences- College of Medical and Dental Sciences, Birmingham, United Kingdom
[3]University of Birmingham, Institute of Biomedical Research. Institute of Cancer and Genomic Sciences College of Medical and Dental Sciences, Birmingham, United Kingdom

Study question: To elucidate if the chronic treatment of morphine could have an impact on imprinted genes at transcriptional an epigenetic level.

Summary answer: Morphine modifies the expression of the imprinted genes and increases the enrichment of H3K27me3 at the ICR/DMR of imprinted genes in mESC.

What is known already: Normal mammalian development requires maternal and paternal contribution, attributed to imprinted genes. Those are controlled by cis-acting regulatory elements, termed imprinting control regions (ICRs) and have parental-specific epigenetic modifications. ICRs are CG-rich sequences, differentially methylated in a region called DMRs. We have found that the epigenetic regulator complex polycomb/H3K27me3; involved in processes such as cellular memory, genomic imprinting, X-inactivation, and the transgenerational epigenetic memory; can play an important role in the epigenetic memory induced by morphine in mESC. Therefore, our aim is to analyze, if the impact of morphine or other external stimuli, could have important consequences at genomic imprinting.

Study design, size, duration: Chronic morphine treatment was performed incubating mESC during 24 h. Gene expression and epigenetic analysis was carried out by qRT-PCR and ChIP-sequencing approaches.

Participants/materials, setting, methods: The global expression of H3K27me3 was quantified by immunoblotting analysis. Imprinted gene expression was carried out by qRT-PCR. The genomic distribution of the epigenetic mark H3K27me3 was explored by the chromatin immunoprecipitation with subsequent High Throughput Sequencing (ChIP-seq). Following the sequencing, the bioinformatic resources allowed to study the imprinted genes.

Main results and the role of chance: qRT-PCR showed that morphine changes the gene expression of imprinted genes, confirming that those genes are the targets of morphine in mESC. For example, we observed that paternally expressed Rasgrf1 and Peg1 showed a significant decrease in their expression while paternally expressed Peg5 and Peg10 presented an increased expression. Moreover, immunoblotting analysis indicated a significant down regulation in H3K27me3 at protein level. ChIP-Seq analysis confirmed the previous results, showing a decrease in the number of peaks and genes enriched by H3K27me3 after morphine treatment. The alterations induced by morphine at H3K27me3

gene enrichment were not restricted to promoter. In fact, they were more frequent in the gene body and transcription start site regions and, mostly, they matched with CpG island sites. Analyzing the distribution of the H3K27me3 along the landscape of imprinted genes, surprisingly, we observed an increase of H3K27me3 enrichment at ICRs/DMRs, providing an epigenetic mechanism that can be modified by morphine. Maternally expressed Meg3 and paternally expressed Peg1 were affected in the DMRs, and maternally expressed H19 and paternally expressed Peg3 and Peg10 in the ICRs, all of them colocalizing with CpG island regions.

Limitations, reasons for caution: Further methylation analysis would be of interest to complete and support our study.

Wider implications of the findings: Morphine modifies the epigenetic status of imprinted genes at ICRs/DMRs providing an epigenetic mechanism that can be modified by external environmental agents. The effect of morphine on imprinting could have an impact on the cellular memory, genomic imprinting, X-inactivation, embryionic development and transgenerational epigenetic inheritance, worthy to be study.

Trial registration number: N/A.

P-803　Study of the reparative effects of human mural granulosa iPSCs-derived granulosa cells on premature ovarian failure in mice

C. Bing

First Affiliated Hospital of SunYat-sen University, reproductive medicine center, Guangzhou-Guangdong, China

Study question: Can graulosa-like cells which derived from human mural granulosa iPS(GiPS) restore ovarian dysfunction associated with premature ovarian failure (POF)?

Summary answer: Graulosa -like cells derived from human GiPS, may restore damaged ovarian function and offer a suitable clinical strategy for regenerative medicine.

What is known already: Young female patients who receive chemotherapy frequently face premature ovarian failure (POF),for which there are currently no ideal treatments or medications. Furthermore, apoptosis of ovarian granulosa cells is an important mechanism underlying the decline in ovarian reserve and function.

Study design, size, duration: Mice ovaries were injured with cyclophosphamide to create a damaged ovary mice model. Transplanted GiPS-derived granulosa like cells were injected into the tail vein of sterilized mice (n = 20), or culture medium was injected into the sterilized mice via the tail vein as chemoablated group (n = 20). Non-sterilized mice were untreated controls (n = 20). ovarian tissue weight,plasma E2 level,and the number of follicles was compared in all groups.

Participants/materials, setting, methods: Human mural granulosa cells were collected from egg follicles retrieved from women undergoing infertility treatment.After short-term culture, the granulosa cells were infected with Sendai viral vectors. GiPSCs were subjected to further determin their pluripotent characteristics. We used two step approaches comprising in vitro treatments with cocktails of growth factors (Wnt 3a,ActivinA,BMP4,ect) for 12days. Expression of granulosa cell markers were analyzed using immunohistochemistry,FACS,and quantitative PCR.

Main results and the role of chance: Ovarian tissue weight,plasma E2 level,and the number of follicles were all significantly higher in cell treated group compared with chemoablated group.These results suggest that GiPS-derived granulosa like cells may not only effectively enhance granulosa cells growth and repair damaged ovarian tissue, but may also maintain the ovarian tissue niche, promoting follicular development and maturation.

Limitations, reasons for caution: Although GiPSCs-derived granulosa cells did not induce teratoma formation in vivo in the POF mice,the undifferentiated iPSCs are still potential risk in clinical trial in future.

Wider implications of the findings: Our research results showed that GiPSCs-derived granulosa cells can repair ovarian injury, stimulate regeneration, and improve ovarian function. GiPSCs-derived granulosa cells transplantation may provide an effective and novel method for treating POF.

Trial registration number: not applicable.

P-804　Identification of integrin heterodimers expressed on the surface of spermatogonial stem cells in inbred mice

N.R. Han[1], M.H. Park[1], H.J. Park[1], H.J. Song[2], J.I. Yun[3], S.T. Lee[4]

[1]*Kangwon National University, Department of Animal Life Science, Chuncheon, Korea- South*
[2]*Kangwon National University, Division of Animal Resource Science, Chuncheon, Korea- South*
[3]*Seoul Women's Hospital, Fertility Medical Center, Bucheon, Korea- South*
[4]*Kangwon National University, Department of Animal Life Science and Division of Applied Animal Science, Chuncheon, Korea- South*

Study question: What is type of integrin heterodimers expressed functionally on the undifferentiated spermatogonial stem cells (SSCs) derived from mouse with inbred strain?

Summary answer: The inbred (C57BL6) mouse-derived SSCs have integrin $\alpha_4\beta_1$ and $\alpha_V\beta_1$, $\alpha_V\beta_3$ and/or $\alpha_V\beta_5$ on plasma membrane.

What is known already: Microenvironments surrounded with various extracellular matrix (ECM) components can decide specifically the fate of SSCs and integrin heterodimers recognizing directly ECM proteins play an important role in transporting ECM-derived signals into cytoplasm, resulting in inducing a variety of biological functions such as cell attachment, self-renewal and differentiation. However, to date, studies on type of integrin heterodimers expressed functionally on the undifferentiated SSCs derived from mouse with inbred strain with reproducibility of conclusions remain unclear.

Study design, size, duration: We tried to investigate systematically what kind of integrin heterodimers are expressed transcriptionally, translationally and functionally in the SSCs derived from testis of inbred (C57BL/6) mouse.

Participants/materials, setting, methods: Magnetic activated cell sorting (MACS) using Thy1 antibody was used for isolating SSCs from testis, and real-time PCR or fluorescence immunoassay was conducted for measuring transcriptional or translational level of integrin α and β subunits in the isolated SSCs. Subsequently, antibody inhibition assay was conducted for confirming functionality of presumed integrin heterodimers.

Main results and the role of chance: In quantifying transcriptional levels of genes encoding total 25 integrin subunits, 4 integrin α (α_3, α_4, α_V and α_L) and 5 integrin β (β_1, β_3, β_4, β_5 and β_7) subunit genes showed significantly increased transcriptional up-regulation, compared to the other integrin subunit genes. When translational levels of the integrin α subunits showing high transcription level (α_3, α_4, α_V and α_L) were measured, significantly strong translational up-regulation of integrin α_V and α_L subunit genes were detected, whereas integrin α_3 and α_4 subunit genes were translated weakly. Moreover, integrin β_1 and β_4 subunit genes showed significantly stronger translational up-regulation than integrin β_3, β_5 and β_7 subunit genes. Based on these results, we speculated that the undifferentiated SSCs derived from C57BL/6 mouse might express integrin $\alpha_3\beta_1$, $\alpha_4\beta_1$, and $\alpha_V\beta_1$, $\alpha_V\beta_3$ and/or $\alpha_V\beta_5$ on plasma membrane. Subsequently, attachment of integrin $\alpha_4\beta_1$ and $\alpha_V\beta_1$, $\alpha_V\beta_3$ and/or $\alpha_V\beta_5$ in SSCs to fibronectin and vitronectin showed significantly higher levels of adhesion, whereas attachment of integrin $\alpha_3\beta_1$ to laminin didn't showed significantly adhesion. Moreover, functional blocking of integrin $\alpha_4\beta_1$ and $\alpha_V\beta_1$, $\alpha_V\beta_3$ and/or $\alpha_V\beta_5$ in SSCs significantly inhibited attachment to fibronectin and vitronectin, respectively.

Limitations, reasons for caution: This results were derived from only mouse with inbred strain. Therefore, studies on the expression of integrin heterodimers in hybrid strain mouse, other species and human should be conducted in the future.

Wider implications of the findings: This information will greatly contribute to constructing non-cellular niche supporting self-renewal of SSCs derived from inbred mouse in the future.

Trial registration number: N.A.

P-805　A Simple Method to Differentiate Mouse Embryonic Stem Cells into Male Germ Cells

V. Lu, A. Parrella, S. Chow, C. O'Neill, M. Irani, Z. Rosenwaks, G. Palermo

Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.

Study question: We evaluated several methods for creating and maintaining differentiating cells in order to induce primordial germ cell (PGC) appearance.

Summary answer: Creation of embryoid bodies (EB) in hanging droplets (HD) supplemented with differentiating factors yielded PGCs more consistently and at a higher proportion.

What is known already: Differentiation of embryonic stem cells (ESC) often proceeds through the formation of EBs, three-dimensional aggregates of stem cells which have the ability to spontaneously form ectodermal, mesodermal, and endodermal layers. EBs can be formed in HDs or in suspension. After formation, EBs can be cultured with growth factors in order to obtain PGCs. Development of PGCs has also been reported without the need to go through EB formation by simply adding growth factors to cells cultured in wells.

Study design, size, duration: From April 2016 to January 2017, 260 EBs were formed from mouse embryonic stem cells (mESC) via the hanging drop method. After formation, EBs were maintained with media supplemented with differentiating factors in either HDs or in culture dishes. ESCs were also separately cultured with differentiating factors in well-plates. PGC differentiation was assessed by germ cell-alkaline phosphatase (GCAP) and immunofluorescence staining.

Participants/materials, setting, methods: mESCs were maintained on mouse embryonic fibroblast (MEF) cells. Confluent colonies were passaged by trypsinization. 1000 feeder-free mESCs were placed in 25uL HDs. After 2 days, EBs were either transferred to HDs containing RA or cultured in dishes with RA. On day 8, EBs were treated with collagenase and stained for AP/OCT4/DAZL. A separate cohort of mESCs were maintained in well-plates supplemented with Activin A/bFGF/KSR. Cells were re-plated after 3 days and maintained with LIF/BMP4/BMP8b/SCF/EGF.

Main results and the role of chance: After the development of 260 EBs in their respective HDs, 100 EB were re-plated on day 2 to corresponding HDs containing RA while the remaining 160 EBs were transferred to RA-supplemented Petri dishes. On day 8, EBs cultured in HDs reached approximately 150um in diameter, while EBs in dishes reached 280-300um. All EBs were frozen in a DMSO solution at day 8 for later analysis. After thawing, EBs were treated with collagenase IV to isolate individual cells for staining. GCAP staining of EBs cultured in HD yielded an average of 77% GCAP positive cells, while those in dishes only presented 22% GCAP postivity. EBs were also assessed for OCT4 activity to determine loss of stemness. In HD-cultured EBs, 40% of isolated cells were strongly positive for OCT4, compared to 60% of cells isolated from EBs cultured in dishes, indicating a higher level of cell differentiation in the former. DAZL staining was also performed to undoubtedly detect male germ cell appearance. EBs cultured in HDs yielded 5% DAZL-positive cells, whereas EBs cultured in dishes only yielded 1% DAZL-positive cells. Because of the peculiarity of the multi-well culture, assessment for PGD appearance is still being carried out.

Limitations, reasons for caution: This is a preliminary study assessing only the early stages of differentiation with somewhat limited efficiency. Once confirmed that HD culture in the presence of differentiating factors is the best method to expeditely generate PGCs, the next step would be toward enhancing efficiency and coaxing towards post-meiotic stages.

Wider implications of the findings: ESC differentiation offer the possibility to generate gametes in vitro. Mouse ESCs provide a great inexpensive and ethically acceptable model to experiment with these procedures. These cells, however, are not genotyped to the individual. Using pluripotent stem cells would ultimately generate genotyped gametes useful for patient treatment.

Trial registration number: Not applicable.

P-806 Differentiation of primordial germ cells from premature ovarian insufficiency-derived induced pluripotent stem cells under 3i culture system

S. Yang[1], S. Peng[2], S. Ding[3], Q. Xu[3], Q. Xiong[3]

[1]Human Reproduction Center, Hongkong University-Shenzhen Hospital, Shenzhen, China
[2]The Key Laboratory of Carcinogenesis and Cancer Invasion of the Chinese Ministry of Education- the Key Laboratory of Carcinogenesis of The Chinese Ministry of Health and Cancer Research Institute, Central South University, changsha, China
[3]Department of Obstetrics and Gynecology, First Affiliated Hospital of Anhui Medical University, Hefei, China

Study question: Can the induced pluripotent stem cells (iPSCs) derived from patient with primary ovarian insufficiency (POI) differentiate into germ cells for potential disease modeling in vitro?

Summary answer: POI-iPSCs under 3 inhibitors (3i) culture system have potential of germline competence and could differentiate into primordial germ cells (PGCs) with potential for meiotic progression.

What is known already: iPSC technology is an approach for generating patient-specific stem cells for disease modeling and for developing novel therapies. It has also been confirmed that iPSCs differentiate into germ cells under routine culture. But we did not know if the iPSCs derived from POI patients had the potential of germline competence, and if PGCs differentiated from POI-iPSCs could initiate the meiotic progression.

Study design, size, duration: We compared the differentition ability of PGCs, the gene expression level of germ cell-related genes, and the potential of initiating the meiotic progression in iPSCs derived from POI patients with an iPSCs derived from normal fibroblasts, and in 3i culture system with routine culture system.

Participants/materials, setting, methods: We established 12 POI-iPSCs by retroviral transduction using defined factors under 3i culture system. The morphology, growth characteristics, gene expression profiles, and differentiation in vitro and in vivo of POI-iPSCs were analyzed. Then, POI-iPSCs were pre-induced in N2B27 medium, then were transfer to PGCs medium for further induction. We analyzed some critical determinant for human PGC gene induction, such as sox17, BLIMP1, CD38, and meiotic progression assay.

Main results and the role of chance: Our results showed the POI-iPSCs were successfully generated from POI patients' adult cells under 3i culture system. The POI-iPSCs can be induced to differentiation into PGCs with normal karyotypes. This study proved that disease special iPSC lines derived from POI patients could be generated and successfully differentiated into PGCs with the potential for meiotic progression.

Limitations, reasons for caution: In this study, the differentiated PGCs could progress further to meiosis, and form follicles remains to be determined in the study of POI.

Wider implications of the findings: This provide a new biological cell model and approach for studying pathogenesis of POI with genetic tendency and discovering potential drugs for POI.

Trial registration number: No clinical trial.

P-807 Systemic administration of bone marrow derived stem cells or uterine derived stem cells is superior to local injection in a mouse uterine injury model

Y. Liu[1], R. Tal[2], N. Pluchino[2], R. Mamillapalli[2], H.S. Taylor[2]

[1]Beijing Obstetic and Gynecology Hospital, Department of Reproductive Medicine, Beijing, China
[2]Yale University School of Medicine, Obstetrics- Gynecology & Reproductive Sciences, New Haven, U.S.A.

Study question: It is unknown whether uterine-derived cells (UDCs) may confer an advantage over bone marrow derived cells (BMDCs) by local intra-uterine injection or systemic administration

Summary answer: BMDCs is greater than UDCs, and systemic administration results in better recruitment to the uterus than local injection

What is known already: Stem cells have been shown to undergo recruitment into the uterus where they can differentiate into endometrial cells

Study design, size, duration: Eight-week-old C57BL/6 J wild-type mice underwent local uterine injury to the left horn following laparotomy. Mice were divided into four treatment groups (n = 14 in each group) as BMDCs-iv, BMDCs-iu, UDCs-iv and UDCs-iu groups. BMDCs (1×10^7 cells), UDCs (5×10^5 cells) from green fluorescent protein (GFP transgenic donors) or saline (control) were injected either intravenously or locally (uterine lumen) into wild-type recipients. Additionally, groups PBS-iv and PBS-iu received saline injection serving as controls.

Participants/materials, setting, methods: Mice were sacrificed following 2 or 3 weeks after BMDCs or UDCs injection, and uteri tissues were collected for FACS analysis and immunohistochemistry/immunofluorescence studies.

Main results and the role of chance: FACS analysis showed that mice injected intravenously with BMDCs had increased recruitment of GFP$^+$ cells at

2 weeks and 3 weeks compared to those injected locally (0.264% vs.0.042%, P = 0.0075,2 weeks; 0.217% vs. 0.03%,P = 0.004, 3weeks, to the non-injured uterus) (0. 261% vs.0.0475%, P = 0.0024,2 weeks; 0.22% vs. 0.058%, P = 0.029, 3 weeks, to the injured uterus). Moreover, mice injected intravenously with UDCs demonstrated greater recruitment of GFP$^+$ cells to the injured uterus at 3 weeks compared with those injected locally (0.048% vs. 0.022%) (P = 0.0029). In addition, systemic injection BMDCs led to significantly greater recruitment of GFP$^+$ cells at 2 weeks and 3 weeks to the uterus compared with UDCs (0.252% vs.0.022%, P = 0.0042, at 2 weeks; 0.217% vs. 0.0225%, P = 0.0237, at 3 weeks, to the non-injured uterus) (0.288% vs.0.044%, P = 0.0053, at 2 weeks; 0.22% vs. 0.048%, P = 0.0162, at 3 weeks, to the injured uterus). For local injection, there were no significant differences between BMDCs or UDCs Cells at 2 weeks or 3 weeks (P > 0.05). Immunohistochemical staining of uterine tissues demonstrated that GFP$^+$ cells were found in stroma but not in epithelium or blood vessels. Immunofluorescence results revealed that GFP$^+$ cells were mostly CD45 negative, and were negative for CD31 and cytokeratin, confirming their stromal identity.

Limitations, reasons for caution: Further studies are necessary to investigate the differences in therapeutic potential and mechanisms between BMDCs and UDCs in repairing the uterus.

Wider implications of the findings: These findings may inform investigators developing stem-cell based therapies targeting the uterus.

Trial registration number: not applicable
