Study design, size, duration: This is a retrospective study including 1528 intracytoplasmatic sperm injection (ICSI) cycles performed from January 2012 to December 2017, in which time lapse technology and static embryo morphology were utilized to assess embryo development across different BMI groups. Main morphokinetic endpoints were time intervals from the beginning of embryo culture to reach two (t2), three (t3), four (t4), five (t5) and eight (t8) blastomeres-stages. Multivariate linear regression was used to analyze continuous variables.

Participants/materials, setting, methods: Women included in this study were in their first ICSI cycle utilizing autologous oocytes. The cohort was divided into four groups: 593 embryos from 128 underweight women (BMI<18.50 kg/m^2) in group A; 5248 embryos from 1107 normoweight women (BMI 18.50–24.99 kg/m^2) in group B; 1053 embryos from 226 overweight women (BMI 25.00–29.99 kg/m^2) in group C and 286 embryos from 67 obese women (BMI≥30 kg/m^2) in group D.

Main results and the role of chance: A total of 1528 ICSI cycles and 7180 embryos were assessed with time lapse technology. No statistical differences across BMI groups were found for female age, male age, number of oocytes retrieved, percentage of mature oocytes and embryo quality score based on static morphology. Data were normalized for maternal age, paternal age and cause of infertility. Embryos from obese women showed a delay in t5 in comparison with normoweight women [50.84 h (46.31 - 55.29) *vs.* 49.24 h (45.69 - 53.22), adjusted p <0.05)], while embryos from both overweight and obese patients showed a delay in t8 in comparison with normoweight women [56.72 h (51.83 - 63.92) and 57.89 h (51.60 - 65.94) *vs.* 55.66 h (50.89 - 62.89), respectively, adjusted p <0.01]. These results suggest that maternal obesity and overweight slows embryo development during embryo culture, which can be observed by assessing embryo morphokinetics, but not static morphology.

Limitations, reasons for caution: We acknowledge that our study is limited by its retrospective nature and by the utilization of data generated in a single IVF center.

Wider implications of the findings: Our results suggest that standard embryo morphology is not sufficiently accurate to detect effects of obesity and overweight on embryo development. The use of time lapse technology may be useful to improve embryo selection and ART prognosis for obese and overweight patients.

Trial registration number: None

P-213 Dual buffering handling medium is better on Blastocyct development

K. Yildiz[1], U. Ucar[2], A. Akinci Bak[2], D. Denizhan[2], R. Pabuccu[2]

[1]*Dogufertil IVF Center, Assisted Reproductive Technology Department, MALATYA, Turkey*

[2]*Private Dogufertil IVF Center, Assisted Reproductive Technology Department, malatya, Turkey*

Study question: Does dual buffering handling medium has superiority over single buffering handling medium on in vitro oocyte handling?

Summary answer: Blastocyst development and cryopreservation of embryo rates are significantly higher in dual buffering medium. No differences in fertilization and on going pregnancy rates.

What is known already: Appropriate culture conditions is needed for gametes and embryos to minimize stress of in vitro conditions. Therefore a stable pH is crucial for oocytes which are lack of robust mechanisms especially without protective cumulus cells. Some laboratory procedures like oocyte pick-up, denuding oocytes or microinjection are susceptible to pH fluctations which can affect outcomes. Most IVF handling media utilize HEPES or MOPS to stabilize enviromental pH as single-buffering systems. Use of dual buffering system containing HEPES and MOPS together may have beneficial effects over single systems.

Study design, size, duration: Prospective randomized comperative study from 2018 to 2019. Fresh Tese+ICSI and Thaw Tese+ICSI patients excluded from the study. In total 385 fresh ICSI cycles randomized as 212 dual buffering medium(MOPS+HEPES) usage and 175 single buffering medium (HEPES) usage. In all the procedure like oocyte pick-up, denudation of oocytes and microinjection, one of these handling mediums used. When we see at least three good quality embryos on day three we extended the culture to day 5.

Participants/materials, setting, methods: We used as a dual buffering handling medium MHM (Irvine Scientific) and a single buffering medium QA with HEPES (CooperSurgical). Primary outcome measure was fertilization and ongoing pregnancy rates between the groups and also day 5 blastocycst development and cryopreservation rates was evaluated. Groups were comparable according to women age. Presence of fetal heart beats at 12 weeks of gestation assumed as ongoing pregnancy positive. Chi-square is the statistical test. P<0.05 is significant.

Main results and the role of chance:

Table A	MHM (MOPS+HEPES) n=212	QA (HEPES) n=175	P Value
Fertilization rates in general	% 69 (1090/1578)	% 66.5 (833/1252)	0.15
On going Pregnancy rates in general	% 42.4 (90/212)	% 39.4 (69/175)	0.54
Day 5 blastocycst transfer rate	% 52.8 (112 / 212)	% 40.5 (71/175)	0.016
Fertilization rates in day 5 blastocycst group	% 71.6 (802/1119)	% 69.1 (536 / 775)	0.2
On going Pregnancy rates in day 5 blastocycst group	% 55.3 (62/112)	% 53.5	0.8
Cryopreservation rates of good quality surplus embryos in general	% 50 (106/212)	% 37.1 (65/175)	0.011

According to our results there is no significant difference between fertilization rates and on going pregnancy rates in general groups. And also there isn't a significant difference in day 5 blastocycst formation groups according to fertilization and ongoing pregnancy rates. However day 5 blastocyst transfer rate is significantly increased with dual buffering handling media and cryopreservation of good quality surplus embryos increased significantly in dual buffering handling medium group (Table A).

Limitations, reasons for caution: This study is compared HEPES+MOPS medium and HEPES only medium, therefore may not fully reflect the situation of MOPS only buffered medium.

Wider implications of the findings: This study demonstrates that dual buffering handling medium(MOPS+HEPES) has more stable pH as a result with better and more blastocycst development than single HEPES buffering medium. And though more embryos for cryopreservation which may be good for PGD on the way for getting a healthy baby.

Trial registration number: not applicable

P-214 Granulocyte macrophage colony-stimulating factor (GM-CSF) influences pre-implantation embryos by modulating cell fate and cell identity in the trophectoderm

T. Pock[1], K. Schulte[2], S. Schlatt[1], M. Boiani[3], V. Nordhoff[1]

[1]*Centre of Reproductive Medicine and Andrology, Experimental embryology, Münster, Germany*

[2]*Central Animal Facility of the Faculty of Medicine, Experimental embryology, Münster, Germany*

[3]Max Planck Institute for Molecular Biomedicine, Mouse embryology, Münster, Germany

Study question: Does GM-CSF influence expression patterns of cell lineage markers in murine blastocysts during pre-implantation development?

Summary answer: Mouse embryos cultured in medium supplemented with GM-CSF show a dose-dependent increase of ectopic expression of the pluripotency marker NANOG in trophectoderm cells.

What is known already: GM-CSF is a cytokine influencing the maternal-fetal interface and supporting placental development in mouse and human. It is expressed in epithelial cells of the endometrium under regulation of estrogens. A large clinical trial showed that GM-CSF supplemented embryo culture medium leads to an increased survival of embryos up to week 12. Especially in women with previous miscarriages GM-CSF supplementation of culture medium improved implantation rates. Animal and cell culture studies on isolated trophectoderm cells supported an effect on cellular expansion and pluripotency pathways after exposure to GM-CSF.

Study design, size, duration: Mouse zygotes were produced *in vivo* and cultured *in vitro* up to the blastocyst stage (day 4.5) in culture media supplemented with mouse and human recombinant GM-CSF (1, 2, 5, 10 and 20 ng/ml). A total of 715 blastocysts were fixed and subjected to immunohistochemical staining. Markers of the three cell lineages trophectoderm (CDX2), epiblast (NANOG) and primitive endoderm (SOX17) enabled selective scoring of absolute cell numbers. 604 immunostained blastocysts were eligible for further analysis.

Participants/materials, setting, methods: 68 female mice (B6C3F1, 5-10 weeks old) were superovulated by injection of 5 IU PMSG and 10 IU hCG and mated to males (C57BL/6J). Zygotes were isolated on day 0.5 post coitum, pooled and randomly allocated to KSOM(aa) with or without GM-CSF. Medium refreshment was applied on day 2.5.

Main results and the role of chance: 604 blastocysts were scored. Total blastocyst cell numbers changed significantly between KSOM(aa) with 0, 2 and 5ng/mL mouse GM-CSF and between 2 and 5ng/mL and 20 ng/mL ($p<0.005$; mean values: 0 ng/mL mGM-CSF: 80.2±18.8; 1ng/mL: 84.5±15.7; 2ng/mL: 90.9±16.7; 5ng/mL: 91.4±13.5; 10ng/mL: 86.1±14.9; 20ng/mL: 76.2±17.1). Total cell numbers did not change in human GM-CSF groups (mean values: 0 ng/mL hGM-CSF: 78.4±18.7; 1ng/mL: 73.9±14.8; 2ng/mL: 74.7±14.5; 5ng/mL: 75.7±13.4; 10ng/mL: 78.7±15.6; 20ng/mL: 68.0±17.7). 519 of 604 embryos (86%) showed normal expression of specific cell lineage markers, whereas 85 of 604 embryos (14%) showed an ectopic expression of NANOG among CDX2-positive trophectoderm cells at increasing concentrations of either mouse or human GM-CSF supplemented media. While embryos cultured in medium supplemented with mouse GM-CSF showed abnormalities only in the highest concentrations (KSOM(aa) +10ng/mL: 40%; +20ng/mL: 39%), embryos cultured in human GM-CSF showed abnormalities already from the lowest concentration onwards (0 ng/mL: 0%; 1ng/mL: 11%; 2ng/mL: 15%; 5ng/mL: 29%; 10ng/mL: 24%; 20ng/mL: 35%).

Limitations, reasons for caution: This study was performed in a mouse model and would need further investigation in other animal models or experiments with human embryos to elucidate and validate the influence of GM-CSF on ectopic NANOG expression and its consequences on trophectoderm cells during pre-and post-implantation development.

Wider implications of the findings: GM-CSF has led to an ectopic expression of the pluripotency marker NANOG in trophectoderm cells. This may be due to a change of identity because of a false reprogramming or due to change of location because of false positioning. Either way, these errors could impact the pre- and post-implantation processes.

Trial registration number: DFG NO 413/3-3 and BO2540/4-3

P-215 Pilot study of novel noninvasive imaging approach for determination of meiotic status in intact human cumulus-oocyte-complexes.

D. Albertini[1], J. Hu[2], N. Gleicher[2], V. Kushnir, A[2], Y. Ohara[3], A. De Grand[3], D. Barad, H[2]

[1]Center for Human Reproduction, Division of Laboratories, Salisbury, U.S.A.

[2]Center for Human Reproduction, n/a, New York, U.S.A.

[3]Olympus America- Inc, n/a, Waltham, U.S.A.

Study question: Can the maturation status of intact human cumulus-oocyte-complexes (COCs) be determined noninvasively without removal of cumulus cells?

Summary answer: Combinatorial imaging using of intact COCs revealed properties of cell-cell and cell-zona adherence correlated with oocyte meiotic stage and quality in 36/38 samples tested.

What is known already: Cumulus cell metabolic support is vital to acquisition of developmental competence in human oocytes. It may be compromised when removing somatic cells to visualize maturity status and to enable ICSI. Resistance to gonadotropin stimulation, as occurs with advancing maternal age, often leads to the retrieval of immature oocytes that, once denuded, exhibit impaired developmental potential.

Study design, size, duration: Prospective cohort study, to evaluate oocyte maturity in intact COCs.

Participants/materials, setting, methods: Intact COCs retrieved from 11 patients undergoing routine IVF. Five (5) were oocyte donors (24-29 years), and 6 were infertility patients (36-43 years). Individual COCs were imaged under polarization, relief contrast, and bright field optics in 35mm glass-bottom dishes for 5-7 min at 36 degrees C, and incubated for 2-4 hours prior to stripping with hyaluronidase. Each sample was re-imaged, and mature oocytes underwent ICSI with resulting embryos cultured to day-3.

Main results and the role of chance: Combinatorial optics and image analysis revealed distinct changes in zona pellucida (ZP) and adhesion sites of cumulus cells to the outer surface of the ZP. In 36 of the 38 samples analyzed. Oocyte maturity status was predictable based on retardance values in the ZP (positive if mature in 18/24 M2s; negative in 10/12 GV, M1, or atretic oocytes). An inverse correlation was noted between stage of maturity and cumulus cell cortical birefringence for cells remaining attached to the ZP.

Limitations, reasons for caution: Descriptive study awaits confirmation that imaging conditions do not impair oocyte quality or adversely affect pregnancy chances after IVF. As a pilot study, this work is limited by low number of samples and need to optimize laboratory workflow.

Wider implications of the findings: If confirmed, noninvasive imaging approach may offer poor prognosis patients opportunities to conceive using autologous oocytes by allowing such oocyte to achieve maturation under conditions retaining cumulus cell somatic support. Moreover, this technique should aid in the optimization of *in vitro* maturation protocols for patients undergoing fertility preservation.

Trial registration number: n/a

P-216 Laser Assisted Hatching in cryopreserved blastocysts: a randomized study.

J. Muñoz Ramírez[1], C. Cordero Rosales[1], A. Rodrigo Carbajosa[1], M. Saladino[1], R. Pandolfi[1], C. Andrés Santé[1], S. Cortés Gallego[1]

[1]Clinica Tambre, IVF Laboratory, Madrid, Spain

Study question: Does LAH improve the clinical outcomes in embryo cryopreservation program?

Summary answer: LAH could enhance clinical pregnancy rates in vitrified/warmed embryo cycles.

What is known already: Assisted Hatching (AH) has been proposed as an useful tool to improve the outcomes of different groups of patients, like advanced Maternal Age, implantation failure, Zona Pellucida defects or frozen embryos transfers.

AH can be performed with two techniques: chemically or mechanically.

Not clear evidences have been published about real benefits of AH in previous mentioned groups(Some papers were published for and against, without find clear evidences of the benefits of AH).

With the appearance and improvement of the Laser devices for PGD cycles, Laser devices were proposed to do AH (LAH) taking into account the safety, effectivity and reliability of this technique.

Study design, size, duration: This RCT was taking out between September 2018 and December 2018. Patients underwent blastocyst (day 5/6) cryotransfer were considering. Patients underwent PGD cycles and day 3 frozen embryo transfers were excluded. A total number of 88 patients were included in the study: 44 LAH cycles and 44 without LAH.

Participants/materials, setting, methods: Oocyte origin (fresh/frozen, and autologous/donor), age and blastocyst quality were recorded, and randomizely, LAH or not were realized in every warmed blastocyst.

We correlated LAH with implantation: gestational sacs/embryos transferred. Clinical pregnancy(CP)was confirmed with the presence of fetal heart beat by ultrasound.

The size of the Zona Pellucida hole was standardized with the width of one-single 2 ms shoot in Octax Laser system (Vitrolife).

Chi-square test was performed as statistical analysis, and $p<0.05$ were considered statistically significant.

Main results and the role of chance: A total of 37 CP were achieved, 50% in LAH group and 34.9% in non LAH group (p=0.1306).

Regarding oocyte origin, in autologous cycles 9 pregnancies out of 21 cycles with LAH were achieved (42.8%) and 6 out of 17 cycles without LAH (35.3%; p=0.6353). In oocyte donated cycles, 13 out of 23 CP were achieved in LAH group and 9 out of 26 in non LAH cycles (56.5% vs 34.6 %; p=0.1239 respectively).

Donated oocyte cycles (49) were also divided according with oocyte status (fresh or frozen) and no statistical differences were found. With fresh oocytes, 5 CP were obtained (55.6%) using LAH, and 4 without it (30.8%; p=0.2450) and in the frozen-donated group, the results were similar (57.1 % vs 38.5 %; p=0.3317, respectively).

Limitations, reasons for caution: This preliminary data must be confirmed increasing the size of the population, in order to improve the robustness of the conclusions.

Wider implications of the findings: No differences were observed between groups, considering autologous and donated oocytes, and fresh and frozen oocytes. Nevertheless, we found a point in favour of performing LAH, and no detrimental effect.

Trial registration number: Not applicable

P-217 Live birth following embryo transfer using new media composed of human oviductal amino acid fluid for IVF-ET: A randomized trial.

T. Utsunomiya[1], Y. Kumasako[2], E. Otsu[2], Y. Kai[1]

[1] *St. Luke Clinic, Dept. of Ob/Gyn, Oita city, Japan*

[2] *St. Luke Clinic, IVF Laboratory, Oita city, Japan*

Study question: Is human oviductal amino acid medium more clinically effective in human IVF than the commonly used single step medium?

Summary answer: Media composed of human oviductal amino acids better enhance embryonic ability than the current single step media.

What is known already: Sequential media and single step media are the most widely used embryo cultures in human IVF. The amino acid concentrations of most of these media were set in 1959 by Dr. Eagle on the basis of somatic cell requirements such as HeLa cells and L cells. However, these animal based media do not reflect the requirements of human embryos. This may negatively impact on human embryo developments in vitro. Efficacy of media composed of amino acid concentrations of human oviductal fluid has yet undergo rigorous analysis.

Study design, size, duration: Human oviductal fluid samples were collected in our clinic laparoscopically from 28 women aged 26-39 years, and were analyzed to formulate the components of new embryo culture media. In 2017, medium composed of amino acid concentrations of human oviductal fluid became available in Japan. We conducted an RCT to evaluate the new medium using 2,986 embryos from 581 cycles of patients who underwent IVF or ICSI between August 2017 and December 2018.

Participants/materials, setting, methods: Before fertilization, the oocytes were randomly divided into two groups: cultured using the new medium composed of human oviductal amino acid (OVIT, FUSO Pharmaceutical Industries, Japan); and cultured using the current medium (Medium A). The embryo development status during culture period (day 0 to day 5) and clinical outcome after embryo transfer (ET) to the uterus were compared using OVIT and Medium A group. After the ET, subsequent outcomes of neonatal findings were evaluated.

Main results and the role of chance: Between the two groups, patient characteristics including women's age, husband's age, the number of previous IVF-ET failure cycles were not significantly different. The number of blastomeres on day 3 was significantly larger in the OVIT group than in the Medium A group (7.3±2.1 versus 7.1±2.2, $P<0.05$). The OVIT group showed significantly higher rates of blastocyst development than the Medium A group (60.5% (904/1,493) versus 56.2% (839/1,493), $P<0.01$). The number of embryos which were elected for ET or cryopreserved was larger in the OVIT group compared with the Medium A group (45.1% (673/1,493) versus 36.6% (547/1,493), $P<0.01$). Furthermore, in the OVIT group had higher implantation rates after vitrified - warmed ET than that in the Medium A group (37.4% (82/219) versus 31.6% (54/171)). Neonatal birth weight showed a similar level after the vitrified-warmed ET using the OVIT versus the Medium A: Birth weight of the OVIT group was 3,150.3±461.6 grams (n=21) versus the Medium A group was 3,127.8±387.0 grams (n=9). The ratio of male to female was 11/10 in the OVIT group (n=21), and 3/5 in the Medium A group (n=8). One trismus nascentium child was confirmed in the OVIT group.

Limitations, reasons for caution: Due to this research being conducted by only one clinic, the sample size is limited.

Wider implications of the findings: Our findings indicate that the new media composed of human oviductal amino acid may improve the embryo development and the implantation rate. More embryos were able to be transferred or frozen using the OVIT, thus, the chance of a successful pregnancy rate may be better than with the current media.

Trial registration number: UMIN-CTR (UMIN000030904)

P-218 Outcomes of in vitro fertilization-embryo transfer in poor ovarian responders with growth hormone-pretreated: a prospective cohort study.

Y. Chen[1], L. Tao[1], Y. Lin[1], C. Ma[1]

[1] *Peking University Third Hospital, 49 North Garden Rd.-Haidian District Beijing - P.R.China, Beijing, China*

Study question: Are the IVF-ET outcomes different in poor responders after pretreatment with growth hormone compared to non-pretreatment women?

Summary answer: Pretreatment with growth hormone improves ovarian response to stimulation and embryological parameters in women with poor ovarian response in IVF-ICSI cycles.

What is known already: Growth hormone is used as an adjuvant therapy in ART for poor ovarian responders, which is associated with ovarian steroid and follicular development. It remains unclear, whether poor ovarian responders with growth hormone-pretreated who undergo IVF-ICSI have different response to ovarian stimulation and whether the reproductive outcomes in these women are different from those in women without pretreatment.

Study design, size, duration: A prospective cohort study was conducted at the Reproductive Medical Center of Peking University Third Hospital from Jun to July, 2018. The participants included poor-responder women who fulfilled the criteria defined by ESHRE consensus and had at least one controlled ovarian hyperstimulation cycle without oocyte or embryo achieved or non-pregnancy after embryo transfer. Overall 184 women were included in the study.

Participants/materials, setting, methods: Women who willing to receive treatment with growth hormone over 30 days averaging 2 IU per day were included in study group (n=92). Propensity score matching (PSM) method was used to choose control group in our database by matching age and body mass index (BMI) (n=92). The evaluation parameters included ovarian response and embryological parameters, and pregnancy outcomes after fresh embryo transfer.

Main results and the role of chance: Demographic characteristics were comparable between the two groups. The duration and amount of gonadotrophin therapy tended to be shorter in the participants treated with GH, but the difference did not reach statistical significance (p=0.104 and p=0.570, respectively). Peak E2 level were significantly higher in the GH group (p=0.003), but there was no difference in the mean endometrial thickness on the day of hCG trigger between the two groups (p=0.844). The mean number of retrieved oocytes was significantly higher after GH pretreatment (8.29±4.82), than in controls (6.02±3.27), p=0.000. The fertilization rate was significantly higher in women treated with GH than in controls, $p < 0.05$. The number of available embryos in the GH group was 3.89±2.97 and in control

group was 2.52±1.81, was significant difference in favor of GH pretreatment, p=0.000. In women treated with GH the implantation rate was 12.4% and in the control group, the implantation rate was 9.8%. Clinical pregnancy rate and ongoing pregnancy rate per fresh embryo transfer cycle were 17.9% and 16.1% in women treated with GH, and 12.3% and 10.5% in controls, respectively. Miscarriage rate was 10.0% in women from the GH group and 14.3% in controls.

Limitations, reasons for caution: The important limitation of our study was its small sample size. Due to the study duration constraints, follow-up did not achieve live births.

Wider implications of the findings: One month pretreatment with GH increases ovarian response to stimulation and improves oocyte and embryo quality in low prognosis patients with diminished ovarian response. There is a possible beneficial effect on clinical pregnancy, but this needs to be confirmed in larger studies.

Trial registration number: Not applicable

P-219 Does increased number of oocytes retrieved improve the cumulative live birth rate in women aged 40-44 years?

L. Jia[1], P. Chen[1], Z. Zhang[1], S. Zhang[1], C. Fang[1], X. Liang[1]

[1]The 6th Affiliated Hospital of Sun Yat-sen University, center for reproductive medicine, Guangzhou, China

Study question: Does increased number of oocytes retrieved improve the cumulative live birth rate in women aged 40-44 years?

Summary answer: The cumulative live birth rate per ovum pick-up was maximal in women aged 40-44 years whose number of oocytes retrieved was beyond 20.

What is known already: Advanced maternal age is a strong predictor of live birth in IVF treatment, especially for those who are over 40 years old. It is clear that the age-related reduction in fecundity is primarily due to oocyte aging, which includes the decrease in oocyte number and the increase in aneuploidy rates.

Study design, size, duration: A retrospective cohort study of 1660 IVF/ICSI cycles was performed at the Reproductive Medicine Center of the sixth affiliated hospital of Sun Yan-Sen University from 2013 to 2017. Outcome data were compared with t-test, Chi-squared test and Cochran-Armitage test for trend.

Participants/materials, setting, methods: Infertile patients aged from 40-44 years were categorized into five groups based on the number of oocytes retrieved (0-5, 6-10, 11-15, 16-20 and >20 oocytes). For the purpose of this study, cycles involving oocyte donation, oocyte thawing or patients who had not achieved a live birth but still had frozen embryos left were excluded from our analysis.

Main results and the role of chance: Basic characteristics of live birth group and no live birth group:

There was no significant difference in duration of infertility, insemination method, BMI or fertilization rate between live birth group and no live birth group. The number of oocyte retrieved(8.0±6.07 vs. 4.75±3.7, P<0.05) and transferable embryo (4.53±3.43 vs. 2.53±1.95, P<0.05) was significantly higher in live birth group

Women in live birth group was significantly younger (41.06±1.15 vs. 41.67±1.30, P<0.01).

Cumulative live birth in five groups:

The overall cLBR was 14.7 % per ovum pick up. There was a positive correlation between the number of oocytes retrieved and cLBR. The cumulative live birth in five different groups was 9.8%(0-5), 18.9%(6-10), 24.6%(11-15), 45.7%(16-20) and 80.0%(>20), respectively. Statistical testing by means of Cochran-Armitage test of trend revealed a trend that cLBR was elevated with the increasing number of oocytes (P<0.05).

Limitations, reasons for caution: As a retrospective study, our analysis depends on previously recorded data which means certain variables could not be collected.

Wider implications of the findings: Women over 40 years of age are faced with diminishing opportunities to achieve a live birth. Our results suggest that increased number of oocytes retrieved improves the cumulative live birth rate.

Trial registration number: not applicable

P-220 Optimising a vitrification programme – lessons learned

S. Adamiak[1], P.A. Milne[1], S.E. Drew[1]

[1]ACU Dundee, Ward 35- Ninewells Hospital, Dundee, United Kingdom

Study question: Have changes made to a vitrification programme improved blastocyst survival rates and clinical outcomes?

Summary answer: Use of Cryotop, Embryo Glue as post-warming medium and artificial blastocoel collapse using laser significantly improved the blastocyst survival rates and clinical outcomes.

What is known already: In the UK the drive to reduce multiple pregnancy rates has lead to an increase in single embryo transfers. Therefore, a good vitrification programme is essential to preserve surplus good quality blastocysts. It is known that survival rates can be influenced by storage devices (closed vs open systems) and use of artificial blastocoel collapse (mechanical or laser). There is a lack of information on the use of different post-warming media and their impact on clinical outcomes. Also there is an ongoing debate as to whether vitrified blastocysts can be safely stored in a vapour phase of nitrogen.

Study design, size, duration: A retrospective data analysis of frozen embryo transfer (FET) cycles performed between May 2010 and December 2018. A total of 947 day 5 blastocysts were thawed in 722 FET cycles. Since February 2013 the majority of embryos have been stored in a vapour phase. Treatment cycles (n=64) using High Security Vitrification (HSV) straws were only included for the comparison of the storage devices; due to significantly reduced clinical outcomes they were excluded from further analysis.

Participants/materials, setting, methods: Patients (mean age 34.7±4.7 years) underwent a hormone regulated FET cycle. Top quality (grade ≥3Bb) blastocysts were vitrified using Medicult Vitrification solutions and HSV straws (closed system) or Irvine Scientific solutions and Kitazato Cryotop (open system). From March 2016, blastocoels were artificially collapsed using laser prior to vitrification. Embryos were transferred after 2 - 3 hour incubation post-warming, in either culture medium (CM), CM with 20% human serum albumin (CM20%) or Vitrolife Embryo Glue (EG).

Main results and the role of chance: Survival rates (SR) and clinical outcomes: pregnancy rates (PR), clinical pregnancy rates (CPR) and implantation rates (IR), have progressively improved since our vitrification programme was introduced in 2009. Changing from HSV straw to Cryotop did not improve SR (87% vs 89% respectively) but significantly (P<0.01) improved clinical outcomes (PR: 21% vs 57%; CPR: 11% vs 43%; IR: 12% vs 39%, respectively). Embryos stored in a liquid phase of nitrogen (n=101) had significantly (P<0.05) greater SR (96%) compared to vapour stored (n=496) embryos (92%) however, clinical outcomes did not vary. Embryo Glue significantly (P<0.01) improved SR and clinical outcomes compared to CM and CM20% (SR: 92% vs 86% and 80%; PR: 65% vs 55% and 49%; CPR: 51% vs 42% and 40%; IR: 49% vs 41% and 39%, respectively). Laser artificial blastocoel collapsing further increased SR to 97% (P<0.01) and clinical outcomes (PR to 70%, CPR to 56% and IR to 54%), although not statistically significant. Overall, EG had the most positive impact on PR (OR 1.57, 95% CI 0.95-2.6, P=0.18) and laser artificial blastocoel collapsing on CPR and IR (OR 1.6, 95% CI 0.95-2.6, P=0.18; OR 1.4, 95% CI 0.91-2.15, P=0.124, respectively) irrespective of liquid nitrogen phase.

Limitations, reasons for caution: Not a randomised controlled trial. The group sizes relatively small for some variants and uneven distribution of cycles between groups. Patient's age was not taken into consideration.

Wider implications of the findings: In accord with current literature, open system and laser artificial blastocoel collapsing significantly improved survival and clinical outcomes. Other factors such as post-warming medium also play a role in the vitrification programme and should be considered. Blastocysts can be stored in a vapour phase of nitrogen without compromising success rates.

Trial registration number: Not applicable.

P-221 Fresh cycle outcome as a possible predictive factor of post-warming survival and pregnancy in the same cohort of egg donation cycles. A retrospective study.

G. Campos Guillaumes[1], E. Francisco-Busquets[1], E. Boix Illa[1], T. Francisco Mendez[1], M. Brossa Llibre[2], L. Bellapart Diaz[2], A. Rocas Huertos[3]

[1]Clinica GIREXX, Assisted reproduction laboratory, Girona, Spain

[2]Clinica Girexx, Assisted reproduction laboratory, Barcelona, Spain

[3]Clinica Girexx, Assisted reproduction, Girona Barcelona, Spain

Study question: Within the same donor cohort, can a previous fresh oocyte cycle predict post-warming survival and clinical outcome of a sibling vitrified oocytes cycle?

Summary answer: Clinical outcome of a donor fresh cycle can not estimate neither the survival rate nor the pregnancy rate of a later vitrified sibling oocytes cycle

What is known already: Clinical outcomes with vitrified and fresh oocytes are comparable in egg donation cycles.

Donor's oocyte survival can not be estimated by baseline characteristics, oocyte morphology, storage time or stimulation parameters. Only vitrification within 2 hours post follicular puncture has shown to be significant.

Actually, the pregnancy rate increases progressively with the number of vitrified eggs consumed.

Study design, size, duration: Retrospective study performed since August 2012 to September 2018.

A total of 3425 mature oocytes (MII) from 154 egg donations were distributed between synchronous recipient (1808 MII inseminated in fresh cycles) and asynchronous recipient (1617 vitrified MII).

Participants/materials, setting, methods: On the retrieval day, after denudation, the oocytes assigned to the synchronous recipient were inseminated and the rest, assigned to the asynchronous recipient, were vitrified. Vitrified eggs were inseminated by ICSI 2-3 h post warming and the embryo transfer was performed on day 3. Survival rate, fertilization rate and clinical outcome were reported.

$\chi 2$ test and Mann-Whitney test were used for the statistical analysis, both two-tailed with a significance level set to $\alpha = 0.05$.

Main results and the role of chance: A previous positive pregnancy with fresh oocytes does not affect either the oocyte survival rate (77.7% vs. 78.8%), the fertilization rate (72.2% vs. 71.9%) nor the pregnancy rate (44.7% vs. 36.8) of a later vitrified sibling oocytes cycle. No significant differences were found.

Limitations, reasons for caution: Oocytes from healthy young donors were used in this study, so the results should not be extrapolated to others populations.

Wider implications of the findings: No factors can predict post-warming survival or the clinical outcome in donors.

Oocytes from a donor which are able to get a fresh pregnancy are not more resistant to vitrification and do not have any implications in the clinical outcomes of the later thawing cycles.

Trial registration number: none

P-222 Spent culture media from embryos transferred at day 5 show significant altered protein profile subject to ART outcome possibly allowing non-invasive embryo assessment

A. Freis[1], S. Roesner[1], K. Von Horn[1], A. Doster[1], J.E. Dietrich[1], T. Strowitzki[1], A. Germeyer[1]

[1]Universitäts-Frauenklinik, Department of Gynecologic Endocrinology and Fertility Disorders, Heidelberg, Germany

Study question: Do media from embryos show a significant altered protein profile subject to IVF outcome?

Summary answer: Media from implanted embryos show a significant altered protein profile compared to media from non-implanted embryos with MCP-1, SELE and PECAM-1 as possible key proteins

What is known already: Successful implantation requires a receptive endometrium a well as a competent blastocyst. In order to improve ART outcome, non-invasive embryo assessment is gaining more and more attention. Progress in methodology allows collecting more information about blastocyst metabolism. However, so far no satisfying analysis tool has been established to determine the secretome, mainly due to the small volume of blastocyst media used in IVF culture. The aim of this study was to investigate if protein secretion differs between blastocysts with consecutive implantation compared to those without implantation and to analyze possible interactions between these proteins.

Study design, size, duration: In this prospective study, 69 spent culture media from embryos transferred at day 5 were collected from patients undergoing IVF/ICSI-treatment at the University Hospital Heidelberg between 04/15-10/18. The study was approved by the Ethical Committee of Heidelberg University (S572/2014). Embryos were cultured using Sidney IVF® blastocyst medium (Cook K-SIBM-20) until 09/16 or CSC-Complete-Medium (Fujifilm Irvine Scientific 90165) since 10/16. Exclusion criteria were the absence of informed consent, PCOS, endometriosis and maternal age > 41 years

Participants/materials, setting, methods: Dependent on the treatment outcome, medias were subsequently divided in two groups: (1) from embryos who implanted successfully ($n = 37$) and (2) from embryos without implantation ($n = 32$). 92 proteins were measured simultaneously using the Proximity Extension Assay (PEA) technology with the Olink® CVDIII panel employing oligonucleotide-labeled antibodies. Results are presented in Normalized Protein eXpression (NPX) values, which is an arbitrary unit on a log2-scale. Statistical analysis was performed using students-t-test and Fishers-exact-test.

Main results and the role of chance: There were no significant differences in maternal age (33.95 ± 4.01 years vs 35.85 ± 3.65 years), maternal BMI (26.20 ± 4.84 kg/m^2 vs. 24.29 ± 2.73 kg/m^2), embryo quality, infertility treatment (ICSI in 59.45% vs 50.00%), percentage of frozen IVF-cycles (16.2% vs 15.6%) or percentage of single-step-medium used (48.64% vs. 46.86%).

Media from implanted blastocysts showed significantly higher expression of ephrin type-B receptor 4 (EPHB4), activated leukocyte cell adhesion molecule (ALCAM), cystatin b (CSTB), monocyte chemotactic protein 1 (MCP-1), bleomycin hydrolase (BMH), tissue Inhibitor of Metalloproteinase-4 (TIMP4), CC-chemokine ligand 24 (CCL24), selectin E (SELE), first apoptosis signal (FAS), junctional adhesion molecule-A (JAM-A), paraoxonase 3 (PON3), plateled-derived growth factor (PDGF) subunit A and platelet endothelial cell adhesion molecule-1 (PECAM-1) compared to media from blastocyst without subsequent implantation. The highest relative expression change in media from implanted embryos compared to media from embryos without implantation can be demonstrated for PECAM-1 (1.48). We analyzed the potential protein network using STRING database (version 11.0) and found the following proteins coexpressed with each other: MCP-1 (with SELE and FAS), SELE (with MCP-1 and PECAM-1) and PECAM-1 (with SELE and potentially with EPHB4).

Limitations, reasons for caution: Main limitation of this study is the fact that two different culture media were used, even if the distribution in between the groups was similar (single-step medium in 48.64% vs. 46.86%). Due to the innovative methodology, defining a threshold for the use as biomarker remains to be assessed.

Wider implications of the findings: Our results may be used for individual non-invasive embryo assessment. In literature, especially EPHB 4, ALCAM, MCP-1, BMH, CCL24, FAS and PDGF-A have already been described in early embryonic development and metabolism. Therefore, these proteins together with SELE and PECAM-1 indicate possible biomarkers for non-invasive embryo assessment in the future.

Trial registration number: not applicable

P-223 Impact of day 5 vs. day 6 blastocyst transfer on the pregnancy outcome of frozen thawed donor recipient cycles

S. Mittal[1], G. Majumdar[2], A. Majumdar[2]

[1]Sir Ganga Ram Hospital, Centre of IVF and Human Reproduction, Delhi, India
[2]Sir Ganga Ram Hospital, Centre of IVF and Human Reproduction, New Delhi, India

Study question: To compare the pregnancy outcome and miscarriage rates in day 5 versus day 6 frozen thawed donor recipient embryo transfer cycles.

Summary answer: Similar initial pregnancy rate, however statistically higher miscarriage rate in day 6 embryo transfer group in donor recipient cycles

What is known already: There are conflicting results regarding pregnancy impact on transferring delayed development of blastocyst (day 5 vs. Day 6)

Metanalysis in 2010 suggested similar on going pregnancy rates in both day 5 vs. day 6 embryo transfer group

In 2018 there is emergence of data suggesting lower on going pregnancy rats in day 6 blastocyst transfers

none of the studies have compared exclusive donor recipient cycles where there would be low expected chance of miscarriage due to younger age of donors, thus expecting similar results in day 5 vs. day 6 blastocyst transfers

Study design, size, duration: Retrospective observational study of three years

Four hundred and fourteen consecutive donor recipient programmed frozen thawed elective single blastocyst transfer cycles (FET)..All the embryos were non Preimplantation genetic tested (PGT) embryos.

Participants/materials, setting, methods: Highgrade blastocysts were frozen by vitrification on day 5 (n=335) or day 6 (n =79). Endometrial preparation was performed using estradiol valerate. Progesterone supplementation was commenced when the endometrial thickness had reached 7mm or more. Frozen blastocysts were thawed after 5 days of progesterone supplementation and assessed immediately after thawing

Thawed blastocyst clinical pregnancy and early pregnancy loss rates in fully expanded day 5 (Group A) versus day 6 FET donor recipient cycles (Group B).

Main results and the role of chance: Statistical analysis was done using chi square test**.** All parameters like average age of oocyte donor (25.03 years vs 24.97 years,p=0.986),endometrial thickness (8.06 mm vs 8.23 mm, p=0.961)and embryo survival (97% vs 98%,p=0.776) were comparable in both the groups respectively. The clinical pregnancy rate was similar between Group A vs. Group B (50.74% versus 49.36%, P =0.825, OR 1.05,CI 0.645-1.724). Clinical miscarriage rate in Group B was 33.33% as compared to 17.05% in Group A, p=0.022, OR 2.43, CI 1.12-5.28) which was statistically significant.

Robustness of this study is good sample size

All confounding factors like adenomyosis, untreated hydrosalpinx, intramural fibroids more than 3 cm, previous recurrent miscarriages in recipient were excluded.

Limitations, reasons for caution: none

Wider implications of the findings: In donor recipient cycles having younger age of donors with low expected pregnancy loss rates, from our study it raises an important question if these cycles would perform better if preimplantation genetic testing is offered when only day 6 embryos are available for transfer .

Trial registration number: NA

P-224 The 1st polar body transfer technique: it works despite the use of fresh or thawed oocytes

I. Ilyin[1], N. Buderatskaya[2], J. Gontar[3], S. Lavrynenko[2], N. Kazachkova[3], O. Parnitskaya[2], K. Ilyina[1], E. Kapustin[1], Y. Lakhno[3], M. Yaroshyk[3]

[1]*Medical Centre IGR, IVF Department, Kiev, Ukraine*

[2]*Medical Centre IGR, Embryology, Kiev, Ukraine*

[3]*Medical Centre IGR, Diagnostic Laboratory, Kiev, Ukraine*

Study question: Does the 1st polar body (PB) transfer technique using both fresh and thawed donor oocytes increase blastocyst yield in patients with poor response?

Summary answer: The transfer of the patient's 1st PB to donor oocyte cytoplasm using both fresh and thawed oocytes enhances success in IVF programs

What is known already: Patients with poor response require special methods in the infertility treatment. As shown by a previous study, the application of the 1st PB transfer technique is appropriate in doubling the number of oocytes suitable for further fertilization. This technique allows getting high quality blastocysts from modified oocytes in addition to embryos derived from maternal eggs. To increase the efficiency of these manipulations, many optimizations were performed at all stages of the procedure. One of them is the use of thawed donor oocytes instead of fresh.

Study design, size, duration: The study was performed in the Medical Centre IGR from March 2017 to December 2018. It involved 168 oocytes (group A) obtained from 39 patients and 162 oocytes (group B) that were received from 28 donors. The mean age of the oocyte donors and patients was 28.2±2.4 and 40.7±5.3 years, respectively. We evaluated the number of blastocysts from maternal and modified oocytes by the 1st PB transfer obtained from fresh and thawed donor oocytes.

Participants/materials, setting, methods: We used patients' oocytes obtained from 39 women with poor response. Donor oocytes have been previously enucleated and modified by the transfer of patients' 1stPB with further fertilization. The procedure was carried out using Nikon Ti Eclipse (Japan) inverted microscope, Saturn 3 laser console(UK). Statistical analysis was carried out using Chi-square test, Spearman correlation and pair exponential regression.

Main results and the role of chance: The total number of oocytes in this study comprised 330 cells. The mean numbers of original oocytes per patient were 4.3±2.2 and modified oocytes were 4.2±2.1. Thereby, aggregated amount of oocytes suitable for the fertilization has grown up to 8.5±4.2 per patient. 50 (29.8%) high quality blastocysts developed from the oocytes of group A. In the group B there were 29 blastocysts (17.9%), that had statistically significant difference (SSD) compared to the group A. ($p<0.01$). Spearman correlation ($r=-0.827, p<0.05$) demonstrated strong and negative correlation between the patient's age and the number of blastocysts obtained from modified oocytes. The pair exponential regression confirmed that 13.96% of the variability in the number of embryos from modified oocytes is explained by patient's age. Further, the oocytes from group B were also divided into two subgroups: fresh (n=56) and thawed (n=106) donor oocytes used for modification. Embryos obtained from fresh oocytes comprised 14 blastocysts (25.0%), from thawed oocytes – 15 blastocysts (14.5%). SSD was found between fresh and thawed subgroups ($p<0.05$), it can be explained by the average age in groups, namely 39.6±4.6 and 41.2±5.4, respectively.

Limitations, reasons for caution: Importantly, oocytes from certain donors give a greater yield of blastocysts, regardless of whether they were fresh or thawed. Therefore, the success of the 1st PB transfer technique depends directly on the accuracy of donors' selection and the ability of their oocytes to overcome the stress after performed manipulations

Wider implications of the findings: Research shows that use of the1st PB transfer technique increases the yield of high qualitative blastocysts at least by 18%. The use of thawed oocytes will allow rational use of donor material, especially in cases with low patient's oocytes number, to avoid stimulation of a personal donor for oocytes doubling.

Trial registration number: N/A

P-225 In silico assessment of different embryo time-lapse algorithms suitability for an individual clinic

N. Hesketh[1], T. Wilkinson[1], F. Kylie[1], A. Murray[1], S. McArthur[1]

[1]*Genea, Embryology, Sydney, Australia*

Study question: Is it possible to test and develop embryo time-lapse morphokinetic algorithm(s) for use with the Geri time-lapse system using an *in silico* testing model?

Summary answer: Simplified testing based in Microsoft Excel allows clinics to assess and develop most suitable morphokinetic algorithm for its individual circumstances using the Geri time-lapse system.

What is known already: Different morphokinetic algorithms that may be used for assessing the developmental potential of an embryo have been published, but it has been shown that these algorithms are not necessarily applicable to all clinics due to different clinical practices. Hence any algorithm, published or customised, needs to be assessed against a clinic's own clinical outcomes data. Testing algorithms within a time-lapse system may be time-consuming, whereas *in silico* testing facilitates convenient analysis of several algorithms against a large amount of data. This model allows for customisation and development of algorithm with minimal effort.

Study design, size, duration: Four different algorithms, based on published studies, were adapted to the Geri Assess® 2.0 custom algorithm format. The algorithms were then applied to time-lapse data collected in clinical laboratories utilising Geri Assess® 2.0 automated annotations feature for capturing data for developmental time points. Clinical outcomes of the embryos were then analysed and algorithms assessed for their potential to predict clinical results.

Participants/materials, setting, methods: Only non-PGT embryos were included in the study. Algorithms were based on early developmental events (PN disappearance, 2 - 6-cell divisions) in different combinations. A maximum of three different conditional rules were applied to each algorithm, the final embryo grade dictated by different combinations of whether the rules were met or not. Clinical outcomes data was captured from BabySentry™ database management system. Microsoft Excel software was used to combine and analyse all the datasets.

Main results and the role of chance: Three clinical outcomes were analysed: 1) Embryo utilisation (transfer or cryopreservation) at Day 5/6, and 2) βHCG and 3) Fetal Heart pregnancy rates after transfer of fresh or vitrified embryos at Day 5/6. Total of 3,948 embryos were included into the study. In principle, an applicable predictive algorithm should show increasing utilisation and pregnancy rates from lowest to the highest scoring embryos. When excluding embryos where algorithms didn't return a grade, two algorithms

displayed a fair predictability for embryo utilisation, the other two exhibiting weaker predictive power. Only one algorithm showed some predictivity for pregnancy outcomes, however, number of pregnancies in some categories was low, making drawing conclusion difficult. The next phase of the work will be to modify algorithms to adjust them for differences between the clinic where they were developed and the clinic where they are to be used, to assists in finding the most suitable and predictive algorithm to be used with the Geri system.

Limitations, reasons for caution: The number of embryos in some grade categories was low, especially in βHCG and Fetal Heart pregnancy groups, allowing for disproportioned distribution which impacted algorithm performance assessment. Event annotations were collected via automatic annotation software and any limitations in their accuracies might have had impact on the outcomes.

Wider implications of the findings: The ability to test and modify algorithms *in silico* with retrospective data allows accurate selection and application of an algorithm(s) most suitable for an individual clinic in an efficient manner. Besides clinical practices, the time-lapse system that is used may also have an impact to the applicability of published algorithms.

Trial registration number: Not applicable

P-226 time-lapse analysis of the relationship between cytoplasmic wave location, pronuclei formation, and the developmental competence of single pronuclei (1PN) zygotes

R. Matsunaga[1], S. Watanabe[1], R. Sakuma[1], H. Morita[1], R. Hasegawa[1], Y. Ohnuki[1], K. Isobe[1], M. Miura[1], Y. Kobayashi[1], M. Kamihata[1], T. Maeda[1], H. Makino[1], M. Ochi[1], T. Horiuchi[2]

[1]*Ochi Yume Clinic Nagoya, IVF laboratory, Nagoya, Japan*

[2]*Prefectural University of Hiroshima, Department of Life Sciences, Shobara, Japan*

Study question: Is the location of the cytoplasmic wave related to the incidence rate of 1PN zygotes and developmental competence?

Summary answer: 1PN zygotes can be formed by sperm penetrating beneath the second polar body of the oocyte.

What is known already: The rate of diploidy in 1PN zygotes is higher for in vitro fertilization (IVF) than for intracytoplasmic sperm injection (ICSI) . Furthermore, blastocysts derived from 1PN zygotes exhibit a higher rate of diploidy than embryos that have become arrested in cleavage stage. One potential cause of 1PN is fusion of the maternal and paternal genomes fuse before the pronuclear envelope has formed. During fertilization, a cytoplasmic wave originates from the initial position go the male pronucleus (PN), while the female PN is formed close to the site where the second polar body (PB) is emitted.

Study design, size, duration: We retrospectively analyzed 927 zygotes (2PN:725, 1PN:202) derived from IVF or ICSI using time-lapse microscopy (TLM).These zygotes were collected from 427 patients (age range: 26 to 47 years) between 2016 and 2018. We used only zygotes for which the presence of a second PB was confirmed.

Participants/materials, setting, methods: Following insemination, all oocytes were cultured in a TLM system from day0 and the cytoplasmic wave was recorded. Each zygote, obtained from either IVF and ICSI, were divided into two groups according to the position of the cytoplasmic wave: near Abs (NPB) and distant from PBs or unclear (DPB). We then studied whether the position of the cytoplasmic wave affected the incidence of 1PN zygotes and their developmental competence.

Main results and the role of chance: The NPB rates for 1PN zygotes from IVF and ICSI were 70.4% and 26.4% respectively. These rates were significantly higher than that for 2PN (13.7% in IVF and 5.0% in ICSI, $P<0.05$). For both IVF and ICSI, the blastocyst developmental rates of 1PN embryos weresignificantlylower than for 2PN zygotes (55.3% vs. 68.6% in IVF and 21.2 % vs. 60.0% in ICSI). Blastocyst developmental rates for IVF and ICSI in the 1PN-NPB group were significantlyhigher than for the 1PN-DPB group (69.0% vs. 13.0% for IVF; 45.0% vs. 10.9% for ICSI). Blastocyst developmental rates in the 1PN-NPB group were comparable with that of 2PN zygotes, both for IVF and ICSI. None of the 1PN embryos, derived from IVF, developed to blastocysts; in these embryos the cytoplasmic wave was clearly distant from the PBs (0/12).

Limitations, reasons for caution: 1PN embryos in the NPB group had better developmental competence. However, it remains unknown as to whether these embryos were biparental or not.

Wider implications of the findings: In most of the 1PN embryos, especially from IVF, the cytoplasmic wave originated close to the PBs and had better developmental competence. We suggest that 1PN embryos could be formed incidentally due to the position of the sperm penetration site.

Trial registration number: not applicable

P-227 Embryo diameter and implantation potential after direct unequal cleavage of the blastocyst

H. Ta kahashi[1], R. Hirata[1], T. Habara[2], N. Hayashi[2]

[1]*Okayama couple's clinic, laboratory, Okayama, Japan*

[2]*Okayama couple's clinic, Physician, Okayama, Japan*

Study question: Is direct unequal cleavage (DUC) an additional parameter to assist in embryo selection for blastocyst transfer?

Summary answer: In blastocyst transfer, DUC has little significance as an indicator in embryo selection because it does not affect potential blastocyst expansion and implantation.

What is known already: DUC is defined as the abrupt cleavage of one blastomere into three daughter blastomeres or an interval of cell cycles less than five hours. The incidence of DUC is 10-30%. Embryos with DUC have lower rates of blastocyst formation and expanded blastocyst formation than embryos with a normal cleavage pattern. Furthermore, on day 3 of fresh embryo transfer, embryos with DUC have lower rates of implantation and live births than embryos with a normal cleavage pattern.

Study design, size, duration: This was a retrospective study of data acquired by time-lapse imaging of human embryos during in vitro growth. A total of 379 IVF cycles were cultured and observed in a time-lapse system between May and December of 2018. Of these, 232 embryos in 189 cycles from 184 patients were analyzed on which, single frozen blastocyst transfer was performed during December 2018.

Participants/materials, setting, methods: Embryos with DUC were recorded as DUC(+), and embryos with a normal cleavage pattern were recorded as DUC(-) using time-lapse monitoring. We compared the diameter of DUC (+) and DUC (-) blastocysts at the time of cryopreservation. In addition, we compared the implantation rates and miscarriage rates in frozen-thawed single embryo transfer cycles between the two groups. Statistical significance was determined by Chi-Square test.

Main results and the role of chance: A total of 232 frozen-thawed embryos were transferred. Of these, 68 (29.3%) were DUC(+). The mean patient age (mean±SD) in DUC(+) and DUC(-) were 35.1±5.1 (95% CI: 33.9-36.4) and 35.5±4.9 (95% CI: 34.7-36.3), respectively. The mean transfer counts were 2.3±1.9 (95% CI: 1.9-2.9) in DUC(+) vs. 2.2±2.1 (95% CI: 1.9-2.5) in DUC(-). No significant differences were found regarding patient age or transfer counts between the two groups (P=0.608 and P=0.684, respectively). The diameter of blastocysts were 174.9 μm (95%CI: 168.6-181.2) in DUC(+) versus 175.4 μm(95% CI: 171.3-179.5) in DUC(-), and no statistical differences were detected (OR=0.56, 95% CI: -7.0-8.08, P=0.883). The implantation rates were 41.2% (95% CI: 30.3-53.0) in DUC(+) vs. 40.9% (95% CI: 33.6-48.5) in DUC(-), and no significant differences were detected (OR=1.01, 95% CI: 0.57-1.80, P=0.934). No significant differences were found regarding miscarriage rates (14.3% in DUC(+) vs. 19.4% in DUC(-))(OR=0.69, 95% CI: 0.20-2.34, P=0.546). Furthermore, DUC(+) showed a similar implantation rate to DUC(-) when high quality blastocysts were transferred (48.4% vs. 48.7%) (OR=0.99, 95% CI: 0.45-2.20, P=0.979). No significant differences were found regarding miscarriage rates (6.7% vs. 20.4%) (OR=0.28, 95% CI: 0.03-2.36, P=0.177).

Limitations, reasons for caution: In this study, live birth or neonatal outcomes could not yet be analyzed. Because chromosomal analysis is strictly prohibited in Japan, this study had no data regarding the chromosomal integrity of the blastocysts.

Wider implications of the findings: Our results suggest that when an embryo with DUC reaches a blastocyst, it has a similar implantation potential as an embryo with a normal cleavage pattern.

Trial registration number: Not applicable

P-228 A multivariate logistic regression model for predicting live births improves clinical outcomes in frozen single blastocyst transfer cycles.

T. Habara[1], Y. Miyagi[2], R. Hirata[1], N. Hayashi[1]
[1]*Okayama Couple's Clinic, Infertility, Okayama, Japan*
[2]*Medical Data Labo-, Department of artificial intelligence, Okayama, Japan*

Study question: Can a prediction model improve live birth rates (LBRs) in frozen-thawed embryo transfer (FET) compared to conventional embryo evaluation (CEE)?
Summary answer: The multivariate logistic regression model can predict the probability of live births better than CEE in single blastocyst transfers.
What is known already: Morphological parameters for the degree of blastocoele expansion, trophectoderm (TE), and the inner cell mass (ICM) have been used to select the best blastocysts for transfer, but it is difficult to weigh the importance of each parameter in embryo selection. Moreover, this process is subjective for some embryos and thus prone to human bias. As a result, morphological assessment results may vary extensively between embryologists and/or may fail to accurately predict embryo implantation and live birth potential. However, few studies have evaluated the effectiveness of a prediction model (PM) on live birth outcomes in frozen single blastocyst transfer cycles.
Study design, size, duration: We performed a retrospective cohort study for construction of a prediction model (PM) from a database of known live birth outcomes originating from 4717 blastocysts transferred between January 2009 and December 2015 in a single clinic in phase I. Data from 2092 FETs were collected between January 2016 and December 2017 for validation of the PM in phase II.
Participants/materials, setting, methods: The relationships between live birth outcomes and each factor included in the CEE were investigated. We constructed a model to predict live births using univariate and multivariate logistic regression analysis and the dataset. To validate the model, we compared the accuracy of prediction between when PM was applied and when CEE was applied. The area under the receiver-operating characteristic curve (AUC) was calculated, and model calibration was assessed.
Main results and the role of chance: In phase I, a total of 4717 frozen single blastocyst transfers were performed that resulted in 1490 live births (31.2% of the patients). The significant factors that showed no multicollinearity, indicating a state of high correlation among the independent variables, were selected for use in the multivariate analysis. The prediction model, constructed after multivariable logistic regression analysis, demonstrated that blastocyst diameter (odds ratio (OR) 678.7, 95% confidence interval (CI): 83.5–5517.3), embryo cryopreservation day (OR 26.9, 95% CI: 2.4–305.3), TE (OR 5.3, 95% CI: 1.5–19.3), and ICM (OR 4.1, 95% CI: 1.0–17.7) were predictive factors for live birth outcomes. The value of AUC for the prediction model for live births was 0.70 (95% CI: 0.67–0.72). The accuracy, sensitivity, specificity, positive predictive value, and negative predictive values for live births were 0.65, 0.63, 0.65, 0.41, and 0.82, respectively. In phase II, a validation study (n=2092) showed that use of this logistic model resulted in a significantly higher probability for predicting live births (0.71 vs. 0.69, p=0.0368). In addition, the values of the AUC revealed that the prediction model performed better than CEE in non-good blastocysts (0.69 vs. 0.61, p=0.007) compared to good blastocysts (0.65 vs. 0.64, p=0.18).
Limitations, reasons for caution: In this study, the morphokinetic variables provided by time-lapse monitoring could not be assessed, and embryo evaluation was limited to static observations. The interpretation of the findings of this study was limited by the retrospective nature of the analysis and the potential for unmeasured confounding.
Wider implications of the findings: Our results indicated that this logistic model could be useful for ranking embryos in frozen single blastocyst transfer. Improving the ability to select the embryos with the highest implantation potential would increase LBRs as well as shorten the time to pregnancy.
Trial registration number: not applicable

P-229 Impact of co-administration of cyclophosphamide with imatinib or dasatinib on in vitro mice preantral follicle development and oocyte acquisition

Abstract withdrawn by the authors

P-230 Embryoglue® as medium for embryo transfer: does it really improve the outcomes? A prospective randomized controlled trial.

J. Ten[1], R. Sellers[1], A. Rodríguez-Arnedo[1], J. Guerrero[1], J.A. Ortiz[2], B. Moliner[3], R. Bernabeu[3]
[1]*Instituto Bernabeu, Embryology Unit, Alicante, Spain*
[2]*Instituto Bernabeu Biotech, Molecular Biology and Genetics, Alicante, Spain*
[3]*Instituto Bernabeu, Reproductive Medicine, Alicante, Spain*

Study question: Can Embryoglue® (EG) culture medium improve clinical outcomes versus other conventional culture media?
Summary answer: EG offers the same clinical outcomes than other culture media for embryo transfer.
What is known already: Despite the advances in the IVF lab the embryo transfer (ET) success rate remains relatively low. One strategy to improve the results is the use of special culture media for ET.

In the past EG has been advocated for it but the evidence is scarcy and contradictory. In an attempt to elucidate this question we designed this RCT.
Study design, size, duration: Randomized controlled trial (RCT) carried out since March 2018 to January 2019, in which we randomized all the cycles with donated oocytes, performing a fresh transfer on day 5. The randomization included a control (GLOBAL® TOTAL®, LifeGlobal® or Continuous Single Culture® Complete, IrvineScientific®) and a study group (EG) and was done with a randomization program RNDSEQ V2011.09.09. Clinical parameters studied were implantation, clinical pregnancy and clinical miscarriage rates.
Participants/materials, setting, methods: Sixty one patients were included in the control group (GLOBAL® TOTAL®, LifeGlobal®) and 48 in the study group (EG). We performed a second randomization in which we included a total of 157 patients. Seventy six were included in the control group (Continuous Single Culture® Complete, IrvineScientific®) and 81 in the study group (EG). Patients that were diagnosed of recurrent implantation failure (RIF) were excluded.
Main results and the role of chance: In the first randomization we did not reach any statistically significant differences for implantation, clinical pregnancy and miscarriage rates between Global Total and EG, respectively (60.7% vs. 50.0%, p=0.628; 60.7% vs. 51.1%, p=0.335 and 1.7% vs. 8.5%, p=0.166).

In the second randomization we also had no statistically significant differences for implantation, clinical pregnancy and miscarriage rates between Continuous Single Culture and EG, respectively (35.4% vs. 38.8%, p=0.726; 44.4% vs. 53.4%, p=0.361 and 3.2% vs. 10.3%, p=0.346).
Limitations, reasons for caution: The study design is powered due to the fact that is a RCT with a sufficient number of patients. Notwithstanding, a higher number of cycles may vary these results. Also, we have to take into consideration that this study is focused only in recipients.
Wider implications of the findings: In our experience, hyaluronate enriched media, as EG did not improve the clinical outcomes. Even if statistically significant differences were not achieved in both randomizations, miscarriage rates should take into account in order to elucidate what implication could have EG in those outcomes.
Trial registration number: None

P-231 the challenges of temperature control in the IVF laboratory during necessary manipulations and assessments

A. Blasco Navarro[1], R. Smith[1]
[1]*Care Fertility, Embryology, Sheffield, United Kingdom*

Study question: How do dishes, processes and durations on heated surface can all impact temperature within the IVF culture drops?
Summary answer: Detailed temperature mapping of IVF procedures highlights temperature variations caused by equipment and consumables in IVF laboratories and informs best practice.
What is known already: The recommended temperature range for human cells (embryos and oocytes) is 37-38 °C and pH of 7.3. During IVF processes, necessary manipulations and assessments, can cause changes in these optimal conditions. Time-lapse monitoring system (TMS) minimise the need for time outside of the culture environment, as assessments can be made using the imaging system, but many embryology procedures including oocyte retrieval and

insemination takes place outside the TMS, in ambient atmospheric conditions with the use of heated microscope stages.

Study design, size, duration: The study was designed to measure temperature changes within IVF culture dishes during routine procedures involving varied equipment and consumables. Small thermobuttons were placed inside culture medium microdrops to record temperature variation during IVF procedures. Each experiment was repeated at least twice and to confirm the temperature and timing data logged for analysis during October to December 2018 within a clinical IVF laboratory.

Participants/materials, setting, methods: Materials – Media (Supplier), Class II cabinets (Supplier), thermobuttons (Mintrone), thermocouple (Madgetech), incubators (Labotech, Cooper and Supplier), tube warmer (Supplier), Micromanipulator (Cooper), IVF dishes and tubes (Vitrolife).

Methods – Recording the media temperature variations for the mimicked IVF procedures with 1 minute intervals. Using the thermobuttons to trace the path of cells within the same dishes across equipment used for each stage of the process from oocyte recovery (OR) to insemination for a patient's treatment.

Main results and the role of chance: Temperature changes within the culture dishes during key processes in the IVF laboratory were evaluated.

The temperatures recorded for the whole oocyte retrieval (OR) to Fertilisation process pathway was maintained between 37°C and 39.5 °C. The mini incubator G85 was the most reliable for providing a constant and stable temperature within the required range (exactly 37.42 °C). The heated stages impacted the media temperature the most with the highest (39.64°C) and lowest temperatures 36.5°C recorded, these variation in temperature are outside of the required range and could impact embryo development.

Limitations, reasons for caution: These values are not transferable to every laboratory – as each different laboratory uses different equipment or consumables.

Wider implications of the findings: This is an effective procedure which enables mapping not only of the heated surfaces but temperature changes within culture dishes in order to protect gametes and embryos from unnecessary stress. This could have a positive impact on clinical results and arm the embryologists with information to avoid compromising temperature conditions.

Trial registration number: Not applicable

P-232 High levels of Follicular fluid oxidative stress are present in younger patients and fertile donors

D. Castello Salom[1], R. Del Gallego[1], L. Bori[1], I. Hervas[1], L. Alegre[1], T.C. Cnaani[2], S.S. Shnizer[2], M. Meseguer[1]

[1] *IVIRMA, IVF Department, Valencia, Spain*

[2] *Carmel Diagnostics, Development Department, Kiryat-Tivon, Israel*

Study question: Is the information provided by the oxidative status of the follicular fluid related with fertility and maternal age?

Summary answer: A correlation was found among the follicular fluid oxidative status, its fertility status (donor/patient), woman age and number of retrieved oocytes.

What is known already: Oxidative stress has been reported in literature as a useful biomarker in male and female infertility. A novel technique detecting the oxidative status of different biological fluids, the Thermochemiluminescence (TCL) Analyzer™ (Carmel Diagnostics, Israel), has proved to be effective in different studies regarding seminal plasma, amniotic fluid and the spent embryo culture media. In this last one, we found a close relationship between the oxidative status of media and the subsequent clinical outcomes. Our present purpose is to examine the relationship between follicular fluid's oxidative status and relevant characteristics of an *in vitro* fertilization (IVF) treatment.

Study design, size, duration: This prospective observational study included 40 patients (from 31 to 45 years) undergoing an IVF cycle and 17 donors (from 20 to 34 years) enrolled in an egg donation program during the period from March 2018 to October 2018. The oxidative analysis was performed with the TCL Analyzer™ and embryos were cultured and evaluated in a time-lapse technology system.

Participants/materials, setting, methods: A total of 57 follicular fluid samples were collected during oocyte retrieval. 50 µl samples were assessed by the TCL Analyzer™, based on a heat-induced oxidation of biological fluids leading to the production of light energy, counted as photons emitted per second (cps), recorded after 55 seconds (H1), 155 seconds (H2) and 255 seconds (H3). A smoothing algorithm (sm) was used to normalize data. Data was statistically analyzed with Pearson chi-square test and one-way ANOVA.

Main results and the role of chance: Donor follicular fluid showed significantly higher values ($p<.05$) for the oxidative parameters than patients ones: **H1sm=** 290.53 ± 85.59 cps for patients vs. 361.88 ± 124.46 cps for donors, **H2sm=** 412.09 ± 116.92 cps for patients vs. 514.71 ± 133.20 cps for donors and **H3sm=** 628.37 ± 213.23 cps for patients vs. 783 ± 173.62 cps for donors. Regardless the follicular fluid origin (donor or patient), a significantly negative correlation was found between woman age and the level of oxidative stress in the sample ($p<.05$). The mean and standard deviation of the TCL parameters were as follows (cps): 555.39 ± 130.84 for ≤26 years, 506.11 ± 125.29 from 27 to 35 years, 429.10 ± 166.81 from 36 to 40 years and 424.37 ± 135.08 for ≥41 years. Congruent with the above results, significantly higher TCL parameters were found as number of retrieved oocytes increased ($p<.05$). For less than 20 oocytes retrieved: **H1sm** = 297.89 cps, **H2sm** = 418.53 cps and **H3sm** = 634.46 cps and for more than 20 oocytes retrieved: **H1sm** = 367.49 cps, **H2sm** = 534.69 cps and **H3sm** = 823.49 cps. However, no differences in TCL results were found regarding Body Mass Index (BMI).

Limitations, reasons for caution: The study of the follicular fluid can only give us information about the full oocyte and embryo cohort development, but never individual information of each embryo. This is a pilot study with a small sample size which must be increased in order to verify our conclusions.

Wider implications of the findings: An increase of the sample size would allow us to assess the impact of follicular fluid oxidative status over the embryo development and clinical outcomes. The measurement of follicular fluid oxidative status might help us designing improved strategies to better and more personalized IVF treatments.

Trial registration number: not applicable

P-233 Can apply Artificial Chemical Oocyte activation with Strontium Chloride for couples with severe male factor infertility or previous failed IVF cycles?

N. Thondehal Math[1], G. Uttur[1], D. Ganesh[1], S. Weon Young[2]

[1] *Gunasheela Surgical & Maternity Hospital, embryology, Bangalore, India*

[2] *McGill University, Embryology, Montreal, Canada*

Study question: Does activation with Strontium chloride($SrCl_2$) improve fertilization and embryo development in patients with severe male factor infertility or history of failed IVF cycles?

Summary answer: Application of AOA with $SrCl_2$ leads to an increased fertilization rate and blastocyst formation rate in patients with severe male factor or previous failed cycles..

What is known already: In patients with a history of previous fertilization failure with ICSI, artificial oocyte activation (AOA) after ICSI (ICSI-AOA) has been used to improve the fertilization and pregnancy rates. In addition,few studies recently reported that embryo development also improved with the ICSI-AOA method. However, these studies were done on women-based randomization and not on oocyte-based randomization. Studies on oocyte-based randomization still remain elusive. This study compares reproductive potential between ICSI-AOA and conventional ICSI on sibling oocytes from the same patients with severe male factor or previously failed IVF cycles.

Study design, size, duration: This prospective study was conducted in a private hospital between June 2016 and December 2018. In each case, the allocation of sibling mature oocytes (MII) to either the AOA (ICSI-AOA) or the control group (ICSI)was randomized. Fertilization and good blastocyst formation rates (≥ 4BB) in ICSI-AOA group were compared to conventional ICSI group with sibling oocytes. The best blastocysts formed were transferred.

Participants/materials, setting, methods: This study was conducted in patients (38.7 ± 4.6 years old) with male factor infertility (n=23) or a history of failed implantation following conventional ICSI (n=22). In the next treatment cycle, ICSI-AOA was performed on approximately half of the MII oocytes and conventional ICSI on the rest. For ICSI-AOA, the oocytes were exposed to 10 mM $SrCl_2$ for 60 min after performing ICSI. All fertilized embryos were cultured to blastocyst stage.

Main results and the role of chance: Fertilization and blastocyst utilization rates were higher in ICSI-AOA (77.9%, 116/149; 69.8%, 81/116) than

conventional ICSI group (50.3%, 72/143; 50.0%, 36/72) in patients with male factor infertility ($P< 0.05$). In the patients with previous failed pregnancy, fertilization rates did not differ (77.1%, 118/153 versus 74.8%, 107/143); however, significantly more ($P< 0.05$) good-quality blastocysts formed in the ICSI-AOA compared with the conventional ICSI group (57.6%, 68/118 versus 38.3%, 41/107, respectively). After transferring the embryos produced only from ICSI-AOA group, all babies born at the time of writing (9 babies) were healthy.

Limitations, reasons for caution: The sample size is low. More patients and a high number of mature oocytes available for injection per patient are needed.

Wider implications of the findings: Due to variable factors between patients, study on sibling oocytes might be the actual valid method to see usefulness of AOA. Our study implies that AOA treatment is an option to improve blastocyst formation rate for the couples who have severe male factor infertility or failed pregnancies in previous cycles

Trial registration number: Not applicable

P-234 Distribution of FSH Receptor polymorphism (FSHR) at position 680, in South Indian women and their responses to Controlled Ovarian Stimulation (COS) for ICSI cycles

K. Karthik[1], S.R. Nellapalli[1], A. Nandakumar[1], R. Vembu[1], M. Pandurangi[1], S. Nagireddy[1]

[1]Sri Ramachandra Medical College and Research Institute, Reproductive Medicine and Surgery, Chennai, India

Study question: Does FSH receptor (FSHR) polymorphism at position 680 have any effect on controlled ovarian stimulation (COS) in ICSI cycles in South Indian population?

Summary answer: To determine the association of FSHR polymorphism at position 680 in predicting ovarian responses to COS in South Indian women and the distribution of polymorphism.

What is known already: The first SNP studied was the FSH receptor polymorphism Asn680Ser, which affects FSH level and increases gonadotrophin requirements during COH.Increasing the dose of FSH administration does not improve the oocyte development due to insufficient FSHR expression of the granulosa cells. In support of this,a SNP model at position 680 was reported to be associated with low response to exogenous FSH stimulation during COS .The expression of receptors differ in three genotypes (AA, AS, SS) which influences ligand/receptor interaction. Women of different ethnic population were studied and different distribution of allele pattern was noted .The response to COS were also assessed.

Study design, size, duration: Retrospective observational study conducted at Sri Ramachandra Medical College and Research Institute, Chennai, India from October 2013 to December 2016. Hundred and fifty normogonadotrophic women undergoing ICSI cycles were included after obtaining a written consent.

Participants/materials, setting, methods: Controlled Ovarian Stimulation (COS) was done using gonadotropins and antagonist protocol. Blood samples were collected in sterile EDTA vacutainers on the day of stimuation. DNA was extracted and were subjected to PCR amplification, Sequencing followed by elution. Final analysis was done using SeqScape genetic analyzer and the distribution of alleles were interpreted with specific color code signals for each allele AA, AS and SS SNP's.

Main results and the role of chance: FSH is essential for follicular growth and oocyte maturation. FSHR gene is essential for FSH for its action. A structural change in the FSHR gene changes the amino acid configuration which leads to altered ovarian response to gonadotropin stimulation. Our study showed 50% of women had AA polymorphism, 42% of women had AS and only 8% had SS polymorphism.The distribution of SS polymorphism was much lower in south Indian women, when compared to Caucasian and Chinese women which were 31.7% and 13% respectively. It was noted that women who had SS polymorphism were not poor responders when compared to women with AA and AS polymorphism. Women with SS polymorphism had higher MII oocytes (12.31±5.15) than the AA and AS group (7.27±4.65), (8.77±7.54) respectively and was statistically significant. There were no significant differences in duration of stimulation, fertilization rates, total dose of gonadotropins used between the three polymorphisms at position 680. Our study also showed that the cumulative pregnancy rates were slightly higher in patients with SS polymorphism which was 51% than AA (40%) and Asn/Ser (48%) and this may indirectly due to higher number of oocytes obtained during COS.

Limitations, reasons for caution: The sample was confined only to people proceeding for ART. Women who underwent COS in view of PCOS, endometriosis, Decreased Ovarian reserve, Previous ovarian surgeries for ovarian pathologies were excluded. Larger sample size may help to exactly find the distribution of polymorphism in Indian population.

Wider implications of the findings: Assessing polymorphism at position 680 will not improve the outcome of ART results by predicting the response in south Indian population. Women with SS polymorphism will have lesser chances of poor response and slight increase in MII oocytes number although this may not help in deciding the dose for COS.

Trial registration number: Not Applicable

P-235 The clinical outcome of ultra-low oxygen tension on post-thawed human blastocyst

S. El Tanbouly[1], A.G. Hussin[1], H. El Khedr[1], H. Zaki[1]

[1]Ganin Fertility Center, ivf, Cairo, Egypt

Study question: Does ultra low oxygen tension (2%) have an advantage over low oxygen tension (5%) for post-thawed human blastocyst?

Summary answer: Ultra-low oxygen tension (2%) did not show superiority over low oxygen tension (5%) regarding degree of blastocoel expansion and clinical pregnancy rate

What is known already: In the female reproductive tract, oxygen concentration fluctuates between 2-8%, which is considered to be at its highest level in the fallopian tube, while the lowest level is in the uterus. Pre-implantation embryo crosses the uterotubal junction after the time of compaction on Day 3, where it is exposed to a shift in oxygen tension to 2%. This variation may have a role in the metabolic reactions of the embryo, and in its preparation for implantation process. Some studies suggested that culturing embryos with oxygen tension below 5% might have an embryological advantage mimicking nature.

Study design, size, duration: A prospective randomized trail included 60 participants who underwent frozen embryo transfer cycles at Ganin Fertility Center from November 2018 to January 2019 and still recruiting patients. One day before embryo transfer, cases were randomized in to two equal arms; Control arm (Low oxygen tension 5% O2), and experimental arm (Ultra low oxygen tension 2% O2). Thawed embryos were cultured according to their assigned conditions until embryo transfer.

Participants/materials, setting, methods: Participants with female age below 40 years and had vitrified blastocysts on day 5/6 were enrolled in the study. Thawed blastocysts were cultured in pre-equilibrated media covered with oil in two different incubators: (5.7% CO2, 5% O2, and 89.3% N2 at 37°C) for the control arm, and (5.7% CO2, 2% O2, and 92.3% N2 at 37°C) for the experimental arm. Embryos were assessed for the degree of blastocoel expansion at the time of embryo transfer.

Main results and the role of chance: One hundred forty four embryos were included in this study. Control arm 5% O2 (81 embryos) and experimental arm 2% O2 (63 embryos). There were no significant differences in the female age (29.8 vs. 31.3 years), time till vitrification (132.6 vs. 129.1 hours), and time from embryo thawing till transfer (2.25 vs. 2.14 hours) between control arm (5%O2) and experimental arm (2%O2) respectively. Regarding embryological parameters, statistical analysis using SPSS showed no significance in degree of blastocoel expansion (48.6% vs. 55.7%) ($P> 0.05$) or clinical Pregnancy rate (46.6% vs. 53.3%) ($P> 0.05$) for control arm and experimental arm respectively. However, there is a higher tendency for blastocoel expansion and clinical pregnancy rate to the experimental arm (ultra-low oxygen tension 2%) than the control arm (low oxygen tension 5%).

Limitations, reasons for caution: The study was performed on small sample size, so more large well-conducted randomized controlled trials are needed.

Wider implications of the findings: The promising tendency towards more expanding blastocyst make 2% O2 need to be explored by more means of assessment of blastocyst viability.

Trial registration number: ClinicalTrails.gov ID: NCT03817671

P-236 BESST, a non-invasive computational tool for embryo selection using mass spectral profiling of embryo culture media

F.I. Sharara[1], P. Ricardo[2], Z. Raminta[2], K. Sholeh[2], I. Ray[2], B. Steven[2]
[1]Virginia Center for Reproductive Medicine, REI, Reston, U.S.A.
[2]MAP Sciences, MAP sciences, London, United Kingdom

Study question: Can a non-invasive mass spectrometry-based tool be used to identify embryos that result in ongoing pregnancy?

Summary answer: Algorithmic pattern scoring based analysis of embryo culture mass spectra provides a score of probability of implantation and ongoing pregnancies, identifying 76.9% of life birth.

What is known already: The current gold standard of embryo evaluation is based on morphology and morphokinetics, however there have been many efforts to design non-invasive tests to assess embryo viability, including imaging of embryo metabolism by Fluorescence Lifetime Imaging Microscopy (FLIM) and High-Resolution Nuclear Magnetic Resonance (H-NMR) for metabolic biomarker detection. Matrix Assisted Laser Desorption Ionisation Time of Flight (MALDI-ToF) mass spectrometry offers an immediate, sensitive and straightforward analysis of spent embryo culture to give a confirmation of embryo viability within minutes. It is now possible to confirm pregnancy outcome using the retrospective analysis of embryo culture fluid.

Study design, size, duration: A retrospective cohort study, including 1190 spent media samples from embryo cultures collected from a single IVF clinic in USA. The samples were collected between March 2014 and March 2018. Outcomes subsequent implantation were intra uterine, negative, biochemical pregnancy and spontaneous abortion and preimplantation genetic screening outcomes of euploid and aneuploid. Only fresh single transfers embryos were used in the development of the tool.

Participants/materials, setting, methods: Upon receiving, embryo culture media was thawed, diluted and analysed using MALDI ToF mass spectrometry in a laboratory in the UK. Analysis was performed with CHCA matrix, spectra obtained in a mass range of 200 to 2000 m/z. Data files were subject to semi-quantitative computational analysis using Python programming language.

Main results and the role of chance: The Blastocyst and Embryo Screening and Selection Tool (BESST) was developed following the analysis of embryo culture media from a single, fresh transfer embryo culture media. The automated computational workflow was applied to generate a reference spectral pattern of ideal embryo profile with chosen samples. Criteria for sample selection included: highest quality scores as determined by Blastocyst Quality Score, a numerical blastocyst-morphology grading system, ongoing pregnancy outcome and euploids as tested by PGS.

Similarities to the reference pattern were computed, based on peak positions and intensity values, assigning a score for each embryo. The resulting complex, non-linear scores were subject to cluster analysis and subsequently mapped into five distinct classes of 0 to 5 with continuous numerical values, which can be interpreted linearly. With this method we were able to identify 76.9% of ongoing pregnancy cases for embryos that score >4, while score of <1.5 predicts that embryo have a 35.7% chance of ongoing pregnancy.

It is important to note that result of 100% or close cannot be achieved due to underlying confounding factor that is cases of unreceptive endometrium, regardless of how good the quality of the embryo. Hence the PPV of 76.9% shown here is a favourable result.

Limitations, reasons for caution: The study is limited in that the tool was developed on single fresh embryo samples only. Embryo freezing prior PGS testing requires a separate algorithmic tool. Furthermore, the study was based on data from one IVF centre and prospective validation studies should be carried out in different practices.

Wider implications of the findings: BESST (Blastocyst and Embryo Screening and Selection Tool) when applied prospectively, immediately prior to embryo transfer, could enable the objective, consistent and non-invasive analysis of the likelihood of achieving ongoing pregnancy and compared to morphology alone could be optimised to see improvement in pregnancy rates for any clinic using BESST.

Trial registration number: None

P-237 Evaluation of developmental competences of paired blastomeres of mouse 2-cell embryos and establishment of splitted monozygotic twin embryos model

J. Lee[1], Y.J. Choi[1], J.E. Park[1], J. Kim[2], W. Kim[1], J.W. Choi[1], J.H. Jun[3]
[1]Eulji University, Biomedical laboratory science, Gyeonggi do, Korea- South
[2]Korea Institute of Oriental Medicine, Clinical Medicine Division, Daejeon, Korea- South
[3]Eulji University, Dept. of Biomedical Laboratory Science- Dept. of Senior Healthcare- BK21 plus program- Graduated School- Eulji Medi-Bio Research Institute EMBRI, Gyeonggi do, Korea- South

Study question: Are there inter-embryonic variations of developmental pattern and competence between paired blastomeres of mechanically splitted monozygotic twin embryos (SMTE) from a 2-cell embryo?

Summary answer: Each blastomere of a 2-cell embryo has no significant differences in embryo development. SMTE model might be valuable for subtle experiments for *in vitro* culture.

What is known already: Experiments with mouse pre-implantation embryos might have the inter-embryonic variations. Owing to these variations, exact differences of developmental competence and epigenetic alterations by culture conditions are hard to find during *in vitro* cultured preimplantation embryos. Several studies were reported that *in vitro* culture of splitting and isolating blastomeres of mouse and human cleavage-stage embryos. It has been applied to increase the number of embryos with same genetic backgrounds. However, the SMTE model has not been evaluated and established.

Study design, size, duration: We examined the developmental pattern and competence between paired blastomeres of SMTE from a 2-cell embryo. The developmental pattern was analyzed using the time lapse-lapse monitoring system from 1-cell to blastocyst stage. In vitro cultured blastocysts of paired SMTE were fixed and counted the number of nuclei. The paired SMTE were cultured and analyzed 17 times experiments.

Participants/materials, setting, methods: Mouse 2-cell embryos were collected and zona pellucida was removed by acid Tyrode's solution. The embryos were mechanically divided into a paired blastomere of SMTE-A and -A'. The developmental patterns and consequences of the paired SMTE were assessed with the time-lapse monitoring system. The developmental competences were analyzed by comparing the mean interval and cumulative time for next pre-implantation embryonic stage, and blastulation rate and the number of nuclei of blastocysts in the paired SMTE.

Main results and the role of chance: Blastomeres of 2-cell embryos were successfully splitted without any damage, and cultured individually. The interval times from 1-cell to 2-cell and 4-cell to morula, and the cumulative times from 1-cell to 4-cell were significantly different between paired SMTE. However, the times of further development to blastocyst stage were similar between paired SMTE. Overall development rate of paired SMTE-A and SMTE-A' were 71.2 ± 6.1% and 71.6 ± 5.8%, respectively. The numbers of nuclei of blastocysts were similar between paired SMTE-A and SMTE-A' as 48.5 ± 2.3 and 49.9 ± 2.1, respectively.

Limitations, reasons for caution: This study showed only morphological analysis of developmental competence in mouse SMTE. Lack of certain evidences which are able to evaluate SMTE model is valuable model in pre-implantation embryo research. Gene regulations, epigenetic modification, and other embryo developmental competence should be more clearly analyzed in the next study.

Wider implications of the findings: In order to minimize the number of sacrificed animals used in the various researches, SMTE model would be an alternative and efficient method. Also, the SMTE model could be utilized for comparing the epigenetic modification including DNA methylation, histone acetylation and others species including human in pre-implantation embryos.

Trial registration number: Not applicable

P-238 Should ICSI be the first line treatment for patients where low numbers of oocytes are retrieved during assisted fertility treatment?

Abstract withdrawn by the authors

P-239 Day 4 embryo vitrification: is it a valid option for IVF lab practice?

A. Chatziparasidou[1], S. Sgoura[1], M. Martha[1], N. Christoforidis[1]

[1]Embryolab, ivf, Thessaloniki, Greece

Study question: To assess the efficiency of day 4 vitrified embryos after warming in terms of survival, development and pregnancy rate.
Summary answer: Vitrification of day 4 embryos is a valid alternative for embryo cryopreservation as it demonstrates high survival, and pregnancy rates.
What is known already: Vitrification has become the most commonly used method for embryo cryopreservation and has almost replaced slow freezing. The available data demonstrate that more than 90% of the vitrified cleavage embryos and blastocyst survive after warming and perform equally to the fresh. However, very little is known about the survival and overall performance after warming of embryos vitrified on day 4. In the absence of a common grading system for day 4 embryos, their morphological assessment may become a challenge; this may explain the preference for vitrification of cleavage embryos or blastocysts, where morphological assessment is more standardized and less operator-depended.
Study design, size, duration: This retrospective study was contacted from May 2015 to December 2018. During the study period, in total, 235 patients underwent frozen embryo replacement cycles (FERC) and received warmed embryos vitrified on day 4. For the statistical analysis the IBM SPSS program was used in combination with the X^2 Pearson test.
Participants/materials, setting, methods: Only embryos with clear signs of compaction were considered suitable for vitrification on day 4. The vitrified embryos were warmed on the 4th day after the onset of progesterone administration; and according to the number of the available vitrified embryos a day 4 transfer was scheduled for the patients with 1 to 2 vitrified embryos (Study Group 1) or a day 5 transfer (Study Group 2), for the patients with 3 or more vitrified embryos.
Main results and the role of chance: In total 674 vitrified embryos were warmed for the 235 patients and 650 were fully recovered (96,4%). For study group 1, 53 patients (mean age 36,8) received day 4 embryos (mean embryos transferred 1,64), 25 patients had a positive pregnancy test (47,2%) and 19 progressed to a clinical pregnancy (35,8%). For study group 2, 182 patients (mean age 35,9) received day 5 embryos (mean embryos transferred 1,98), 114 had a positive pregnancy test (62,6%) and 85 progressed to a clinical pregnancy (46,7%). Of the remaining embryos 97 reached blastocyst stage and were re-vitrified. As expected patients in study group 2 demonstrated significantly higher pregnancy rates compared to study group 1 ($p<0,005$). This finding could be explained by the fact that, a more advanced embryo selection was possible for study group 2 patients, as they had more available embryos, which were left to grow to blastocyst stage before 1 or 2 were selected for transfer.
Limitations, reasons for caution: There is not a commonly accepted grading system for day 4 embryos. Embryos on day 4 may present varying degrees of compaction, as a result, their assessment is subjective and operator depended. The data of this study, while promising, are still very limited due to the small number of patients.
Wider implications of the findings: Day 4 vitrification may become a new valuable treatment option for IVF practitioners by increasing flexibility for embryo vitrification and allowing tailor-made to patient needs, lab-approaches. For FERCs, vitrification of day 4 embryos in combination with day 5 transfer, may provide a more advanced embryo selection strategy for blastocysts.
Trial registration number: Not applicable

P-240 Role of major endocannabinoid-binding receptors during mouse oocyte maturation and spindle organization

V. Di Nisio[1], G. Rossi[1], S. Oddi[2], M. Maccarrone[3], S. Cecconi[1]
[1]University of L'Aquila, Dept. of Life- Health and Environmental Sciences, L'Aquila, Italy
[2]University of Teramo, Faculty of Veterinary Medicine, Teramo, Italy
[3]Campus Bio-Medico University of Rome, Department of Medicine, Rome, Italy

Study question: Are main endocannabinoids-binding receptors (CBRs) involved in mouse oocyte maturation and in proper spindle organization?
Summary answer: The different expression of CBRs during meiotic maturation reflects their role in the control of meiotic resumption (CB_1R, CB_2R) and in spindle organization (GPR55).
What is known already: Endocannabinoid system (ECS) includes lipid messengers termed endocannabinoids (eCBs), their receptor targets type-1 (CB_1R) and type-2 (CB_2R) cannabinoid receptors, G-protein coupled receptor 55 (GPR55), transient receptor potential vanilloid type 1 channel (TRPV1) and a number of metabolic enzymes. ECS has a key-role on virtually all steps of female reproduction. To date, among the main receptors, only 2 receptors have been extensively studied in the mammalian oocytes, i.e. CB_1R and CB_2R. In mouse oocytes, both receptors were modulated during meiotic maturation, and CB_1R signaling was linked to the activity of ERK and Akt.
Study design, size, duration: CBRs localization, mRNA and protein contents were determined in oocytes collected *in vivo* at germinal vesicle (GV), metaphase-I (MI) and -II (MII; n=180/group). CB_1R, CB_2R and GPR55 roles during meiotic resumption or maturation were assessed by incubating oocytes in the presence/absence of receptor antagonists SR1, SR2 and ML193 and a) by measuring intraoocyte cAMP concentration (n=600 oocytes/group); b) by evaluating spindle morphology at MI and MII (n=30 oocytes/group).
Participants/materials, setting, methods: Adult CD1 female mice were primed with 5 IU PMSG, and sacrificed: (a) 44 h later to obtain GV oocytes, (b) 8 or 12h after hCG (5 IU) injection to obtain MI or MII oocytes. CBRs mRNA and protein contents were assessed by qRT-PCR and Western blot; CBRs localization by confocal microscopy. cAMP concentration was assessed by EIA kit; MI/MII spindle morphology by appropriate immunofluorescent antibodies. Experiments were repeated at least 3 times.
Main results and the role of chance: Despite a significant decrease of CB_1R, CB_2R and GPR55 mRNAs (GV vs MI, MII: $P<0.05$), CB_2R and GPR55 protein contents increased from GV to MI and MII (vs GV: $P<0.05$). At GV, only CB_1R was localized in oolemma, although it disappeared at MI. TRPV1 (mRNA/protein) was always undetectable. When oocytes were *in vitro* matured with CB_1R and CB_2R but not GPR55 antagonists, a significant delay of GV breakdown occurred (Ctr vs SR1, SR2, $P<0.05$; vs ML193, $P>0.05$), sustained by higher intraoocyte cAMP concentration. Although CBRs antagonists did not affect polar body I emission nor chromosome alignment at metaphase plates (vs Ctr, $P>0.05$), ML193 impaired in about 75% of oocytes the formation of normal MI or MII spindles. Indeed, ML193-incubated oocytes showed a significant reduction of spindle length (MI=24,34±0,44 µm, MII=22.96±0.30 µm) as compared with Ctr (MI=35,20±0,13 µm, MII= 32,64±0,17 µm; $P<0.05$). These results suggest that while CB_1R and CB_2R are engaged in the control of meiotic resumption, GPR55 play a surprising and unexpected role in meiotic spindle formation.
Limitations, reasons for caution: The present study was performed in a mouse model, because it allows reproducible results. Any correlation with humans should be considered and adjusted accordingly.
Wider implications of the findings: In mouse oocytes all the major eCB-receptors are differentially expressed during meiotic maturation. CB_1R and CB_2R have prominent role in the control of meiosis resumption, GPR55 in MI and MII spindle organization. These findings open a new avenue to interrogate oocyte pathophysiology and offer potentially novel biomarkers for fertility problems.
Trial registration number: None

P-241 A non-invasive, rapid method to discriminate euploid and aneuploid embryo by MALDI Tof MS of culture media.

S. Keshavarz[1], F. Sharara[2], R. Pais[1], R. Zmuidinaite[1], R. Iles[1], S. Butler[1]
[1]MAP Sciences Ltd, Research, Bedford, United Kingdom
[2]Virginia Centre for Reproductive Medicine, Embryology, Reston, U.S.A.

Study question: Can a difference in mass spectral data from the culture media of embryos be used to discriminate between euploid and aneuploid genotypes without genetic testing?
Summary answer: It is possible to identify patterns of change in mass spectral data to discriminate between embryos with euploid and aneuploid phenotypes.
What is known already: PGS of biopsied blastocyst stage embryos is currently used to discriminate between euploid and aneuploid genotypes. However, randomized prospective clinical trials failed to show an increase in live birth rates after PGS selection of embryos. This could be assigned to the technical drawbacks and chromosomal mosaicism. Thus, the clinical cost benefits of PGS is questioned. Nevertheless, faster and more affordable means to screen for aneuploidies that persist to life birth are a needed. It has been shown that MALDI-ToF mass spectrometry of embryo culture media can detect differences between the phenotypes, offering rapid, sensitive analysis without requirement of vitrification.

Study design, size, duration: A retrospective cohort study, including 1190 spent media samples from embryo cultures collected from a single IVF clinic in USA. The samples were collected between March 2014 and March 2018. There were 149 euploid and 165 aneuploid embryos as analysed by PGS next-generation sequencing technique.
Participants/materials, setting, methods: Upon receiving, embryo culture media was thawed, diluted and analysed using MALDI-ToF mass spectrometry in a laboratory in the UK. The spectra were generated using CHCA matrix, obtained in a mass range of 200 to 2000 m/z to identify proteomic profile. Characteristic regions to discriminate euploids and aneuploids, enrichment analysis and intensity differences were obtained using automated computational workflow implemented in Python.
Main results and the role of chance: Different spectral patterns were found for two outcomes of euploid and aneuploid genotype in embryo culture media. Nine characteristic regions were identified that were statistically significant ($p < 0.001$). These regions had variable window size, ranging from 3 to 10 m/z, representing the peaks in the spectra. The peaks were localised in a mass range of 235 to 864 m/z. The obtained intensity differences between median values of peak intensity were substantially high going up to ten-fold. Enrichment analysis demonstrated between three to six-fold higher predominance of characteristic peaks for aneuploidies when compared to euploids.
Limitations, reasons for caution: Spectral pattern of aneuploidies is complicated to as there is such a wide range of chromosomal abnormalities observed. The spectral pattern is therefore identification of variance from Euploidy and not for specific aneuploidies such as T21.
Wider implications of the findings: PGS is invasive, expensive, time-consuming test that requires embryo vitrification. Embryo culture media analysis by MALDI offers a non-invasive method to assess euploidy of an embryo prior to transfer which could positively affect both clinics and patients.
Trial registration number: not applicable

P-242 Mitochondrial (mt) DNA copy number may affect blastulation timing

D. Beltrán Torregrosa[1], C. Albert[1], A. Mifsud[1], A. Mercader[1], A. Pellicer[2], M.J. De los Santos[1]
[1]*IVIRMA Valencia, IVF Lab, Valencia, Spain*
[2]*IVIRMA Valencia, Obgyn, Valencia, Spain*

Study question: Is the mtDNA content affecting embryo development ability?
Summary answer: Embryos carrying higher mtDNA copy number seem to need more time to achieve blastocyst stage, but it's not related with the expansion capacity after warming.
What is known already: Descriptive studies looking at the mtDNA load in blastocysts have shown that those blastocyst with higher quantities have more chances to be aneuploid, to have lower embryo quality as well as worst implantation potential. Few studies speaks about timings during embryo development, since cellular differentiation during blastulation have high energy demands, and mitochondria may supply the required ATP, we aimed to evaluate the relationship between mtDNA copy number and the time of blastulation and recovery after warming.
Study design, size, duration: Retrospective study comprising a total of 229 embryos from a total of 134 patients undergoing PGT-A between 2017 and 2018. Embryos were divided in two study groups depending of the values of mtDNA relative quantities. Group A: 102 embryos carrying values above the median and Group B: 127 with values below or equal to the median value.
Participants/materials, setting, methods: Embryos were cultured under embryoscope and biopsied on day 5 or 6. The calculation the mtDNA score was done by NGS. The number of reads mapping to the mitochondrial genome was divided by the number of reads mapping to the nuclear genome T-student was used for statistical comparisons
Main results and the role of chance: The relative mtDNA content in the analyzed blastocysts ranged from 4 to 135. When comparing the two groups, we observed that blastocysts with higher mtDNA values, group A, needed more time to commence blastulation (101.64 h) and to expand (108.54 h) that the group B, 97. 78 h and 104.16 h respectively ($p < 0.0001$). Patient with embryos belonging to group B were 38.7+ 3.7 years old compared to patients of the group B 37.8 + 3.9 ($p > 0.05$). Significant lower quality embryos were found in the group A (51%) compared with Group B (32%).Thirty three embryos were warmed and left in culture up to 3.6 h before transfer. In these cases the mtDNA content did not affect to the ability of embryos to re-expand.
Limitations, reasons for caution: Higher mtDNA quantity negatively affected blastulation and expansion timing, however worse embryo quality was observed as well. Body mass index or stimulation parameters can be also contribution factors of the results. In order to confirm these results, other variables and bigger sample size need to be considered.
Wider implications of the findings: Higher mtDNA may be indicative of cellular stress and mitochondrial dysfunction, under this situation embryos not only may encounter more
Trial registration number: Not applicalbe

P-243 Retrospective study of changes in mitochondrial levels of blastocysts in a single-step culture medium

E. Seow Pei Yin [1]
[1]*Kesuburan Sentosa Sdn Bhd IVF Bridge Fertility Center, Embryology Lab, Johor Bahru-Johor, Malaysia*

Study question: Does a single-step culture system affect the mitochondrial level in the blastocyst?
Summary answer: The mitochondria level of the blastocysts is independent of the energy substrates composition and concentration in the medium.
What is known already: Mitochondria is the powerhouse of various cellular functions and in the recent years, its potential as a biomarker for embryo viability has been widely explored. With the introduction of time-lapse technology, single-step medium was developed to allow non-disturbed extended culture from fertilization to blastocyst stage. In order to do this, single-step medium needs to have the energy substrate composition and concentration that supports the embryos development up to blastocysts stage. Therefore, this research aims to study if there is a shift in the mitochondria level of these blastocysts in accordance to the different medium substrates composition and concentration.
Study design, size, duration: Retrospective analysis of 292 biopsied blastocysts cultured for clinical IVF procedures with PGT option between July 2017 to January 2019.
Participants/materials, setting, methods: From July 2017 to August 2018, sequential medium (Vitrolife, G1-Plus & G2-Plus) was used for blastocysts culture (n=142) according to the manufacturer protocol i.e. fresh medium change on Day 1, Day 3 and Day 5. From September 2018 to January 2019, the blastocysts (n=150) were cultured in single-step medium (Vitrolife, G-TL) using the same volume. The blastocysts were biopsied on Day 5/6 and mtDNA was analysed using the Ion Torrent NGS platform.
Main results and the role of chance: There was no significant difference in the mtDNA level of the blastocysts in the sequential medium (0.0012±0.0007) compared to the single-step medium (0.0013±0.0008), p=0.253. It was also found that there was no significant difference in the mtDNA level of euploid blastocysts vs aneuploid blastocysts in both groups (0.0013±0.0006 vs 0.0014±0.0009), p=0.314. Similar results were also obtained for euploid blastocysts vs mosaic blastocysts (0.0013±0.0006 vs 0.0012±0.0008), p=0.69.
Limitations, reasons for caution: The mitochondrial content can also differ depending on the site of biopsy and sampling handling time before amplification. Hence, in order to use this indicator as a biomarker of implantation potential, it has to be complemented with other evidence such as morphological findings and PGT status.
Wider implications of the findings: The change in media composition from sequential to single-step does not affect the energy level in the embryos. The use of single step medium can help to reduce the workload of embryologists and reduces the cost of consumables in an IVF cycle.
Trial registration number: Not Applicable

P-244 Does the thaw to transfer interval (TTI) affect the outcome of a frozen embryo transfer (FET) cycle?

G. Woodhead[1], A. Beccles[1], L. Kellam[1], K. Berrisford[1], A. Campbell[2]
[1]*CARE Fertility Nottingham, Embryology, Nottingham, United Kingdom*
[2]*CARE Fertility, Embryology, Nottingham, United Kingdom*

Study question: Does the time between embryo thawing and transfer affect the positive test (POS), clinical pregnancy (CP) or live birth rates (LB) of a FET cycle?

Summary answer: TTI does not affect POS or CP. However, a TTI of >4 hours does significantly increase the LB.

What is known already: Literature is limited regarding TTI and outcome. However, a study by Rato et al (2012) suggests an inverse correlation between TTI and implantation rates (IR) and LB for cleavage stage embryos. A previous retrospective data analysis by Woodhead et al (2019), suggests no significant difference in POS, CP or LB for blastocyst FETs with varying TTIs (ranging from <2 to >6 hours).

Study design, size, duration: 4374 standard FET cycles from January 2014 to March 2018 were retrospectively analysed. The data was collated from 4 UK clinics using the same protocols. Results were statistically analysed using ANOVA and subsequent t-test.

Participants/materials, setting, methods: Data included patients of all ages that had a single blastocyst FET. Failed thaws were excluded to avoid the impact of freezing or warming complications. The data was grouped into 6 main groups of TTI (<2, 2-3, 3-4, 4-5, 5-6, >6 hours). All outcomes (POS, CP, LB) were measured per embryo transfer.

Main results and the role of chance: The overall POS, CP and LB were 53.1%, 39.2% and 20.7% respectively (n=4374). Relatively equal sizes were observed between the TTI groups (from short to long, n=885, 750, 588, 998, 812 and 341 respectively). The POS for each TTI group, from shortest (<2 hours) to longest (>6 hours), were 53.8%, 51.9%, 54.3%, 51.8%, 55.2% and 51.0% respectively. The CP for each TTI group, from shortest to longest, were 39.8%, 37.9%, 39.3%, 38.6%, 41.5% and 37.2% respectively. ANOVA testing showed no significant differences between either of these results (p=0.89 and 0.86 respectively). The LB for each group, from shortest to longest, were 18.4%, 16.1%, 19.6%, 22.1%, 23.8% and 27.0%. ANNOVA testing showed significant differences between the groups (p<0.001). Subsequent t-tests showed a significant increase in the LB of 4-5 hours TTI compared with <2 and 2-3 hours TTI (p<0.05, p<0.01). A TTI of 5-6 hours showed and significant increase in LB when compared to <2, 2-3 and 3-4 hours TTI (p<0.01, p<0.001, p<0.05). A TTI of >6 hours showed a significant increase in LB when compared to <2, 2-3 and 3-4 hours TTI (p<0.01, p<0.001 and p<0.05).

Limitations, reasons for caution: Factors such as patient age, cause of infertility and blastocyst age or quality were not accounted for. Further analysis may be needed to ensure the differences in LB are solely due to TTI, rather than these additional factors.

Wider implications of the findings: Immediately thawing and replacing of cryopreserved blastocysts may not be the optimal way to perform FETs. Post thaw assessments could be implemented to aid the embryologist in determining blastocyst survival and this extended TTI would maximise the take home baby rate.

Trial registration number: N/A

P-245 Efficacy of embryo culture in dry and wet system: a prospective randomized sibling-oocyte study

E. Rega[1], M.F. Starita[1], M. Izzo[1], R. Ruggiero[1], A. Ianniello[1], A. Colicchia[1], C. Piscitelli[1]

[1]Clinic Nuova Villa Claudia, Assisted Reproductive Technology, Rome, Italy

Study question: To compare the impact of different Embryos Culture System (ECS) of sibling-oocytes cultured in wet and dry incubators, on embryo development and clinical outcomes.

Summary answer: The humidified and dry atmosphere has no impact on efficacy of ECS.No significant differences were found in blastocyst formation rate in those two culture systems.

What is known already: The incubator plays a critical role in providing a stable culture environment to support embryo development.With technological advances a "dry culture system" (DCS) which has no tray of water in the incubator has been designed for embryos culture and the DCS is replacing the wet one. A comparative study showed that the blastocyst formation, implantation, and clinical pregnancy rate was lower in DCS compared to humidified culture, however there is no universal agreement among scientist and the choice of the best incubator is still controversial. To date, most studies not compare the sibling embryos development

Study design, size, duration: Prospective randomized study of 350 sibling oocytes from 40 women (aged ≤ 39 years) undergoing oocyte retrieval procedure for intracytoplasmic sperm injection (ICSI) at Nuova Villa Claudia, from July to December 2018

Participants/materials, setting, methods: A total of 350 injected oocytes were randomly cultured in two different incubators: the conventional humid incubator containing a water tray (ASTEC; Group A) and the bench-top dry incubator (MIRI; Group B). Culture was performed up to blastocyst at 37°C, 5% O2, 6% CO2. The single oocyte is placed in a single drop covered with mineral oil. Logistic regression analysis was used to control for confounding factors

Main results and the role of chance: The fertilization rate was similar between the two groups [group A 77,65% (139/179) vs group B 75.88% (129/170) *p*=NS]. Blastocyst formation rate was not significantly different between group A 51,79% (72/139) and group B 62,79% (81/129) (*p*=NS). The clinical pregnancy rate of group A and B [50% (N=18) vs 47.61% (N=21) *p*=NS] respectively was similar as well.

Limitations, reasons for caution: The number of oocytes must be increased to have more evidence about the culture systems efficiency. These data should be confirmed by careful multi-center studies and by extend the clinical analysis to live birth rate

Wider implications of the findings: Although *in vitro* culture system under conventional humidification conditions simulates the *in vivo* situation and appears to be physiologically sound, our results suggest that the dry culture system is as efficient as the wet one. Moreover, the dry incubation system greatly reduces costs, space and the risk of microbial contamination

Trial registration number: NA.

P-246 High culture media oxidative profile as a biomarker of good quality embryos: a non-invasive tool to select the embryo to transfer.

M.D.M. Nohales Corcoles[1], R. Del Gallego[1], L. Bori[1], L. Alegre[1], S. Shnizer[2], M. Meseguer[1]

[1]IVI-Valencia, IVF laboratory, Valencia, Spain

[2]Carmel Diagnostics, Carmel Diagnostics, Israel, Israel

Study question: Is the spent´s embryo culture media oxidative profile, provided by Thermochemiluminescence (TCL) Analyzer™, a good biomarker of embryo quality?

Summary answer: Although each culture media shows different oxidative status, good quality embryos remain having higher oxidative parameters, which indicate more extensive oxidative metabolism.

What is known already: Novel non-invasive strategy TCL (Carmel Diagnostics, Israel), based on spent culture media analysis, proved to provide additional valuable data to morphology and morphokinetic analysis in the selection of the best embryo for transfer. In particular, the assessment of the embryo's oxidative profile with the Thermochemiluminescence (TCL) Analyzer™ suggests a new approach in determining embryo's quality or viability and subsequent implantation potential.

Study design, size, duration: A total of 683 spent embryo culture media from 174 *in vitro* fertilization (IVF) cycles, incubated and monitored with the time-lapse incubator Embryoscope®, were collected for analysis from May 2017 to December 2018.

Participants/materials, setting, methods: Oxidative status of 15 µl/embryo of culture media was measured with the use of the TCL assay, as photons emitted per second (**cps**) amplitude after 55 seconds (**H1**), 155 seconds (**H2**) and 255 (**H3**), in a 300-second period. The **Ratio**, as the slope of the three parameters, and the **Average** were also calculated. Different culture media were assessed. Oxidative data was normalized with a smoothing algorithm (**sm**) and analyzed by the statistical test ANOVA.

Main results and the role of chance: Different oxidative profile was noticed among the media culture included (p<.001). The average of the TCL parameters (**AVEHsm**) were (cps): 81.38 for Cook® (n=367), 114.29 for Genea Biomedx®, (n=228), 68.20 cps for Irvine Scientific® (n=42) and 95.79 cps for Life Global® (n=39). Despite using different culture media, transferred and vitrified embryos (V) remain showing higher values for the oxidative parameters than no viable embryos (NV): **H1sm**= 85.88 for NV vs. 88.70

for V, **H2sm**= 87.82 for NV vs. 91.03 for V and **H3sm**= 93.78 for NV vs. 98.17 for V. Regarding day 5 quality embryos, according to ASEBIR classification criteria, oxidative stress level decreased as the embryo quality got worse: AVEHsm=**95.56 cps** for embryos of type A (n=47); **94.04 cps** for embryos of type B (n=269); **92.70 cps** for embryos of type C (n=125) and **72.52 cps** for embryos of type D (n=26). This therefore implies high quality embryos have a more extensive oxidative metabolism exerting an oxidative load on their surrounding media.

Limitations, reasons for caution: No balanced sample size was assessed in different media culture niether in embryo quality. Oxidative status database will increase while using TCL to pursue an accurate optimal range for oxidative parameters. Additionally, present study would require a prospective validation for its routine clinical use.

Wider implications of the findings: The fair correlation between TCL oxidative results, embryo quality proves its application as a clinical biomarker. A more accurate selection of the best embryo, especially in good-quality embryo cohorts, would determine IVF success.

Trial registration number: None

P-247 Prospective, multi-center, randomized, open, 2-arm, non-inferiority trial comparing a semi-automated, closed vitrification system with a manual, open vitrification system

J. Hajek[1], N. Sandi-Monroy[2], S. Schansker[3], B. Schöpper[1], M. Depenbusch[1], A. Schultze-Mosgau[1], K. Neumann[1], F. Gagsteiger[2], S. Von Otte[1], G. Griesinger[1]

[1]University Hospital of Schleswig Holstein, Universitäres Kinderwunschzentrum Lübeck und Manhagen, Lübeck, Germany

[2]Kinderwunschzentrum Ulm, Ulm, Ulm, Germany

[3]University Hospital of Schleswig Holstein, Universtiäres Kinderwunschzentrum Kiel, Kiel, Germany

Study question: Does the semi-automated, closed vitrification system Gavi™ provide as good survival rates after thawing zygotes as the standard procedure with manual open vitrification (Cryotop®)?

Summary answer: The survival rate of 2PN-oocytes is similar when using the semi-automated, closed Gavi™ system or the manual, open Cryotop® system for vitrification.

What is known already: Standardization is expected to play an ever-increasing role in clinical laboratory technology. For cryopreservation of oocytes and embryos, the manual, open Cryotop® vitrification method offers extremely high cooling and warming rates and survival rates of >90% have consistently been reported. The semi-automated Gavi™ unit automates key steps of the vitrification procedure (microfluid exchange by robotic handling unit, equilibration times) in a stable temperature environment Oocytes or embryos are kept in a pod (automated heat-sealing following equilibration) and manually plunged into liquid nitrogen for storage. Gavi™ has become commercially available; however, comprehensive testing in a clinical setting has not been performed.

Study design, size, duration: Prospective, randomized, open, non-inferiority trial conducted at three German IVF centers (NCT03287479; EC Luebeck: 17-093; 10/2017 to 12/2018). Randomization 1:1, stratified by center and by freshET/surplus2PN or freeze-all/2PN, cryopreservation of 2PN-oocytes by Gavi™ or Cryotop®. Taking attrition into account (mostly pregnancies from fresh ET), it was planned to randomize 180 patients to generate minimally one warming procedure with all subsequent events up to live-birth in minimally 122 patients within the study period.

Participants/materials, setting, methods: Eligibility: women, 18-40 years, COS, IVF or ICSI, hCG or GnRH-agonist trigger, cryopreservation of surplus 2PN-oocytes or freeze-all of 2PN-oocytes. Exclusion: PGD-AT/PGD cycles, uterus malformation and low responders. Primary outcome: survival rate of 2PN-oocytes after warming (assessment 2hrs after warming: intact oolemma, regular cytoplasm, later cleavage). Secondary outcomes: number and quality of embryos, pregnancy (PR) and live birth rates, procedure duration and staff convenience (questionnaire). All investigators received Gavi™ training before embarking on the study.

Main results and the role of chance: Overall, 149 patients were randomized to the Gavi™ (n=75) and Cryotop® (n=74) group. The mean female age (33.4±3.7 *vs.* 33.6±4.0; *p*=0.87) and the mean number of vitrified 2PN-oocytes (9.0±5.9 *vs.* 7.6±4.9, *p=0.25*) was similar between the Gavi™ and Cryotop® groups. At the time of writing, 50/75 (67%) patients in the Gavi™ and 60/74 (81%) patients in the Cryotop® group had started a frozen-thawed embryo transfer (FET) cycle and 4.9 ±2.2 and 4.4 ±1.8 2PN-oocytes, respectively, were warmed for transfer (*p=0.21*). The mean survival rate of 2PN-oocytes after warming was 89.0% (±21.4) in the Gavi™ and 95.2% (±13.5) in the Cryotop® group (adjusted difference: -2.11%, CI: -5.11 – 0.89; *p*=0.17). The incidence of a 100% survival rate was 35/50 (70%, 95%CI: 56.2-80.9) and 51/60 (85%, 95%CI: 73.9-91.9) in the Gavi™ and Cryotop® group, respectively (difference -15%, 95% CI: -30.4 – 0.6%; *p*=0.057). The mean number of transferred embryos was 1.5±0.6 and 1.6±0.5 (*p*=0.64) in the two groups. The clinical PR per FET was 12/50 (24.0%, 95%CI: 14.3-37.4) in the Gavi™ group vs. 12/60 (20.0%, 95%CI: 11.8 – 31.8) in the Cryotop® group (difference: 4%, 95%CI: -11.3 – 19.7; *p*= 0.61). Data are presented as mean±SD or numbers (percentage).

Limitations, reasons for caution: At the time of writing (30-Jan-2019), the sample size is still increasing as not all patients have utilized their cryopreserved 2PN-oocytes. Some patients will undergo more than one FET cycle and cumulative outcomes are still missing.

Wider implications of the findings: A semi-automated vitrification system appears well suited for clinical use. Further investigations need to be done on issues of practicability, procedure duration and financial costs.

Trial registration number: NCT03287479

P-248 Effect of culturing human embryos in group on the composition of spent culture media

J. Sousa Emídio dos Santos[1,2], A. Reis Braula[1], P. Ferreira[1], L. Ramalhete[2], A.P. Soares[1], F. Sánchez Martín[1], M. Gallardo[1], C. Ribeiro Calado[2]

[1]Malo Clinic - Ginemed, IVF unit, Lisbon, Portugal

[2]ISEL-Instituto Superior de Engenharia de Lisboa- IPL, Biomedical engineering, Lisbon, Portugal

Study question: Does culturing human embryos in group improve their development and the culture molecular profiles compared to individual culture?

Summary answer: In IVF technologies the number of human embryos per culture drop will affect the molecular signature of spent culture and the embryo development until blastocyst.

What is known already: Embryos modify the culture media in which they are suspended as they grow, establishing autocrine and paracrine communication. Paracrine signals from adjacent embryos may replace similar paracrine interactions occurring in the reproductive tract, so it is hypothesized that group culture of embryos may enhance their development by this positive interaction. Up to 35 % of IVF laboratories perform group embryo culture, in which developing embryos share the same culture media. However, a standard approach to this technique is currently lacking, with each centre applying different protocols, namely in terms of physical contact and embryo density.

Study design, size, duration: Prospective sibling study of oocytes derived from the same women following Assisted Reproduction Treatment (ART). A total of 349 zygotes from 45 patients were included in the study from May 2017 to January 2018 in a single private IVF setting. Part of them were made spectroscopic analysis of the spent culture medium. Only IVF/ICSI cycles in which the whole cohort of embryos was cultured to blastocyst stage were included.

Participants/materials, setting, methods: Embryos were cultured in 30µL medium, covered by oil at 37°C, 6% CO_2, 5% $O_2$and 90% humidity, till day 3 on G1Plus being transferred on day 3 to G2Plus, been maintained till blastocyst achievement between day 5 and 6. Embryos were cultured individually or in group of 2 or 3 embryos per drop.Disposable medium at the day 3 and day 5 or day 6, was analysed by FTIR spectroscopy.

Main results and the role of chance: In the group culture (GC) arm, the average group size in Day 1-3 was 2.54 embryos per 30 µL drop, and 2.41 on Day 3-6. Day 3 good quality embryo rates were 0.83 vs. 0.72 (p=0.019) per zygote in group GC vs. individual culture (IC) respectively. The usable blastocyst rate was 0.60 in GC vs. 0.51 in IC (p=0.102) per total Day 3 embryos, and

0.72 in vs. 0.71 in IC (p=0.785) per good quality embryo. Of 45 cycles, 27 underwent fresh embryo transfers, with 16 (59%) achieving positive biochemical pregnancy. Of 38 embryos with known implantation data, 17 (44%) produced a gestational sac.

Differences between the molecular composition of culture media at day 3 and day 5 or 6 were observed by principal component analysis of the second derivative spectra, independently of the number of embryos cultures per drop.

Differences in the culture molecular composition were identified, based on analysis of ratios of spectral bands, at 10% of significance, between ICandGC, andbetween cultures with 2 and 3 embryos per drop. These results highlight the high impact of the number of embryos perculture drop, in the culture media composition and consequently on the embryo metabolism.

Limitations, reasons for caution: Zygotes from good prognosis patients were included. The analysis was conducted with embryos obtained by different procedures and with oocytes from different origins. The potential confounding factor of variables that can influence the analysis outcome, such as media type, volume of the culture drops, culture conditions, has to be identified.

Wider implications of the findings: Despite a tendency towards improvement in the total usable blastocyst rates per cultured zygote, it is unclear whether GC in the described conditions is superior to IC. The informative MIR spectra shows potential to be used as a predictor of embryo development to blastocyst stage.

Trial registration number: not applicable

P-249 Utilization of hyaluronic acid-alginate hydrogel for encapsulation and culture of mouse preantral follicles

P. Jamalzaei[1], M. Rezazadeh Valojerdi[1], L. Montazeri[2], H. Baharvand[3]

[1]*Faculty of Medical Sciences- Tarbiat Modares University, Department of Anatomy, Tehran, Iran*

[2]*Cell Science Research Center- Royan Institute for Stem Cell Biology and Technology-ACECR, Department of Cell Engineering, Tehran, Iran*

[3]*Cell Science Research Center- Royan Institute for Stem Cell Biology and Technology-ACECR, Department of Stem Cells and Developmental Biology, Tehran, Iran*

Study question: Does hyaluronic acid-alginate (HAA) hydrogel improve *in vitro* growth and development of mouse preantral follicles in comparison with alginate (ALG) hydrogel?

Summary answer: HAA hydrogel is a promising hydrogel for follicle culture and could relatively ameliorate the culture condition when compared to ALG hydrogel.

What is known already: *In vitro* culture of ovarian follicles is one of the potential approaches for fertility preservation in patients with cancer. Recently, ALG hydrogel has been used for encapsulation and culture of isolated follicles and yielded desirable results; however, it has some disadvantages such as slow biodegradability and poor bioactivity. Hence, the combination of ALG with more degradable and bioactive compounds is suggested. Hyaluronic acid can combine with ALG to make a composite hydrogel suitable for follicle culture. Although HAA has been used for the culture of different cell types, it has not been yet applied for follicle culture.

Study design, size, duration: Preantral follicles (n=188) were isolated from mice ovaries, encapsulated in ALG and HAA hydrogels and cultured for 13 days. The follicles' diameter, survival and antrum formation rates were evaluated during culture. After hormonal induction, the oocytes' maturation was assessed on day 14. The next step, follicles were cultured and on day 13, survived follicles (75 follicles/group) were collected to evaluate their genes expression and their conditioned media also were gathered to measure follicles hormonal secretion.

Participants/materials, setting, methods: Preantral follicles (100-130 µm in diameter) were mechanically isolated from the ovaries of 2-week-old NMRI mice and individually encapsulated and cultured in freshly prepared ALG (0.5% w/v) and HAA (0.5% ALG+5 mg/ml hyaluronic acid) hydrogels. The follicles diameters were determined as the mean of two perpendicular measurements. Gene expressions were analyzed using qRT-PCR. Hormonal secretions were measured by ELISA. All statistical analyses were conducted in SAS version 9.4. Differences were considered significant at $P<0.05$.

Main results and the role of chance: The data revealed that there was no significant difference in the diameter, survival and antrum formation rates of ALG- and HAA-cultured follicles. Nevertheless, evaluation of obtained oocytes after hormonal induction showed that a higher percentage of HAA-developed oocytes resume meiosis up to GVBD/MII stages in comparison with ALG-developed ones (74.50 vs. 55.55%, respectively; $P<0.05$). Moreover, HAA-cultured follicles expressed *Gdf9*, *Bmp15*, and *Gja4* genes more marked than ALG-cultured ones ($P<0.05$); while the expressions of *Gja1*, *Bax*, and *Bcl2* genes did not significantly differ between groups. Finally, data of hormonal secretion indicated that HAA-cultured follicles secreted higher levels of estradiol compared to ALG-cultured ones (28.27±1.67 vs. 10.08±0.79 ng/ml, respectively; $P<0.05$); however, no significant differences were found in the levels of progesterone and androstenedione between groups.

Limitations, reasons for caution: None.

Wider implications of the findings: Despite the better results obtained from HAA-cultured follicles compared to ALG-cultured ones, further optimization of the hydrogel characteristics may be necessary to enhance survival and maturation rates. Also, future studies should determine the functional competence of *in vitro* matured oocytes, their ability to become fertilized and form blastocysts.

Trial registration number: Not applicable.

P-250 The result obtained in the first transfer of an IVF cycle could predict the success probability in the second transfer

F.J. Prados-Mondéjar[1], V. Santos[1], G. Pérez-Bermejo[2], Y. Cardeña[1], I. Bruna[1]

[1]*Hospital HM Montepríncipe, HM Fertility Center, Madrid, Spain*

[2]*Hospital Fundación Alcorcón, IVF Laboratory, Alcorcón, Spain*

Study question: The result of the first embryo transfer of one IVF cycle can be predictive of the probability of success in the second one?

Summary answer: Achievement of a delivery after the first embryo transfer is of good prognosis for the success of the second transfer from the same oocyte retrieval.

What is known already: IVF cycles often led to the production of several morphologically good quality embryos. More than one embryo transfer is performed in some of those cycles. IVF cycles with several good morphology embryos are obviously more likely to end up in a delivery or even in more than one delivery. On the other hand, it is believed that only a few of the total oocytes retrieved after ovarian hyper-stimulation led to truly viable embryos. The role of embryologists would then be to accurately identify those viable embryos to reach pregnancy in as few embryo transfers as possible.

Study design, size, duration: Retrospective analysis of 301 good morphological quality- frozen-embryo replacements. Oocyte retrievals performed after 2004 to women <40 y/o. Embryos were morphologically evaluated for the first transfer of each cycle either fresh of after cryopreservation ("Freeze-all" cycles). We analysed each of the next frozen-embryo replacement cycles after the completion of that first transfer. The transfers included in this analysis were the second transfer of each IVF cycle and were all performed before 2018.

Participants/materials, setting, methods: We compared two groups of IVF cases: Those with (Group A) or without (Group B) live birth after the first transfer of every cycle. In both groups, the result of the following cycle of (good quality) embryo thawing was studied. This was the first thawing of the cycle for cases with fresh embryo transfer and the second thawing for freeze-all cycles. Main endpoint was delivery rate per thawing. Chi-square was used for statistic significance evaluation.

Main results and the role of chance: The percentage of "very good" (57% / 54%) and "good" (43% / 46%) morphological quality embryos was similar in the thawed embryos included in the analysis for Group A / Group B.

In Group A (second transfer after delivery in the previous one) 117 embryos were thawed in 67 cycles and in Group B (second transfer after a previous one without successful delivery), 427 embryos in 234 cycles; 1,8 embryos per thawing in both groups. Survival rate and transfer cancellation rate were similar: 92,3% and 1,5% in Group A and 95,1% and 0,9% in Group B. The percentage of intact embryos after thawing was 70,1% in Group A and 72,4% in Group B. The clinical pregnancy rate (FHB+) per thawing was 53,7% in Group A and 37,2% in Group B (p<0,03). The delivery rate per thawing was 46,3% in Group A and 30,8% in Group B (p<0,02). Twin delivery rate was lower in Group A (3,2%) than in Group B (22,2%)(p<0,02). Clinical pregnancy and delivery rate per thawing was higher in Group A than in Group B.

Limitations, reasons for caution: This is a retrospective study that spans several years. The number of cases is different in both groups and not very high

although the differences both in pregnancy rate and delivery rate per thawing cycle were statistically significant.
Wider implications of the findings: In IVF cases with a cohort of embryos that allows for more than one good-quality embryo transfer; achievement of a successful implantation with delivery after the first transfer predicts higher probability of delivery after the following transfer of frozen embryos originated in the same oocyte retrieval.
Trial registration number: Not applicable

P-251 Comprehensive examination of the ICSI-related procedural timings and their effect on mean blastulation rates per cycle

L. Papini[1], D. Cimadomo[2], R. Maggiulli[2], G. Fabozzi[2], L. Dovere[2], A. Giancani[2], S. Romano[2], M. Stoppa[2], D. Soscia[2], F.M. Ubaldi[2], L. Rienzi[2]
[1]*Genera Umbertide, G.en.e.r.a. centers for reproductive medicine, Umbertide, Italy*
[2]*Clinica Valle Giulia, G.en.e.r.a. centers for reproductive medicine, Rome, Italy*

Study question: Do the ICSI-related procedural timings affect the mean blastulation rate (m-BR) per cycle?
Summary answer: A model entailing maternal age, sperm concentration, time from ovulation-induction (OI) to oocyte-denudation (OD) and number of same-day ICSI procedures partially explains m-BR per cycle.
What is known already: In IVF, specific timings must be complied with to preserve gamete viability/competence. During IVF procedures, oocyte exposure to suboptimal environmental conditions should be minimized. Nevertheless, mainly old-fashioned studies examined the putative impact deriving from daily schedules, number/timings of procedures, as well as operators' skills and experience. A careful inspection of the performance levels of each operator/laboratory is although critical to outline guidelines and key-performance-indicators. ICSI represented a ground-breaking advancement in IVF that has been quickly and widely implemented. In this study, we attempted to define whether and to what extent the ICSI-related procedural timings might impact m-BR per cycle.
Study design, size, duration: Observational study conducted at a private IVF clinic (January-2016 to January-2018). All ICSI cycles (n=1444) with ≤12 fresh autologous oocytes (n=7999) inseminated with ejaculated sperm were included. All operators and critical procedural timings (OI-to-OD, OD and ICSI) were automatically-recorded through an electronic-witnessing-system (RI Witness^{TM}). The primary outcome was the m-BR among inseminated oocytes per cycle. All confounders were prospectively registered in a relational database (Fertilab Manager) and used as corrective measures in regression analyses.
Participants/materials, setting, methods: Controlled ovarian stimulation was performed with recombinant-gonadotrophins in an antagonist protocol. Fourteen and twelve operators were involved in denudation and ICSI procedures, respectively. Beyond procedural timings and operators, the other confounders registered were: maternal/paternal age and karyotype, history of recurrent-implantation-failure and/or miscarriage, categorized sperm concentration (>15mil/ml, 6-15mil/ml, 1-5mil/ml, <1mil/ml), main cause of infertility, number of same-day ICSI procedures, culture media, incubator, number of inseminated oocytes.
Main results and the role of chance: The mean female age and number of inseminated oocytes were 38.6±3.9yr (range:21-45) and 5.5±3.2 (range:1-12), respectively. The sperm concentration was >15mil/ml,6-15mil/ml,1-5mil/ml,<1mil/ml in 1037 (71.8%), 224 (15.5%), 129 (8.9%) and 54 (3.7%) ICSI-cycles, respectively. The mean OI-to-OD time was 39.3±1.3hr (36-42). The mean procedural timings for OD and ICSI were 8.1±3.8min (range:2-20) and 12.6±6.4min (range:2-36); both these variables were significantly ($p<0.01$) dependent on the number of inseminated oocytes (η^2:0.38 and 0.71;power=100%) and the operator (η^2:0.15 and 0.25;power=100%). The overall m-BR per inseminated oocyte per cycle was 34.0%±27.9% (range:0-100). Among all the confounders under investigation, maternal age was the variable showing *per se* the highest association with the m-BR per cycle (η^2:0.03;$p<0.01$ and power=100%). When adding sperm concentration, OI-to-OD time and number of same-day ICSI procedures performed to the model, a significant ($p<0.01$ and power=100%) adjusted-r^2=0.06 could be achieved. Of note, OD and ICSI procedural timings and operators instead did not show any association with the m-BR per cycle. When the primary outcome under investigation was inspected versus OI-to-OD timings, the highest values were reported for ICSI procedures performed earlier than 38hr (n=223 ICSI-cycles, m-BR:40%±28%) and were then stably-lower (m-BR:33%±28%; $p<0.01$) for ICSI procedures (n=1221 ICSI-cycles) started later than 38hr.
Limitations, reasons for caution: This is a single private IVF center study. The limited number of cycles cultured in an undisturbed incubator (n=415, 28.7%) and with a sequential culture media (n=279, 19.3%) might have hindered their potential beneficial/detrimental effect. Lastly, an investigation of ICSI-related procedural timings effect on blastocyst implantation potential is also needed.
Wider implications of the findings: Maternal age and sperm concentration represent the main variables affecting the m-BR during ICSI-cycles. Nevertheless, to efficiently schedule the daily workload considering time of OI, egg-retrieval and insemination to comply with the number of same-day procedures might result in better outcomes in the hands of well-trained and constantly-monitored operators.
Trial registration number: None

P-252 High male birth rate in the patients with higher blastocyst grades

S. Idei[1], F. Yachiyo[1], H. Wakana[1], R. Tomomi[1], S. Naomi[1]
[1]*Omiya Ladies Clinic, Gynecology, Saitama, Japan*

Study question: Differences in sex ratio at birth depending on the stages and grades of transplant embryos were studied.
Summary answer: The male birth rate is markedly higher in patients with higher inner cell mass (ICM) grades and in those with higher trophectoderm (TE) grades.
What is known already: In recent years, there have been several studies on children born with assisted reproduction technologies, including a higher male birth rate with blastocyst transfer, and higher birth weight in children associated with frozen-thawed embryo transfer (FET) than in those associated with fresh embryo transfer (ET).
Study design, size, duration: This is a retrospective study, including 568 patients (age, 34.8 ± 4.16 years) who underwent single ET at the author's clinic between May 2007 and 2017, and the patients were later reported to deliver a full-term infant.
Participants/materials, setting, methods: The male birth rates among 109 fresh ET cases (ET group) and 459 FET cases (FET group) were compared by transplant embryo stages [cryopreserved embryo transfer (CET subgroup) and blastocyst embryo transfer (BET subgroup)] and by grades for blastocyst embryo transfer cases (Grade A and Grade B subgroups for ICM, and Grade A and Grade B subgroups for TE based on Gardner's grading criteria).
Main results and the role of chance: No significant difference was found in the male birth rate between the ET and FET groups (47.7% vs. 51.4%), and by stages, between the CET and BET subgroups in the ET group (42.9% vs. 52.8%) and between the CET and BET subgroups in the FET group (50% vs. 52.6%). By grades, the male birth rate was significantly higher ($p < 0.05$) in the subgroups of Grade A for ICM and TE: 66.7% vs. 26.7% between Grade A and B subgroups for ICM and 73.7% vs. 35.0% between Grade A and B subgroups for TE in the ET group; and 62.7% vs. 47.2% between Grade A and B subgroups for ICM and 69.4% vs. 49.1% for TE in the FET group.
Limitations, reasons for caution: Effects of the embryo culture solution used at the author's clinic could not be eliminated. Cases of *in vitro* fertilization and intracytoplasmic sperm injection were not separately considered.
Wider implications of the findings: Selection of desired sex may be possible without damaging embryos.
Trial registration number: None.

P-253 C-kit signaling promotes pre-implantation embryonic development and blastocyst formation

J. Tan[1], Q.F. Wu[1], Z.H. Huang[1], C.L. Xin[1]
[1]*Jiangxi Provincial Maternal and Child Health Hospital, Reproductive Medicine Center, Nanchang, China*

Study question: To determine whether c-kit is expressed in human pre-implantation embryos, and to investigate the possible regulatory mechanism of c-kit signaling in the process of embryonic development.

Summary answer: C-kit signaling might promote human pre-implantation embryonic development by up-regulating ETV5 transcription factor via MEK/ERK pathway.

What is known already: Although the in vitro culture system has been optimized in the past few decades, few or no high quality embryos to transfer caused by abnormal embryonic development from in vitro culture has been still not completely solved. Accordingly, fully understanding the regulatory mechanism of pre-implantation embryonic development would be beneficial to further optimize the in vitro embryo culture system. Recent studies have found the expression of c-kit in mouse embryo and its promotion effects on mouse embryonic development. However, it is unclear the expression, the role and the related molecular regulatory mechanism of c-kit in human pre-implantation embryo development.

Study design, size, duration: 457 women (age: 22-37 years) who underwent IVF therapy were enrolled. 100 human immature oocytes (GV: 50 and MI: 50) and 660 human 3PN embryos resulting from one oocyte fertilized by two spermatozoa simultaneously were collected. 600 mouse embryos from 50 ICR female mice were used.

Participants/materials, setting, methods: Samples were distributed randomly into three different experimental groups: SCF group: G-1TM or G-2TM+HAS solution+rhSCF; SCF+imanitib group: G-1TM or G-2TM+HAS solution+rhSCF+imanitib; Control group: G-1TM or G-2TM+HAS solution+PBS; The rate of good quality embryos at day 3, blastulation at day 6 and good quality blastulation at day 6 were analysis. RT-PCR, western blot and immunofluorescence staining were applied to detect the target genes and proteins in samples collected from human or mice, respectively.

Main results and the role of chance: c-kit mRNA and protein were expressed unexceptionally in all human immature oocytes, 3PN embryos (day 3) and 3PN blastocysts (day 6). In the experiment of human 3PN embryos, compared with other groups, SCF group showed obviously higher rate of good quality at day 3, better rate of blastocyst formation at day 6 and higher rate of good quality blastocyst formation at day 6. There was no difference between SCF+imatinib group and PBS group. Furthermore, we observed a higher ETV5 expression in SCF group than that in other groups. Similar results were also found in animal experiment. Interestingly, we also found a higher phosphorylation level of MEK/ERK signal molecule in mice embryos from SCF group than those from other groups.

Limitations, reasons for caution: The present results were obtained from human abnormal fertilization embryos and mouse embryos, which might not be representative of the true human normal embryonic development.

Wider implications of the findings: The findings of this study are valuable for further understanding the regulatory mechanism of human pre-implantation embryonic development. Furthermore, our results provide a new idea for optimizing the *in vitro* embryo culture system during ART program, which is beneficial to obtain high quality embryos for infertile patients.

Trial registration number: non-clinical trials

P-254 The Effect of Reduced Glutathione and Ulinastatin on Improving the Xenotransplantation Efficiency of Frozen-thawed of Human Ovarian Tissue

L. Long[1], Y. Li[2], X. Li[3]

[1]*first affiliated hospital of Sun Yat-sen university, Translation Research medicine center, Guangzhou, China*

[2]*The First Affiliated Hospital- Sun Yat-Sen University-, The Reproductive Center, Guangzhou, China*

[3]*he First Affiliated Hospital- Sun Yat-Sen University, Department of Spine Surgery, Guangzhou, China*

Study question: Do reduced glutathione (GSH) and ulinastatin (UTI) can improve follicular pool in human ovarian xenografts by intramuscular injection into hosts?

Summary answer: The follicular survival rate can be increased in patient ovarian xenografts as the administration of GSH, UTI and GSH+UTI into hosts.

What is known already: In decade, an increasing number of medical institutions can help patients prepare cryopreserved ovarian tissue prior to ovary operation or chemo- or radiation therapy, as a means of preservation of fertility potential, because those cryopreserved ovarian tissues can be autotransplanted for natural pregnancy

Dominant follicle was formed 10 weeks after subcutaneous transplantation of ovarian tissue which was sustained at least 21 months. Another study proven that oocytes originated from subcutaneous transplantat of cryopreserved ovarian tissue can be fertilized by intracytoplasmatic sperm injection (ICSI), in which hCG can be measured from the resulting embryo.

Study design, size, duration: Cryopreserved human ovarian tissue was xenografted into NOD-SCID mice (total number: 96), which were intramuscular injected GSH, UTI and GSH+UTI. The ovarian grafts were collected after xenotransplantation. The ovarian grafts were collected at the 1st, 3rd, 7th, 14th, 28th, 56th, 85th days after xenotransplantation.

Participants/materials, setting, methods: Observation of follicle survival rate was performed by H&E staining. Angiogenic activity was evidenced by immunohistochemical staining with anti-VEGF, anti-CD31 mice and anti-CD34 human antibodies. Macrophage recruitment during the ischemia reperfusion period was evaluated by immunohistochemical staining. The transcript levels of antioxidant enzymes and inflammatory cytokines in ovarian grafts were measured by real-time PCR. Malondialdehyde (MDA) levels in ovarian grafts were test by microplate assay.

Main results and the role of chance: 1. SCID mice with the treatment of GSH, UTI, and GSH + UTI show a higher survival rate than control group at the same period. GSH + UTI group presented an obviously high survival rate from the 1st day to 85th day after xenotransplantation.

2. Hosts with the treatment of GSH, UTI and GSH+UTI had a higher expression level of VEGF in the ovarian grafts.

3. Human ovarian grafts were underwent the loss of its microvessels, at the same time the SCID mice's microvessels were reconstructed, especially during the IR period. In addition, hosts with the treatment of GSH, UTI and GSH+UTI showed higher MVD of mice microvessels than control group

4. During the IR period, GSH, UTI, and GSH+UTI could suppress the recruiting response of macrophages and inflammatory cytokine, while GSH+UTI showed the best effective.

5.Hosts with the treatment of GSH, UTI, and GSH+UTI could eliminate oxidative stress in ovarian grafts by increasing the level of SOD1 and SOD2. GSH+UTI showed the best effects among all groups.

In summary, hosts with the treatments of GSH, UTI and GSH+UTI accelerated angiogenesis and increase the follicular survival rate in human ovarian xenografts by suppressing oxidative stress and inflammations during ischemia reperfusion periods.

Limitations, reasons for caution: We should knock-down VEGF expression to confirm the role of VEGF

Wider implications of the findings: Therapeutic strategies employing GSH+UTI have become a promising method to increase the survival rate of follicles in the human ovarian xenografts.

Trial registration number: 23455

P-255 assessment of the relationship between artificial oocyte activation and early embryo development

H.J. Yoon[1], Y.J. Lee[1], H.J. Yoon[1], H.S. Oh[1], I.H. Bae[1], W.D. Lee[2], J.H. Lim[2]

[1]*Maria Fertility Hospital, Fertility Laboratory, Seoul, Korea- South*

[2]*Maria Fertility Hospital, Ob/Gyn, Seoul, Korea- South*

Study question: Does artificial oocyte activation (AOA) influence in development patterns of early embryos?

Summary answer: The cell cycle of early embryos activated with calcium ionophore is significantly faster in old age group (38yr≤).

What is known already: AOA is beneficial method for patients with a history of fertilization failure. In the previous study, we found AOA with calcium ionophore can have a positive effect on both fertilization and pregnancy rates for patients who failed fertilization or showed less 50% fertilization in their previous ICSI cycles.

However, the relationship between morphokinetics of embryo development and AOA following ICSI is not well known.

Study design, size, duration: A retrospective study was conducted on 488 patients from January 2017 to December 2018. All embryos obtained after ICSI conducted in a time-lapse system were included (n = 1,946).

To examine the effect of AOA on early embryo development, we compared the time-points of morphokinetic events between ICSI and ICSI-AOA according

to age (≤37yr; ICSI, n = 737 versus ICSI-AOA, n = 256 and 38yr≤; ICSI, n = 700 versus ICSI-AOA, n = 253, respectively).

Participants/materials, setting, methods: Oocytes were exposed to 10 µmol/L calcium ionophore (A23187) for 30 min after ICSI for AOA.

Both age groups, younger (≤37yr) and older (38yr≤), were divided into ICSI and ICSI-AOA and all embryos were assessed in EmbryoScope™. We compared time-points of each morphokinetic events and morphokinetic variables (time of cell division, interval of cell cycle, multinucleation or uneven division at 2cell, direct division (<5h) and irregular division).

Main results and the role of chance: Student's t-test was used to compare the timing between the groups and Chi-square test was used to compare properties. The timing of the early cell division between ICSI and ICSI-AOA did not differ statistically in younger group. Additionally, no statistically significant difference was observed for multinucleation, uneven division, direct division and irregular division.

On the other hand, the embryos of ICSI-AOA in older group showed a significant faster timing in tPNf (24.05 ± 3.56, 24.67 ± 4.21, p = 0.026), t2 (26.55 ± 3.73, 27.19 ± 4.40, p = 0.026), t3 (35.74 ± 5.88, 36.71 ± 5.76, p = 0.025), t4 (38.12 ± 5.77, 39.14 ± 6.24, p = 0.018), t5 (48.16 ± 8.60, 49.89 ± 8.64, p = 0.006) and t6 (51.59 ± 7.70, 52.85 ± 7.54, p = 0.033) compared to the embryos of the ICSI. Whereas, the abnormal development was not significantly different between ICSI and ICSI-AOA.

Limitations, reasons for caution: The study was retrospective and more data will be collected in future prospective studies.

Wider implications of the findings: The present study shows an impact of AOA in early embryo development for the old age group. Therefore, it is necessary to set the proper time-lapse score of the activated embryos for transfer by morphokinetic analysis to improve the success rate for old age group.

Trial registration number: not applicabke

P-256 effect of women's age on cleavage time and abnormal cleavage event prior to 3rd cleavage: a retrospective study time-lapse imaging

O. Hwa Soon[1], J. Jung mi[1], H.J. Yoon[1], H.J. Yoon[1], W.D. Lee[2], J.H. Lim[2]

[1]*Maria Fertility Hospital, laboratory of reproductive medicine, Seoul, Korea- South*
[2]*Maria Fertility Hospital, Ob/Gyn, Seoul, Korea- South*

Study question: Does female age have an impact on timing of embryo development and abnormal events before the 8-cell stage?

Summary answer: Female age was found to affect events of uneven cleavage and multinucleation prior to 3rd cleavage, even though no significant difference appeared in cleavage timing.

What is known already: It was well known that increasing female age has been associated with anomalies of oocytes and poor embryo quality.

But knowledge of morphokinetic developmental parameters as female age is still limited.

Moreover, there is no information on the comparison to abnormal cleavage events using time-lapse according to female age.

Study design, size, duration: This retrospective study examined 1191 embryos resulting from normal fertilization in 608 patients between January 2014 and June 2018. Embryonic events were analysed in three age categories, less than 35 years old (Group A); 35–38 years old (Group B), over 39 years old (Group C).

Participants/materials, setting, methods: All embryos were cultured and assessed in the EmbryoScope™ time lapse incubator until day 3. Statistical analysis was performed with SPSS ver. 12.0 (SPSS Inc., Chicago, IL, USA). Student's t-test was used for statistical analyses. Average hour±SD from ICSI insemination are reported for all stages.

Main results and the role of chance: We analyzed 12 parameters and abnormal cleavage event. Regarding the mean timings of the tPB2, tPNa, tPNf, t2, t3, t4, t5, t6, t7, t8, s2, cc2, there were no significant differences between the three groups.

We compared abnormal cleavage events in embryonic development. There were no differences between the three groups in the direct cleavage from 1 to 3-cell (19.4% vs. 21.0% vs. 20.3%, P = 0.062).

Regarding the rate of multinucleation and uneven blastomere size at the 2-cell stage, there was no significant difference between group A and B or group B and C.

However, the rate of multinucleation at the 2-cell stage showed statistically significant difference between group A and C (44.4% vs. 37.8%, P < 0.05).

In addition, significant difference was observed between group A and C for the uneven blastomere size at the 2-cell stage (14.8% vs. 16.8%, P < 0.05).

Limitations, reasons for caution: This study was limited to the analysis of embryos from Maria fertility hospotal. Developmental speed of embryos can also be impacted by the culture environment, therefore these findings apply only to this patient group.

Wider implications of the findings: Patient age seems to be an important variable to consider when scoring embryo development events through time-lapse technologies.

Trial registration number: None

P-257 Zygote state parameters assessed by time-lapse monitoring correlate with morphological good quality embryo

J. BYUN[1], J.K. Park[1], S.K. Paek[1], Y. Jeon[1], S.H. Seok[1], S.Y. Lee[1], J.W. Kim[1], S.W. Lyu[1], I.P. Kwak[1], W.S. Lee[1]

[1]*Fertility Center of CHA Gangnam Medical Center, CHA University-College of Medicine, Seoul, Korea- South*

Study question: Can zygote state parameters such as pronuclear time points, pronuclear morphology and presence of halo predict the best embryo?

Summary answer: The disappearance time of pronuclear (tPNf) and orientation of polar bodies (PBs) are related to embryo quality.

What is known already: It is important to select and transplant good quality embryos during the ART procedure. Zygote state parameter is the first assessment of the serial embryo quality evaluation. Pronuclear morpho-kinetics such as the timing of the appearance(tPNa) and disappearance(tPNf) of pronuclear are known to be related to the embryo quality. However, other parameters of zygote state such as pronuclear morphology or halo has been limited to observation, so there are still rare known. Recently, time-lapse monitoring has been used to monitor and analyze early stage of embryonic development. So it is effective to get dynamic information about the zygote state.

Study design, size, duration: This was a retrospective study involving a total of 502 embryos cultured in the time-lapse system (Embryoscope®, Vitrolife) from January 2017 to November 2018. Monopronuclear (1PN), multipronuclear and those not clearly captured were excluded. The embryo quality was evaluated on day 3, and blastocyst formation was observed on day 5. Statistical analysis was performed by SPSS 23.0 using a t-test, chi-square test or logistic regression analysis. P-values<0.05 were considered significant.

Participants/materials, setting, methods: The tPNa, tPNf, pronuclear morphology and halo were observed through a time-lapse system. Pronuclear morphology was based on Scottet al., 2000, and simply modified into type A and B so that any evaluator can make a clear reading; pronuclear position: (A)juxtaposed, (B)non-juxtaposed, different size or fragmented, nucleolar morphology: (A)large size in both pronuclei; (B)small size in at least one pronucleus-scattered, the orientation of PBs: (A)the longitudinal or perpendicular axis of pronuclei and PBs; (B)different positions.

Main results and the role of chance: The results showed a statistically significant association between tPNa/tPNf and and good-quality embryos at day 3. In good-quality embryos, tPNa and tPNf were quicker than poor-quality embryos (9.46h vs 10.5h, p=0.002; 24.48h vs 27.61h, p<0.001, respectively). The PBs alignment of type A was related to good-quality embryos (66.7% vs 53.3%, p=0.002). However, the pronuclear position and distribution of NPBs were not related to embryo quality (63.2% vs 53.8%, p=0.066; 62.3% vs 56.9%, p=0.290, respectively). Also, the presence of halo is not correlated with embryo quality (61.1% vs 60.6%, p=0.904). Multivariate analysis showed that tPNf and orientation of PBs were associated with good quality embryo(OR=0.89, 95% CI=0.85-0.92, p<0.001, OR=0.56, 95% CI=0.38-0.82, p=0.003, respectively).

Furthermore, the blastocyst formation rate (BFR) showed the same result. The blastocyst formed on day 5 had a quicker tPNf (23.78h vs 26.49h, p<0.05). Also, the PB alignment of type A had a higher BFR (44.3% vs 32.0%, p=0.032). But, the tPNa, pronuclear position, distribution of NPBs and halo were not related to BFR (8.72h vs 9.38h, p=0.67; 40.9% vs33.8 p=0.296; 41.6% vs

32.5%, p=0.156, respectively). The tPNf and orientation of PBs remained significant after controlling for confounding factors (OR=0.86, 95%, CI=0.81-0.93, p<0.05; OR=0.55, 95%, CI=0.33-0.91, p=0.091, respectively).
Limitations, reasons for caution: While observing the nucleus form for 16-20 hours, its type is prone to misleading due to dynamic changes. Most of the parameters were from a single observation at a static time point. Thus, the evaluation of parameters based on the dynamic approach of the time-lapse system remains a challenge.
Wider implications of the findings: Using the time-lapse system, we have observed the dynamics of zygote state in detail. We found a relationship between zygote status and embryo quality, suggesting that tPNf and orientation of the PB could be one of the predictor. This may help when selecting the best embryo for embryo transfer.
Trial registration number: None.

P-258 FOR ABSOLUTE ASTHENOZOOSPERMIA IN IVF/ICSI: IS LASER-ASSISTED IMMOTILE SPERM SELECTION (LAISS) EFFECTIVE AND SAFE?

L. Dinh[1], T.T.P. Dao[2], T.T.C. Bach[1], V.L. Nguyen[1], T.N. Nguyen[1]
[1]Post hospital, Assisted reproductive technology center, Hanoi, Vietnam
[2]Hanoi Medical University, Histology and Embryology Department, Hanoi, Vietnam

Study question: Laser-assisted immotile sperm selection (LAISS) to collect viable spermatozoa for Intra-cytoplasmic sperm injection (ICSI) in complete asthenozoospermia cases: is it effective and safe?
Summary answer: Five out of eight absolute asthenozoospermia couples achieve pregnancy ranging from 10 to 33 weeks without any detected abnormalities for both mothers and fetuses.
What is known already: Absolute asthenozoospermia (100% spermatozoa are immotile) has been reported to happen once in every 5000 men, in which the percentage of "alive" sperms ranges from 0% to 100%. To identify viable spermatozoa in complete immotile samples for ICSI remains a challenge for embryologists. Despite the fact that the use of laser for cases with total immotile sperms was firstly reported in 2004, the feasibility, effectiveness and safety of this procedure requires to be well investigated.
Study design, size, duration: In 2018, nine absolute asthenozoospermia couples were enrolled in the study. After IVF and embryo transfer cycles, mothers' and fetuses' health is ongoing monitored. This study also includes verbal interview on reproductive medical history and continuous communication between staff and patients.
Participants/materials, setting, methods: The absolute asthenozoospermia couples underwent IVF/ICSI cycles with controlled ovarian stimulation. Sperms either from ejaculated semens or surgical procedures were LAISS-applied prior to ICSI: A single laser beam of 1.48 µm diode was shot at the far end of the tail. Viable sperms were collected if they had positive reaction to the laser beam: tail curling or a single immediate tail wagging movement. Frozen or fresh embryos were transferred day 3 or day 5.
Main results and the role of chance: All nine couples had fertilization; the average number of MII occytes retrieved and average fertilization rate was 14.3 and 66.8%, respectively, resulting in 90 day-2 embryoes in total. As on 31/01/2019, eight couples have had their embryo transfered, in which five couples are currently pregnant (33, 27, 16, 14 and 10 weeks respectively): four singleton and one twin pregnancy. From verbal interview data, the reproductive medical history of these five couples was revealed as followed: the duration of infertility was ranging from 3.5 to 7 years; all five couples had undergone andrology treatments using various Western and traditional herbal medicines without any improvement in sperm motility. Currently, the twin pregnant woman has been indicated a cervical cerclage at week 13. Otherwise, the mothers' health is in normal condition, no fetal anormaly has been detected.
Limitations, reasons for caution: To prove the safety of LAISS, besides monitoring mothers', fetuses' and take-home-babies' health, it is required to develop a method to confirm that LAISS does not affect DNA integrity and the centriole-containing neck of sperm. We currently investigate the cellular mechanisms of absolute asthenozoospermia and propose genetic tests for embryos.
Wider implications of the findings: LAISS together with IVF/ICSI appears to be a feasible and effective solution for infertile couples with 100% immotile spermatozoa. The safety of this procedure has been partly proved by normal condition of the fetuses. LAISS would propose great clinical value in asthenospermia treatment.
Trial registration number: Not applicable

P-259 The greater the number of oocytes, the worse the embryo quality in young donors

N. Ruiz Espinosa[1], I. Ochando Sánchez[1], J. Ten Morro[2], J. Ortiz Salcedo[3], L. Luque Martínez[4], M.A. López Rubio[4], R. Benabeu Pérez[5]
[1]Instituto Bernabeu Albacete, Biología de la Reproducción, Albacete, Spain
[2]Instituto Bernabeu Alicante, Biología de la Reproducción, Alicante, Spain
[3]Instituto Bernabeu Alicante, IB Biotech, Alicante, Spain
[4]Instituto Bernabeu Albacete, Ginecología, Albacete, Spain
[5]Instituto Bernabeu Alicante, Ginecología, Alicante, Spain

Study question: Is the number of oocytes retrieved in an egg -donor cycle related to the embryo quality?
Summary answer: The number of oocytes retrieved in an egg-donor cycle is directly associated with a decrease in embryo quality and in the number of useful embryos.
What is known already: There is a strong correlation between the number of oocytes collected after pick up and the IVF outcomes. The objective of this study was to analyze if there was an association between the number of oocytes retrieved in egg donors and the quality and number of useful embryos obtained after IVF/ICSI.
Study design, size, duration: This is a retrospective study including 1131 cycles of fresh oocyte donation carried out during the period 2015-2017.
Participants/materials, setting, methods: We only included fresh egg donors cycles with normozoospermic samples. In all cycles day five not biopsied blastocyst were transfered. We evaluated the quality and the number of embryos that were able to transfer and/or freeze according to number of eggs retrieved. We also checked our clinical results.

Univariate comparisons were performed using Pearson's Chi-square test for categorical data and the T-student test for continuous measures. All of the multivariate analysis were adjusted by confounding factors.
Main results and the role of chance: An increase in the number of oocytes retrieved was correlated with a decrease in the percentage of good-quality embryos (p=0.0002) and with a smaller number of useful embryos (p=0.0002). However, we did not find any significant difference according to our clinical outcomes.

Finally, we analyzed our data according to the technique we used (conventional IVF or ICSI). We observed that the blastocyst quality and the number of useful embryos were significantly higher with conventional IVF rather than with ICSI (p=0.000) and (p=0.007), respectively.
Limitations, reasons for caution: This is a retrospective study. All oocytes were used for a single recipient, rarely we shared the donor or freeze some oocytes.
Wider implications of the findings: It has been proven that more retrieved ooyctes are not the best. We should adjust the donor's dose of gonadotrophins to avoid collecting a large number of oocytes, which affects the embryo quality at the blastocyst stage. The use of conventional IVF in normozoospermic samples generated more good quality blastocysts.
Trial registration number: .

P-260 Embryo culture conditions under high humidity significantly enhances blastocysts formation and quality according to an automatic time-lapse algorithm

S. Perez Albala[1], B. Aparicio-Ruiz[1], C. Albert[1], P. Gámiz[1], A. Galán[1], J. Remohí[2], M. Meseguer[3]
[1]IVICO & IVI Teaching Program Equipo IVI, Laboratorio FIV, Valencia, Spain
[2]IVICO & IVI Teaching Program Equipo IVI, Gyneacologist Department. IVIRMA., Valencia, Spain
[3]IVICO & IVI Teaching Program Equipo IVI, Gyneacologist Department.. IVIRMA., Valencia, Spain

Study question: Is blastulation and quality rate conditioned by morphokinetics at early stages of embryo development?Is the humidity in an incubator chamber affecting morphokinetics and blastocyst rates?

Summary answer: There is a correlation between blastulation rates and quality with the Xtend-classification and a higher proportion of embryos with better Xtend scores in high humidity.

What is known already: Blastulation may be predicted by early stages of embryo development although controversial results still are present in the literature. The optimal incubator humidity is still a controversial topic in IVF laboratories. Even though the in vivo condition is humid, the possible growth of microorganisms under these conditions are higher than with dry incubators.

However recent studies have shown better results in humidified chambers probably due to more stable culture conditions regardless oil overlays in culture dishes (Fawzy et al Fert Ster 2017).

Study design, size, duration: University-affiliated infertility clinic. Retrospective cohort study in ovum donation program from January 2018 to October 2018. In the first part of the study, we analyzed 3001 embryos from 361 patients. In the second part, 116 patients with 1016 embryos were randomly distributed under high or low humidity in a continuous embryo monitoring incubator.

Participants/materials, setting, methods: Embryos were generated by ICSI and incubated in a Time-lapse incubator (Geri, Genea, Australia) that used an automatic cell-tracking software. An improved version of this algorithm was developed taking into the values of P2 and P3, egg age, number of cells on day3 and a texture image analysis correlated with fragmentation.

In the second part, the embryos were randomly distributed in chambers with or without humidity.

Main results and the role of chance: The Xtend classification was directly correlated with higher blastocyst rates and better good quality embryos. With an average blastulation rate of 73.6%, we studied rates in each category (1:91%; 2:86.30%; 3:79.7%; 4:63%; 5:38.3%). We studied the percentage of good-quality blastocysts (A/B ASEBIR morphological classification) in each Xtend category (1:57%; 2:47%; 3:36%; 4:25%; 5:11%)($p<0.001$).

A total of 1016 embryos were incubated in the Geri system under different humidity conditions, 561 in chambers with humidity and 455 in chambers without humidity. All of them were classified according to the Xtend algorithm. In the humidity chamber, 23.5% were classified as 1, 22.1% as 2, 17.6% as 3, 18.2% as 4 and 18.5% as 5.

In the dry chambers 26.2% were classified as 1; 18.9% as 2, 12.7% as 3, 17.6% as 4 and 24.6% as 5. We assembled the Xtend categories in two groups(1-2-3 vs 4-5)and compared the proportion of embryos in each group (humid vs dry incubation) showing more embryos classified as 1-3 in humid (63.30%) compared with dry incubation (57.26%), even though differences were not statistically significant($p=0.075$).

Moreover, blastocyst rate in humidity chambers was 77.2% versus 70.9% in dry chambers and percentage of good quality blastocysts 42.8% (humidity) vs 35.8% (dry)($p=0.022$).

Limitations, reasons for caution: The retrospective nature of this study may be a reason for caution. The classification system itself has some errors due to difficulties in cell tracking generating "none result", however we only included cases where classifications were provided. A further analysis could include different humidity measurements to establish the optimal value.

Wider implications of the findings: This study correlates Xtend categories with blastulation rates, demonstrating a direct link with the diagnostic test. According to humidity,results obtained show a higher proportion of good-quality embryos(classified as 1-2-3)as well as higher blastocyst rates under humidity conditions.

Therefore, incubation under high humidity might improve the final outcome of the cycle.

Trial registration number: Not applicable.

P-261 What is the implantation potential of vitrified average quality blastocysts?

M. Patel[1], R. Salim[1], A. Rattos[1], M. Jansa Perez[1]

[1]*Wolfson Fertility Centre- Hammersmith Hospital, IVF, London, United Kingdom*

Study question: The aim of this study was to determine whether the survival rate and implantation potential of frozen average quality blastocysts justified its clinical application.

Summary answer: The survival rates of vitrified-warmed average quality blastocysts (AQB) are comparable to vitrified-warmed good quality blastocysts (GQB), and implantation rate is comparable to fresh AQBs.

What is known already: Average quality blastocysts have a lower implantation potential than good quality blastocysts. On this basis, it may not be routine practice in many IVF clinics to freeze embryos of this quality due to their lower potential. However, the potential of vitrified average quality blastocysts is still relatively unclear.

Study design, size, duration: This is a retrospective study of 1905 blastocysts, either fresh or frozen, that were transferred between July 2015 and December 2018. The data was divided into three groups, frozen average quality blastocysts, frozen good quality blastocysts and fresh average quality blastocysts. Survival and implantation rates were compared between groups. Patients with a blastocyst grade $\leq$ Cc, as per the Gardner blastocyst grading scheme and those without known implantation data were excluded.

Participants/materials, setting, methods: The data was initially divided into good (Aa, Ab, Ba, Bb; n=1121) and average quality (Ac, Bc, Cb, Ca; n=403) vitrified blastocysts, as per the Gardner blastocyst grading scheme, and the survival and implantation rates (IR) were compared. The data was also divided into fresh (n=381) and frozen AQBs (n=403) and IR were compared. Chi-squared analysis was performed on the data and a p value <0.05 was considered to be statistically significant.

Main results and the role of chance: This study shows that there was no significant difference in survival rates between vitrified-warmed AQB and GQB (96% vs 97%, respectively, $p=0.2656$). However, vitrified-warmed AQBs had a significantly lower IR compared with GQBs (23.3% vs 38.7%, respectively, $p<0.05$). When comparing the IR of vitrified-warmed AQB to fresh AQB, there was no significant difference (23.3% vs 23.1%, respectively, $p= 0.9398$). Blastocysts were vitrified and warmed using the same cryopreservation media (Cook Blastocyst vitrification kit/ warming kit), therefore reducing a possible effect of cryopreservation media on survival and success rates.

Limitations, reasons for caution: Despite a large sample size, the study groups are not evenly distributed; with a larger number in the GQB group. Our vitrification protocol was modified prior to this study to include laser-induced collapsing; however some of the warmed embryos in this study may have been vitrified prior to this modification.

Wider implications of the findings: Our research suggests that it is advisable to vitrify AQBs, particularly for patients that have no GQBs available after transfer. This provides these patients with the opportunity to freeze embryos and offers them a further treatment attempt without undergoing the higher costs and strenuous stimulation required for a fresh cycle.

Trial registration number: Not applicable

P-262 Single frozen-thawed embryo transfer after time-lapse culture is associated with higher implantation rates and lower miscarriage rates in young patients

L. Dyachenko[1], P. Mazur[1], V. Zukin[2]

[1]*Clinic of Reproductive Medicine 'NADIYA', Embryology, Kyiv, Ukraine*

[2]*Clinic of Reproductive Medicine 'NADIYA', Administration, Kyiv, Ukraine*

Study question: Does time-lapse embryo selection have preferential results for embryo quality evaluation compared with conventional assessment?

Summary answer: Better clinical outcomes in IVF cycles are achieved using time-lapse embryo selection than during conventional embryo selection.

What is known already: Optimal conditions for embryo culture and possibility of proper assessment are key factors in assisted reproductive technology. Time-lapse follow-up of embryo development has become popular worldwide. The most significant benefits of this method include the possibility to maintain undisturbed culture and the morphokinetic evaluation of embryo development. Nevertheless, there are a lot of debates about the effectiveness of the time-lapse culture compared with conventional culture. There is still lack of evidences to support one of these approaches, so the question remains open.

Study design, size, duration: In this retrospective study implantation rates and early pregnancy loss were analyzed after 456 embryo transfers in the five-year period (2013-2017). Oocyte donation and array comparative genomic hybridization (aCGH) cycles were excluded from the study. Only the first Day 5 single frozen-thawed embryo transfers for each patient were included.

Participants/materials, setting, methods: Two randomized groups of patients under the age of 36 (Mean age was 31±3.31) were compared. Embryos of the first group (group A: n = 232) were cultured with the application of time-lapse monitoring. Embryos of the second cohort (group B: n = 224) were

assessed by conventional method. ICSI as well as vitrification were performed for all cycles. Embryos were cultured under stable conditions (5.3% CO2, 5.0% O2, 37°C) within the same culture medium.

Main results and the role of chance: The analysis showed that the application of time-lapse monitoring was associated with a higher implantation rate in the group A compared with the group B (59% versus 48%; OR: 1.55; P<0.05). The level of miscarriages was lower in the group A (13.9% versus 26.9%; OR: 0.44; P<0.05).

Limitations, reasons for caution: There was no control group for assessing the time-lapse incubator itself. Male factor infertility cause wasn't excluded from both groups of this investigation. However, all ongoing pregnancies resulted in births, stillbirths were not evaluated.

Wider implications of the findings: Time-lapse monitoring could serve as a platform for more detailed researches in future. It worth mentioning that according to our previous investigation the miscarriage rates in aCGH cycles with time-lapse culture were dramatically lower (2.7%) even for the patients of advanced maternal age.

Trial registration number: None.

P-263 cryopreservation in very low number sperm count

R. Marthasari[1], A. Hinting[1], A. Agustinus[1], P. Supardi[1]

[1]*Medical Faculty Airlangga University, Medical Biology, Surabaya, Indonesia*

Study question: Can we determine the minimum amount spermatozoa to be cryopreserved but still had a good quality to be used and assess motility and viability after being cryopreserved?

Summary answer: Sperm in any amount could be cryopreserved with a good result.

What is known already: Cryopreservation of sperm today is the most widely procedure because by using cryopreservation it means that the necessary biological material can be available at the time it is needed and can be stored for a certain period of time.

Conventional cryopreservation is an obstacle to achieve sufficient harvest in cases of severe oligospermia.

Sometimes cryopreservation can not be performed because too little sperm count and it means that the sperm can not pass the freeze-thaw procedure.

Until now there is no marker or cut off value that can predict how much sperm can be carried out by cryopreservation.

Study design, size, duration: This was an experimental pretest post test group design study.

This study was conducted at Medical Biology Laboratory Faculty of Medicine Airlangga University. Sample of the study was ejaculate obtained from patients attending Ferina Center for Reproductive Medicine. Thirteen patients were included in this study. Inclution criteria are men 21-40 years old with sperm oligoastenoteratozoospermia sperm analysis with concentrations range 7-9 million / ml.

Hematospermia and leucospermia were excluded from this study.

Participants/materials, setting, methods: Sperm preparation by using simple washing technique followed by side migration technique.

We devided the subgroups into 4 group: group of 71-100 sperm, group of 31-70 sperm, group 11-30 sperm and group 1-10 sperm.

Moving spermatozoa were aspirated into pippete in certain amount and put into 2 µl microdrops of freezing medium. The drops were put in the tip of Cryologic® and left in liquid nitrogen vapour for 1 min prior to be plunged in it.

Main results and the role of chance: This study showed there was a significant differences of motility rate between groups (p<0,05, Confidence Interval 95%), The highest result obtained from group 1-10. There was no significant differences of viability between groups (p>0,504, CI 95%). We also count living motile spermatozoa, living immotile spermatozoa and non living spermatozoa. In some immotile spermatozoa did not mean they are non viable, there was still possibility that some on them were viable, only need time to make a progressive movement.

Limitations, reasons for caution: This study was not a real situation, this was just a model of a very low sperm obtained from oligozoospermic patients.

We should use hypoosmotic swelling test to assess viability instead of Eosin test

We did not have enough time to assess motility because the drop could dry immediately.

Wider implications of the findings: By using this technique, sperm in any amount even one or two sperm could be cryopreserved with a good result.

Trial registration number: Not applicable

P-264 Correlation between number of oocytes retrieved during a single IVF/ICSI cycle and cumulative live birth rate in different age groups

I. Vrabtcheva[1], C. Kleanthis[1], J. Kopeika[1]

[1]*Guy's and St Thomas' NHS Trust, Assisted Conception Unit, London, United Kingdom*

Study question: What is the association between number of oocytes collected from different age categories and the cumulative live birth rate (CLBR) in a single IVF/ICSI cycle?

Summary answer: Cumulative live birth rate continues to increase with oocyte number

What is known already: Controlled ovarian stimulation (COS) aims to create surplus embryos. Assessment of its effectiveness is most valid per full cycle, including fresh and frozen embryo transfers (ETs). It has been reported there is no benefit to live birth rate (LBR) if >15 oocytes are created, with 13-15 oocytes suggested to be optimum for the generation of an adequate number of embryos for fresh and frozen ETs. However, such studies primarily looked at oocyte number and LBR in relation to fresh ETs. Other studies have discussed CLBR over a number of stimulation cycles, but few reported results from one complete COS.

Study design, size, duration: This study is a large cohort analysis of retrospective data from January 2009 to December 2015 in a tertiary centre - Guy's and St Thomas' Hospital, Assisted Conception Unit

Participants/materials, setting, methods: 754 patients, aged 19-46 years, planning a single embryo transfer (sET) following IVF/ICSI were selected. Only patients with one completed cycle (fresh and frozen embryos) were included in the analysis (n=470). Slow freezing was the method of cryopreservation used for storing surplus embryos. To evaluate the impact of oocyte yield on CLBR, patients were divided into 5 groups based on the oocyte number for their cycle.

Main results and the role of chance: The average age of the patients included was 35.3+/- 4.3, whilst the average number of eggs and 2pn embryos was 12+/- 6.8 and 6.6+/ 4.2 respectively. In addition, the mean number of embryo transfers resulting from one stimulation was 1.7+/- 1.1. The overall CLBR from one complete cycle, taking into account all oocyte numbers and age groups, was found to be 42%. It was found that in patients <35 years old the CLBR was 85% over 4 transfers, when >20 oocytes were collected, compared to 40% over the same number of transfers, when <6 oocytes were available. For those patients in the >40 years old category the CLBR over 4 transfer was 38% when >20 oocytes and 18% when <6 oocytes,. Finally, the regression analysis shows that overall there is a significant increase in CLBR when compared to the oocyte yield (P<0.032).

Limitations, reasons for caution: This is a cohort analysis using retrospective data collection based on relatively limited figures. Despite the use of a statistical analysis, the presence of biases due to retrospective data cannot be excluded. Furthermore, these results need to be supported with the generation of larger, prospective investigations.

Wider implications of the findings: Our findings contradict previous studies that discuss an 'optimal' oocyte number for high LBR. With increasing oocyte number, there is increasing CLBR thus patient's expectations can be more adequately managed depending on oocyte yield following a single COS.

Trial registration number: Not applicable

P-265 Total mitochondrial DNA (mtDNA) content decreases along embryo development, insights of mtDNA turnover in human preimplantation development.

M.F. Insua[1], A. Díez-Juan[2], A. Mercader[3], J. Bellver[4], L. Escrich[1], A. Pellicer[5], M.J. De los Santos[6]

[1]*IVI Valencia, IVF laboratory, Valencia, Spain*

[2]*Igenomix, PCR Laboratory, Paterna, Spain*

[3]*IVI Valencia, PGT Laboratory, Valencia, Spain*

[4]*IVI Valencia, Reproductive Medicine, Valencia, Spain*

[5]*IVI Roma, Reproductive Medicine, Roma, Italy*

[6]IVI Valencia, IVF Laboratory Director, Valencia, Spain

Study question: To assess the mtDNA content along the human embryo development.
Summary answer: This study demonstrates that not only the mtDNA content per cell decreases but also the total mtDNA copy number experiences a significant reduction before implantation.
What is known already: It has been shown that mtDNA has a half-life in culture of 2-4 days. In animals, mtDNA copy number has been revealed to change depending on the species. Hashimoto et al., (2017) observed that total and per cell mtDNA copy number decreased along human embryo development, however there was an increase of total mtDNA copy number at the blastocysts stage. mtDNA content along embryo development has not been widely studied in humans but this is an important topic to address in order to better understand the mitochondrial dynamics in preimplantation embryos under in vitro culture conditions.
Study design, size, duration: An observational prospective study was performed with a total of 89 samples. 36 fresh unfertilized oocytes, 21 vitrified day 3 embryos and 32 vitrified aneuploid blastocysts were warmed and immediately collected in PCR tubes with 2,5 µl of PBS. Finally, a Q-PCR was performed to determine total and per cell mt DNA copy number.
Participants/materials, setting, methods: Q-PCR was performed with SurePlex DNA Amplification System (Illumina) using specific primers for the ATP8 and β-Actin genes to assess the total and per cell mtDNA copy number. Data was statistically analysed by ANOVA test with Scheffé multiple comparison for categorical variables and linear regression for numerical variables.
Main results and the role of chance: Fresh oocytes have significantly more total and per cell mtDNA copy number (Log_2 ATP8= 20.32, Log_2 ATP8/β-Actin=7.49) than embryos on day 3 of development (Log_2 ATP8= 18.26, Log_2 ATP8/β-Actin=5.46; $P<0.05$). At the same time, day 3 embryos have more total and per cell mtDNA copy number than blastocysts (Log_2 ATP8= 16.39, Log_2 ATP8/β-Actin=3.15; $P<0.05$). Interestingly, mtDNA content increased significantly ($P<0.05$) with age in oocytes (18-34 years) and embryos on day 3 of development (25-37 years) but not statistically significant ($P>0.05$) in blastocysts (24-44 years). Once fertilization takes place, mtDNA content in embryos on day 3 of development decreases along cleavage achieving minimal levels at blastocyst stage. No differences on mtDNA content were found when grouping blastocysts by quality or by day of development ($P>0.05$). This study shows that mtDNA content diminishes along embryo development and no mitochondrial biogenesis takes place at blastocyst stage. Also we have found a relation with the patient age in oocytes and embryos on day 3 of development within the age ranges of the study.
Limitations, reasons for caution: All the analyzed blastocyst were aneuploid, so we need to check whether euploid human blastocysts will have similar behavior. Moreover, some of the embryos included were vitrified however, since they were tubed immediately after warming, the impact should be minimal.
Wider implications of the findings: According to previous studies in animals, during preimplantation development human embryos seem to experience a significant decrease on mtDNA content that support the embryo quiet hypothesis. Therefore any situation resulting in mtDNA content increase should be understood as a stress condition. This findings could be used to improve culture conditions.
Trial registration number: Not applicable

P-266 Can we use blastocyst collapsing as a marker of embryo implantation?

A. Navarro-Sánchez[1], N. Vidaurreta-Olmedo[1], S. Marin-Real[1], I. Chapa-Chorda[1], A. Guevara-Zambrano[1], S. Royo-Bolea[1], L. Abad-Velasco[1], C. Olmedo-Illueca[1], M. Barea-Gomez[1], I. Cuevas-Saiz[1]
[1]Hospital General de Valencia, Unidad de Medicina Reproductiva, Valencia, Spain

Study question: Can blastocyst collapses provide information about embryo quality?
Summary answer: According to our results, spontaneous blastocyst collapses are related to implantation rate and embryo morphokinetics.
What is known already: In order to increase results in assisted reproduction techniques, embryo selection criteria are continuously improving. Blastocyst collapses is one of the studied parameters to be included or not as a tool for embryo selection. Some groups have shown that weak collapses help the subsequent hatching of the embryo, however, strong collapses can affect implantation capacity. Studies in mouse blastocysts have shown that collapse is associated with the Na + / K + -ATP pump, which implies an extra energy expenditure. This suggests that repeated strong collapses in human blastocysts, could lead to a lack of energy and subsequent embryo blocking.
Study design, size, duration: We retrospectively analyzed data obtained from 113 blastocysts from 96 patients. All patients carried out an in vitro fertilization treatment, and embryo transfers (ET) were performed on day 5. The treatments were recorded between January of 2015 and December of 2018.
Participants/materials, setting, methods: Embryos were cultured in a MIRI-TL (ESCO-Medical ©) time-lapse incubator in microdroplets of single culture media (CSCC©, Irvine Scientific) covered with mineral oil (Irvine Scientific) until ET. The amount and type of collapses, that defined groups (strong, weak and mixed collapses) were recorded. Morphokinetic characteristics of each embryo were collected too. Statistical analysis was carried out with the SPSS program (V22.0, IBM Statistics), using the t-student test to find differences between groups.
Main results and the role of chance: Observed collapses were classified into three groups: strong, weak and mixed collapses. Number ranged from 0 to 4. Blastocysts that had strong collapses showed a significant negative impact on the implantation rate, observing, in addition, a zero-implantation rate in mixed type collapses. We observed that weak collapses were related to embryo implantation. Regarding number of collapses, those which did not perform any type of collapse did not show significant differences in the pregnancy rate. However, as the number of collapses progressed, there was a notable tendency towards less implantation.

Regarding morphokinetic data, those blastocysts with strong collapse exhibited shorter cell cycles during their development and less synchrony between divisions, as opposed to weak collapses. No significant statistical differences were found, but a trend was observed.
Limitations, reasons for caution: One of the limitations of the study is the number of embryos included. We will go on collecting data to increase sample size in every single group.

In order to visualize all the collapses, time-lapse technology is required, which is not yet available in all laboratories.
Wider implications of the findings: Our results show a correlation between the collapses at the blastocyst stage and the implantation rate probably due to the waste of ATP in expansions and the fast mitotic division.

This information could help us to better select embryos with the highest implantation potential.
Trial registration number: Not applicable.

P-267 Morphokinetic assessment of embryos in carriers with structural chromosome rearrangements undergoing preimplantation genetic testing: a longitudinal cohort study

D. Christopikou[1], S. Davies[2], E. Tsorva[1], S. Zaxaria[1], K. Economou[2], I. Mastromina[2], T. Karagianni[2], V. Sissi[2], M. Argyrou[2], C. Mentorou[2], M. Mastrominas[2]
[1]c/o Embryogenesis, Genetics, Maroussi- Athens, Greece
[2]c/o Embryogenesis, Embryology, Maroussi- Athens, Greece

Study question: Whether unbalanced embryos, arising in meiosis during the gamete formation, in the carriers of structural rearrangements (SR) undergoing preimplantation genetic testing, can be detectable through non-invasive, morphokinetic assessment.
Summary answer: Multivariable analysis of time-lapse morphokinetic parameters at first cleavages and blastocyst formation cannot be used as a predictive factor for selecting balanced embryos.
What is known already: Using morphokinetic data to predict balanced embryos is intriguing since it is non-invasive and could easily be implemented in most IVF laboratories. However, results from studies trying to identify any predictive value of morphokinetic analysis for embryonic chromosomal status are contradictory.
Study design, size, duration: Longitudinal cohort analysis of time-lapse imaging, to measure timing, synchronicity and cleavage patterns of the first embryonic divisions. The frequency of direct cleavage events was introduced

as a dynamic score These parameters were correlated with the chromosome complement of the embryos obtained from 101 couples undergoing 120 IVF cycles of preimplantation testing for structural rearrangements and aneuploidy testing, between 2014 and 2018. All procedures and protocols were carried out in Embryogenesis, Athens, Greece.

Participants/materials, setting, methods: 579 fertilized embryos were monitored using the Embryoviewer™. Trophectoderm and day 3 biopsy was performed in 111 and 468 embryos respectively. Biopsied samples were analyzed for the specific structural rearrangement and for 24 chromosome aneuploidy testing and classified as (a) balanced/euploid, (b) balanced/aneuploid, (c) unbalanced/euploid and (d) unbalanced/aneuploid.

Main results and the role of chance: Statistically significant differences were not observed between groups (a) and (b) for t2 (p=0.55), t3 (p=0.72), t5(p=0.67) and t6 (p=0.8). The time intervals between t5-t2; t5-t3; t5-t4; t3-t2 (p<0,001) and synchrony from 2-4 cells (t4-t3, p=0,03) were significantly different between groups (c) and (d) but not between groups (a) and (b) [t5-t2; t5-t3; t5-t4; t3-t2 (p=0,144) (t4-t3, p=0,12)]. The occurrence of dynamic score was 10%, 12%, 23% & 62% for Groups a, b, c & d respectively.

Multi variable logistic regression analysis identified the time interval t4-t3 (Odds Ratio=0.80;95% Confidence Interval,0.70-0.94) in combination with direct cleavage frequency (OR=0,33;95%CI,0.18-0.61) as the most relevant variables in selecting unbalanced/aneuploid embryos. t3-t2 time interval along with direct cleavage frequency, has also high predictive value when comparing groups (c) versus and (d). In contrast, none of the above parameters have high predictive value when comparing groups (a) and (b).

Limitations, reasons for caution: When biopsy and chromosome analysis is performed on day 3 the high degree of embryonic mosaicism could affect the results and lead to misdiagnosis. Several variables such as ovarian stimulation, maternal age, culture media, culture conditions and BMI can affect time-dependent measurements and create a bias in the morphokinetics analysis.

Wider implications of the findings: Although a relationship between morphokinetic factors and ploidy status has been reported, the predictive values of these markers cannot replace the preimplantation genetic testing for structural rearrangements

Trial registration number: not-applicable

P-268 Reproductive Outcomes of Testicular versus Ejaculated Sperm for Intracytoplasmic Sperm Injection into Sibling Oocytes

B. Teke[1], M.G. Culha[2], E. Ozkok[3], E.C. Serefoglu[3]

[1]*Bahceci Health Group, Embryology, Istanbul, Turkey*

[2]*University of Health Sciences- Okmeydani Training & Research Hospital, Urology, Istanbul, Turkey*

[3]*Bahceci Health Group, Urology, Istanbul, Turkey*

Study question: Is testicular sperm (TS) a better option in infertile couples who failed to achieve clinical pregnancy after intracytoplasmic sperm injection (ICSI) with ejaculated sperm (ES)?

Summary answer: TS-ICSI and ES-ICSI revealed similar fertilization rate(FR), blastocyte development rate(BDR), clinical pregnancy rate(CPR) and live birth rates(LBR) when they are performed on sibling oocytes.

What is known already: The use of TS instead of ES for ICSI has gained popularity in the recent years, because of studies reporting better CPR and LBR especially in cases with severe oligoasthenoteratozoospermia and high sperm DNA fragmentation. However, there is scarce of data in the literature comparing TS and ES in cases of recurrent poor embryo development. Considering the significant role of oocyte quality in the success of assisted reproductive techniques, the impact of sperm retrieval technique on reproductive outcomes can be better demonstrated among sibling oocytes whose qualities are similar.

Study design, size, duration: The records of 51 couples with at least 2 unsuccessful ES-ICSI attempts between January 2014 and April 2017 have been retrospectively evaluated.

Participants/materials, setting, methods: The demographic data, clinical findings and sperm/oocyte characteristics of 51 couples were recorded. Sibling oocytes were fertilized with ES-ICSI and TS-ICSI. FR, BDR, CPR and LBR obtained with ES-ICSI and TS-ICSI were compared.

Main results and the role of chance: The mean age of the female and male patients were 33.49±5.30 (23-44) and 37.35±5.60 (25-47), respectively. The couples had mean 2.82±1.55 unsuccessful previous ES-ICSI attempts. Of the couples 22 and 25 were suffering from female factor and male factors respectively whereas no etiological factors could be identified in 4 couples (unexplained infertility). Mean sibling oocyte number collected for the ES-ICSI and TS-ICSI was 16.75±7.94 (6-40). TS cells have been harvested via testicular sperm aspiration (TESA), testicular sperm extraction (TESE) and microsurgical epididymal sperm aspiration (MESA) in 29, 18 and 4 patients respectively. Of the 327 MII oocytes, which underwent ES-ICSI, 241 fertilized normally (2PN) whereas 334 MII oocytes which underwent TS-ICSI 218 were fertilized normally (73.7% vs. 65.3%, p=0.214).Of the oocytes fertilized with ES-ICSI and TS-ICSI, 63 and 58 blastocyst developed (26.14% vs. 26.61%, p=0.716). Of the couples, 31 and 36 achieved clinical pregnancy with ES-ICSI and TS-ICSI respectively (50.00% vs. 65.79%, p=0.186).Finally LBRs were 41.18% vs. 60.53% (p=0.065)in ES-ICSI and TS-ICSI groups, respectively.

Limitations, reasons for caution: The sample size was small and embryologists were not blinded to the medical history of the patients which may be prone to operator bias.

Wider implications of the findings: ES-ICSI and TS-ICSI have similar FR, BDR, CPR and LBR among couples with at unsuccessful ES-ICSI attempts. Considering the higher (but statistically insignificant) CPR and LBR in sibling oocytes, TS-ICSI may be recommended to couples with previous unsuccessful IVF treatments with ES-ICSI

Trial registration number: N/A

P-269 2 hours post-thaw survival assessment of warmed blastocysts predicts clinical pregnancy

F. Olivennes[1], B. Gonzalez-Marti[2], D. Cornet[2], A.M. Junca[2], F. Entezami[3]

[1]*Centre Eylau Cherest, Ivf, Paris, France*

[2]*Centre Eylau La Muette, Ivf, Paris, France*

[3]*American Hospital of Paris, Ivf, Neuilly sur Seine, France*

Study question: To determine the shortest relevant recovery time after warming of vitrified blastocyst studied in SET (single embryo transfer) cycles.

Summary answer: A minimum recovery time of two hours before assessing embryo survival is beneficial to clinical outcome and avoids the transfer of fairly survived blastocysts.

What is known already: Several studies have reported on the relevance of blastocoele expansion after thawing as a predictor of implantation in single/-double transfer cycles. In SET frozen/thawed cycles the degree of reexpansion has been shown to be the best predictor for live birth rate.

Manufacturers advise to let the embryos recover from 2 to 4 hours after warming before the transfer. Some studies have reported various recovery delays like as short as 30 minutes post warming before the transfer. The shortest relevant post thaw culture time remains stil unclearly defined.

Study design, size, duration: Prospective observational study during 2017 to compare pregnancy outcome after ≤1 hour post thaw assessment of blastocyst survival and 2 hours post thaw assessment. Two clinicians conducted the study in order to avoid practice variations. Both practitioners performed vitrified/warmed blastocyst transfers either after less than 1 hour post thaw or 2 hours post thaw. Only SET cycles were included to control for embryo competency.

Participants/materials, setting, methods: 251 cycles included: group A (n=76) transferred ≤1 hour post-thawing (8.30AM) and group B (n=175) transferred 2 hours post-thawing (10.30AM). Blastocyst survival was assessed before the catheter load to discard damaged/non-reexpanded ones.

258 thawed blastocysts (Vit Kit® -Thaw, IrvineScientific®) recovered in Sage 1-Step™ (Origio). Catheters were loaded with EmbryoGlue® (Vitrolife) for ultrasound-guided transfers in natural cycle at 6-8 days after LH surge.

Survival and clinical pregnancy rates were compared between groups by t-test and Chi-square test.

Main results and the role of chance: Female age was similar between groups (A : 36.5+/-5.4, B : 35.7+/-3.1, p=0.47).

78 blastocysts were warmed in group A and 180 in group B. Survival rates were similar between groups (A: 97.3%, B: 96.0%, p=0.59).

Clinical pregnancy rates were significantly higher in group B compared to group A (36.3% vs 18.9%, p=0.048).

Limitations, reasons for caution: The study would benefit from a larger data size and from comparison of SET warming cycles in a PGT-A population were the embryo quality bias would be most limited.
Wider implications of the findings: Assessing blastocyst survival before transfer is mandatory to discard embryos with low implantation potential. In our center a minimum recovery time of two hours before survival evaluation enhanced clinical outcome by avoiding damaged blastocysts. Therefore all frozen/thawed transfers shifted after 9.30 AM to allow minimum two hours recovery after warming.
Trial registration number: Not Applicable

P-270 Mechanically disconnected mouse preantal follicles lead to developmentally competent oocytes following follicle culture, likely due to the reestablishment of functional transzonal projections

A.C. Herta[1], N. Akin[1], K. Billooy[1], L. Saucedo-Cuevas[1], F. Lolicato[2], E. Anckaert[1], J. Smitz[1]
[1] *Vrije Universiteit Brussel VUB, Follicle Biology Laboratory, Brussels, Belgium*
[2] *Fertilab, IVF Lab, Barcelona, Spain*

Study question: Are mechanically disconnected mouse preantral follicles able to re-establish transzonal projections (TZPs) connections and acquire competence comparable to oocytes derived from intact cultured follicles?
Summary answer: Reconnection of disrupted mouse preantral follicles, mediated by TZPs reestablishment, leads to embryo formation rates and gene expression comparable to oocytes from intact cultured follicles.
What is known already: Impaired oocyte-granulosa connections can be restored in mouse preantral follicles during *in vitro* follicle culture. Increased TZPs density and function has been shown following 2 days of 3D in vitro culture of disconnected follicles. Oocyte secreted factors support granulosa cells to generate new TZPs to ensure normal follicle growth. The impact of temporary communication disruption between the two follicular compartments, somatic and germ cell, has not been assessed widely with regard to the oocyte developmental capacity.
Study design, size, duration: Mouse secondary follicle culture was performed for a period of 10 days. On day 5 of culture, in half of the follicles, the oocyte was mechanically disconnected from its granulosa cells and placed back in culture, whereas the other half of follicles remained intact. We compared the culture outcome of the disconnected versus the intact follicle group. Two independent experiments, comprising a minimum of 6 culture plates with 10 follicles for each condition, were performed.
Participants/materials, setting, methods: Developmental capacity of mouse (C57BL/6J x CBA/Ca) MII oocytes from intact and disconnected follicles after *in vitro* culture was tested by IVF. Gene expression analysis was performed in MII oocytes and corresponding cumulus cells for oocyte quality markers and early embryo development (Gdf9, Bmp15, Zar1, Mater, Nmp2, Stella, Oct4) and cumulus expansion (Has2, Ptgs2, Ptx3). Two cell embryo and blastocysts rates were assessed. TZPs formation in disconnected follicles was identified by confocal microscopy.
Main results and the role of chance: The disconnected group attained the same morphological features as the control, by the end of the follicle culture period. Presence of TZPs was identified in the experimental group 2 days after mechanical disconnection of the oocyte. By day 9 of culture, an increased density of these connections was notable, presumably due to de novo formation. F actin immunofluorescence staining and confocal imaging were used for TZPs visualization.

The oocyte maturation rates were not significantly different (p=0,5511): 75% for intact follicles and 70% for disconnected ones.

The 2 cell embryo rate did not reach statistical significance (p=0,4604) between the experimental group (58%, n=77) and control (52%, n= 59). The blastocysts formation was comparable in the intact (68%, n=40) and disconnected follicles (71%, n=55).

The qPCR analysis showed a tendency for lower expression levels for all of the selected oocyte quality and early embryo development markers in the experimental group. However, these values did not reach significant differences.
Limitations, reasons for caution: In this study, the oocyte disconnection from the follicles was mechanically induced. In case of spontaneous oocyte release due to abnormal follicle physiology, re-establishing the TZPs might require a different approach.
Wider implications of the findings: Our data expands previous published results. These findings propose a possible strategy for rescuing the competence of partially denuded human COCs undergoing IVM. Oocyte cumulus connections are critical for meiosis inhibition during pre-IVM. Improving these could allow proper oocyte pre-maturation leading to an increased developmental capacity.
Trial registration number: not applicable

P-271 Does the day of blastocyst biopsy alone affect PGD clinical outcome?

Y. Dajani[1], M. Xenariou[1], I. Vrabtcheva[1], M. Onoufriou[1], Z. Roche[1], L. Kadi[1], M. Kanani[1], C. Kleanthis[1], Y. Khalaf[1], T. El-Toukhy[1]
[1] *Guy's and St. Thomas' hospital, Assisted Conception Unit, London, United Kingdom*

Study question: Does the day of trophectoderm biopsy affect PGD clinical outcome?
Summary answer: Trophectoderm biopsy (TEBx) of day 5 (D5) blastocysts is associated with a significantly improved clinical outcome compared to that of day 6 (D6) blastocysts.
What is known already: Increased clinical pregnancy rates (CPR) have been reported following D5 versus D6 transfer in frozen embryo transfer (FET) cycles (Haas *et al*, 2016). Similarly, higher ongoing pregnancy rates were reported following the transfer of D5 versus D6 embryos for PGS (Liebermann *et al*, 2017). However, the impact of blastocyst quality on D5 or D6, followed by TEBx and vitrification, on CPR has not been adequately explored. In addition, data investigating the clinical outcome of biopsied and vitrified blastocysts, selected for FET based on the day of biopsy and/or quality, are limited (Yang *et al* 2016; Wang *et al* 2016).
Study design, size, duration: This retrospective study included 1058 single FET cycles following TEBx on D5 and D6 blastocysts. In those 1058 cycles, 1069 blastocysts were warmed and 1031 were transferred between December 2013 and October 2018. Transferred embryos were divided according to the day of biopsy into D5 and D6 groups. Each group was subdivided based on embryo quality into good (>BB), average (AC, CA, BC, CB) and poor (CC). The CPR was compared between the different groups.
Participants/materials, setting, methods: Blastocysts subjected to laser-assisted TEBx and vitrification on D5 (n=726), and D6 (n=305) were warmed and transferred individually. Blastocyst grading was carried out on the day of TEBx using the Gardner grading system. CPRs were reported according to the day of biopsy and embryo quality. Chi-squared test was used to compare the CPR. The association between the day of biopsy, embryo quality and CPR was evaluated by multivariable logistic regression.
Main results and the role of chance: There was no significant difference in patient age between the two groups (32.7±3.85 vs 32.9, ±3.85; *P*=0.44). The overall blastocyst survival rate (SR) per embryo warmed was 1031/1069=96.4%. SR was significantly higher in D5 compared to D6 (726/742=96.5% and 305/327=91.1%, *p=0.003*). CPR per transfer was also significantly higher in D5 compared to D6 (CPR: 384/726=52.9% and 96/305=31.5%, *P*<0.05). Logistic regression analysis identified the day of biopsy and embryo quality as significant predictors of pregnancy in PGD-FET cycles (*P*<0.001). Our results showed that D5 poor quality embryos had similar CPR to good quality D6 embryos (D5: 20/58=34.5% *vs* D6: 54/143=37.8%, P>0.05). The CPR of the 6 sub-categories was the following: D5-good 314/565=56%, D5-average 41/103=40%, D5-poor 20/58=35%; D6-good 54/143=38%, D6-average 27/88=31%, D6-poor 13/74=18%.
Limitations, reasons for caution: Blastocyst grading, was based on subjective assessment, by different scientists performing the biopsy (practitioners) and the possible effect of other confounding variables.
Wider implications of the findings: This is the first study investigating CPR in relation to day of TEBx and blastocyst quality. Preference should be prioritised to D5 biopsied blastocysts for PGD-FET cycles to achieve higher CPR regardless of blastocyst quality. Continuous D5 embryo monitoring will maximize the number of D5 biopsied blastocysts compared to D6.
Trial registration number: N/A

P-272 Implantation rate of vitrified-warmed blastocysts according to their expanding blastulation time : assessment by time-lapse technology.

J. Vandame[1], A. Benammar[1], S. Ranga[1], C. Fossard[1], P. Pirtea[1], D. De Ziegler[1], J.M. Ayoubi[1], M. Poulain[1]
[1] *Foch Hospital, Reproductive Biology Unit, Suresnes, France*

Study question: Is expanding blastulation (B3 degree) time efficient, in addition to morphologic criteria, to select blastocyst in frozen embryo transfer (FET) cycles?
Summary answer: There is a strong likelyhood for a better implantation when embryo reach B3 expansion degree earlier.
What is known already: Routinely, day 5 (D5) and day 6 (D6) blastocysts morphology is evaluated at 116+/- 2 and 140+/-2 hours after fertilization (hAF) respectively (ESHRE 2011 consortium). There is a consensus indicating that fresh transfer of late blastulating embryos leads to lower implantation rates (IR). However a debate persist regarding implantation chances of D6 embryos transferred after cryopreservation. Time-lapse allows continuous follow-up of embryo development and therefore could serve to identify this embryo-specific timing, whether it has been vitrified on D5 or D6. In this context, we queried whether exact expanding blastulation time (tB3ED) is more predictive than the day of vitrification.
Study design, size, duration: A single center retrospective cohort analysis realized on 143 frozen blastocysts with known outcome. Including all single embryo transfers and double embryo transfers with either 2 or no implanting embryos that have been cultured in time-lapse system during 2 years. These included 102 D5 and 41 D6 blastocysts cryopreserved from autologous IVF cycles (137 FET) without any age or other clinical criteria exclusion.
Participants/materials, setting, methods: Blastocysts achieving a B3 expansion degree (B3ED), at 118 or 142 hAF, with at least one B grade for inner cellular mass and/or trophectoderm were frozen on D5 or on D6 respectively. We compared 3 groups of frozen embryos: D5 embryos reaching B3ED before 118 hAF (group 1), D6 embryos reaching B3ED between 118 and 122 hAF (group 2) and slower ones (group 3). Primary outcomes were tB3ED and IR. A Mann-Whitney test was used.
Main results and the role of chance: Regarding transfer outcomes, we observed that embryos leading to pregnancy reach a B3ED earlier than those with no implantation (median 106.7h [94.5-129.3] and 110.8h [90.4-138.3] respectively). Amongst our studied blastocysts, 75.5% (108/143) reached B3ED before 118 hAF and 24.5% (35/143) after. Furthermore, we observed a tendency for a higher IR for embryos that reached B3ED before 118h compared to the others: 31.5% (34/108) *vs* 14.3% (5/35) respectively. This difference was though no statistically different *(p=0.058)*. More precisely, in group 1, the IR was higher when embryos reached B3ED before 114 hAF (32.3% *vs* 26.7%). For groups 2 and 3, IR was 27.3 % (3/11) and 8.3 % (2/24) respectively. When we look at the day of vitrification: third of frozen D6 embryos (31.4%) had actually reached B3ED later on D5 and could have been frozen routinely on D5 instead of D6. These embryos seems to have a better outcome than those with a delayed development (B3ED after 122h): 27.3% (3/11) *vs* 8.3% (2/24) respectively, *p=0.15*.
Limitations, reasons for caution: The main limitation was the size of the sample; due to the availability of only one time-lapse incubator, the exclusion of single pregnancies after DET and our thawing strategy. Indeed, D5 blastocysts are firstly warmed for FET cycles leading to several D6 still frozen at the time of the study.
Wider implications of the findings: Our study is preliminary : if the tendency becomes significant with a higher number of embryos included, it could be interesting to define a B3ED time to optimize blastocyst selection in addition to morphologic criteria.
Trial registration number: None

P-273 Current laboratory standards for assessing vitrified-warmed blastocyst viability fail to accurately predict their implantation potential.

J.B. Whitney[1], R. VanTol[2], A. Miller[3], K. Mayer[4], M.C. Schiewe[1]
[1] *Ovation Fertility, ART Lab, Newport Beach- CA, U.S.A.*
[2] *Carmel- IN, U.S.A.,*
[3] *Austin- TX, U.S.A.,*
[4] *Cincinanti- OH, U.S.A.,*

Study question: Do current standard assessments of vitrified-warmed embryo survival and cellular viability accurately predict blastocyst functionality post-transfer? Do all embryos deemed viable at 3hr sustain development?
Summary answer: Blastocysts appearing viable at +180min may not continue development 24hr later, confirming that standard laboratory yiability assessments are visual not functional determinants of cellular health.
What is known already: Vitrification has revolutionized cryopreservation in the field of reproductive medicine by achieving >95% complete blastocyst survival rates. A variety of open and closed device vitrification techniques use mixed solutions of cryoprotectants and concentrated macromolecules to form a supercooled vitreous solid. These methods rely on faster warming rates than cooling rates to avoid damaging ice formation and optimize post-warming/dilution survival. Pre-transfer embryo survival evaluation typically occurs between 0 and 3hr post-warming. Although high live rate rates are associated with vitrified embryo transfer cycles, it is unknown if current survival assessments at 3hrs accurately identify viability.
Study design, size, duration: Research consented vitrified blastocysts (n=60), from four Ovation laboratories, were warmed using standardized, published protocols. Survivability and blastocoele expansion measurements were assessed at +1min, +30min, +60min, +120min, +180min, and +24hr post-warming. Initial survival was determined at +30min, while two viability assessments were made, the first at +3hr post-warming using standard transfer viability criteria. At +24hr, a second viability determination was based on complete hatching or positive growth from +180min to +24hr.
Participants/materials, setting, methods: Blastocysts were warmed using standardized, published protocols based on the vitrification system used: Cryolock, Cryotech, or µicroSecure devices. Post-thawing and dilution, all blastocysts were incubated in low O2, humidified, tri-gas environments at 37°C. At designated time intervals, blastocysts were analyzed for continued development and documented by photography (200X). Subsequently, measurements of blastocoele diameter were estimated along the longest axis of the trophectoderm. Differences in survival and viability were determined using a χ^2test ($p<0.05$).
Main results and the role of chance: Initial survival was 97% (58/60) at +30min post-thaw. The first viability assessment at +3hr post-warming determined no change in developmental status, with a non-viable rate of 3.33% (2/60) maintained. After +24hr, the second viability assessment resulted in a higher ($p<0.05$) non-viable rate of 13.8% (8/58). The latter 8 blastocysts failed to exhibited blastocoele growth past the +3hr mark and were deemed non-viable. Growth rates assessing increases in blastocoele diameter between time intervals and laboratories were significant between vitrification methods. Not surprisingly, notable blastocoele recovery and trophectodermal expansion was evident between +30min to +180min, with non-DMSO exposed, microSecure-treated blastocysts tending ($p<0.10$) to be more expanded up to +120min. Overall, our preliminary data reveals that viability assessments between laboratories (non-DMSO, closed device, n=20; D
Limitations, reasons for caution: Survival and viability are two separate assessments that are commonly performed simultaneously to determine blastocyst implantation potential. Current embryo viability evaluations at 0-3hr post-warming can be inaccurate predictors of implantation potential. In turn, alternative methods, perhaps integrating short-term time lapse imaging, are needed to improve our estimation of embryo viability.
Wider implications of the findings: The viability of embryos post-warming is difficult to assess as most laboratories artificially collapse or biopsy the trophectoderm of blastocysts prior to vitrification. Robust expansion may take several hours. Time-lapse imagery may prove beneficial to identify key growth rates to more accurately identify viability.
Trial registration number: None

P-274 Suboptimal oocyte cohort maturity impairs the implantation potential of euploid blastocysts

R. Anderson[1], J.B. Whitney[2], C.M. Rios[3], K. Balloch[2], M.C. Schiewe[2]
[1] *The Southern California Center for Reproductive Medicine, ART Clinic, Newport Beach, U.S.A.*
[2] *Lab, Newport Beach-CA, U.S.A.*

[3]Ovation Genetics, NGS Lab, Henderson-NV, U.S.A.

Study question: Can oocyte cohort maturity predict the implantation potential of euploid blastocysts? Do stimulation protocols influence aneuploidy and the ability of euploid blastocysts to implant?

Summary answer: Ovarian hyperstimulation protocols yielding reduced oocyte maturity rates(<70%) are associated with lower (P<0.05) blastocyst development, euploidy and implantation rates, likely correlated to incomplete cytoplasmic maturation.

What is known already: Controlled ovarian hyperstimulation in IVF has greatly improved the success of assisted reproduction. Stimulation protocols, medications, duration and LH trigger timing are used by physicians to optimize mature oocyte production, and have been studied rigorously to identify their effect on oocyte quality and pregnancy. Oocyte quality is difficult to independently quantify, while nuclear maturation of oocyte cohorts indexes overall stimulation effectiveness. Applying PGT-A technology, euploid blastocysts are transferred with the expectation of a constant implantation potential across age groups. However, it is unknown what role oocyte cytoplasmic preparedness (i.e., maturation) could play on the implantation potential of euploid embryos.

Study design, size, duration: A 5-year (2014-2018) retrospective analysis of 1358 autologous and donor stimulation cycles using PGT-A and 1002 vitrified-thawed euploid embryo transfers was examined. Nuclear maturity was defined by the presence of a polar body at ICSI and cycle cohort comparisons were separated by Group 1: ≥70%(n=1124) and Group 2: below 70% (n=234). Data comparisons using t-test and chi-square were performed for cycles failing to produce blastocysts, cycles resulting in normal embryos, aneuploidy rates and implantation success.

Participants/materials, setting, methods: Single physician clinic stimulated 1138 patients for 1358 cycles having a cohort of oocytes retrieved. All ICSI-derived zygotes were grown to the blastocysts stage for PGT-A and vitrification. Only the first transfer attempt was counted in our analysis. Stimulation protocols varied but were predominantly antagonist based. Oocytes were retrieved 35-36 hours post-hCG trigger and cumulus complexes denuded 2-3 hours post-retrieval. Patient's percent mature oocytes were calculated based on Metaphase II status upon denuding.

Main results and the role of chance: Average patient age was 37 and 38 for groups 1 and 2, respectively. Oocyte cohort maturity of 70% or greater (Group 1) occurred in 83% of the cycles,with 17% considered suboptimal at less than 70% maturity (Group 2). Embryo development comparisons focusing on blastocyst yield, aneuploidy and whether a normal embryo was produced/cycle exhibited a lower (p<0.01) blastocyst yield (mean=2.7) in Group 2 compared to Group 1 (mean=5.7 blastocysts). Furthermore, Group 2 had a statistically higher aneuploidy rate of 61% and more cycles (41%) failing to result a normal embryo, in contrast to Group 1 having an aneuploidy rate of 54% and 23% of its cycles not resulting in a normal embryo. Most importantly, the implant ability of euploid embryos was lower (p<0.05) for Group 2 at 61% compared to 70% in Group 1. The reduced cytoplasmic preparedness of Group 2 oocytes led to developmental incompetence as indicated by 18% more cycles failing to develop a euploid blastocyst and significantly more aneuploidy. The issue of reduced cytoplasmic maturation of Group 2 oocytes was further manifested when they produced top quality euploid blastocysts with a lower(p<0.05) implantation potential upon transfer.

Limitations, reasons for caution: Multiple factors influence ovarian stimulation responsiveness and oocyte cohort maturity, nonetheless 5 years of data has identified a group of cycles that increased the risk of aneuploidy and produce euploid embryos with reduced implantation potential. These significant trends suggest possible adverse developmental events associated to related incomplete cytoplasmic maturation.

Wider implications of the findings: Many factors can influence controlled ovarian stimulation, oocyte maturity and subsequent negative cycle outcomes. Further investigations and evidence of oocyte-cellular cytoplasmic proteomics, metabolomics and gene activation/regulation is needed to better identify how sub-optimal maturity can adversely influence subsequent embryo viability and healthy, term live birth success.

Trial registration number: none

P-275 Histone methyltransferase Setd2 is required for mouse oocyte early development

C. YAO[1], T. Mixue[1], Y. Yanyun[1], L. Juan[1], Z. Dan[1]

[1]Women's Hospital- Zhejiang University School of Medicine, Department of Reproductive Endocrinology, HangZhou, China

Study question: Does histone methyltransferase *SET domain containing 2 (Setd2)* play an important role in mouse oocyte early development and how it works?

Summary answer: Setd2 is essential for oocyte early development, mediating H3K36me3 in maintaining dynamic DNA methylation and normal DNA damage response.

What is known already: *Setd2* is responsible for lysine-36 of histone H3 trimethylation (H3K36me3), which is associate with actively transcription, transcriptional elongation, DNA damage response and DNA methylation dynamic. Primordial oocytes arrest from embryonic day 18.5 till day 10 post-partum to build *de novo* DNA methylation and restart transcription, which might accumulate DNA damage triggering cell cycle checkpoint. Products of the oocyte genome support oocyte growth and development till silencing, when oocyte grow to Graafian follicles, and are stored for use during the silencing supporting oocyte maturation. *Setd2* defect results in embryonic lethality while conditionally knockout in sperm could cause aberrant spermatogenesis.

Study design, size, duration: We generate $Setd2^{fl/fl}$; *Zp3*+ conditional knockout mouse line, and set mice with $Setd2^{fl/fl}$ genotype as control group. Each experiment included at least 3 independent samples and was repeated 3 times. Morphology phenotype were observed in at least 15 oocytes each. Growing oocytes were digested from 10, 15, 18 day-old mice while GV oocytes were super-ovulated from 21-23-day-old mice.

Participants/materials, setting, methods: We collected surrounding nucleoli germinal vehicle (SN-GV) oocyte and the growing oocytes. The efficiency of knockout was verified by WesternBlot using 150 oocytes each. Germinal vehicle break down (GVBD) rate, MII rate and fertilization rate were calculated in 150 oocytes each. We performed Chromatin Spreading and Immunocytochemistry staining of β-tubulin, 5-Methylcytosine, H3K36me3, H4K20me3, phosphor-histone H2A.X (γH2AX), etc. We also performed RNA sequencing from single oocyte using Smart-seq2.

Main results and the role of chance: We cross female mice with wild type C57 male mice, *Setd2*-deficient mice presented totally infertility for 6 months while control female mice had produced the expected range of pup number. While total number of observed oocytes were comparable, *Setd2*-deficient oocytes display significantly lower GVBD rate (16% vs 81%), fertilization rate (9% vs 78%). After 12.5h of in-vitro maturation, 90% of *Setd2*-deficient oocytes still contain GV (90% vs 5%).Immunocytochemistrystaining of β-tubulin shows *Setd2*-deficient oocytes present a rim of Hoechst-positive chromatin that surrounds the nucleolus and a thread-like chromatin organization while control oocytes present barrel-shaped bipolar spindle with all the chromosomes aligned at the equator plate. The result of Chromatin Spreading matches Immunocytochemistryphenotype above. *Setd2*-deficient oocytes shows lower signal and different DNA methylation pattern revealed by Immunocytochemistrystaining of 5-Methylcytosine.Immunocytochemistrystaining of γH2AX shows accumulated DNA damage in *Setd2*-deficient oocytes during its early development, 10 dpp, 15 dpp, 18 dpp, 21dpp. Single cell RNA sequencing finds 192 genes with increased RNA copy (fold>2) and 231 genes with decreased copy. The different expressed genes are enriched in GO biological pathways of DNA repair, Nuclear division, DNA metabolic process, cell cycle transition, etc.

Limitations, reasons for caution: The clinical significance of *SETD2* in human oocyte development is not explored yet.

Wider implications of the findings: This study might identify *Setd2* as a key regulator in oocyte, demonstrating essential role of *Setd2*-mediated H3K36me3 in maintaining dynamic DNA methylation and DNA damage response in post-proliferative cells. Deficiency of *SETD2* could be a hallmarker of human infertility and even the gene therapy target in the future.

Trial registration number: Not applicable.

P-276 Effect of different commercial media on spontaneous in vitro maturation and kinetics of germinal-vesicle human oocytes

L. Escrich[1], N. Soler[2], A. González-Picazo[1], P. Buendía[1], M.J. Escribá[3], M.J. De los Santos[1]

[1]IVI-RMA Valencia, IVF Laboratory, Valencia, Spain
[2]Universidad de Valencia, Facultad Medicina, Valencia, Spain
[3]IVI-RMA Valencia- Fundación IVF, IVF Laboratory- Research, Valencia, Spain

Study question: To assess the maturation in vitro rates and dynamics of germinal-vesicle (GV) oocytes recovered from stimulated donors' cycles, depending on different commercial culture media

Summary answer: G2 PLUS medium is the best option to in-vitro maturing germinal-vesicle oocytes. In their absence, continuous media or Sequential Cleav could be used equally.

What is known already: Following controlled ovarian stimulation, nearly 15% retrieved oocytes are immature and usually reproductively discarded. Recently, Escrich et al (2018) reported that nearly 70% GV oocytes, retrieved from stimulated cycles and cultured in CCM progressed spontaneously in vitro to the MII stage and were able to be used for reproductive endings. Now, Vitrolife has removed the CCM medium from the market. Thus, it is needed to test different commercial media in order to determine an efficient medium in terms of allowing the nuclear oocyte maturation, at first.

Study design, size, duration: A prospective study including 1260 cumulus-free GV oocytes, recovered from donors, who underwent standardized ovarian stimulation protocols between February 2017 to October 2018.

Participants/materials, setting, methods: 4 hours after aspiration, GVs were cultured in 10 different media in a time-lapse system at 37°C, 6% CO2 and 5% O2 for 24h. Denudation was considered as time point zero, and the first polar body (1PB) extrusion were assessed. We calculated also the MI duration by subtraction of these timings (1stPB – GVBD). Nuclear maturation rate was calculated as a percentage of MII oocytes per cultured GV.

Main results and the role of chance: Concerning the spontaneous nuclear maturation, the highest rates were observed for the Sequential Cleav- Origio (55.3%), G2 PLUS - Vitrolife (56.7%), IVM - Origio supplemented with hormones (45.5%), GEMS - Genea Biomedx and GLOBAL media - Life Global (52.1% and 46.0%, respectively; $p>0.05$). Moreover, these rates were significantly higher (51.9% in average) than

those observed for GV oocytes cultured in phase 0 media (LAG medium - Origio, LAG supplemented with hormones, Sydney IVF Fertilization Medium – Cook and IVM media non-supplemented with hormones) and CSCM – IrvineScientific, all ranged from 16.4% to 40.2%, showing HLAG medium the lowest nuclear maturation rates (16.4%; $p<0.05$).

According to the kinetics, there were significant differences amongst media for all analyzing timings. Regarding the 1PB extrusion, it occurred at comparable timing in all experimental groups, exception made for the LAG and G2 medium ($p<0.05$). However, there were significant differences in the timing of occurrence of the GVBD and therefore, in the MI duration. Thus, regarding the latter, and taking as a MI duration reference that achieved by oocytes cultured in G2 medium, there were no significant differences between G2 and all media, with the exception of the Sequential Cleav, and all three tested one-step media.

Limitations, reasons for caution: Despite the ability of the analyzed media to sustain the GV progression on meiosis, there were no tests on the cytoplasmic competence of in vitro rescued GV oocytes.

Wider implications of the findings: Our results suggested that G2-PLUS (Vitrolife), Sequential Cleav (Origio), GEMS (Genea Biomedx) and GLOBAL TOTAL (Life Global) are efficient media in terms of nuclear maturation rates and dynamics to be used in a GV rescue scenario.

Trial registration number: 1301-C-111-MJE

P-277 Spontaneous ovulation versus human chorionic gonadotropin (hcg) triggering for intrauterine insemination(IUI): a retrospective study with meta-analysis.

A. Vitagliano[1], A. Andrisani[2], M. Noventa[3], F. Esposito[4], G. Ambrosini[4]

[1]University of Padua, Woman and Child Health, Padova, Italy
[2]women and children's health, padua, Padova, Italy
[3]Women and children's health, Padua, Padua, Italy
[4]padua, childrens' health, padua, Italy

Study question: To evaluate whether IUI syncronization with spontaneous serum LH surge or r-hCG trigger in women undergoing gonadothropin-stimulated IUI may provide different chances for pregnancy

Summary answer: hCG administration improves clinical pregnancy rates and ongoing live birth rate in women undergoing gonadotropins-stimulated IUI cycles.

What is known already: There are different factors that may influence IUI outcome, of which one of the most important is the timing of IUI. Nevertheless, there is still no consensus whether timing IUI with spontaneous ovulation (i.e. by detecting LH-surge) or by administering hCG may provide higher pregnancy rates. Recent studies on women undergoing gonadotropins-stimulated IUI cycles found controversial evidence on the effectiveness of each single strategy for IUI timing, concluding that further studies were needed.

Study design, size, duration: We performed a single-center observational study on 391 consecutive women undergone IUI after ovarian stimulation with gonadotropins from 2012 to 2017. 104 women were included in Group_A (LH surge) and 287 in Group_B(r-hCG trigger). Our data was pooled with that from other studies in a meta-analysis.

Participants/materials, setting, methods: Participants were young normo-ovulatory women (18-37 years) undergoing COS before IUI. Gonadotropin injections were administered starting on day 3 of the menstrual cycle and continued until ovulation. Patients were monitored with ultrasound and serum estradiol, LH, and progesterone until the time of either serum LH surge or hCG administration. IUI was performed approximately 24 hr after either observation of a spontaneous serum LH surge or 32 hr after r-hCG administration.

Main results and the role of chance: Group_B experienced a significantly higher clinical pregnancy rate in comparison to Group_A (21.3% vs 12.5%; p=0.032). Similarly, ongoing pregnancies were considerably higher in Group_B (13.94% vs 5.77%; p=0.032); no difference was observed in the miscarriage rates (p=ns). A subgroup analysis was performed in Group B, splitting patients in two subgroups according to the presence (Subgroup B_1) or absence (Subgroup B_2) of LH surge at the time of hcg administration. No significant difference was found between subgroups in terms of clinical pregnancy rate (19.4% vs 21.8%), ongoing pregnancy rate (12.9% vs 14.2%) and miscarriage rate (33.3% vs 34.7%). Our results were pooled in a meta-analysis of five studies (n=1532 IUI cycles). In line with our results, meta-analysis found a significantly higher pregnancy rate in patients receiving hcg administration before IUI compared to those inseminated after spontaneous LH surge (OR 2.28, 95% CI 1.06–4.92, I2=29%, p=0.03). No difference was found between women receiving hcg after LH surge and those in which LH surge did not occur (OR 1.03, 95% CI 0.63–1.69, I2=35%, p=0.90).

Limitations, reasons for caution: Some limitations must be considered; first, the design of our study was retrospective, potentially limiting the reliability of our findings. Secondly, the size of LH surge group was limited, potentially introducing bias due to imprecision.

Wider implications of the findings: This present study found a significant increase in the clinical pregnancy rate in gonadotropins-stimulated IUI cycles after hcg administration. Our findings may suggest that hcg may positively act on the mechanisms involved in follicular rupture, eggs maturation or embryo implantation in women undergoing IUI after ovarian stimulation with gonadotropins.

Trial registration number: Not applicable

P-278 Is it ethical to perform ICSI in all assisted reproductive treatment cycles: Does the method of fertilisation confer an additional benefit?

R. Venkatakrishnan[1], P.R. Supramaniam[2], C.M. Becker[2], L.N. Lim[2], I. Granne[2], M. Mittal[2]

[1]Leicester Royal Infirmary, Womens and Childrens, Leicester, United Kingdom
[2]Oxford University Hospitals NHS Foundation Trust, Womens and Childrens, Oxford, United Kingdom

Study question: Does the method of fertilisation impact the live birth outcome in the absence of a clinical indication?

Summary answer: Intracytoplasmic sperm injection (ICSI) has a lower failed fertilisation rate and higher clinical pregnancy rate, but this is not reflected in the live birth outcome.

What is known already: ICSI plays a central role in the management of male factor subfertility, with some advocating the use of ICSI for all types of infertility to reduce the risk of failed fertilisation. However, given the complex and more invasive nature of ICSI, adoption of such a policy would have wide implications for the future of assisted reproductive treatments (ART), with a major effect on the use of resources and safety. Currently, little evidence exists regarding the optimal method of fertilisation in cases of non-male factor subfertility, with the two main RCTs not identifying benefit conferred by ICSI in these patients.

Study design, size, duration: Retrospective cohort analysis of ART cycles between 1991-2016 from the Human Fertilisation and Embryology Authority (HFEA) database. 453,847 fresh cycles excluding male factor subfertility were undertaken. Of these, 340,773 and 113,114 underwent IVF and ICSI, respectively. Assuming a 30% live birth rate for IVF and 40% for ICSI, a power calculation demonstrated that 712 cycles would need to be analysed for 80% power and a 5% significance level to detect 10% difference.

Participants/materials, setting, methods: The singleton live birth rate (SLBR) was stratified by maternal age and adjusted by the type of treatment cycle (fresh IVF versus fresh ICSI). Cycles complicated by male factor subfertility were excluded from the analysis as the method of fertilisation is predetermined in these cases. Statistical significance was determined using Multiple Logistic Regression and Chi-square; $p<0.05$ was considered statistically significant.

Main results and the role of chance: The overall IVF to ICSI ratio in 1991, is solely dominated by IVF (100:0), with a continuous rise seen in ICSI cycles from 1999, to 66:34 in 2016, with an associated rise in ICSI cycles undertaken in the absence of male factor subfertility.

The clinical pregnancy rate is statistically lower with IVF cycles (n=81322; 30.0%) compared with ICSI cycles (n=30653;31.2%) (odds ratio [OR] 0.89, 95% confidence intervals [CI] 0.88-0.92, $p<0.0001$).

The overall live birth rate per embryo transferred is lower in the IVF group (n=86970;17.5%) compared with ICSI cycles (n=37003;20.8%), however, this did not reach statistical significance (OR 1.01, 95% CI 0.99-1.03, p=0.251) when adjusted for female age, number of previous IVF cycles attempted, previous live births through IVF and stage of embryo transfer.

The failed fertilisation rate was statistically higher for IVF cycles (n=13638; 4.00%) compared with ICSI (n=3925;3.47%) (relative risk [RR] 1.17, 95% CI 1.13-1.21, $p<0.0001$). Based on this, 189 ICSI cycles would need to be performed, to avoid one failed fertilisation through IVF.

Limitations, reasons for caution: The accuracy of the database is dependent on the information submitted to the HFEA. Until 2007, this data was manually captured adding the risk of data entry error. Furthermore, information on embryo quality is not available including the inability to account for cumulative pregnancy rates in women with previous attempts.

Wider implications of the findings: ICSI does not confer additional benefit in achieving a live birth in cases of non-male factor subfertility when adjusted for compounding variables. The additional complexity of ICSI including unknown long-term medical outcomes of the conceived children and costs to the patient are not supported by the findings of this study.

Trial registration number: Not applicable

P-279 Is there a relationship between time-lapse parameters and neonate gender? An analysis of 102 live births conceived through single fresh embryo transfer

A. Wertheimer[1,2], O. Sapir[1,2], A. Ben- Haroush[1,2], G. Oron[1,2], E. Shlush[1,2], E. Altman[1,2], T. Schohat[1,2], Y. Shufaro[1,2]

[1]Helen Schneider Hospital for Women- Rabin Medical Center-Beilinson Hospital-, IVF and Infertility Unit, Petach-Tiqva, Israel

[2]Tel Aviv university, Sackler school of medicine, Tel Aviv, Israel

Study question: Is there a relationship between morphokinetic time-lapse parameters and embryo gender?

Summary answer: Although time-lapse morphokinetic parameters do not differ between genders, a high known implantation data (KID) score was more prevalent among male embryos.

What is known already: Previous studies that focused on morphologic embryo assessment are controversial regarding the existence of a correlation between embryo development in-vitro and embryo gender. Only few studies have investigated the association between time-lapse morphokinetic parameters and embryo gender, and in only three gender determination was based on live births. The results of these studies are controversial. While one study showed similar cell division kinetics in male and female embryos, others suggested different morphokinetic parameters that may be associated with embryo gender.

Study design, size, duration: A retrospective cohort study reviewing files of all live births from successfully treated infertile patients, who underwent ovarian stimulation, IVF, embryo culture in time-lapse monitoring incubators and fresh single embryo transfer in a tertiary medical center between 2013 and 2017. The study group consisted of 102 single embryos transfers that resulted in 102 live births; 57 females (56%) and 44 males (43%). One case was excluded as a result of missing data regarding fetal sex.

Participants/materials, setting, methods: Sixty-four embryos were transferred on day 3 (26 male/37 female) and 38 embryos (18 male/20 female) were transferred on day 5. Embryos selection was based on locally established annotation criteria and the KID score provided by the Embryoscope^{tm}. Morphokinetic parameters of male and female embryos were compared. Main outcome measures were early morphokinetic parameters and day 3 KID score, and secondary outcome measurements were late morphokinetic parameters of the embryos cultured to day 5.

Main results and the role of chance: Maternal baseline and treatment characteristics were similar in both groups except for older maternal age in the female embryos group (31.7 years vs. 29.3 in the male embryos group, p=0.016). High KID score ($\geq$4) was more prevalent in male compared to female embryos (100% of males vs. 74.1% of females, p=0.04). Early morphokinetic time-lapse parameters of male and female embryos including pronucleus fading, cleavage timings (t2-t8), second cell cycle duration (CC2= T3-T2) synchrony (S2=T4-T3) and interval between 8 and 5 cells (S3=T8-T5) were similar. Late morphokinetic parameters including full compaction at morula stage (tM), start of blastulation (tSB), full blastocyst (tB), and hatching (tHB) were similar between the groups as well.

Limitations, reasons for caution: Retrospective design and sample size. Nevertheless, our findings are statistically and clinically significant.

Wider implications of the findings: Although morphokinetic parameters were not associated with embryo gender, a high day 3 KID score was more prevalent among male embryos. This suggests that the KID score might favor male embryos and that it's relevancy to female embryos might be lower.

Trial registration number: not applicable

P-280 Can oocyte DNA repair mechanisms counteract impaired sperm genomic integrity?

L. Zimmerman[1], D. Keating[1], A. Parrella[1], Z. Rosenwaks[1], G.D. Palermo[1]

[1]Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.

Study question: Can proportional oocyte maturity at retrieval shed light on an oocyte's ability to repair fragmented sperm chromatin and support embryo implantation?

Summary answer: When the proportion of mature oocytes was below a certain threshold, implantation rates of couples with compromised sperm chromatin fell drastically, regardless of maternal age.

What is known already: Abnormally elevated sperm chromatin fragmentation (SCF) has been linked to a reduced ability to achieve a pregnancy and to an increased risk of pregnancy loss. Oocytes have DNA repair mechanisms that play a role in repairing damaged sperm chromatin during early embryonic development. These repair mechanisms are known to be less effective as an oocyte ages. The ability to obtain mature oocytes is contingent on the female partner's response to a superovulation protocol, which may affect cytoplasmic maturity.

Study design, size, duration: This study included couples treated by intracytoplasmic sperm injection (ICSI) using ejaculated spermatozoa between 2006 and 2017. Female partners were limited to $\leq$35 years of age to control for

female-related aneuploidy. Nuclear maturity was assessed after the patient's own oocytes were denuded.

Cycles were allocated into two groups classified by the SCF of the male partner, normal and abnormal, and then stratified by the proportion of mature oocytes obtained at retrieval.

Participants/materials, setting, methods: All treatments took place at our center. Female patients ≤35 years old underwent ovarian superovulation by pituitary suppression utilizing either gonadotropin-releasing hormone agonist or antagonist, were treated with daily gonadotropins, and were triggered with human chorionic gonadotropin. ICSI was performed in the standard fashion.

SCF was assessed by terminal deoxynucleotidyl dUTP nick-end labeling (TUNEL) on ejaculated spermatozoa using a commercially available kit. At least 500 spermatozoa were assessed with a normal threshold of ≤15% SCF.

Main results and the role of chance: A total of 84 couples where the male partner had a normal TUNEL underwent 124 ICSI cycles, while 43 couples where the male partner had a compromised SCF underwent 67 ICSI cycles. The average SCF in the normal and abnormal groups was 9.8±3% and 24.1±11%, respectively ($P < 0.0001$). When oocyte maturity was greater than 80% at the time of retrieval, the groups had comparable implantation and clinical pregnancy rates (CPRs); the normal SCF group had 21.5% implantation and 27.0% clinical pregnancy rates, and the abnormal SCF group had 23.4% implantation and 30.0% clinical pregnancy rates, respectively, supporting the ability of the oocyte to correct the male genome.

However, once the proportional oocyte maturity fell below 80%, cycles with abnormal ejaculate SCF (n=27) appeared to lose ability to achieve a pregnancy when compared to cycles with intact sperm chromatin (n=62). The CPR trended lower in the group with compromised sperm genomic integrity (14.8%) when compared to the group with normal SCF (32.2%), and the implantation rate drastically fell to 8.3% while it was 23.6% ($P = 0.02$) in the normal SCF group.

Limitations, reasons for caution: This is a preliminary study on a relatively small study group. Based on the longevity of the study, it is not possible to remove all biases and variables that may affect the results, despite controlling for maternal age, body mass index, smoking and drinking habits, and ethnicity.

Wider implications of the findings: These findings provide further support of the existence of oocyte repair mechanisms as well as their relationship to oocyte maturity. This may help providers obtain superior ICSI outcomes despite aberrant SCF by tailoring superovulation protocols that yield higher proportional oocyte maturity.

Trial registration number: N/A

P-281 Trophectoderm biopsy may be associated with increased risk of anatomic and vascular placental pathology

A. Harris[1], C. Sacha[1], K. James[1], J. Yeh[1], I. Souter[1], D. Roberts[1]
[1]MGH Fertility Center, Harvard School of Medicine, Boston, U.S.A.

Study question: Does biopsy of the trophectoderm for pre-implantation genetic testing (PGT) impact placentation?

Summary answer: Pregnancies from blastocysts that underwent trophectoderm biopsy may have an increased risk of marginal cord insertion, membranous placental vessels, accessory lobes, and intervillous/subchorionic/septal placental thrombi.

What is known already: Increases in placental pathologies, including cord insertion anomalies have been associated with IVF compared to spontaneously conceived pregnancies. Trophectoderm biopsy is now a commonly performed procedure on blastocysts for pre-genetic testing (PGT) to diagnose monogenic disorders or aneuploidies. Despite its increasing use and relative safety in terms of blastocyst survival, its potential effects on placentation are unknown.

Study design, size, duration: A cohort of live births with placental pathology arising from autologous IVF/ICSI cycles between 2004 and 2017 was retrospectively reviewed.

Participants/materials, setting, methods: We compared placental pathology reports from IVF pregnancies who conceived with fresh transfers, cryothaw transfers, and transfers of cryopreserved embryos after blastocyst biopsy at a large academic fertility center. We used Pearson's chi-squared test for analysis. Placental pathology was categorized by an experienced placental pathologist as: anatomic (e.g. cord insertion), infectious (e.g. acute chorioamnionitis), inflammatory (e.g. villitis of unknown etiology (VUE) or chronic plasma cell deciduitis), and vascular (e.g. maternal or fetal vascular malperfusion).

Main results and the role of chance: Pathology was available for 933 fresh transfers, 192 cryothaw transfers, and 22 cryothaw transfers after PGT. There was no difference in mean age, BMI, or Day 3 FSH between women undergoing fresh and cryothaw transfers. The mean number of embryos transferred was 2.0 (fresh) and 1.6 (cryothaw). No differences were observed in infectious and inflammatory pathology. Compared to fresh transfers, there was a significantly increased incidence of anatomic pathology in the cryothaw and cryothaw with PGT groups, including marginal cord insertion (10.9% for fresh vs. 17.2% vs. 22.7% for cryo and cryo with PGT, respectively, $p = 0.02$); accessory placental lobes (5.1% vs. 9.9% vs. 13.6%, respectively, $p = 0.01$), and membranous vessels in absence of a membranous cord (3.2% vs. 5.2% vs. 18.2%, respectively, $p < 0.001$). Placental thrombi were also found more frequently with cryothaw and cryothaw with PGT transfers (intervillous thrombi, 16.7% vs. 24.5% vs. 18.2%, respectively, $p = 0.04$; subchorionic thrombi, 2.3% vs. 6.8% vs. 18.2%, respectively, $p < 0.001$; septal thrombi: 0.1% for fresh vs. 2.6% for cryo, respectively, $p < 0.001$).

Limitations, reasons for caution: The relatively small number of PGT cycles performed limits the power of our database, and thus we were unable to control for potentially confounding variables in our analysis. The retrospective design of this study is also a limitation.

Wider implications of the findings: Our findings suggest that other anatomic and vascular pathologies may occur more frequently in cryopreserved embryos that have undergone trophectoderm biopsy. Further research with a larger cohort is needed to better understand the effects of trophectoderm biopsy, particularly given its rise in use, while controlling for potential confounding variables.

Trial registration number: Not Applicable

P-282 To biopsy or not to biopsy? Laboratory and clinical outcome after embryo biopsy, cryopreservation and warming of previously vitrified-warmed human blastocysts

N. Findikli, M.Sc.- Ph.D.[1], M. Gultomruk[2], T. Aksoy[1], O. Olcay[3], K. Boynukalin[4], M. Bahceci[4]
[1]Bahceci Health Group, Fulya IVF Center- Embryology Laboratory, Istanbul, Turkey
[2]Bahceci Health Group, R&D Department, Istanbul, Turkey
[3]Bahceci Health Group, Umut IVF Center- Embryology Laboratory, Istanbul, Turkey
[4]Bahceci Health Group, Fulya IVF Center, Istanbul, Turkey

Study question: Does subsequent biopsy, vitrification and warming have any effect on the laboratory & clinical outcome of previously vitrified-warmed human blastocysts during PGT-A?

Summary answer: Subsequent embryo biopsy, vitrification and warming of previously vitrified-warmed human blastocyst can result in increased embryonic loss and lower clinical pregnancy rate.

What is known already: Successful cryopreservation of biopsied human blastocysts is a prerequisite in PGT-A cycles. Currently, PGT-A with comprehensive chromosomal screening involves embryo biopsy, subsequent vitrification & warming (where available) of chromosomally normal day 5 or day 6 human blastocysts for embryo transfer. In some cases, previously-vitrified human blastocysts are preferentially considered for PGT-A through warming and a second vitrification-warming cycle after embryo biopsy. However, data in the literature regarding if this strategy brings any harm/benefit on the laboratory & clinical outcome are scarce and controversial.

Study design, size, duration: This retrospective study included PGT-A cycles performed as blastocyst biopsies on day 5 and day 6 of embryo development between January 2013 and October 2018. Based on the availability of a euploid embryo after comprehensive chromosomal screening (CCS), a subsequent frozen embryo transfer was performed after warming. Embryo survival after warming, embryo euploidy rate after biopsy and clinical pregnancy rate (Presence of a sac under ultrasound) were primary outcome measures.

Participants/materials, setting, methods: A total of 4216 PGT-A cycles were started and 2850 could reach the blastocyst biopsy stage (67.6%). During

the same period, 122 previously frozen blastocysts of 33 patients were subsequently warmed, biopsied and re-vitrified again for the purpose of PGT-A. Laboratory and clinical outcome were documented and compared with general PGT-A cases.

Main results and the role of chance: Out of 122 previously vitrified blastocysts of 33 patients, 107 (87.2%) survived after warming, 71 (58.2%) biopsied and re-vitrified on either day 5 afternoon or day 6. In 5 patients (15 embryos), no embryos showed enough expansion for embryo biopsy after warming hence the cycle was cancelled (15.2%). Out of 71 embryos were biopsied, 68 (95.7%) of them could be successfully analyzed and 50.7% of the analyzed embryos were found to be euploid. Eleven patients could not reach the embryo transfer stage due to the lack of a euploid embryo (39.2%). Twenty euploid embryo transfers with re-vitrified embryos in 17 patients were performed, resulting in 45% (9/20) clinical pregnancy rate. In the same time frame, out of 4216 PGT-A cycles started, in 1366 cycles embryo biopsy could not be performed due to the lack of blastocyst development (32.4%). A total of 7842 embryos were biopsied, 6785 of them were sent for CCS analysis, 6696 embryos (98.6%) were successfully analyzed and 2586 embryos were found to be euploid (38.6%). At least one euploid embryo was found in 1538 cycles (53.9%). One thousand four hundred twenty-three vitrified euploid embryo transfers resulted in 70.7% clinical pregnancy rate in the general PGT-A population.

Limitations, reasons for caution: Main limitation of the study is its retrospective nature. Secondly, the number of cases and embryos in the study group needs to be increased in order to draw a firm conclusion.

Wider implications of the findings: Our findings show that the approach involving subsequent warming, biopsy and re-vitrification of human blastocysts brings increased embryonic loss and lower clinical pregnancy when compared with the results of PGT-A cycles involving single vitrification & warming approach. Possible effect of embryo storage duration remains to be explored.

Trial registration number: None.

P-283 Evaluation of protein supplementation in culture medium after blastocyst thawing in frozen-thawed embryo transfer cycles.

L. Ferreux[1], J. Tek[1], M. Bourdon[2], A. Chargui[1], A.S. Gille[1], DEZOU054 C. Maignien[2], P. Santulli[2], C. Patrat[1], K. Pocate[1]

[1]*Hopital Cochin, Department of Histology- Embryology- and Biology of Reproduction, Paris, France*

[2]*Hopital Cochin, Department of Gynecology- Obstetrics- and Reproductive Medicine, Paris, France*

Study question: To evaluate if protein supplementation in culture media after blastocyst thawing improves clinical outcomes in single frozen-thawed embryo transfer cycles.

Summary answer: Protein supplementation in culture medium after blastocyst thawing seems to improve clinical and ongoing pregnancy rates.

What is known already: To date, few studies have investigated the cellular effects of embryo vitrification and its impact on the ability for the thawed embryos to implant after transfer. The cellular dehydration induced by the cryoprotectants would be responsible of a protein aggregation and a denaturation leading to a precipitation causing a qualitative and quantitative protein depletion. Thus, some authors recommend supplementing the embryo culture medium with proteins after embryo thawing. However, this strategy is still under controversy due to a lack of scientific evaluation of protein supplementation in biological and clinical outcomes in frozen-thawed embryo cycles.

Study design, size, duration: This was an observational cohort study including all the frozen-thawed blastocyst transfer cycles performed in our center between November 2017 and May 2018. Vitrified blastocysts at day 5 (D5) or day 6 (D6) derived from frozen oocytes or obtained after prolonged culture of frozen zygotes or cleaved embryos were excluded from the study. Only D5 or D6 vitrified blastocysts derived from fresh oocytes and scheduled for an elective single thawed embryo transfer (eSET) were included.

Participants/materials, setting, methods: Frozen-thawed blastocysts were allocated between two groups: (i) those cultured during 2-3h after thawing in a culture media already containing 10% HSA and (ii) blastocysts cultured in the same culture media supplemented with 20% HAS. Clinical outcomes including clinical and ongoing pregnancy rates and miscarriage rate were evaluated in the two groups. Embryo survival rate after thawing was also studied. Statistical analysis of the data was carried out using univariate and multivariate logistic regression models.

Main results and the role of chance: A total of 785 vitrified blastocysts were thawed for an eSET (441 in group 1 with 10% HSA and 344 in group 2 with 20% HAS). After univariate analysis, women age, fertility background, fertilization method, D5 and D6 blastocysts allocation and good quality blastocyst distribution were comparable between the 2 groups. The clinical pregnancy rate was significantly higher in group 2 (32,4% vs 39,2%; p = 0,048). The ongoing pregnancy rate was not significantly higher in group 2 but a tendency emerged (22,0% vs 27,9% ; p = 0,056). The miscarriage rate was similar in the two groups (32,2% vs 28,9% ; p = 0,553). The embryo survival rate after thawing was also comparable between group 1 and 2 (96 .4% vs 95.1% ; p = 0,363).After a multivariate analysis, female age > 35 years old, blastocyst expansion at D6 and a fair embryo quality at D5 or D6 were independently associated with a significantly lower ongoing pregnancy. A tendency emerged concerning 20% HAS supplementation (OR = 1.339; IC= 0.956-1.876; p = 0,09).

Limitations, reasons for caution: This study was not prospective and randomized. Nevertheless, a larger series should be analyzed in order to confirm these results with the evaluation of the live birth rate as the main outcome of this evaluation.

Wider implications of the findings: Our study findings seem to describe an improvement of the intrinsic embryo quality thanks to a protein supplementation in the culture media after thawing (higher pregnancy rate associated to an unchanged miscarriage rate). These findings could lead to a systematic protein supplementation after embryo thawing.

Trial registration number: Not applicable

P-284 Effect of zona pellucida drilling time on blastocyst development in preimplantation genetic testing for aneuploidy cycles

S. Zhang[1], G. Lin[1]

[1]*Reproductive & Genetic Hospital CITIC-Xiangya, IVF center, Changsha, China*

Study question: Is the day of zona pellucida (ZP) drilling affect blastocyst development in preimplantation genetic testing for aneuploidy (PGT-A) cycles?

Summary answer: ZP drilling on day3 has a better blastocyst formation rate than on day5.

What is known already: ZP drilling is routinely adopted in blastocyst biopsy cycles for hatching trophectoderm. Drilling on Day3 and Day5 both can be selected, but it is not known which time is better.

Study design, size, duration: This is a retrospective cohort study analyzing 1644 Day3 drilling cycles and 1577 Day5 drilling cycles between May 2016 and May 2018.

Participants/materials, setting, methods: In July 2017, a significant change was made on the time of ZP drilling, which was performed on Day3 a.m. before July 2017, and on Day5 a.m. after July 2017. In all PGT-A cycles, the blastocysts were scored and biopsied on Day6 a.m. The overall blastocyst formation rate and high-quallity blastocyst (Gardner score $\geqq$ 3BB) formation rate on Day6 were compared in two groups.

Main results and the role of chance: There was no significant difference in maternal age (38.74±4.66 vs 38.52±4.52), the mean number of antral follicles (12.05±9.11 vs 12.36±9.06), the mean AMH (2.69±2.6 vs 2.78±2.72), the mean number of retrieved oocytes (7.68±5.58 vs 7.71±5.62) and the mean number of normal fertilized oocytes (5.24±4.02 vs 5.21±3.94) between Day3 and Day5 drilling groups. The overall blastocyst formation rate (46.3% vs 44.1%) and high-quallity blastocyst formation rate (27.0% vs 23.7%) on Day6 were both significant higher in Day3 drilling group than in Day5 drilling group.

Limitations, reasons for caution: This study is retrospective and some bias cannot be excluded. The embryo implantation outcome must be tracked.

Wider implications of the findings: This study suggested an appropriate time for ZP drilling.

Trial registration number: None

ENDOMETRIOSIS, ENDOMETRIUM AND FALLOPIAN TUBE, AND BENIGN DISORDERS OF THE ENDOMETRIUM AND FALLOPIAN TUBE

P-285 Metabolomics shows no impairment of the microenvironment of the oocyte-cumulus complex in the follicular fluid of women with isolated endometriosis

P.E. Bouet[1], J.M. Chao de la Barca[2,3], H. El Hachem[4], P. Descamps[1], G. Legendre[1], P. Reynier[2,3], P. May Panloup[3,5]

[1]*University of Angers, Medicine / Obstetric Gynecology, Angers, France*
[2]*University of Angers, Medicine / Biochemistry and Molecular Biology, Angers, France*
[3]*University of Angers, MITOVASC Institute- CNRS 6015- INSERM U1083, Angers, France*
[4]*Clemenceau Medical Center, Reproductive Medicine, Beirut, Lebanon*
[5]*University of Angers, Medicine / Biology of Reproduction, Angers, France*

Study question: Is there any metabolomic evidence of oocyte-cumulus complex microenvironment impairment in the follicular fluid (FF) of women with isolated endometriosis?

Summary answer: Metabolomics shows no impairment of the microenvironment of the oocyte-cumulus complex in the FF of women with isolated endometriosis.

What is known already: Although discriminant metabolomic signatures have been detected in the endometrium, plasma and peritoneal fluid of women affected by endometriosis, very few studies have investigated the metabolomic profiles of endometriosis in the FF. FF reflects the exchanges occurring between the oocyte and its microenvironment during the acquisition of gametic competence. The aim of our study was to compare the metabolomic profiles of the FF in patients undergoing IVF for isolated forms of endometriosis to those of patients free from endometriosis to evaluate the impact of the disease on the microenvironment of the oocyte-cumulus complex with potentially deleterious consequences on oocyte quality.

Study design, size, duration: We performed a prospective observational study on the FF retrieved from 79 women undergoing IVF from January to July 2018 at the Angers University Hospital, France.

Participants/materials, setting, methods: The patients were divided into two groups: the study group and the control group. The study group comprised 39 patients with isolated endometriosis, i.e. without any other diagnosis of infertility. The control group included 40 patients free from endometriosis. A targeted quantitative metabolomic and lipidomic analysis of the FF was performed using high-performance liquid chromatography coupled with tandem mass spectrometry. The FF levels of 188 metabolites were assessed by univariate and multivariate analyses.

Main results and the role of chance: The patients' characteristics, including age, body mass index, tobacco usage, hormonal profile, antral follicle count, were similar in the endometriosis group and the control group. Fifty-four percent of the patients (21/39) in the endometriosis group received an antagonist protocol compared to 98% of the patients in the control group (39/40) ($p<0.001$). There was no significant difference in the cumulative FSH dose used for stimulation between the endometriosis and the control groups (2732 *vs.* 2257 IU, p=0.09, respectively). Twenty patients in the endometriosis group (51%) had intracytoplasmic sperm injection (ICSI) compared to 24 (60%) in the control group (p=0.43). The oocyte maturation rates in ICSI were similar in the two groups (72.2% *vs* 77.7%, respectively, p=0.6). The fertilization rates in IVF and ICSI did not differ significantly between the two groups (49.4% *vs.* 50.2%, p = 0.9 and 76.4% *vs.* 68.8%, p = 0.53 respectively). Among the 188 metabolites analysed, 141 were accurately measured. Univariate analysis did not reveal any significant modification of metabolite concentrations, and none of the multivariate models discriminated between the two groups of patients, even when the study was restricted to the severest forms of endometriosis.

Limitations, reasons for caution: One potential limitation of our study could be the fact that with this targeted metabolomics analysis we have explored only a limited portion of the FF metabolome.

Wider implications of the findings: The impact of endometriosis on the follicular microenvironment and the quality of the oocyte remains debated. In the absence of a metabolomic signature of endometriosis in the FF, our results indicate no micro-environmental impairment of the oocyte-cumulus complex in cases of isolated endometriosis among women undergoing IVF.

Trial registration number: na

P-286 5 years long term follow- up results of endometriosis combined with infertility patients after laparoscopic surgery

Q. Ruiya[1], D. Lu[1]

[1]*Beijing obstetrics & gynecology hospital- capital medical university, gynecology department, Beijing, China*

Study question: Postoperative pregnancy rate of endometriosis women is the core part in gynecological field .How to improve the postoperative pregnancy rates of endometriosis patients with infertility?

Summary answer: EFI guidance, strict post-operation management , positive pregnancy scheme and GnRh-a use in severe patients can significantly improve pregnancy rate of endometriosis patients with infertility

What is known already: EFI score was a useful evaluation in predicting and guiding pregnancy in endometriosis patients combined with infertility.

Using GnRH-a 3-6 cycles in patients with r-AFS stages III/IV can decrease recurrence.

Study design, size, duration: From January 2010 to June 2011, after laparoscopic surgery, 146 endometriosis patients with infertility were divided into 3 major groups (EFI≥9 group, EFI5-8 group, EFI≤4 group). In each major group, patients with different situations were divided into more detailed small groups. Different group using different pregnancy guidance methods , these patients were also divided into 4 groups by r-AFS score/ stages to statistics pregnancy rates. All these patients had finished 5 years follow-up after operation.

Participants/materials, setting, methods: partiipant; Beijing obstetrics & gynecology hospital , gynecology department

146 patients were divided into 3 major groups by EFI score(EFI≥9 group, EFI5-8 group, EFI≤4 group). In each major group, patients with different situations were divided into more detailed small groups. Different group using different pregnancy guidance(methods including expectant pregnancy, ovulation detection/induction, artificial insemination and IVF-ET) ,

Main results and the role of chance: ∗The overall pregnancy rate was 89.04%. After 2 years of operation, the pregnancy rate was 95.7% (45 /47) in EFI≥9 group, 83.1% (69 /83) in EFI 5-8 group and 50% (8/16) in EFI≤4 group, the rate of the first two groups had no statistically significance(P=0.498), but had significant difference with the last group (P<0.001). These three groups were all reach satisfactory pregnancy rate.

∗Postoperative application of GnRH-a did not delay patient's relative pregnancy time. Patients who using GnRH-a with EFI ≥5 had highest pregnancy rate within 6 months after menstrual cycle recovery.

Patients with endometriosis stage III-IV were treated with GnRH-a 3-6 times after operation.If the gestation time was calculated from menstrual recovery after GnRH-a treatment, this study showed that the use of GnRH-a after endometriosis did not prolong the pregnancy time of patients

∗The r-AFS score had no statistics relativity with post-operation natural pregnancy rates(χ^2=4.069,P=0.254), term labor rates(χ^2=0.605,P=0.895)and spontaneous abortion rates(χ^2=0.394,P=0.942).

∗The EFI score could predict pregnancy rate of endometriosis patients combined with infertility effectively, EFI ≥9 group had the highest natural pregnancy rate, natural pregnancy rate was significant statistical different (P=0.001) in different EFI groups.

∗Postoperative 5 years recurrence rate was 9.6%(14/146).

Limitations, reasons for caution: Sample size is a little small, because it is not easy to get the proper patients. (We have strict criteria for study patients selection). Follow up for five years is also a difficult task.

Wider implications of the findings: There is a great controversy about whether to us GnRh-a after operations of endometriosis patients combined with infertility. Our research shows that postoperative application of GnRH-a did not delay patient's relative pregnancy time.

Trial registration number: 201015

P-287 High number of endometrial polyps co-exist at a high rate with chronic endometritis: a possible etiopathogenetic link

F. Gu[1], L. Guo[1], L. Luo[1], C. Zhou[1]

[1]The First Affiliated Hospital- Sun Yat-sen University- Guangzhou- Guangdong- China., Reproductive Medicine Center, Guangzhou, China

Study question: Is there any association between high number of endometrial polyps (EPs' number ≥6) and chronic endometritis?

Summary answer: High number of EPs was closely related with elevated risk of CE, while the link between classical single EP and CE has not been found.

What is known already: CE and EP were both subclinical inflammatory diseases that may cause uterine bleeding, pregnancy loss and impaired reproduction. However, the association between CE and EP has not been studied. Previous studies found that women with high number of EPs(≥6)had a significantly higher risk of recurrence rate than those with classical single EP after polypectomy, indicating that it might be a distinct polyp subtype with different etiology.

Study design, size, duration: Retrospective study. From June 2017 to May 2018, endometrial samples were obtained from patients with high number of EPs or single EP under hysteroscopy during the proliferative phase. Non-polypoid endometrium specimens were obtained from infertile patients with normal uterine finding as control. All patients had no history of hormone or antibiotic treatment for at least three months. Repeated implantation failure, recurrent pregnancy loss, heavy uterine bleeding, potential neoplasms, submucosal uterine fibroids, intrauterine adhesion were excluded.

Participants/materials, setting, methods: Seventy-one patients with high number of EPs (≥6 polyps), 50 with single EP and 74 non-polypoid controls were enrolled. Clinical parameters were collected including age, BMI, infertile, parity and gynecological histories.CE was diagnosed based on conventional histology with immunohistochemistry to identify CD138 plasma cells. Density of plasma cell infiltrations and prevalence of CE were compared between the three groups and multivariable logistics regression was used to investigate the independent risk factors of CE.

Main results and the role of chance: Compared with the non-polypoid endometrium, single EP contained a similar density of plasma cells without statistically difference (2.5 [range 1.0-5.0]/HPF in single EP vs. 2.0[range 0.0-4.0]/HPF in non-polypoid endometrium, $p>0.05$), whereas the high number EPs had a significantly higher density of plasma cells (5.0 [range 3.0-13.0]/HPF). The prevalence of CE was significantly higher in women with high number of EPs than those with single EP(38 of 71, 53.5% vs. 13 of 50, 26.0% , $p<0.001$). However, there was no significant difference on the incidence of CE between single EP group and non-polypoid endometrium (13 of 50, 26.0% vs. 18 of 74, 24.3%, $p>0.05$). With univariable analysis, parity was associated with a lower risk of CE and high number of EPs was associated with increased risk of CE. Using multivariable analysis, high number of EPs was found to be associated independently with CE (Odds ratio [OR] 3.42, 95% confidence interval [CI] 1.86-7.06), while single EP did not increase the risk of CE as compared to non-polypoid endometrium (OR 1.065, 95%CI 0.46-2.50).

Limitations, reasons for caution: This is a retrospective study with small size. Results were relied on endometrial biopsy specimens, of which immunological conditions may not always represent the whole endometrium.

Wider implications of the findings: High number of EPs was closely associated with CE, suggesting that CE may play an important role in the development of this distinct subgroup. CE should be ruled out in women with polyps, especially those with high number EPs and appropriate treatment of CE may improve the pregnancy outcome.

Trial registration number: not applicable

P-288 Fulvestrant, an estrogen receptor antagonist, downregulates the expression of aromatase gene in eutopic endometrial stromal cells of women with endometriosis

N. Miyanmahaleh[1,2], Z. Borandegi[1,2], A. Moieni[3,4], P. Afsharian[2], M. Shahhoseini[2]

[1]University of Science and Culture- Faculty of Basic Sciences and Advanced Technologies in Biology, Department of Molecular genetics, Tehran, Iran

[2]Royan Institute for Reproductive Biomedicine-ACECR- Reproductive Biomedicine Research Center, Department of Genetics, Tehran, Iran

[3]Royan Institute for Reproductive Biomedicine- ACECR-Reproductive Biomedicine Research Center, Department of Endocrinology and Female Infertility, Tehran, Iran

[4]Tehran University of Medical Sciences- Arash Women's Hospital, Department of Obstetrics and Gynecology, Tehran, Iran

Study question: Does Fulvestrant change the expression of aromatase gene expression in eutopic endometrial stromal cells of women with endometriosis?

Summary answer: Fulvestrant could significantly suppress the aromatase expression in endometrial stromal cells of women with endometriosis.

What is known already: Endometriosis is an estrogen dependent disease caused by presence and growth of endometrial cells in extra uterine environment. Estrogens play their role in gene expression regulation through the estrogen receptors (ERs). Activation of ERs' transcriptional domains, leads to binding of these receptors to the regulatory region of many genes or recruitment of the other transcription factors. *CYP19A1* gene encodes Aromatase, the key enzyme in estrogens biosynthesis, and is stimulated by estrogens and upregulated via activation of aberrant promoters in endometrial stromal cells in endometriosis. This phenomenon is involved in formation of a positive feedback cycle in estrogen biosynthesis in endometriosis.

Study design, size, duration: We compared the *CYP19A1* expression between the control and treated endometrial stromal cells with different concentrations of a selective estrogen receptor down regulator, Fulvestrant, (10^{-6}-10^{-8} M) for 48 hours. In addition, a vehicle control group was considered to assess the effect of vehicle of Fulvestrant (DMSO). Endometrial tissues were obtained from patients with ovarian endometriosis (endometrioma) during the proliferative phase of the menstrual cycle. All the procedures were applied in three biological replicates.

Participants/materials, setting, methods: Human endometrial stromal cells were isolated from sample tissues and cultured in stromal cell medium (SCM) including phenol red free Dulbecco's Modified Eagles medium (DMEM) with 10% fetal bovine serum (FBS) and sodium pyruvate 1%. The cells were treated with different concentrations of Fulvestrant, after evaluation of their purity by FACS in the third passage. The effects of Fulvestrant on cell viability and *CYP19A1* expression were examined by MTT assay and quantitative PCR respectively.

Main results and the role of chance: Fluorescence activated cell sorting (FACS) analysis showed more than 99% purity of stromal cells in the third passage of culture in which the treatment was applied. Our data demonstrated that Fulvestrant could significantly suppress the aromatase expression in endometrial stromal cells of women with endometriosis compared to non-treated control (P <0.0001) and vehicle control (P <0.05). In addition, no negative effect was observed on the cells' viability during the treatment with neither of Fulvestrant concentrations. It seems that Fulvestrant downregulates the *CYP19A1* expression and eliminates the positive feedback cycle in estrogen biosynthesis via suppression of estrogen receptors and their binding to the regulatory region of this gene in endometrial stromal cells of women with endometriosis.

Limitations, reasons for caution: This study only showed the Fulvestrant effects on human endometrial stromal cells in vitro and there should be more studies to investigate the potential role of Fulvestrant in endometriosis treatment, as selective estrogen receptors down regulators have been recently considered as a potential hormonal therapy targets for this disease.

Wider implications of the findings: Our findings are in agreement with other studies demonstrating that Fulvestrant antagonizes estradiol function in gene expression regulation via downregulation of estrogen-upregulated genes and upregulation of estrogen-downregulated genes.

Trial registration number: not applicable

P-289 In-vitro effect of Ulipristal on proliferative and apoptotic indices and steroid hormone receptor expression in endometriotic stromal cells

M.W. Lui[1], R.H.W. Li[2], R.W.S. Chan[2], W.S.B. Yeung[2], E.H.Y. Ng[2]

[1]Queen Mary Hospital- Hong Kong, Obstetrics and Gynaegolocy, Hong Kong, Hong Kong

[2]*The University of Hong Kong, Obstetrics and Gynaegolocy, Hong Kong, Hong Kong*

Study question: Does ulipristal acetate (UPA) affect cell proliferation, apoptosis and expression of estrogen and progesterone receptors in human endometriotic stromal cells in-vitro?

Summary answer: In-vitro treatment of endometriotic stromal cells with UPA did not affect cell proliferation and apoptosis nor expression of steroid receptors.

What is known already: UPA is a selective progesterone-receptor modulator (SPRM), which binds to the progesterone receptor with high affinity and suppresses proliferation of endometriosis. In a rat model with surgically induced endometriosis, UPA treatment leads to regression and atrophy of endometriosis in terms of volume of endometriosis and expression of apoptotic and proliferative markers. Currently there are no data on the effect of UPA on human endometriotic tissue.

Study design, size, duration: Endometriotic cyst wall tissue was collected and dissociated with collagenase. Stromal cells were separated from epithelial cells using CD326 microbeads and cultured for 10 days until the cells reached 60-80% confluence. Equal portions of stromal cells were seeded into 6-well plates and treated with graded concentrations (0, 0.1, 1, 10 and 100 ng/ml) of UPA for 48 hours.

Participants/materials, setting, methods: Ovarian endometriotic cyst samples were obtained from four women undergoing ovarian cystectomy or salpingo-oophorectomy. Endometriotic stromal cells were cultured on 25-mm Thermanox coverslips and treated with UPA for 48 hours. Immunohistochemical staining for proliferative marker Ki-67, apoptotic marker Bcl-2 and receptors for oestrogen (ER-α) and progesterone (PR) was performed. H-score was used to evaluate the protein expression. Control cells were not treated with UPA.

Main results and the role of chance: Endometriotic stromal cells after treatment with UPA remained characteristically flat and spindle shaped demonstrating no morphological changes when compared with the control. UPA administration exhibited no significant change in the expression of proliferative (Ki-67) (1.55 +/- 0.77, 1.29 +/- 0.31, 1.36 +/- 0.56, 1.24 +/- 0.43, 1.35 +/- 0.22 for UPA concentration 0, 0.1, 1, 10 and 100 ng/ml respectively, p = 0.721) and apoptotic (Bcl-2) markers (2.59 +/- 0.66, 1.76 +/- 0.95, 2.58 +/- 1.42, 2.02 +/- 0.78, 1.86 +/- 0.55 for UPA concentration 0, 0.1, 1, 10 and 100 ng/ml respectively, p = 0.165). There were also no significant change in the expression of hormone receptors of ER-α (0.54 +/- 0.25, 0.63 +/- 0.18, 0.64 +/- 0.24, 0.69 +/- 0.26, 0.67 +/- 0.33 for UPA concentration 0, 0.1, 1, 10 and 100 ng/ml respectively, p = 0.76) and PR (2.21 +/- 1.16, 2.33 +/- 1.80, 2.54 +/- 1.17, 2.25 +/- 1.32, 2.56 +/- 1.34 for UPA concentration 0, 0.1, 1, 10 and 100 ng/ml respectively, p = 0.970).

Limitations, reasons for caution: The limited sample size contributed to high patient variation. Only one apoptotic and proliferative markers were assessed. There was no co-culture of oestrogen and progesterone with the endometriotic stromal cells which may underestimate the effect of UPA.

Wider implications of the findings: Whether there was any role of UPA on endometriosis remained uncertain. Evaluation of other apoptotic and proliferative markers should be performed for understanding the effect of UPA on endometriosis.

Trial registration number: Non-applicable

P-290 The effects of dienogest on ovarian endometriotic cyst are mediated by ER stress induction

D. Choi[1], J. Choi[1], M. Jo[2], E. Lee[1], D.Y. Lee[1]

[1]*Sungkyunkwan University School of Medicine- Samsung Medical Center, Dept. of Ob/Gyn, Seoul, Korea- South*

[2]*Samsung Biochemical Research Institute, Center for Clinical Research, Seoul, Korea- South*

Study question: Whether dienogest induces endoplasmic reticulum (ER) stress in human endometriotic stromal cells and if this is associated with endometriotic cell apoptosis and invasiveness?

Summary answer: Dienogest upregulated ER stress in human endometriotic stromal cells, which led to increased apoptosis and decreased invasiveness.

What is known already: Dienogest, a specific progesterone receptor agonist, is used in the treatment of endometriosis. However, it is still unclear as to the mechanisms of therapeutic effects on endometriosis. Our recent study showed that endometriosis may be the result of aberrant ER stress induction due to progesterone resistance. This finding suggests that the regulation of ER stress induction may play a key role in treatment of endometriosis. Therefore, the anti-endometriotic effects of dienogest may be mediated by regulation of ER stress.

Study design, size, duration: To evaluate the effects of progesterone and dienogest on ER stress induction and its correlation with apoptosis and invasiveness in endometriotic cells, human endometriotic cyst stromal cells (ECSCs) were cultured with progesterone or dienogest. And, salubrinal (ER stress inhibitor) was added in culture medium to block ER stress. Specifically, unfolded protein response signaling pathways (PERK/elf2*a*/AKT4/CHOP and IRE1/TRAF2/ASK1/JNK) were evaluated to elucidate the effects of ER stress induction on apoptosis and invasiveness.

Participants/materials, setting, methods: The expression level of GRP78 and GRP94 was measured by Western blot to evaluate ER stress induction. The activity of ER stress-mediated PERK/elf2*a*/AKT4/CHOP and IRE1/TRAF2/ASK1/JNK pathways was elucidated by measuring PREK, CHOP, IRE1 and phosphorylated JNK expression. In addition, apoptosis and invasiveness of ECSCs were evaluated by apoptosis maker proteins (cleaved caspase-3 and PARP) and invasion associated proteins (MMP2 and MMP9) expression, respectively.

Main results and the role of chance: Progesterone treatment did not have any significant effect on GRP78, GRP74, cleaved caspase-3 and PARP, MMP2 and MMP9 expression in estrogen-treated ECSCs. However, dienogest treatment upregulated GRP78 and GRP94 expression, which was accompanied by increased expression of cleaved caspase-3 and PARP and decreased expression of MMP-2 and MMP-9. This dienogest-induced change in cleaved caspase-3, PARP, MMP-2 and MMP-9 expression was reversed by inhibition of ER stress using salubrinal (ER stress inhibitor). These results suggest that dienogest increases ER stress, which is involved in regulation of apoptosis and invasiveness in ECSCs. Furthermore, our results showed that dienogest-induced ER stress increases the expression of PREK, CHOP, IRE1 and phosphorylated JNK. Especially, the downregulation of PERK and IRE1 expression by siRNA, which blocked ER stress-mediated activation of PERK/elf2*a*/AKT4/CHOP and IRE1/TRAF2/ASK1/JNK pathways, decreased apoptosis and increased invasiveness of dienogest-treated ECSCs.

Limitations, reasons for caution: Only primary human cell cultures were used in this study, therefore the results may not fully represent the *in vivo* situation.

Wider implications of the findings: We found here that dienogest treatment regulates endometriotic cell apoptosis and invasiveness via ER stress, and we suggest that this pharmacological action of dienogest might contribute to an effective suppression of ovarian endometriotic lesion.

Trial registration number: This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education (grant # NRF-2016R1D1A1B03931692).

P-291 Autophagy role in the human endometrium: Effect of partial autophagy impairment on human endometrial stromal cells proliferation and differentiation

A.C. Mestre[1], T. Strowitzki[1], A. Germeyer[1]

[1]*Heidelberg University - Women's Hospital, Department of Gynecologic Endocrinology and Fertility Disorders, Heidelberg, Germany*

Study question: Is autophagy important for the correct function of endometrial cells? Are the proliferation and differentiation of human endometrial stromal cells affected by autophagy impairment?

Summary answer: Autophagy flux is increased during human endometrial stromal cells (HESC) *in vitro* decidualization. Furthermore, the partial impairment of autophagy diminishes HESC proliferation and differentiation.

What is known already: Macroautophagy (autophagy) is a highly conserved intracellular degradation pathway that serves as an adaptive role against stressful situations, contributing to the maintenance of vital cellular functions. Besides, it plays an important role during cellular proliferation, differentiation and growth.

In the endometrium, the increase in autophagy markers correlates with the progression of the menstrual cycle, reaching its maximum towards the late secretory phase. Furthermore, autophagy has been studied in relation to endometrial pathologies, suggesting that defective autophagy can affect

endometrial function. However, to date, no functional assay has been performed to study in depth the role of autophagy in the endometrium.

Study design, size, duration: This study was performed using immortalized human endometrial stromal cells (HESC). HESC were decidualized (dec) *in vitro* with medroxyprogesterone_(MPA), estradiol_(E2) and 8-Br-cyclicAMP_(cAMP) or vehicle-treated (non-dec). To interfere with autophagy pathway, knockdown of the autophagy-related protein 7 (ATG7, component of the core machinery of autophagy pathway) with small interference RNA (siRNA) technology was performed. Decidualization experiments and proliferation assays were started 24hs after transfection of specific siRNA against ATG7 or a non-target (NT) siRNA into HESC.

Participants/materials, setting, methods: Changes in autophagy flux (AF) were compared between decidualized and non-decidualized cells by flow cytometry (FC) using CYTO-ID kit and chloroquine (CQ) to block autophagy. For siRNA experiments, knockdown of ATG7 was confirmed by western blot (WB) and RT-qPCR and the impairment of autophagy was evaluated by FC. Cell proliferation in siRNA-transfected cells was evaluated using MTS Assay and cell decidualization was evaluated by RT-qPCR of prolactin (PRL) and IGFBP1, both well-known decidualization markers.

Main results and the role of chance: Flow cytometry analysis showed that AF is increased during *in vitro* decidualization of HESC (CQ/no-CQ dec:1,35; non-dec:0,96; P<0,05) and that the overall median intensity (reflecting the quantity of autophagy vesicles -autophagosomes- per cell) is higher in dec compared to non-dec cells (dec: 2506±122; non-dec: 2093±150; P<0,05).

ATG7-siRNA transfection, performed to define the role of autophagy during decidualization, effectively down-regulated ATG7 expression both at the mRNA (fold change compared to NT-siRNA at day four of decidualization protocol: 0,11±0,01; P<0,001) and protein level (evaluated at day two of decidualization protocol). Furthermore, AF was partially diminished after ATG7-siRNA transfection.

In relation to HESC function, ATG7-siRNA transfection was effective to reduce cell proliferation (measured four days after transfection protocol) in non-dec cells (40%; P<0,005), however it had nearly no effect on proliferation of dec cells (9% reduction). Besides, cells transfected with ATG7-siRNA, followed by decidualization showed a decrease of PRL expression both at protein (ATG7-siRNA: 121,75±12,87mU/l; NT-siRNA: 196,75±18,54mU/l; P<0,001) and mRNA level (fold change over NT-siRNA: 0,59±0,03; P<0,001) and of IGFBP1 at mRNA level (fold change over NT-siRNA: 0,13±0,01; P<0,001).

These results indicate that autophagy contributes to the normal function of HESC, affecting the proliferation of non-decidualized cells and contributing with decidualization.

Limitations, reasons for caution: This study was performed using immortalized cells, further studies are necessary to define the role of autophagy during *in vivo* decidualization. Besides, the role of autophagy was evaluated in a system where AF was partially diminished, limiting the strength of our results. Non-autophagy functions of ATG7 should be also considered.

Wider implications of the findings: These results show that autophagy is an important cellular process needed for the correct function of HESC. Dysregulation of autophagy could be related to several endometrial-related pathologies. Further insight into the regulation and specificity of autophagy could facilitate the identification of new therapeutic targets for the improvement of women´s health.

Trial registration number: Not applicable.

P-292 Randomized controlled trial of intrauterine infusion of autologous platelet rich plasma (PRP) versus granulocyte colony stimulating factor (G-CSF) in thin endometrium in frozen embryo transfer.

Z. Godha[1], K.D. Nayar[1], S. Gupta[1], M. Singh[1], M. Gupta[1], G. Kant[1], R. Gahlot[1], K. Nayar[1]

[1]Akanksha IVF Centre- Mata Chanan Devi Hospital, Reproductive medicine, New Delhi, India

Study question: To compare the effect of intrauterine infusion of PRP and G-CSF on endometrial thickness and clinical pregnancy rate in resistant thin endometrium cases

Summary answer: PRP and G-CSF are both effective in improving endometrial thickness in resistant thin endometrium patients, which might improve clinical pregnancy rates in such patients

What is known already: Resistant thin endometrium still remains a big challenge for clinicians, creating burden in form of cycle cancellation, unplanned freezing of embryos and need for surrogacy in extreme cases. There is no proven recommended treatment for resistant cases of thin endometrium. Intrauterine infusion of PRP and G-CSF are newer modalities of treatment, found to be effective in unresponsive thin endometrium in various studies. The current study was undertaken to compare their effects on endometrial thickness and clinical pregnancy rates

Study design, size, duration: A prospective randomized controlled trial was carried out from 1st January 2018 to 31st Decemebr 2018 at a tertiary infertility centre in India. Forty patients undergoing frozen embryo transfer (FET) with history of thin endometrium (<7 mm) but with normal hysteroscopic examination were randomized by computer generated table into two groups of 20 each(Group A =PRP, Group B= G-CSF). Patients with platelet count < 1.50000/dl and with any history of systemic diseases were excluded.

Participants/materials, setting, methods: All patients received oral estradiol valerate (6 mg/day) from day 2 of cycle which was increased gradually up to 12 mg/ day. Patients with thin endometrium on day 11 were randomized to receive PRP (Group A) or G-CSF (Group B) and the dose was repeated after 48 hours if endometrial thickness was still < 7mm. Frozen embryo transfer was performed when the endometrium reached an optimal thickness (at least 7 mm) and appearance.

Main results and the role of chance: The mean pre- treatment endometrial thickness in Group A was 5.38 ±0.57 mm and in Group B was 5.24 ± 0.51 mm which significantly increased to 6.62 ± 0.98mm and 6.60 ±0.93 mm post treatment in Group A and Group B respectively, the difference was statistically significant (p< 0.001). In each group, 7 patients could not achieve an optimal endometrial thickness of 7 mm after treatment and embryo transfer was postponed. The positive beta Human chorionic gonadotropin rate in Group A and Group B was 53.84% vs. 38.46% (p=0.69), and clinical pregnancy rate in Group A and Group B was 38.46% vs. 23.07% (P=0.59), which was not statistically significant.

Limitations, reasons for caution: The study was done at a single centre with small sample size, replication with more subjects and in different centers is needed.

Wider implications of the findings: Autologous PRP and G-CSF hold promise in the treatment of women with sub optimal endometrial thickness for embryo transfer. It would help to reduce the incidence of cycle cancellations and thus help reduce the financial and psychological burden of repeated cancelled cycles.

Trial registration number: MCDH/2018/65

P-293 Dienogest is effective for a progestin-primed ovarian stimulation protocol for in vitro fertilization while continuing the treatment of endometriosis

N. Iwami[1], M. Mizuuchi[2], M. Kawamata[1], N. Ozawa[1], T. Yamamoto[1], E. Watanabe[1], O. Moriwaka[1], H. Kamiya[1]

[1]Kamiya Ladies Clinic, Center of reproduction, Sapporo, Japan

[2]Sapporo Medical University, gynecology and obstetrics, Sapporo, Japan

Study question: Is progestin-primed ovarian stimulation (PPOS) protocol with dienogest effective for patients with endometriosis during controlled ovarian hyperstimulation (COH), compared to PPOS with dydrogesterone (DYG)?

Summary answer: Dienogest can be used as an appropriate progestin in PPOS protocol for women with endometriosis in terms of comparable clinical outcomes of PPOS with DYG.

What is known already: PPOS is a new COH regimen using a progestin as alternative to GnRH antagonist for blocking the LH surge, and several reports have shown that DYG is an appropriate progestin for PPOS protocol. Dienogest is an oral progestin effective for the treatment of endometriosis, such as reduction of endometrial lesion and control of pain intensity with safety profile and good tolerability. Dienogest also provides complete ovulation inhibition at a daily dose of 2mg, and a rapid return to normal ovarian function after cessation

of its administration. However, dienogest has not been used in PPOS protocol yet.

Study design, size, duration: This was a prospective controlled study of 84 women with endometriosis (aged <41) undergoing COH for IVF/ICSI and frozen embryo transfer (FET) at our infertility center from February to November in 2018. The patients were allocated alternately into two groups, one with dienogest (2mg/day) protocol (n=42) and the other with DYG (20mg/day) protocol (n= 42). Dienogest was administered orally from the previous cycle. DYG was started from day3 of COH cycle.

Participants/materials, setting, methods: Of the participants, 36 patients were histologically confirmed as endometriosis and 48 patients were diagnosed with published imaging criteria using transvaginal ultrasonography, respectively. Patients were administrated with 150-225 IU of human menopausal gonadotropin (hMG) daily for COH, both progestins were administered continuously until 5 days after the oocytes picking up.All viable embryos were cryopreserved for FET. The primary outcome was the clinical pregnancy rate. Statistical analysis was performed using unpaired t-test and chi-square contingency.

Main results and the role of chance: Patient characteristics: the age, body mass index, duration of infertility, AMH level, and endometriosis stage (r-AFS) were similar in the two groups. In the dienogest protocol, LH level on the trigger day was significantly lower than in the DYG protocol (1.44±1.60 vs. 2.98±2.34, P=0.002), suggesting that dienogest leads to stronger pituitary suppression. Still, no significant difference was found between the two groups for the hMG dose and the stimulation duration of hMG. Moreover, the number of oocytes retrieved, fertilization rate, and viable embryo rate were comparable between the two groups. During the follow-up period, the rate of mature oocytes in dienogest regimen was significantly higher than in DYG regimen [89.7% vs. 81.8%, P=0.005]. The clinical pregnancy rate did not differ between the two groups [Odds ratio (OR) 1.07, 95%CI: 0.490∼2.32, P=0.87]:40.0%for the dienogest group vs. 38.5% for the DYG group. Additionally, no significant difference was found in the ongoing pregnancy rate [OR 1.02, 95%CI: 0.45∼2.31, P=0.97]:31.1%for the dienogest group vs. 30.8% for the DYG group, and early miscarriage rate [OR 1.14, 95%CI:0.26∼5.03, P=0.84]:22.2%for the dienogest group vs. 20.0% for the DYG group.

Limitations, reasons for caution: Since the follow-up of these pregnancies is still ongoing, this study is lacking in the live-birth outcomes following PPOS. In addition, the sample size is small, further prospective studies including larger populations are needed to confirm the efficacy of PPOS protocol with dienogest.

Wider implications of the findings: This is the first study demonstrating that dienogest is an effective progestin for PPOS protocol in IVF, while maintaining the comparable outcomes of PPOS with DYG. Moreover, PPOS with dienogest has a number of potential advantages over DYG, including suppression of recurrence after surgical intervention and relieving pain with endometriosis.

Trial registration number: UMIN000031111

P-294 Should we care about polyps detected during the follicular phase of intrauterine insemination treatments?

V. Schutyser[1], S. Santos-Ribeiro[2], M. De Vos[1], L. Boudry[1], H. Tournaye[1], C. Blockeel[1]

[1] *Universitair Ziekenhuis, Centre for Reproductive Medicine- CRG, Brussels, Belgium*
[2] *IVI, Clinica de Fertilidade IVI Lisboa, Lisboa, Portugal*

Study question: Does the suspicion of an endometrial polyp during follicle tracking for intrauterine insemination (IUI) change the cumulative reproductive outcome of these treatment cycles?

Summary answer: The detection of a polyp during follicle tracking for IUI does not seem to decrease cumulative live birth rates (CLBR).

What is known already: Endometrial polyps are a frequent uterine finding in infertility patients. Based on available evidence, there seems to be a benefit of removing a polyp when detected prior to intra-uterine insemination (IUI), regardless of its size, even though up to 27% of all small polyps (<10mm) regress spontaneously. However, the potential benefit of cancelling an IUI when a polyp is detected for the first time during follicle tracking is unknown.

Study design, size, duration: In this retrospective cohort study, all patients who underwent an IUI between May 2009 and March 2017 were included, all having a normal baseline uterine ultrasound and/or hysteroscopy. In 160 out of 6127 patients (2,6%) or in 415 out of 14498 cycles (2,8% of cycles) a polyp was diagnosed during the follicular phase. Each patient was included only once and performed a maximum of 3 consecutive IUI cycles.

Participants/materials, setting, methods: We compared the CLBR between women with and without newly-diagnosed polyps using multivariable Cox regression analysis in order to adjust for the following potential confounding factors: female age, body mass index (BMI), use of gonadotrophins for ovarian stimulation, peak estradiol level, number of follicles >14mm prior to the administration of human chorionic gonadotropin (hCG), as well as sperm concentration and motility.

Main results and the role of chance: Female age was significantly higher in the polyp group, compared with the control group (33.1±4.7 versus 34.9±4.9, p<0.001). Conversely, other relevant baseline characteristics did not vary significantly between both study groups, namely BMI (24.0±4.7 versus 24.3±4.2), sperm concentration after capacitation (32.7±40.4 versus 31.7±41.2), sperm motility after capacitation (99.9±11.4 versus 99.5±6.5), peak estradiol levels (380.0±367.2 versus 380.5±350.1), number of follicles >14mm (1.3±0.7 versus 1.3±0.8) and use of gonadotrophins (13.8% versus 10.8%). The unadjusted CLBR after up to 3 IUI cycles for the women with and without a polyp were 18.4% versus 26.0% (p=0.066), showing a deleterious effect of the presence of a recently-diagnosed polyp of borderline significance. However, after performing multivariate Cox regression analysis, the presence of a polyp detected during treatment no longer seemed to influence CLBR significantly (adjusted hazard-ratio 0.839, 95% confidence interval 0.568-1.239).

Limitations, reasons for caution: The presence of biases related to the retrospective design of this study cannot be excluded. Furthermore, as in-cycle hysteroscopies were not performed (to avoid a potential hindering effect on the IUI cycle outcome), one cannot exclude the possibility of misdiagnosis associated with the sole use of pelvic ultrasound.

Wider implications of the findings: This study, which included a large dataset, may be reassuring for physicians and patients, as the new detection of a polyp during the follicular tracking for an IUI cycle did not seem to be associated with a reduction in CLBR, if left untreated.

Trial registration number: B.U.N. 143201836012

P-295 Inhibition of STAT3 as novel immunotherapy target for treatment of endometriosis

Y. HE[1], S.W. Hung[1], R. Zhang[1], H. Xu[1], C.C. Wang[1]

[1] *The Chinese University of Hong Kong, Department of Obstetrics & Gynaecology, Hong Kong, China*

Study question: To identify specific immunomodulator targeting myeloid-derived suppressor cells (MDSCs) for potential therapy of endometriosis.

Summary answer: STAT3 inhibition by Sunitinib can eliminate MDSCs, inhibit G-MDSC immunsuppressive function and induce neutrophil production which suppresses the growth and development of endometriosis.

What is known already: The development of endometriosis involves alterations of immunological factors, disfunction of immune cells, secretion of immunsuppressive chemokine and cytokines, in order to facilitate ectopic endometrium escape from immune surveillance. Our team has previously reported that MDSCs are significantly increased in early development of endometriosis in mouse model which inhibit T cell proliferation and promote endometriosis development.

Study design, size, duration: Eight specific immunomodulators targeting various MDSCs pathways were administrated to mouse model of endometriosis. MDSCs subsets in peritoneal fluid, peripheral blood, bone marrow and endometriotic lesions during and after treatment were monitored and compared. $CD11b^{+}Ly6G^{+}$ cells from each compartment were isolated for further cellular and molecular characterisation. At least five mice were included in each pharmaceuticals in every experiment.

Participants/materials, setting, methods: C57BL/6 female mice age 7 to 8 weeks old were used. After treatment, peritoneal fluid, peripheral blood, bone marrow immune cells were collected, endometriotic lesions size and weight were compared. Mouse body weight was continuously monitored for side effect.

Main results and the role of chance: Sunitinib selectively targets JAK/STAT3 signallingfor exapanison of MDSCs significantly decreased endometriosis

lesion size and weight without affecting body weight. Sunitinib markedly increased the percentage of $CD11b^+Ly6G^+$ cells in peritoneal fluid. Morphology showed the $CD11b^+Ly6G^+$ cells with no MDSCs features but rather neutrophils. Sunitinib significantly decreased p-STAT3 expression in G-MDSC but not in M-MDSC; and significantly down-regulated TGF-β in peritoneal fluid. RNA sequencing of the isolated $CD11b^+LyG^+$ cells show Sunitinib with differential cytotoxic features which characterised its underlying anti-endometriosis mechanism.

Limitations, reasons for caution: Further experiments are need to be testified in human samples.

Wider implications of the findings: Inhibition of STAT3 can be developed as novel immunotherapy target for treatment of endometriosis.

Trial registration number: Not applicable.

P-296 Changes in expression of thioredoxin and thioredoxin binding protein-2 according to histone deacetylase inhibitor treatment in human endometrial cells from patients with endometriosis

I. Lee[1], Y.B. Won[1], J.H. Lee[1], B.H. Yun[1], S. Cho[1], Y.S. Choi[1], B.S. Lee[1], S.K. Seo[1]

[1]Severance Hopital- Yonsei University College of Medicine, Obstetrics and Gynecology, Seoul, Korea- South

Study question: Does histone deacetylase inhibitor(HDACi) reverse cell proliferation and apoptosis associated with endometriosis by regulating thioredoxin(TRX) and thioredoxin binding protein(TBP)-2 expression?

Summary answer: Suberoylanilide hydroxamic acid(SAHA) may affect the cell proliferation and apoptosis induced by oxidative stress in development of endometriosis, via resuming the TRX and TBP-2 expression.

What is known already: Oxidative stress and chronic inflammation play important roles in the pathophysiology of endometriosis. TRX is a redox regulating antioxidant protein that prevents cell damage from oxidative stress and TBP-2 are regulatory protein of TRX. Altered TRX and TBP-2 expressions in endometrium are known to be associated with the development of endometriosis. SAHA, a HDACi, induces reactive oxygen species formation and activation of caspase pathway in transformed cells, leading to apoptosis. This mechanism appears to involve TRX system which makes normal cells resistant to SAHA-mediated cell death.

Study design, size, duration: In-vitro, experimental study using primary cell culture and molecular biologic methods. From July, 2015 to June, 2016, eutopic endometrium was obtained from the patients who had undergone hysterectomy, and ectopic endometrium from the patients who had undergone ovarian cyst enucleation due to endometriosis. Primary stromal cell culture was performed using eutopic and ectopic endometrial cells in vitro. Recombinant high mobility group box(rHMGB)-1 was used to induce oxidative stress on the cells.

Participants/materials, setting, methods: The cultured human endometrial stromal cells (HESCs) and ishikawa cells were treated with rHMGB-1 and SAHA for 48 hours. Cell proliferation was assessed by CCK-8 assay, cell apoptosis was measured by flow cytometry, and cell viability by MTT assay. To assess the effect via TRX, siTRX transfection was performed on stressed cell by rHMGB-1, and SAHA was treated. mRNA and protein expression of TBP-2, TRX and TRX/TBP-2 ratio were estimated.

Main results and the role of chance: rHMGB-1 treated HESCs and ishikawa cells showed increased cell proliferation with decreased cell viability, decreased apoptosis and increased cell necrosis on CCK, MTT and flow cytometry. After treating SAHA, cell proliferation was decreased significantly with increase of apoptosis, especially in ectopic HESCs and ishikawa cells. mRNA and protein expression of TBP-2 were decreased in HESCS and ishikawa cells, whereas it was reversed after SAHA treatment. TRX expression was significantly decreased after SAHA treatment comparing to pre-SAHA treatment in ectopic HESCs and ishikawa cells, however, increase of TRX expression was shown in eutopic HESCs after SAHA versus pre-SAHA treatment. After blocking TRX gene by siTRX transfection, SAHA treated cells showed increased TBP-2 expression comparing to the control.

SAHA has been suggested to act selectively in transformed cells(cancer cell), by targeting low TRX cells in transformed cells. Our study shows ectopic endometrial cells show reduced level of TRX than eutopic cells, increasing cell apoptosis by SAHA, so that may assume SAHA as a specific treatment for the endometriosis.

Limitations, reasons for caution: Our study is limited in that we only performed in vitro analysis using HESCs. Therefore, in vivo studies are required.

Wider implications of the findings: Our results support that cell proliferation and decreased apoptosis caused by oxidative stress in the progression of endometriosis may be reversed by SAHA only in specific transformed cells, leading a potential treatment option in endometriosis.

Trial registration number: This research was supported by a faculty research grant of Yonsei University College of Medicine for 6-2015-0466.

P-297 Innate immune function is altered in endometrial epithelial and stromal cells of infertile patients with endometriosis

S. Matsuzaki[1], C. Chauffour[1], A.S. Grémeau[1], M. Canis[1], J.L. Pouly[1]

[1]CHU Clermont-Ferrand, Gynecology, Clermont-Ferrand, France

Study question: Is innate immune function altered in endometrial epithelial and stromal cells of patients with endometriosis?

Summary answer: Innate immune function is altered in endometrial epithelial and stromal cells of patients with endometriosis.

What is known already: Pathophysiology of endometriosis remains to be clarified. However, eutopic endometrium of patients with endometriosis may be responsible for the pathogenesis and related-infertility. There are growing evidence that the uterus is a non-sterile compartment. The human endometrium is an important site of innate immune defense. Autophagy balances inflammation in innate immunity and impaired autophagy may be involved in pathophysiology of endometriosis. Numerous studies showed that immunological dysfunction is involved in pathophysiology of endometriosis. However, it is not clear whether innate immune function is altered in endometrial cells of patients with endometriosis.

Study design, size, duration: For this laboratory study, endometrial samples of patients with endometriosis undergoing laparoscopy for infertility (n=46) were collected throughout the menstrual cycle. In addition, we included infertile patients with hydrosalpinx caused by chlamydia trachomatis infection (n=16), and healthy fertile women (n=18) with macroscopically normal pelvic cavities who undergoing laparoscopic tubal ligation or reversal of tubal sterilization as controls.

Participants/materials, setting, methods: We evaluated the effects of lipopolysaccharide (LPS; 0.1μg/ml or 1 μg/ml) or polyinosinic:polycytidylic acid (Poly I:C; 10 or 25 μg/ml) for 4h or 24h on cell proliferation, IL-1β and TNF α mRNA expression by real-time PCR, pro-IL-1β synthesis by western blot analysis and secretion of mature IL-1 β and TNF α by ELISA in endometrial epithelial and stromal cells, with and without autophagy inhibition by knockdown of the ATG13. Statistical significance was defined as $p<0.05$.

Main results and the role of chance: Endometrial epithelial cells (EECs) secreted significantly more mature IL-1 β and TNF α than endometrial stromal cells (ESCs).

Menstrual phase: Mature IL-1 β levels of EEC/ESC of fertile healthy controls (EEC/ ESC-C) were significantly decreased after 24h stimulation with LPS or Poly I:C compared to those at 4h, whereas autophagy inhibition further promoted mature IL-1 beta levels at 24h. Vehicle, LPS or Poly I:C treated EEC/ESC of patients with endometriosis (EEC/ESC-Endo) secreted no detectable or very low levels of mature IL-1 β. TNF α levels in vehicle, LPS or Poly I:C treated EEC/ESC-endo were significantly higher than those of EEC/ ESC-C.

Early- and mid-secretory phases: Vehicle, LPS or Poly I:C treated EEC-C&Endo and ESC-C&Endo secreted no detectable or very low levels of mature IL-1 β. Vehicle, LPS or Poly I:C treated EEC/ESC of patients with hydrosalpinx (EEC/ESC-H) secreted significantly more mature IL-1 β than those of the other two groups. TNF α levels were significantly lower in vehicle treated EEC/ESC-C compared to those of EEC/ESC-endo and EEC/ESC-H. Either LPS or Poly I:C did not significantly increase TNF α secretion in ESC-C, whereas both significantly increased TNF α secretion in EEC/ESC-endo. In EEC/ESC-H, only Poly I:C significantly increased TNF α secretion

Limitations, reasons for caution: This study was only performed in vitro and only proinflammatory cytokines, IL-1 β and TNF α were analyzed. Furthermore, no cellular interactions between endometrial and immune cells were investigated.

Wider implications of the findings: Altered endometrial innate immunity may facilitate the survival of shed endometrial tissue and have detrimental effect on endometrial receptivity in patients with endometriosis. Further studies that investigate the mechanisms underlying altered innate immune function of endometrial cells in patients with endometriosis will provide novel therapeutic strategies for endometriosis.
Trial registration number: N.A.

P-298 Biomarker discovery associated with endometrial-related conditions is biased by the menstrual cycle effect in the transcriptomic analysis

A. Devesa Peiro[1,2], P. Sebastian-Leon[1,3], A. Pellicer[2,3,4], P. Diaz-Gimeno[1,3]
[1]*IVI Foundation- IVI-RMA Global, Genomic & Systems Reproductive Medicine, Valencia, Spain*
[2]*University of Valencia, Pediatrics- Obstetrics & Gynaecology, Valencia, Spain*
[3]*Health Research Institute la Fe, Reproductive Medicine, Valencia, Spain*
[4]*IVI-RMA Rome, Reproductive Medicine, Rome, Italy*

Study question: Does menstrual cycle affect the results of case versus control gene expression studies searching for endometrial-related-condition biomarkers?
Summary answer: Menstrual cycle effect is a confounding variable that must be considered at case versus control gene expression studies to identify reliable biomarkers of endometrial-related conditions.
What is known already: The endometrium is a dynamic tissue involving many genes whose expression changes throughout the menstrual cycle. Consequently, it is important for differential expression analyses to accurately define at molecular level the cycle phase of the endometrial biopsies. Transcriptomic approaches are increasingly used in Reproductive Medicine to identify genes associated to endometrial-related conditions. However, the menstrual cycle has not been properly considered in these studies and it is an important issue to ensure that biomarker discovery is not biased by the menstrual cycle phase, masking the genes associated to the endometrial condition.
Study design, size, duration: This *in-silico* analysis involves case vs control studies evaluating endometrial-related conditions: 3 of endometriosis (n=37, n=19, n=111), 1 of recurrent implantation failure (n=115), 1 of recurrent pregnancy loss (n=20) and 1 of uterine pelvic pathology (n=71). The original raw data was re-analysed using the same procedure; and the menstrual cycle effect was evaluated comparing the differentially expressed genes with and without removing the registered menstrual cycle phase in the analysis.
Participants/materials, setting, methods: Keywords of endometrial transcriptomics and related conditions were searched at Gene Expression Omnibus (GEO). For each included study, raw data were pre-processed, normalized using quantile method and explored through Principal Component Analysis (PCA) to estimate the menstrual cycle effect on the data. Significant differentially expressed genes (False Discovery Rates (FDR) <0.05) were compared (Fisher's exact test, FDR) for each individual study before and after removing the menstrual cycle effect using linear models (Limma R-package).
Main results and the role of chance: A total of 42 gene expression individual studies evaluating endometrial-related conditions were retrieved from GEO. Of these, 14.3% had not registered the menstrual cycle phase at the time of endometrial biopsy collection. From the remaining 85.7%, the studies with cycle phase registered for all samples, raw data available, and n > 3 per group were included. In all of them, the three first PCA's components grouped the samples according to the cycle phase rather than to the condition. This menstrual cycle bias was demonstrated in all studies, as a significant increment of an average of 4.6 times more differentially expressed genes were detected when this effect was removed (Fisher's exact tests FDR < 0.0006, 4.40E-16 < FDR < 5.06E-04). For these studies, on average 46.78% new genes associated with the endometrial-related conditions were highlighted as new condition-specific biomarkers that would not have been detected without removing the menstrual cycle bias in the analysis. Consequently, the cycle phase of endometrial biopsies should not only be registered, but also controlled at a molecular level in the data analysis, to optimize the detection of reliable biomarkers of endometrial-related conditions.
Limitations, reasons for caution: The bias of the menstrual cycle effect in biomarker discovery has only been evaluated on the available GEO endometrial-related-condition studies that met the criteria. Since this effect has been demonstrated in all of them, it could be extrapolated to case vs control studies evaluating other endometrial-related conditions.
Wider implications of the findings: This research demonstrates the menstrual cycle bias in biomarker discovery of endometrial-related conditions, introducing a new biomarker taxonomy that could distinguish between genes affected by the menstrual cycle and/or the researched condition. These results establish new guidelines to accurately detect endometrial biomarkers, improving reproducibility and gaining statistical power.
Trial registration number: not applicable. Research supported by IVI Foundation, IVI-RMA Global. A.Devesa-Peiro is granted by the Ministry of Science, Innovation and Universities (FPU/15/01398).

P-299 Alteration in gene expression of CREB, TNF-α and BCL6 in endometriosis

A. Saadat Varnosfaderani[1,2], S. Kalantari[1,2], F. Ramezanali[3], E. Amirchaghmaghi[4], M. Shahhoseini[2]

[4]*Royan Institute for Stem Cell Biology and Technology- ACECR, Department of Regenerative Biomedicine- Cell Science Research Center, Tehran, Iran*

Study question: Is gene expression of CREB, TNF-α, and BCL6 different in women with endometriosis?
Summary answer: Overexpression of CREB, TNF-α, and BCL6 was detected in ectopic endometrium of women with endometriosis
What is known already: Endometriosis is a multi-factorial disease. Several genetic, immunological and hormonal factors are suggested in its pathogenesis. cAMP response element (CRE) binding protein (CREB) is a transcription factor that mediated many different processes such as cell proliferation, survival, and differentiation. CREB has a CRE site in the promoters of many different genes including interleukin 2 (IL-2), IL-6, cyclooxygenase-2 (COX-2), macrophage migration-inhibitory factor (MIF) and tumor necrosis factor alpha (TNF-α). TNF-α is one of inflammatory cytokines that participate in angiogenesis and immune responses. Another transcription factor is B cell lymphoma 6 (BCL6) which is associated with cellular proliferation as nuclear gene repressor.
Study design, size, duration: In this case-control study, 10 endometriotic lesions (ectopic), 10 endometrial samples (eutopic) of women with endometriosis and 10 endometrial control samples were studied. Control samples were obtained from women who had no evidence of endometriosis during laparoscopy. Ectopic samples were obtained during laparoscopy surgery. All women signed the informed consent form and did not receive any hormonal treatments during the last three months.
Participants/materials, setting, methods: After endometrial tissue collection, RNA extraction and cDNA synthesis were done. Real-time PCR technique was used for quantitative gene expression of CREB, TNF-α, and BCL6. Gene expression data were analyzed based on $2^{-\Delta\Delta CT}$ to estimate the relative fold change value. One-Way ANOVA was used for data analysis.
Main results and the role of chance: Gene expression profile of CREB, TNF-α, and BCL6 was increased in ectopic lesions compared with control samples. These increases were statistically significant ($p<0.05$) except for TNF-α ($p>0.05$).

In addition, overexpression of BCL6 was detected in eutopic endometrial tissues compared to controls while this difference was not significant.
Limitations, reasons for caution: For getting more information, we can study these genes in a large number of women with and without endometriosis and also to investigate gene expression of other transcription factors influencing inflammatory cytokines expression. Epigenetic studies such as CREB and BCL6 binding to the promoter regions of target genes are recommended.
Wider implications of the findings: Dynamic expression of CREB, TNF-α, and BCL6 could play an essential role in the development of endometriosis. Higher expression of these genes in ectopic endometrial

lesions can be considered as a molecular scenario for the pathophysiology of endometriosis by induction of inflammatory cascades and cellular proliferation.
Trial registration number: N/A

P-300 Web-based survey of fertility issues in women with endometriosis

I. Navarria-Forney[1], J. Bénard[1], L. Aerts[2], N. Pluchino[2], I. Streuli[1]
[1]University hospitals of Geneva and the Faculty of medicine of the Geneva University, Reproductive medicine unit- division of gynaecology, Geneva, Switzerland
[2]University hospitals of Geneva and the Faculty of medicine of the Geneva University, Endometriosis center- division of gynaecology, Geneva, Switzerland

Study question: What are the fertility issues and the attitude towards reproductive techniques and fertility preservation options in women with endometriosis?
Summary answer: The risk of infertility is a major issue for many women with endometriosis. Few women consider themselves well-informed about fertility preservation options.
What is known already: Fertility preservation in women with endometriosis in a debated topic with only scarce medical literature on the subject.
Study design, size, duration: We conducted a one-time web-based survey about fertility issues and attitudes towards reproductive techniques and fertility preservation in women of reproductive age with endometriosis over a four month period in 2018. Women were recruited via advertisement on social media or via the social media pages of local endometriosis-patients associations.
Participants/materials, setting, methods: There were 270 female participants, with a mean age of 31.9 years. Each participant completed the online survey, a questionnaire in French (37 items) exploring the following dimensions: socio-demographic (5 items) and medical data on endometriosis (6 items), family planning and fertility (7 items), knowledge and attitudes toward endometriosis and fertility (4 items), means used/wished to access information (5 items), attitudes in the context of infertility (10 items).
Main results and the role of chance: A majority of women are worried (96%) about the impact of endometriosis on their fertility. Half (52%) of the participants have received, from their doctor, enough information concerning the possible effect of endometriosis on their fertility, whereas 31% have discussed the issue but wish further information. In contrast, only a minority (27%) of women consider themselves well-informed about fertility preservation options. Information given by endometriosis and reproductive specialists is considered most useful. Information mediated through patient associations and group discussions is also highly rated, whereas information given by the general gynaecologist is considered less useful. A majority of women would consider assisted reproductive techniques (74%) or adoption (70%) in case of infertility. Interestingly 72% of women would undergo oocyte vitrification for fertility preservation, whereas only 37% would resort to oocyte donation.
Limitations, reasons for caution: Diffusion via social media allows the participation of women from the general population and avoids the bias of hospital recruitment. We can however suspect that women most concerned about fertility issues were more likely to participate. Another limitation is the self-declared nature endometriosis-diagnosis.
Wider implications of the findings: This is the first survey addressing the topic from the patient's perspective. Our results highlight the importance of addressing the issue of fertility in women with endometriosis. Special attention should be given to information and counseling about fertility preservation since most women consider their knowledge on the topic as insufficient.
Trial registration number: Not applicable

P-301 Anogenital distance and endometriosis: results of a case-control study

L. Buggio[1], E. Somigliana[2], F. Facchin[3], F. Ottolini[4], D. Dridi[4], P. Vercellini[4]
[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Gynecology Unit, Milan, Italy
[2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Infertility Unit, Milan, Italy
[3]Catholic University of Milan, Faculty of Psychology, Milan, Italy
[4]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Gynecology Unit, Milan, Italy

Study question: Is anogenital distance (AGD) associated with the presence of endometriosis?
Summary answer: AGD is not associated with the presence of endometriosis.
What is known already: AGD is the distance measured from the anus to the genital tubercle. Recent evidence suggests that a shorter AGD, a sensitive biomarker of the prenatal hormonal environment, could be associated with higher endometriosis risk, in particular, with deep infiltrating forms. Prenatal exposure to androgens results in a longer AGD, whereas a prenatal estrogenic environment results in a shorter AGD. Hypothetically, a shorter AGD, reflecting the intrauterine hormonal milieu, could represent an indicator of the presence of endometriosis. However, studies investigating AGD in affected women are scanty.
Study design, size, duration: Case-control study recruiting nulliparous women (aged 18-40 years) with endometriosis between 2017 and 2018. Cases were women with a surgical diagnosis of endometriosis in the previous 24 months or with a current nonsurgical diagnosis of endometriosis. Controls were asymptomatic women referring for periodical gynecological care and without a previous diagnosis of endometriosis. They were matched to cases for age and BMI. Exclusion criteria included previous or current pregnancy and presence of genitourinary prolapse.
Participants/materials, setting, methods: 90 women with endometriosis (*n*= 45 with deep infiltrating endometriosis (DIE), and *n*=45 with ovarian endometrioma (OMA)) and 45 controls were enrolled. For each woman, two measures were obtained using a digital caliper: AGD_{AC}, from clitoral surface to the upper verge of the anus, and AGD_{AF}, from the posterior fourchette to the upper verge of the anus. Each distance derived from the mean of six measurements acquired from two different gynecologists.
Main results and the role of chance: Baseline characteristics were comparable in the three study groups (age, BMI, smoking status). The mean ± SD AGD_{AC}in women with DIE, OMA and without endometriosis was 76.0 ± 12.1, 76.1 ± 11.1, and 77.8 ± 11.4 mm, respectively (p = 0.55). The mean ± SD AGD_{AF}in women with DIE, OMA and without endometriosis was 22.8 ± 5.0, 21.7 ± 9.0, and 23.7 ± 7.8 mm, respectively (p = 0.38).
Limitations, reasons for caution: Selection and measurement bias need to be considered. The decision of performing six measurements for each AGD from two different gynecologists should have limited measurement variability.The choice of controls may be cause of concern; we cannot exclude to have inadvertently included some cases among controls.
Wider implications of the findings: Our study failed to find an association between AGD and presence of endometriosis. Therefore, our findings do not support a crucial role of intrauterine exposure to steroidal hormones in the pathogenesis of the disease. Moreover, AGD does not seem to represent a reliable indicator of the presence of endometriosis.
Trial registration number: Not applicable

P-302 Effect of metformin on endometrial receptivity of diet-induced obese mice

A. Machado Weber[1], M. Handwerk[2], T. Kretschmer[2], E.M. Turnwald[2], A. Sarah[2], T. Strowitzki[1], A. Germeyer[1]
[1]Heidelberg University Women's Hospital, Department of Gynecological Endocrinology and Reproductive Medicine, Heidelberg, Germany
[2]University Hospital of Cologne, Department of Paediatrics and Adolescent Medicine, Cologne, Germany

Study question: Evaluate the effects of metformin on endometrial implantation markers expressed in endometrium of mice feed with standard or high fat diet.
Summary answer: Metformin therapy seems to exert a beneficial effect not only on body weight, but also on endometrial receptivity factors in diet-induced obese mice.
What is known already: Women withpolycystic ovary syndrome (PCOS) present with an increased risk of subfecundity and infertility, as partially associated with insulin resistance and obesity. Furthermore, significant changes in uterine receptivity and markers of decidualization and implantation have been

discovered in obese women, suggesting molecular mechanisms of endometrial dysfunction. Metformin is widely used as treatment for type 2 diabetes mellitus and it is considered a promising drug for treating anovulatory obese women with PCOS. However, the direct effects of metformin on endometrial receptivity of those patients remain unclear.

Study design, size, duration: This study is an *in vivo* experimental study using diet-induced obese female C57Bl/6J mice (~14 weeks) treated with or without metformin (~21 days) and their nonfat controls also treated with and without metformin (~21 days).

Participants/materials, setting, methods: Beginning at 3 weeks of age, female C57Bl/6J mice were fed with standard low or high fat (60% fat) diet for ~ 14 weeks, then each group either received or did not receive metformin (380mg/kg mice) via drinking water for 14 to 24 days. Animals were weighted before and after the intervention, endometrium was collected during secretory phase and the mRNA expression of *IL8*, *HbEGF*, *Maoa*, *IGF1* and *IR* was evaluated by qRT-PCR.

Main results and the role of chance: Animals who received standard diet (SD) did not change their body weight (BW) after metformin treatment, however metformin did reduce the BW of the animals who were fed a high fat diet (HFD). In the endometrium, metformin treatment did not interfere in the mRNA expression of *IL8* in SD animals, however in HFD animals the expression was upregulated. Metformin treatment increased the *HbEGF* expression of animals fed in both diets. Furthermore, the mRNA expression of *Maoa* and *IGF1* was downregulated with metformin treatment in SD and HFD animals. Additionally, the IR expression increased with metformin treatment in both SD and HFD, however more pronounced in SD animals.

Limitations, reasons for caution: These results are seen in an animal model, which does not perfectly reproduce the complex composition of human fertility.

Wider implications of the findings: Giving the pivotal role obesity plays in the etiopathogenesis and progression of PCOS, our data suggest that metformin might be considered an essential therapeutic option to ameliorate fertility of those patients.

Trial registration number: Not applicable.

P-303 Microenvironmental regulation of human endometrial mesenchymal stem-like cells

R. Chan[1], M. Cao[1], E. Ng[1], W. Yeung[1]

[1] *The University of Hong Kong, Obstetrics & Gynecology, Hong Kong, Hong Kong*

Study question: Do myometrial cells function as niche cells regulating the biological activities of endometrial stem cells?

Summary answer: Soluble factors derived from myometrial cells increased self-renewal and proliferation activities of endometrial mesenchymal stem-like cells (eMSCs) by activating WNT/β-catenin signaling.

What is known already: Adult stem cells contribute to regeneration of endometrium. Data from human and mouse endometrium localized eMSCs preferentially to regions adjacent to the myometrium. In mice, active β-catenin was highly expressed in proliferating endometrial label-retaining cells after parturition. We hypothesized that the myometrial cells provided niche signals regulating the biological activities of eMSCs.

Study design, size, duration: Sequential beading with magnetic beads coated with anti-CD140b and anti-CD146 antibodies was used to isolate eMSCs from endometrial tissues from proliferative (n = 24) and secretory (n = 16) phase. The eMSCs were seeded at low density, and indirectly co-cultured with myometrial cells at ratio of 1:90 for 15 days. Functional stem cell assays were performed and the proportion of cell expressing the eMSCs markers was evaluated.

Participants/materials, setting, methods: Proliferative and secretory phase samples obtained from women aged 35- to 50-years undergoing total abdominal hysterectomy. Endometrial cells were isolated enzymatically and the percentage of eMSCs after co-culture with myometrial cells was analyzed by flow cytometry. Western blot analysis for active β-catenin validated the activation of Wnt/β-catenin signaling. The role of WNT/β-catenin signaling in eMSCs self-renewal was confirmed by gain-of (activator: Wnt3a conditioned medium and recombinant WNT3A) and loss-of (inhibitors: XAV939 and IWP-2) function approaches.

Main results and the role of chance: *In vitro* co-culture of myometrial cells enhanced the colony forming and self-renewal ability of eMSCs. The expanded eMSCs after coculture retained multipotent characteristic and exhibited a greater total cell output when compared to medium alone culture. The level of active β-catenin in eMSCs increased significantly after co-culture with myometrial cells suggesting activation of the WNT/β-catenin signaling. Secretory factors from myometrial cells produced the same stimulatory effect on eMSCs. The functional WNT/β-catenin signaling in eMSCs self-renewal was determined with WNT activator (Wnt3a conditioned medium) and WNT inhibitors (XAV939 and IWP-2). Addition of Wnt3a CM or recombinant WNT3A increased the clonogenic activity and number of eMSCs. While, the stimulatory effect of myometrial cells on eMSCs was suppressed by the Wnt inhibitors.

Limitations, reasons for caution: The behavior of the cells may be altered during culture. The functionality of myometrial derived factors on eMSCs needs to be determined with *in vivo* studies.

Wider implications of the findings: Myometrial cells provide paracrine factors to eMSCs via Wnt/β-catenin signaling. Secretory factors derived from the myometrial cells offer a specialized microenvironment modulating eMSC activities. By gaining a better understanding of the niche composition, it will be possible to recreate a milieu for stem cell expansion and control their biological activities.

Trial registration number: Not applicable

P-304 Laparoscopic investigation and correction of undiagnosed endometriosis may enable natural conception and avoidance of In Vitro Fertilization (IVF) overuse in unexplained infertility patients

A. Pantou[1], M. Simopoulou[2], K. Sfakianoudis[1], P. Giannelou[1], A. Rapani[2], E. Maziotis[2], S. Grigoriadis[2], P. Tsioulou[2], M. Koutsilieris[2], K. Pantos[1]

[1] *Athens Genesis Clinic, Reproductive Medicine Unit, Athens, Greece*

[2] *National and Kapodistrian University of Athens, Department of Physiology, Athens, Greece*

Study question: Could laparoscopic surgery on women with unexplained infertility and recurrent implantation failure (RIF) enable natural conception by identifying and correcting underlying endometriosis?

Summary answer: Employing laparoscopic surgery in women initially diagnosed with unexplained infertility and RIF, resulted to natural conception following correction of underlying endometriosis.

What is known already: Twenty-five percent of infertile couples are being diagnosed with unexplained infertility. RIF is a clinical categorization referring to patients subjected to over 3 IVF cycles associated with failure in achieving a clinical pregnancy following embryo transfers including good quality embryos. Endometriosis is a polymorphic disorder that could go undiagnosed, in influencing infertility, and ultimately hindering natural conception fueling the requirement for IVF treatment. If left undiagnosed this could lead to RIF and IVF overuse. The need to avoid IVF over-treatment and effectively manage patients that are categorized as unexplained infertility coupled by RIF has been identified and highlighted.

Study design, size, duration: Medical records between 2004 and 2017 from women initially diagnosed with unexplained infertility and RIF while still pursuing fertility treatment were retrospectively analyzed. One-hundred and twenty women underwent laparoscopy as a last resort leading to identification and correction of the hitherto undiagnosed endometriosis.

Participants/materials, setting, methods: The patient study group included women diagnosed with unexplained infertility and RIF. Laparoscopic surgery was performed under general anesthesia in Genesis Athens Clinic. Following identification and correction of endometriosis patients were invited to conceive naturally. Patients were divided into 2 groups depending on achieving clinical pregnancy status. Statistical comparison was attempted based on years of infertility, number of previous failed IVF attempts, grade of endometriosis, female age and CA-125 levels between the two groups.

Main results and the role of chance: Following laparoscopy 81 out of the 120 patients (67.5%) were diagnosed with endometriosis. Seven were diagnosed with stage I endometriosis, 31 with stage II, 35 with stage III and 8 with stage IV endometriosis. Eighty-one patients were diagnosed with endometriosis as the sole infertility finding. Endometriosis lesions were laparoscopically

corrected. The 81 patients were invited to conceive naturally. Forty-seven patients (58.02%) achieved a pregnancy within the 1-year time-frame. In fact, the time-frame required for pregnancy to be ensued was less than 6 months for the majority of our patients 36 out of 47 (76.6%) as presented in Table 1. It should be noted that women who achieved a pregnancy within the first year were statistically significant younger than women that failed to achieve a pregnancy (35.55±4.81 vs 37.50±4.42, p=0.02) and presented with statistically significant lower CA–125 levels (17.38±2.44 U/ml vs 23.79±2.40 U/ml, p<0.001). No statistically significant difference was presented regarding the years of infertility, previous failed IVF attempts or grade of endometriosis.

Limitations, reasons for caution: The retrospective nature along with the small sample of the study is an identified limitation. Moreover patients who achieved a natural conception were statistically significantly younger. The invasive nature of laparoscopy accounts as a reason for caution prior to concurring on optimal practice.

Wider implications of the findings: Laparoscopic investigation should be employed for women diagnosed with unexplained infertility coupled by RIF in order to exclude diagnosis of endometriosis or alternatively correct it. This approach appears to enable natural conception for couples that could otherwise run the risk of being subjected to futile IVF attempts resulting to overuse.

Trial registration number: Not applicable.

P-305 Efficacy of Dienogest versus oral contraceptive pills (OCPs) on pain associated with endometriosis: Randomized Controlled Trial

A. AbuMusa[1], L. El Taha[1], D. Khalife[1], S. Ghunaim[1], A. Khalil[1], J. Nassif[1]
[1]American University of Beirut Medical Center, Dept. of Ob/Gyn, Beirut, Lebanon

Study question: Is Dienogest (Visanne) superior in efficacy to oral contraceptive pills (Yasmin) in controlling pain associated with endometriosis?

Summary answer: Dienogest at a dose of 2mg/day showed no significant benefit to OCP in relief of endometriosis related pelvic pain but had a better tolerability profile.

What is known already: Endometriosis is a chronic inflammatory disease, frequently associated with dysmenorrhea, dyspareunia and abdomino-pelvic pain limiting quality of life. Most medical therapies aim to alleviate the severity of symptoms. Recent guidelines recommend the use of either OCPs or progestins as a first-line treatment of pain associated with endometriosis. The effectiveness of both OCPs and dienogest, a fourth-generation progestin, for endometriosis treatment has been demonstrated. The literature is rich with data comparing the use of Visanne or OCPs to placebo or GnRH analogs. However, there are no head to head studies comparing their efficacy in the management of endometriosis associated pain.

Study design, size, duration: We conducted a blinded randomized controlled clinical pilot study that compared the efficacy of dienogest with that of OCP for the treatment of endometriosis patients. Sample size consisted of 50 patients, 25 in each arm. Endometriosis patients, 20-45 years of age, diagnosed clinically, surgically or via imaging analysis suggestive of endometrioma with no contraindications to suggested therapy were randomized to receive Visanne 2mg/day or Yasmin (0.03mg ethinyl estradiol and 3mg drospirenone) daily for 24 weeks.

Participants/materials, setting, methods: Fifty endometriosis patients were assessed at baseline, at 3 months and 6 months interval. The primary outcome was the change in endometriosis associated pelvic pain from baseline to end of treatment, assessed by the Visual Analogue Scale (VAS). The secondary outcome quality of life was assessed using Endometriosis Health Profile 30 (EHP30) and other secondary outcomes such as side effects on similar numerical scales from one to ten regarding the tolerability and satisfaction.

Main results and the role of chance: In total, 50 women were randomized to treatment with Dienogest (n=25) or OCPs (n=25). Overall, 20 women in the Dienogest group and 18 women in the OCP group completed the study. Both groups were comparable at baseline, with a mean BMI of less than 25 in 60% of patients and a mean age of less than 35 in 51 % of patients. The reduction in mean VAS score was not significantly different between the 2 groups at 3 and 6 months (p=0.51 and 0.27 respectively). The use of analgesics was comparable between the 2 groups at baseline. However, the intake was lower in the Dienogest group at 3 and 6 months when compared to the OCP, yet it did not reach any statistical significance (p=0.19, p=0.06 respectively). Dienogest was well tolerated with fewer adverse events; mainly significantly lower nausea and lower premenstrual symptoms (p=0.035, p=0.04 respectively). In terms of quality of life related to sleep or work, there is no significant difference between the use of dienogest and OCP (p=0.13 and 0.36 respectively).

Limitations, reasons for caution: The small sample size in a single center randomized clinical trial limits the generalizability of the results.

Wider implications of the findings: Our results show that dienogest is comparable to OCPs in controlling pain associated with endometriosis however with less side effects and hence better safety and tolerability profile. While larger studies are needed, such a difference between dienogest and OCPs is considered valuable from a public health perspective.

Trial registration number: No trial registration number

P-306 lncRNA MEG3-210 regulates endometrial stromal cells via PKA/SERCA2 and p38 MAPK signaling pathway through galectin-1 in endometriosis

Y. Liu[1], J. Ma[1], L. Jun[2]
[1]Women's Hospital- School of Medicine- Zhejiang University, Department of Key Laboratory, Hangzhou, China
[2]Women's Hospital- School of Medicine- Zhejiang University, Department of Gynecology and Obstetrics, Hangzhou, China

Study question: What is the role of lncRNA MEG3-210 in endometriosis?

Summary answer: lncRNA MEG3-210 regulates endometrial stromal cells migration, invasion and apoptosis via PKA/SERCA2 and p38 MAPK signaling through interaction with galectin-1.

What is known already: MEG3 is considered as tumor suppressor in many diseases. Expression patterns of MEG3 transcripts are specific to tissue and cell type. Galectin-1(Gal-1) is expressed in human endometrium and endometrial stromal cells selectively. Gal-1 is involved in cell proliferation, motility, apoptosis and angiogenesis. Gal-1 promotes angiogenesis and growth of lesions in endometriosis.

Study design, size, duration: Tissue specimens came from eutopic endometrium of women with endometriosis (EU, n=28) or not (NE, n=29). Endometrial stromal cells (ESCs) were isolated from eutopic endometrium of women with endometriosis (EuESCs, n=13) or not (NeESCs, n=14).

Participants/materials, setting, methods: We used RT-qPCR to determine the expression of MEG3-210 in tissues and endometrial stromal cells. Then we learned about the role of MEG3-210 in ESCs by loss-of and gain-of function assays. We performed RNA pull-down and mass spectrum analysis to explore the potential interaction between MEG3-210 and proteins in ESCs. We used RNA immunoprecipitation (RIP) to confirm the interaction. With the inhibitor of pathway, we identified the regulatory axis involved in biological functions.

Main results and the role of chance: MEG3-210 is expressed lower in eutopic endometrium and stromal cells from patients with endometriosis. Downregulation of MEG3-210 could promote NeESCs migration and invasion but inhibit apoptosis via PKA/SERCA2 and p38 MAPK signaling pathway. In contrast, overexpression of MEG3-210 could inhibit EuESCs migration and invasion but induce apoptosis. Gal-1 is confirmed to interact with MEG3-210 by RNA pull-down and RIP. Furthermore, Gal-1 could activate p38 MAPK signaling and inhibit PKA/SERCA2. Of note, p38 MAPK signaling was responsible for the effects of MEG-210 on apoptosis, and SERCA2 played a more important role in migration and invasion.

Limitations, reasons for caution: Our major limitation is lacking endometrium from women diagnosed with endometriosis in stage I or II according to revised AFS classification. Furthermore, the detailed relationship between Gal-1 and PKA/SERCA2 needs to be explored further.

Wider implications of the findings: Our study is the first to demonstrate the functions and potential mechanism of MEG3-210 in endometriosis. These findings suggest that MEG3-210 contributes to pathogenesis of endometriosis. These results indicate that MEG3-210 may be used as diagnostic marker and Gal-1/p38 MAPK axis could be the potential target of treatment.

Trial registration number: not available

P-307 Oxytocin receptor antagonism improves receptivity-related parameters of cultured human endometrium.

Study question: What is the effect of oxytocin (OT), oxytocin receptor (OTR) antagonism and high concentrations of estradiol (E_2) on receptivity - related parameters of cultured human endometrium.

Summary answer: E_2 and OT limited endometrial viability and decidualisation, increased cyclooxygenase-2 (COX-2) activity and formation of prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$). All were inhibited by OTR antagonist, atosiban.

What is known already: Endometrial receptivity is affected in patients undergoing controlled ovarian hyperstimulation (COH), mostly due to exposure to supraphysiological levels of E_2. It has been confirmed that E_2 stimulates formation of OTRs in uterus. OT is a known factor stimulating the local release of prostaglandins, which decrease endometrial perfusion and receptivity. It has been shown that OTR antagonists might improve embryo implantation, possibly by decreasing the uterine contractions. Such an effect was also observed in patients without elevated uterine contractions. It could point to an additional mechanism of support of embryo implantation in patients receiving OTR antagonists.

Study design, size, duration: In vitro study on cultured endometrial tissues samples collected by aspiration biopsy from 30 women undergoing In Vitro Fertilisation – Embryo Transfer (IVF-ET) treatment between 2016 and 2017.

Participants/materials, setting, methods: In vitro study performed on a model of endometrial tissues explants and endometrial tHESC cell line. Receptivity-related parameters were investigated using cells viability and COX-1/2 activity assays and $PGF_{2\alpha}$ and prolactin secretion measurements. Changes in expression of OT receptors and COX-2 genes (*OXTR* and *PTGS2*, respectively) were examined with qPCR.

Main results and the role of chance: High E_2 and OT limited the endometrial viability and decidualisation, stimulated COX-2 activity and formation of prostaglandin $PGF_{2\alpha}$. All the above were alleviated by OTR antagonist, atosiban.

Limitations, reasons for caution: It is a preliminary in vitro study. Its findings require further preclinical and clinical confirmation.

Wider implications of the findings: Once confirmed in further studies, the results might point that OTR antagonists could be helpful in improving endometrial receptivity in patients undergoing COH.

Trial registration number: Not applicable

P-308 Relationship between the percentage of senescent endometrial cells and pregnancy outcome in women with recurrent pregnancy failure

D. Parvanov[1], R. Ganeva[1], N. Vidolova[1], G. Stamenov[2], T. Chaushev[1]

[1]*MHAT Nadezhda, Research, Sofia, Bulgaria*

[2]*MHAT Nadezhda, Obstetrics and gynaecology, Sofia, Bulgaria*

Study question: Is there a relationship between the percentages of senescent cells in human endometrium during the mid-luteal phase of the menstrual cycle and pregnancy outcome ?

Summary answer: Women with miscarriage have significantly lower percentage of p16-positive senescent endometrial stromal cells during the mid-luteal phase of the menstrual cycle.

What is known already: Endometrial abnormalities that involve cell functionality changes could have an adverse impact on pregnancy outcome. Some of these transformations are probably associated with cellular senescence. Recently, it was found that p16-positive senescent cells in human endometrium are responsible for acute cellular remodelling at the time of embryo implantation. In addition, the number of senescent cells and their communication with uNK cells was suggested to be tightly bound with the endometrial receptivity. However, little is known about the influence of senescent cells on the pregnancy outcome.

Study design, size, duration: This is a cohort study of 90 women with recurrent implantation failure (RIF) who had an endometrial biopsy during the mid-lutheal phase and live birth or miscarriage after in-vitro fertilization (IVF) within 14 months of biopsy. We used immunohistochemical (IHC) biomarkers, p16 and p21, to identify senescent endometrial stromal and epithelial cells.

Participants/materials, setting, methods: Our study was performed at Nadezhda Women's Health Hospital, Bulgaria. Patient biopsies with known pregnancy outcome were retrieved from our tissue bank. IHC staining for senescence with antibodies do detect p16-positive and p21-positive cells was used to search for biomarkers that differentiated women who had a miscarriage (Group1, n=45) from those who had a successful pregnancy (Group2, n=45). The percentage of senescent cells was calculated after enumeration by two independent investigators in multiple endometrial sections.

Main results and the role of chance: The studied senescent markers p21 and p16 were expressed in the endometrial tissue samples of all patients with a relatively high variability in the percentage of p21-positive and p16-positive cells. The mean percentage of p16-positive cells was significantly higher in all tissue compartments compared to the percentage of p21-positive cells (3.91% vs. 0.01% stromal cells, 3.18% vs. 2.17% glandular cells, 32.46% vs. 11.23% luminal cells, respectively, $p<0.05$).

The performed t-test showed that there was no significant difference in female patient's age and blastocyst quality between the studied patient groups ($P<0.05$, Student t-test). The percentages of p21-positive cells in endometrial stroma, glands and luminal epithelium and those of p16-positive cells in glands and luminal epithelium were also not significantly different between women with miscarriage and live birth ($P>0.05$). However, the mean percentage of p16-positive stromal cells was significantly lower in women with miscarriage compared to patients with live birth (2.4% vs. 5.3%, respectively, $P=0.04$).

Limitations, reasons for caution: The study cohort was limited in sample size. Not all confounding factors such as potential immunological and genetic reasons for miscarriage have been taken into account. In addition, the endometrial biopsy could also have an effect on pregnancy outcome.

Wider implications of the findings: This work marked differences in the percentage of certain types of senescent endometrial cells (p16-positive stromal cells) in relation to the pregnancy outcome. These findings emphasize the essential impact of cell senescence in human endometrium on the normal course of pregnancy and potential complications.

Trial registration number: Not applicable.

P-309 Follicle-stimulating hormone (FSH) induces apoptosis in endometrial cells. Luteinizing hormone (LH) activity prevents this effect

S. Sacchi[1], E. Cuttone[1], C. Addabbo[1], P. Sena[2], A. La Marca[1]

[1]*University of Modena and Reggio Emilia, Mother-Infant Department, Modena, Italy*

[2]*University of Modena and Reggio Emilia, Department of Biomedical- Metabolic and Neural Sciences, Modena, Italy*

Study question: Are the exogenous gonadotrophins follicle-stimulating hormone (FSH), luteinizing hormone (LH) and human chorionic gonadotrophin (hCG) able to alter the physiology of endometrial cells?

Summary answer: Different exogenous gonadotrophins specifically affect endometrial cell viability differently: FSH promotes autophagy and apoptosis while LH and hCG alone or combined with rhFSH does not.

What is known already: Within ovary, FSH induces autophagy and apoptosis of granulosa cells leading to atresia of non-growing follicles, whereas LH has documented anti-apoptotic functions. Endometrial cells express functioning gonadotrophin receptors (FSH receptor, FSHR; LH/hCG receptor, LHCGR). Physiological cross-talk between autophagy and apoptosis has been reported in decidualized endometrial cells in late secretory phase of the menstrual cycle.

Study design, size, duration: Endometrium sample biopsies were collected during the proliferative phase of the menstrual cycle from healthy patients undergoing diagnostic hysteroscopy, dissected in smaller pieces then cultured

for 24 hours to avoid side effects due to previous surgery. Primary cultured endometria were then treated for further 48 or 72 hours with supraphysiological doses (100 ng/ml) of FSH, LH or HCG alone or combined. Controls omitted gonadotrophins.

Participants/materials, setting, methods: Endometrium tissue cultures were adopted as experimental model. Controls and gonadotrophin-treated biopsies were paraformaldehyde-fixed or processed for total RNA extraction. Immunohistochemistry was performed using anti-microtubule-associated proteins 1A/1B light chain 3B (MAP1LC3B, autophagy marker) and anti-apoptotic protease activating factor 1 (APAF1, apoptosis marker) primary antibodies. Expression of *aromatase* (positive control of treatments), *hypoxia-inducible factor 1-alpha*, *MAP1LC3B*, *epiregulin* (anti-apoptotic), *FAS receptor* (pro-apoptotic) normalized by *β-actin* as reference gene, was evaluated by RT-qPCR. Reactions were repeated in triplicate.

Main results and the role of chance: Supraphysiological doses of FSH impairs the endometrial receptivity during the embryo window of implantation by promoting endometrial cells death. FSH induces primarily autophagy (48 hours) which triggers apoptosis with cross-talk mechanism in longer incubation (72 hours). FSH increases the relative expression of *MAP1LC3B* assumed as autophagy marker as well as the pro-apoptotic gene *FAS receptor* and the protein APAF1. LH/hCG alone or combined with FSH prevents autophagy and apoptosis by inducing the anti-apoptotic gene *epiregulin*. Culture conditions were investigated for effectiveness of treatments (positive controls) and hypoxia. Results were supported by both immunohistochemistry and RT-qPCR. Statistical analysis was performed with Kruskal-Wallis test followed by the Dunn-Bonferroni's test ($P<0.005$).

Limitations, reasons for caution: This study was conducted only *in vitro*. Results obtained should be confirmed *in vivo* in the context of the whole human endometrial tissue and hormonal milieu. Indirect effects of activated gonadotrophin receptors on genes transcription, that lead to the overlap of autophagy and apoptosis signalling pathways are actually under study.

Wider implications of the findings: This study demonstrates that supraphysiological doses of gonadotrophin FSH impairs the endometrial cell viability, promoting anticipated physiological cell death. These effects are prevented/inhibited by LH/hCG

Trial registration number: Not applicable

P-310 Obstetrical and neonatal outcomes for Fresh versus Frozen-thrawed embryo transfer in women with endometriosis

L. Sebbag[1], M. Bourdon[1], C. Maignien[1], L. Marcellin[1], P. Santulli[1], C. Chapron[1]

[1] *Hôpital Cochin, Ile de France, Paris, France*

Study question: Does the frozen embryo transfer (ET) affect obstetrical and neonatal outcomes compared to fresh ET in endometriosis pregnant women after In Vitro Fertilization (IVF) ?

Summary answer: Endometriosis-women who conceive after frozen-ET have increased risk of induced labor, caesarian and post-term delivery but lower risk of low birth weight compared to fresh-ET.

What is known already: In endometriosis, it is known that there are endometrial local modifications, apart from any ovarian stimulation. Furthermore, there is accumulating evidence suggesting that obstetrical complications may originate from local disturbances occurring at the time of implantation. Indeed, after IVF, obstetrical and neonatal outcomes seem modified by the type of embryo transfer –in frozen cycles, the endometrial environment during the implantation window is probably modulate thanks to the absence of ovarian stimulation contrary to the fresh ET.

In the specific population of endometriosis women, no data are available concerning neonatal outcomes according to the type of transfer.

Study design, size, duration: An observational cohort study in a tertiary care university hospital was conducted between march 2010 and June 2017. Endometriosis infertile women achieving IVF singleton pregnancies progressing beyond 12 weeks' gestation were included. The diagnosis of endometriosis was based on published imaging criteria (transvaginal sonography or magnetic resonance imaging) or on histology for patients with a previous history of endometriosis surgery. Pregnancies obtained after a frozen ET were compared to those obtained after a fresh ET.

Participants/materials, setting, methods: A total of 339 pregnant women were allocated to two groups according to the type of ET performed to obtain the pregnancy: The Fresh ET group (n=112) and the frozen ET group (n=227). Main outcomes were the birth weight and the rate of low birth weight (<2500g). Secondary analyses were performed for the most common obstetrical and neonatal complications. Statistical analyses were conducted using univariate and multivariate logistic regression models.

Main results and the role of chance: Among included women, 109/112 (97.3%) and 222/227 (98.2%) women had a delivery of a live child after 24 weeks in fresh and frozen ET groups respectively (p=0.526). The mean birth weight was similar in the two study groups after univariate (3181,09 ± 572,28 and 3249,01 ± 519,59, respectively, p = 0.117) and multivariate analysis (p=0,578). Risk of low birth weight was significantly lower in the frozen ET compared to the Fresh ET group after multivariate analysis (OR 0,185 CI95% [0,040-0,856], p= 0,031). However, the rate of labor induction (93/222 (41,9%) and 20/109 (18,3%), p<0,001) and caesarian section (93/222 (41,9%) and 28/109 (25,7%), p=0.004) was increased in frozen ET group, compared to the fresh ET group after univariate and multivariate analysis (OR 6,9 CI95% [2,47-19,3], p<0,001 and OR1,9 CI95% [0,12-3,19], p=0,017 respectively). The rate of post term birth (>41 weeks) was also significantly higher after multivariate analysis in the Frozen ET group (OR 2,0 CI95% [1,0-4,1], p=0,042). The incidence of hypertensive disorders, gestational diabetes antepartum and post-partum hemorrhage, preterm rupture of membranes and neonatal problems did not differ between groups.

Limitations, reasons for caution: One limitation is linked to the observational design of this study: confounders cannot be totally excluded. In addition, women in whom the diagnosis of endometriosis was based on imaging are possibly not as accurately phenotyped as those who had surgery.

Wider implications of the findings: Our results suggest that in endometriosis infertile women, perinatal outcomes are negatively affected by ovarian stimulation associated with a fresh ET but also by the vitrification process in case of frozen ET.

Trial registration number: NA

P-311 IL-10-IL-10R pathway promotes angiogenesis in the development of endometriosis

E.M. Tsai[1]

[1] *Graduate Institute of Medicine, College of Medicine, Kaohsiung Medical University*

Study question: Elevated IL-10 level in endometriotic milieus has been considered as a critical factor in endometriosis; however, the detail mechanism and causal relationship remain unclear.

Summary answer: This study provides a scientific basis for potential therapeutic strategy targeting IL-10-IL-10R pathway in endometriotic milieu

What is known already: Elevated IL-10 level in endometriotic milieus has been considered as a factor in endometriosis

Study design, size, duration: A surgical endometriosis murine model and IL-10 knockout mice (IL-$10^{-/-}$) were used to elucidate the role of IL-10 in the early development of endometriosis.

Participants/materials, setting, methods: Standardized *in vitro* and *in vivo* assays were used to analyze the angiogenic activity of IL-10, including transwell migration, tube formation assay, *in vivo* matrigel plug assay and zebra fish model.

Main results and the role of chance: In a murine model, exogenous recombinant IL-10 (rIL-10) local treatment on the day of surgery significantly enhanced endometriotic lesion growth and angiogenesis, whereas blocking local IL-10 activity using mAb suppressed those effects. Adoptive transfer of IL-10-deficient plasmacytoid dendritic cells (pDCs) into mice significantly inhibited lesion development. *In vitro* analyses demonstrated that IL-10-IL-10R pathway stimulated the migratory and tube formation ability in human umbilical vein endothelial cells (HUVECs) as well as ectopic endometrial stem cells (ENMSCs), at least in part, in a vascular endothelial growth factor-dependent pathway. We also found that rIL-10 directly stimulated angiogenesis using matrigel plug assay as well as zebra fish model. Pathological results from human endometrioma tissues also showed the increased infiltration of $CD123^+$ pDCs and higher percentages of $IL\text{-}10R^+$ and $CD31^+$ cells compared to the corresponding normal counterparts. These results show that IL-10 secreted

from local pDCs promotes endometriosis development through pathological angiogenesis in the early stage.
Limitations, reasons for caution: Most studies are conducted in the animal model, the clinical interpretation needs further investigation
Wider implications of the findings: IL-10-IL-10R pathway can provide a novel therapeutic target for endometriosis.
Trial registration number: None

P-312 Identification of involvement of developmental, metabolic and nervous systems in endometriosis by network-based bioinformatics analysis of HOX genes and their related genes

F. Chitsazian[1], R. Favaedi[1], M. Golestan jahromi[2], M. Bazrgar[1], R. Aflatoonian[3], A. Aflatoonian[4], P. Afsharian[1], M. Shahhoseini[1]
[1]Reproductive Biomedicine Research Center- Royan Institute for Reproductive Biomedicine- ACECR- Tehran- Iran, Department of Genetics, Tehran, Iran
[2]Reproductive Biomedicine Research Center- Royan Institute for Reproductive Biomedicine- ACECR- Tehran- Iran, Department of Genetics, Tehrani, Iran
[3]Reproductive Biomedicine Research Center- Royan Institute for Reproductive Biomedicine- ACECR- Tehran- Iran, Department of Endocrinology and Female Infertility, Tehran, Iran
[4]Yazd Reproductive Sciences Institute- Shahid Sadoughi University of Medical Scienses- Yazd- Iran, Research and Clinical Center for Infertility, Tehran, Iran

Study question: Which genes and gene networks contribute to endometriosis in eutopic and ectopic lesions and what role do they play in the pathogenesis of this disease?
Summary answer: Some networks were identified that involved in development processes especially skeletal system in ectopic and eutopic tissues and in nervous system in eutopic tissues.
What is known already: Endometriosis is a complex gynecologic disorder that affects as many as 10-15% of premenopausal women. The pathogenesis of endometriosis, as the presence of endometrium-like tissue outside the uterine cavity, is largely unknown. *HOX* genes, encoding homeodomain transcription factors, are dynamically expressed in endometrium, where they are necessary for endometrial growth, differentiation, and implantation. Some studies on *HOX* genes and other genes have shown that dysregulation of some of them such as *HOXA10* are important for the development of endometriosis. But few investigations have studied in this vast range of *HOX* family genes and with a network-based view.
Study design, size, duration: Fifteen samples of eutopic and ectopic endometrium collected from patients in proliferation phase. Five tissue samples in each ectopic, eutopic and normal group were pooled as three biological repeats, and all following analyses were performed on the nine sample groups. To minimize the genetic heterogeneity, the same patients provided both eutopic and ectopic endometrium. Fifteen control individuals who underwent diagnostic laparoscopy participated in this study as control group.
Participants/materials, setting, methods: PCR array was performed for 84 *HOX* genes and their related genes. The statistical significance was determined using t-test. PCA and Hierarchical clustering were carried out between different groups. The genes co-expression networks were constructed based on correlation between normalized gene expression data. Gene function was annotated based on Gene Ontology, the intervention in other diseases and expression in other tissues using the DAVID to clarify the function of important genes and mechanism of endometriosis.
Main results and the role of chance: Among the analyzed genes, 33.33% (28) genes had no significant alteration in none of the patient samples. The expression levels of 33 and 44 genes were significantly altered in eutopic and ectopic samples, respectively. PCA and hierarchical clustering analyses were performed using the normalized expression data of the DEGs (Differentially Expressed Genes) and non-DEGs. These analyzes of the DEGs revealed three distinct clusters of eutopic, ectopic and normal samples and the analyzes of the non-DEGs didn't separated precisely these three groups.

Five co-expression networks were constructed based on gene expression data. DEGs in diseased tissues were significantly abundant in the network B2, especially DEGs in the ectopic tissues(73.1%).

Many DEGs in ectopic tissues play a role in developmental diseases class, such as cleft lip and metabolic diseases class like bone mineral density. The most DEGs in the eutopic and ectopic tissues, and genes of networks A, D, C, B1 and B2, other than the PDHX gene in network B2, were involved in the development or morphogenesis of various systems, especially skeletal system. Also, most genes in network D play roles in the development of the nervous system. Most genes in each network were expressed in one or two tissues.
Limitations, reasons for caution: It would be interesting that more patient samples could be collected with more accurate phenotypic data in order to more precisely evaluate the relationship between phenotype and genotype. This helps in identifying the pathogenesis of the disease.
Wider implications of the findings: Non-DEGs that connected to many DEGs in networks are likely effective in development of endometriosis but their expression has not been significantly altered. More experimental researches such as epigenetic studies and investigations of the genes in many patients can determine the effect of the non-DEGs in the development of endometriosis.
Trial registration number: not applicable

P-313 Evidence synthesis on the effectiveness of endometrial scratching - where did we go wrong?

W. Li[1], S. Suke[1], R. Wang[2], B. Mol[1]
[1]Monash University, Department of Obstetrics and Gynecology, Melbourne, Australia
[2]The University of Adelaide, Robinson Institute, Adelaide, Australia

Study question: Why meta-analyses on endometrial scratching prior to IVF or IUI suggested that the treatment is effective while we know now that it is not?
Summary answer: Meta-analyses suggesting endometrium scratching is effective are erroneous because of the overall low quality of included studies.
What is known already: The Cochrane Review on endometrial scratching in IVF published in 2015 reported that moderate-quality evidence suggested a beneficiary effect of endometrial injury on live birth or ongoing pregnancy (RR 1.42, 95% CI 1.08 to 1.85). The Cochrane review on endometrial scratching before IUI or sexual intercourse published in 2016 reported that very low quality evidence suggested a positive association between endometrial injury and live birth or ongoing pregnancy (RR 2.22, 95% CI 1.56 to 3.15). However, well designed and powered RCTs, including a recent study with 1300 women (Lensen et al., 2019), indicated that endometrial scratching is not effective.
Study design, size, duration: We analyzed the quality of RCTs included in two Cochrane Reviews investigating the effectiveness of endometrial scratching in IVF and IUI or sexual intercourse (Nastri et al., 2015; Lensen et al., 2016). We identified 18 RCTs with full text from these Cochrane Reviews (11 on endometrial scratching in IVF, 7 on endometrial scratching in IUI /sexual intercourse).
Participants/materials, setting, methods: We assessed the RCTs on the following criteria:

1. inadequate trial registration (no registration, registered during or after recruitment);
2. problematic randomization as assessed by the low probability of random sampling for baseline variables using Monte Carlo simulations;
3. possible inadequate data handling as indicated by the violation of Benford-Newcomb's law for the distribution of first leading digits;
4. low quality of statistical analysis (critical concerns about statistical methods description and not repeatable univariable statistical analysis using summary statistics).

Main results and the role of chance: There were only 3 (17%) out of 18 RCTs with adequate registration. The numbers of RCTs with no registration and late or retrospective registration were 7 (39%) and 8 (44%), respectively. There were 3 (17%) RCTs with possible problematic randomization as assessed from the baseline data, while the distribution of first leading digits of all numbers violated Benford-Newcomb's law in 7 (39%) RCTs. In total, 7 (39%) RCTs had critical issues in terms of the description of statistical methods. There were 12 (67%) and 9 (50%) RCTs that had not repeatable statistical tests for continuous and categorical baseline variables respectively. The statistical results

of outcome(s) were not repeatable in 12 (67%) RCTs. Overall, no RCTs were without any concerns.

Limitations, reasons for caution: Monte Carlo simulations tend to be stricter in RCTs using block randomization. Using Benford-Newcomb's law to examine the distribution of first leading digits has a high sensitivity but low specificity in detecting inadequate data handling. For statistical assessment, we could only use summary statistics but not individual participant data.

Wider implications of the findings: The initial promising reports on the effectiveness of endometrial scratching are misleading due to the low quality of the initial RCTs, which could not be identified by the conventional risk of bias assessments. Rigorous evidence synthesis incorporating RCTs of low quality cannot overcome bias from uncontrolled or poorly conducted studies.

Trial registration number: Not applicable.

P-314 Epigenetic Aberration of E-Cadherin Gene (CDH1) in Eutopic and Ectopic endometrium of Endometriosis Patients

A. Poursadoughian Yaran[1], E. Rastegari[1], R. Aflatoonian[2], P. Afsharian[1], M. Shahhoseini[1]

[1]*Reproductive Biomedicine Research Center- Royan Institute for Reproductive Biomedicine- ACECR, Department of Genetics, Tehran, Iran*

[2]*Reproductive Biomedicine Research Center- Royan Institute for Reproductive Biomedicine- ACECR, Department of Endocrinology and Female Infertility, Tehran, Iran*

Study question: Is there any alterations in expression and epigenetic profiles of *E-Cadherin* in eutopic and ectopic tissues of women with endometriosis?

Summary answer: *CDH1* is down-regulated in ectopic endometrial tissues through hyper methylation and hypo acetylation of histone H3 in its promoter region.

What is known already: Endometriosis is defined as the presence of endometrial-like tissue outside the uterine cavity. There is evidence that endometriotic cells have behavior same as cancer cells. In addition, cell-culture studies of epithelial endometriotic and carcinoma cells indicated that both cell types have the ability to invade collagen gels, and this ability is associated with the absence of the intercellular adhesion molecules. One major member of the classical cadherin family is epithelial (E)-cadherin which plays an important role in cell-cell adhesion. On the other hand, accumulating evidence suggests that endometriosis may be an epigenetic disease.

Study design, size, duration: In this case-control study, patients with endometriosis (n = 36) and healthy fertile women (n = 21) were included in the study. Ectopic biopsies were obtained by laparoscopic procedure and eutopic and control biopsies were gained with Pipelle. Women with other uterine abnormalities were excluded. Informed written consent was obtained from all women according to local ethical approval.

Participants/materials, setting, methods: The expression level of *CDH1* gene was evaluated in eutopic, ectopic and normal endometrium during the menstrual cycle by the use of quantitative real-time (qRT)-PCR. Also, Chromatin Immunoprecipitation (ChIP) coupled with real-time PCR was used to determine the epigenetic modifications on the regulatory region of *CDH1* gene. All data were analyzed using One-Way ANOVA and the Tukey's test.

Main results and the role of chance: *CDH1* gene expression in endometriotic samples was significantly lower than normal endometrium. In addition, the expression level of *CDH1* in normal endometrium was significantly lower during proliferative phase *vs.* secretory phase. Otherwise, epigenetic analysis data showed hypoacetylation and hypermethylation of *CDH1* promoter in endometriotic samples *vs.* control.

Limitations, reasons for caution: For getting more evidence, we need a large number of patients and control groups to examine *CDH1* gene also to evaluate expression of other related genes. Moreover, other Epigenetic studies such as DNA methylation of *CDH1* promoter region are suggested.

Wider implications of the findings: Our study declared that epigenetic modifications in *CDH1* promoter cause to significant down-regulation of *CDH1* gene in ectopic tissues, which lead to invasion in endometriosis lesions.

Trial registration number: not applicable

P-315 Inhibition of KIF20A reduces endometriosis implants in a randomized xenograft mouse model

H. Ferrero[1,2], A. Corachán[1,3], A. Quiñonero[1], C. Bougeret[4], A. Pellicer[1,3], F. Dominguez[1,5]

[1]*IVI Foundation, Innovation, Valencia, Spain*

[2]*INCLIVA, Biomedical Research Institute, Valencia, Spain*

[3]*University of Valencia, Department of Pediatrics- Obstetrics and Gynecology-, Valencia, Spain*

[4]*BIOKINESIS, Biokinesis, París, France*

[5]*IIS la Fe, Health Research Institute, Valencia, Spain*

Study question: To assess effects of *KIF20A* inhibition by BKS0349, a high-affinity new inhibitor derived from Paprotrain, in endometriotic lesions generated in an endometriosis xenograft mouse model.

Summary answer: *KIF20A* inhibition by BKS0349 decrease cell proliferation, induces cell cycle arrest and promotes apoptosis of endometriotic lesions, reducing their size in a xenograft mouse model.

What is known already: Several studies have reported that ovarian endometriotic may be the origin of ovarian carcinoma or ovarian endometrioid cancer types, suggesting a possible etiological association between endometriosis and ovarian cancer. In this regard, accumulating evidence has shown that ectopic *KIF20A* overexpression might confer malignant phenotype to ovarian tumors by promoting cell proliferation and inhibiting apoptosis. In addition, it has been reported that *KIF20A* downregulation inhibits cell proliferation, induces cell cycle arrest in G0/G1 phase, and promotes apoptosis, proposing *KIF20A* as a therapeutic target for numerous tumors. However, to date, no data about the role of *KIF20A* in endometriosis has been described.

Study design, size, duration: This is a prospective study in which human endometrial biopsies (n=4) were transfected by mCherry adenovirus and intraperitoneally implanted in mice, generating a xenograft mouse model of endometriosis. Female mice were divided in Vehicle group (n=8), BKS0349 group (n=8) and Cabergoline (positive control) group (n=8). Vehicle and BKS0349 were administrated once a week and Cabergoline was orally administrated every day for 21 days. Mice were sacrificed 72 hours after last administration.

Participants/materials, setting, methods: Human endometrial tissue was obtained from egg donor women at the time of oocyte retrieval procedure. mCherry adenovirus was used to label endometrial tissue. mCherry-labeled endometriotic lesions were introduced in 6-week-old athymic nude female mice and monitored over time using IVIS Spectrum Preclinical *in vivo* Imaging System. Cellular proliferation was assessed by immunohistochemistry for Ki67 and apoptosis was evaluated with TUNEL staining. *CCND1* gene expression was measured by qRT-PCR using StepOnePlus System.

Main results and the role of chance: A significant reduction in fluorescent signal was observed 72 hours after treatment end (D24) for BKS0349 group (*p*-value=0.0313) and from D14 for Cb2 group (*p*-value=0.0313 on D14-21; *p*-value=0.0156 on D24) compared to D0, while this reduction was not highly pronounced in control group. In addition, fluorescent signal on D24 showed a significant decrease in BKS0349 group compared to control group (40% ± 19.3 vs. 81% ± 30.7; *p*-value=0.0303), according with significant size reduction of endometriotic lesions observed in BKS0349 group (0.073mm^2 ± 0.022; *p*-value=0.0006) compared to control group (0.128 mm^2 ± 0.019) at the end of the experiment. Functional studies showed significant reduction of proliferating cells in BKS0349 group compared to control group (3.5% ± 3.4 vs 9.2% ± 3.8; *p*-value=0.0082), which was even more pronounced than our positive control group (Cb2) (5.7% ± 5.8). In addition, C*CND1* expression was decreased in BKS0349 group compared to control group (Fold Change=0.259; *p*-value=0.049). Finally, while endometriotic lesions in control group were practically absent of apoptotic cells (25.48% ± 13.3), an increase of apoptotic cells in endometriotic lesions from BKS0349 (39.73% ± 22.95) and Cb2 (37.7% ± 24.87) group was observed, being statistically significant in animals treated with the *KIF20A* inhibitor, BKS0349 (*p*-value=0.0317).

Limitations, reasons for caution: Results obtained in this mouse model of endometriosis could not be directly assumed in humans due to the phylogenetic distance with mouse.

Wider implications of the findings: KIF20A inhibition by BKS0349 induces apoptosis and inhibits cell proliferation by cell cycle arrest in G0/G1 phase and consequently reduces endometriotic lesions size. This suggest that KIF20A could

be used as a novel therapeutic treatment for endometriosis due to its important role in cell cycle regulation and apoptosis.
Trial registration number: NA

P-316 A 3D culture system to study early stages of endometriosis

A. Stejskalova[1], L. Kiesel[1], M. Götte[1]
[1]Münster University Hospital, Department of Gynecology and Obstetrics, Münster/Westf., Germany

Study question: Is it possible to study early stages involved in the establishment of new endometriotic lesions in vitro?
Summary answer: The 3D culture based model system is suitable to study extracellular matrix remodeling and different forms of invasive growth, including mesenchymal and epithelial sheet-like migration.
What is known already: Early studies suggested endometrial cells are highly invasive. However, another recent study suggested that an ectopic-lesion derived lesion does only form small spheroids on top of Matrigel and does not invade the hydrogel. One approach to evaluate invasive behaviour in a more robust and reproducible manner is to use spheroids containing 5,000-20,000 cells. This approach additionally provides more insight into the mechanism by which the cells migrate and is routinely used in cancer research. Moreover, it has been recently demonstrated that such spheroids mimic several aspects of endometriosis better than single cells, partially also because these cells experience hypoxia.
Study design, size, duration: Experimental in vitro study using immortalized endometriotic epithelial (12Z), immortalized endometrial stroma (ST-T1b) and primary endometriotic stroma cells (N= 20,000 cells/culture) cultured in collagen type I or basement-membrane-like Matrigel matrices after formation of spheroids using the hanging drop method for 4 days. Experiments were replicated at least 3 times.
Participants/materials, setting, methods: Cell spheroids formed by the hanging drop method were placed on 3mg/ml collagen type I or Matrigel and their growth and invasive behaviour was monitored on days 1, 3, 5 and 7 using microscopy. qPCR for markers of epithelial-to-mesenchymal transition was used to evaluate matrix-dependent differences in cellular phenotype. A range of inhibitors (Rac, ROCK, MMP, miR-200b, miR-145) was assessed with regard to their migration/invasion modulatory effect.
Main results and the role of chance:
Our study revealed that all the studied cell types were able to form spheroids. Statistical analysis showed that the spheroids formed by 12z cells are bigger and thus likely less compact compared to the other cell types ($p<0.05$). Surprisingly, while both the primary cells and St-t1b cells have stromal cell morphology, they exhibited differing characteristics when placed on Matrigel. While the St-t1b cells did not migrate on Matrigel, 12z cells and primary ectopic lesion-derived cells were spreading on this hydrogel. On the other hand, when placed on collagen, both primary cells and St-t1b cells migrated on the material, frequently forming holes in the material. This process could be slowed down or abrogated using Rac and MMP inhibitor in St-t1b cells, but not by the ROCK inhibitor. The 12z cells on collagen exhibited sheet-like collective migration that was not affected by any of these inhibitors.
Limitations, reasons for caution: The use of immortalized cell linesis a limitation of the study, as is the study of singular cell types compared to the more complex in vivo environment. While collagen I and matrigel are representative of interstitial matrices and basement-membrane-like matrices, respectively, the extracellular matrix in vivo is more complex.
Wider implications of the findings: Diseased and healthy cells have a different phenotype with regards to their interaction with extracellular matrix components, which may contribute to their increased migratory potential. Our results suggest that all studied cell types thrive on collagen I, suggesting scar tissue might be especially prone to the attack by endometrial cells.
Trial registration number: not applicable

P-317 Presence of Focal adenomyosis based on MRI is associated with presentation for infertility

J. Cormier[1], M. Bourdon[1], C. Maignien[1], K. Pocate-Cheriet[2], L. Marcellin[1], C. Chapron[1], P. Santulli[1]
[1]Service de Gynécologie Obstétrique II and Reproductive Medicine Professor Chapron, Université Paris Descartes- Faculté de Médecine- Assistance Publique - Hôpitaux de Paris AP-HP, Paris, France
[2]Service d'Histologie-Embryologie and Reproductive Medicine, Faculté de Médecine- Assistance Publique - Hôpitaux de Paris AP-HP, Paris, France

Study question: Is there an association between the adenomyosis appearance (focal or diffuse) by magnetic resonance imaging (MRI) and presentation with infertility?
Summary answer: In a population of operated patients, presenting adenomyosis on MRI, focal adenomyosis was identified as a risk factor for infertility.
What is known already: Uterine adenomyosis is characterized by the presence of endometrial glands and stroma deep within the myometrium. Various forms have been described including Focal adenomyosis (Foc-ADE), which corresponds to well-circumscribed nodular lesions within the myometrium and Diffuse adenomyosis (Dif-ADE) characterized by endometrial implants scattered throughout the myometrium. Although adenomyosis pathophysiology is not clearly understood, several evidences suggest that those two forms could be considered as two distinct entities. This disease exhibits various clinical presentations, notably infertility but reasons for reproduction impairment are still unknown. The role that play one or other of the adenomyosis forms on infertility must be explore.
Study design, size, duration: This was an observational study using data prospectively collected in all non-pregnant patients aged between 18 and 42 years, surgically explored for benign gynaecological conditions at our institution between May 2005 and May 2018. For each patient, a standardized questionnaire was completed during face-to-face interview conducted by the surgeon during the month preceding surgery. Only women with a uterine MRIs performed by one senior radiologist during the preoperative work-up were retained for this study.
Participants/materials, setting, methods: MRI was performed in 496 women operated in our center for a benign gynaecological disease. Among them, 248 women have a radiological diagnosis of adenomyosis. According to MRI findings, women were diagnosed for Foc-ADE and/or Dif-ADE forms. Of them, two groups were compared: the infertile women (n=75) and the non-infertile women (n=173). Correlations were sought with univariate analysis and a multiple regression logistic model to determine characteristics of infertile patients compared to adenomyosis non-infertile patients
Main results and the role of chance: In infertile women suffering from adenomyosis, the presence of a focal lesion was significantly more frequent (59/75 (78,7%) versus 111/175 (64,2%); p=0,024) than in non-infertile women. The diffuse form was no more present in infertile than in non-infertile women. Distribution of others benign gynecologic disease, notably endometriosis or leiomyomas was not significantly different between both groups. After a multivariate regression model including women age and endometriosis phenotype, the presence of a Foc-ADE lesion was identified as risk factor for adenomyosis-related infertility: OR= 2.1; 95% CI: 1.1 - 3.9.
Limitations, reasons for caution: Inclusion of only surgical patients may constitute a possible selection bias. In addition, it cannot be excluded that other non–explored causes of infertility are present in infertile women.
Wider implications of the findings: In women presenting adenomyosis, the practitioner should perform an appropriate imaging work-up to plan the strategy of patient management in the setting of infertility.
Trial registration number: none

P-318 Impact of extra-ovarian deep endometriosis surgery on AMH, a prospective study

C. Calabre[1], E. Faller[2], F. Lefebvre[3], C. Rongières[1]
[1]CMCO Schiltigheim, Strasbourg fertility unit- CMCO, Schiltigheim, France
[2]University Hospitals of Strasbourg- Hautepierre, Gynaecological surgery, Strasbourg, France
[3]University Hospitals of Strasbourg, Division of Public Health- Methodology and Biostatistics, Strasbourg, France

Study question: Does the surgery of extra-ovarian deep endometriosis have an impact on AMH level at 6 and 12 months after surgery?
Summary answer: AMH level decrease 6 and 12 months after surgery of extra-ovarian endometriosis.

What is known already: Deep endometriosis is a usual gynaecologic disease, affecting women of reproductive age. The first-line surgical treatment of endometrioma is cystectomy but several studies show a decreasing AMH level after surgery, which is a hormone representing ovarian reserve. However, up to date, no study concerning AMH level after extra-ovarian deep endometriosis surgery has been published.

Study design, size, duration: Prospective single-center study comparing the variation in the AMH serum 6 and 12 months after surgery of deep endometriosis isolated (Group A) with deep endometriosis surgery associated with endometrioma's cystectomy (Group B) , in Gynaecological surgery departments of the University Hospital of Strasbourg (HUS), Francebetween June 2015 and March 2018. An AMH sample was collected at the HUS the day before or the day of the surgery, 6 months and 12 months after surgery

Participants/materials, setting, methods: 101 patients were included after exclusion of hysterectomy, adnexectomy or no deep surgery, 53 in the group A and 48 in the group B. Up this day, 29 AMH serum are available at 12 months in the group A and 20 in the group B. Primary outcome was the variation in the AMH level 12 months after surgery, secondary outcomes were pregnancy rate after surgery and variation in the AMH serum at 6 months

Main results and the role of chance: Patients in group A had a significantly decreasing AMH level of 1.07 ng/mL 12 months after surgery p: 0.00481 and patients in group B had a significantly decreasing AMH level of 1.37 ng/mL 12 months after surgery p: 0.00289, but no difference was founded between group A and B p :0.60.

Patients in group A had a significantly decreasing AMH serum of 0.85 ng/mL 6 months after surgery p: 0.00245 and patients in group B had a significantly decreasing AMH serum of 1.14 ng/mL 6 months after surgery p: 0.00022, but no difference was founded between group A and B p :0.47.

Type of surgery and AFS scale doesn't seem to have an impact on the AMH level's change.

However, in patients reporting preoperative infertility, we found pregnancy rates of 44 % in group A and 61 % in group B 1 year after surgery.

Limitations, reasons for caution: Final results of our study should be available in March 2019. Many patients were lost to follow-up during the study because all the samples were analysed in the same laboratory to limit AMH variation due to different laboratories, and some patients couldn't come 6 and 12 months after surgery.

Wider implications of the findings: the surgery of deep endometriosis seems to reduce AMH level 12 months after surgery even if endometrioma's cystectomy is not performed but pregnancy rate one year after surgery is encouraging.

Trial registration number: NCT02400684

P-319 Antibacterial and antifungal activity of the human endometrial fluid during the natural cycle

M.B. Prieto Molano[1], M. Bregon[2], D. Moragues[2], M. Azkargorta[3], M. Diez-Zapirain[1], M. Iglesias[1], A. Exposito[1], F. Elortza[3], R. Matorras[1]

[1] *Cruces University Hospital, Human Reproduction Unit, Barakaldo, Spain*
[2] *Faculty of Medicine and Nursing, Department of Nursing, Leioa, Spain*
[3] *CIC bioGune, Proteomics Platform, Derio, Spain*

Study question: What is the antibacterial protein content of human endometrial fluid aspirate (EFA) in IVF cycles?

Summary answer: Human endometrial fluid aspirate shows an antimicrobial activity that was always present against *S. aureus* and against *Candida spp.*, *S. agalactiae* and *E. faecalis*

What is known already: The role of uterine microbiota is not well understood. Some microbiota patterns have been associated with favorable IVF prognosis and others with some pathological conditions. On the other hand, the endometrial fluid aspirate (EFA) contains antibacterial proteins that are enriched in implantative IVF cycles. However, the antimicrobial effect of raw EFA, where interactions among different regulating factors are plausible, has not been addressed. Moreover, the possible modifications over the natural cycle have not been analyzed.

Study design, size, duration: During a 3 month period, 38 women were recruited for the analytical study. The study was approved by our Institutional Ethical and Investigation Board (CEIC code 11/45)

Participants/materials, setting, methods: EFA was obtained by means of an embryo transfer catheter, under ultrasound guidance in 38 healthy women, aged between 18- 40 years, with regular cycles. EFA was tested against 9 different microorganisms

Main results and the role of chance: All the tested samples exhibited antibacterial activity against *Staphylococcus aureus*. Apart from inhibiting *S. aureus*, 32.4% of EFA were active against only one of the remaining microorganisms assayed, 16.2% against two of them, and 5.4% against four microorganisms. Concerning other microorganisms (*Candida albicans*, *Candida glabrata*, *Candida krusei*, *Streptococcus agalactiae*, *Enterococcus faecalis*) the antibacterial activity was present in 10.8-24.3% of EFA. On the other hand, none exhibited antibacterial activity against *Escherichia coli* or *Klebsiella pneumoniae*. The intensity of antimicrobial activity differs considerably among EFA samples, and we failed to observe a cycle related pattern for antimicrobial activity.

Limitations, reasons for caution: This is the first report on the direct antimicrobial activity of EFA samples from healthy women. Further studies are warranted to characterize the endometrial fluid of women undergoing IVF procedures in order to assess if there is a relationship between raw EFA antimicrobial activity and implantation success.

Wider implications of the findings: Endometrial fluid aspirate exhibited antimicrobial activity, which can be described according to two patterns: a pattern common to all the samples and an individualized pattern. Our data suggest that the uterus plays a role controlling the uterine microbiota by means of the endometrial fluid components.

Trial registration number: not applicable.

P-320 Cumulus cells and follicular fluid show alterations in bone morphogenic protein 15 (BMP-15), growth differentiation factor 9 (GDF-9), and oxidative status in patients with endometriosis

H. Ruso[1], D. Dayanir[2], Z. Kalem[1], R. Tural[3], S. Saribas[4], A. Sepici Dincel[5], C. Ozogul[6], T. Gurgan[1]

[1] *Gurgan Clinic Women's Health and IVF Centre, IVF unit, Ankara, Turkey*
[2] *Gazi University- Faculty of Medicine, Histology and Embryology, Ankara, Turkey*
[3] *Sinop University- Vocational School of Health Services, Medical Services and Techniques, Sinop, Turkey*
[4] *Ahi Evran University- School of Medicine, Histology and Embryology, Kirsehir, Turkey*
[5] *Gazi University- Faculty of Medicine, Medical Biochemistry, Ankara, Turkey*
[6] *University of Kyrenia- School of Medicine, Histology and Embryology, Kyrenia, Cyprus*

Study question Is there relationship between oocyte-secreted factors BMP-15 and GDF-9 of cumulus cells and oxidative stress in the follicular fluid in patients with endometriosis.

Summary answer: GDF-9 and BMP-15 levels were decreased in cumulus cells and oxidative stress levels were found to be increased in the follicular fluid of endometriosis patients.

What is known already: Both GDF-9 and BMP-15 are oocyte-secreted factors and belong to the transforming growth factor beta (TGF-β) superfamily. They have pivotal role ranging from follicle maturation, fertilisation, and early embryo development. Oxidative stress, on the other hand, is documented to be present in follicular fluid of endometriosis patients. However, although alterations in GDF-9, BMP-15, and oxidative stress levels are documented in endometriosis, it remains unclear to what extend the combined effects have on clinical outcomes.

Study design, size, duration: This was a prospective study investigating the relationship between GDF-9, BMP-15, and oxidative stress levels of patients with END. The study was approved by the ethical committee of Gazi University Faculty of Medicine and 10 patients with endometriosis(test) and 10 patients with male factor (control) without any documented female factor were recruited between March 2018 and December 2018. Two independent and blinded researchers run the experiments and analysed the data.

Participants/materials, setting, methods: Consented patients with endometriosis(test) and male factor (control) were recruited. Any further experiments were performed at Biochemistry and Histology Departments of Gazi University Faculty of Medicine. Cumulus cells were mechanically dissected, fixed on polylysine processing slides and pre-treated with paraformaldehyde for immunohistochemical assays to analyse GDF-9 and BMP-15. Follicular

fluids (without flushing) were collected during oocyte pick-up, centrifuged and subjected to total antioxidant status (TAS) and total oxidant status (TOS) assays using UV-visible spectrophotometry.

Main results and the role of chance: No significant difference was found in TAS levels of follicular fluid. However, TOS results of follicular fluid of endometriosis (22.527 ± 3,410 vs 10,631 ± 2,150, $p<0.05$) patients were significantly higher than control group. This finding showed increased oxidative stress level was not balanced with an anti-oxidant response in endometriosis group. Irregular cellular lines and nuclear fragmentations were detected in cumulus cells of endometriosis group. Both GDF-9 and BMP-15 markers were detected in cytoplasm of cumulus cells and found to bedecreased in the endometriosis group. Correspondingly, patients with low GDF-9 and BMP-15 findings in cumulus cells had high TOS levels and low TAS levels in follicular fluid. In response to these findings, reduced GDF-9 and BMP-15 expressions in cumulus cells and higher TOS values in follicular fluid of patients diagnosed with endometriosiswere interpreted with decreased long-term developmental potential of oocytes

Limitations, reasons for caution: Both the cumulus cells and follicular fluids were obtained from patients that received gonadotropins. The sample size of the study is small and further studies are required.

Wider implications of the findings: It is clear that GDF-9 and BMP-15 levels show differences in the cumulus cells as well as the TAS levels of the follicular fluid from patients with END. Further studies should be designed to confirm the therapeutic modalities targeting these findings.

Trial registration number: Not applicable

P-321 Transvaginal hydrolaparoscopy versus hysterosalpingography to assess tubal pathology in subfertile women: a randomised controlled trial.

M. Van Kessel[1], R. Tros[2], J. Oosterhuis[3], W. Kuchenbecker[4], S. Van Kuijk[5], M. Bongers[6], B.W. Mol[7], C. Koks[8]

[1]*Medische Spectrum Twente, Gynecology, Enschede, The Netherlands*
[2]*VU medical center, gynecology, Amsterdam, The Netherlands*
[3]*St. Antonius Hospital, gynecology, Nieuwegein, The Netherlands*
[4]*Isala, gynecology, Zwolle, The Netherlands*
[5]*Maastricht University Medical Centre, Department of Clinical Epidemiology and Medical Technology Assessment, Maastricht, The Netherlands*
[6]*Maastricht University Medical Centre, GROW – School for Oncology and Developmental Biology, Maastricht, The Netherlands*
[7]*Monash University, gynecology, Clayton, Australia*
[8]*Maxima Medical Center, gynecology, Veldhoven, The Netherlands*

Study question: What is the cumulative live birth rate after a diagnostic strategy using transvaginal hydrolaparoscopy (THL) compared to hysterosalpingography (HSG) in subfertile women?

Summary answer: In subfertile women, a diagnostic strategy with THL and HSG results in comparable cumulative live birth rates.

What is known already: THL and HSG are safe and feasible diagnostic techniques for testing tubal pathology in subfertile women.

Study design, size, duration: We performed a multicenter randomised non-interiority trial (NTR3462) in 4 teaching hospitals in the Netherlands. After informed consent, women were randomised to a strategy starting with THL or a strategy starting with HSG. While we originally aimed to recruit 1,330 women, the study was halted after randomization of 300 women due to limited funding.

Participants/materials, setting, methods: We studied subfertile women scheduled for tubal patency testing. Women with a positive Chlamydia PCR, prior tubal testing or tubal surgery, retroverted uterus, masses or cysts in the pouch of Douglas, and allergies to iodine or methylene blue were not eligible. The primary outcome of the trial was conception leading to live birth within 24 months after randomisation.

Main results and the role of chance: Between May 2013 and October 2016, we randomly allocated 149 women to THL and 151 women to HSG. Bilateral tubal occlusion was detected in 1 versus 3 women (0.9% versus 2.2%) in the THL group and HSG group respectively, while unilateral tubal occlusion was detected in 7 (6.2%) versus 8 (5.9%) women.

In the THL group, 86 women (63.7%) had a liveborn child within 24 months after randomization compared to 85 women (59.9%) in the HSG group. Time to pregnancy and time to live birth were not statistically different in both groups. Miscarriage occurred in 16 women (11.9%) in the THL group, versus 20 women (14.1%) in the HSG group. Multiple pregnancies occurred in 12 women (8.9%) in the THL group compared to 19 women (13.4%) in the HSG group.

Limitations, reasons for caution: The calculated sample size of 1,330 was not reached, due to lack of funding. Although our data in 300 women suggest superiority of THL over HSG with respect to live birth rates, the non-inferiority limit delta of 6% was not reached and therefore, the results are still inconclusive.

Wider implications of the findings: Both THL and HSG are in terms of safety and pain acceptable methods to test tubal patency. THL gives more information about endometriosis and adhesions than HSG. In this study we found comparable live birth rates and no statistical difference in time to pregnancy.

Trial registration number: NTR3462

P-322 Changes in some transcription factors expression influencing on CD4+ T cells differentiation in endometriosis

Study question: Is there any different in gene expression of transcription factors *c-Maf* , *FOXP3* and *GATA3* in endometrial tissues (ectopic and eutopic) of women with endometriosis?

Summary answer: The gene expression of c-Maf and GATA3 was up-regulated while FOXP3 was down- regulated in women with endometriosis compared to the control group.

What is known already: Endometriosis is a chronic inflammatory disease of women in reproductive age. This disease is one of the most common causes of infertility. Pathogenesis of endometriosis has not been completely understood, however several studies suggest that immunologic alterations contribute in initiation and progression of the endometriosis. One of these alterations is change in different subsets of T cells. Forkhead box P3 (FOXP3) is a master transcription factor of regulatory T cells (Treg), GATA binding protein 3 (GATA3) is a proprietary transcription factor of T helper 2 (Th2) while **c-**Musculoaponeurotic Fibrosarconna (c-Maf) is a transcription factor expressed in Th2, Th17 and Treg.

Study design, size, duration: In this case-control study, 13 women with endometriosis and 13 women without the disease were enrolled after diagnostic laparoscopy. Ectopic endometrial biopsies were obtained through laparoscopic procedure while eutopic endometrial tissues and endometrial samples of controls were obtained by pipelle. Women with any other uterine abnormalities were excluded. Informed consent was obtained from all women according to local ethical approval.

Participants/materials, setting, methods: After endometrial tissues collection, RNA extraction and cDNA synthesis was done. The relative mRNA expressions of *c*-Maf, FOXP3 and GATA3 were studied by quantitatively real-time polymerase chain reaction (real time-PCR). The data were analyzed using One-way ANOVA followed by post-hoc Tukey Test. The comparison between the gene expression of c-Maf –FOXP3 and c-Maf –GATA3 was analyzed using T-test.

Main results and the role of chance: The results showed significant increase in the gene expression of GATA3 in eutopic and ectopic tissues compared to controls ($p<0.05$). In addition, the gene expression of c-Maf was statistically higher in ectopic endometriotic tissues compared to eutopic tissues and control ones while a significant decrease in the gene expression of FOXP3 was detected in ectopic and eutopic tissues of women with endometriosis compared to the control ones ($p<0.05$). The results of T-test analysis indicated a significant increase of *c-Maf* gene expression versus *FOXP3* in eutopic and ectopic tissues.

In addition, a significant increase in *GATA3* was observed in comparison with *c-Maf* gene only in the eutopic tissue of women with endometriosis.
Limitations, reasons for caution: For getting more information, we need to evaluate these transcription factors in a large number of endometriosis women and also to investigate expression of other transcription factors influencing on T cells differentiation such as RORγt. Epigenetic modifications such as DNA methylation at regulatory regions of these genes are also recommended.
Wider implications of the findings: These data collectively identify *FOXP3* and *GATA3*, c-*Maf* as candidate transcription factors critically involved in development of endometriosis beyond their role in induction of $CD4^+$ T cells differentiation.
Trial registration number: -

P-323 Evaluation of tubal patency in 2018 : the place of ultrasound with the use of an hyperechogenic medium, a franco-belgian survey

M. Pinto[1], A. Delevigne[2], C. Villette[1], M. Pasquier[1], C. Pietin-Vialle[1], J.M. Levaillant[1], N. Massin[1]
[1]*Intercommunal Hospital of Creteil, Department of Gynecology-Obstetrics and Reproductive Medicine, Creteil- 94000, France*
[2]*Saint Vincent Private Hospital, Department of Reproductive Medicine, 4000 Rocourt, Belgium*

Study question: In the fertility workup, what is the current place of tubal exploration with ultrasound in France and Belgium, particularly in prescribing and performing Hycosy/Hyfosy ?
Summary answer: Despite its benefits, tubal exploration with ultrasound is largely under-prescribed, due to a lack of knowledge of prescribers and their poor availability in practice.
What is known already: The use of a contrast medium during vaginal ultrasound to visualize the flow through the fallopian tube to test its patency was first describe in 1991. The feasibility, diagnostic efficacy and patient tolerance were demonstrated with this new diagnostic tool named hysterosalpingo-contrast sonography (HyCoSy). In 2007, a new hyperechogenic fluid (Exem Foam Kit) was introduced, having a more steady state, used for hysterosalpingo-foam sonography (HyFoSy) with a better accuracy and a shorter learning curve. The tubal exploration with ultrasound is simple and well-tolerated by women. It allows advance selection of patients in whom more invasive diagnostic procedures may be required.
Study design, size, duration: A web survey was created using doc.google with 23 questions regarding fertility workup, especially uterine and tubal examination. The survey was created in french and flamish. The physicians, gynecologists and reproductive endocrinologists, were invitated to participate by french and belgian societies of reproductive medecine. The link to the survey was posted on their website. The survey was open from October, 2017 to November, 2018. The Exem Foam Kit is reimbursed by social security in Belgium.
Participants/materials, setting, methods: There were 369 participants in the survey of whom 270 French and 60 Belgian. 39 were from other countries and were excluded from the analysis. Both French and Belgian groups were comparable regarding age, part of reproductive medicine in their practice, as well as their use of ultrasound in routine practice. The answers to the survey between the 2 groups were compared with Chi2 or Fischer exact test.
Main results and the role of chance: French physicians prescribed hysterosalpingography (HSG) more frequently (82% versus 42%, $p < 0.001$), while Belgians prescribed more frequently HyFoSy/HyCoSy (48% vs. 7%, $p < 0.001$). Regarding tubal exploration with ultrasound, 57% of Belgians prescribe a HyFoSy vs 33% of French ($p = 0.004$). 44% of French physicians left the choice between HyFoSy and HyCoSy to the operator. 60% of physicians in both groups did not prescribe routine antibiotic therapy with HyFoSy/HyCoSy. 62% of French and 70% of Belgians ($p = 0.7$) performed a laparoscopy in a second step. Among the reasons of non-prescribing HyFoSy/HyCoSy by French and Belgian physicians, there was a lack of knowledge of the procedure in 37% and 58%, the lack of a competent correspondent for these techniques for 49% and 35%, and insufficient data validating the technique for 14% and 7%, respectively. These differences were not significant.
Limitations, reasons for caution: This is a study based on volunteering, we can not be certain that our ample is representative of all french and belgian physicians working in the field of reproductive medicine. In addition the number of Belgian physicians was significantly lower than the French.
Wider implications of the findings: There is often a delay between the theoretical validation of a technique and its wide dissemination. As HyFoSy has proven its effectiveness, physician need to be more wisely informed and trained to this technique. The reimbursement of the Exem Foam Kit by the French social security will probably help.
Trial registration number: Not applicable

P-324 Interleukin-33 modulates inflammation and may be treated as a biomarker in endometriosis

S. Ghosh[1], P. Chakraborty[2], S. Chatterjee[3], R. Chattopadhyay[4], S.K. Goswami[4], P. Ghosh[5], K. Dutta Chowdhury[5], M. Chakravarty[4], B. Chakravarty[4]
[1]*Institute of Reproductive Medicine, ART, Calcutta, India*
[2]*Institute of Reproductive Medicine, Department of Infertility, Calcutta, India*
[3]*Vidyasagar College, Tissue culture and Molecular Biology Laboratory, Calcutta, India*
[4]*Institute of Reproductive Medicine, Department of Assisted Reproduction, Calcutta, India*
[5]*Rammohan College, Department of Zoology, Calcutta, India*

Study question: Does IL-33 contribute an important role towards inflammation observed in endometriosis and can be considered as a biomarker?
Summary answer: IL-33 posts its importance as biomarker by perpetuating inflammation, angiogenesis and lesion proliferation; critical events in progression of endometriosis.
What is known already: Endometriosis is a chronic inflammatory, estrogen-dependent disease that affects 6–10% of reproductive-aged women. Interleukin (IL)-33 is a critical regulator of number of processes including chronic inflammation, vascularization, hyper-nociception, and fibrosis; known associates of the pathophysiology. Although increased plasma and peritoneal fluid levels of IL-33 and its receptor ST2 had been associated with deep infiltrating endometriosis, whether IL-33 is playing an active role in the disease progression or if it is a bystander, is unknown. In a syngeneic mouse model supported by *in-vitro* findings we tried to delineate the possible contribution of IL-33 to the disease pathology.
Study design, size, duration: Syngeneic model of endometriosis was established in ∼10-week-old Balb/C mice (n=20). Treatment and positive-control group/s (n=6) were administered intraperitoneally mouse recombinant (r)-IL-33 at 1mg/100mL biweekly for two weeks. Control group (n=8) received phosphate-buffered-saline (PBS) in parallel. Endometrial epithelial carcinoma cells (EECC) and Human Umbilical Venule Endothelial Cells (HUVEC) were treated *in-vitro* with concentrations (10, 50 and 100 ng/mL) of human rIL-33 for 24 hours. Study was approved by Animal Ethics Committee (IAEC-56/PC/2018/10) of the institute.
Participants/materials, setting, methods: Plasma cytokine profile and pro-inflammatory marker/s were assessed by mouse multiplex assay and immunohistochemistry (IHC) respectively. Cell proliferation was evaluated using IncuCyte cell confluence proliferation assay. Cell-supernatant cytokine/s and effect of human rIL-33 on proliferation of cell lines and/or angiogenesis was assessed using human multiplex assay and fluorescence-kit based method in EECC, and HUVEC respectively. Data were evaluated by two-way analysis of variance using Graphpad Prism 7.0. $P < 0.05$ was considered as statistically significant.
Main results and the role of chance: Syngeneic model of endometriosis demonstrated significantly higher ($p<0.01$) plasma cytokine (chemokine (C-X-C motif) ligand 1 (CXCL1), IL -5, 6, 7, 33, and Granulocyte-macrophage colony-stimulating factor (GM-CSF)) level/s on day 20, day 27 following mouse rIL-33 injection compared to control, cueing to systemic inflammation. Positive control cohort revealed significantly elevated levels ($p<0.01$) of plasma cytokine/s in parallel authenticating mouse rIL-33 can promote systemic inflammation. Treatment with mouse rIL-33 produced qualitatively larger lesions and enhanced vascularization compared to control. Supernatants from EEECs and HUVECs revealed significantly higher concentrations of angiogenic (VEGF and PDGF-AA; $p< 0.001$) and pro-inflammatory (IL-1α and Tumor necrosis factor-a (TNF-α); $p< 0.05$) cytokines compared to PBS-treated cells. Varying concentrations of human rIL-33 on EECCs, and HUVECs did not have any effect on proliferation, however, tubule branch length in HUVECs was significantly increased ($p<0.05$, $p<0.01$ $p<0.0001$ corresponding to (10, 50 and 100) ng/ml)). IHC findings of

endometriotic lesions showed significantly increased Proliferating cell nuclear antigen (PCNA) and cluster of differentiation (CD)-31 staining in rIL-33 treated compared to control. PCNA immunolocalization was widely dispersed whereas quantitative analysis documented with an increased trend of CD-31 in treated mice, however, not statistically significant ($p = 0.09$).

Limitations, reasons for caution: Syngeneic model of endometriosis may not be a true reflection of human condition. Additionally, influence of intrinsic estrogen along with evaluation of short soluble form of ST2 (sST2), mature IL-33, and complexes of sST2 and IL-33 haven't been done which may increase the understanding of IL-33-related pathophysiology in endometriosis.

Wider implications of the findings: Whether IL-33 is involved in endometriosis alone or in combination with other factors is unclear; however, this molecule is possibly a potential biomarker and novel therapy target for managing endometriosis. Furthermore, the inhibitor of IL-33 (CNTO-7160), currently examined in clinical trials, may possibly be developed as new therapy for endometriosis.

Trial registration number: Not applicable

P-325 INFLUENCE OF TUBAL PATENCY ON ENDOMETRIOSIS RECURRENCE

S. Neutens[1], B. Van Elst[2], A. Laenen[3], C. Tomassetti[4], C. Meuleman[4]

[1]*AZ Groeninge, Gynaecology-Obstetrics, Kortrijk, Belgium*

[2]*CHIREC Delta Hospital, Gynaecology-Obstetrics, Brussels, Belgium*

[3]*KU Leuven, Interuniversity Institute for Biostatistics and Statistical Bioinformatics, Leuven, Belgium*

[4]*University hospital of Leuven, Department of Gynecology and Obstetrics, Leuven, Belgium*

Study question: Does bilateral non-patency or absence of fallopian tubes decrease the recurrence rate of endometriosis?

Summary answer: Lower endometriosis recurrence rates were observed in women with bilateral occlusion/absence of the fallopian tubes after endometriosis surgery, although differences were not statistically significant.

What is known already: Despite effective surgical treatment for endometriosis, disease recurrence remains an important issue with incidences ranging from 5% to 25% more than two years after treatment. The exact pathogenesis of neither endometriosis, nor endometriosis recurrence is known. However, retrograde menstruation may play an important role according to Sampson's transplantation theory. Our study hypothesis is that non-patency of both fallopian tubes (because of surgical removal or by disease) and therefore absence of retrograde menstruation will lead to lower rates of recurrence of endometriosis. If this hypothesis would be confirmed, this could be an indirect confirmation of the transplantation theory.

Study design, size, duration: Retrospective 2:1 matched case control study on data of 895 women who underwent laparoscopic treatment for endometriosis between 2010 and 2014. From these 895 women, 49 had bilateral non-patent or absent fallopian tubes. They were compared with 98 matched controls with at least one patent fallopian tube.

Participants/materials, setting, methods: All women underwent complete laparoscopic excision of any rASRM-stage endometriosis in a tertiary referral center. Matching was based on relevant determinants of recurrence (e.g. rASRM-stage, postoperative treatment. . .). Primary outcome was the recurrence rate over a mean duration of 20 months (range 0-83 months). Recurrence was analyzed on 3 levels: symptom recurrence, recurrence on imaging and need for reintervention. Linear mixed models were used for continuous variables, logistic regression was used for binary variables.

Main results and the role of chance: Analysis showed a general trend towards lower recurrence rates in patients with non-patent fallopian tubes, however these findings failed to be significant. The majority of patients in both groups were treated with hormonal therapy after surgery to prevent recurrence (58.2% of the control group vs 59.2% in the study group).

72% of the patients with child wish in the control group and 80% of the patients with child wish of the study group underwent an assisted reproductive treatment. Postoperative pregnancy rates for patients with child wish were similar in both groups i.e. 53.2% in the control group and 65.6% in the study group.

Symptoms reoccurred in 30.6% of the control group (n=30) and 20.8% of the study group (n=10). Recurrence was confirmed by imaging in 7.14% of the control group (n=7) and in none of the patients of the study group.

12 patients of the control group and 3 patients of the study group needed reintervention over a period of 83 months. In those undergoing reintervention, recurrence of endometriosis was confirmed by anatomopathological examination in 5 patients of the control group and in none of the patients of the study group.

Limitations, reasons for caution: A retrospective file study may over/underestimate recurrence rates, although this is applicable for both groups. Only a small number of women could be selected for matched analysis (even with 2:1 matching-ratio), due to the low prevalence of bilateral tubal problems (49/895 women or 5.5%), which may result in a type-II-error.

Wider implications of the findings: If the trend observed in our study could be confirmed more strongly in a future larger study, this indirectly confirms the transplantation theory of Sampson. In that case, bilateral tubal occlusion/resection may become a future option for prevention of endometriosis recurrence in women who have completed their family.

Trial registration number: Internal institutional study number: S59032

P-326 Biophysical and molecular characterization of endometrial exosomes as non-invasive biomarkers of physiological modifications during implantation window

P. Piomboni[1], A. Luddi[1], M. Camilla[1], C. Angela[2], P. Valentina[1], D.L. Vincenzo[1], M. Erika[3], G. Laura[1], M. Criscuoli[1], Q.E. Louis[4], Z. Natasa[5]

[1]*University of Siena, Department of Molecular and Developmental Medicine, Siena, Italy*

[2]*Siena Univesrity Hospital, Gynecology and Obstetrics Unit -Centre for Diagnosis and Treatment of Couple Sterility, Siena, Italy*

[3]*Exosomics SpA, 3Exosomics SpA, Slena, Italy*

[4]*Imer Clinica Fertilidad, Clinica Fertilidad, Valencia, Spain*

[5]*Exosomics SpA, Exosomics SpA, Slena, Italy*

Study question: Does exosomal profile of different endometrial surrogate biofluids is a non-invasive biomarker source for guiding a successful embryo implantation?

Summary answer: The evaluation of the endometrial exosomes (EVs) isolated from the surrogate biofluids, indicates EVs as possible bio-vectors to depict a typical receptive endometrial profile.

What is known already: The implantation window is mainly detected by monitoring the hormonal profile and with invasive methods requiring an endometrial biopsy, followed by histological or mRNA expression profile testing. To regulate blastocyst development and modulate the embryo-endometrial cross talk, the endometrium releases several factors in uterine fluid. Some of these are sorted from cytoplasmic endosomal compartments into secretory EVs and are thus delivered to target tissues in a paracrine and autocrine manner. EVs contain and transport several molecules that include a wide range of proteins, lipids and nucleic acids, according to their biogenesis, biophysical properties, surface proteins, transported content and biological role.

Study design, size, duration: Different biofluids such as uterine flushes (UF), cervix brush (B), urine (U) and serum (S) were collected from women volunteers with proven fertility after signing an informed consent, from February 2017 to September 2018. All biofluids were collected at different times after the LH surge. EVs isolation and molecular analyses were performed by researchers blinded to the study.

Participants/materials, setting, methods: UF, B, U and S were scheduled in LH+3/LH+5/LH+7/LH+9, from women volunteers with proven fertility (n= 14) at the Couple Sterility Centre, Siena University Hospital and IMER, Clinica Fertilidad, Valencia. EVs were isolated by chemical precipitation and then the concentration and size distribution in the different EVs subpopulations were determined with Nanoparticle Tracking Analysis (NTA). Transmission Electron Microscopy (TEM) and immunoelectron microscopy as well as RTq PCR, TaqMan miRNA arrays and Elisa have been applied.

Main results and the role of chance: Exosomes largely contribute to a proteome of UF, as indicated by exosome associated CD9 levels. Relative EVs content maintained the same pattern. when compared across the cycle phases, while an increase of EVs was detected in B sample in advanced cycle phases.

TEM analysis via negative staining confirmed ELISA data, Immunogold further confirmed the identity of EV-like structure by detection of EV markers like tetraspanins, CD9, CD63, Flotilin1. The profile of EV RNA confirms a fair recovery of RNA from B and UF samples, with the typical profile attributed to EV RNA, enriched in small RNA portion. A consistent expression of endometrial markers, namely PAEP (glycodelin A) and receptors for estrogen and progesterone, (ESR1, PGR) has been detected in vesicles recovered from UF, confirming that EV encapsulated RNA holds the advantage of the stability and traceable tissue origin. We can overall conclude that both measurement of a vesicle number, of a specific EV protein and a mRNA content confirms the efficient recovery of EVs suitable for the analysis of either protein and RNA composition from all the samples, in particular from UF that is confirmed to be most relatively enriched with EVs

Limitations, reasons for caution: A larger cohort of patients/samples may be useful to validated the data. Moreover, the molecular crosstalk between the embryo and human endometrium involves a complex molecular network, therefore embryo derived exosomes must be taken into account and integrated with the present results concerning the maternal influence.

Wider implications of the findings: A totally non-invasive diagnostic method, limiting as much as possible the stress of the patients undergoing assisted reproductive techniques, could be based on the precise definition of the exosomal profile of the receptive endometrium, depicting the expression of validated biomarkers, for guiding a successful embryo implantation.

Trial registration number: None

P-327 Organoids of human endometrium: is this a powerful 3D culture model in replicating the endometrial glandular epithelium?

P. Valentina[1], F. Ietta[2], A. Luddi[1], B. Semplici[1], C. Marrocco[1], S. Luisi[1], P. Piomboni[1]

[1] *Siena University, Dept. of Molecular and Developmental Medicine- Siena University- Siena- Italy, siena, Italy*

[2] *Siena University, Dept. of Life Science- Siena University- Siena- Italy, siena, Italy*

Study question: Does a three-dimensional culture model of endometrial glandular organoids mimic the uterine microenvironment at the maternal-foetal interface?

Summary answer: Organoids replicate endometrial epithelium, including its glandular-type organization. They reproduce functional behaviour such as responsiveness to the core regulatory hormones, modulating Glycodelin A (GdA) expression

What is known already: Due to ethical concerns, most of knowledge on mechanisms underlining human implantation derives from animal models, but they cannot always be translated to humans. Therefore, the development of an *in vitro* model allowing the opportunity to study the endometrial microenvironment and to investigate molecular mechanisms underlying the implantation process, is desirable. Nowadays, three-dimensional culture gained increasing interest and considerable importance has been ascribed to uterine glands and their secretions. In this regard, few studies addressed the expression and the glycosylation pattern of GdA, one of the major glycoprotein synthesized by endometrium, strongly modulated during the menstrual cycle.

Study design, size, duration: Endometrial biopsies have been collected from healthy and endometriosis-affected women, who underwent laparoscopic surgery from january to october 2018. The epithelial cells were isolated and 3D culture was applied to obtain organoids. Morphology, ultrastructure as well as GdA expression profile have been evaluated, both in unstimulated condition and after hormonal treatments able to induce the morphological and molecular modifications typical of the proliferative and secretive phase of the menstrual cycle

Participants/materials, setting, methods: Endometrial specimens have been collected from women of proven fertility (n=3) and endometriosis-affected patients (n=3). Obtained epithelial cells organoids were exposed for 4 days to estrogen alone or in combination with progesterone and cAMP, mimicking the proliferative and the secretory phase, respectively. Then, organoids were fixed and processed for TEM analysis or solubilized and analysed by 2D-electrophoresis followed by immunoblotting with a GdA-antibody or fixed and treated for immunofluorescence analysis using the same antibody.

Main results and the role of chance: Our data highlight that organoids obtained from human endometrial epithelial cells represent a good model to study the physiological function of the endometrial epithelium. TEM analysis showed that organoids preserve glandular organization as well as ultrastructural characteristics. Moreover, organoids retain the responsiveness to hormone treatment mimicking the in vivo glandular aspect and functions specific of the corresponding phase of the menstrual cycle. This was demonstrated by the analysis of GdA, a cycle-dependent marker of endometrial receptivity, that resulted to be expressed in cultured organoids with the same pattern detected in the endometrium in vivo, thus confirming the cycle-dependent modifications typical of this glycoprotein in epithelial endometrial cells. Finally, the GdA glycosilation pattern in organoids isolated from eutopic endometrium of endometriotic women significantly differs from that detected in healthy organoids, confirming data from endometrial tissues and supporting the idea that GdA deregulation may be a typical feature of this pathology

Limitations, reasons for caution: Larger study needs to validate these findings. Organoids seem to mimic endometrial tissue modifications dependent on cycle phase, even in the absence of endometrial mesenchymal compartment. Nevertheless, co-culture with endometrial stromal cells is advisable, to investigate these complex molecular pathways in light of reciprocal epithelium-stroma interactions operating in the tissue

Wider implications of the findings: We describe an endometrial glands 3D culture closely recapitulating molecular and functional characteristics of their cells of origin. This model could represent a valuable research tool to study implantation in vitro, and to test therapies for endometrial pathologies or implantation problems, allowing the possibility to build up patient-specific biobank resurces

Trial registration number: Not applicable

P-328 Upregulation of ROS genes may contribute to poor oocyte quality in women with endometriosis.

S. Gupta[1], M. Saxena[1], A. Srivastava[1], H. Kalra[1]

[1] *Medicover Healthcare Pvt. Ltd., IVF, Gurgaon, India*

Study question: Are reactive oxidative species (ROS) genes upregulated in women with endometriosis contributing poor oocyte quality?

Summary answer: ROS genes and genes generating a response to ROS are upregulated in women with endometriosis

What is known already: Endometriosis is a chronic inflammatory disease which leads to infertility. Infertility in women with the endometriosis may be due to poor oocyte quality. A number of mechanisms are associated with oocyte maturation may be disrupted in women endometriosis thereby impacting oocyte quality. A balance between the ROS and antioxidants is essential for oocyte maturation and quality. This balance is dysregulated in women with endometriosis. Reactive oxidative species genes may be upregulated in women with endometriosis.

Study design, size, duration: A meta-analysis was conducted on data from 17 studies to compare women with and without endometriosis between 25 November 2018 and 30 December 2018.

Participants/materials, setting, methods: Suitable studies and data identified from electronic databases and gene expression repositories. Peer reviewed, publicaly available studies investigating genetic expression of endometrial tissue from premenopausal women with endometriosis were included. Studies had individual participant gene expression data and published gene lists available. Dysregulated gene expression was determined through meta-analyses of microarray data. Data analysis was conducted by GeneSpring version 4.0.4. T-test using P value <0.05 and fold-change expression >1.5 was applied for statistical significance.

Main results and the role of chance: This study has shown that in eutopic endometrium of women with endometriosis, genes involved in generation of reactive oxidative species and the genes involved in generating a response to oxidative stress were significantly upregulated.

Limitations, reasons for caution: The limitation of the study may be the sample size.

Wider implications of the findings: Upregulation ROS genes likely contributes to poor oocyte maturation and quality in women with endometriosis. Increased ROS may lead to decreased antioxidants levels. Increased oxidative stress leads to DNA damage, meiotic abnormalities and chromosomal

instabilities, impairing oocyte quality. IImpaired oocyte quality may contribute to infertility in women with endometriosis.
Trial registration number: NA

P-329 Uterine immune profiling and endometriosis: any particularities in patients with repeated implantation failures?

C. Sandra[1], P. Marie[2], C. Lucie[2], V. Katia[2], L. Nathalie[1]
[1]*Centre d'assistance médicale à la procréation-, Hôpital des Bluets, Paris, France*
[2]*MatriceLAB Innove, Pepinière Paris Santé Cochin- Hopital cochin, Paris, France*

Study question: Do patients with endometriosis and repeated implantation failures (RIF) exhibit any specificity regarding their uterine immune profile compared with RIF patients with male infertility ?
Summary answer: Patients with endometriosis and a RIF history show some immune particularities regarding their endometrial immune profile when compared with RIF patients with male infertility.
What is known already: Despite extensive studies, the pathogenesis of endometriosis is still perceived as complex and unknown and the pathogenesis of infertility associated with endometriosis remains elusive. The involvement of the endometrium itself as an actor of embryo implantation failures in patients with endometriosis is still a matter of debate.
Study design, size, duration: A Case – Control cohort analysis compared the endometrial immune profile among RIF patients with endometriosis (n=176 patients) versus male infertility (523 patients) between 2012 to 2017. The endometrial immune profiling details the Th-1/Th-2 immunoregulated equilibrium, as well as the maturation and activation state of uterine NK cells. A classification in four types of uterine immune profiles is established to detail the local equilibrium: normal, over-activated, low activated, mixed profiles.
Participants/materials, setting, methods: The immune profiling is a diagnostic method detailing from an endometrial biopsy collected in the mid luteal phase the uterine natural killer cells (uNK) mobilization/ activation/ maturation state as well as the local immunoregulated equilibrium between the Th-1 (cytotoxic)and the Th-2 (angiogenic/ immunotrophic) cytokines. The biomarkers IL-15/Fn-14 (maturation and hyper-activation state of uNK) and IL-18/TWEAK (Th-1/ Th-2 equilibrium) mRNA ratios were determined by quantitative RT-PCR and CD56 mobilization per Immunochemistry.
Main results and the role of chance: The global repartition of the distinct immune profiles was not significantly different among endometriosis or male RIF patients (p=0.07). However, patients with a low-activated immune profile were significantly over-represented in the endometriosis RIF group (33% versus 23% respectively, p=0.03). More local depletion of Th-2 cytokines (p=0.03) associated with an higher rate of immature uNK cells (p=0.03) were observed in the RIF endometriosis group when compared to the RIF male group.
Limitations, reasons for caution: The observed differences were based on the retrospective analysis of the two groups and could not exclude some bias.
Wider implications of the findings: As patients with endometriosis show some immune particularities, personalized measures based on the precise documentation of their uterine immune profile may be beneficial in order to promote embryo implantation.
Trial registration number: not applicable

P-330 Neuropathic endometriosis-associated pain: Can we subgroup women on the basis of their sensory descriptors?

L. Coxon[1], K. Wiech[2], K. Vincent[1]
[1]*University of Oxford, Nuffield Department of Women's & Reproductive Health, Oxford, United Kingdom*
[2]*University of Oxford, Nuffield Department of Clinical Neurosciences, Oxford, United Kingdom*

Study question: In neuropathic endometriosis-associated pain, do patients cluster on responses to PainDETECT questions? If so, are there clinically meaningful differences between these groups?
Summary answer: Two clusters are identified, with strength of abnormal sensations having importance in prediction. These clusters differ in psychological profile and pain intensity scores.
What is known already: Endometriosis-associated pain has been traditionally thought of as arising from peripheral mechanisms in the pelvis. However, it is only recently that the potential role of neuropathic pain has been considered. Our previous work suggests that 75% of women with endometriosis-associated pain have a neuropathic or mixed neuropathic/nociceptive component to their pain. We now investigate if there are clusters within this group which could be used to further stratify patients for optimum treatment.
Study design, size, duration: A novel questionnaire was created using the Bristol Online Survey Tool. It included painDETECT^{TM} (a measure of neuropathic pain) as well as other validated questionnaires. The survey was distributed to women with endometriosis to complete online through patient support groups (approved by the Central University Research Ethics Committee, University of Oxford). 1615 responses were received, with 1444 meeting the inclusion criteria of having had at least one laparoscopy and a diagnosis of endometriosis.
Participants/materials, setting, methods: painDETECT^{TM} was used to group participants into nociceptive, mixed and neuropathic pain groups (nociceptive $\leq$12, mixed 13-18, neuropathic $\geq$19). Only mixed and neuropathic groups were further analysed here (n=904).

Data were computed using SPSS. Two-step cluster analysis with Schwarz Bayesian Criterion (BIC) was used to determine the number of clusters. Responses to painDETECT^{TM} questions were used as classification variables. Subsequent group analysis was performed, using Mann-Whitney U tests.
Main results and the role of chance: Two major clusters were identified. For both clusters the variable which had the greatest predictive importance was 'Do you have a tingling or picking sensation in the area of your pain (like crawling ants or electrical tingling)?' (importance=1.0), followed by 'Do you suffer from a burning sensation (e.g. stinging nettles) in the area of your pain?' (importance=0.88), both of which indicate abnormal sensations in the area of pain. All other questions had predictive importance <0.2. Cluster 1 (n=388, 39.7%) had stronger responses to both these questions, with 'strongly' being the most common response for both questions. For cluster 2 (n=590, 60.3%) the most common response was 'slightly' for both questions.

Group comparisons demonstrated that those in cluster 1 have significantly higher scores for: depression (Beck's Depression Inventory); anxiety (Trait Anxiety Inventory); catastrophising (Pain Catastrophising); dysmenorrhea, dyspareunia and non-cyclical pain (Numerical Rating Scale) ($p<0.006$ corrected). Further analysis, limiting to only those with definite neuropathic pain (n=573), the same questions are identified as having predictive importance in clustering.
Limitations, reasons for caution: Participants self selected from patient support websites, potentially producing a biased sample.
Wider implications of the findings: These results suggest that the presence/absence of abnormal sensations in women with neuropathic endometriosis-associated pain may be of particular clinical relevance. A better understanding of the mechanisms generating these sensations and potential therapeutic options is therefore urgently needed to improve quality of life for these women.
Trial registration number: Not applicable.

P-331 Free 25(OH)-vitamin D and vitamin D binding protein are potential biomarkers for leiomyoma and are associated with the leiomyomas size

A. Fattahi[1], Z. Latifi[2], Z. Salemi[3], S. Kamalipooya[4], H.R. Nejabati[2], M. Nouri[5]
[1]*Tabriz University of Medical Sciences, Department of Reproductive Biology, Tabriz, Iran*
[2]*Tabriz University of Medical Sciences, Department of Biochemistry and Clinical Laboratories, Tabriz, Iran*
[3]*Arak University of Medical Sciences, Department of Biochemistry-, Arak, Iran*
[4]*Arak University of Medical Sciences, Department of Biotechnology, Arak, Iran*
[5]*Tabriz University of Medical Sciences, Department of Reproductive Biology, Tabriz, Iran*

Study question: Are there associations between serum levels of vitamin D binding protein (DBP) and free 25(OH)-vitamin D with leiomyoma and the lesions characteristics?
Summary answer: Free 25(OH)-vitamin D and DBP had respectively positive and negative correlations with the leiomyomas size and could be potential biomarkers for leiomyoma.

What is known already: Role of vitamin D particularly its free form and also DBP as the modulator has been demonstrated in tumor progression. Moreover, the association of the blood levels of total vitamin D with the prevalence of uterine leiomyoma has been reported. Furthermore, the inhibitory effect of vitamin D on leiomyoma formation and progression has been documented. Previous studies also showed significantly lower and higher levels of respectively vitamin D and DBP in the blood of women with leiomyoma compared to healthy subjects.

Study design, size, duration: Leiomyoma was diagnosed using transabdominal ultrasound screening and confirmed by histological analysis. In the patients, the number, size and location (Intramural, Subserosal, Transmural, Submucosal, Intramural- Subserosal, and Intramural- Submucosal) of the leiomyomas were determined.

Participants/materials, setting, methods: Forty-four leiomyoma patients aged 35.32±6.15 and forty-one healthy women with age of 32.69±6.44 were enrolled in this study. In all the participants, serum levels of total 25(OH)-vitamin D and DBP were measured using commercial ELISA kits. Furthermore, serum levels of 25(OH)-vitamin D/DPB ratio and free 25(OH)-vitamin D were calculated.

Main results and the role of chance: Levels of 25(OH)-vitamin D/DPB ratio and free 25(OH)-vitamin D were significantly lower in patients group compared to the controls ($p<0.001$). We also found statistically higher levels of DBP in the patient with leiomyoma in comparison with the healthy women ($p<0.001$). There was no significant association between the evaluated serum factors with the location and number of the leiomyomas ($p>0.05$). However, the size of the largest leiomyomas had negative correlations with 25(OH)-vitamin D/DPB ratio and free 25(OH)-vitamin D levels and a positive correlation with DBP. Based on receiver operating characteristic (ROC) analyses, cutoff values for free 25(OH)-vitamin D and DBP as markers for leiomyoma diagnosis were 4.36 (pg/ml) and 251.7 (µg/ml) with sensitivity 78% and 88% and specificity of 76.7% and 71%, respectively.

Limitations, reasons for caution: Our study had a relatively small sample size.

Wider implications of the findings: Free 25(OH)-vitamin D and DBP had a role in leiomyoma pathogenesis and were associated with the size of leiomyomas. Serum levels of these factors can be used as biomarkers for the leiomyoma diagnosis.

Trial registration number: not applicable

P-332 The effect of Thymoquinone on experimental endometriosis rat model

S. Kabil Kucur[1], A. Seven[2], E. Koçak[3], A. Değer[4], B. Yüksel[5], İ. Gozukara[6]

[1]*Kosuyolu Memorial Hospital, Obstetric and Gynecology, İstanbul, Turkey*

[2]*Dumlupinar University Medical Faculty-, Department of Gynecology and Obstetrics-, Kutahya-, Turkey*

[3]*Dumlupinar University Medical Faculty-, Department of Biochemistry, Kutahya, Turkey*

[4]*Dumlupinar University Medical Faculty, Department of Pathology, Kutahya, Turkey*

[5]*Dumlupinar University Medical Faculty, Department of Gynecology and Obstetrics, Kutahya, Turkey*

[6]*Mustafa Kemal University, Department of Obstetric and Gynecology, Hatay, Turkey*

Study question: To evaluate the effect of Thymoquinone (TQ) in a rat model of surgically induced endometriosis.

Summary answer: TQ significantly regressed endometriotic implants and decreased immunoreactivity for VEGF.

What is known already: Endometriosis incidence is a chronic disease. Although endometriosis is one the most investigated disorders of gynecology, it's pathogenesis is still unclear. Investigations have demonstrated a role for immune dysregulation, oxidative stress and angiogenesis in endometriosis. TQ is the principle active ingredient of Nigella Sativa seeds. TQ as a natural agent, has become a favourable compound in studies due to its potent anti-inflammatory, anti-oxidant, antiangiogenic and immune enhancement capacity. TQ, has attracted much scientific attention in recent years for its high biological activity with low toxicity. Therefore, this preliminary study was designed to evaluate the effect of TQ on surgically-induced endometriosis.

Study design, size, duration: This was an experimental animal model study. Fourty-four female rat with induced endometriotis were diveded in 4 groups. Group 1; 20 mg/kg TQ , group 2 ; 1mg/kg subcutaneus single dose leuprolide acetate, group 3; 1mg/kg LA and 20 mg/kg TQ , and group 4;control. After four weeks of medication rats were sacrificed and size, histopathology and immunreactivity to vascular endothelial growth factor (VEGF) of the endometriotic implants and ovarian follicular counts were evaluated.

Participants/materials, setting, methods: The formalin- fixed tissues (endometriotic foci and ovaries) were embedded in paraffin blocks and stained with H&E after being sectioned to 5 µm thickness. Tissue slides were evaluated by a blinded pathologist to determine endometriosis score by the persistence of epithelial cells in endometriotic implants. The immunohistochemical staining of endometriotic foci was evaluated by the sme pathologist blind to the groups using semiquantitative method.

Main results and the role of chance: The post-treatment volumes of implants in groups 1, 2, and 3 were significantly less than those of group 4 ($p<0.001$). Post- treatment implant volumes in group 1, 2, and 3 were comparable to eachother ($p>0.05$). The histopathological scores of the implants were compared between the groups. Immunohistochemical staining of implants to evaluate VEGF revealed significant reduction in scores in group 1, 2, and 3 when compared to group 4 ($p<0.001$). The lowest score was noted in group 3 which was comparable to that of groups 2 and 3 ($p>0.05$). Antral follicle count in TQ group was comparable that of control group in contrast to LA group.

Limitations, reasons for caution: The study was limited by its design as an experimental rat model, which may have limited applicability to human. Besides, we examined only VEGF expression on the endometriotic implants which may also be a limitation

Wider implications of the findings: Our study demonstrated for the first time the TQ significantly regressed endometriotic implants and decreased immunoreactivity for VEGF without affecting ovarian follicle numbers.

Trial registration number: not applicable

P-333 Analysis of mi20a_1, mi145_1 and 320a_1 levels in follicular fluid of endometriosis patients. Their role as putative biomarkers for outcome of assisted reproductive technology (ART).

Study question: Could levels of mi20a_1, mi145_1 and 320a_1 in follicular fluid be used as biomarkers for fertility outcome in endometriosis patients?

Summary answer: The studied miRNAs increased in patients with endometriosis relatively to controls, suggesting their use as markers for assessment of outcome of assisted reproductive technology (ART).

What is known already: Endometriosis is a gynaecological disorder characterized by ectopic vascularized endometrial tissue growth, mainly in pelvic cavity, which provokes pain and infertility. Globally, endometriosis affects up to 40% of infertile women.

Endometriosis associates to an imbalance in microRNAs produced in eutopic and ectopic endometrial tissue that affects disease progression, angiogenesis and reproductive condition. MicroRNAs are found in Follicular Fluid (FF) and are easily collected from patients under fertility treatments. In this setting, the analysis of specific microRNAS in the FF from women with endometriosis could represent a promising approach to identify biomarkers with application in diagnosis and prognosis of fertility treatments.

Study design, size, duration: We used FF obtained from women aged 26-42 years (n=32) submitted to medically ART and divided in two groups according to the clinical infertility diagnosis: endometriosis and controls (male factor infertility). FF samples were assigned by CETI (Centro de Estudos e Tratamento de Infertilidade) – Porto, Portugal.

Participants/materials, setting, methods: Total MicroRNA were extracted from Follicular Fluid using miRNA easy mini kit. MicroRNAs 20a_1, 145_1, 320a_1 were quantified using RT-PCR. To compare the study variables, student t-test was used.

Main results and the role of chance: An increase of mi20a_1, mi145_1 and mi320a_1 was found in FF from women with endometriosis comparing with healthy women. The expression of mi20a_1 was found 4,5 times increased in the samples from endometriosis, comparing with controls (p=0,037); mi145_1 was 2,85 times higher in the samples from endometriosis, comparing with controls (p=0,003) and mi320a_1 was 4,5 times higher in the samples from endometriosis, comparing with controls (p=0,006). While mi20a is involved in hypoxia, angiogenesis, cell proliferation mechanisms, mi145_1 is involved in cell proliferation, and mi320a intervenes in the inhibition of cell proliferation, migration and invasion and may also be involved in embryo quality. The upregulation of mi320a may constitute a compensatory mechanism that counteracts the up regulation of mi20a and mi145_1, that favours the endometriosis pathology.

Limitations, reasons for caution: Despite the strong increase in mi20a_1, mi145_1 and mi320a_1 found in FF of patients with endometriosis, further investigation is needed to validate this data, including an increase of the number of studied women. As well, the correlation of levels of the studied microRNAs with ART success is ongoing.

Wider implications of the findings: The findings involving specific microRNAs help to refine diagnostic tools to be employed in FF analysis during ART. The increase of mi20a_1, mi145_1 and mi320a_1 in FF from women with endometriosis favors their ability to be accounted as biomarkers for pregnancy outcomes, after ART treatments.

Trial registration number: not applicable

P-334 INTRA -UTERINE INSTILLATION Versus SUBCUTANEOUS-INJECTION OF GRANULOCYTE COLONY-STIMULATING FACTOR (G-CSF) BEFORE EMBRYO-TRANSFER IN RESISTANT THIN ENDOMETRIUM IN IVF-ICSI CYCLES: A comparative study

A. Jindal[1], R. Singh[2], M. Singh[2]
[1]*Bhopal Test Tube Baby Centre, Infertility, Bhopal, India*
[2]*B T T B Centre- Bhopal, iNFERTILITY, Bhopal, India*

Study question: Whether intrauterine administration of G-CSF (granulocyte colony-stimulating factor) prior to Embryo Transfer in patients with resistant thin endometrium yield better pregnancy rates than subcutaneous injection of G-CSF?

Summary answer: Intrauterine administration of G-CSF (granulocyte colony-stimulating factor) prior to ET in patients with resistant thin endometrium yields better pregnancy rates than subcutaneous injection of G-CSF

What is known already: Endometrial thickness is an important index evaluating endometrial receptivity .Endometrial thickness below a threshold is associated with implantation failure and reduced pregnancy rate . Many therapies have been attempt to enhance the endometrial thickness and improve the endometrial receptivity, such as extending estrogen administration , low-dose aspirin , combination pentoxifylline and tocopherol , vaginal sildenafil citrate , and stem cells treatment . These treatments have improved endometrial receptivity and increased implantation and pregnancy rate in ART cycles in some extent. However, many cases still remain unresponsive.Lately, granulocyte colony-stimulating factor (G-CSF) has been used in the treatment of thin endometrium.

Study design, size, duration: 112 Infertile patients with thin endometrium below 40 years age (2016 to 2018) were included in this study , in whom traditional treatment with estradiol, sildenafil etc had been unsuccessful.

Patients were randomly divided into two groups using computer generated list after proper consent .The study group received intrauterine & Subcutaneous G-CSF before Embryo Transfer in IVF-ICSI cycles.

Primary Outcome : Endometrial-thickness , Implantation & Pregnancy rates.

Secondary-outcome: Abortion-rate

Participants/materials, setting, methods: One group (n = 56) received intrauterine infusion of 300 microgramme / 1ml of G-CSF, and the other group (n = 56) underwent sub-cutaneous before Embryo-Transfer.

G-CSF was administered by an intrauterine catheter by slow instillation on the day of hCG administration.

If the endometrium had not reached at least a 7-mm within 48 h, a second dose was administered following oocyte retrieval.

Main results and the role of chance: G-CSF administrated via uterine infusion resulted in significantly increased Pregnancy Rates , whereas G-CSF administrated subcutaneously had less effect on the Pregnancy Rates.

The IR and PR were statistically significantly higher in the group receiving intrauterine G-CSF (18% and 32%, respectively) as compared to the subcutaneous group (10% and 16%, respectively).

Abortion Rates were comparable in both the groups and difference was not significant.

Intrauterine instillation of G-CSF is more effective in expanding chronically unresponsive thin endometrium, as compared to sub-cutaneous injection.

This treatment needs more multicentric trials to assess its potential in improving the implantation chances in IVF-ICSI cycles , thereby improving pregnancy rates.

Limitations, reasons for caution: Limitations to this study are the small sample size, and less number of cycles .

Wider implications of the findings: The ideal route of G-CSF administration has not been identified yet.

Studies have used G-CSF via either subcutaneous injection or intrauterine infusion.

In order to explore which route was better, we evaluated the effect on outcome with different routes of G-CSFWe found that G-CSF administrated intrauterine resulted in significantly increased results.

Trial registration number: not applicable

POSTER VIEWING
ETHICS AND LAW

P-335 Surrogacy in the Czech Republic from the point of view of the law office: experience for the years 2009-2018

H. Konecna[1], I. Honzová[2], L. Prudil[3], L. Prudilova[4], A. Zemandlova[3], E. Michelova[3], T. Rumpikova[5], D. Rumpik[5]
[1]*Univerzity of South Bohemia in Ceske Budejovice, Faculty of Health and Social Sciences, Ceske Budejovice, Czech Republic*
[2]*AK Prudil a spol.- s.r.o., AK Prudil. a spol.- s.r.o., Brno, Czech Republic*
[3]*AK Prudil a spol.- s.r.o., AK Prudil a spol.- s.r.o., Brno, Czech Republic*
[4]*AK Prudil a spol. s.r.o., AK Prudil a spol- s.r.o., Brno, Czech Republic*
[5]*The Clinic of Reproductive Medicine and Gynecology Zlin, Assisted reproduction, Zlin, Czech Republic*

Study question: *What is the interest in surrogacy in the Czech Republic, who are the applicants and who are surrogate mothers?*

Summary answer: Interest in surrogacy in the CR is steeply growing, with growing number of non-standard applicants and surrogate mothers in a difficult financial situation.

What is known already: The Czech Republic has ratified the Convention on Biomedicine**,** the human body must not be a source of financial profit. Surrogacy is not legally regulated, it is carried out. The change of legal parenting is done through adoption. According to the recommendation of the Czech

Society for ART, surrogacy should be done solely for health reasons, donated gametes should not be used, the surrogate mother should be a citizen of the CR, she should have a recommendation of a gynecologist, practitioner and psychologist. Czech IVF centers generally accept only applicants who have evidence of consultation with a lawyer.

Study design, size, duration: Cross-sectional study, 330 serious candidates for surrogate motherhood who underwent a legal consultation between 2009 and 2018.

Participants/materials, setting, methods: Applicants for surrogacy who approached one of the very few Czech law offices dealing with this issue, with a request to consult the procedure, or the legal representation in the adoption process. In the documentation we looked back at data about the number of clients, some sociodemographic characteristics, or the continuation of the cooperation between the client and the law office. The data processing method is a basic retrospective descriptive statistics.

Main results and the role of chance: The interest in surrogacy is steeply increasing, from single candidates in 2009 to several candidates a week in 2018. Early on, only Czech heterosexual couples in reproductive age with medical fertility disorder appeared, at the moment there are also homosexual couples or individuals, as well as applicants who are not Czech citizens. Altogether 330 clients were interested in the procedure, mostly heterosexual couples. Increasingly, the applicants are less wealthy. Intrafamiliar surrogacy is rare, applicants with mothers are mostly contacted via the Internet. There is a growing number of candidates to surrogate mothers in a difficult financial situation. From 2009 to 2018, 103 children were handed over. There is one case in the CR where the disabled child was nothanded over.

Limitations, reasons for caution: We consider the study to be representative, other Czech law offices have probably not addressed the issue yet. However, it looks like the issue attracts interest of other Czech law officess.

Wider implications of the findings: *Lack of regulation can lead to trafficking in children and women. It is necessary to carry out an analysis of the motives of surrogate mothers.. This should be followed by the legislation of surrogacy, with taking into account that the CR is the target country for cross border care.*

Trial registration number: not applicable' for non-clinical trials.

P-336 Policy recommendations for queer and trans reproduction with Assisted Reproductive Technologies in Europe

D. Leibetseder [1]

[1] *Uppsala University, Centre for Gender Research, Uppsala, Sweden*

Study question: How can the access to Assisted Reproductive Technologies (ARTs) be improved for queer and trans people in six purposely

selected European countries (Austria, Estonia, Poland, Spain, Sweden, the UK)?**Summary answer:**

Improvements are needed in: providing information, change legal regulations for ARTs, for obtaining parenthood and citizenship, and for gender recognition, LGBT-training for medical staff.

What is known already: Queer, as in non-heterosexual relationships, and transgender kinship and family structures are increasingly formally recognized, and queer and trans research on ARTs is an established field (mostly in English-speaking countries, less in central and eastern Europe) and has demonstrated that a range of subjects use them.These studies show that one social group particularly affected by biotechnological and legislative changes around ARTs are queer and transgender people and that they are making use of cross-border reproductive care, which brings often challenges for obtaining legal parenthood and citizenship for their child.

Study design, size, duration: This is a participative, multi-method research project (2 years duration), drawing on a range of interconnecting qualitative sociological, ethnographical, feminist,queer, and philosophical (ethical) methods. It thus reflects the interdisciplinarity of the knowledge domains on which this project is based, where qualitative (interviews, focus groups, content analysis, discourse analysis, use of CAQDAS) but also quantitative (surveys) methods are used. So far 901 participants took part in the online-survey, interviews and focus groups.

Participants/materials, setting, methods:

Participants are self-defined queer and trans people (older than 21 years) who want to use or have used ARTs.

Methods/Materials: Literature review, document and content analysis of the ART guidelines in laws and recommendations show the differences between the 6 chosen EU-countries concerning ART and LGBT policies. Through purposive sampling data of the experiences of queer and trans people with ARTs is/was gathered with an online-survey, interviews and focus groups.

Main results and the role of chance: The main results of my Marie-Skłodowska Curie project (Horizon2020) "QTReproART -Towards an Inclusive Common European Framework for Assisted Reproductive Technologies (ART): Queer & Transgender Reproduction in the Age of ART" are policy recommendations and guidelines for the improvement of access to ART for queer and trans people in Europe, which cover the following areas: providing information, change legal regulations for ARTs, for obtaining parenthood and citizenship, and for gender recognition, LGBT-training for medical staff. A general recommendation for the EU is the main result, as well as individual results for each of the six selected EU-states. The details of the policy recommendations are presented at the conference, as the analysis of the collected data is still work in progress at the time of the submission of this abstract.

Limitations, reasons for caution: Not applicable.

Wider implications of the findings:

The findings of my project are mostly in agreement with studies on queer and trans reproduction so far, but my findings contain a more detailed analysis of different factors (e.g. where to find information about ART access for queer and trans people, legal challenges, treatment by medical and psychological staff).

Trial registration number: Not applicable.

P-337 Reproductive rights: status & future?

J. Rothmar Herrmann [1], **F. Hogholm Pedersen** [1]

[1] *University of Copenhagen, Faculty of Law, Copenhagen, Denmark*

Study question: What is the current human right status for the right to procreate, and which legal principles/developments are currently driving liberalization?

Summary answer: Human rights recognition of a right to procreate lacks, however increased marketization and due legal concern for children's rights has improved the legal status.

What is known already: International and regional human rights instruments protect the "right to found a family", the "right to respect for private and family life" and the right to have disease addressed through the "right to health" Yet, a right to procreate utilizing ART has not been recognized. However, when a child is born the best interests of the child shall be a primary consideration, enabling users of cross-border treatment to pursue legal recognition of their private and family life upon their return, by emphasizing the right of the child.

Study design, size, duration: Analysis of relevant Danish statutory law, Danish judgments and administrative decisions, human rights conventions and judgments.The project combines a dogmatic legal methodology with a sociolegal analysis of legal genealogy (Foucault 1980). Hence, the status for reproductive rights is expounded and it is demonstrated how subversive practices (cross-border reproductive care, and "activist"/reproductive justice practices meant to challenge prohibitive legislation) can drive legal development and effectively create an increased legal status for the right to procreate.

Participants/materials, setting, methods: Statutes, conventions, judicial and administrative decisions. The material is extensive – includes the legislative material regulating assisted reproduction as well as human rights, children's rights, international private law, EU law, and family and adoption law. Also, data retrieved from health authorities, patient organisations and professional societies describing the expansion in use of domestic and cross-border reproduction is included.

Main results and the role of chance: In Denmark, expansion and liberalization of reproductive rights is currently driven by the marketization of infertility care which allows for both cross-border circumvention of domestic regulation and allows for subversive practices at a scale that eventually drives regulatory response or that are designed to actively test the limits of the law by litigation. We demonstrate this using examples from Danish law and legal practice. Moreover, this development is not isolated to Denmark, but illuminate what is likely a European trend.

The status for reproductive rights is that to a high extend liberalization comes through the back door. For those who do not have the resources for cross-border care or for testing the law the improvements are smaller.

Limitations, reasons for caution: not applicable

Wider implications of the findings: Reproductive rights have been on the human rights agenda for 70 years yet the current human rights conceptualization of reproductive rights has seems to have reached the end of its evolutionary capacity. As the marketization of fertility care increases, so does the legal basis for bringing reproductive rights forward.
Trial registration number: not applicable

P-338 Egg providers' views on the use of surplus eggs in the UK, Spain and Belgium: implications for information giving and informed consent

N. Hudson[1], C. Coveney[2], L. Culley[1], T. Goethals[3], C. Herbrand[1], S. Lafuente[4], V. Pavone[4], G. Pennings[3], V. Provoost[3], C. Weis[1]
[1]*De Montfort University, Centre for Reproduction Research, Leicester, United Kingdom*
[2]*Loughborough University, Department of Social Sciences, Loughborough, United Kingdom*
[3]*Ghent University, Bioethics Institute Ghent, Ghent, Belgium*
[4]*Consejo Superior de Investigaciones Cientificas, Institute of Public Goods and Policies, Madrdid, Spain*

Study question: How do women who provide eggs for use in fertility treatment perceive practices related to the use, storage and distribution of surplus eggs?
Summary answer: Egg providers expressed concerns about the potential ways surplus eggs might be used following donation, suggesting that processes of information giving may need improvement.
What is known already: Within Europe, donor eggs are used in over 56, 000 cycles of fertility treatment per year. Vitrification allows clinics increased flexibility in the management and storage of eggs and permits separation of the traditional link between donor and recipient since technically they can be stored indefinitely. Vitrification and banking also increase possibilities for commercialisation and movement of 'surplus' eggs (i.e. eggs remaining after the initial recipient has completed their first cycle of IVF). Existing research tends to focus on egg providers' motivations and experiences, but little is known about their views of the use, storage and export of vitrified eggs.
Study design, size, duration: This paper is part of a larger, multi-phased comparative study (the 'EDNA' study, 2017-2020), which explores egg provision in the UK, Belgium and Spain, using multiple and largely qualitative methods of data collection. A maximum variation sample of egg providers was recruited from a range of sites in each country including fertility clinics, egg banks and via social media. This paper draws on interviews conducted between April 2018 and January 2019.
Participants/materials, setting, methods: In-depth, face-to-face interviews with 68 egg providers (n=27 in the UK, n= 20 in Spain, n= 21 in Belgium) were conducted. Interviews included questions about personal experiences as well as the use of elicitation techniques designed specifically to generate data on values and principles relating to the use, storage, and export of surplus eggs. Interviews were fully transcribed and entered into NVivo for analysis using a systematic, thematic method.
Main results and the role of chance: Egg providers were asked to consider a range of scenarios relating to possible uses for surplus eggs. Participants expressed uncertainty and that they did not feel well informed about the possible uses of surplus eggs. Women in all three countries supported eggs being divided amongst several recipients, but a majority (n= 51, 75%) expressed negative values relating to the trade of surplus eggs between clinics for profit. Shipping eggs to another country generated variable preferences: in Belgium there was a positive response (76% agreed), whilst in the UK and Spain half of women felt unsure or that this should not be possible. The majority of women in all three countries (n=55, 81%) felt positive about the option to store surplus eggs for their own personal later use. Our findings also demonstrate a desire for explicit informed consent with regards to the use of eggs and in some cases, for direct involvement in future decision-making about surplus eggs, especially after longer periods of storage.

Role of chance:

Our qualitative findings are not intended to provide statistical generalisation but instead aim to provide in-depth understanding and theoretical inferences about egg providers' motivations, experiences and moral reasoning about contemporary egg donation practice.

Limitations, reasons for caution: Despite the careful construction of the interview guide, participants may have given socially desirable answers, particularly given the sensitive nature of the statements. Given the sample size and character, views from specific groups may not be well-represented.
Wider implications of the findings: Egg providers may have concerns regarding the use of surplus eggs by clinics. Information giving and the taking and ensuring on-going consent need to ensure that egg providers have a more complete understanding of the possible ways in which eggs may be used or stored for future use.
Trial registration number: Not applicable

P-339 Should long-term follow-up post-mitochondrial replacement be left up to physicians, parents, or offspring?

T. Ishii [1]
[1]*Hokkaido University, Office of Health and Safety, Sapporo, Japan*

Study question: The UK requires only a long-term follow-up 'plan' for each mitochondrial replacement (MR) case. Then, should the follow-up be left up to physicians, parents, or offspring?
Summary answer: Physicians and parents should take coordinated efforts for the practical and offspring-centred follow-up, while entitling the resultant youth to refuse follow-up.
What is known already: Due to the experimental stage, MR can fail to prevent serious mitochondrial disease in offspring, or can unexpectedly affect the first and subsequent generations. Accordingly, the need for long-term and even intergenerational follow-up of resultant offspring born via MR has been underscored. Although some suggested making parental consent to long-term follow-up a condition for undergoing MR, parents can withdraw consent. Eventually, a UK regulator only requires a long-term follow-up plan in each MR protocol. Thus, follow-up post-MR is not mandatory. Those raise the question of whether follow-up post-MR should be left up to physicians, parents, or resultant children.
Study design, size, duration: First, case reports of germline mtDNA modification were surveyed. Then, identified cases were investigated as to whether resultant children were followed up. Next, major mitochondrial diseases were compared regarding those pathologies. After the ethical assessment of MR for prenatally preventing mitochondrial disease, practical and humane long-term follow-up post-MR was explored using knowledge obtained. Finally, its wider implications were considered regarding the use of MR for treating intractable female infertility.
Participants/materials, setting, methods: PubMed survey of germline mtDNA modification reports with English abstract, published until April 2018, identified 14 relevant cases. There was only one report that addresses the follow-up of resultant children, namely one survey of children born via ooplasmic transfer. For the pathological comparison, myoclonus epilepsy associated with ragged-red fibers (MERRF), mitochondrial myopathy, encephalopathy, lactic acidosis, and stroke-like episodes (MELAS) and Leigh syndrome were selected.
Main results and the role of chance: Long-term follow-up post-MR to safeguard children from serious mitochondrial disease should not simply be left up to physicians, parents, or the resultant children.

At clinics, physicians must carefully inform couples of the risks of MR and the importance of long-term follow-up tailored to a specific mitochondrial disease. Namely, according to the presumed timing of onset of MELAS and Leigh syndrome, the clinically minimum required period for follow-up can be approximately one or two decades. Regarding MERRF, the minimum required period ranges from childhood to around 40 years of age. Importantly, an adequate follow-up plan might extend several decades even in cases of MR for preventing MELAS and Leigh syndrome.

Given that the use of MR is a responsible excise of one's reproductive freedom to have genetically-related children free from mitochondrial disease, parents who understand those points should ensure long-term follow-up be properly performed in the best interest of their offspring. On becoming legally competent, the resultant youth should be entitled to refuse follow-up if mitochondrial disease has been adequately prevented with medical proof. This offspring-centred follow-up approach is applicable to the use of MR for preventing early-onset type of MERRF as well as MELAS and Leigh syndrome.

Limitations, reasons for caution: This clinical and ethical consideration depends on the pathology of three major mitochondrial diseases and MR regulation in the UK. In other countries and/or other conditions, more practical and humane follow-up approaches may be conceivable.
Wider implications of the findings: This long-term follow-up approach could also be, to some extent, applicable to the use of MR for infertility treatment, although the primary endpoint is live births. At least, immediate follow-up of resultant infants should be performed through collaborative efforts by fertility physicians and pediatricians.
Trial registration number: not applicable

P-340 Strong fertility patients´ concerns about frozen embryos: a pilot descriptive study in an Argentinean fertility center

S. Lancuba, M.D.[1], N. Lima, Salome[2], C. Branzini[3]
[1]*CIMER Centro de Investigaciones en Medicina Reproductiva, Dirección Médica, Buenos Aires, Argentina*
[2]*National Scientific and Technical Research Council - CONICET Argentina, Facultad de Psicología- Universidad de Buenos Aires, Buenos Aires, Argentina*
[3]*CIMER Centro de Investigaciones en Medicina Reproductiva, Head of the Embryology Laboratory, Buenos Aires, Argentina*

Study question: What is the relation between an embryo representation and the disposition decisions among fertility patients in the countries with insufficient regulations like Argentina?
Summary answer: Several patients who undergo fertility treatments and don't have children represent the embryo as a child. When this happens, patients face difficulties in decision making.
What is known already: Reproductive decision making is a dynamic process. Many studies suggest that embryo representation is a crucial factor to identify those patients who experience difficulties in decision-making. This is shaped by multiple reasons, for instance, experience during past IVF treatments, life events, psychosocial factors, beliefs and personal values. However, despite this, the nature of the links between embryo representation and decision to donate or discard, remain unclear. It seems that couples undergoing fertility treatments find it difficult to donate embryos to other couples when they, themselves, are not guaranteed to have children of their own.
Study design, size, duration: A descriptive study using a survey method research was conducted to know what are the embryo perceptions and opinions of fertility patients at their first visit to a fertility center. The population under study was men and women who started fertility treatments in a specialized fertility facility of Buenos Aires City. This pilot study analyses a non-probabilistic sample and was performed between April and December 2018.
Participants/materials, setting, methods: 59 fertility patients were studied, 37.2% (22 participants) have cryopreserved embryos at the time the survey was administered. The participants are working Argentinean citizens with a good educational level (36.8% complete university studies) and are either married (46.7%) or in cohabitation (35%). The data was collected through an anonymous and self-administered questionnaire that was completed in the fertility center where the participants made their first time consultation.
Main results and the role of chance: Patients face uncertainties when they were asked to select between the conventional embryo disposition options: with 37% of respondents choosing *store for reproduction*; 8% *donate to another couple*; 2% would *thaw and discard*, but 25% have still not come to a decision and 28% do not know or do not answer. Among the patients who did not make any decision or do not answer, 47% have chosen "child" as the option that best represents the embryo. The absence of children in the majority of the sample (61.1% still have no children) makes '*store for reproduction*' the prevailing option. Although there are relatively few participants who have decided to donate their surplus embryos (5 participants), many of them reported having considering it (43%). When the patients were asked their opinion about the possibility that the Fertility Center could dispose of the embryos that are presumed "abandoned" (meaning 5 or more years without any contact with the progenitors despite the efforts made to contact them), the majority totally agree (41%), partially agree (29%), partially disagree (12%) and disagree totally (18%). The vast majority of respondents (86.5%) would not be willing to face the costs of maintaining long-term cryopreservation.
Limitations, reasons for caution: Sample size could be more robust. The conclusions are related to the context where the study was performed. The patient's indecisiveness regarding embryo disposition decisions are deepened in a context of legal uncertainty.
Wider implications of the findings: After more than three decades of assisted reproduction, the problem of the embryo moral status still persist. In this context, gaining in-depth knowledge of the decision-making process and factors that influenced it might be useful to improve the communication strategies.
Trial registration number: not applicable

P-341 Attitudes towards in vitro gametogenesis in a representative sample of the Belgian population

H. Mertes[1], S. Segers[1], V. Provoost[1], G. Pennings[1]
[1]*Bioethics Institute Ghent BIG Ghent University, Department of Philosphy and Moral Sciences, Gent, Belgium*

Study question: What are the current attitudes towards the possibility of in vitro gametogenesis (IVG) in the Belgian population?
Summary answer: Attitudes towards the importance of genetic parenthood are ambivalent. There is limited acceptance of safety and efficacy testing of IVG (embryo and animal research).
What is known already: The great majority of people attending a fertility clinic prefer genetic over non-genetic parenthood. A previous Dutch study indicates that there is widespread acceptance of stem cell based fertility treatments, both for heterosexual and same-sex couples, but low acceptance for the treatment of single women and women who are infertile due to aging.
Study design, size, duration: A questionnaire was developed and incorporated into a web-based online survey and sent out to Belgians 18 years or older in September/October 2018 by a market research and polling agency (iVOX) until a representative sample (by age, gender and region) of 1000 participants was reached.
Participants/materials, setting, methods: The survey contained questions about the general attitude towards IVG, attitudes towards the different goals of IVG, the importance of several potential uses of IVG, risks and means of risk mitigation, different settings in which IVG might be used and other potential future reproductive technologies. Data were analyzed and correlated with socio-demographic variables.
Main results and the role of chance: There is generally an ambivalent attitude towards the importance of genetic parenthood. While 64,4% of respondents believe that families resulting from donor conception and families in which children are genetically linked to both parents are equally valuable, 26,5% of respondents indicate that a genetic relationship between parents and children is necessary for a good parent-child relationship and 67,6% consider the possibility of establishing genetic parenthood to be an important advantage of IVG. French-speaking participants adhere a greater importance to the genetic link than Dutch-speaking participants.

A quarter of our respondents (25.2%) objected to the use of IVG to accomplish full genetic reproduction in lesbian couples, while a majority (64.7%) objected to the use of IVG in post-menopausal women. The impact of religion and level of education was very limited.

A minority (16.7%) of participants was willing to accept greater risks for IVG than for other ARTs, but the use of spare IVF embryos to study those risks was acceptable for only 54.7% of participants, embryo creation for 39.7%, experiments on mice for 33.0% and on monkeys for 29.0% (with a significantly greater acceptance by men than women).

Finally, 85,9% agreed that the government should strictly regulate IVG.
Limitations, reasons for caution:

Between 8 and 15% indicated that they had "no opinion" about the statement. The characteristics of this group of respondents and the impact on the sample's representativeness need to be taken into consideration.
Wider implications of the findings: Balancing the benefits of IVG with the risks and the measures needed to mitigate those risks is compromised by a great diversity of attitudes towards the importance of genetic parenthood and the acceptability of embryo and animal research. There is a need for public education and dialogue on those topics.

Trial registration number: not applicable

P-342 The moral relevance of egg donors' drive to donate: a study of online forums in the UK

V. Provoost[1], M. De Proost[2], N. Hudson[3]
[1] *Ghent University, Bioethics Institute Ghent BIG, Gent, Belgium*
[2] *Free University Brussels, Centre of Expertise Gender- Diversity and Intersectionality RHEA, Brussels, Belgium*
[3] *De Montfort University, Centre for Reproduction Research, Leicester, United Kingdom*

Study question: How do (potential) egg donors frame egg donation on online forums and what is the moral relevance of this for the regulation of egg donation?
Summary answer: Apart from language of helping and giving, we found a discourse of egg donation as something one could experience as a deeply felt desire.
What is known already: Online information shapes egg donation practices in salient ways. Online spaces become ever more important in users' quests for information and support. Previous studies point to the gendered rhetoric of altruism that draws on constructions of ideal motherhood and to the use of emotional language (e.g. words as 'gift' or 'gift of life') to target egg donors. Studies have shown how agencies attempt to recruit potential donors through both monetary and non-monetary benefits that may focus on personal gain, rather than on other considerations.

This is the first study on egg donation and Internet forums in the UK.
Study design, size, duration: A google search using the words 'Egg donation' and 'UK' was conducted to replicate potential forum users' searches. Purposeful sampling was used to guarantee variation in user profiles and forum initiators. Four freely accessible forums (active between 2015 and 2017) were included led by patients (1), private fertility clinics (1), and parenting communities (2). Posts of eggs sharers and intra-family donors were excluded. We studied 193 posts from 33 threads involving 125 unique contributors.
Participants/materials, setting, methods: The length of posts varied between 16 and 295 words. The second author carried out the initial coding using in-depth inductive thematic analysis. Code samples were checked by the first author and discussed by all three authors until a consensus was reached about a coherent and internally consistent thematic map. Here, we describe three themes: 'presenting selves as available', 'helping by giving' and 'the drive to donate'. (Potential) egg donors are described here as 'donors'.
Main results and the role of chance: Forum posters represented themselves as the 'ideal donor' via messages varying between subtle offers of help to those in the style of personal ads, which were marked by positively articulated self-disclosure. Donors wanted to help others and strongly emphasised how special their donation was using phrases like 'the greatest gift'. Reimbursement was never directly mentioned as a motive and many women explicated that it was not their main motivation.

Donors often expressed the desire to establish some kind of relationship with the recipients and/or the donor-conceived child and several appeared to use forums as a way to side-step current UK regulations that guarantee anonymity for all involved parties until the age of 18.

In many posts, an eagerness to donate was phrased as 'wanted to for a long time' or 'nothing will stop me'. These posts described how the act of donating eggs required bodily investment or even a form of self-sacrifice and risk-taking for the sake of others. In these posts, concerns or even negative experiences were overruled by a clear drive to donate.

In addition, we will consider the moral acceptability of aspirations like physical self-sacrifice, attention seeking, and the desire for contact with and impact on recipients/children.
Limitations, reasons for caution: The research data were forum posts, rather than the donors posting them. Therefore, they may provide a partial and limited picture of lived experiences. This qualitative study does not aim to make empirical generalisations but rather to generate theoretical inferences. The ethical analysis uses the empirical data as cases.
Wider implications of the findings: In contrast to the dominant view of egg donors as passive and purely altruistically motivated responders to needs of others, we urgently need to construct a view that takes into account the interests as well as the ambitions of some donors and study the ethical implications thereof.
Trial registration number: not applicable

IMPLANTATION AND EARLY PREGNANCY

P-343 HIF2α in the uterine stroma permits embryo invasion through detachment of uterine luminal epithelium

L. Matsumoto[1], Y. Hirota[1], T. Saito-Fujita[1], T. Tanaka[1], S. Akaeda[1], T. Hiraoka[1], Y. Fukui[1], M. Matsuo[1], H. Haraguchi[1], N. Takeda[2], T. Fujii[1], Y. Osuga[1]
[1] *Graduate School of Medicine- The University of Tokyo, Department of Obstetrics and Gynecology, tokyo, Japan*
[2] *Graduate School of Medicine- The University of Tokyo, Department of Cardiovascular Medicine, tokyo, Japan*

Study question: Hypoxia inducible factor 2α (Hif2α) is expressed in the mouse uterus during embryo implantation. This study aimed to clarify functions of uterine Hif2α using conditional knockout mouse models.
Summary answer: This study provided a new insight that stromal Hif2α allows trophoblast invasion through detachment of the luminal epithelium and activation of an embryonic survival signal.
What is known already: It has been reported that Hif2α, a major transcriptional factor inducible by low oxygen tension, is expressed in the mouse uterus during embryo implantation, its role in pregnancy outcomes remains unclear.
Study design, size, duration: In vivo study using mouse models
Participants/materials, setting, methods: Mice with deletion of Hif2α in the whole uterus (UKO) and in the stroma (SKO) were generated by crossing Hif2α-floxed mice with Pgr-Cre and Amhr2-Cre mice, respectively. Reproductive phenotypes of these mice were evaluated after mating with wild-type fertile male mice.
Main results and the role of chance: UKO mice showed infertility due to implantation failure. Supplementation with progesterone and leukemia inhibitory factor restored decidual growth arrest and aberrant position of implantation sites in UKO mice, respectively, but did not rescue pregnancy failure. Histological analyses in UKO mice revealed persistence of the intact luminal epithelium, which blocked direct contact between stroma and embryo, inactivation of embryonic PI3K-AKT pathway, and failed embryo invasion. UKO mice showed the reduced expression of membrane type 2 metalloproteinase, lysyl oxidase, VEGF, and adrenomedullin in the stroma at the attachment site. In addition, SKO mice showed infertility with impaired embryo invasion, suggesting the importance of stromal Hif2α in embryo invasion.
Limitations, reasons for caution: This study did not use human cells and tissues but mouse models.
Wider implications of the findings: There is a new therapeutic potential to prevent conception by blockade of HIF2α
Trial registration number: not applicable

P-344 Deciphering the trophoblast-epithelium dialogue: a time course study of in vitro early attachment

P. Vergaro[1], G. Tiscornia[1], F. Zambelli[1], A. Rodríguez[1], J. Santalo[2], R. Vassena[1]
[1] *Clínica EUGIN, Assisted Reproduction, Barcelona, Spain*
[2] *Universidad Autónoma de Barcelona, Facultad de Biociéncias- Departamento de Biología Celular- de Fisiología y de Immunología, Barcelona, Spain*

Study question: What is the evolution of the transcriptional dynamics of both the trophoblast and the endometrial epithelium in early attachment during implantation?

Summary answer: Successful attachment produced an early and transient transcriptional response in the receptive epithelium, in contrast to a more dynamic transcriptional response in the trophoblast

What is known already: Embryo implantation is the most limiting step in success of infertility treatments. Many studies have focused on this process using *in vitro* models of embryo-endometrium co-culture as well as animal models. Although a number of molecules have been reported to be involved in the embryo-endometrium interaction, the bulk of molecular mechanisms regulating human implantation still remain elusive. In order to understand the requisites for successful implantation and the establishment of pregnancy, a comprehensive description of the compartment-specific gene expression responses that both the embryo and the endometrium undergo during implantation is urgently required.

Study design, size, duration: We developed an *in vitro* co-culture model of confluent monolayers of a cell line mimicking receptive epithelium (Ishikawa) combined with spheroids of an engineered, Green Fluorescent Protein (GFP) expressing, trophoblast line (JEG-3) in 96-well plates. After 0hrs, 8hrs and 24hrs of interaction, the co-cultures were pooled and sorted by FACS; GFP+ (trophoblast spheroids) and GFP- (epithelial substrates) as well as control fractions non-co-cultured were collected for RNA extraction (in triplicate) and analyzed by RNA-seq.

Participants/materials, setting, methods: The transcriptional changes of both compartments (GFP+ trophoblast and GFP- epithelium) at different time points were analyzed using Illumina Hiseq 2500 system. Differential expression was performed with DESeq2; statistical significance was set at Log2 fold change $\geq$1 and p-value $<$0.05. Gene set enrichment analysis (GSEA) was performed using GOBP and Broad Hallmarks databases, with false discovery rate cut-off $<$10%. Further, an *in-silico* strategy was used to predict protein interactions in the trophoblast-epithelium crosstalk.

Main results and the role of chance: After 8 hrs of co-culture, 200 genes were up-regulated and 95 genes were down-regulated in the epithelial compartment; from 8 to 24 hrs, 127 genes were up-regulated and 131 were down-regulated. Trophoblast challenge induced a wave of epithelial transcriptional changes that resulted in overrepresentation of epithelial to mesenchymal transition (EMT), cell movement, apoptosis, hypoxia, inflammation, allograft rejection, myogenesis and cell signalling (*e.g.,* TNFa/NFkb, KRAS, JAK-STAT cascades) at 8 hrs. Interestingly, most pathways subsided at 24 hrs (*i.e.,* EMT, cell movement, allograft rejection, myogenesis and cell signaling), while others did not change (hypoxia, inflammation and apoptosis). In the trophoblast compartment, the transcriptional changes upon co-culture were more dynamic. A total of 1201 and 46 genes were up- and down-regulated after 8 hrs, respectively; from 8 to 24 hrs, 458 genes were up-regulated and 23 were down-regulated. The GSEA revealed that angiogenesis and hypoxia were overrepresented at both 8 and 24 hrs, while EMT and cell signalling were only increased at 8 hrs; from 8 to 24 hrs, inflammation and estrogen response were increased, while proliferation was decreased. The *in silico* protein interaction analysis, based on our transcriptional profiling, predicted 87 early trophoblast-epithelium membrane interactions (e.g., LAMA3-CD44, CD44-EGFR and ITGA5- NRP1).

Limitations, reasons for caution: Our *in vitro* model is based on cell lines of carcinoma origin; therefore, caution is warranted when extrapolating our results to other systems. We describe a 2-D model that does not take into account the involvement of other cell types in the transcriptional changes during implantation.

Wider implications of the findings: We provide a comprehensive description of the molecular events regulating early implantation in a time and compartment specific manner; although the results cannot be directly extrapolated, our data can be a source of candidate molecules important for successful embryo attachment.

Study question: Does induced cycles achieve the better pregnancy outcomes compared to hormone replacement therapy during endometrial preparation (EP) for frozen-thawed embryo transfer (FET) in women who suffered from intrauterine adhesion (IUA).

Summary answer: Induction cycles achieved significantly higher rates of live birth, ongoing pregnancy and implantation when compared to artificial cycles in patients with moderate to severe IUA.

What is known already: Artificial cycles (ACs) are most commonly used to prime the endometrium before FET. However, poor endometrial response to exogenous hormone treatment could be observed in many patients with IUA. Moreover, high estrogen exposure may accelerate endometrial fibrosis. Additionally, patients need to be administered the prolonged hormonal treatment in case of pregnancy, leading to an increased cost, inconvenience and risk of venous thrombosis. Alarmingly high pregnancy wastage in AC has been noted. There are many studies to research which is the best protocol to prepare the endometrium for FET, but there are no studies that aim at the IUA patients only.

Study design, size, duration: A retrospective, matched, cohort study including 202 women who underwent autologous FET after hysteroscopic adhesiolysis was conducted at a university-affiliated center between January 2017 and March 2018. The patients with induced cycle (IC) were matched to those with AC by using propensity score matching, in a 1:1 ratio. The matching variables were the age at FET, body mass index, American Fertility Society (AFS) score before operation and the number of embryos transferred.

Participants/materials, setting, methods: The inclusion criteria were: (1) age at FET $<$40 years, (2) BMI $<$30 kg/m^2, (3) moderate to severe IUA according to the AFS classification (1988 version) (a score of 5-12). The exclusion criteria were: (1) using embryos originating from donor oocytes or preimplantation genetic testing, (2) pathology conditions such as hydrosalpinx, uterine adenomyosis, uterine fibroids and uterine malformations, (3) IUA present at COOK balloon removal. The pregnancy outcomes were compared between ICs and ACs.

Main results and the role of chance: Of the initial 499 cycles, 150 ICs and 132 ACs met the inclusion and the exclusion criteria. A total of 101 ICs and 101 ACs were included in the final analysis after matching. There was no difference in patient baseline characteristics between the two groups. The rates of live birth (44.6% vs 30.7%), ongoing pregnancy (48.9% vs 36.2%) and implantation (45.3% vs 32.6%) were significantly higher in the IC group ($p < 0.05$). The clinical pregnancy rate (58.4% vs 45.5%) and early miscarriage rate (9.1% vs 18.6%) were similar between the IC group and AC group ($p > 0.05$). There were 9 (20.0%) pairs of twins in the IC group and 5 (16.1%) in the AC group, respectively. No differences were observed in adverse pregnancy outcomes including premature delivery (13.3% vs 9.7%), low birth weight (14.8% vs 13.9%), placenta accreta and placenta previa (6.7% and 4.4% in IC group vs 16.1% and 3.2% in AC group, $p > 0.05$).

Limitations, reasons for caution: The main limitation of the current study is its retrospective nature and the sample size was not large enough. Moreover, it should be cautious in interpreting the results in patients with severe IUA due to the small proportion.

Wider implications of the findings: This study supports the limited evidence that, for women with moderate to severe IUA, FET using IC results in significantly improved rates of live birth, ongoing pregnancy and implantation when compared with AC. A randomized controlled trial (clinical trial registration number: NCT03578172) with adequate sample size is being conducted.

Trial registration number: Ethical Committee of the hospital no. LL-SC-2018019.

P-346 Predictive factors for biochemical pregnancy in intracytoplasmic sperm injection cycles

B. Zanetti[1], D. Braga[1,2], A. Setti[1,2], R. Ferreira[3], A. Iaconelli Jr.[1,4], E. Borges Jr.[1,4]

[1]*Associação Instituto Sapientiae, Scientific research, Sao Paulo, Brazil*
[2]*Fertility Medical Group, Scientific research, Sao Paulo, Brazil*
[3]*Fertility Medical Group, IVF laboratory, Sao Paulo, Brazil*
[4]*Fertility Medical Group, Clinical department, Sao Paulo, Brazil*

Study question: Which factors contribute to the incidence of biochemical pregnancy in intracytoplasmic sperm injection (ICSI) cycles?
Summary answer: The combination of suboptimal endometrial development, and poor semen and embryo quality contribute to an increased incidence of biochemical pregnancy in ICSI cycles.
What is known already: Human reproduction is marked by its inefficiency. It is estimated that 70% of all pregnancies are lost prior to live birth; among these, 25% to 50% end up as biochemical pregnancies (BP). Most BP losses go unrecognized in natural pregnancies, because the menstrual cycle is not significantly altered. Nevertheless, in patients undergoing assisted reproduction technology (ART) treatments, in which β-hCG levels after embryo transfer are actively monitored, BP is diagnosed in up to 20% of the cycles. Despite the high incidence of BP, its predictive factors and precise etiologies remain unknown.
Study design, size, duration: This historical cohort study included data from 3,134 ICSI cycles performed from June/2010 to September/2016. The sample size was determined by considering effect size of 10%, α of 5%, β of 80% and 11 covariates for 1,634 subjects. Cycles were split into four groups, depending on the pregnancy outcomes: Clinical Pregnancy (CP, n = 903), Biochemical Pregnancy (BP, n = 55), Miscarriage (Mis, n = 142) and Negative Pregnancy (NP, n = 2,034).
Participants/materials, setting, methods: The study was performed in a private university-affiliated IVF center. In the first analysis, the effects of controlled ovarian stimulation, laboratory data and seminal parameters on pregnancy outcomes from the four different groups were evaluated using general linear models adjusted for potential confounders. Then, a discriminant analysis was conducted by the stepwise method for ICSI cycle prediction of BP or CP outcomes, to establish cut-offs for BP.
Main results and the role of chance: The results from the first analysis showed that the total sperm count ($p = 0.035$), total and progressive sperm motility ($p = 0.001$ and $p = 0.023$, respectively), total motile sperm count (TMSC, $p = 0.029$) and the endometrial thickness ($p < 0.001$) were significantly lower in the BP group compared to the other groups. Lower rates of high-quality embryos on days two and three of development were observed in the BP group compared to the CP and Mis groups ($p < 0.001$). In the second analysis, the cut-offs for BP prediction established by the discriminant analysis were endometrial thickness < 11 mm, total sperm motility < 55.5% and total dose of FSH > 2,400 IU.
Limitations, reasons for caution: The main limitation of the present is the reduced number of cycles included in BP group. Moreover, cut-offs values for the prediction of BP must be used in combination, which prevents the use of a single parameter to predict BP chance.
Wider implications of the findings: Biochemical pregnancy can be predicted by utilizing combined cut-offs of endometrial thickness, sperm motility and total dose of FSH. This approach can both improve the understanding concerning mechanisms responsible for biochemical pregnancy and assist in the management of cases of previous pregnancy losses.
Trial registration number: None

P-347 Transcriptional analysis of the trophoblast-epithelium interaction: how do they respond to each other?

G. Tiscornia[1], P. Vergaro[1], A. Rodriguez[1], J. Santaló[2], R. Vassena[1]

[1]*Clinica Eugin, Assisted reproductive, Barcelona, Spain*
[2]*Univesidad autónoma de barcelona, Professor, Barcelona, Spain*

Study question: Which are the transcriptional changes specific to the trophoblast *vs*. the receptive or non-receptive endometrial epithelium upon their interaction?
Summary answer: Endometrial receptivity requires a transcriptional signature that determines the trophoblast response. A series of coordinated compartment-specific transcriptional responses drive attachment and implantation.
What is known already: Human implantation is a highly orchestrated process essential for the establishment of pregnancy, and currently, implantation failure is a major cause of human infertility and the most limiting step in ART. Implantation failure can be caused by both maternal and embryonic factors, as well as by a defective crosstalk between them. However, the molecular mechanisms underlying human implantation are poorly understood and cannot be studied *in vivo*. Although several *in vitro* models have been developed to study human implantation, the specific transcriptional dynamics of the trophoblast and receptive *vs*. non-receptive endometrial epithelium during their interaction have not been described.
Study design, size, duration: We developed an *in vitro* model by co-culturing a) immortalized cell lines of non-receptive (HEC-1-A) or receptive (Ishikawa) epithelium and b) GFP expressing spheroids of a trophoblast line (JEG-3). 96-well plates containing a confluent layer of substrate were co-cultured with one spheroid per well, in triplicate. After 48h, all the wells of each plate were pooled and sorted by FACS for the isolation of epithelial and trophoblast compartments, including non-co-cultured controls of each cell line.
Participants/materials, setting, methods: The transcriptional profiles of the trophoblast (GFP+) and non-receptive *vs*. receptive epithelium (GFP-) were separately characterized by RNA-seq (Illumina Hiseq 2500). Statistical significance of gene expression differences was set at Log2 fold change ≥ 1 and p-value <0.05. Gene set enrichment analysis (GSEA) was performed to reveal the biological function of differentially expressed genes using GOBP and Broad Hallmarks databases, with false discovery rate cut-off <10%. An *in-silico* strategy predicted protein interactions in the trophoblast-epithelium crosstalk.
Main results and the role of chance: After co-culturing Ishikawa cells with trophoblast spheroids, 310 and 298 genes increased or decreased their expression compared to non-co-cultured Ishikawa control cells, respectively; only 9 genes were differentially expressed in HEC-1-A upon co-culture with trophoblast spheroids. Compared to HEC-1-A, the trophoblast challenge to Ishikawa cells differentially regulated the expression of 495 genes; these differences highlighted an important role for cell adhesion and extracellular matrix (ECM) molecules in the trophoblast-epithelium interaction. GSEA revealed enrichment of cell division, cell cycle regulation and metabolism in the Ishikawa substrate. Both differential gene expression and functional analysis suggested that the trophoblast spheroid response depended on the receptivity of the substrate. Comparing the gene expression profile of trophoblast spheroids revealed that 1877 and 323 genes were up-regulated or down-regulated when co-cultured on Ishikawa (compared to HEC-1-A) substrates, respectively. Pathways favourable to development, including tissue remodelling, organogenesis and angiogenesis were enhanced in the trophoblast compartment after co-culture of spheroids with the receptive epithelium. By contrast, the co-culture of trophoblast spheroids with the non-receptive epithelium enriched pathways mainly related to trophoblast cell proliferation and cell cycle regulation. Our *in silico* interactome network approach, based on our transcriptomic profile, predicted 21 direct protein partners presumably involved in trophoblast-epithelium crosstalk.
Limitations, reasons for caution: Our model, based on immortal carcinoma cell lines (widely used as models for receptive and non-receptive epithelium) may not exactly reflect the behaviour of primary endometrial epithelial cells. Also, the trophoblast spheroids may not fully represent the response of human embryos
Wider implications of the findings: Our system allows analysis of transcripts and proteins involved in embryo attachment in a compartment specific manner, superseding previous approaches which analyze both compartments together, and led to the identification of trophoblast or the epithelial molecules that might play a role in successful embryo attachment.
Trial registration number: not applicable

P-348 Frozen embryo transfer in hormone replacement cycle contributes to the development of subchorionic hematoma

O. Mochizuki[1], S. So[2], N. Murabayashi[2], W. Yamaguchi[1], N. Miyano[1], F. Tawara[1]

[1]*Tawara IVF clinic, Reproductive Medicine, Shizuoka, Japan*

[2]Hamamatsu University of School of Medicine, Reproductive and Perinatal Medicine, Shizuoka, Japan

Study question: Does the difference in endometrium preparation [hormone replacement cycle (HRC) vs. natural cycle (NC)] in frozen embryo transfer affect the development of subchorionic hematoma (SCH)?
Summary answer: Based on our multivariate analysis, frozen embryo transfer in HRC increases the risk of developing SCH.
What is known already: Although this is debatable, SCH is known to be a cause of miscarriage and preterm birth. It was recently reported that frozen embryo transfer contributes to the development of SCH in assisted reproductive technology (ART). Moreover, it has been reported that taking aspirin during ART also contributes to increased SCH.
Study design, size, duration: This study was approved by the Institutional Review Board (IRB) of Tawara IVF clinic (Shizuoka, Japan). Between Mar. 2015 and Oct. 2018, 1947 pregnant women (HRC: n=1211, NC: n=736) involved in frozen embryo transfer in Tawara IVF clinic were included in this cross-sectional study. Pregnant women with echo-free space outlining the intact gestational sac who presented with vaginal bleeding at a gestational age of 9 weeks or less were judged to have SCH.
Participants/materials, setting, methods: In the HRC, a transdermal estradiol was started on day 2-4 of menstruation and was applied at 2.26 mg every 2 days until the 4th week of gestation, and continued at 1.44 mg every 2 days until gestation week 7. For luteal phase support, oral dydrogesterone (15 mg/day) was used for both HRC and NC. Furthermore, vaginal progesterone (300-800 mg/day) was used for HRC, but none or small amount of this was used for NC.
Main results and the role of chance: Patient backgrounds : Age, HRC 35.8±4.2, NC 35.8±4.1 (p=0.76); BMI, HRC 20.7±2.9, NC 20.8±2.9 (n.s.); Abortion history, HRC 0.38±0.74, NC 0.31±0.60 ($p<0.05$); Percentage taking aspirin during the cycle, HRC 23.0%, NC 10.9% ($p<0.05$). Pregnancy rate was not significantly different between HRC and NC (36.6% and 37.7%, respectively), and in the case of a single blastocyst transfer (SBT), not significant difference was also observed between both groups (42.6% and 44.4%, respectively). In total, 206 pregnant women had SCH (10.6%, only limited SBT, 10.0%). Univariate analysis showed that HRC increased the risk of developing SCH, compared to NC (14.3% vs 4.5%, respectively, OR: 3.55 [95% CI 2.45-5.30]; only limited SBT, OR: 3.93 [2.51-6.44]). In a multivariable analysis, controlling for age, BMI, abortion history, taking aspirin, the adjusted odds ratio (OR) for developing SCH was 3.08 [2.05-4.78] for HRC and 3.24 [2.00-5.49] for only limited SBT. Furthermore, we found that HRC also increased the risk of miscarriage after adjusting the confounding factors described above (OR: 1.71 [1.32-2.23], only limited SBT, OR: 1.66 [1.22-2.26]). However, in this multivariate analysis, the presence of SCH was not associated with increased risk of miscarriage (0.71 [0.46-1.06], only limited SBT, OR: 0.89 [0.53-1.45]).
Limitations, reasons for caution: This was a non-randomized study. The size and location of SCH were not considered in this study.
Wider implications of the findings: Interestingly, we found that frozen embryo transfer in HRC increases the risk of developing SCH. However, SCH does not contribute to increased miscarriage rates. It is necessary to further investigate long-term perinatal outcomes.
Trial registration number: not applicable

P-349 Serum progesterone level and ongoing pregnancy rate following frozen-thawed embryo transfer (FET) after hormone replacement therapy (HRT): a monocentric retrospective cohort study

M. Commissaire[1], S. Epelboin[2], M. Vigan[3], S. Tubiana[3], M.A. Llabador-de-Royer[4], C. Gauché-Cazalis[1], S. Gricourt[1], X. Ferraretto[4], M. Peigné[1]

[1]AP-HP - Hôpital Bichat-Claude Bernard, Unité de Médecine de la Reproduction - Service de Gynécologie-Obstétrique, Paris, France
[2]AP -HP- Hôpital Bichat-Claude Bernard, Unité de Médecine de la Reproduction - Service de Gynécologie-Obstétrique, Paris, France
[3]AP-HP - Hôpital Bichat-Claude Bernard, Department of Epidemiology- Biostatistic and Clinical Research, Paris, France
[4]AP-HP - Hôpital Bichat-Claude Bernard, Service de Biologie de la Reproduction, Paris, France

Study question: To compare, among patients with clinical pregnancy (CP) after FET with hormone replacement therapy (HRT), serum progesterone levels between those with early pregnancy loss or ongoing pregnancy (OP).
Summary answer: Serum progesterone level was lower in women experiencing early pregnancy loss after FET with HRT, potentially reflecting a lack of luteal phase support.
What is known already: Early pregnancy losses rate is higher with HRT for FET than with other protocols even though pregnancy rates are similar. A potential defect in the luteal phase (LP), maybe due to a suboptimal exogenous progesterone substitution, could explain these findings. Progesterone being exogenous in HRT, serum progesterone level reflects what was absorbed by the patient. Data is scarce and contradictory on whether this rate is related to ongoing pregnancy rate (OPR) and on the level required to optimize OPR after FET. The optimal route of progesterone for LP support in HRT is yet to be determined.
Study design, size, duration: A monocentric retrospective cohort study was conducted at a University affiliated fertility center in Paris, France. Between June 2016 and July 2017, 301 FET cycles were fulfilled entirely, thus included: 130 FET were performed after HRT; 171 after mild-ovarian stimulation protocol (OS). All women underwent FET in either cleavage or blastocyst stage. Embryos were mainly frozen by vitrification.
Participants/materials, setting, methods: For HRT, estradiol was administrated orally from the first day of the cycle (4-6mg/day). Vaginal micronized progesterone (600mg/day) was added once endometrial thickness reached 7 mm. Serum beta-hCG and progesterone rates were measured 10- or 12-days following FET, according to embryo stage, and every 48 hours until serum beta-hCG levels reached 1000 UI/ml. CP was defined as hCG>100 UI/ml and OP as fetal heartbeat at 12 weeks of gestation.
Main results and the role of chance: Among the 130 patients who had FET after HRT, 33 had clinical pregnancies (25.4%) and 18 ongoing pregnancies (13.5%). Among patients who had a CP after HRT, serum progesterone levels were higher in case of an OP than an early pregnancy loss at 3 times of measurements, but only significantly 48h after first pregnancy test (4 gestational weeks and 2 days) : PG0 12.4 ng/ml [7.5-14.6] vs 8.2 ng/ml [6.0-13.0], p = 0.320; PG1 15.0 ng/ml [14.0-15.9] vs 8.5 ng/ml [5.9-13.8], p = 0.048. No significative difference was found regarding demographic and cycles characteristics between women with early pregnancy losses and women with ongoing pregnancies. In the HRT group, PG0 (on the day of the first pregnancy test) was not different between pregnant and non-pregnant women (11.6 ng/ml [6.1-14.4] vs 11.2 ng/ml [8.2-14.1] p = 0.8). As expected, pregnancy loss rate was higher after HRT than after OS for endometrial preparation (OPR 13.5% vs 19.0%; p= 0.004) despite same clinical pregnancy rates (25.4% vs 23.4%; p = 0.7).
Limitations, reasons for caution: The small number of patients included and the retrospective nature of the study are the main limitation leading to heterogeneity of population. We calculated afterwards that 400 people per group were needed to show a statistically significant difference at PG0.
Wider implications of the findings: A cycle test before FET with HRT combining serum progesterone level measurement and if possible, an endometrial receptivity test, could help physicians to choose and to optimize the LP support dose and route of administration for each patient.
Trial registration number: The hospital ethics committee gave its unrestricted approval to use anonymously records from all patients who had previously given their informed consent (IRB 00006477).

P-350 Large refractile / lipofuscin bodies are present over a year prior to ovulation

M. Takeshita[1], P. Ferre Pujol[2], M. Nakatsuka[2], H. Funahashi[2], J. Otsuki[2]

[1]Okayama University, Faculty of Agriculture, Okayama, Japan
[2]Okayama University, Assisted Reproductive Technology Center, Okayama, Japan

Study question: When do large refractile / lipofuscin bodies (LB) appear and is the presence of these large bodies determined by the patient's condition?
Summary answer: LBs are present over a year prior to ovulation and their presence seems to be patient- specific.

What is known already: LB is one of the main morphological abnormalities in the cytoplasm of human oocytes. It consists of a mixture of lipids and dense granular materials and exhibits the typical autofluorescence of lipofuscin. Lower fertilization rates and lower embryo development rates have been consistently reported when embryos with LBs have been transferred. LBs appear in both mature and immature oocytes and there is a strong tendency for recurrence in the same patient.
Study design, size, duration: This is a prospective study, conducted with a total of 585 primordial oocytes, which were obtained from four patients with gender identity disorder. Their oophorectomies were performed between November 2018 and January 2019. Informed consent for the use of their ovaries and institutional review board approval were both obtained for this research.
Participants/materials, setting, methods: Primordial oocytes were isolated from the ovaries after the oophorectomies of patients with gender identity disorder. The autofluorecence of the LBs was confirmed by fluorescent microscopy. The presence of lipids in the LBs was confirmed by lipid staining using Nile Blue and Sudan Black. The number of primordial oocytes with and without large LBs was recorded and the percentage of large LBs was compared among the four patients.
Main results and the role of chance: Small and large LBs were found in primordial oocytes from all four patients with gender identity disorder. Both large and small bodies exhibited autofluorescence and were positively stained by Sudan Black and Nile blue. The number of primordial oocytes with large LBs (>5μm) and with only small bodies was calculated for the four patients. The percentage of primordial oocytes with large LBs in patients #1 (28 years old), #2 (44 years old), #3 (30 years old), and #4 (36 years old) was 24.4% (30/123), 5.2% (8/154), 49.0% (70/143) and 28.5% (47/165) respectively.
Limitations, reasons for caution: These results are limited to patients with gender identity disorder who have been treated with testosterone injections until 6 weeks prior to oophorectomy. Therefore, the effects of testosterone on the appearance of LBs cannot be ruled out as effecting the results of this study.
Wider implications of the findings: As LBs were present in primordial oocytes prior to ovulation, and these oocytes require a full year to reach maturity, the cause of the bodies may not be related to stimulation protocols nor the timing of ovulation, but the environment in each patient's ovaries. Thus, recurrence is likely to occur.
Trial registration number: not applicable

P-351 Another cause of fertility-loss

P. Ferre Pujol[1], J. Otsuki[1], H. Funahashi[1], M. Nakatsuka[1]
[1]*Okayama University, Assisted Reproductive Technology Center, Okayama, Japan*

Study question: Is the loss of fertility due to changes in the extracellular environment?
Summary answer: Yes, it may be related to fibrosis beneath the tunica albuginea, which causes an increase in the total thickness of the dense connective tissue.
What is known already: Loss of fertility in women due to old age is a great concern, especially in developed countries. It is well known that the age-related loss of female fertility occurs as a result of the gradual decline in both the quality and quantity of eggs. A recent hypothesis suggests that the loss of fertility may be due to changes in the extracellular environment, which could negatively affect the quality of oocytes.
Study design, size, duration: This is a prospective study, conducted with a total of 18 ovaries, which were obtained from 18 patients with gender identity disorder. Their oophorectomies were performed between April 2014 and April 2016. Informed consent for the use of their ovaries and institutional review board approval were both obtained for this research.
Participants/materials, setting, methods: Slices of these ovaries, 5 μm thick, were prepared for histological analysis by picrosirius red staining (a specific dye for collagen I and III fibers). The mean thickness and density of the outermost part of the ovary, the tunica albuginea (TA) was calculated by computer-image analysis. To assess the effects of the patients' age and androgenic treatment on the ovaries; the data underwent statistical analysis by Pearson's correlation and Logistic regression.
Main results and the role of chance: The mean age of patients was 30.1 ± 7.5 (SD) years, ranging from 21 to 46 years old. There was no correlation between the dosage or length of the androgenic treatment and the thickness and density of the TA ($p = 0.76$ and $p = 0.14$, respectively). However, when the age of the donor was analyzed against the aforementioned parameters, a significant positive correlation ($r = 0.52$, $p < 0.05$) was detected between the thickness of the TA and the age of the patient. Furthermore, when the density of the TA was assessed, the results indicated the presence of another significant positive correlation ($r = 0.55$, $p < 0.05$) between age and TA density. More exhaustive histological analysis revealed that the increase in the thickness of the TA seems to be due to fibrosis beneath it, causing an increase in the total thickness of the dense connective tissue, whereas in normal ovaries, the thick connective tissue capsule of the TA is generally easily distinguished from the cortical tissue area. No interconnection with the pre-existence of polycystic ovarian syndrome was detected.
Limitations, reasons for caution: As human ovaries are a very valuable sample for the use of research, the number of samples available for this study was limited.
Wider implications of the findings: As an increased thickness in the dense connective tissue of the ovarian cortical area, which was found to be correlated with aging, makes it difficult for follicles to grow and ovulate, this could be a contributing factor as to why older women have a reduced oocyte development and ovulation.
Trial registration number: Not applicable

P-352 Concentrations of steroids in endometrium are not based on passive diffusion but altered by local steroid metabolism called intracrinology. A novel concept in endometrial receptivity

L. Brentjens[1], J. Den Hartog[1], B. Delvoux[2], J. Koskivuori[3], P. Koskimies[3], S. Auriola[3], M. Häkkinen[3], N. Van Hoogenhuijze[4], H. Torrance[4], F. Broekmans[4], SCRaTCH-2 study group(5), R. Van Golde[1], A. Romano[2]
[1]*Maastricht University Medical Centre, Obstetrics and Gynaecology, Maastricht, The Netherlands*
[2]*Maastricht University, GROW School for Oncology and Developmental Biology, Maastricht, The Netherlands*
[3]*University of Eastern Finland, School of Pharmacy, Kuopio, Finland*
[4]*Universitair Medisch Centrum Utrecht, Divisie Vrouw en Baby- Gynaecologie & Voortplantingsgeneeskunde, Utrecht, The Netherlands*
[5]*Amsterdam Medisch Centrum, F. Mol, ; Jeroen Bosch Ziekenhuis, J.P. de Bruin, ; Radboud Universitair Medisch Centrum, K. Fleischer, ; Isala, G. Teklenburg,*

Study question: Does the concentration of steroids in circulation reflect steroid concentrations in the endometrium of IVF patients and could IVF outcome be related to these differences?
Summary answer: This proof of principle study shows that steroid concentrations in circulation do not reflect the concentrations in the endometrium of IVF patients due to intracrinology.
What is known already: Too often, IVF cycles lead to disappointment for patient and doctor due to implantation failure *e causa ignota*. Omics' studies gave insight about expression of genes associated with endometrial receptivity and many are under influence of the ovarian steroid hormones estrogen and progesterone. Recent research suggests that the endometrium is not passively exposed to these steroids present in the circulation. Few reports showed that, to create the optimal steroid milieu, the endometrium can fine-tune intra-tissue steroid concentrations. This local steroid biosynthesis and metabolism process is referred to as 'intracrinology', a network of reactions that can synthesize, interconvert and metabolise steroids.
Study design, size, duration: Endometrial tissue and serum were retrieved from another study in which patients were randomized for endometrial biopsy or no intervention, to study the effectiveness of endometrial 'scratching' on pregnancy outcome (SCRaTCH-study). Patients were included after a first failed IVF treatment in which at least one embryo was transferred. Once randomized for the endometrial biopsy, ovulation was monitored and biopsies (Pipelle) and serum were obtained 5-7 days after a positive urinary LH-test in a natural cycle.
Participants/materials, setting, methods: After endometrial biopsy, patients continued with a second IVF treatment. Patients who became pregnant after fresh embryo transfer in the second IVF treatment (n=3) were compared to patients who did not (n=3). Cases and controls were matched for primary

versus secondary subfertility, embryo quality and age. Steroid concentration was determined in endometrial tissue homogenates and serum with the liquid chromatography mass spectrometry analysis. A Pearson Correlation and unpaired Student's *t*-test were used for statistical analyses.

Main results and the role of chance: The endometrial tissue concentrations of the steroids estradiol, estrone, 17-hydroxypregnenolone, 11-deoxycortisol, corticosterone, DHEA, testosterone, 17-hydroxyprogesterone, androstenedione, 21-hydroxyprogesterone and progesterone were not correlated to their corresponding concentrations in the circulating blood. Only the cortisone concentrations in blood were correlated to the concentrations observed in the endometrial tissue ($r=0.93$, $p=0.01$). The concentrations of estradiol, estrone, androstenedione and 17-hydroxyprogesterone were significantly higher ($P<0.05$) in the circulating blood than in the endometrial tissue. Testosterone, 17-hydroxypregnenolone, 11-deoxycortisol, corticosterone and 21-hydroxyprogesterone values were higher in the circulating blood as well, albeit not statistically significant. When the steroid concentrations in the endometrial tissue and circulating blood were compared between women who became pregnant after fresh embryo transfer in the second IVF cycle, and patients who did not become pregnant, we did not observe any statistically significant differences. Due to the pilot nature of this study, we restricted our analysis to only a low number of tissues.

Limitations, reasons for caution: We were unable to correct for confounders that determine endometrial receptivity due to a low number of included patients. Also, we were unaware of euploidy status of the embryo. Furthermore, the relative contribution of stromal versus epithelial cells in the endometrial tissue homogenate was unknown which might have caused bias.

Wider implications of the findings: This proof of principle study shows that concentrations of steroids in circulation do not reflect endometrial tissue concentrations in IVF patients. Although the concept of local steroid metabolism (intracrinology) is well established, its role in endometrium and especially in endometrial receptivity has not gained attention before and merits further evaluation.

Trial registration number: The SCRaTCH study is registered under NTR 5342

P-353 Is uterine natural killer (uNK) cells density related to the number of embryo transfer failure?

W.J. Yang[1], X. Chen[2], Y. Zhao[2], T.C. Li[2]

[1]*Taiwan IVF Group Center, Department of Infertility and Reproductive Medicine, Hsinchu City, Taiwan R.O.C.*

[2]*The Chinese University of Hong Kong, Department of Obstetrics and Gynecology, Shatin, Hong Kong*

Study question: Is uNK cells density around the time of implantation affected by the number of embryo transfer (ET) failure?

Summary answer: Uterine NK cells density significantly increased steadily with the number of ET failure

What is known already: Earlier studies have demonstrated an increase in number of uNK cells in women with recurrent implantation failure, compared with fertile controls. However, it is not known that if the number of ET failure has any impact on the uNK cells density.

Study design, size, duration: It was a retrospective cohort study. A total of 55 women were recruited in the study, including 12, 22, 14 and 7 women who failed to conceive after 2, 3, 4 and ≥5 embryo transfers, respectively. All endometrial biopsies were collected precisely on the putative day of blastocyst transfer of a mock non-conception hormonal replacement treatment (HRT) cycle, that is five days after initiation of progesterone (P+5).

Participants/materials, setting, methods: Endometrial sections were immunostained for CD56 to identify uNK cells. Image capture and cell counting were performed according to a standardized protocol. Results were expressed as percentage of positive uNK cells/ total stromal cells.

Main results and the role of chance: The median uNK cells density was 1.8% (range 0.9-3.2%), 2.1% (range 0.8-3.5%), 3.8% (range 1.7-5.8%) and 4.1% (1.9-5.8%) in women who failed to conceive after 2, 3, 4 and ≥5 embryo transfers, respectively. The median uNK cells density in women with 4 and 5 or more ET failures was significantly higher than those in women who had 2 or 3 ET failures.

Limitations, reasons for caution: The prognostic value of uNK cells measurement in women with recurrent implantation failure has yet to be confirmed.

Wider implications of the findings: The uNK cells density is related to the number of embryo transfer failure. The clinical value of uNK cells measurement in women with recurrent implantation failure is worthy of future study.

Trial registration number: None

P-354 Genome-wide DNA methylation analysis of chorionic villi and decidua in patients with recurrent miscarriage

Y. MATSUMOTO[1], M. Sugiura-Ogasawara[1], A. Kaneda[2], M. Fukuyo[2], F. Ozawa[1], S. Mase[1], T. Kitaori[1], Y. Ozaki[1], Y. Kondo[3]

[1]*Nagoya City University- Graduate School of Medical Sciences, Department of Obstetrics and Gynecology, Nagoya, Japan*

[2]*Graduate school of Medicine- Chiba University, Department of Molecular Oncology, Chiba, Japan*

[3]*Nagoya University Graduate School of Medicine, Division of Cancer Biology, Nagoya, Japan*

Study question: Is an altered DNA methylation program in chorionic villi (embryo factor) and/or decidua (maternal factor) associated with recurrent miscarriage (RM)?

Summary answer: Specific alterations of DNA methylation in gene regulatory regions in chorionic villi but not in decidua are associated with RM.

What is known already: While identifiable causes of RM include antiphospholipid syndrome, uterine anomalies and parental chromosomal abnormalities, we found that embryonic aneuploidy is the most common cause with a frequency of 41%, in a quarter of cases, the causes of this disease are unknown. Although disordered epigenetic transcriptional control owing to aberrant DNA methylation is a critical mechanism in abnormal fetal development, a simultaneous genome-wide DNA methylation analysis of chorionic villi and decidua in RM patients has not been carried out

Study design, size, duration: We examined genome-wide DNA methylation profiles in chorionic villi and decidua of 5 patients with unexplained RM (4.8±1.47) and compared them with 5 matched healthy controls who had undergone an artificial abortion (AA) in the first trimester. All chorionic villi were confirmed as karyotypically normal using comprehensive genome hybridization. Samples were collected in Nagoya City University Hospital from 2012 to 2017. In total, 19 patients and 19 control women were studied.

Participants/materials, setting, methods: DNA was extracted from each chorionic villi and decidua separately. Using the HumanMethylation450k BeadChip, we analyzed genome-wide DNA methylation in both chorionic villi and decidua, and the methylation profiles were compared using unsupervised hierarchical clustering analysis between patients and controls. Gene ontology (GO) analysis was performed to compare differently methylated genes in promoter and enhancer regions. Furthermore, the results were validated by bisulfite pyrosequencing using chorionic villi of 19 patients and 19 controls.

Main results and the role of chance: We extracted Infinium probes with a difference in the average b-value of >0.1 (mean level >10%), and found that 13,426 and 5,816 CpG sites were differently methylated in chorionic villi and decidua of patients in comparison with the controls, respectively. Interestingly, clear distinct DNA methylation signatures were observed between patients and controls by means of an unsupervised two-way hierarchical clustering analysis using the differently methylated probes, on analyzing chorionic villi, but not decidua. Notably, characteristic DNA methylation signatures were more obvious in gene enhancer and promoter regions, both of which are important for the regulation of gene expression. GO analysis revealed that the genes which were methylated differently in chorionic villi were associated with functionality related to multicellular organism processes and system development. Among these methylated genes, we identified gene X, whose enhancer region was highly methylated (mean methylation level, 23.8%) compared to the control ($P<0.001$). Taken together, our data indicate that an altered DNA methylation process during the early development of an embryo may affect the establishment and maintenance of a successful pregnancy.

Limitations, reasons for caution: Our sample size was relatively small. Therefore, a further study of a large cohort should enhance our findings. We are now investigating why the mechanism controlling the altered DNA methylation pattern was particularly established in embryos of RM patients.

Wider implications of the findings: This is the first analysis of genome-wide DNA methylation in chorionic villi and decidua of patients with RM. Our data show that an altered DNA methylation program active in early embryonic development may be one of the causes of RM.

not applicable

P-355 Effect of supplementation with oral dydrogesterone and vaginal progesterone for luteal-phase support in frozen embryo transfer at natural ovulatory cycle

F. Tawara[1], S. So[2], N. Murabayashi[2], N. Miyano[1], O. Mochizuki[1], W. Yamaguchi[1]

[1]*Tawara IVF clinic, Reproductive Medicine, Shizuoka, Japan*
[2]*Hamamatsu University School of Medicine, Reproductive and Perinatal Medicine, Shizuoka, Japan*

Study question: Does the difference in methods for luteal phase support (LPS) affect the rates of miscarriage in frozen embryo transfer (FET) at natural ovulatory cycle (NC)?

Summary answer: Compared to a combination of dydrogesterone (DG) and vaginal progesterone (P), LPS with oral DG had a lower rate of miscarriage in FET at NC.

What is known already: LPS with oral DG or vaginal P in FET during hormone replacement cycle (HRC) prevents miscarriage. In FET at NC with spontaneous or induced ovulation, LPS administered during the luteinized unruptured follicle (LUF) phase may possibly be effective in preventing miscarriage as well. However, it is unknown what type of LPS is effective for the prevention of miscarriage in FET at NC.

Study design, size, duration: In all, 3886 women undergoing single FET at the Tawara IVF clinic (Shizuoka, Japan) between March 2015 and October 2018 received oral DG and/or vaginal P for LPS. Of these, 1462 women who underwent good morphological blastocyst transfer with no history of miscarriage were included in this cross-sectional study (HRC: n=802, NC: n=660). In the FET at NC group, 230 women received oral DG, while 432 women received oral DG with vaginal P as LPS.

Participants/materials, setting, methods: For LPS, oral DG (15 mg/day) was administered for both, the HRC and NC groups. Additionally, vaginal P (90–800 mg/day) was used for HRC, while no or a small dose (100–400 mg/day) of vaginal P was used for NC. Pregnancy was defined as a gestational sac detected on ultrasound at a gestational age of ~8 weeks. Miscarriage was defined as loss of a pregnancy after the presence of gestational sac had been confirmed.

Main results and the role of chance: The rate of pregnancy was not significantly different between the NC and HRC groups (50.0% and 49.4%, respectively). However, the rate of miscarriage was significantly lower in the NC than in the HRC group (15.5% and 20.7% respectively, $p<0.05$). Furthermore, in FET at NC, the oral DG group had a lower rate of miscarriage than the oral DG with vaginal P group (10.4% and 17.8% respectively, $p<0.05$). The age-adjusted odds ratio (AOR) for the rate of miscarriage was 0.52 [95%CI: 0.25–1.02]. Next, we performed an age-related subgroup analysis. The rate of pregnancy was not different between the oral DG and oral DG with vaginal P groups in women aged less than 35 years and in those aged 35 years and above. Although there was no significant difference in the rate of miscarriage rate between the groups for women aged less than 35 years (7.7% in the oral DG group and 6.7% in the oral DG and vaginal P group: AOR 1.06 [0.27–3.79]), the rate of miscarriage was lower for women aged 35 years or above in the oral DG group than in the oral DG with vaginal P group (12.5% and 25.8%, $p<0.05$: AOR 0.41 [0.17–0.91]).

Limitations, reasons for caution: This was a non-randomized study. Moreover, women who underwent NC without any LPS were not included in this study. Therefore, the effectiveness of LPS for prevention of miscarriage in NC is not clear.

Wider implications of the findings: LPS during the LUF phase might be effective in preventing miscarriage. Our results suggest that LPS with oral DG may be more effective in the prevention of miscarriage, especially in women aged 35 and above compared to LPS using oral DG with vaginal P.

Trial registration number: not applicable

P-356 Single nucleotide polymorphisms in PAPP-A affects its proteolytic activity and the biological activity of IGFs: Potential effects on pregnancy outcome

J.A. Bøtkjær[1], P.R. Noer[2], C. Oxvig[2], C.Y. Andersen[1]

[1]*University Hospital of Copenhagen- Rigshospitalet, Laboratory of Reproductive Biology- The Juliane Marie Centre for Women- Children and Reproduction, Copenhagen, Denmark*
[2]*Aarhus University, Department of Molecular Biology and Genetics, Aarhus, Denmark*

Study question: Does the common single nucleotide polymorphism (SNP), rs7020782, in pregnancy-associated plasma protein-A (PAPP-A) show functional effects and does it have prognostic potential?

Summary answer: The minor rs7020782 allele encodes a protein with reduced activity towards insulin-like growth factor (IGF) binding proteins, that may affect IGF bioactivity and pregnancy outcome.

What is known already: PAPP-A is an integral part of prenatal screening and adverse pregnancy outcomes have been associated with aberrant PAPP-A levels. The IGF signalling pathway is important for follicular development and pregnancy outcome. PAPP-A upregulates IGF signalling by liberating IGFs from their corresponding binding proteins. The rs7020782 SNP in PAPP-A has been associated with increased risk of recurrent pregnancy loss. Women homozygous for the minor SNP (7% of Caucasian women) displayed significant reduced levels of PAPP-A in ovarian follicles together with significantly altered hormone levels. Finally, this SNP is positioned in a potential N-glycosylation motif that may alter the properties of PAPP-A.

Study design, size, duration: Molecular characterization of the genetic rs7020782 (SNP) variant in PAPP-A was achieved by comparing recombinant produced PAPP-A proteins manufactured by mutagenesis and subsequently transfection into human embryonic kidney 293T (HEK293T) cells.

Participants/materials, setting, methods: HEK293T cells were transfected with cDNA constructs encoding the two rs7020782 PAPP-A variants ("serine variant": minor allele, "tyrosine variant": major allele). Levels of PAPP-A were measured with ELISA in the cell supernatants. Proteolytic activity of PAPP-A towards radiolabelled IGF binding protein (IGFBP)-2, -4, and -5 was quantified. PAPP-A complex formation with its inhibitors, proMBP and STC2, was evaluated by Western blotting. Cell surface binding of PAPP-A was examined using flow cytometry.

Main results and the role of chance: This study demonstrates for the first time a significant effect of the rs7020782 SNP in PAPP-A on the proteolytic specificity of PAPP-A. A significant reduced cleavage rate of radiolabelled IGFBP-4 was presented for the serine variant (minor allele) of the rs7020782 SNP compared to the tyrosine variant (major allele). In addition, a non-significant reduced cleavage rate of radiolabelled IGFBP-2 and IGFBP-5 was displayed for the serine variant. Unlike IGFBP-5, IGFBP-4 exhibits complex interaction with PAPP-A by interacting directly with substrate-binding exosite(s) in PAPP-A. The serine variant of the rs7020782 in PAPP-A may disturb this proteinase/substrate interaction and consequently result in reduced proteolytic cleavage. Thus, women carrying the serine variant of the rs7020782 SNP in PAPP-A may present with an altered IGF regulation with a limited amount of free IGF to initiate signalling, which in turn affect pregnancy outcome.

PAPP-A cell-surface adhesion to HEK293T cells was not observed to be affected by the rs7020782 SNP and adhesion does not seem to depend on this specific site of variation. Additionally, complex formation between PAPP-A and its inhibitors, STC2 or proMBP, was not influenced by the rs7020782 SNP.

Limitations, reasons for caution: Additional studies are needed to apply the genetic rs7020782 (SNP) variant as a biomarker in a clinical setting.

Wider implications of the findings: We suggest that the rs7020782 SNP in PAPP-A could be used to identify women with high risk of adverse pregnancy outcomes such as recurrent pregnancy loss. Identification of these patients may allow for risk-specific treatment and improve reproductive outcome.

Trial registration number: not applicable

P-357 Impact of MTHFR C677T polymorphism on the levels of vitamin D and homocysteine and NK cell cytotoxicity in women with recurrent pregnancy losses

K. Ota[1], T. Takahashi[1], H. Mizunuma[1], J. Kwak-Kim[2]

[1] Fukushima Medical University, Fukushima Medical Center for Children and Women, Fukushima, Japan
[2] Rosalind Franklin University of Medicine and Science, Reproductive Medicine and Immunology, Chicago, U.S.A.

Study question: How does affect the MTHFR C677T polymorphism on the levels of vitamin D and homocysteine and NK cell cytotoxicity in women with recurrent pregnancy losses?
Summary answer: The levels of vitamin D and homocysteine and NK cell cytotoxicity in MTHFR C677T homozygous were significantly different from both heterozygous and wild-type genotypes.
What is known already: Vitamin D deficiency is a risk for recurrent pregnancy losses through modulating immunological pathways, such as peripheral natural killer (NK) cell activity. MTHFR C677T gene polymorphism, which plays a critical role in modulating plasma homocysteine concentrations, is also a risk for recurrent pregnancy losses.
Study design, size, duration: This study is a cross-sectional study of 837 women with recurrent pregnancy losses during 9 years.
Participants/materials, setting, methods: Total of 837 women with two or more unexplained consecutive recurrent miscarriage was registered, and routine biochemical data including plasma vitamin D and homocysteine and MTHFR C677T genotypes, CC (wild type), CT (heterozygous), TT (homozygous) were examined. We analyzed the immunophenotypes of peripheral blood mononuclear cells from the registered women, and NK cell cytotoxicity assay was performed.
Main results and the role of chance: The rate of MTHFR C677T genotypes with CC (wild type), CT (heterozygous), and TT (homozygous) were 47%, 43%, and 11%, respectively in women with recurrent pregnancy losses. Although the level of vitamin D in homozygous was significantly lower compared to that in heterozygous (p=0.001) and wild-type genotype (p=0.003), the level of homocysteine in homozygous was significantly higher than that in heterozygous (p=0.001) and wild-type genotype (p=0.001). There was a significant negative correlation between the levels of vitamin D and homocysteine in hetero- and homozygous but not wild-type genotypes (Pearson's correlation coefficient was 0.39, 0.41, and 0.23, respectively). In multivariate analysis, vitamin D insufficiency (<30 ng/ml) was an independent predictive factor for hyperhomocysteinemia (adjusted odds ratio 1.89, 95% CI 1.41-2.52). The value of NK cytotoxicity in homozygous was significantly higher than that in heterozygous (p=0.01) and wild-type genotype (p=0.04).
Limitations, reasons for caution: Since this study was a cross-sectional in design, it is insufficient to evaluate the effects of MTHFR C677T genotypes on the prognosis of subsequent pregnancy successes.
Wider implications of the findings: The MTHFR C677T gene polymorphism may involve the pathogenesis of unexplained recurrent pregnancy losses via elevated hyperhomocysteinemia, which is associated with an increased thrombotic risk. An improvement of vitamin D insufficiency might be effective for the success of subsequent pregnancy to those who have a certain condition.
Trial registration number: obgyne001

P-358 External validation of prediction model (M4) for pregnancy of unknown location (PUL) in IVF patients presenting at very erly gestation

P. Doncheva[1], J. Kopeika[1]
[1] Guy's and St Thomas' Hospital, Assisted Conception Unit, London, United Kingdom

Study question: Is the M4 logistic regression model able to predict accurately ectopic pregnancy (EP) in women with IVF pregnancies less than 6 weeks gestation?
Summary answer: M4 prediction model has a high negative predictive value for ectopic pregnancies in women after IVF treatment, however the positive predictive value was relatively low.
What is known already: M4 is a multinomial logistic regression model based on initial serum b-HCG level and the HCG ratio (48h/0h). Entering these values into the M4 formula returns estimated risks of the PUL being failed PUL, intrauterine pregnancy (IUP) or EP. Previous study has demonstrated that this model can be reliably used to rationalize the management of PUL-s with a potential to reduce follow ups in 70 % of PUL-s by reducing the number of visits, scans and blood tests as well as intervention rates. The model demonstrated 80% sensitivity, 88% specificity and 97.5% negative predictive value (NPV) in symptomatic UK population.
Study design, size, duration: This was a retrospective observational study of all women who presented with symptoms of pain or bleeding at less than 6 weeks gestation diagnosed with PUL on transvaginal ultrasound between Jan 2015 and Dec 2017 in a single assisted conception unit. Women were classified as having a PUL if there was no evidence of intra- or extrauterine pregnancy on transvaginal ultrasound. In these women, the M4 model was used to predict the outcome of pregnancy.
Participants/materials, setting, methods: During the study period of three years, there were 3064 pregnancies, of which 408 women presented with symptoms before 6 weeks of gestation. Of these, 37.2% (152/408) were diagnosed with IUP; 26.2% (107/408) had PUL, 7.8% (32/408) had EPs and 28.5% (116/407) did not undergo transvaginal scan due to the rate of falling b-HCG-s. 14 of the PUL-s were excluded as hCG-s were inappropriately timed. The model was applied in 93 women diagnosed with PUL.
Main results and the role of chance: The M4 model predicted 24 failing PUL-s (25%), 18 IUPs (19%) and 51 EPs (54%). However, the final outcome in the studied cohort was as following: 48 failing PULs (51%), 20 IUPs (21%) and 25 EPs (26%).

The sensitivity for prediction of EP was 84%, specificity 72%, positive predictive value (PPV) 52.5% and NPV 92.4%. Comparison with studies in non-IVF population showed similar sensitivity and NPV, 80.8% and 98.6% respectively, with higher specificity (88.9%) and lower PPV (31.8%) in the non-IVF patients.

For prediction of low risk pregnancy (failing PUL and IUP) our results demonstrated sensitivity of 55.5%, specificity 84%, PPV 90.4% and NPV 41.1%. The results significantly differ from the data published for non-IVF population excluding the PPV.

One possible explanation for these differences is that IVF patients often present at much earlier gestation than their non-IVF counterparts. In addition, their characteristics may differ: we are certain about their gestational age and, frequently, the investigations are started because of patient's anxiety or having mild symptoms only.

In conclusion, M4 model has high ability to predict EP with some overestimation in an IVF population but lower ability to predict failing PUL and/or IUP compared with the one in non-IVF patients.
Limitations, reasons for caution: This is a retrospective observational study that includes relatively small number of patients. It included a selective population with IVF pregnancies from a single assisted conception unit. However this is the biggest population of IVF patients with PUL that has been studied.
Wider implications of the findings: According to our knowledge, this is the first study validating the M4 regression model in IVF pregnancies. The results confirm findings from other studies that M4 model has high sensitivity and NPV for EPs, however it has low PPV that can overestimate the risk of ectopic pregnancies in this population.
Trial registration number: n/a

P-359 Antibiotic treatment for chronic endometritis shows more efficacy in success rates of assisted reproductive technology than endometrial scratch in women with repeated implantation failure

D. Kadogami[1], Y. Nakaoka[1], Y. Morimoto[2]
[1] IVF namba clinic, medical office, Osaka, Japan
[2] HORAC Grand Front Osaka Clinic, medical office, Osaka, Japan

Study question: Is the efficacy of antibiotic treatment for chronic endometritis (CE) not due to antibacterial effect but the impact of endometrial scratch?
Summary answer: Antibiotic treatment for CE significantly improves the clinical outcomes in IVF over endometrial scratch alone.
What is known already: CE is defined as a local inflammatory disease and is diagnosed by the presence of plasma cells in the endometrial stroma. Some studies show that CE negatively impacts reproductive outcomes by endometrial receptivity and its prevalence is high in women with repeated implantation failure (RIF). Furthermore, it is also unknown that antibiotic treatment significantly improves the reproductive outcome in women with CE. Alternatively, some authors report that the endometrial scratch has a positive effect on reproductive

outcome. So, whether improvement of reproductive outcomes of women diagnosed as CE is due to antibiotic therapy or scratch remains controversial.
Study design, size, duration: Retrospective study in our clinic, between January 2017 to August 2018. Endometrial biopsy was performed in 156 women with RIF. CE was histopathologically diagnosed using immunohistochemistry. The histopathologic cure of CE was evaluated in the second/third-look biopsy obtained during the following menstrual cycle. Subsequent two cryopreserved-thawed ET cycles were follow-up.
Participants/materials, setting, methods: Biopsy was performed from 2-site in Uterus. CE was diagnosed with the presence of plural CD138 positive cells within the stromal in HPF. Women diagnosed as CE(Group1) had a 14-day oral antibiotic administration. After confirming the absence of CE, they had further embryo transfers (ET). Women without CE(Group2) had further ET promptly. Implantation rate (IR), pregnancy rate (PR), miscarriage rate (MR) and mean endometrial thickness on the day of ET (MET) were compared.
Main results and the role of chance: The prevalence of immunohistochemically confirmed CE was 38.5%(60/156). All of them underwent oral doxycycline(200mg/day) and metronidazole(1000mg/day) administration. In the second-look biopsy, the cure rate of CE was 71.7% (43/60). Seventeen women who did not confirm absence of CE were further treated with a combination of oral ciprofloxacin(800mg/day) and metronidazole(1000mg/day). The overall cure rate following two-step oral antibiotic treatment strategy was 98.3% (59/60). At IVF attempt after treatment, in both groups, reproductive outcome in cumulative two ET cycles was improved. Especially, a significantly higher IR and PR was reported in women from Group 1 compared with women from Group 2 (62.0 versus 35.8%, OR 2.60, 95%CI 1.44-4.20; 48.4 versus 29.3%, OR 2.22, 95%CI 1.52-3.80). Moreover, in MR, Group1 was significantly lower than Group2 (39.5 versus 54.5%, OR 0.51, 95%CI 0.30-0.85). MET was similar between the Group1 and Group2 (10.89±1.79mm versus 10.87±1.82mm p=0.97). No side effects due to antibiotics were observe.
Limitations, reasons for caution: Possible biases related to retrospective studies and to preferential referral of patients with CE, and limited number of cases. Moreover, embryo quality which potentially affect the reproductive outcome is not considered.
Wider implications of the findings: Antibiotic therapy for endometriosis has an positive effect for IVF success rate that exceeds endometrial scratch. This result is encouraging in women with RIF. Studies which consider embryo factor are required. And the association with endometrisis and uterine microbiota is very interesting.
Trial registration number: Not applicable

P-360 Study protocol: The association of paternal factors on recurrent pregnancy loss - REMI III study. (15/25 words)

N. Du Fossé[1], M.L. Van der Hoorn[1], L. Lashley[1]
[1]Leiden University Medical Center, Obstetrics and Gynaecology, Leiden, The Netherlands

Study question: What is the effect of paternal lifestyle and somatic health factors on the development of unexplained recurrent pregnancy loss (RPL)?
Summary answer: We hypothesize that RPL is caused by both maternal and paternal factors; several paternal factors may be associated with the development of RPL.
What is known already: RPL, defined as 2 or more spontaneous pregnancy losses, affects 3% of all fertile couples. The current diagnostic work-up in these couples focusses on maternal conditions such as anti-phospholipid syndrome, structural uterine abnormalities, endocrine factors, thrombophilia and chromosomal translocations. Paternal investigations are currently limited to a male karyotype. Disappointingly, an underlying cause may be identified in only 30-50% of affected couples. Studies focusing on paternal influences are scarce, but some retrospective studies indicate an association of paternal factors such as advanced age, smoking and high sperm DNA damage with RPL or spontaneous miscarriage.
Study design, size, duration: This is a multicenter hospital-based research project consisting of two study designs: a case-control study to identify etiologic paternal factors for the development of RPL and a cohort study to investigate the prognostic effect of the paternal factors on the outcome of next pregnancies. Based on sample size calculations, at least 88 couples in each arm will be included prospectively and another 600 in each arm retrospectively. Follow-up of the RPL cohort is five years.
Participants/materials, setting, methods: Couples that visit the recurrent miscarriage outpatient clinics in the participating centers and fulfil the criteria of unexplained RPL will be included. Couples from the obstetrics outpatient clinic with ≤ 1 pregnancy loss will be included as controls. Obstetric and general medical history will be documented, data about lifestyle will be collected, as well as semen (for investigation of DNA fragmentation by TUNEL assay) and a peripheral blood sample (for immunomodulatory investigations) of the male.
Main results and the role of chance: The primary exposure of the case-control study is paternal age; secondary exposures are BMI, alcohol consumption, smoking, physical exercise, sperm DNA fragmentation and immunomodulatory factors in blood and seminal fluid. Primary outcome of the cohort study is the development of live birth within 5 years after initial visit of the recurrent miscarriage outpatient clinic. Secondary outcomes are development of ongoing pregnancy (>24 weeks), time interval until next pregnancy and development of pregnancy complications such as growth restriction, preterm delivery and preeclampsia. Since the design of this study is observational, there is need to control and adjust for confounding factors. Therefore, stratification and regression models will be used.
Limitations, reasons for caution: Besides the risk of bias by confounding, there also needs to be caution for the risk of recall and response bias with respect to data about lifestyle factors such as smoking and drinking behavior and physical exercise.
Wider implications of the findings: Findings of this study may ultimately lead to new diagnostic tools, new insight in therapeutic options and -by developing a couple-specific prediction model- to a tailored prognosis on future pregnancies for couples with RPL.

Not applicable.

P-361 Three different endometrial receptivity profiles can be defined in patients with previous failed embryo transfer

L. Bissonnette[1], C. LeSaint[2], J. Choi[2], F. Bissonnette[3], I.J. Kadoch[1]
[1]Clinique ovo, Ovo R&D, Montreal, Canada
[2]Clinique ovo, Ovo Labo, Montreal, Canada
[3]Clinique ovo, Ovo Fertility, Montreal, Canada

Study question: What are the different profiles of the implantation window (IW) in patients with previous failed transfer under hormonal replacement therapy cycle?
Summary answer: Three profiles were observed: shorter IW (less than 48h), wide highly receptive IW (over 48h) and progressive sub-optimal IW (partially-receptive before becoming receptive).
What is known already: The implantation window is referred as a receptive period of the endometirum that is limited in time during which the embryo implantation is possible. This crucial step is a major limitation in the success of embryo transfer in IVF cycle. Recent studies have revealed that the timing and the length of the receptive stage is patient dependant. adhesio is a molecular diagnostic tool that determines the receptivity status by analyzing the expression level of 11 specific and predictive genes in the endometrial biopsies using quantitative RT-PCR.
Study design, size, duration: We analyzed the data from the patients that underwent an endometrial receptivity test (adhesio) at clinique ovo between June 2016 and December 2018 and had signed the research consent form. This retrospective study includes 118 endometrial biopsies form 51 patients with at least one previously failed transfer.
Participants/materials, setting, methods: In a mock hormonal replacement therapy cycle, biopsies were collected at progesterone (PG)+6 days and PG+8. Additional biopsies (PG+7, PG+9) were retrieved in a subsequent cycle if the initial samples were non-receptive. The expression level of 11 genes was quantified by qRT-PCR for the receptivity prediction. Using an algorithm, samples were classified receptive, non-receptive or partially-receptive and the optimal frozen embryo transfer day was recommended. The patient's mean count of previous failed transfer was 3.1±1.8.
Main results and the role of chance: The endometrial receptivity profiles measured with adhesio were grouped into 3 categories: shorter, wide highly receptive and progressive IW. A majority, 55% of the patients (n=28), had a

non-receptive endometrium in one sample and a receptive endometrium in the other sample collected at 48h interval. One patient had a very delayed and short IW: the PG+9 biopsy was the only receptive sample. 16% of the patient (n=8) had a wide highly receptive IW with both samples (PG+6, +8) being receptive, their IW lasted over 48h. 24% of the patients (n=12) had a partially-receptive endometrium and then a receptive endometrium 48 to 72 hours later. For 2 patients (4%), their endometrium was never found receptive after the analysis of 4 biopsies (PG+6, 7, 8 and 9). Twenty-two of the patients with a shorter IW had personalized frozen embryo transfer resulting in 32% cumulative pregnancy rate. Four patients with a wide IW had a personalized frozen embryo transfer resulting in a 50% pregnancy rate. Even through these patients had previous implantation failure, their infertility is clearly not due to the endometrial receptivity. Conversely no pregnancy was achieved in the progressive IW group (n=7), more investigation have to be complete for this profile.

Limitations, reasons for caution: The data was collected in a single IVF center. A multi-centric study with an increased sample size would give a better understanding of the endometrial receptivity profiles of patients with previous failed transfer under hormonal replacement therapy cycle.

Wider implications of the findings: This study demonstrates the variability in endometrial receptivity profiles and thus the importance of detecting the IW in patients with previous failed transfer in order to offer a personalized frozen embryo transfer.

Trial registration number: not applicable

P-362 Is the uterine immune profiling affected by maternal age?

N. Ledee[1], L. Chevrier[2], K. Vezmar[2], M. Petitbarat[2]

[1] *Hôpital les Bluets, Service d'AMP, Paris, France*

[2] *MatriceLab Innove, Research, Paris, France*

Study question: Is the endometrial immune profile influenced by maternal age as it is observed for the oocyte quality?

Summary answer: The endometrial immune profile does not seems to be influenced by maternal ageing in patients with recurrent implantation failures

What is known already: Advanced maternal age is associated with reduced fertility and adverse pregnancy outcomes. Maternal age mainly negatively affects the oocyte quality. Regarding the putative negative effects of ageing on the uterus, the association is largely undefined but potentially relates to impaired decidual and placental development and embryo interaction with the uterus. During "the implantation window", a transient immune switch of cells, together with an adequate uterine Natural Killer (uNK) cell activation occur. Such reaction appears fundamental in enabling the establishment of local maternal tolerance and survival of the fetus. We investigate the effect of age on this endometrial immune reaction.

Study design, size, duration: Between 2012 and 2018, 6151 patients with an history of implantation failures benefitted of an endometrial immune profiling because of their history of RIF. We compared the repartition of the uterine immune profiles among patients below 30 years (529 patients), between 30-35 y (1780 patients), 36-38 y (1552 patients),39-40 y (1030), 41-43 (944 patients), over 44 years old (382 patients).

Participants/materials, setting, methods: Patients included had an history of implantation failures with their oocytes (more than 6 embryos replaced) or after oocytes donation (more than 4 embryos replaced). An endometrial biopsy was performed under substituted cycle in the luteal phase. We quantified uNK by immunohistochemistry and mRNA of IL-15 (uNK cells activation/maturation state), IL-18 (Th-1/Th-2 cytokines balance) and TWEAK/Fn-14 (immuno-regulation) by Real-Time PCR. The uterine profile defined four categories of profile: not deregulated, over-regulated, under-regulated, mixt deregulation.

Main results and the role of chance: We recorded the same repartition of immune disequilibrium in the five categories of maternal age with no variation according to the category of age: 27.2% did not show deregulation, 30.6 % were over-activated, 31.6% were under-activated and 10.3% had a mixt profiles

Limitations, reasons for caution: The uterine immune profiling only explores immune local parameters related to the Th_1/ Th-2 equilibrium as well as recruitment, maturation state and activation of uNK cells. Immune profiling does not explore T regulatory cells, dendritics cells and macrophages recruitment and expression

Wider implications of the findings: As local disequilibrium does not seem not variate with maternal age, effective understanding of local uterine deregulations may be proposed in function of the clinical context but not iun function of the maternal age

Trial registration number: Not applicable

P-363 New biomarker predicts the odds of a live birth in women experiencing secondary recurrent pregnancy loss after a first-born boy

M.C. Krog[1], M. Georgsen[1], A.M. Kolte[1], W. De Jager[2], L. Meyaard[2], L. Lunoee[1], O.B. Christiansen[3], H.S. Nielsen[1]

[1] *Copenhagen University Hospital- Rigshospitalet, Recurrent Pregnancy Loss Unit- The Fertility Clinic 4071, Copenhagen Ø, Denmark*

[2] *University Medical Center Utrecht, Multiplex Core Facility- Laboratory of Translational Immunology, Utrecht, The Netherlands*

[3] *Aalborg University Hospital, Department of Obstetrics and Gynaecology, Aalborg, Denmark*

Study question: Does soluble-leucocyte-associated immunoglobulin-like receptor-1 (sLAIR-1) in serum reflect immune activation and predict a poor pregnancy outcome in women experiencing secondary recurrent pregnancy loss (SRPL)?

Summary answer: High level of sLAIR-1 in gestational week (GW) 5 predicts low odds of live birth in women with SRPL after the birth of a boy.

What is known already: Immunology has been shown to be the cause of pregnancy loss (PL) in some women with SRPL. A first-born boy before the PLs is significantly more frequent than first-born girls and half of these pregnancies are obstetrically complicated, indicating that the first pregnancy initiated an abnormal immune reaction**.** LAIR-1 is an inhibitory immune receptor expressed by immature immune cells. The expression decreases in activated immune cells, partly by shedding the receptor, transforming LAIR-1 to soluble LAIR-1 (sLAIR-1). Thus, higher levels of sLAIR-1 in serum reflect an activated immune system and have been found in patients rejecting their transplanted organ.

Study design, size, duration: A single-center, double-blinded, placebo-controlled trial including 82 women with SRPL between August 2008 - August 2013. The patients were randomized to either infusions with "Immunoglobulin Human" 120 mg/ml or "Privigen® " 100 mg/ml (IVIg) or placebo infusions with "Human Albumin" 5 % infusion. Eight infusions were given between GW 5-16 or until PL. The patients were block-randomized 1:1 having either 4 or $\geq$ 5 previous PLs.

Participants/materials, setting, methods: The trial was conducted at the RPL Unit at Copenhagen University Hospital in Denmark. Eighty-two women with unexplained SRPL and at least four PLs (at least three consecutive PLs after birth) were included. Serum samples were taken before the first infusion in GW 5 in the trial and 77 women gave consent to participate in this study. Multiple logistic regression was performed to evaluate predictors of live birth.

Main results and the role of chance: Median sLAIR-1 serum level in GW 5 was 268 pg/ml (from not detectable – 5122 pg/ml) in 77 women. Thirty-nine of the women had a first-born boy. The trial pregnancy resulted in a live birth in 20/39 women with a first-born boy equally distributed between the intervention groups (IVIg and placebo, 1:1). Median age in the live birth group was 34.5 years which is comparable to 34 years in the PL group. Number of previous PLs, BMI and smoking were comparable between the two groups. sLAIR-1 was dichotomized as either positive or negative with a positive cut-off in sLAIR-1 based on a ROC-curve predicting outcome of pregnancy (sLAIR-1 >499 pg/ml). Among women with a first-born boy, positivity for sLAIR-1 was a significant negative predictor for live birth (aOR 0.19, 95% CI 0.04-0.83, *p-value*= 0.027) adjusted for number of previous PLs, female age and IVIg treatment, which were not predictors of live birth in a multiple logistic regression analysis. A follow-up in January 2019 showed no association between positive sLAIR-1 in the trial pregnancy and cumulative live birth rate. There was no association between positive sLAIR-1 and outcome of the trial pregnancy when including women with first-born girls in the analysis.

Limitations, reasons for caution: Even though the study includes highly selected patients with more than four previous PLs and no risk factors of RPL

after standard clinical evaluation the numbers are still relatively small. Despite the significant findings, they need to be evaluated in a larger study.

Wider implications of the findings: A high level of sLAIR-1 in GW 5 in women with SRPL after a first-born boy is a predictor of loss of that pregnancy, but not long-term outcome. Thus, sLAIR-1 has potential for optimal selection of women with suspected immunological disturbances eligible for participation in RCTs with immune modulatory treatments.

Trial registration number: Clinicaltrials.gov NCT00722475.

P-364 To screen or not to screen? Prevalence of thrombophilia in patients with recurrent miscarriage and healthy controls

A. Herzog[1], K. Vomstein[1], A.L. Zippl[1], K. Feil[1], R.J. Kuon[2], B. Toth[1]

[1]*Medical University Innsbruck, University clinic of Gynecological Endocrinology and Reproductive Medicine, Innsbruck, Austria*

[2]*Ruprecht-Karls University Heidelberg, Department of Gynecological Endocrinology and Fertility Disorders, Heidelberg, Germany*

Study question: Does the prevalence of inherited and acquired thrombophilia differ between patients with recurrent miscarriage (RM) and healthy controls?

Summary answer: There is no difference in the prevalence, neither in inherited nor in acquired thrombophilia between RM patients and healthy controls.

What is known already: Screening for thrombophilia is discussed controversially in clinical guidelines for RM whereas screening for Anti-phospholipid Antibody Syndrome (APS) is highly recommended. Several studies investigated the impact of inherited and acquired thrombophilia in RM and found contradictory results. Possible pathophysiological mechanisms concerning thrombophilia and RM include development of microthrombosis in the early placentation. However, the association between thrombophilia and RM seems to vary according to the type of inherited or acquired thrombophilia.

Study design, size, duration: A retrospective observational study was performed. The study group consisted of n= 207 patients with ≥3 miscarriages, screened for inherited and acquired thrombophilia in the outpatient clinic of the Department of Gynecological Endocrinology and Reproductive Medicine, Medical University Innsbruck, between January 2010 and January 2018. The control group (n= 141) consisted of young healthy women who underwent a routine screening for inherited and acquired thrombophilia before prescription of contraceptives between 01/2011 and 04/2018.

Participants/materials, setting, methods: Medical history (gravidity, parity, number of previous miscarriages, history of thrombosis), anatomical malformations (myomas, adhesions, septate uterus), haemostaseological alterations (APC resistance, protein C/S deficiency, factor VIII activity), autoimmunological changes (anti-nuclear antibodies, anti-phospholipid antibodies, thyroid antibodies), endocrine disorders (thyroid function, PCOS) and genetic data was assessed in patients and controls. The prevalence of alterations in APC resistance, protein C/S deficiency, factor VIII activity and anti-phospholipid antibodies were defined as primary outcome measures and compared between groups.

Main results and the role of chance: The mean age was 33.4±5.2 years in the RM group and 15.6±1.9 in the control group (mean±SD, p< 0.001). The BMI was higher in the RM group (mean±SD: 24.1±4.4 vs. 21.5±4.4, p< 0.001). 1.6% of the RM patients had a history of venous thrombosis and 23.8% had a positive family history of thromboembolism, compared with 0.85% and 15.1% in the controls.

No significant differences in the prevalence of protein C/S deficiency, APC resistance and factor VIII elevation were observed in RM patients and controls (RM vs. control: protein C 0.51% vs. 0.0%, p> 0.05 ; protein S 2.5% vs. 3.55%, p= 0.09; APC resistance 4.85% vs. 11.35%, p= 0.29; factor VIII elevation 11% vs. 10.95%, p= 0.78). The occurrence rate of antiphospholipid antibodies was the same in both groups (RM vs. control: anti-phospholipid-screen IgG 0.99% vs. 0,72%; anti-phospholipid-screen IgM 1.48% vs. 0.72%; anti-prothrombin antibodies 2.96% vs. 0%; beta-2 glycoprotein antibodies 1.97% vs. 0.0%; anti-cardiolipin antibodies 0.99% vs. 0.0%). One patient in the RSA group fulfilled the Sydney criteria and was therefore diagnosed with an APS, whereas no patient in the control group was diagnosed with APS (prevalence for APS 0,5% vs 0%).

Limitations, reasons for caution: Due to the younger age of the control group it is not predictable whether they will experience RM in future. However, the control group is representative for the population.

Wider implications of the findings: Our data does not show a significant difference neither for inherited nor acquired thrombophilia in RM. The conflicting results of other studies may be due to small study sizes and the inconsistent definition of RM. Moreover, the prevalence of inherited or acquired thrombophilia may be overestimated in RM patients.

Trial registration number: not applicable

P-365 Is embryonic aneuploidy rate higher in abortuses of early spontaneous abortions of D6 blastocyst than D5?:a retrospective study

W. Zhao[1], P. Chen[1], Y. Li[1], X. Liang[1]

[1]*Sixth Affiliated Hospital of Sun Yat-sen University, Reproductive Medicine Research Center, Guangzhou, China*

Study question: The purpose of this study was to compare the aneuploidy rate in first trimester abortion after frozen-thawed Day 5 and Day 6 blastocyst transfer.

Summary answer: Embryonic aneuploidy does not account for inferior pregnancy outcome after D6 TBT. Women's age was independently associated with the embryonic aneuploidy rate.

What is known already: Although there is a better endometrial–embryonic synchronization in frozen cycles, many studies have reported lower clinical pregnancy rate and live birth rate while higher spontaneous abortion rate after D6 thawed blastocyst transfer (TBT). It remains uncertain whether the inferior outcome after D6 TBT is caused by embryonic chromosomal abnormalities. Some reports demonstrated higher aneuploidy rates in embryos that blastulate on D6 compared with those on D5. But some research did not find the same trend. However, all these studies were just on the basis of preimplantation embryos while we focus on arrested embryos during early pregnancy.

Study design, size, duration: This is a retrospective cohort study examining the rate of embryonic chromosomal anomalies in the abortuses of early spontaneous abortions between March 2012 and February 2018 in an university-based reproductive medicine center. All the recruited patients were conceived after frozen blastocyst transfer and only hormone replacement cycles were included.

Participants/materials, setting, methods: Chorionic villus samples were collected from a total of 324 patients defined as missed abortion. Conventional chromosome karyotyping and a multiplex ligation dependent probe amplification subtelomere assay combined with fluorescence in-situ hybridization were performed for genetic analysis. The aneuploidy rate was compared according to the blastocyst development stage: D5 (n =226) and D6 (n =98).Multivariate logistic regression model was conducted to demonstrate the risk factors affecting the embryonic aneuploidy.

Main results and the role of chance: Patients' characteristics, including age, BMI, basal FSH, type of infertility, IVF/ICSI procedures, gestational age did not differ between the two groups (all P values>0.05). Although mean number of embryo were significantly higher in D6 than in D5 group (P<0.001), the mean number of high-quality embryo were similar (P=0.334). In D5 group, 39.38% (89/226) of abortuses demonstrated aneuploidy, which was comparable with 40.82% in D6 group (40/98, P=0.808).

A multivariate logistic analysis was performed to adjust for potential confounders such as the women's age during OPU, BMI, and type of infertility, IVF/ICSI procedures, and the day of blastocyst (D5 or D6), number and quality of embryo. The results showed that women's age at the time of OPU was found to be independently associated with the embryonic aneuploidy rate (OR = 0.89; 95% CI: [0.85–0.96]; P =0.001). Other factors, including blastocyst expansion stage were not important predictors of aneuploidy (OR = 0.93; 95% CI: [0.54–1.59]; P =0.792). When we further analyzed them according to women's age (>35 years or ≤35 years),embryonic aneuploidy rates were both comparable in older group (62.0% versus 53.5%; P=0.468) and younger group (32.9% versus 35.71%; P = 0.68) after D5 or D6 TBT.

Limitations, reasons for caution: The study was limited by its inherent shortcomings of retrospective studies and relatively small sample size.

Wider implications of the findings: The inferior developmental potential of D6 blastocysts may not be due to chromosomal abnormalities. We need to focus on different aspects related to blastocyst development.

Trial registration number: not applicable

P-366 Early, previously unrecognized, implantation of a second embryo detected using single-nucleotide polymorphism (SNP)-based non-invasive prenatal testing (NIPT)

A. NORVEZ[1], S. Goel[2], M. Pastrick[3]
[1]*Natera- Inc., Medical Advisory, San Carlos, U.S.A.*
[2]*Natera- Inc., Scientific Communications, San Carlos, U.S.A.*
[3]*Natera- Inc., Medical Education, San Carlos, U.S.A.*

Study question: Can single-nucleotide polymorphism (SNP)-based non-invasive prenatal testing (NIPT) detect cell-free DNA (cfDNA) from two embryos in maternal circulation despite clinical records indicating a singleton pregnancy?
Summary answer: SNP-based NIPT can establish whether cfDNA is present from one or more fetal haplotypes in maternal blood from a double embryo transfer (DET), singleton pregnancy.
What is known already: The frequency of singleton pregnancies resulting from DET is ~50%. Early implantation, resulting in a non-viable embryo, is difficult to ascertain using late, first-trimester ultrasound and chromosomal abnormalities are common in this scenario. Quantitative NIPT results may be confounded if cfDNA from a chromosomally abnormal, non-viable embryo persists in the maternal bloodstream. These methodologies cannot account for additional haplotypes, indicative of a multiple gestation or triploid pregnancy. Studies have previously demonstrated the unique ability of SNP-based NIPT to detect the presence of cfDNA eight-fifteen weeks post fetal-demise, however this research did not specifically address the in-vitro fertilization (IVF) cohort
Study design, size, duration: This series includes nine pregnancies, noted as singletons on the test requisition, with SNP-based NIPT results between January 11, 2018 and November 28, 2018. All cases were identified by the testing algorithm as having results indicative of a pregnancy with a vanished twin, unrecognized multiple gestation or fetal triploidy, due to evidence of an additional haplotype. As part of standard protocol, the ordering clinician's office was contacted for further discussion.
Participants/materials, setting, methods: Confirmation of a viable singleton gestation achieved with in-vitro fertilization (IVF) and DET was confirmed by the ordering clinician's office. Records did not indicate evidence of vanished or ongoing twins and none of the cases had any reported clinical findings suggestive of triploidy in the first trimester. The gestational age of the cases at the time of the blood draw for NIPT ranged from 10w1d–13w1d.
Main results and the role of chance: In the setting of IVF pregnancies achieved with DET, obstetricians ordering NIPT at 9+ weeks gestation may lack clinical evidence regarding implantation of one or both embryos. This case series demonstrates the unique ability of SNP-based NIPT to identify the presence of multiple fetal haplotypes in this scenario. If one set of cfDNA is identified, during analysis, the provider can be confident that the results are representative of the viable singleton pregnancy. Conversely, if multiple haplotypes are seen, the patient is not a good candidate for any NIPT as cfDNA may persist in the maternal blood stream for an undetermined number of weeks. In addition, multiple haplotypes can be suggestive of a singleton triploid pregnancy, so further evaluation should be considered.
Limitations, reasons for caution: A limitation of this study is the incomplete follow-up with unobtainable clinical details such as early ultrasound and cytogenetic reports, and/or pregnancy outcome. Larger, blinded, prospective studies in collaboration with IVF centers utilizing SNP-based NIPT are needed to further investigate the frequency of unrecognized early implantation of a second embryo.
Wider implications of the findings: In singleton pregnancies achieved with IVF and two- embryo transfer, knowledge of additional haplotypes has implications for pregnancy management. The use of SNP-based NIPT should be considered in this setting in order to avoid false positive results leading to unnecessary invasive testing and parental concern.
Trial registration number: N/A

P-367 Increased miscarriage rates following follicular-phase endometrial scratching

S. Mackens[1], A. Racca[1], H. Van de Velde[1], H. Tournaye[1], D. Stoop[1], C. Blockeel[1], S. Santos-Ribeiro[2]
[1]*UZ Brussel, Centre for Reproductive Medicine, Jette- Brussels, Belgium*
[2]*IVI Lisboa, IVI Lisboa, Lissabon, Portugal*

Study question: Does intentional endometrial injury (scratching) during the follicular phase of ovarian stimulation (OS) increase pregnancy rates in ART?
Summary answer: Pregnancy rates did not vary significantly between the endometrial injury and the control group. However, significantly higher clinical miscarriage rates were observed after endometrial injury.
What is known already: Intentional endometrial injury has been put forward as an inexpensive clinical tool capable of enhancing endometrial receptivity. However, despite its widespread use, the benefit of endometrial scratching remains controversial, with several recent randomized controlled trials (RCTs) not being able to confirm its added value. So far, most research has focused on endometrial scratching during the luteal phase of the cycle preceding the one with embryo transfer (ET), while only few studies investigated in-cycle injury during the follicular phase of OS. Also, the persistence of a scratch effect in subsequent treatment cycles remains unclear.
Study design, size, duration: This RCT included women performing IVF/ICSI in a gonadotrophin-releasing hormone antagonist supressed cycle between 2014-2018. Participants were randomized to either undergo an endometrial biopsy between day 6 to 8 of OS or to be in the control group. The primary outcome was clinical pregnancy at 7 weeks. Secondary outcomes included live birth, early pregnancy loss, procedure pain/bleeding and cumulative live birth following all ETs performed within 6 months of the study cycle.
Participants/materials, setting, methods: A total of 200 subjects (100 per study arm) were recruited, with 1 (in the control group) later withdrawing consent to participate further. In 4 patients allocated to the intervention group biopsy was impossible due to cervical stenosis or intolerable pain. The trial was stopped prematurely after an analysis in 200 of the required 360 patients. During this interim analysis, a statistically significant higher clinical miscarriage rate in the intervention group was found.
Main results and the role of chance: The study arms did not vary significantly in terms of relevant patient and IVF/ICSI cycle characteristics. The intention-to-treat clinical pregnancy rates did not vary significantly among the biopsy and the control arms (respectively, 44.0% versus 40.4%, p=0.61), nor did the live birth rates (respectively, 32.0% versus 36.4%, p=0.52). Biochemical pregnancy loss was comparable between both groups (10% in the intervention group versus 15% in the control, p=0.49), however, clinical miscarriage occurred significantly more frequent in the biopsy group (25% versus 8%, p=0.032). In the intervention group, 3% of the patients experienced procedure pain and 5% bleeding. Cumulative live birth rates taking into account all ETs performed within 6 months of the study cycle were not significantly different between the biopsy and the control group (respectively, 54.0% versus 59.6%, p=0.43).
Limitations, reasons for caution: These results are limited by the fact that the trial was stopped prior to the predetermined sample size. This, together with the pragmatic design of the study, may have limited the detection of specific subgroups of women who may benefit from endometrial scratching.
Wider implications of the findings: These findings add to the growing evidence that scratching in an unselected patient population, regardless of the period when it is done, seems to be useless. They strongly discourage intentional endometrial injury during the follicular phase of OS as it is potentially harmful. Moreover, no long-lasting benefit was found either.
Trial registration number: ClinicalTrials.gov identifier NCT02061228.

P-368 The use of granulocyte macrophage colony-stimulating factor (GM-CSF) containing media for embryo transfer increases the clinical pregnancy and ongoing pregnancy rate

M. Kinoshita[1], M. Fujita[1], K. Takahashi[1]
[1]*TAKAHASHI WOMEN'S Clinic, Reproductive Medicine, Chiba, Japan*

Study question: Is it possible to improve the clinical outcome of vitrified-warmed embryo transfer by using a medium containing GM-CSF as a medium for embryo transfer?
Summary answer: It was suggested that clinical pregnancy rate and ongoing pregnancy rate are increased by using GM-CSF containing medium as the embryo transfer medium.

What is known already: GM-CSF is one of various cytokines and growth factors present in the female reproductive tract that are known to play an important role in embryonic development, embryo implantation and subsequent development.The expression level of GM-CSF usually increases at the time of implantation. However, among those who have undergone implantation failure or repeated miscarriage, the expression level and the concentration of GM-CSF may be low. This condition is thought as one of the causes of recurrent implantation failure and miscarriage.

Study design, size, duration: A retrospective observational study was performed by 473 cycles with patient ages 30 - 39 who underwent vitrified-warmed single blastocyst transfer at our clinic from February to November 2018.

Participants/materials, setting, methods: We investigated 148 cycles using GM-CSF containing culture medium (SAGE 1-Step with GM-CSF; CooperSurgical, Denmark) (test group) and 325 cycles using GM-CSF free medium (NAKA ONE STEP MEDIUM; NakaMedical, Japan) (control group) at the time of post-thaw culture and embryo transfer.Clinical pregnancy rate, miscarriage rate and ongoing pregnancy rate were compared and examined.In both groups, embryo culture was carried out in the GM-CSF-free medium before the blastocysts were cryopreserved.

Main results and the role of chance: Clinical pregnancy, miscarriage and ongoing pregnancy rates after embryo transfer were compared between the two groups.There was no significant difference in the mean age between the test group and the control group (p = 0.24, 35.2±2.8years vs. 35.5±2.7years).The clinical pregnancy rate in the test group was higher than that in the control group (p = 0.045, 52.0% vs. 42.2%). The miscarriage rate in the test group was lower than that in the control group (p = 0.076, 10.4% vs. 19.7%). The ongoing pregnancy rate in the test group was higher than that in the control group (p = 0.007, 46.6% vs. 33.8%).

Limitations, reasons for caution: This study was limited by the data based on a small sample size and lack of data about live birth rates after embryo transfer.

Wider implications of the findings: It was suggested that medium containing GM-CSF improves implantation and ongoing pregnancy rate when used for embryo transfer.Using GM-CSF-containing medium for embryo transfer may be an effective treatment strategy for some patients by shortening the time to pregnancy.

Trial registration number: Not applicable.

P-369 The prognostic value of Endometrial Receptivity Array in women with Recurrent Implantation Failure

D. P S[1], N. Singh[1], G. Tumkur Pranesh[2], M. Dwarakanath B[1], K. A Rao[1]
[1]*Milann- The Fertility Centre, Reproductive Medicine, Bengaluru, India*
[2]*Milann- The Fertility Centre, Basic Medical Scientist, Bengaluru, India*

Study question: To compare patients who had a receptive ERA to those who had a non-receptive ERA and to describe clinical outcomes of embryo transfer after a personalized ET (pET)

Summary answer: Women with advanced age and POR had higher probablilty of having nonreceptive ERA.

In RIF patients, a nonreceptive endometrium suggests a poorer outcome even after pET.

What is known already: Embryo implantation requires that the blastocyst will attach during the receptive stage of the endometrium, known as window of implantation (WOI).

Molecular analyses of endometrial receptivity demonstrates a personalized WOI (pWOI) that is displaced in one out of four patients suffering from recurrent implantation failure (RIF) of endometrial origin and illustrates the utility of a personalized endometrial diagnostic approach

Study design, size, duration: This is an observational study conducted between January 2013 and September 2018 at Milann Fertility Centre Bengaluru, India where 60 patients with recurrent implantation failure who underwent endometrial receptivity array were included.

Participants/materials, setting, methods: Out of 60 patients, 39 had an ET after ERA testing. Patient demographics and cycle characteristics were collected.

Baseline characteristics were compared between patients who tested receptive and non-receptive. Implantation rates were compared for the receptive and non-receptive groups after all subsequent ETs.

Pregnancy outcomes were compared for the receptive and non-receptive groups after the first ET after ERA.

Excel and SPSS were used to perform permutation analyses and t-tests.

Main results and the role of chance: Out of 60 patients,41(68.3%) had receptive ERA result while 19(31.6%) had non receptive ERA result.

Women with advanced maternal age(p =0.02) and poor ovarian reserve (p=0.08), had statistical significant probability of being non receptive on ERA.

30 patients out of 41 in receptive group and 9 patients out of 19 in the nonreceptive group underwent subsequent personalized embryo transfer.

When analyzing implantation rates and clinical pregnancy rates, clinical pregnancy was significantly higher (p=0.03) in the receptive group compared to the nonreceptive group even after pET.

Limitations, reasons for caution: Our studyis limited by its smaller sample size.

Wider implications of the findings: Furtherstudies should be done to confirm the benefit of pET in patients with a non-receptive endometrium.

Trial registration number: 043/I/19/02

P-370 Comparison of low molecular weight heparin (LMWH) plus Aspirin, versus Aspirin only treatment on pregnancy outcomes of unexplained recurrent early miscarriage: a randomized clinical trial

A. Mohammad Akbari[1], S. Ansaripour[1], M. Tavakoli[1], A. Mohazzab[1], A. Karimi[1], R. Tokhmechi[2], S. Fazli[2], A. Hadavand[2], A. Rezanejad[2]
[1]*Avicenna Research Institute, Reproductive Biotechnology Research Center, Tehran, Iran*
[2]*Avicenna Ferility Clinic, Recurrent miscarriage cllinic, Tehran, Iran*

Study question: Does LMWH medication affect pregnancy outcome of early recurrent pregnancy loss (RPL) concurrent with aspirin treatment?

Summary answer: Although a minimally improvement in pregnancy outcomes has been observed following LMWH medication in patients with RPL, but the difference was not statistically significant.

What is known already: Recurrent abortion is still an issue for both physicians and patients. Especially in early abortions when the cause is largely unexplained. Despite the fact that fetal aneuploidies is the most causes of early abortions, use of heparin and aspirin and other treatments continues in this group of patients. Previous studies were largely unproductive, since heterogeneity and intervention time were different.

Study design, size, duration: The study was performed as a single blind randomized clinical trial between years 2015-2018. The sample size was calculated 164 (two groups of 82 patients) and patient were included into the study timely. At the time of abstract submission, the outcomes of 132 patients were completely determined.

Participants/materials, setting, methods: Samples were selected from patients who was referred to Avicenna RPL clinic with a history of at least 2 previously happened early un-explained miscarriages (G.A <10 weeks) based on diagnostic laboratory, imaging and genetic tests. Patients who got pregnant recently were divided randomly in two groups: low dose Aspirin plus LMWH treatment (4000 IU) (group A) and low dose Aspirin treatment only (group B) and the patients were followed up till their pregnancy termination (delivery/abortion).

Main results and the role of chance: 132 Patients were divided in two groups (group A =65 and group B=67 patients). Considering the significant P-value level < 0.05 there were no difference between two groups in age (CI = -1.580 - 1.37) and BMI (CI = -1.26 -2.32). Both study groups were also homogeneous in terms of abortion time, primary and secondary miscarriage, interventions before and during pregnancy, doses and timing of prescribe heparin and aspirin and enough follow up till birth. The live birth rates in groups A and B were 80% VS 73.1 % respectively which did not show any statistically significant difference between Aspirin plus LMWH treatment comparing Aspirin treatment only (Pearson chi square P-value = 0.352). Based on multivariate analysis using logistic regression model there were significant adverse relationship between successful pregnancy outcome and both of age (β= -0.179) and the number of previous miscarriage(β= -0.827) but none of them did not affected by LMWH additive treatment.

Limitations, reasons for caution: Although evidences about positive effect of LMWH on un-explained RPL outcomes aren't convincing, the main limitation

was pseudo-ethical issue in depriving patients from conventionally prescribing of heparin. Patients with bad experiences of RPL (especially when abortion ≥ 5) hardly accept to be allocated in control group with minimal medical interventions.

Wider implications of the findings: In patients with early recurrent abortions, it seems aspirin prescription is good enough to reach a satisfying result and benefit of excessive anticoagulant was not proven statistically in the study. Similar trials are suggested for evaluation of anticoagulant treatments in 2nd trimester recurrent pregnancy loss.

Trial registration number: The"Clinical Trial of LMWH plus Aspirin versus Aspirin Alone in Unexplained Recurrent Miscarriage" has been registered in Iranian registry of clinical trial by number IRCT20160403218 9N1

P-371 Prospective comparative analysis of WNT4, WNT6 and b-catenin expression in trophoblast tissue from first trimester miscarriages versus terminations of pregnancy for social reasons

E. Chronopoulou[1], A. Kaponis[2], V. Koika[3], K. Tsiveriotis[4], G. Decavalas[5], N. Georgopoulos[5], G. Adonakis[5]

[1]General University Hospital of Patras, Obstetrics and Gynaecology, Patras, Greece
[2]General University Hospital of Patras- Patras Medical School, Obstetrics and Gynaecology, Patras, Greece
[3]Patras University- School of Medicine, Obstetrics and Gynaecology, Patras, Greece
[4]Patras University- School of Medicine, Fetal Medicine, Patras, Greece
[5]General University Hospital of Patras- Patras University- School of Medicine, Obstetrics and Gynaecology, Patras, Greece

Study question: Is there a difference in the expression of WNT4, WNT6 and b-catenin in trophoblast tissue from first trimester miscarriages versus normal controls (social abortions)?

Summary answer: WNT4 expression was statistically significantly altered in first trimester miscarriages versus controls. There was no significant difference for WNT6 or b-catenin.

What is known already: The role of wnt pathway in pre-implantation events remains to be elucidated. Animal studies have shown than wnt signaling is important for embryo development and is involved with blastocyst activation and implantation potential. Especially WNT4 expression has been associated with normal uterine decidualization in mice and seems critical for embryo implantation. Reduced WNT4 expression has been observed in women with severe preeclampsia. Furthermore, WNT6 seems critical for normal stromal cell proliferation in mice. B-catenin, key component of the canonical wnt pathway, also has a role to play in the regulation of implantation although the results so far have been conflicting.

Study design, size, duration: The gene expression of WNT4, WNT6, b-catenin and Alu repeat amplification (used for normalization) was studied using reverse transcription PCR and real time PCR in trophoblast tissue retrieved after evacuation of retained products of conception due to early embryonic demise, incomplete miscarriage or termination of pregnancy for social reasons. The protocol of the study was approved by the Institutional Review Board of Patras Medical School, in accordance with Declaration of Helsinki. Participants signed informed consent.

Participants/materials, setting, methods: 14 samples were included for each study group. Only euploid conceptions were included. The quality of the PCR reactions was confirmed by melting curve analysis and the $2-\Delta\Delta Ct$ algorithm was used to analyze the relative expression of the target genes in comparison to the Alu repeat amplification. Kolmogorov-Smirnov test and Shapiro-Wilk test showed that the ΔCp was normally distributed in all groups. Independent sample t-test was used to compare the data.

Main results and the role of chance: There was a significant difference in the ΔCp of WNT4 for terminations of pregnancy and miscarriages ($p=0.002$, power=0.98). Significant difference was also identified between terminations of pregnancy and complete miscarriages ($p=0.014$, power=0.73) and terminations of pregnancy and incomplete miscarriages ($p=0.004$, power=0.86). There was a 7.04 fold increase in the expression of WNT4 gene in miscarriages compared to terminations of pregnancy, 5.5 fold increase in early embryonic demise compared to terminations and 9.02 fold increase in incomplete miscarriages compared to terminations of pregnancy. No significant difference was documented for the expression of WNT6 and b-catenin. There were no significant differences in patients' demographic background and gestational age.

Limitations, reasons for caution: Gene expression was explored at the mRNA level. The next step will be to analyze protein expression since b-catenin is mostly regulated through proteasome degradation. Although in pregnancy terminations fetal heart activity was detected on the day of the procedure, we cannot be certain that these pregnancies would develop normally.

Wider implications of the findings: This is to our knowledge the first study in human trophoblast to demonstrate statistically significant alteration in the WNT4 expression in miscarriages versus normal pregnancies. This highlights a potential role of the WNT pathway in placentation and trophoblast function and offers a potential target for future strategies to prevent miscarriage.

Trial registration number: not applicable

P-372 New relation between dysbiosis of the vaginal and endometrial microbiota and RIF found

T. Ichiyama[1], Y. Nagai[2], D. Urushiyama[3], M. Ohno[1], T. Yamaguchi[1], M. Nagayoshi[1], Y. Sakuraba[2], F. Yamasaki[4], K. Kuroda[5], K. Hata[6], S. Miyamoto[3], A. Itakura[7], A. Tanaka[1]

[1]Saint Mother Hospital, Department of Obstetrics and Gynecology, Kitakyushu, Japan

[3]Faculty of Medicine- Fukuoka University, Department of Obstetrics and Gynecology, Fukuoka, Japan
[4]Japan Community Health care Organization Saga Central Hospital-, Division of Pathology, Saga, Japan
[5]Sugiyama Clinic Shinjuku, Department of Obstetrics and Gynecology, Tokyo, Japan
[6]National Research Institute for Child Health and Development, Department of Maternal-Fetal Biology-, Tokyo, Japan
[7]Juntendo University School of Medicine, Department of Obstetrics and Gynecology, Tokyo, Japan

Study question: Is dysbiosis of the vaginal and endometrial microbiota a causing factor of repeated implantation failure (RIF)?

Summary answer: The dysbiosis of vaginal and endometrial microbiota was identified to be a strong biomarker for RIF.

What is known already: It is now possible to comprehensively analyze the microbiota of reproductive organs by using the next generation sequencer (NGS), the results of microbiota analysis have been reported not only for the vagina but also for the uterus, which was conventionally thought to be aseptic. In the uterine microbiota analysis, it was reported that when the *Lactobacillus* ratio was 90% or more, the implantation rate, pregnancy rate, and birth rate were significantly higher.

Study design, size, duration:

This study was conducted from October 2017 to June 2018. It was performed retrospectively for 166 women (RIF patients : 145 , Controls : 21) who consented to participate. It was approved by the Saint Mother Clinic's ethical committee.

Participants/materials, setting, methods: 145 women with a blastocyst Gardner's classification of 3BB or higher who had had more than three unsuccessful embryo transfers were the subjects of this study..21 healthy women were also enrolled as controls.

We investigated their vaginal and endometrial microbiota using 16S rRNA gene pyrosequencing.

We measured the α diversity of the microbiota in the samples and then compared the bacterial percentages in the RIF and control groups.

Main results and the role of chance: The endometrial microbiota had a higher α diversity than the vaginal microbiota(Controls $p=2.41e-07$;RIF patients $p<2.2e-16$).

In the endometrial microbiota, 20 kinds of bacteria genera (*Delftia, Schlegelella, Burkholderia, Gardnerella, Sphingobacterium, Prevotella, Megasphaera, Cloacibacterium, Dietzia, Rothia, Enterococcus, Atopobium, Micrococcus, Staphylococcus, Ralstonia, Exiguobacterium, Hydrogenophaga, Sediminibacterium, Limnohabitans,* and *Vagococcus*) showed significantly different levels between controls and RIF patients (all, $p < 0.05$). In the vaginal microbiota, 7 kinds of bacteria genera (*Corynebacterium, Atopobium, Megasphaera, Varibaculum,*

Gardnerella, Peptoniphilus, and *Prevotella*) showed significantly higher levels in the RIF patients ($p < 0.05$).

Unlike previous reports, we discovered that there was no significant difference in the endometrial *Lactobacillus,* where average levels of *Lactobacillus* were 51.6 ± 38.33 % in controls and 51.15 ± 37.48 % in the RIF patients ($p = 0.961$). However, average levels of vaginal *Lactobacillus* were 91.8 ± 22.73 % in controls and 76.38 ± 38.85 % in the RIF group ($p = 0.015$) This is a significant difference.

Limitations, reasons for caution: Even thought we found that microbiota seems to play a role in RIF, it is not the only cause. We must conduct further studies to clarify this role.

Wider implications of the findings: Analysis of the vaginal and endometrial microbiota using 16S rRNA gene pyrosequencing may be a new biomarker of RIF, it may help treat it and consequentially help raise the implantation success rate of RIF patients.

Trial registration number: Medical Information Network-Clinical Trial Registration, Japan (UMIN-CTR000031731) on March 15, 2018.

P-373 Efficacy of intrauterine administration of autologous peripheral blood mononuclear cells prior to embryo transfer in patients with recurrent implantation failures in assisted reproductive technology programmes

T. Amyan[1], S. Perminova[1], L. Krechetova[1], V. Vtorushina[2], A. Abubakirov[1], N. Tatyana[3], G. Vlaova[1]

[2]*Federal State Budgetary Institution "V. I. Kulakov National Medical Research Centre of Obstetrics- Gynaecology and Perinatology" of the Ministry of Health of the Russian Federation- Moscow- Russian Federation, Clinical Laboratory Diagnostics, Moscow, R*

[3]*Federal State Budgetary Institution "V. I. Kulakov National Medical Research Centre of Obstetrics- Gynaecology and Perinatology" of the Ministry of Health of the Russian Federation- Moscow- Russian Federation, Institution of Reproductive Medicine, Mosc*

Study question: To evaluate the efficacy of intrauterine administration of autologous peripheral blood mononuclear cells (PBMC) prior to embryo transfer in patients with recurrent implantation failures in IVF programmes

Summary answer: Intrauterine administration of autologous PBMC prior to embryo transfer in an IVF/ICSI programme increases the efficacy of IVF programmes in patients with recurrent implantation failures

What is known already: The direct effect of PBMC on implantation was first investigated by Yoshioka who demonstrated that intrauterine administration of autologous PBMC prior to transfer of embryos cultured with hCG significantly increased the rates of implantation, clinical pregnancy and delivery in patients with recurrent implantation failures during an IVF programme.Later studies showed that intrauterine administration of PBMC increases the implantation rate in FET cycles in women with a history of up to 3 implantation failures.Further studies also demonstrated positive effects of autologous PBMC activated by hCG prior to embryo transfer in patients with a history of two or more implantation failures

Study design, size, duration: To obtain the PBMC fraction, blood samples were obtained from the ulnar vein, under fasting conditions: on the transvaginal ovum retrieval day during a stimulated cycle and on the first day of micronized progesterone administration during an FET cycle.

Participants/materials, setting, methods: Group 1-autologous PBMC activated with Pregnyl 500 IU prior to embryo transfer.Group 2-PBMC without hCG activation prior to embryo transfer.Group 3-intrauterine administration of saline prior to embryo transfer.Based on different ART protocols two subgroups were formed within each of the three groups:Subgroup 1a-PBMC+hCG group in stimulated cycle,Subgroup 1b-PBMC+hCG group in FET.Subgroup 2a-PBMC group in stimulated cycle; Subgroup 2b- patients of the PBMC group in FET;Subgroup 3a-placebo group in stimulated cycle;Subgroup 3b-placebo group in an FET

Main results and the role of chance: We performed a comparative assessment of ART outcomes obtained after intrauterine administration of autologous PBMC, with or without hCG activation prior to embryo transfer in a stimulated cycle or FET cycle in patients with recurrent implantation failures.During a stimulated cycle, the rates of positive blood beta-hCG tests, implantation, and clinical pregnancy were significantly higher in the group of patients receiving intrauterine administration of autologous PBMC, both with and without hCG activation, as compared with the respective rates in the placebo group ($p<0.05$).Patients receiving hCG-activated PBMC had higher rates than subjects who received PBMC without hCG activation; however, the differences were not statistically significant ($p<0.05$). During an FET cycle, the rates of positive blood beta-hCG tests, clinical pregnancy, and implantation were higher in the group of patients receiving hCG-activated PBMC, as compared with the respective rates in the non-activated PBMC group and in the placebo group ($p<0.05$). In the hCG-activated PBMC group, these rates were higher than in the non-activated PBMC group, although these differences did not reach statistical significance ($p<0.05$).

Limitations, reasons for caution: intrauterine administration of hCG-activated autologous PBMC prior to embryo transfer during stimulated cycles or FET cycles increases the implantation rate and the occurrence of clinical pregnancy in women with a history of recurrent implantation failures.The obtained data lead us to recommend this immune-targeted method for patients with recurrent ART failures.

Wider implications of the findings: no

Trial registration number: not applicable

P-374 Effect of autologous platelet-rich plasma treatment on refractory thin endometrium during the frozen embryo transfer cycle

J.H. Kim[1], E. Kim[1], E. Kim[1], H. Kwon[1], D.H. Choi[1]

[1]*Fertility Center of CHA Bundang Medical Center- CHA University School of Medicine, Obstetrics and Gynecology, seongnam, Korea- South*

Study question: Does intrauterine administration of autologous platelet rich plasma (PRP) for treating refractory thin endometrium have a beneficial effect on the implantation and pregnancy rates?

Summary answer: The use of autologous PRP improved clinical pregnancy and live birth rates (LBR) of the patients with refractory thin endometrium.

What is known already: Thin or damaged endometrium remains to be an unsolved problem in the treatment of patients with infertility. The empirical preference for endometrial thickness (EMT) among clinicians is >7mm, and the refractory thin endometrium, which doesn't respond to standard medical therapies, can be the etiology of recurrent implantation failure (RIF). Autologous platelet-rich plasma (PRP) is known to help tissue regeneration and is widely used in various fields

Study design, size, duration: A prospective cohort study was conducted in a university hospital between January 2015 and December 2018. Women who had a history of two or more failed IVF cycles and refractory thin endometrium were enrolled in this study. The main inclusion criteria were EMT of < 7 mm after more than 2 cycles of previous medical therapy for increasing the EMT. 40 women were enrolled in this study

Participants/materials, setting, methods: The subjects were treated with intrauterine infusion of autologous PRP 2 or 3 times from menstrual cycle day 10 of their frozen-thawed embryo transfer (FET) cycle, and ET was performed 3 days after the final autologous PRP infusion. The primary outcomes were the ongoing pregnancy rate and LBR. The secondary outcomes were the implantation rate, clinical pregnancy rate, and EMT increment compared with those on the previous cycle

Main results and the role of chance: 40 women underwent FET, and 3 patients were lost to follow up. The clinical pregnancy rate was 29.7%. The ongoing pregnancy rate and LBR were 16.2% and 13.5%, respectively. All the differences were statistically significant. One patient is still on-going pregnancy state. The implantation and clinical pregnancy rates were 14.7%. The average increase in the EMT was 0.7 mm compared with the EMT of their previous cycle. However, this difference was not statistically significant. Further, EMT of 21 patients increased (mean difference: 1.6 mm), while that of 11 patients decreased (mean difference: 0.9 mm); the EMT of 5 patients did not change. There were no adverse effects reported by the patients who were treated with autologous PRP.

Limitations, reasons for caution: This is not a randomized controlled study and a relatively small number of patients were enrolled
Wider implications of the findings: We assume that the mechanism of endometrial receptivity restoration after autologous PRP treatment has some aspects other than increasing the EMT. The molecular basis of the treatment needs to be revealed in future studies
Trial registration number: KCT0003375 at https://cris.nih.go.kr/cris

P-375 Hysteroscopy, performed before IVF/ICSI in patients with a normal transvaginal ultrasound and/or hysterosalpingography, improves the clinical pregnancy rate. A meta-analysis of randomized controlled trials (RCTs).

A. Allegra[1], S. Gullo[2], A. Volpes[1], P. Scaglione[1], F. Sammartano[1], A.A. Marino[1]
[1]*ANDROS Day Surgery Clinic, Reproductive Medicine Unit, Palermo, Italy*
[2]*ANDROS Day Surgery Clinic, Medical Statistics Unit, Palermo, Italy*

Study question: Does routine hysteroscopy improve the clinical pregnancy rate before the first IVF/ICSI cycle in patients with a normal transvaginal ultrasound and/or hysterosalpingography?
Summary answer: Routine hysteroscopy improves the clinical pregnancy rate in patients with a normal transvaginal ultrasound and/or hysterosalpingography scheduled for their first IVF/ICSI treatment.
What is known already: The embryo implantation failure still today represents a challenge for reproductive physicians. Hysteroscopy represents the standard procedure for evaluating uterine cavity and it is offered routinely in patients scheduled for IVF/ICSI, because it seems to be associated with higher success rates, as observed in previous meta-analyses (Pundir et al., 2014; Di Spiezio Sardo et al., 2016). Nevertheless, a well-designed multicenter RCT, involving 750 women (Smit el al., 2016) and not included in those meta-analyses, showed no effect of hysteroscopy before IVF/ICSI in improving the live birth rate. For better understanding the role of hysteroscopy, we performed a new updated meta-analysis.
Study design, size, duration: A meta-analysis, based on PubMed, ISI-Web, Cochrane CENTRAL, EMBASE, was conducted to verify the effectiveness of routine hysteroscopy in patients with normal uterine cavity detected at transvaginal ultrasound and/or hysterosalpingography, scheduled for their first IVF/ICSI cycle. According to *PICO* format, inclusion criteria were: *Population*, infertile patients; *Intervention*, hysteroscopy; *Control*, no hysteroscopy; *Outcome*, clinical pregnancy rate (CPR). Secondary outcomes were: live birth rate, implantation rate, miscarriage rate.
Participants/materials, setting, methods: A bibliographic search was undertaken from 1998 to 2018, yielding 327 studies. Two researches (A.M., S.G.) reviewed independently the studies. After the first screening (title, abstract), 312 articles were excluded and 11 after the second screening. The Mantel-Haenszel method was used to calculate odds ratios (OR) and heterogeneity among studies (I^2). The results were expressed as OR with 95% confidence intervals (CI). Standardized mean differences (SMD) between groups were used for continuous outcomes.
Main results and the role of chance: Four RCTs were included (El-nashar et al., 2011; Elsetohy et al., 2015; Smit et al., 2016; Alleyassin et al., 2017). No significant differences between the hysteroscopy group and the control group in female age (p=0.29), BMI (p=0.21), number of retrieved oocytes (t=1.33, p=0.18), fertilization rate (Z=0.82, p=0.41) and transferred embryos (t=0.75, p=0.45) were observed. The studies did not report sufficient data for evaluating total dose of gonadotropins, stimulation duration and number of mature oocytes.

CPR was reported in all the four trials with 1,279 participants and it was significantly different in women receiving hysteroscopy [357/640] compared with the controls [304/644] (OR 1.67, 95% CI 1.08 to 2.58, I^2=64%).

In the two studies reporting live birth rate and including 935 patients (Elsetohy et al., 2015; Smit et al., 2016), no difference was observed between the hysteroscopy group [265/466] and the control group [232/469] (OR 1.69, 95% CI 0.71 to 4.00, I^2=86%). The miscarriage rate, reported in two studies with 962 participants (Smit et al., 2016; Alleyassin et al., 2017), showed no significant difference between women receiving hysteroscopy [54/319] and controls [41/273] (OR 1.16, 95% CI 0.74 to 1.80, I^2=13%). The selected studies did not report sufficient data to analyze implantation rate.
Limitations, reasons for caution: The couples' basal characteristics (FSH, AMH, AFC, seminal parameters) were not indicated in all the RCTs, as the drugs used for the ovarian stimulation.
Wider implications of the findings: Hysteroscopy may be offered in women with a normal transvaginal ultrasound and/or hysterosalpingography undergoing their first IVF/ICSI cycle. Further multicenter, well-designed RCTs with the live birth rate as the primary outcome are necessary for obtaining stronger evidence to support the use of routine hysteroscopy before IVF/ICSI.
Trial registration number: Not applicable for non-clinical trials.

P-376 Prevalence of Thrombophilic and folate metabolism mutations in embryos with different clinical outcomes

R. Abramov[1], S. Madjunkova[1], R. Antes[1], S. Chen[1], C. Librach[2,3,4,5,6]
[1]*CReATe Fertility Centre, Reproductive genetics, Toronto, Canada*
[2]*CReATe Fertility Centre, Clinic director, Toronto, Canada*
[3]*University of Toronto, Department of Obstetrics and Gynecology, Toronto, Canada*
[4]*University of Toronto, Institute of Medical Sciences, Toronto, Canada*
[5]*University of Toronto, Department of Physiology, Toronto, Canada*
[6]*Women's College Hospital, Department of Gynecology, Toronto, Canada*

Study question: Is there an association of thrombophilic and folate metabolism mutations in preimplantation embryos with pregnancy outcomes?
Summary answer: Homozygous FXIII (V34L) mutation is associated with poor implantation. MTHFR1298 AC/CC and MTHFR1298 AC (CC)/MTRR 66 AG(GG) genotype are associated with early miscarriage.
What is known already: Embryo implantation is a complex interplay of embryonic and maternal factors that requires controlled placental vascular invasion. Maternal mutations affecting coagulation cascade and one carbon metabolism are explored in cases of repetitive miscarriages or implantation failures, and for some of them, there is an established association with subfertility. Mutations in folate metabolism may compromise methylation and metabolism of DNA and proteins that can potentially affect embryo development in the early stages of implantation and placentation. The frequency of mutations in thrombophilia and folate metabolism genes in preimplantation embryos and their association with pregnancy outcomes is lacking.
Study design, size, duration: This is a retrospective study on 96 blastocysts with known clinical outcome after single euploid embryo transfer (41.6% - not-implanted, 33.3% - ongoing pregnancy and 25.0% - early miscarriage <12 gestational weeks). Clinical and demographic data of the patients were obtained (n=77). 47.9% of the embryos were derived from oocytes of young anonymous donors (25.3±3.4 years); 17.7% of women <35; 27.1% of women 35-40 and 7.3% of women >40. 19.8% were transferred to gestational carriers.
Participants/materials, setting, methods: We analyzed 10 different mutations in thrombophilia- and folate-related genes (Factor V-Leiden G1691A,

Factor V-H1299R, Factor II-G20210A, Factor XIII-V34L, PAI-1 -675 4G/5G, FGB -455G/A, MTHFR-C677T and -A1298C, MTR-A2756G, and MTRR-A66G) using single base sequencing method. Stored whole genome amplified (WGA) DNA from trophectoderm biopsies (4-6 cells) of euploid blastocysts with known pregnancy outcomes was used. SPSS software was used for statistical analysis, and p<0.05 with CI 95% was considered as significant.
Main results and the role of chance: Embryos that implanted, did not implant or resulted in a miscarriage had similar allele and genotype frequencies for MTHFR C677T, MTR A2756G, Factor V-Leiden G1691A, Factor V-H1299R and Factor II-G20210A mutations. PAI-1 -675 4G/4G genotype was more frequent in embryos that did not implant (12.5%) vs implanted (1.9%) (p=0.08, non significant-NS). Interestingly FGB -455G/A mutation was only found in the embryos that implanted (n=56, 8%, NS). Homozygous XIII-V34L mutation was associated with lower embryo implantation potential (OR 2.2, 95% CI[1.06-4.6]). Minor allele and genotype frequency of MTHFR A1298C mutation were significantly higher (p=0.03 and p=0.009 respectively) in embryos that miscarried (q=0.35, [AC] genotype=0.66, [CC] genotype=0.042) compared to embryos with ongoing pregnancy (q=0.20, [AC] genotype=0.34, [CC] genotype=0.03) and non-implanted ones (q=0.175, [AC] genotype=0.3, [CC] genotype=0.025). Furthermore this effect of the MTHFR A1298C mutation was potentiated when a mutation in another folate metabolism gene MTRR A66G was present (OR 4.2, 95%CI[1.32-13.47]).
Limitations, reasons for caution: The small sample size and the data was obtained from a single IVF center. Although powered to detect difference in

allele and genotype frequency of individual mutations, larger sample size will allow for examination of the compound effect of more than one mutation on embryo implantation and development potential

Wider implications of the findings: Our results present for the first time the frequency of 10 mutations associated with thrombophilia and folate metabolism, and association of embryonic MTHFR A1298C genotype with miscarriages. Embryo selection for transfer can be improved by testing for these mutations at the same time of ploidy screening.

Trial registration number: not applicable

P-377 Diagnosing the Endometrium after Recurrent Implantation Failure (RIF)

M. Hviid[1], G. Persson[2], T. Hallager[3], L. Grupe[3], T. Hviid[2], N. Macklon[4]

[1]*Zealand University Hospital, Fertility Clinic- Zealand Region, København Ø, Denmark*

[2]*Zealand University Hospital, Department of Biochemistry, Roskilde, Denmark*

[3]*Zealand University Hospital, Pathology department, Næstved, Denmark*

[4]*Zealand University Hospital, Gynecology and Obstetrics, Roskilde, Denmark*

Study question: What endometrial dysfunctions can be identified in a cohort of women with RIF, and do they point to independent causalities?

Summary answer: Multiple endometrial aetiologies are observed in RIF, no single endometrial receptivity test can fully guide management. uNK-cell-counts correlate to histological and gene-markers of endometrial maturation.

What is known already: The endometrial factor is recognized as a cause of RIF. However management remains largely empirical and of questionable efficacy. There is a need to guide therapy by making an endometrial diagnosis.

Study design, size, duration: Prospective cohort study. Between November 2017 – January 2019 80 women with a history of RIF were referred to a new University based 'Implantation Clinic'. Patients underwent timed endometrial diagnostic profiling in a hormone substituted cycle. Endometrial biopsies were analysed by histology, immune cell profiling, and ERA testing (Igenomix). The vaginal microbiome was analysed (ART-PRED) and blood profiling for putative causes of implantation failure was performed.

Participants/materials, setting, methods: RIF was defined as failure to conceive after at least three transfers of high quality, fresh and/or frozen embryos. All participants were treated with a standard hormone substituted cycle using oral estradiol and vaginal progesterone. All samples were taken after 5 full days of progesterone. Blood tests included estrodiol, progesterone, prolactin, TSH, thrombophilia screening, and vitamin D. CD56 and CD16 cell counts were divided into three categories: low, medium and high based on pathology description.

Main results and the role of chance: In 67% of the women one or more possible explanatory reasons for implantation failure was identified. A low serum progesterone $\leq$ 35 nmol/L suggesting poor vaginal absorption was observed in 41%. The ERA revealed displacement of the receptive window in 51%. Endometrial CD56 and CD16 counts were low in 30% and 23% of the women, respectively, and high in 6% and 19% women, respectively. Only one patient was identified to have antiphospholipid antibodies, and none showed evidence of chronic endometritis. uNK cell counts in the endometrium showed a positive correlation with the maturity of the endometrium assessed independently by both the ERA (p-value 0.0003) and by Noyes histological criteria (p-value 0.0064). The proportion with an abnormal vaginal microbiome is under analysis and will be presented.

Limitations, reasons for caution: The tests performed in the study were taken in a standard hormone substituted cycle and results should be interpreted in that clinical content. The findings require comparison with a control group and this work is ongoing.

Wider implications of the findings: In the majority of women with RIF a potential endometrial factor can be identified. Diagnosing the endometrium could reduce the empirical use of unproven treatments, by providing a rationale for individualised treatment. Future trials of therapies for RIF should target the underlying diagnosis rather than test their empirical use.

Trial registration number: REG-117-2017 Registered with the local data protection authority.

P-378 Endometrial scratching for women with one or more embryo transfer failures: a systematic review and meta-analysis of randomized controlled trials

E. Riviello[1], A. Vitagliano[1], G. Ambrosini[1], A. Andrisani[1], A. Politi[1], S. Mosele[1], B. Bellamio[1], L. Marin[1], F. Esposito[1], S. Borgato[1], M. Calanducci[1], M. Noventa[1]

[1]*Università degli Studi di Padova, Ginecologia e Ostetricia, Padova, Italy*

Study question: To examine endometrial scratch injury (ESI) as an intervention to improve in vitro fertilization (IVF) outcomes in women with history of previous embryo-transfer (ET) failure

Summary answer: ESI improves IVF success in patients with $\geq$2 previous ET failures undergoing fresh ET; its timing and technique may provide variable effects on embryo implantation

What is known already: It is assumed that up to two-thirds of implantation failures could be secondary to defects in endometrial receptivity. Endometrial scratch injury (ESI) is an intervention widely offered to tnhance endometrial receptivity in women with a history of IVF failure. The rationale of ESI is to trigger a local acute inflammation, with release of cytokines and growth factors, that could help the implantation process. Howeverthere is still no agreement on the most appropriate timing (day of the menstrual cycle) and tecnique (number of performed endometrial injuries and optimal device) to be used

Study design, size, duration: This is a systematic review of all randomized controlled trials (RCTs) investigating the effects of ESI on IVF outcomes in women with at least one previous ET failure. Electronic databases were searched from their inception until November 2017. Ten studies were included (1,468 partecipants), of which 733 were assigned to the intervention group and 735 to the control group. All studies were open-label except for one trial (double-blinded) . three studies were multicentre trials

Participants/materials, setting, methods: Meta-analysis was conducted using the random-effect model with an intention-to-treat approach. Ovarian stimulation protocols included FSH or FSH/hMG mainly adapting dose of gonadotropins (150–375 IU daily) on patients' characteristics. The mean number of previous failed ET was between two and three in all studies, except for two. All patients received ESI during the menstrual period preceding the ET. The majority of women underwent a single homologous IVF-ICSI cycle with fresh ET

Main results and the role of chance: The meta-analysis included 1.468 partecipants from 10 RCTs. Intervention group showed higher live birth rate (LBR) (RR 1.38, 95% CI 1.05–1.80, P = 0,02) and clinical pregnancy rate (PR) (RR 1.34, 95% CI 1.07–1.67, P =0.01) compared with controls, without difference in terms of multiple PR, miscarriage rate (MR) and ectopic pregnancy (EP) PR. Subgroup analysis showed that double-luteal ESI with pipelle had maximum effect on LBR (RR 1.54, 95% CI 1.10–2.16, P = 0.01) and clinical-PR (RR 1.30, 95% CI 1.03–1.65, P = 0.03). Single follicular ESI with Novak curette showed too benefit on LBR (RR 2.36, 95% CI 1.16–4.81, P = 0.03) and clinical-PR (RR 1.78, 95% CI 1.07–1.96, P =0.03). No effects of single luteal ESI by pipelle and double follicular-luteal ESI were observed. ESI was beneficial only for patients with two or more previous ET failure (LBR: RR 1.64, 95% CI 1.21–2.21, P =0.001; clinical-PR: RR 1.57, 95% CI 1.22–2.03, P =0.0005). ESI improved IVF success only in women undergoing fresh ET cycles (RR 1.44, 95% CI 1.05–1.97, P =0.002 - RR 1.49, 95% CI 1.12–1.99, P =0.006). No complications associated with ESI occurred

Limitations, reasons for caution: The main point of weakness of this study is the heterogeneity between original studies in patients' characteristics, tools for identification of uterine diseases, IVF-ET cycles tecniques, types of embryos transferred and cointerventions. In addition, ebryo aneuplidy and endometrial inflammation as caouses for implantation failure were not ruled out

Wider implications of the findings: We recommend further well-designed RCTs on ESI, focusing on patients with homogeneous characteristics and avoiding bias due to cointerventions and due to the lack of preimplantation genetic testing. Future RCTs comparing types of intervention are needed to establish the most effective numnber, timing and device for performing ESI

P-379 Placental histopathology in IVF pregnancies resulting from the transfer of frozen-thawed embryos compared with fresh embryos

Y. Mizrachi[1], M. Kovo[1], G. Buchnik[1], M. Torem[1], L. Schreiber[2], A. Raziel[1], A. Weissman[1]

[1]Edith Wolfson Medical Center, Obstetrics and Gynecology, Holon, Israel
[2]Edith Wolfson Medical Center, Pathology, Holon, Israel

Study question: Do placentas of pregnancies resulting from fresh embryo transfer (ET) contain more histopathologic lesions compared with placentas of pregnancies resulting from frozen embryo transfer (FET)?
Summary answer: Placental histopathology analysis was comparable between pregnancies resulting from fresh ET and FET.
What is known already: An increasing amount of evidence has shown that pregnancies resulting from FET are less likely to be complicated with preterm deliveries, intrauterine growth restriction, and even antepartum death. It has been suggested that the supraphysiological estradiol levels in fresh cycles interfere with placentation, resulting in obstetric complications later on during pregnancy. It is yet unknown whether the differences in obstetrical outcome between fresh and FET cycles are also associated with certain patterns of placental histopathology.
Study design, size, duration: A prospective cohort study of pregnancy outcome and placental histopathology, in 89 women who conceived by IVF and delivered in a single tertiary medical center, between December 2017 and December 2018. Exclusion criteria were multiple pregnancies and egg donation. The prevalence of different placental histopathology lesions was compared between women who conceived after either fresh ET or FET. Thirty-eight placentas in each study group were sufficient to detect a 60% increase in vascular malperfussion lesions.
Participants/materials, setting, methods: During the study period, 89 women gave birth in our center and met the inclusion criteria, out of whom 49 had a fresh ET and 40 had a FET. Placental histopathology lesions were classified according to 'Amsterdam' criteria into maternal and fetal vascular malperfusion lesions, acute inflammatory response lesions, and chronic inflammatory lesions. All placentas were examined by a single pathologist who was blinded to the type of embryo transfer.
Main results and the role of chance: Women conceived after fresh ET did not differ from women conceived after FET with regard to maternal age (34.3 vs. 33.3, respectively, p=0.38), gestational week at delivery (38.3 vs. 38.9, respectively, p=0.33), preterm birth (14.3% vs, 5.0%, respectively, p=0.14), mean birthweight (2995 vs. 3219 gr, respectively, p=0.08), birthweight $<10^{th}$ percentile (14.3% vs. 12.5%, respectively, p=0.80), or the incidence of hypertensive disorders (14.3% vs. 5.0%, respectively, p=0.17), gestational diabetes (10.2% vs. 7.5%, respectively, p=0.72) and cesarean delivery (36.7% vs. 25.0%, respectively, p=0.23). Placental histopathology analysis from pregnancies conceived by fresh ET was comparable to pregnancies conceived by FET, with regard to the prevalence of maternal vascular malperfusion lesions (49.0% vs. 45.0%, respectively, p=0.83), fetal vascular malperfusion lesions (14.3% vs. 22.5, p=0.31), acute inflammatory response lesions (26.5% vs. 30.0%, respectively, p=0.71), and chronic inflammatory lesions (6.1% vs. 12.5%, respectively, p=0.45). Mean placental weight was comparable as well (453 vs. 476 gr, respectively, p=0.33).
Limitations, reasons for caution: The main limitations of the study are its small sample size and the limited information regarding the characteristics of IVF cycles.
Wider implications of the findings: In this preliminary study we did not find significant differences in pregnancy outcome and placental histopathology between IVF pregnancies conceived by either FET or fresh ET. These results are reassuring for clinicians and patients who wish to pursue with transferring fresh embryos.
Trial registration number: 0181-17-WOMC

P-380 Endometrial three-dimensional ultrasonographic evaluation is not associated to higher clinical pregnancy rate in infertile women submitted to frozen embryo transfer

M. Rufato[1], J. Barreto[1], D.C.C. Pedroso[1], A.S. Bassani[1], A.B. Silva[1], M.A.F. Rufato[1], C.T.V. Paula[1], A.S. Melo[1]

[1]Centro de Fertilidade de Ribeirão Preto CEFERP Fertility Center of ribeirão Preto, Human Reproduction, Ribeirão Preto, Brazil

Study question: Is endometrial three-dimensional (3D) ultrasonographic (US) evaluation associated with higher clinical pregnancy rate in frozen embryo transfer (FET) cycles?
Summary answer: The clinical pregnancy rate is not higher in women submitted to endometrial evaluation performed by 3D US in FET cycles when compared to two-dimensional(2D) evaluation.
What is known already: Although some studies have evaluated multiple markers of endometrial receptivity through Doppler 3D US, endometrial thickness has been the most widely used variable in clinical practice. Despite this, there are no studies that have compared the measurement of endometrial thickness through 2D and 3D ultrasonography in frozen embryo cycles.
Study design, size, duration:
Retrospective study with infertile women submitted to FET and recruited between 01.08.2017 and 30.10.2018. Considering a clinical pregnancy rate of 40% and that a 20% difference between the groups would be significant, 97 patients per group (194 patients total) would be required for a power of 80% and alpha 5%.
Participants/materials, setting, methods: Three hundred and thirteen women aged 39 years or less were recruited and were divided into two groups: 1)2D:endometrial evaluation by 2D US(n = 135) and 2)3D: endometrial evaluation by 3D US(n = 109). All women underwent 2D or 3D evaluation until the day of embryo transfer. The examinations were performed by two observers through the Voluson E8 Expert (GE Healthcare). Seventy-four women were excluded [uterine alterations low ovarian reserve, poor embryo quality, thin endometrium.
Main results and the role of chance: Clinical pregnancy rate was similar between the 2D and 3D groups (p = 0.32). Logistic regression showed that the type of US (2D vs. 3D) [Relative Risk (RR) 0.84 Confidence Interval (CI95%) (0.58-1.2), p = 0.34], age [RR 0.97 (0.94-1.0), p = 0.06] and the cause of infertility [(Endometriosis - 0.95 (0.53-1.71), p = 0.86), (Polycystic ovary syndrome - 0.95 (0.53-1.71), p = 0.86), (Unexplained infertility - 0.98 (0.44-2.18), p = 0.95), (Tubal factor - 0.53 (0.25-1.14), p = 0.1), (Male factor - 0.96 (0.62-1.47), p = 0.84)] were not independent predictors of clinical pregnancy rate.
Limitations, reasons for caution: As the realization of 3D US depends on 2D image capture of reasonable quality, 3D evaluation may present limitations in some cases. However, to minimize such effect, changes in the uterine anatomy were considered as exclusion criteria and all exams were performed by two observers.
Wider implications of the findings: The assessment of 3D endometrial thickness is not associated with a higher clinical pregnancy rate in relation to 2D analysis in frozen embryo transfer cycles.

P-381 MicroRNA let-7 in endometrial extracellular vesicles induces embryonic diapause

W. Yeung[1,2], W. Liu[3], Y.L. Lee[3], C.H. Chen[3], R. Cheng[3], R.T.K. Pang[2], P.C.N. Chiu[3]

[1]The University of Hong Kong, Queen Mary Hospital- Dept. of OB/GYN, Hong Kong, China
[2]The University of Hong Kong-Shenzhen Hospital, Shenzhen Key Laboratory of Fertility Regulation, Shenzhen, China
[3]The University of Hong Kong, Obstetrics and Gynaecology, Hong Kong, China

Study question: How does let-7 suppresses implantation? Does it affect human blastocyst implantation?
Summary answer: Let-7 in endometrial extracellular vesicles induces embryo diapause to suppress implantation in both human and mouse models.
What is known already: Let-7 force-expression suppresses mouse embryo implantation. Mouse embryos can be induced to undergo diapause (delayed implantation), when the blastocysts become dormant and do not implant in the uterus but can be activated to implant and produce pups. The expression of let-7 family members is high in the dormant mouse blastocysts. Endometrial epithelial

cells including those from humans secrete extracellular vesicles containing microRNAs including let-7.

Study design, size, duration: Laboratory experimental study

Participants/materials, setting, methods: The actions of let-7 on survival of mouse blastocysts in vitro and in delayed implanting mice, and on differentiation and implantation potential of human blastocyst surrogates were studied.

Main results and the role of chance: Electroporation of let-7 prolonged the survival of mouse blastocysts in vitro. The treated blastocysts had reduced proliferation, nutrient metabolism and apoptosis when compared to the control blastocysts and the normal Day 4 blastocysts prior to implantation. They produced pups after transfer to foster mothers.

Two observations demonstrated that the let-7 in delayed implanting mouse blastocysts were derived from endometrium: (1) the expression profile of let-7 in endometrial epithelial cells, extracellular vesicles of uterine luminal fluid and blastocysts before, during diapause, and after estradiol-induced activation were identical; (2) Wildtype mouse blastocysts acquired a unique let-7 transgene after transfer into delayed implanting transgenic mice carrying the sequence. Let-7-enriched extracellular vesicles from endometrial epithelial cells prolonged mouse blastocysts survival in vitro. The treatment also down-regulated the target genes of let-7 in the treated embryos.

Human embryonic stem cells were induced to form spheroids and differentiate into human blastocyst surrogates; they possessed blastocoel-like structure, expressed trophoblast genes and attached specifically onto receptive human endometrial epithelial cells. Treatment with let-7-enriched extracellular vesicles reduced mRNA expression of syncytiotrophoblast and extravillous cytotrophoblast marker genes, suggesting blockage of trophoblast differentiation. The attachment potential of the treated spheroids on receptive human endometrial epithelial cells was also significantly reduced.

Limitations, reasons for caution: The observations on human blastocyst surrogates may not truly reflect those that would happen in human blastocysts.

Wider implications of the findings: Embryonic diapause is an evolutionary conserved phenomenon. The results suggested that endometrial let-7-enriched extracellular vesicles retarded embryo development. Thus dysregulation of microRNAs production may alter developmental rate of embryos causing embryo-endometrium asynchrony and infertility. (The study is supported by GRF 17119117, GRF 17107915 and NSFC 31471398)

Trial registration number: Not applicable for non-clinical trials.

P-382 Recurrent Implantation failures – Is there a role for PGT-A?

K.C. Mantravadi[1], D.R. Gedela[2]

[1]*Oasis Centre for Reproductive Medicine, EMBRYOLOGY, Hyderabad, India*

[2]*Oasis Centre for Reproductive Medicine, Infertility, Hyderabad, India*

Study question: Is Pre-Implantation Genetic Testing for Aneuploidy (PGT-A) a beneficial intervention for patients with Recurrent Implantation Failures (RIF)?

Summary answer: PGT-A for RIF doesn't seem to improve Live Births. Considering lesser multiple pregnancies and lesser time to pregnancy we could still consider PGT-A for RIF.

What is known already: Role of PGT-A for couples with RIF is still un-certain.

Study design, size, duration: This is a retrospective study of couples that underwent fertility treatments at our center from 2014-2017 with history of RIF.

140 couples with RIF underwent PGT-A screening, of which 68 underwent a successful transfer with one Euploid Blastocyst (n=68).

34 couples with history of RIF underwent blastocyst transfers without PGT-A screening (n=34).

Participants/materials, setting, methods: Patients who had minimum two transfers (Fresh or Frozen) and not conceived were classified as RIF and recruited. Retrospectively we grouped the couples into PGT-A (n=68) and Non PGT-A group (n=34)

All women underwent Blastocyst transfers in a frozen cycle (FET)

For PGT-A, embryos were biopsied at Blastocyst stage and subjected to Next Generation Sequencing (NGS)

Multiple pregnancy rates (MPR), Live Births (LBR), number of FET attempts to pregnancy and time to pregnancy were compared between the groups

Main results and the role of chance: LBR in PGT group was 61.7% (n=42/68), all pregnancies were singletons with no incidence of multiple gestations.

LBR in Non-PGT-A group was 55.8% (n=19/34) with 11.7% multiple pregnancies.

Most of the women in PGT-A group conceived in the first embryo transfer (40 women conceived in the first FET) and the average time take to conceive was there months.

In Non PGT-A group women conceived either in the 3rd or 4th FET attempt and took an average of 9months to attain pregnancy.

Though the live births were comparable between both the groups, time to pregnancy was shorter in PGT-A screened group with lesser attempts.

Considering the shorter time to conceive and lower incidence of multiple pregnancies, PGT-A could still be offered to couples with RIF.

Limitations, reasons for caution: Retrospective data, Small sample size

Wider implications of the findings: Though live births do not seem to be better after PGT-A intervention, considering the psychological aspects associated with every failed attempt; PGT-A still could be a beneficial intervention to shorten time to pregnancy. PGT-A could be an active intervention for clinics with a strict policy for elective single embryo transfer

Trial registration number: NA

Retrospective Data

P-383 E4 allele of Apolipoprotein E (APOE) gene is associated with recurrent implantation failure

P. Mohtasebi[1], M.R. Zamanian[2], F. Ramezanali[3], M. Eslami[4]

[1]*Tehran Medical Sciences- Islamic Azad University- Tehran- Iran, Genetics, Tehran, Iran*

[2]*Reproductive Biomedicine Research Center- Royan Institute for Reproductive Biomedicine, Genetics, Tehran, Iran*

[3]*Reproductive Biomedicine Research Center- Royan Institute for Reproductive Biomedicine, Endocrinology and Female Infertility, Tehran, Iran*

[4]*Applied Biotechnology Research Centre- Tehran Medical Sciences- Islamic Azad University, Genetics, Tehran, Iran*

Study question: Present study was aimed to evaluate whether there is an association between *APOE* genotypes with recurrent implantation failure cases.

Summary answer: Endometrial gene expression pattern is an important determinant of its receptivity during implantation, and allelic polymorphisms may alter the level of expression in particular genes.

What is known already: Recurrent implantation failure (RIF) which involves 10% of assisted reproductive technology (ART) treatments may happen due to maternal or embryonic etiologies. Previous studies have shown an up-regulation in *APOE* gene expression inside the endometrial tissue during the window of implantation. Furthermore, several reports have emphasized on the association of *APOE* allelic polymorphisms with female infertility and recurrent pregnancy loss. *APOE*, an important effector in cholesterol and lipid metabolism and transport, is encoded by three major polymorphic alleles (E2, E3 and E4) which may produce six different genotypic combinations.

Study design, size, duration: 100 infertile women (age<40 years) with at least three episodes of ART failure with minimum of four good quality embryo transfers and any known risk factors were compared to 100 normal fertile controls with at least one live birth and no history of infertility.

Participants/materials, setting, methods: Genomic DNA was extracted by standard salting out method from 5ml peripheral blood samples of all participants and amplified through polymerase chain reaction. finally genotyping and allele determination was performed using RFLP method.

Main results and the role of chance: Genotype frequencies among patients and controls were as follows in respect: E2/E3: 5% vs 8%, E3/E3: 66% vs 77%, and E3/E4: 28% and 15%. Statistical analysis revealed significant higher frequency for E3/E4 genotype in RIF group compared to control (P=0.038; OR=2.203; 95%CI =1.092 to 4.443). The allele frequencies in patients and controls were respectively as follows: E2: 2.5% vs 4%, E3: 82.5% vs 88.5% and E4: 15% vs 7.5%. Once again, statistical analysis showed significant higher frequency for E4 allele in RIF group compared to control (P = 0.026; OR=2.176; 95%CI =1.131 to 4.185). Our data supports the association of E4 polymorphism with recurrent implantation failure (E3/E3 vs E3/E4: P =0.031; OR = 2.177; 95%CI = 1.072–4.421, and E3 vs E4: P = 0.022; OR = 2.145; 95%CI =1.114–4.130). Due to significant higher frequency of E4 allele and E4 carrier genotypes in RIF patients, for the first time, we propose the *APOE*-E4 polymorphism as a potential risk factor for human embryonic implantation process.

Limitations, reasons for caution: Sample size of the study including patients and fertile controls was relatively small, because of inadequate accessible RIF patient samples. In addition, Ethnic backgrounds of participants were not considered in the study.
Wider implications of the findings: Evaluation in a larger cohort of RIF patients, APOE genotyping in ART success cases and RIF cases with different ethnic backgrounds can help to establish present data.
Trial registration number: not applicable

P-384 Bed rest following embryo transfer – Freedom of choice doesn't impair pregnancy rates

M. Schenk[1], Z. Eisner[2], G. Weiss[3]
[1]*Das Kinderwunsch Institut Schenk GmbH, Science Department, Dobl, Austria*
[2]*Das Kinderwunsch Institut Schenk GmbH, central supply, Dobl, Austria*
[3]*Das Kinderwunsch Institut Schenk GmbH, Science Department, Dobl bei Graz, Austria*

Study question: Is there a difference in life birth rates in patients with bed rest following fresh/frozen embryo transfer?
Summary answer: There is no difference in life birth rates between patients with and without bedrest following fresh/frozen embryo transfer.
What is known already: Bed rest following embryo transfer has always been controversially discussed. While it has been recommended as a way to prevent embryo expulsion by gravity, a recent meta-analysis showed no benefit to improve clinical pregnancy and live birth. However, implantation rates were found to be reduced in patients choosing bed rest. The big heterogeneity in different study designs makes a general consensus very complex. Hence, we wanted to add further knowledge about the necessity and influence of bed rest after embryo transfer considering fresh versus frozen embryo transfer.
Study design, size, duration: The study was designed and conducted at the Kinderwunsch Institut Schenk GmbH (Dobl, Austria) between February 2017 and September 2018. 1000 embryos from patients undergoing IVF (*in vitro* fertilization) and ICSI (intracytoplasmic sperm injection) treatment were included and retrospectively analyzed. 535 patients (53.5%) had fresh embryo transfer, while 465 patients (46.5%) had frozen embryo transfer. Patients who decided to have bed rest following embryo transfer stayed in bed for 10-15 minutes.
Participants/materials, setting, methods: Embryos from women (aged 18 - 41) with good embryo quality, according to the Istanbul consensus criteria, cultured in time-lapse system were included in the study while embryos from patients with known genetic predispositions were excluded. Cryopreservation was performed using GAVI vitrification system (Merck). Embryo transfer (fresh and frozen) was performed on day 3 or day 5 taking into consideration the number of fertilized oocytes, patient age and embryo quality in previous attempts (if any).
Main results and the role of chance: Overall, embryo transfers (fresh and frozen) resulted in a life birth rate of 29.9% in patients with subsequent bed rest and 30.1% in patients who were immediately discharged after transfer. Pregnancy termination after positive beta-hCG was equal in both groups (10.87% versus 10.94% respectively). In detail, patients with bed rest achieved life birth with fresh transfer in 30.1% of all cases, while 29.7% achieved pregnancy with frozen transfer. Without bed rest pregnancy with fresh transfer was achieved in 28.9% of all cases while 31.6% achieved pregnancy in the frozen embryo transfer group. Overall, there were no statistical differences in the above-mentioned parameters between the two groups.
Limitations, reasons for caution: The retrospective data analysis may be seen as study limitation. Nonetheless, results should be confirmed with a higher sample size in future studies.
Wider implications of the findings: The data show no difference in life birth rates with or without bed rest following embryo transfer, independent from fresh or frozen cycles. It is tempting to speculate that the empowerment of the patients to decide about their post-transfer routine is the best advice for a successful treatment outcome.
Trial registration number: not applicable

P-385 OUTCOMES OF A LARGE TRIAL TO DEVELOP A LOW COST, MASS MARKET, NON-INVASIVE, URINARY, PRENATAL DIAGNOSTICS TEST FOR TRISOMIES AND PREECLAMPSIA FOR THE CHINESE MARKET

S. Butler, B.Sc.- Ph.D.[1], R. Pais[1], R. Zmuidinaite[1], S. Keshavarz[1], R. Iles[1]
[1]*MAP Sciences, Research & Development, Bedford, United Kingdom*

Study question: Is it possible to apply a computational-based mass spectral data analysis workflow previously developed for UK, to urinary prenatal screening in a Chinese population?
Summary answer: The automated computational workflow made it possible to rapidly and affordably screen urine-derived mass spectral data for prenatal diagnosis in a large Chinese population.
What is known already: Prenatal testing is rapidly changing the way in which early pregnancies are being managed. However, with the exception of serum marker assays and confirmatory amniocentesis, prenatal testing is still only offered to the privileged few or those in developed countries with national health systems. Despite the rapid growth in NIPT, the high cost associated with blood based DNA testing has meant that pregnancies in low/middle income countries, including China, rely on more invasive methods, late screening (3rd trimester), or not at all. This puts patients at risk and leads to uninformed, underprepared healthcare decisions and provision for pregnant women.
Study design, size, duration: A screening test study to analyse the urine from 4751 pregnant women collected in an 11 month period from two hospitals in the Jiangsu province in China. 8692 analyses were performed on two different MALDI instruments which were benchmarked against each other to determine if the Chinese manufactured instrument could match the performance of the established UK manufactured instrument. The data was systematically analysed for quality and normalized using our currently available pre-processing bioinformatic pipeline.
Participants/materials, setting, methods: The analysis of urine using MALDI mass spectrometry was developed in the UK and applied in this study to determine the potential sensitivity and specificity of detecting Downs syndrome, T18 and preeclampsia in this large cohort. The average gestational age was 13 weeks and maternal age 29 years. Quality control assessment, pre-processing and data analysis of all samples from UK and Chinese instruments was conducted respectively using an automated pipeline which was implemented in Python.
Main results and the role of chance: A subset of samples was randomly selected from a pre-processed data set and their peak positions and intensities were systematically compared within a range of 50 m/z windows using a previously developed computational workflow. Mass spectra from both MALDI instruments had patterns of peak enrichment and intensity differences in urine samples for aneuploidies (T21, T18) and preeclampsia pregnancies when compared with a representative set of non-aneuploids or with non-preeclamptic outcomes. The identified patterns from selected representative samples (training data sets) were used to develop 12 predictive models to identify T21, T18 and preeclampsia in pregnancies. The models were validated using a larger testing data sets, which were not used for model development. Data was analysed and validated in sets grouped by gestational age to eliminate bias due to changes occurring with gestational age. ROC analysis showed that all predictive models developed for identification of T21 and T18 have good performance with 100% sensitivity and false positive rates between 0 and 20%. For preeclampsia the best performing algorithm gave 83.3% sensitivity for 35% FPR.
Limitations, reasons for caution: The number of trisomy outcomes analysed in the cohort was small, even though this was representative of the true population rate. Furthermore, urine samples were frozen prior analysis and in some cases more than one freeze thaw cycle, poor spectra resulting from this process were not used in the study.
Wider implications of the findings: Earlier, cheaper, urine-based testing can be implemented to increase the ease and availability of prenatal testing in low/medium income countries like China, enabling better informed healthcare decisions earlier in a pregnancy without having to rely solely on NIPT or traditional biomarker screening tests which require advanced and expensive infrastructure.
Trial registration number: N/A

P-386 Evaluating the risk of ectopic pregnancy and spontaneous abortion in early pregnancy using a serum hCG and CA125 measurement algorithm

R. Zmuidinaite[1], S. Butler[1], F. Sharara[2], J. Saadeh[3], R. Iles[1]
[1]*MAP Sciences, Research, Bedford, United Kingdom*
[2]*Virginia Centre for Reproductive Medicine, Embryology, Reston, U.S.A.*
[3]*Al Enaiah Medical Lab, Medical laboratory, Sharjah, United Arab Emirates*

Study question: Can a mathematical algorithm based predictive model, utilising serum biomarkers, be a viable test to predict risk of ectopic pregnancy or spontaneous abortion?
Summary answer: Single point hCG and CA125 combined measurement gives an accurate risk score, detecting ectopic pregnancy or spontaneous abortion in the second month of gestation.
What is known already: About 10–15% (increasing to 18-30% for IVF patients) of all spontaneous pregnancies end in recognised spontaneous abortion and 1-2% result in ectopic pregnancy. Currently, diagnosis is based on repeat hCG measurement and ultrasound scan and results are often inconclusive, requiring repeat follow up causing patient anxiety and increased risk of tubal rupture. Both hCG and CA125 have been used extensively in management of viable pregnancies, spontaneous abortion and ectopic pregnancy but not in combination with mathematical modelling following single point measurement to predict risk.
Study design, size, duration: This was a diagnostic test study including serum samples from 380 pregnancies. Serum samples were collected from the A&E and EPAU at London Hospital from pregnant women (average gestational age: 7 weeks) presenting with lower abdominal pain and/or vaginal bleeding between 2002 and 2003. Serum hCG and CA125 of 137 samples were included in the study. Outcomes were confirmed by the follow up. Analysis of data using supervised machine learning was performed in 2017.
Participants/materials, setting, methods: There were 13 cases with 124 controls for ectopic pregnancy and 62 cases with 75 controls for spontaneous abortion models. Multiple algorithms were built and tested from the data which were then validated by ten-fold cross-validation to ensure reproducibility and reliability. Quadratic and linear discriminant analysis algorithms based predictive models were built on a log normalised data. Data analysis was performed in R.
Main results and the role of chance: Two separate models were developed which combined serum measurements of hCG and CA125 to calculate the relative risk for either ectopic pregnancy or spontaneous abortion. Ectopic pregnancy test performance was 100%, 73% and 77% for sensitivity, specificity and accuracy respectively and an ROC of 0.87. The ROC for spontaneous abortion was 0.74 with sensitivity of 63% and specificity of 72%. This diagnostic test reports the relative risk comparing an adjusted risk based on the results of the general risk. Five categories of risk were modelled for both ectopic pregnancy and spontaneous abortion which included: low, normal, moderate, elevated and high risk.

Following the cross validation, the study resulted in a user friendly, clinical decision making support system being created. The system requires simple data input of serum marker values and patient information to rapidly provide a calculated risk score. This risk score can enable clinicians to make informed decisions regarding patient management and pregnancy advice.
Limitations, reasons for caution: This study is limited by the cohort size and the limited number of ectopic pregnancy cases.
Wider implications of the findings: This study has shown that simple, single point measurement test can be used quickly at the most critical time to identify women with high risk for ectopic pregnancy or spontaneous abortion when compared to serial measurement and ultrasound scan alone.
Trial registration number: not applicable

P-387 Evaluating the clinical utility of endometrial biopsy for chronic endometritis screening in patients who experience implantation failure following euploid embryo transfer

C.A. Hernandez-Nieto[1], L. Sekhon[1], J. Lee[1], T. Alkon[1], M. Luna-Rojas[1], B. Sandler[2], A. Copperman[2], T. Mukherjee[2]
[1]*Reproductive Medicine Associates of New York, Reproductive endocrinology and Infertility, New York, U.S.A.*
[2]*Icahn School of Medicine at Mount Sinai, Obstetrics- Gynecology and Reproductive Science, New York, U.S.A.*

Study question: Does endometrial biopsy (EMB) and chronic endometritis (CE) screening offer clinical utility in patients following euploid embryo implantation failure?
Summary answer: Patients, regardless of endometrial biopsy findings, have similar IVF outcomes on a subsequent treatment cycle as compared with patients who do not undergo endometrial biopsy.
What is known already: Chronic endometritis is a local inflammatory disease characterized by plasmacyte infiltration within the endometrial stroma and is found within 8-72% of tested infertile patients (Kitaya K, 2018). Recent studies showed that CE may exert a negative effect on embryo implantation through impairing decidualization and altering the expression of proteins involved in endometrial receptivity (Wu D, 2017). Further study findings have suggested that antibiotic treatment for CE can improve IVF success rates. Clinical evidence is still scarce regarding the value of performing an endometrial biopsy for screening CE in patients with a history of failed implantation after a euploid blastocyst transfer.
Study design, size, duration: A retrospective, cohort study included infertile patients who failed a euploid embryo transfer and thereafter underwent an endometrial biopsy for CE screening, received antibiotic treatment (if indicated), and had a subsequent single, euploid frozen embryo transfer from January 2016 to December 2018. A sample size of 70 patients per group was calculated to be necessary to detect a 15% difference in clinical pregnancy rates with 80% power. Alpha=0.05.
Participants/materials, setting, methods: Cohorts were segregated into two groups (Group 1: patients who had a failed euploid embryo implantation that underwent EMB, this group also included patients in which EMB was negative for CE. Group 2: Control patients who had an unsuccessful euploid embryo implantation and did not undergo EMB). For EMB cases, CE was diagnosed using CD138 immunohistochemistry staining. All patients in the study underwent a subsequent single, euploid frozen embryo transfer (FET).
Main results and the role of chance: Group 1 included 241 patients of which 42% (n=90) were diagnosed with CE and received antibiotic therapy; while the remaining 124 patients were found to be negative for CE. Group 2 included 985 control patients.

On an unadjusted comparison, no differences were found in age, baseline FSH, baseline AFC, previous number of stimulation/IVF cycles, and embryonic quality among cohorts. However, a significant difference in AMH levels (3.3±2.9 vs 4.0±4.7, p=0.02), BMI (24.5±4.6 vs 23.5±4.2, p=0.002), and endometrial thickness (8.6±1.3mm vs 9.0±1.6mm, p=0.03) was observed. When analyzing a subsequent FET cycle, no differences were found in clinical pregnancy (CPR) rates 76% vs 81.1%(p=0.28), ongoing pregnancy rate (OPR) 78.8% vs 85.9(p=0.36) clinical loss rate (CLR) 10.6% vs 17.1%(p=0.09) or multiple pregnancy rate (MPR) 0.06% vs 1.6%(p=0.41) among Group 1 vs Group 2 respectively.

Using a logistic regression analysis fitted with a GEE model, and after adjusting for age, BMI, endometrial thickness at FET, embryo quality, and day of embryo biopsy, there was no positive association to performing an EMB and FET cycle outcomes (CPR (OR 1.01 CI95% 0.7-1.4,p=0.9), OPR (OR 1.16 CI95% 0.8-1.6, p=0.3), CLR (OR 0.6 CI95% 0.3-1.3, p=0.3) and MPR (OR 0.6 CI95% 0.05-3.3, p=0.4)).
Limitations, reasons for caution: This study is limited by its retrospective nature. Also, there is limited evidence and differences in worldwide standardization for the ideal time to perform an endometrial biopsy, methodology for CE diagnosis, and treatment protocols. These caveats might reduce this study findings generalizability. Future randomized controlled trials are needed.
Wider implications of the findings: Understanding the clinical utility of CE screening and the potential therapeutic advantages on embryo implantation is of critical importance for guiding patients during ART treatment. To date, there is limited evidence to support performing endometrial biopsies in patients with a history of failed implantation following euploid embryo transfer.
Trial registration number: This study was approved by the Western Institutional Review Board (Study Number: 1167398).

P-388 Mancozeb but not its metabolite ethylene thiourea (ETU) affects the embryo implantation process via modulating trophoblast invasion in vitro models

Z. Wang[1], S.P. Kodithuwakku[2], K.S.A. Kottawatta[3], C.K.F. Lee[1]

[1]*The University of Hong Kong, Department of obstetrics and gynaecology, Hong Kong, Hong Kong*

[2]*The University of Peradeniya, Department of Animal Science- Faculty of Agriculture, Peradeniya, Sri Lanka*

[3]*The University of Peradeniya, Department of Veterinary Public Health and Pharmacology- Faculty of Veterinary Medicine and Animal Science, Peradeniya, Sri Lanka*

Study question: Will Mancozeb and its metabolite ETU play a novel regulatory role in the invasion and migration of trophoblast cells? What is the underlying mechanism of Mancozeb?

Summary answer: Mancozeb but not ETU suppresses the invasion and migration through down-regulation of MMP-2 via ERK1/2 signaling pathway in trophoblastic cells.

What is known already: Mancozeb is a zinc/manganese-containing fungicide belonging to the subclass of ethylene-bis-dithiocarbamate (EBDC), which is largely used in agriculture. Mancozeb is classified as an endocrine disrupting chemical (EDC) modulating human reproductive and endocrine systems. Ethylene thiourea (ETU) is the main metabolite of Mancozeb with higher water-solubility and longer half-life period. Mancozeb and ETU were found to have teratogenic, mutagenic and carcinogenetic effects in vivo models. Successful pregnancy requires optimal trophoblast cell invasion into the uterine decidua soon after embryo implantation. However, the roles of Mancozeb and ETU on trophoblast invasion and migration remain largely unknown.

Study design, size, duration: The roles of Mancozeb and ETU on trophoblast biological function were investigated with human trophoblast cell lines JEG-3 and BeWo. The expression of metalloproteinases (MMPs) and pERK/ERK after Mancozeb treatment was analyzed. The effects of Mancozeb and its metabolites ETU and zinc salt on MMP-2 expression and activity were compared.

Participants/materials, setting, methods: Cell viability was quantified with CyQUANT NF cell proliferation assay. Matrigel-coated transwell assay and wound healing assay were used to study trophoblast invasion, outgrowth and migration after Mancozeb or ETU treatment. The expression and activity of MMP-2 in JEG-3 and BeWo cells were detected by qPCR, Western blotting, and gelatin zymography, respectively. Differential expression of MMP-9, TIMP1, TIMP3 and ERK/pERK in the JEG-3 cells after Mancozeb treatment were measured by qPCR and Western blotting.

Main results and the role of chance: Mancozeb and ETU strongly reduced cell viability at a concentration higher than 10μg/ml and 5000μg/ml after 48h treatment, respectively. Mancozeb at 3μg/ml significantly inhibited trophoblast invasion, outgrowth and migration of JEG-3 cells, but ETU had no effect at the same concentration. Mancozeb but not ETU decreased MMP-2 expression in both JEG-3 and BeWo cells, as well as MMP-2 activity in the conditioned culture medium. Furthermore, Mancozeb at 3μg/ml induced ERK1/2 phosphorylation from 15min to 1h and reduced ERK1/2 phosphorylation from 2h to 48h in the JEG-3 cells. No change was observed for the expression of MMP-9, TIMP1 and TIMP3. Our results show that Mancozeb induces cytotoxic effect at concentrations 100-fold lower than ETU. The inhibition effect of Mancozeb on the invasion and migration of trophoblast cells is not through its metabolite ETU and zinc salt. Mancozeb suppressed the invasive ability of JEG-3 cells via inhibiting MMP-2 expression and reducing MMP-2 enzyme activity trough modulating ERK1/2 phosphorylation.

Limitations, reasons for caution: The present study was based on in vitro models established with JEG-3 and BeWo cells which belong to human choriocarcinoma cell lines. Human primary trophoblast cells and in vivo studies will be carried out in our future Mancozeb investigation.

Wider implications of the findings: This study first reports that Mancozeb is more cytotoxic than ETU. Mancozeb is often applied to the plant through aerial spraying, which elevates the potential acute exposure to pregnant women nearby. Because Mancozeb has a short half time, measures should be taken to decrease acute environmental and occupational exposures.

Trial registration number: N/A

P-389 Differentiated approach to immunotherapy in patients with recurrent implantation failure.

I. Gyulmamedova[1,2], T. Tatarchuk[3], Y. Bogoslav[4], V. Sosnina[1], E. Gyulmamedova[1]

[1]*Medical Center IPF, ivf, Kyiv, Ukraine*

[2]*Center IVF, ivf, Moscow, Russia C.I.S.*

[3]*Institute of Pediatrics Obstetrics and Gynecology, Department of Endocrine Gynecology, Kyiv, Ukraine*

[4]*Kyiv International University, - Department of Endocrine Gynecology, Kyiv, Ukraine*

Study question: Personalized immunotherapy: will it improve the chance of pregnancy occurring in women with recurrent implantation failure (RIF)?

Summary answer: In RIF patients were 3 types of immunogram. Personalized approach to choosing medication for particular patient improves frequency of implantation, onset and outcome of pregnancy**.**

What is known already: The process of preparing the endometrium for implantation is determined by the coordinated interaction of the endocrine and immune systems. Hyperestrogenism, which occurs during Controlled Ovarian Stimulation (COS), affects the function of immunocompetent cells. Although the main events of the immunological dialogue between the embryo and the endometrium occur at the implantation site, changes in the peripheral immune system (blood) to some extent reflect the state of endometrial immunity. The role of the immunological factor in RIF is a subject of numerous discussions. Randomized controlled clinical trials in this area were disappointing, but they lacked a personalized approach.

Study design, size, duration: Randomized controlled trial of 143 patients with RIF, IVF / ICSI program (June 2013- April 2018). 3 months before ART, general and local immunity was studied. Women with endometrial pathology were excluded. 1. Inhibition of phagocytosis and / or T-cell immunity was detected in 74 (51.75%) patients. 2. Increased NK activity - in 70 (48.95%). 3. The presence of various autoantibodies in 21 (14.61%) women. Imbalance of local immunity in 65 (45.48%).

Participants/materials, setting, methods: 74 RIF and reduced immunity indicators patients were randomized into 2 groups. Intervention group (IG) - n = 37 received marine mollusks hydrolyzate preparation two months before ART for 20 days according to manufacturer's scheme. Afterwards, a control immunogram was performed. Control group (CG) - n = 37 received only folic acid preparations. Outcomes measured were the implantation rate and clinical pregnancy rate. No adverse effects of the marine mollusks hydrolyzate were observed.

Main results and the role of chance: Groups were comparable in age, body mass index, reproductive and gynaecological history, endocrine and somatic morbidity. The average number of IVF attempts was (2.53 ±0.5) in both the groups, minimum and maximum of 2 and 3 previous failed IVF. **Reduction:** absolute leukocyte count in 12 (32,43%) patients of **IG** and 13 (35,14%) patients of **CG** (P>0,05); **absCD3** in 18 (48,65%) and 16 (43,24%) respectively; **absCD4** in 24 (64,86%) women in both groups; **absCD8 –** 19 (51,35%) **IG** and 16 (43,24%) **CG** (P>0,05) respectively; Reduced immunoregulatory index in 25 (67,57%) and 26 (70,27%) (P>0,05); neutrophil phagocytic activity was reduced in 6 (16,22%) patients of both groups.

After immunocorrection, before IVF protocol incusion, leukocytes in **IG** amounted to - 6,83±0,21 G /l in **CG** 5,87±0,03 gig/l (p<0,05); CD3- 1, 39±0,03 and 1,03±0,02 G /l (p<0,05) ; **CD4-**0,81±0,02 and 0,58±0,01 gig/ /l (p<0,05); **CD8 -** 0,65±0,01 and 0,50±0,01 (p<0,05); Clinical pregnancy rate as determined by sonographic fetal cardiac activity was 18 (48,65 %) and 8 (21,62%) in IG and CG (p<0.05). In IG, 16 pregnancies ended in timely deliveries (88.89% of pregnancies; 48.65% of all women in the group); In CG, childbirths were in 3 women (37.50% and 8.11%, respectively) (p <0.05).

Limitations, reasons for caution: This work presented the results of treatment of only one of the three types of identified immunity disorders

Wider implications of the findings: This study shows a statistically significant increase in implantation rate and clinical pregnancy rate in women with prior implantation failure after IVF/ICSI receiving personalized immunotherapy, with no adverse effects.

Trial registration number: Not trial; this study was approved by Ethics Committee of the Reproductive Health Institution

P-390 Galectin-14 promotes trophoblast migration and invasion, and may participate in the pathogenesis of early pregnancy loss

M. Wang[1], Y. Xu[1], M. Dong[1,2]

[1]*Women's Hospital School of Medicine Zhejiang University, Department of Key Laboratory, Hangzhou, China*

[2]*Women's Hospital School of Medicine Zhejiang University, Department of Key Laboratory of Reproduction and Heredity, Hangzhou, China*

Study question: Is galectin-14 involved in early pregnancy loss (EPL), and what are its effects on trophoblast function?

Summary answer: The expression of galectin-14 was dramatically decreased in the villi of EPL, over-expression of galectin-14 in HTR-8/SVneo promoted cell migration and invasion.

What is known already: EPL is a common kind of pathologic pregnancy, and is closely associated with abnormal trophoblast function. Galectin-14 is a low-molecular-mass protein, specifically expressed in placenta. It was found highly expressed in extravillous trophoblasts. However there is few study on the effects of galectin-14 on trophoblast function. TGF-β1 can inhibit trophoblast invasion. Vasorin can inhibit TGF-β signaling, and promote cell migration in hepatocarcinoma.

Study design, size, duration: The study was approved by the local ethics committee. Villi from 20 cases of early pregnancy loss and 20 cases of induced abortion with similar gestational age were collected. The expression of galectin-14 was compared by western-blot. HTR-8/SVneo were artificially expressed with galectin-14. The migration and invasion ability of HTR-8/SVneo were measured. Than a RNA-seq was performed on HTR-8/SVneo , to find the underlying mechanisms.

Participants/materials, setting, methods: We collected villi from 20 cases of early pregnancy loss and 20 cases of induced abortion with similar gestational age. The expression of galectin-14 was analyzed by western-blot. The over-expression vector of galectin-14 gene was constructed and transformed into HTR-8/SVneo. Transwell assay was used to study migration and invasion ability of HTR-8/SVneo. RNA-seq was performed on HTR-8/SVneo.

Main results and the role of chance: Compared with normal control, the expression level of galectin-14 significantly decreased in villi from early pregnancy loss ($p<0.001$). The over-expression of galectin-14 in HTR-8/SVneo promoted cell migration ($p<0.05$) and invasion ($p<0.05$). The result of RNA-seq showed the expression level of VASN (vasorin) increased in galectin-14-overexpressed HTR-8/SVneo.

Limitations, reasons for caution: Since no endogenously galectin-14-expressed trophoblastic cell line has been found, a further study in primary trophoblasts can help us further verify these results.

Wider implications of the findings: Our results indicated galectin-14 might play an important role in the function of trophoblasts, thus might participate in the pathogenesis of early pregnancy loss.

Trial registration number: No.

P-391 Polo-like kinase 4, PLK4, is not associated with recurrent pregnancy loss caused by embryonic aneuploidy

H. Yoshihara[1], M. Sugiura-Ogasawara[1], F. Ozawa[1], T. Kitaori[1], Y. Ozaki[1], K. Aoki[2], Y. Shibata[3], S. Ugawa[3], T. Nishiyama[4]

[1]*Nagoya City University Graduate School of Medical Sciences, Obstetrics and Gynecology, Nagoya, Japan*

[2]*Aoki Ladies Clinic, Obstetrics and Gynecology, Nagoya, Japan*

[3]*Nagoya City University Graduate School of Medical Sciences, Anatomy and Neuroscience, Nagoya, Japan*

[4]*Nagoya City University Graduate School of Medical Sciences, Public Health, Nagoya, Japan*

Study question: Is *PLK4* associated with recurrent pregnancy loss (RPL) caused by embryonic aneuploidy?

Summary answer: *PLK4* (rs2305957) was not associated with RPL caused by embryonic aneuploidy.

What is known already: No genetic association with RPL caused by embryonic aneuploidy has been found, although it is well-known that it is the most frequent cause of miscarriage and that the oocyte aneuploidy increases according to the maternal age. Recent studies have indicated that a common genetic variant, rs2305957, encompassing the *PLK4* gene contributed to mitotic-origin aneuploidy risk during human early embryo development and it was associated with early RPL. However, the previous study did not examine the aborted concepti in patients with RPL.

Study design, size, duration: Our case control study included 184 patients with RPL whose previous aborted conceptus was ascertained to be an aneuploidy embryo and 190 fertile control women without a history of miscarriage. The mean (SD) number of miscarriage was 3.09±1.13. Samples were mainly collected from 2007 to 2018 at Nagoya City University Hospital.

Participants/materials, setting, methods: We performed a genetic association study to examine the genotype distribution at rs2305957 of patients with RPL caused by aneuploidy compared with controls. Patients whose previous aborted concepti were normal, polyploidic or 45, X-positive were excluded.

Main results and the role of chance: Minor allele frequencies (MAF) were 0.361 for patients and 0.367 for controls. The frequencies of AA, AG and GG were 12.6%, 46.8%, and 40.5% in patients and 15.8%, 41.8%, and 42.4% in the controls.

No significant differences in MAF or the distribution in the dominant model, recessive model or additive model of rs2305957 (G>A) were found between the patients and controls.

Limitations, reasons for caution:

Whether there is an association between RPL and 45, X is unclear because we excluded patients whose previous aborted concepti were 45,X-positive.

Wider implications of the findings: Maternal rs2305957 spanning *PLK4* was not associated with RPL caused by embryonic autosomal aneuploidy. It is speculated that the *PLK4* dysfunction might cause mosaic aneuploidy. Mosaic aneuploidy except with 45, X is rare in RPL. Further study is needed to examine why rs2305957 is associated with early RPL.

Trial registration number: not applicable

P-392 investigation of inflammatory and oxidative stress factors in recurrent pregnancy loss (RPL) patients with and without metabolic syndrome

Study question: How are the changes in inflammatory cytokines and oxidative stress factors among patients with Recurrent Pregnancy Loss (RPL) with and without Metabolic Syndrome (MetS)?

Summary answer: Significant increase in inflammatory cytokines and oxidative stress factors were seen in RPL patients with MetS compared to RPL patients without MetS and healthy controls.

What is known already: Recurrent miscarriage is defined as three or more consecutive pregnancy losses prior to the 20th week of gestation. Exaggerated maternal immune response and oxidative stress status have been proposed to be the main underlying mechanisms for RPL. MetS is identified to be the accumulation of insulin resistance and cardiovascular risk factors, along with abnormal glucose tolerance, atherogenic dyslipidemia, visceral obesity and hypertension and is caused by several situations like increased free radicals and inflammatory cytokines secretion. Accompaniment of RPL with metabolic syndrome may lead to excessive secretion of inflammatory cytokines, oxidative stress factors and more complications of the disease.

Study design, size, duration: This study designed based on the alterations of effective factors in RPL patients group with and without MetS.

28 RPL patients without Mets and 21 RPL patients with MetS were included. In parallel, 42 healthy women in reproductive age were assigned as the control group. All of the participants signed an informed consent at Al Zahra Hospital of Tabriz University of Medical Science (TUOMS) from February to November; 2017.

Participants/materials, setting, methods: Healthy pregnant women and RPL patient with and without MetS were included. Blood samples were collected and serum levels of IL-1β, IL-6, IL-17, TNF-α, CCL-2, CXCL-8, levels of TAS, TOS, NO, CAT, SOD, AOPP, MPO, gene expression of IL-1β, IL-6, IL-17, TNF-α, CCL-2, CXCL-8, NF-κB, AP-1, miR-21, miR-146-a, miR-223 and the frequency of Th17 and T-reg cells were evaluated by ELISA, spectrophotometry, Real-Time PCR, and flow cytometry, respectively.

Main results and the role of chance: Our results showed statistically significant increase in the gene expression levels of IL-1β, IL-6, IL-17, TNF-α, CCL-2, CXCL8, NF-κB, AP-1 and miR-21 in RPL patients with MetS ($p< 0.05$ was considered to be statistically significant). We also demonstrated significant decrease in the gene expression levels of FoxP3, miR-146-a and miR-223 in RPL patients with metabolic syndrome. Serum levels of IL-1β, IL-6, IL-17, TNF-α, CCL-2, CXCL-8, NO, MPO and TOS were found to be higher in RPL patients with MetS when compared to the other two groups (*P* values of noted cytokines level in RPL patients with MetS in comparison to RPL without MetS and healthy pregnant women were, IL-1β: 0.0004 and <0.0001, IL-6: 0.048 and <0.0001, IL-17: 0.0005 and <0.0001, TNF-α: 0.0004 and <0.0001, CCL-2: 0.0077 and <0.0001, CXCL-8: 0.0069 and 0.0001, NO: 0.0037 and 0.0001, MPO: 0.001 and <0.0001 and TOS: 0.0202 and 0.0038 respectively). In contrast CAT and SOD levels in RPL patients with MetS were decreased. Also, the RPL patients with MetS had higher and lower frequency levels of Th17 cells (*P*=0.0052 and <0.0001) and T-reg cells (*P*=0.0207 and <0.0001) when compared to the other groups, respectively.

Limitations, reasons for caution: Small sample size and unknown genetic background were the most important limitations. Due to the genetic variations in different population, it is necessary to conduct comprehensive studies with large sample size to find exact etiology, clinical diagnoses and best therapy for this disease.

Wider implications of the findings: The results of this study were somewhat in line with previous literature and open new insights in the etiology of RPL. This finding might be valuable as a new therapeutic potential in the prediction or risk assessment of RPL.

Trial registration number: Not Applicable

P-393 Study of 109 triplet pregnancies after single embryo transfer in the Japanese national ART registry

K. Kuroda[1,2], Y. Ikemoto[2], A. Ochiai[2], Y. Matsumura[2], S. Yamashita[3], K. Nakagawa[1], R. Sugiyama[1]

[3]*Oita University- Faculty of Medicine, Department of Obstetrics and Gynecology, Oita, Japan*

Study question: To identify the cases of triplet pregnancies after single embryo transfer (SET) in Japan.

Summary answer: Most patients underwent ART with frozen–warmed embryo transfer (ET), blastocyst culture and assisted hatching (AH) as possible risk factors for zygotic splitting.

What is known already: SET is considered to decrease the risk of multiple pregnancies. However, we reported a 1.60% (4,419 pregnancies) prevalence of multiple pregnancies, including 109 triplets, which is substantially higher than the 0.3%–0.5% rate of spontaneous multiple pregnancies according to 937,848 SET cycles in Japan. Regarding monozygotic triplets after SET, only six sets of pregnancies have been reported worldwide to date. We reported that the possible risk factors for zygotic splitting after SET include frozen–warmed ET, blastocyst culture and AH.

Study design, size, duration: A retrospective observational study was conducted based on 274,605 pregnancies after 937,848 SET cycles in registered ART data from the Japan Society of Obstetrics and Gynaecology (JSOG) between 2007 and 2014. Our study was approved by the Registration and Research Subcommittee of JSOG and our hospital's ethics committee.

Participants/materials, setting, methods: Triplet pregnancy was defined as one or two gestational sacs (GSs) with three foetuses or three GSs with 0–3 foetuses. SET was defined as one ET in one cycle. To analyse data on triplets, we extracted data including age, methods of controlled ovarian stimulation, fertilisation procedures, frozen–warmed/fresh embryos at ET, number/grade of transferred embryos, AH, number of GS/foetus, pregnancy courses and number/findings of liveborn infants from the registered ART database.

Main results and the role of chance: The Japanese ART national registry database demonstrated 109 triplet pregnancies (0.04%), including 37 monochorionic (1 GS), 17 dichorionic (2 GSs) and 55 trichorionic triplets (3 GSs). In trichorionic triplets, 9, 11, 8 and 27 cases showed three GSs with 0–3 foetuses, respectively. Mean ages of women with mono-, di- and trichorionic triplets after SET were 36.1 ± 3.3, 32.0 ± 3.7 and 35.3 ± 4.7 years, respectively. Regarding the risk factors for zygotic splitting, the ratios of ART use were 78.4% (29/37 triplets), 76.5% (13/17) and 76.4% (42/55), respectively, for frozen–warmed ET; 91.9% (34/37), 70.6% (12/17) and 81.8% (45/55), respectively, for blastocyst culture and 67.7% (21/31), 71.4% (10/17) and 76.1% (35/46), respectively, for AH. Most triplet patients conceived after ART using frozen–warmed ET, blastocyst culture and AH. Livebirth (defined as at least one baby born) rates were 57.1% (20/37), 70.6% (12/17) and 71.7% (33/46) with 1–3 foetuses, respectively. Monochorionic triplets had a higher incidence of foetus mortality than the other triplet types, but there was no significant difference ($P = 0.23$).

Limitations, reasons for caution: In the current Japanese ART registry system, data regarding frozen–thawed ET do not include information about ovarian stimulation and fertilisation methods. Moreover, registration for AH started only in 2010.

Wider implications of the findings: Monozygotic triplets occur rarely. After SET was first recommended in Japan in 2008, the SET rate reached 80% for all ET cycles in 2015. Elective SET using frozen–warmed ET, blastocyst culture and AH might result in an increased prevalence of triplet pregnancies iatrogenically.

Trial registration number: None

P-394 The use of autologous immune cell by intrauterine inoculation enhances clinical pregnancy rates in case of recurrent implantation failure following intracytoplasmic sperm injection (ICSI)

K. Ben Rhouma[1], S. Mahjoub[2], O. Triki[1], H. Bahri[1], M. Benkhalifa[3]

[1]*Clinique Alyssa, Alyssa Fertility Group, Tunis, Tunisia*

[2]*CHU La Rabta, Centre de matérnité, Tunis, Tunisia*

[3]*CHU et faculté de médecine- université de Picardie Jules-Verne, Médecine de la reproduction et cytogénétique médicale, Amiens, France*

Study question: To assess the effect of the use of autologous lymphocyte followed by intrauterine inoculation on cases in couple's failure to achieve pregnancy following several intracytoplasmic sperm injection treatment cycles.

Summary answer: These findings indicate that intrauterine administration of autologous AL may promote implantation rates in patients after failure repeated ICSI cycles.

What is known already: Some couples have repeated implantation failures during assisted reproductive technology (ART) programs. Indeed embryo implantation represents a critical step that determines reproductive success. Several factors can influence this implantation rate like the endocrine system that plays a main role to regulate endometrial differentiation. The immune system can also affect endometrial differentiation at the peri-implantation period by some populations of immune cells and support embryo implantation.

Study design, size, duration: In the present study a total of 135 ICSI cycles were included and classified into AL-treated (68 cycles, 50.3%) and non-treated (control) groups (67 cycles, 49.6%). All patients had experienced four or more failures of ICSI–embryo transfer therapy. All females were stimulated using a gonadotropin releasing hormone agonist or antagonist and human FSH. Human chorionic gonadotropin was administered when optimal follicle development was achieved.

Participants/materials, setting, methods: On the day of HCG injection, 5ml of peripheral blood was collected and AL were isolated using Ficoll-Hypaque centrifugation. AL was collected from interphase layer and washed four times with RPMI 1640. AL ($1x10^6$ cells/ml) supplemented with 10% Serum Protein Substitute were incubated in the presence of HCG (5IU/ml) for 72h at 37°C. After culture and centrifugation, the pellet was suspended culture media. The AL suspension was injected in the uterine cavity using insemination catheter

Main results and the role of chance: A total of 972 oocytes were retrieved and 850 metaphase II oocytes were microinjected, 424 for control group (mean 6.3) and 426 for AL-treated group (mean 6.2). The fertilizing rate was 66.9% (284/482) in control group and 66.1% (282/490) in AL group. A total of 67 transfers with a mean of 2.1 embryos replaced in control group and 65 transfers with a mean of 2.2 embryos replaced in AL group. The clinical pregnancy rate per cycle in non-treated groups and AL group was 14.3% and 38.2% respectively. The deliveries rate per transfer in control group and AL group was 5.0% and 29.0% respectively.

Limitations, reasons for caution: The reduced number of patients and the precise mechanism of intrauterine inoculation of lymphocytes that remains unknown may be the limit of this study.

Wider implications of the findings:

This work provides a simple method for improved pregnancy rates for cases of implantation failure in ART programs.

Trial registration number: no trial registration number

P-395 Likelihood of subsequent successful pregnancy outcome after evaluation and management of women with a history of idiopathic recurrent early pregnancy loss (REPL)

J. Izewski[1], M. Kane[1], M. Stephenson[2]

[1]*University of Illinois-Chicago, Department of Obstetrics and Gynecology, Chicago-IL, U.S.A.*

[2]*Univeristy of Illinois-Chicago, Department of Obstetrics and Gynecology, Chicago-IL, U.S.A.*

Study question: What is the likelihood of a successful pregnancy outcome after evaluation and management of women with a history of idiopathic REPL?

Summary answer: In this cohort of women with idiopathic REPL, the live birth rate (LBR) per index pregnancy was 58% (236/410), and cumulative LBR was 74% (201/271).

What is known already: REPL impacts ~5% of couples who are trying to have a child(ren). Despite evaluation for parental translocations, endocrine, uterine, and autoimmune factors, ~40% of couples are classified as idiopathic REPL (Stephenson, 1996).

Clifford et al. (1997) reported a 74% subsequent LBR/index pregnancy in idiopathic recurrent miscarriage (IRM) with close monitoring/without medication. Brigham et al. (1999) reported 75% LBR; >95% seen ≥6 weeks', close monitoring provided/medications unknown.

Since the 1990's, pregnancies are documented <6 weeks', terminology has changed, and pregnant women are generally older. Updated LBRs need reporting for counseling of couples with idiopathic REPL. Empiric medications also need to be addressed.

Study design, size, duration: Observational cohort study using prospectively collected data of 271 women seen in an academic RPL Program, 2004-2012. Inclusion criteria: History of REPL, defined as ≥2 pregnancy losses <10 weeks excluding aneuploid/polyploid miscarriages; Negative REPL evaluation, ≥1 subsequent pregnancy, excluding ectopics and/or terminations, conceived without fertility medication. Timed intercourse to LH surge. Pregnancy defined as positive serum hCG at missed menses. Ultrasound q1-2 weeks between 6-12 weeks'. Subjects gave written informed consent for future REPL research.

Participants/materials, setting, methods: Primary outcome was LBR/subsequent pregnancy. Secondary outcomes were cumulative LBR and LBR/subsequent index pregnancy (aneuploid/polyploid miscarriages excluded) with subanalysis according to empiric medications, time to conception, and descriptive analysis of maternal and neonatal complications.

Continuous variables reported as mean (standard deviation; range). Categorical variables reported as numbers with percentages. Chi-square was used for comparison of categorical variables.

Main results and the role of chance: The cohort consisted of 271 patients, with 410 subsequent pregnancies. Caucasian 85%, non-Hispanic 93%. Mean number of prior pregnancies 3.9 (1.9; 1-14); Mean number of prior pregnancy losses 2.9 (1.4; 2-12); Mean number of prior live births 0.75 (0.5; 0-4), Mean prior cycles to conceive 3.4 (6.1; 1-96).

There were 410 subsequent pregnancies with 236 subsequent live births. Empiric medications included: luteal start progesterone suppositories (prog) (n=59 pregnancies); acetylsalicyclic acid (LDA) (n=34); prog/LDA (n=51); prog/LDA/prophylactic heparin (n=1); prog/levothyroxine (n=14); IVIG (n=6); placebo (n=7); other (n=32), and close monitoring only (n=32).

LBR/subsequent pregnancy was 58% (236/410) with 8% (19/236) preterm births. Mean number of cycles to conceive was 2.2 (2.0; 1-12). Cumulative LBR was 74% (201/271 women). LBR/subsequent index pregnancy was 64% (141/221).

Cesarean section rate was 29% (68/236); mean birthweight was 3,328 grams (613; 1,350-4,819). Other outcomes included hypertensive disorders 13% (13/236), gestational diabetes mellitus 2% (5/236), thromboses 0% (0/236), postpartum hemorrhage 3% (8/236), and Neonatal Intensive Care Unit admission 8% (18/236).

Use of any empiric medication resulted in higher LBR/subsequent index pregnancy compared to close monitoring only, 60% (204/342) vs. 52% (32/61) , *P*=0.002.

Limitations, reasons for caution: Protocol-driven evaluation/management in an academic RPL Program by a single provider should provide consistent results, but may not be generalizable. Maternal/fetal morbidity may have been under reported; based on subject recall if medical records unavailable. Randomized controlled trials are needed to determine if medications are beneficial.

Wider implications of the findings: Despite history of idiopathic REPL, subsequent live birth rate, based on diagnosis of pregnancy at missed menses, are encouraging, along with short time to conception. In addition to first trimester close monitoring/supportive care, data suggests medications may be of benefit for idiopathic REPL, although further studies are warranted.

Trial registration number: not applicable

P-396 HCG activates Wnt signaling pathway through miR-125a-3p in Ishikawa cells to enhance Jeg3 spheroid attachment

S. Qi[1], R.T.K. Pang[2], M.H.Y. Tang[3], W.S.B. Yeung[3]

[1]*The University of Hong Kong, Obstetrics and Gynecology, Hong Kong, China*

[2]*The University of Hong Kong-Shenzhen Hospital- Futian District- Shenzhen- China, Reproductive Medicine Center, Hong Kong, Hong Kong*

[3]*The University of Hong Kong, Obstetrics and Gynecology, Hong Kong, Hong Kong*

Study question: To investigate how blastocyst derived hCG regulates embryo implantation through endometrial miR-125a-3p

Summary answer: **hCG promoted spheroid attachment through activation of Wnt signaling pathway via increasing miR-125a-3p expression in endometrial cells**

What is known already: Accumulating evidence showed that human chorionic gonadotropin (hCG) derived from embryo has paracrine effect on endometrium to modulate endometrial receptivity favorable for implantation. Recent findings suggested that hCG can alter miRNA expression in endometrial cells. We hypothesize that hCG regulated endometrial cell receptivity through regulating miRNA expression.

Study design, size, duration: Ishikawa cell was used as endometrial epithelial cell model. JEG3 cells were used to form spheroids to mimic human blastocysts. Endometrial biopsies were performed to collect hCG+7/8 samples and LH+7/8 samples. hCG (1IU/ml, 5IU/ml 10IU/ml) were used to stimulate Ishikawa cells in for 6h, 24h or 48h *in- vitro*. MiR-125a-3p force-expressed Ishikawa cells was used to identify the miRNA target and to demonstration its role in Wnt signaling.

Participants/materials, setting, methods: miRNAs were isolated from Ishikawa cells that treated with 1,5 or 10IU/ml of hCG for 6 hours. Real-time PCR (Q-PCR) was used to measure the expression levels of miR-125a-3p. Western blotting was used to detect expression of Wnt signaling target

β-catenin and miR-125a-3p target CTNNBIP1in the miR-125a-3p force-expressed Ishikawa cells. Immunostaining was used to observe β-catenin expression under hCG stimulation. Spheroid attachment assay was performed to assess the function of miR-125a-3p in early embryo implantation.

Main results and the role of chance: Q-PCR results showed that hCG had dose-dependently increased miR-125a-3p expression in Ishikawa cells. The expression of miR-125a-3p was significantly increased by 3.04±0.36-fold and 3.89±0.54-fold when stimulated with 5IU/ml and, 10IU/ml of hCG respectively. HCG+7/8 biopsies have significantly higher miR-125a-3p (6.26±1.19-fold) when compared with LH+7/8 biopsies. The expression of active β-Catenin presented dose-dependent increase upon hCG stimulation in Ishikawa cells, which was significantly increased under 10IU/ml hCG treatment. Immunostaining revealed nuclear expression of β-Catenin in Ishikawa cells and β-Catenin signal intensity increased with dose of hCG. Western blotting showed that the active β-Catenin were significantly reinforced by 1.89±9.53-fold in the pre-miR-125a-3p force-expressed cells when compared to the scramble group. ***In-silicon*** analysis identified CTNNBIP1 is a putative target of miR-125a-3p. Western blotting showed the expression of CTNNBIP1 was significantly decreased (0.58±0.31-fold) upon force-expression of miR-125a-3p and significantly increased (2.05±0.32-fold) upon miR-125a-3p suppression. Spheroid attachment assay were performed on miR-125a-3p enriched Ishikawa cell layer with JEG3 cell spheroids. It was found the miR-125a-3p significantly increased spheroids attachment by 1.43±0.20-fold.

Limitations, reasons for caution: It is not ethical to investigate early embryo implantation event in humans, thus, only ***in-vitro*** investigation can be performed. How does ***in-vivo*** situation is different to ***in-vitro*** conditions is unknown.

Wider implications of the findings: We discovered that miR-125a-3p is a regulator for early embryo implantation in endometrial cells; this miRNA may potentially be used as a marker to identify endometrial receptivity.

Trial registration number: not applicable

P-397 Membrane expression of PDIA1 and PDIA6 regulated by steroid hormones affects spheroid attachment onto human endometrial epithelial cells

S. Fernando[1,2], B. Wong[1], K.L. Kwok[1], Y.L. Lee[1], E.H. Ng[1], W.S. Yeung[1], C.K.F. Lee[1]

[1]The University of Hong Kong, Department of Obstetrics & Gynaecology, Pokfulam, Hong Kong

[2]Uva Wellassa University of Sri Lanka, Department of Animal Science, Badulla, Sri Lanka

Study question: Do steroids regulate membrane PDIA1/PDIA6 expression in endometrial cell lines which in turn govern the endometrial receptivity

Summary answer: PDIA1/PDIA6 expression is regulated by steroids and PDIA1/PDIA6 can regulate the receptivity of endometrial cell lines.

What is known already: Differentially expressed proteins at the receptive phase of endometrial epithelium play a pivotal role in embryo implantation. Protein Disulphide Isomerase (PDI) family contains 21 members and PDI function as chaperone protein with redox activity. Recent studies suggested a differential expression of PDI on the cell surface of endometrial epithelial cells RL95-2 and HEC-1A. Results from our mass spectrometry analysis of endometrial surface protein and spheroid-endometrial cells co-culture studies suggested differential expression of PDI in receptive and non-receptive endometrial cells responsible for spheroid attachment.

Study design, size, duration: We used receptive (Ishikawa and RL95-2) and non-receptive (HEC1-B and AN3CA) human endometrial cells lines and Jeg-3 trophoblastic cell line for co-culture study. Ishikawa cells were treated with steroid hormones for 24 hours. Total protein, membrane protein and cytosolic protein were extracted and specific antibodies were used to analyze the enrichment of proteins in different fractions.

Participants/materials, setting, methods: The expressions of PDIA1and PDIA6 in the membrane or cytoplasmic proteins were studied. PDI inhibitors (Bacitracin, 16F16 and LOC14) were used in AN3CA cells and co-culture studies were conducted to confirm the functional role of PDI proteins. The receptive Ishikawa cells were treated with estrogen (0.01-100 nM) and progesterone (0.01-1uM) and the combination of estrogen (743 pM) and progesterone (52.6 nM) for 24 hours. The expressions of PDIA1/PDIA6 were studied by Western blotting and immunohistochemistry.

Main results and the role of chance: The expression of PDIA1 and PDIA6 is high in the 4 endometrial epithelial cell lines; while a high membrane expression of PDIA1 and PDIA6 was found in non-receptive AN3CA cells. No significant difference was found in the PDIA1 and PDIA6 expression between total protein and cytosolic protein fractions of Ishikawa, RL95-2, AN3CA and HEC1B. Interestingly, the spheroid attachment rate was significantly higher in receptive (Ishikawa and RL95-2) than non-receptive (HEC1-B and AN3CA) endometrial cells. The expression of steroid hormone receptors (ERα, ERβ, PRA, and PRB) was found in receptive cells (Ishikawa, RL95-2). Estrogen (0.1nM-100nM) up-regulates membrane PDIA1/PDIA6 expression; while progesterone (0.1uM-1uM) down-regulates PDIA1/PDIA6 expression in Ishikawa cells. Estrogen (743pM) plus progesterone (52.6nM) reduces membrane PDIA1/PDIA6 expression. Inhibition of PDI by Bacitracin (1mM), LOC14 (1uM) or 16F16 (1uM) increased the attachment rate of Jeg-3 spheroids in AN3CA cells when compared with vehicle control. Immunohistochemical staining localized PDIA1/PDIA6 in glandular and luminal epithelium of human endometrial samples.

Limitations, reasons for caution: As PDI family has 21 members, the function of other members in terms of endometrial receptivity is largely unknown. Whether the compensatory role of PDI family members on spheroid attachment exist needs to further investigation.

Wider implications of the findings: Taken together, steroid hormones regulate PDIA1/PDIA6 expression on the endometrial surface, and suppression of membrane PDI expression may increase spheroid attachment and endometrial receptivity to the pre-implantation embryo. Modulation of PDI function with inhibitors may provide a new approach to enhance implantation rate and pregnancy outcome in IVF patients.

Trial registration number: N/A

P-398 Transient suppression of immune checkpoint Tim-3 in peripheral NK cells 3 days after blastocyst transfer is a marker of successful implantation

T. Zhang[1], Y.W. Zhao[1], W.Y. Zhu[1], W.C. Cheung[1], Y.Y. Liu[1], X.Y. Chen[1], C.C. Wang[1], T.C. Li[1]

[1]the Chinese University of Hong Kong, Obstetrics and Gynecology, Hong Kong, China

Study question: Is successful implantation associated with a significant change in immune checkpoint Tim-3 and its ligand Galectin-9 over a nine-day period after blastocyst transfer?

Summary answer: Transient, significant reduction of Tim3+ pNK cells occurred 3 days after blastocyst transfer was correlated with successful implantation.

What is known already: Various immune cells are involved in successful implantation. Several earlier studies suggested that immune cell derangement is an underlying cause of miscarriage; specifically, the role played by Tim-3 has recently received increasing attention because it serves as an immune checkpoint with essential immunological function in many physiological and pathological conditions in Galectin-9 dependent pathway. It has been found that reduction of Tim-3+ pNK cells induce Th1 immune response, leading to influx of pro-inflammatory cytokines, predisposing to immune rejection and leading to early miscarriage. However, the role of Tim-3/Galectin-9 at the time of embryo implantation, has not been previously examined.

Study design, size, duration: Serial blood samples were obtained from 20 women on the day of blastocyst transfer, and repeated 3, 6 and 9 days after for measurement of Tim-3+pNK cells and Galectin-9 levels. Serum β-hCG was measured 9 days after blastocyst transfer; in women who was tested positive for β-hCG, a transvaginal ultrasonography was performed 23 days after embryo transfer to confirm viability. The study was approved by the local ethics committee.

Participants/materials, setting, methods: A total of 20 women were recruited from women undergoing embryo transfer in an IVF unit of a University hospital in Hong Kong over a 4 months period. 13 women did have successful implantation and the remaining 7 did not conceive. Flow cytometry was employed to measure the percentage of Tim-3+ pNK cells and commercial ELISA kits were used to measure the concentration of serum Galectin-9.

Main results and the role of chance: The peripheral blood Tim-3+pNK cells (33.9±9.8) and galectin-9 (4.6±2ng/ml) levels in the pregnant group were not different from that of the non-pregnant group (36±8.1, 3.9±1.2ng/ml) on the day of embryo transfer. In the non-pregnant group, there was no change in the level of Tim-3+pNK cells between baseline (day of blastocyst transfer) and the subsequent time points (ET+3, 39.9±12.1; ET+6, 41±8.9; ET+9, 46.9±13.7). However, in the pregnant group, there was a significant drop in Tim-3+ pNK cells from the baseline to 23.5±10.1 on day ET+3; the level partially recovered to 29±8.9 on day ET+6 and back to the baseline level (43±11.6) on day ET+9. Furthermore, the percentage of Tim-3+ pNK cells was significantly lower in the pregnant group when compared with non-pregnant women on ET+3 (p=0.01) and ET+6 (p=0.03) but not on ET+9 (p=0.59). On the other hand, the concentration of serum Galectin-9 did not show any significant fluctuation between the several time points within each group and between the pregnant and non-pregnant groups.
Limitations, reasons for caution: The number of subjects included in this study was relatively small but the finding of significant difference in a small sample size suggests that the result is likely to be clinically important. Nevertheless, we are continuing the recruitment to increase the sample size.
Wider implications of the findings: The transient and significant reduction of Tim-3 level in pNK cells observed in this study had already returned to baseline level by the time pregnancy was confirmed 9 days after embryo transfer. Tim-3 level in pNK cell may be an important early prognostic marker for successful implantation.
Trial registration number: nil

P-399 An evaluation of first subsequent pregnancy outcomes among women with recurrent miscarriage: a retrospective cohort study.

I. San Campillo[1], S. Meaney[2], O. O'Connell[3], K. O'Donoghue[4]
[1]INFANT Centre- University College Cork, Pregnancy Loss Research Group- Cork University Maternity Hospital, Wilton Cork, Ireland
[2]National Perinatal Epidemiology Centre, Obstetrics and Gynaecology- University College Cork, Cork, Ireland
[3]Cork University Maternity Hospital, Obstetrics and Gynaecology, Cork, Ireland
[4]INFANT Centre- University College Cork, Obstetrics and Gynaecology, Wilton Cork, Ireland

Study question: To investigate pregnancy outcomes among women with recurrent miscarriage (RM) and the potential epidemiological and clinical factors associated with the outcome.
Summary answer: More than 60% of our sample had a livebirth after RM. Advanced maternal age and primary RM increased the risk of a subsequent miscarriage.
What is known already: Contradictory evidence has been published regarding the influence of previous reproductive history among women with RM and the likelihood of having a further miscarriage in subsequent pregnancies. Some studies have shown that women with RM have a 40% increased risk of having a miscarriage in subsequent pregnancies; others have reported that previous live births were not associated with a positive prognosis for further subsequent pregnancies. Only a few epidemiological studies have proved positive prognosis for pregnancy outcomes after RM. Therefore, more research is needed to clarify the influence of past reproductive history, investigations and management and subsequent pregnancy outcomes.
Study design, size, duration: A retrospective cohort study was conducted in a Pregnancy Loss Clinic (PLC) at a large, tertiary maternity hospital in Ireland. It is a dedicated clinic to investigate causes of RM and to provide support to parents with RM. The clinic facilitates the recruitment of a reliable RM cohort. Epidemiological and clinical information was gathered from medical records from 2008 to 2016. Outcomes data included livebirth, miscarriage, other pregnancy loss and loss of follow-up.
Participants/materials, setting, methods: All women who attended the PLC and who had first trimester RM were identified using medical records. A total number of 508 women with RM were included in the analysis. Of these, outcome data were available for 74.4% (n=378) on the first subsequent pregnancies, 10.4% (n=53) on the second subsequent pregnancy and less than 1% (n=4) on the third. Data were analysed using descriptive and inferential statistics.
Main results and the role of chance: In the first subsequent pregnancy after RM, 63% (n=232) had a livebirth and 37% (n=136) had miscarriage. Women who had a livebirth in the first subsequent pregnancy were significantly younger than women who had a miscarriage (34.7 versus 35.8 years respectively; p-value 0.05). Women aged 40 or older had almost four times more risk of having a miscarriage than women aged 29 years or younger. Women with secondary RM (i.e. previous livebirth) had less risk of having a miscarriage than women with primary RM (34.3% versus 38.6%; p-value 0.03). Among women whom cause of RM at recruitment was fetal abnormalities, 37% (n=27) had a livebirth and almost 30% (n=21) had a miscarriage in the first subsequent pregnancy. Almost 41% (n=9) of women who had a metabolic or endocrine factor in the previous RM had a miscarriage in the first subsequent pregnancy, and 32% (n=7) had a livebirth. Causes of RM at recruitment were unexplained or unknown in 26% (n=43) of women. Among these, almost 50% (n=20) had a livebirth in the first subsequent pregnancy and 26% (n=11) had a further miscarriage.
Limitations, reasons for caution: Data were obtained from a single hospital, in a dedicated unit, and therefore, the results might not be generalisable to another countries or populations. Nonetheless this is a large cohort managed by the same clinical team in a standardised manner.
Wider implications of the findings: The proportion of women who had a successful pregnancy after RM was higher in our study population. Our findings illustrate potential factors associated with pregnancy outcomes for women with RM. These findings help inform clinicians when counselling women who present with RM about the prognosis for subsequent pregnancies.
Trial registration number: not applicable

P-400 Does exogenous progestogen administration affect placental steroid production in early pregnancy?

M. Depenbusch[1], K. Neumann[1], A. Schultze-Mosgau[1], T. Osterholz-Zaleski[1], G. Griesinger[1]
[1]University Hospital of Schleswig-Holstein- Campus Lübeck, Department of Gynecological Endocrinology and Reproductive Medicine, Lübeck, Germany

Study question: Is the onset and magnitude of endogenous, placental progesterone production in early pregnancy associated with the dose of exogenous dydrogesterone administered in programmed FET cycles?
Summary answer: Progestogen from exogenous administration is potentially associated with progesterone production of the early placenta.
What is known already: The onset of trophoblastic progesterone production in early pregnancy is termed the luteo-placental shift (LPS). Recently, the kinetics of serum progesterone levels of trophoblastic origin have been described by utilization of dydrogesterone (which is not cross-reacting with endogenous progesterone in the ELISA) in programmed FET cycles where no corpus luteum is present. To date, a modulatory effect of exogenous progestogens or endogenous progesterone released by the corpora lutea after ovarian stimulation on placental activity and growth has not been sufficiently studied. However, early placental development may have far-reaching consequences on the course of pregnancy and the health of the child.
Study design, size, duration: Prospective study of singleton pregnancies resulting from programmed FET cycles with oral E2 (6mg/d for minimal intake 13 days) followed by E2 (6mg/d) and 30mg/d oral dydrogesterone (NCT03507673). On day of a positive pregnancy test (day 9-15 after embryo transfer, patients either continued intake of 30mg (during phase I of the study) or increased dydrogesterone dose to 50mg daily (phase II) till +37d-43d post transfer. The sample collection started in 7/2015 and is currently ongoing.
Participants/materials, setting, methods: Progesterone, E2 and hCG were measured in serum samples by the Roche Elecsys ELISA before dydrogesterone intake on day 13-15 (to confirm absence of ovulation) and weekly in early pregnancy. Progesterone levels are expressed in µg/l (±standard deviation). A two-way repeated measures ANOVA was conducted for statistical analysis.
Main results and the role of chance: Endogenous serum progesterone was similar in both groups on first blood analysis on day +9-15 days following ET (patients later on 50mg/d: 0.26±0.19; n=22; patients continuing on 30 mg/d: 0.28±0.18; n=18) and increased only marginally +16-22d post ET in patients increasing dydrogesterone to 50 mg/d contrary to the group of patients continuing 30 mg/d (patients 50mg/d: 0.35±0.15; n=21; patients 30mg/d: 0.51±0.31; n=17; ANOVA repeated measures P=0.09).

The between group difference in serum progesterone levels was pronounced +23-29d post ET (patients 50mg/d: 1.82±1.5; n=22; patients 30mg/d: 2.22±2.09; n=18;), +30-36d post ET (patients 50 mg/d: 5.07±3.03; n=18; patients 30 mg/d: 4.77±3.32; n=20;) and reached its peak 37-43d post ET (patients 50mg/d: 8.37±2.73; n=20; patients 30mg/d: 9.35±3.99; n=17;). On average, serum progesterone levels were reduced by 16±11% from +16-22d - 37-43d post ET.

Limitations, reasons for caution: Differences in serum progesterone levels do not reach statistical significance yet due to insufficiently large group sizes. Moreover, the observed differences are small and close to the ELISA quantification limits.

Wider implications of the findings: Modulating the progestogen exposure of the early conceptus by exogenous administration or by creating multiple corpora lutea via ovarian stimulation may influence placental growth and activity, which may have far-reaching consequences on fetal growth and well being.

Trial registration number: NCT03507673

P-401 Serial Endometrial Volume Assessment as a predictor of Endometrial Receptivity in Assisted Reproductive Technology Cycles

R. Silva Martins[1], A. Helio Oliani[1], J. Martinez de Oliveira[1], D. Vaz Oliani[1]

[1]Centro Hospitalar Cova da Beira, CICS - Faculdade Ciencias Saúde - Universidade Beira Interior, Covilhã, Portugal

Study question: Investigate the ultrasonographic value of sequenced endometrial volume analysis in ART cycles as a indicator of endometrial receptivity and embryo implantation.

Summary answer: Adjusted endometrial volume, and the pattern of increment volume in a continuous analysis showed significant impact in predicting endometrial receptivity and embryo successful implantation.

What is known already: There is no controversy regarding the importance of precise and specific endometrial maturational development in allowing implantation following assisted reproduction treatment. Adequate proliferation and differentiation during the proliferative phase must be followed by timely secretory changes during luteal phase with stroll decidualization. However there has been many conflicting results in regards to the role of endometrial assessment by ultrasonographic parameters. Although ultrasonographic parameters of endometrial receptivity have a strong negative value in setting some minimum criteria, their prognostic value for implantation following embryo transfer is yet scarce.

Study design, size, duration: Prospective longitudinal study. Continuous, sequenced ultrasonographic analysis from basal point prior to ovarian controlled stimulation to continuous analysis throughout duration of treatment, trigger day with hCG and embryo transfer. From initial 200 recruited subjects, complete full evaluation of 169 subjects that completed treatment and had a successful embryo transfer.

Participants/materials, setting, methods: Short term antagonist ovarian controlled stimulation to all participants. Assessment of Endometrial Thickness, Endometrial pattern, Endometrial Volume and Adjusted Endometrial Volume (in ratio with Uterine Volume for each participant). Excluded patients with clinical risk for ovarian hyper stimulation syndrome and those without viable good qualitiy day 3 double embryos for transfer. Evaluation of remaining 169 subjects complete and sequenced in time.

Main results and the role of chance: There was no statistical difference between groups with and without successful implantation in demographics, cause of infertility, duration and total dose of gonadotropins and treatment course used. Statistical significant difference was found in terms of Endometrial volume between the group with successful implantation versus the one without implantation, not at base line but after day 10 of controlled ovarian stimulation (Mean value at base line , day 6 and day 8 after controlled ovarian stimulation for the non implantation group of 2,52; 3.08 and 3,91 respectively versus 2,77; 3,33 and 4,40 on the implantation group and Mean value at Day 10 and embryo transfer day for non implantation group of 4,12 and 4,83 versus 4,91 and 5,59 on the implantation group). The continuous analysis of endometrial patterns showed statistical difference between the two groups after day 10 of the ovarian controlled stimulation with p values <0.001. With adjusted volume scores the difference between two groups is shown and sustained in all moments except at base line (Mean values at baseline for non implantation versus implantation group 4,60 versus 5,53 and Mean Values of 5,63; 7,23 ; 7,59 and 8,31 versus 6,70; 9,05; 9,92 and 10,77 with p value <0.001).

Limitations, reasons for caution: Differences in ultrasonographic examination techniques do exist, but the use of a rigid protocol and single operator in all evaluations reduces the possibility of conflicting evaluations. The use of high resolution and 3-D analysis further reduces the possibility of inaccurate evaluation.

Wider implications of the findings: The presence of a receptive endometrium is a major factor in deterring implantation and success in reproductive medicine. The possibility of a non invasive ready to use ultrasonographic parameter would allow predicting more accurately the outcome.

Trial registration number: NONE

P-402 Chromosomal testing at the blastocyst stage reduces miscarriages, aneuploid gestations and provides similar cumulative live birth rate per cycle: a large public health-care provider experience.

L. Sacchi[1], A. Cesana[1], A. Smeraldi[1], V. Parini[1], E. Albani[1], A. Baggiani[1], R. De Cesare[1], M. Fabiani[2], M. Poli[2], A. Capalbo[2], P.E. Levi Setti[1]

[1]Humanitas Research Hospital, Department of Gynecology- Division of Gynecology and Reproductive Medicine- Fertility Center, Rozzano MI, Italy

[2]Igenomix Italy, Igenomix, Marostica, Italy

Study question: Is aneuploidy testing at blastocyst stage effective in reducing miscarriages, aneuploid gestations and time-to pregnancy in advanced reproductive age (ARA) women?

Summary answer: Preimplantation genetic testing for aneuploidies (PGT-A) at the blastocyst stage is effective in reducing miscarriages, aneuploid gestations and time to pregnancy in selected IVF populations

What is known already: PGT-A allows the detection of chromosomal abnormalities in preimplantation embryos. However, it is known to be challenging to quantify the benefits that such program brings to the patients treatment outcome. Particularly, long-term clinical data are lacking from single, large IVF centres where inclusion/exclusion criteria for accessing treatment options (i.e., PGT, blastocyst transfer) are standardized for all patients. In this study, we combined laboratory and clinical outcomes, preimplantation and prenatal testing genetic results with detailed effects on pregnancy and neonatal follow-up from a large, public healthcare provider without commercial interest in genetic analysis

Study design, size, duration: Observational cohort study performed between January 2015 and May 2017 at an Academic tertiary care healthcare provider. Couples with female age >38 were counselled for PGT-A before ovarian stimulation. Consenting couples dropped out from PGT-A if <4 fertilized eggs were available after ICSI. In these cases, day3 embryo transfers were performed (DROP-OUT group). All non-consenting couples were included as controls (Standard IVF group). Laboratory, clinical, follow-up and genetic analysis outcomes were compared across all groups.

Participants/materials, setting, methods: This study compares data from groups: PGT-A (273 couples, 312 cycles), DROP-OUT (101-couples, 106-cycles) and Standard IVF (2,168-couples, 2,905-cycles). Confounders-adjusted multivariate analysis was used to compare main outcome measures: miscarriage rate, aneuploid gestation rate, live-birth rate per cycle (LBR) with one year minimum follow-up. Kaplan-Meier and Cox regression were used to compare time-to-pregnancy(TTP) in PGT-A and Standard IVF using as primary outcome the cumulative live birth rate in function of number of transfers required

Main results and the role of chance: Mean female age was higher (P<0.001) in DROP-OUT (41.13 ± 3.03 vs 40.38 ± 3.33 in PGT-A and 39.72 ± 2.37 in Standard-IVF), BMI, infertility duration, FSH and AMH levels, oocyte maturation rate, fertilization and cleavage rates were similar across groups (NS). Euploidy rate in PGT-A group was 56% (306/542). In total, 188 (100% blastocysts), 117 (cleavage-stage) and 3573 (32.1% blastocyst stage) embryo transfers were performed in PGT-A, DROPOUT, Standard-IVF, respectively. PGT-A group showed significantly superior transfer clinical outcomes (P<0.01). Particularly, ongoing implantation (43.1% PGT-A, 18.4% Standard IVF; 10.8% DROPOUT), miscarriage (8.6% PGT-A, 32.0% Standard-IVF; 50% DROPOUT), ascertained

aneuploid gestation (4.3%, 1/23 for PGT-A versus 19.2%, Standard-IVF) and multiple pregnancy rates (0% in PGT-A and 15% in Standard-IVF) were all significantly favourable after euploid embryo transfer. Worst miscarriage rates were recorded in the DROP-OUT group (50%). Multivariate analysis showed no difference in LBR per started cycle between PGT-A and Standard-IVF (23.7% and 23.5%, respectively; OR:0.78; 95%CI=0.57-1.07). Among patients reaching transfer, PGT-A provided a shorter time to live birth. All neonatal outcomes were similar across the groups except low birth weight, which was more frequent in Standard-IVF as a consequence of multiple gestations (14.4% and 4% for Standard-IVF and PGT-A, respectively)

Limitations, reasons for caution: Lack of randomization for patients allocation to PGT-A and control group was the main limitation of this study. However, the large IVF dataset, completed with extensive prenatal and neonatal follow-up, provided reliable and meaningful comparisons.

Wider implications of the findings: Euploid embryo transfer showed to significantly reduce the incidence of aneuploid gestation and miscarriage rate in a public healthcare provider while preserving the cumulative LBR. Shorter time-to-pregnancy was observed when a euploid embryo was transferred. Patients' drop-out from aneuploidy testing due to poor response/prognosis should be carefully considered

Trial registration number: none

P-403 HLA-E is involved in the invasion of trophoblast cell line JEG-3 induced by progesterone

H. Zhongying[1], Q. Ma[2], H. Zhu[3], X. Zeng[2]

[1]*West China Second University Hospital Sichuan University, Department of Obstetrics and Gynecology, Chengdu, China*

[2]*West China second hospital- Sichuan University, Department of Obstetrics and Gynecology, Chengdu, China*

[3]*West China seconde hospital- Sichuan University, Department of Obstetrics and Gynecology, Chengdu, China*

Study question: This study was performed to determine if HLA-E plays a role in the regulation of invasive ability of trophoblast cells.

Summary answer: HLA-E is involved in the stimulatory effects of progesterone on JEG-3 invasion.

What is known already: Progesterone has been considered to be an essential hormone in maintaining pregnancy although its function is not fully elucidated. HLA-E, one of the MHC-Ib molecules, contributed to the establishment of an immune tolerance at maternal-fetal interface during pregnancy. In our previous study, progesterone was found to up-regulate HLA-E expression in JEG-3 cells through the pathway mediated by progesterone receptor, and increase the invasive ability of JEG-3. However, if HLA-E plays a role in the regulatory effect of progesterone on JEG-3 cell invasion has not been studied.

Study design, size, duration: In this study, the human choriocarcinoma JEG-3 cells (Cell Resource Center, IBMS, CAMS/PUMC), a well-established cellular model for extravillous trophoblasts (EVTs), was used to investigate the possible role of HLA-E in the regulation of trophoblasts invasion.

Participants/materials, setting, methods: The expression of HLA-E in JEG-3 was silenced using RNAi technology to examine its role in the regulation of JEG-3 invasion. Transwell invasion assay was performed to evaluate the invasion of JEG-3 48h after the transfection.

Main results and the role of chance: JEG-3 cells were subjected to different treatments including addition of culture medium (group 1, the blank control), progesterone treatment (group 2), transfection of lentivirus carrying siRNA targeting HLA-E before progesterone treatment (group 3), transfection of lentivirus carrying siRNA targeting HLA-E (group 4), and transfection of the negative control siRNA (group 5). Transwell invasion assay showed that the number of invaded cells attached to the lower surface of the filters was significantly increased following treatment of progesterone (group 2)

while decreased after transfection of lentivirus carrying siRNA targeting HLA-E (group 4), compared to the control groups. In group 3, the HLA-E in JEG-3 was blocked by transfection of siRNA targeting HLA-E before progesterone treatment. Data showed that the number of invaded cells was significantly smaller than that of group 2, but larger than group 4, indicating that the up-regulatory effect of progesterone on invasion of JEG-3 was at least partly inhibited by HLA-E silence.

Limitations, reasons for caution: Although JEG-3 is a commonly used in vitro model for EVT, further investigation is required to see whether the changes of JEG-3 invasion observed here also occurs in trophoblasts in placenta.

Wider implications of the findings: The findings in this study might give a new clue to the immunological mechanism supporting placental development.

Trial registration number: Non-clinical trials.

P-404 Relevance of next generation sequencing (NGS) as a tool for chromosomal analysis of products of conception (POC) compared with conventional karyotyping (G-banding).

M. Doshida[1,2], K. Yamaguchi[3,4], K. Kitaya[2], K. Sakaguchi[1], T. Takeuchi[1], H. Matsubayashi[1,2], Y. Araki[5], T. Ishikawa[3,4]

[1]*Reproduction Clinic Tokyo, Gynecology, Tokyo, Japan*

[2]*Reproduction Clinic Osaka, Gynecology, Osaka, Japan*

[3]*Reproduction Clinic Osaka, Urology, Osaka, Japan*

[4]*Reproduction Clinic Tokyo, Urology, Tokyo, Japan*

[5]*Nippon Reprogenetics Inc, embryologist, Maebashi- Gunma, Japan*

Study question: Is NGS valuable as a tool for chromosomal analysis of POC compared with conventional karyotyping?

Summary answer: NGS testing improved diagnostic accuracy compared with conventional karyotyping and the ratio for 46,XX to 46,XY dropped from 8.50 to 2.53.

What is known already: Conventional karyotyping is known to be labor-intensive and time-consuming, requiring reliable cell culture with possible maternal cell contamination leading to failed analysis. While NGS is characterized as a technique demanding smaller specimen with a lower failure rate, higher resolution, and shorter turnaround time than conventional karyotyping when used for the genetic analysis of miscarried fetal tissue and/or chorionic villi.

Study design, size, duration: This retrospective study was conducted between March 2017 and December 2018 at a single reproduction center. All patients involved gave written consent, and institutional review board approval was granted. This study included 160 women with first-trimester miscarriage, wished for POC analysis.

Participants/materials, setting, methods: Patients undergoing dilation and curettage (D&C) after diagnosis as miscarriages the first trimester were involved. Conventional karyotyping (G-banding) was performed in 50 cases, and NGS testing was performed in 110 cases. Among 110 cases, 7 were assessed by both of NGS and conventional karyotyping.

Main results and the role of chance: In G-banding, 11 out of 50 cases (22.0%) were not conclusive due to cell culture failure. In 39 cases analyzed, 17 (43.6%) were 46,XX, 2 were 46,XY, 2 were 45,XO, 1 was triploid, and the remaining 18 (46.2%) were autosomal single or multiple trisomy. In NGS groups, results were obtained in all 110 cases. There were 18 cases where chorionic villi or fetal tissue were not confirmed by dissecting microscopy, the results were all 46,XX. Among 92 cases in which chorionic villi could be detected by dissecting microscopy, 15 cases (16.3%) were 46,XX, 13 (14.1%) were 46,XY, 7 were 45,XO, one was 47,XXY,and the remaining 56 (60.9%) were autosomal single or multiple trisomy. The ratio for 46,XX to 46, XY was 8.50 (17/2) after G-banding, while it was 2.53 (33/13) after NGS. If excluding 18 cases where chorionic villi or fetal tissue was not be detected, the ratio after NGS was 1.15 (13/15). The rate of chromosomal abnormalities detected by NGS was higher than G-banding (69.6% vs 51.3%).

In 7 cases, assessed by both of NGS and G-banding, one was 46,XX in G-banding but 46,XY in NGS, and one was 46,XO,+11 in NGS but culture frailer in G-banding.

Limitations, reasons for caution:

This was a retrospective study. Maternal cell contamination was not definitely confirmed. In the NGS method, balanced reciprocal translocation cases could not be detected. The participants were limited to Japanese women only.

Wider implications of the findings: Because NGS does not require cell/tissue culture, chromosomally abnormal cells that may not survive culture, can be detected by NGS method. Thus, it can eliminate possible maternal cell contamination more effectively than conventional karyotyping, leading to more accurate and conclusive analysis.

Trial registration number: N/A.

P-405 Endometrial receptivity status and live birth rate in patients with a thin endometrium and repeated implantation failures : new considerations

D. Haouzi[1], F. Entezami[1], C. Innocenti[2], A. Ferrières-Hoa[3], A. Gala[3], C. Vincens[3], C. Brunet[3], S. Bringer-Deutsch[3], E. Vintejoux[3], A. Torre[4], S. Hamamah[3]

[1]INSERM U1203, IRMB- Hôpital St-Eloi- CHRU Montpellier, MONTPELLIER, France

[2]Inserm U1203, Univ Montpellier- CHU Montpellier- Hôpital Saint Eloi- IRMB, Montpellier, France

[3]Arnaud de Villeneuve Hospital- CHU Montpellier, ART-PGD department, Montpellier, France

[4]Division of Child Health- University of Nottingham-, Obstetrics & Gynaecology department, United Kingdom, United Kingdom

Study question: To assess the endometrial receptivity and pregnancy outcome in repeated implantation failure patients (RIF) according to the endometrial thickness during the periovulatory period

Summary answer: There were no difference in endometrial receptivity status and live birth rate (LBR) between patients with an endometrial thickness above or under 7 mm

What is known already: To date, the number of molecular diagnostic tools available to characterize the implantation window is very limited. In addition, classical ultrasound parameters such as endometrial thickness have low predictive value in determining endometrial receptivity and IVF outcome. Using an innovative genomic testing that allows to characterize an endometrial biopsy obtained during the implantation window as receptive, partially receptive (ongoing endometrial receptivity acquisition) or non-receptive, we investigated the endometrial receptivity status and reproductive outcome according to the endometrial thickness (< 7 mm *vs.* ≥ 7 mm).

Study design, size, duration: Endometrial biopsies were performed during the implantation windows 6-9 days after the LH surge or 5-9 days after progesterone administration under natural cycles and hormone replacement therapy (HRT) respectively in preparation for frozen embryo transfer. According to a genomic testing result, the transfer strategy was: blastocysts transferred at the specific day where endometrium is identified as 'receptive'; D2/D3 cleavage stage embryos transferred 72/48 hours before the specific cycle day where endometrium is identified as receptive.

Participants/materials, setting, methods: 21 RIF patients with several unsuccessful fresh and/or frozen embryo transfers were included. Endometrial thickness was assessed by ultrasound during the periovulatory period. Genomic testing of endometrial biopsies was performed under natural cycle or HRT. RNAs from biopsies were extracted and mRNA expression levels of specific genes predictive of receptivity were established using RT-qPCR. LBR was recorded after personalized embryo transfer using the genomic testing result and assessed according to endometrial thickness cut-off.

Main results and the role of chance: In RIF patients 12 had an endometrial thickness ≥ 7 mm and 9 patients < 7 mm (mean $\pm$ SD: 10.1 $\pm$ 1.5 vs. 6.2 1.1, p-value < 0.0001). There were no significant differences between the two groups in regard to the average age (mean $\pm$ SD: 38.8 $\pm$ 4.7 *vs.* 37.6 $\pm$ 4.4 yrs, p-value = 0.54), the number of previous failed attempts (mean $\pm$ SEM: 3.9 $\pm$ 0.3 *vs.* 3.4 $\pm$ 0.4, p-value = 0.34) and the number of previous non-implanted embryos (mean $\pm$ SEM: 5.4 $\pm$ 0.7 *vs.* 5.3 $\pm$ 0.6, p-value = 0.93). For each patient, the receptivity window was identified and personalized embryo transfer according to the specific cycle day where endometrium is considered receptive demonstrated no significant difference in live birth rates between the two groups (41.7 vs. 33.3 %, p-value = 0.72).

Limitations, reasons for caution: These results must be validated in a larger cohort of patients.

Wider implications of the findings: RIF patients with a thin endometrium show a well defined receptivity window, comparable to patients with a standard thickness. Personalized embryo transfer according to the specific cycle day where endometrium is said receptive improves life birth rate irrespective of the endometrial thickness.

Trial registration number: not applicable

P-406 Comparable clinical outcome but different hCG values after different post-thaw culture duration in single blastocyst transfer cycles: a single center retrospective study

P. Chen[1], W. Zhao[1], Y. Li[1], C. Fang[1]

[1]The 6th affiliated hospital of Sun Yat-sen University, Reproductive Medicine Research Center, Guangzhou, China

Study question: Whether different cultivation duration after thawing leads to different hCG values on the day of pregnancy test, and whether longer cultivation duration affects pregnancy outcome.

Summary answer: Although different post-thaw culture duration doesn't affect pregnancy outcome. Longer post-thaw culture duration still leads to higher hCG value.

What is known already: Blastocysts regain viability 4～6 hours after thawing and resume mitosis within 24 hours, therefore, blastocysts undergoing long culture may associate with earlier embryo recovery in vitro and earlier implantation when transferred into uterus. Longer culture duration may allow for better observation of embryo quality and natural selection of the best embryo for transfer. hCG were detected to confirm pregnancy 10-15 days after embryo transfer. HCG was considered as a reliable factor for predicting pregnancy outcomes. Higher hCG values are associated with better outcomes such as ongoing pregnancies and live births, while low initial hCG levels indicate poor prognosis.

Study design, size, duration: A total of 2297 single frozen high quality blastocyst transfer cycles involving 707 short culture cycles and 1590 long culture cycles during June 2010 and July 2016 were extracted from the database of the Reproductive Medicine Research Center of the Sixth Affiliated Hospital of Sun Yat-Sen University. Embryos in short culture group were warmed 4 hours before embryo transfer (ET). While embryos in long culture group were thawed a day before ET and cultured overnight.

Participants/materials, setting, methods: Only patients undergoing their first or second embryo transfer cycle were recruited for the purpose of avoiding the influence of recurrent implantation failure. Student's t test or chi-square test Multivariate linear regression analysis, Logistic regression analysis were applied according to the nature of the data. Singleton live births, clinical pregnancy rate and hCG value were compared and regression analysis was run to explore whether different culture duration affect hCG value and clinical outcome.

Main results and the role of chance: The basic characteristics showed no difference. No difference was observed in total hCG positive rate (66.05% and 67.79%, P=0.411,short culture group at front and long culture group at last), clinical pregnancy rate (51.34% and 53.77%, P=0.281), implantation rate (57.99% and 62.01%, P=0.068) . The singleton live birth rate was comparable (44.27% and 47.48%, P=0.154). After analyzing the mean gestational age, neonatal gender ratio and mean birth weight of singletons, we found that there was no significant difference between these two groups. Multivariable logistic regression analysis indicated that duration of culture before embryos transfer was not correlated with clinical pregnancy (P=0.597).

In those 1427 hCG positive cycles, the mean hCG concentrations resulting from long duration culture after thawing were significantly higher than those from short culture group (915.51±637.66mIU/L and 735.35±481.21mIU/L, P<0.001). The differences were also observed when stratified by different pregnancy prognosis, including clinical pregnancies (1059.60±592.18mIU/L and 867.90±429.89mIU/L,P<0.001) and live births (1079.98±641.57mIU/L and 860.35±424.34mIU/L, P<0.001).

A multiple linear regression analysis model was run to assess the relationship between culture duration and hCG and other cofounders, including maternal age, BMI, AMH, the type of infertility and endometrial preparation protocols. The results showed that the difference in hCG values remained after adjusting the covariates (P<0.001).

Limitations, reasons for caution: This study was limited by its inherent shortcomings of retrospective studies.

Wider implications of the findings: Although similar outcomes regardless of different post-thaw culture duration, higher hCG values in long culture group reflects that difference may exist on the function and number of trophoblast cells as well as implantation time in embryos. But the mechanism still needed to be further discussed.

Trial registration number: not applicable

P-407 The molecular mechanism of human chorionic gonadotropin (hCG) increasing the endometrial Tregs in women with RIF.

H. Xiaomin[1], **C. Yunni**[1], **S. Haixiang**[1], **Z. Jianjun**[1]
[1]*Department of Medicine- Nanjing University, Reproductive Medicine Center- The Affiliated Drum Tower Hospital of Nanjing University., Nanjing, China*

Study question: Did intrauterine perfusion of hCG increase the endometrial Tregs in women with RIF to increase the live birth rate and how did hCG take effect?
Summary answer: This study showed that intrauterine perfusion of hCG increased endometrial Tregs and hCG promoted Tregs migrate to endometrium by advancing the expression of chemokine CCL2.
What is known already: The pathogeny of repeated implantation failure was not clear so far. However, study showed that endometrial FoxP3$^+$ Tregs and peripheral FoxP3$^+$ Tregs in women with RIF significantly reduced (0.07% vs. 0.12%, $P<0.05$). And there had study showed that intrauterine perfusion of hCG improve the live birth rates of patients with repeated implantation failure (RIF) (26.97% vs. 17.22%). Meanwhile chemokine CCL2 can target the chemokine receptor of Tregs and migrate it.
Study design, size, duration: This study was aim to prove the effectiveness of intrauterine perfusion of hCG in women with RIF and explore the mechanism of hCG in regulating the immunological tolerance of uterus. And to study that hCG promoted Tregs migrate to endometrium by advancing the expression of chemokine CCL2. This research was included in vivo experiments, in vitro experiments and clinical experiments. And this study lasted for 18 months.
Participants/materials, setting, methods: Nine patients with RIF were included in this study, endometrial Tregs of these patients were analyzed by immunohistochemistry before and after hCG-treated. Meanwhile mice models which horn injected with hCG were included in this study and also tested by immunohistochemistry. The migration ability of Tregs was analyzed by cell migration assay and flow cytometry. The expression of CCL2 was analyzed by Western blotting and qPCR.
Main results and the role of chance: The expression of Foxp3 in women with RIF was significantly lower than other infertility patients (9.4±5.3 vs. 11.2±5.4, $P<0.05$). In this study, the expression of Foxp3 in mice which horn injected hCG was significant higher than that injected PBS (46±16.8 vs. 7±4.3, $P<0.01$). Meanwhile the expression of Foxp3 after intrauterine perfusion of hCG in women with RIF was significant higher than before (18.6±9.8 vs. 9.4±5.3, $P<0.05$). In vitro experiments showed that hCG could increase the quantity of migrated Tregs by enhancing the expression of CCL2 in human endometrium stromal cells (hESCs) (1115±670.7 vs. 2597±833.2, $P<0.05$). When down-regulated the expression of CCL2 in hESCs or add the antagonist of CCR2, the quantity of migrated Tregs decreased significantly. Meanwhile in women with RIF, the expression of CCL2 was higher after intrauterine perfusion of hCG (0.21±0.01 vs. 0.17±0.01, $P<0.001$).
Limitations, reasons for caution: In this study, we found that hCG could increase the expression of CCL2. However the mechanism of hCG increase the expression of CCL2 was not clear. And there have studies showed that hCG could increase Tregs in peripheral blood, the direct interaction between hCG and Tregs was need explore furtherly.
Wider implications of the findings: There have studies showed that intrauterine perfusion of hCG in women with RIF increased the live birth rate in IVF. And our study indicated the molecular mechanism of hCG increasing endometrial Tregs. This study proved the effectiveness of hCG and help doctors to apply intrauterine perfusion of hCG in clinic.
Trial registration number: not applicable

P-408 Analysis of the risk factors and treatment for recurrent implantation failure: OPTIMUM strategy

M. Yuko[1], **T. Segawa**[2], **T. Hashimoto**[3], **J. Fukuda**[4], **K. Nakagawa**[5], **Y. Ikemoto**[1], **A. Ochiai**[1], **R. Ozaki**[1], **K. Murakami**[1], **S. Ikuma**[1], **R. Sugiyama**[5], **M. Kitade**[1], **A. Itakura**[1], **K. Kuroda**[5]
[1]*Juntendo University Faculty of Medicine, Department of Obstetrics and Gynecology, Tokyo, Japan*
[2]*Shinbasi Yume Clinic, Shinbasi Yume Clinic, Tokyo, Japan*
[3]*Kyono ART Clinic Takanawa, Kyono ART Clinic Takanawa, Tokyo, Japan*
[4]*Kato Ladies Clinic, Kato Ladies Clinic, Tokyo, Japan*
[5]*Sugiyama Clinic Shinjuku, the Center for Reproductive Medicine and Implantation Research, Tokyo, Japan*

Study question: What are the pregnancy outcomes after OPtimization of Thyroid function, IMmunity and Uterine Milieu (OPTIMUM) strategy in patients with recurrent implantation failure (RIF)?
Summary answer: Evaluation and treatment related to thyroid function, intrauterine environment and maternal immunity may improve pregnancy outcomes in patients with a history of RIF.
What is known already: Overcoming RIF in patients with a history of multiple high-quality embryo transfer (ET) cycles is considered difficult using common in vitro fertilisation (IVF) procedures. The risk factors for RIF include uterine inhibitory factors of implantation without embryo origin, such as impaired intrauterine circumstances and maternal immunological dysfunction. Persistent inflammation of the local endometrium (chronic endometritis) occurs in 30%–60% of women with RIF. Further, aberrant high T-helper (Th)1/Th2 cell ratio is detected in 50%–60% of such women. Vitamin D insufficiency is associated with high maternal Th1/Th2 cell ratio.
Study design, size, duration: This study was approved by the local ethics committee. Infertile women with RIF after ≥3 ET cycles underwent implantation testing, including hysteroscopy; endometrial biopsy for CD138 immunostaining; determination of interferon-γ-producing Th cell (Th1 cell), IL-4-producing Th cell (Th2 cell), serum 25-hydroxyvitamin D_3 and thyroid-stimulating hormone levels and thyroid peroxidase antibody testing, between April 2017 and August 2018. Preimplantation genetic testing for aneuploidy and endometrial receptivity array were not performed.
Participants/materials, setting, methods: The cornerstone of treatment is the remedy of detected causes by implantation testing. We treated chronic endometritis with antibiotics; aberrant high Th1/Th2 cell ratio with vitamin D and immunosuppressive drug (tacrolimus) supplementation and overt or subclinical hypothyroidism with levothyroxine therapy. Of 92 women with a history of RIF, 72 underwent 105 ET cycles after implantation testing. We conducted a questionnaire-based survey regarding pregnancy outcomes after the OPTIMUM strategy in IVF facilities.
Main results and the role of chance: Women with RIF were aged 38 ± 4 years and had an implantation failure history after 6 ± 3 ET cycles. The prevalence of RIF risk factors in patients aged <40 and ≥40 years was 72% (38/53 women) and 64% (25/39) in impaired intrauterine circumstances, 58% (31/53) and 38% (15/39) for aberrant elevated Th1/Th2 cell ratio, 85% (45/53) and 90% (35/39) for vitamin D insufficiency and 26% (14/53) and 38% (15/39) for thyroid disorder, respectively. Their cumulative clinical pregnancy rates were 60% (25/42) and 30% (9/30) at the first ET and 71% (30/42) and 50% (15/30) at the second ET, respectively. Further, cumulative ongoing pregnancy rates were 52% (22/42) and 17% (5/30) at the first ET and 64% (27/42) and 27% (8/30) at the second ET, respectively.
Limitations, reasons for caution: This study has some limitations. First, this was a retrospective study. Second, we did not compare pregnancy outcomes in patients without implantation testing. Lastly, the sample size was small, complicating data analysis using multivariable analysis.
Wider implications of the findings: Among <40-year-old RIF patients, 64% achieved ongoing pregnancy. However, cumulative ongoing pregnancy rates of ≥40-year-old patients were only 27% after two ET trials, suggesting chromosomal testing of embryos is required for improvement of pregnancy rate in RIF women of late reproductive age.
Trial registration number: not applicable

P-409 The evaluation of efficiency of the treatment of infertile women by elective single embryo transfer (eSET) in IVF programs: cohort study

T. Verkhovnikova[1], **I. Moiseeva**[2], **O. Tyumina**[3], **D. Vlasov**[4]
[1]*Samara Regional Medical Center "Dynasty", IVF, Samara, Russia C.I.S.*
[2]*Samara Regional Medical Center "Dynasty", Invitro Fertilization Department, Samara, Russia C.I.S.*
[3]*Samara Regional Medical Center "Dynasty", Director, Samara, Russia C.I.S.*
[4]*Samara Regional Medical Center "Dynasty", Embryology, Samara, Russia C.I.S.*

Study question: An evaluation of the effect of the treatment of infertile women by elective single embryo transfer (eSET) in InVitro Fertilization (IVF) programs.
Summary answer: eSET can be recommended for wider medical use in IVF cycles; this is an effective method, which reduces maternal and fetal risks.
What is known already: Initially, SET in the IVF cycle was proposed and implemented for patients with contraindications to carrying multiple pregnancies. The current global medical trend is the transfer of the best embryo. In some countries, however, several embryos are still transferred. Of course, SET is only applicable to a specific group of patients with high chances of succes. Various criteria have been proposed by different guidelines all over the world. In Russia, legally "no more than two embryos should be transferred into the uterine cavity". Currently, there is no unanimous opinion regarding that issue and no regulatory solution for the SET problem.
Study design, size, duration: The study included pro- and retrospective efficiency analysis of the treatment of 903 infertile women with normal ovarian reserve undergoing IVF in 2015–2017. In 143 women from the main group, elective single embryo transfer was performed. The comparison group included 760 women, which underwent double embryo transfer in IVF programs. The women in the groups were comparable in age, infertility duration, infertility factor, primary infertility proportion, and mean number of previous IVF cycles.
Participants/materials, setting, methods: The mandatory inclusion criterion in the main group was the presence of at least two embryos of excellent/good quality at the day of transfer. The following parameters were evaluated: number of oocytes obtained; fertilization rate; the number of embryos of good and excellent quality; pregnancy rate (PR); pregnancy termination; the labor number; the number of infants born; and the preterm labor incidence.
Main results and the role of chance: The difference in the efficiency of treatment in eSET and DET settings was not statistically significant. The PR was 55.9% in the main group and 51.9% in the comparison group ($p > 0.05$). However, the incidence of carrying pregnancy in the main group was significantly higher. The number of single pregnancies in the second group was 260 (65.8%). We didn't detect significant differences in pregnancy loss rate in both groups. The percentage of pregnancy loss was 18.8% in the main group and 27.1% in the comparison group ($p > 0.05$). The labor number per cycle was also similar in both groups (45.5% (65 cases) in the main group and 37.9% (288 cases) in the comparison group, $p > 0.05$). In the main group, no twin births were registered; in the comparison group, twin births were observed in 53 (18.4%) cases. We also analyzed perinatal outcomes. The number of preterm labor (22–37 weeks of pregnancy) was significantly lower in the main group than in the comparison group: 6.1 and 27.4% ($p < 0.001$). The incidence of carrying pregnancy until a term of more than 37 weeks was also higher in the main group: 93.9% vs. 72.6% in the comparison group.
Limitations, reasons for caution: The criteria for the exclusion of women from the study were the absence of indications for treatment with the IVF/ICSI method; acute somatic illnesses and/or exacerbations of chronic somatic illnesses; the low and/or decreased ovarian reserve; and the absence of two embryos of excellent/good quality at the day of transfer.
Wider implications of the findings: We propose that the eSET should become the "golden standard" of ART in infertile patients with normal ovarian reserve, and indications for its use should be extended. This will decrease the treatment costs and minimize pregnancy loss.
Trial registration number: not registrated

P-410 Comparison of two endometrial preparation methods for frozen-thawed embryo transfer in anovulatory PCOS patients: impact on miscarriage rate.

V. Simon[1], G. Robin[1,2], D. Dewailly[3], S. Catteau-Jonard[4,5], A.L. Barbotin[6], P. Plouvier[7]

[5]Centre Hospitalier Universitaire de Lille, 2 Avenue Oscar Lambret-, Lille, France
[6]Institut de Biologie de la Reproduction-Spermiologie-CECOS- Lille- France., CHU Lille, Lille, France
[7]Service de Gynécologie Endocrinienne et de Médecine de la Reproduction- Hôpital Jeanne de Flandre., CHU Lille- 2 Avenue Eugène Avinée-, Lille, France

Study question: The aim of this study is to determine which is the best protocol for endometrial preparation between artificial and stimulated cycle for PCOS patients undergoing a frozen embryo transfer (FET)
Summary answer: The two types of endometrial preparation did not influence FET issues, in particular miscarriage and live birth rates.
What is known already: In the literature, artificial cycles and stimulated cycles seem to be comparable for endometrial preparation in term of ongoing pregnancy rate and live birth rate. However, few studies evaluated early pregnancy loss rates, and had a specific interest on PCOS patients.

Yet, some authors suggested that PCOS patients are more at risk of miscarriage but this remains controversial. The association could be explained by several factors such as obesity, hyperinsulinemia and hyperandrogenism. These factors could have effects on PCOS endometrium. Furthermore, some studies suggest that FET may improve live birth rate and induce lower miscarriage rate in PCOS women.
Study design, size, duration: This is a monocentric retrospective cohort study including 255 cycles of frozen-thawed embryo transfer in 135 PCOS patients between 2011 and 2017 in an academic institution. Patients were under 35 years old and have received 2 types of treatment: artificial cycle (estradiol valerate 6mg and micronized vaginal progesterone 800mg daily) or stimulated cycle with hMG or recombinant FSH.

Statistical comparison was carried out by Mann-Whitney test or Chi-square test, when appropriate.
Participants/materials, setting, methods: PCOS was defined by at least two of the three following items: clinical and/or biological hyperandrogenia and/or oligo-anovulation and/or PCOM: ovarian volume > 10 mL and/or follicle number per ovary (FNPO) ≥ 19 and/or AMH ≥35 pmol/l., as previously published. Patients with endometriosis were excluded.

Clinical pregnancy, miscarriage and live birth rates were recorded.

Embryos were transferred at cleavage stage.
Main results and the role of chance: 118 FET were performed with an artificial cycle and 137 with a stimulated one. Our groups were comparable for the age, BMI, cigarette smoking, endometrial thickness and number of embryos transferred.

Implantation rate was similar in the two groups (23% in the stimulated cycle group, 26% in the artificial cycle one, NS).

There was no significant difference between artificial cycle and stimulated cycle in the PCOS patients in term of clinical pregnancy rate (respectively 37,3% versus 30%, NS), ongoing pregnancy rate (27% versus 23%, NS) , miscarriage rate (25% versus 22%, NS) and live birth rate (26,3% versus 23, 4%, NS).
Limitations, reasons for caution: Some bias may have occurred due to the retrospective design of the study.

We used strict criterias to select our PCOS population with home-made AMH and FNPO thresholds to define PCOM.

A prospective randomized study with a larger sample of patients should be realized to corroborate these data.
Wider implications of the findings: For PCOS patients, endometrial preparation doesn't seem to influence miscarriage rate and more generally FET clinical outcome.
Trial registration number: Not applicable

P-411 Medical management of early pregnancy failure (EPF) is highly effective in pregnancies following artificial reproductive techniques (ART)

V. Colleselli[1], M. Hafenmayr[2], A. Ciresa-Koenig[1], B. Toth[2], B. Seeber[2]
[1]University Hospital Innsbruck, Obstetrics and Gynecology, Innsbruck, Austria
[2]University Hospital Innsbruck, Reproductive Endocrinology and Reproductive Medicine, Innsbruck, Austria

Study question: Does mode of conception have an impact on the success rate of uterine evacuation using mifepristone and misoprostol in EPF?
Summary answer: Medical management of EPF is highly effective in women getting pregnant through ART, showing no difference between fresh and frozen cycles

What is known already: Success rates, defined as no need for surgical intervention, for medical management using mifepristone and misoprostol exceed 85% and confirm that this is a safe and effective alternative to surgical evacuation in EPF. There is only one relatively small study from 2009 focusing on the impact of mode of conception onsuccess rate which showed a trend toward more favorable success rate in ART pregnancies. However, in contrast to our study only misoprostol was administered, resulting in a success rate of 77% for spontaneous pregnancies and 92% for ART pregnancies.

Study design, size, duration: This retrospective study evaluated all patients choosing medical management for EPF at our institution from March 2013 to January 2017. In pregnancies following ART we compared success rate in fresh vs. frozen cycles. Exclusion criteria included complete or incomplete abortion, multiple gestation, gestational age over 13 weeks by ultrasound, contraindication for mifepristone or misoprostol and pregnancies with an IUD in place.

Participants/materials, setting, methods: We performed a retrospective review of patients' medical records including sonographic and clinical findings at time of diagnosis and following treatment. Previous history as well as details regarding ART treatment were abstracted. According to our institutional protocol, patients received 200 mg mifepristone orally on an outpatient basis and were admitted 36 to 48 hours later for vaginal administration of misoprostol 800 mcg. Time to passage of pregnancy tissue and overall success rates were evaluated.

Main results and the role of chance: In total we identified 424 patients receiving medical management for EPF in the defined time span, of which 52 were pregnancies achieved following ART. The overall success rate was 92%. Subgroup analysis showed no difference in success rates comparing spontaneous (92%) and ART conceptions (94%), (p=0.524). Moreover, no significantly different success rate was found for ART pregnancies following fresh vs. frozen cycles (97% vs. 88%, p=0.218).

88% of patients reported passage of tissue during their day-clinic stay, with a mean time of 5.1±3.4 hours. If no passage of tissue or bleeding was observed after 6 hours or ultrasound suggested incomplete evacuation, an additional dosage of 400 mcg misoprostol buccally could be administered upon the treating physicians' choice. This was executed in 78 patients (18%) with no significant difference in ultimate success of treatment after performing subgroup analyses.

Of the 51 patients discharged without passage of tissue, the majority achieved a complete abortion. Surgical intervention was necessary in only 13 of these cases andno patient needed a blood transfusion, emphasizing the safety of this protocol.

Limitations, reasons for caution: The study is limited by its retrospective design. We collected data in a real life clinical setting prone to subjective influence by patients' wishes, treating physicians' decisions and preferences. However, this can also be seen as an advantage, reporting results for clinical daily routine, independent of restricted study protocols.

Wider implications of the findings: Up to 20% of pregnancies following ART end in pregnancy failure. Based on our results, we postulate that women should be routinely offered medical management as a highly effective and safe alternative to surgical management, when diagnosed with EPF following fresh as well as frozen ART cycles.

Trial registration number: not applicable

P-412 Multiscale 3D imaging: a useful approach for the study of endometrial glandular architecture in healthy women

J. Pearson-Farr[1], J. Cleal[1], R. Lewis[1], Y. Cheong[2]

[1] *University of Southampton, Faculty of Medicine- Human Development and Health, Southampton, United Kingdom*

[2] *Complete Fertility Southampton, Princess Anne Hospital, Southampton, United Kingdom*

Study question: Can 3D imaging techniques be used for characterising endometrial glands and their component cells types?

Summary answer: Multiscale 3D imaging provides new insights into endometrial gland function during the window of implantation in healthy women.

What is known already: Endometrial glands contribute essential products to the uterine milieu, important for trophoblast implantation and early pregnancy. Previous immunohistochemistry and electron microscopy techniques have identified different cell types of the endometrial gland, including secretory cells and ciliated cells. However, the 3D ultrastructure of endometrial glands has not been characterised. Multiscale 3D architectural characterisation of healthy endometrial glands during the implantation window can provide important topographical insight into this crucial phase of endometrial development.

Study design, size, duration: An observational study on a cohort of healthy egg donor control patients.

Participants/materials, setting, methods: Endometrial samples were collected at the implantation period of the menstrual cycle (LH $^{+}$7-10). To study the spatial distribution of glandular cell types, formaldehyde fixed endometrial tissue was processed for whole-mount immunohistochemistry and imaged on the confocal microscope. To determine the 3D ultrastructure of the endometrial gland, glutaraldehyde fixed endometrial tissue was processed with heavy metals and imaged on the serial block face scanning electron microscope (SBFSEM). Finally, high-speed video observed endometrial glands live.

Main results and the role of chance: Multiscale 3D imaging techniques have been used to investigate endometrial glands. Confocal microscopy demonstrated the 3D spatial distribution of glandular cell types. SBFSEM allowed 3D reconstruction of the glandular luminal surface and high-resolution ciliated glandular epithelial cells. 3D reconstruction of the glandular lumen, shown by 3D video, provides informative insight into how glandular cell types interact in the lumen and suggested sites of microvesicle production. Characterising ciliated epithelial cells in endometrial glands has lead to a greater understanding of their interactive 3D roles during the window of implantation, which can be built upon for future research in infertility and miscarriage.

Limitations, reasons for caution: This is an observational study with a small sample size. 3D analysis of endometrial samples is currently time consuming in comparison to traditional 2D immunohistochemistry methods, therefore more applicable for research studies.

Wider implications of the findings: This 3D approach can potentially be applied to answer questions in relation to defective implantation.

Trial registration number: not applicable

P-413 The evaluation of the presence of CD56+ Natural Killer Cells in Patients with IVF failure.

G. Babayeva[1], M. Colakoglu[1], H. Energin[1]

[1] *Necmettin Erbakan University Meram Medicine Faculty, Obstetrics and Gynecology, konya, Turkey*

Study question: Does endometrial CD56+ Natural Killer cells play role in IVF failure.

Summary answer: Cases of uterine CD56 + NK cells may play significant role in the etiology of recurrent IVFf failure.

What is known already: Uterin natural killer cells plays important role in implantation and vascularization.

Study design, size, duration: Study had been designed as prospective randomized case control study. It was conducted between January 2012 and December 2017. 70 women were randomly selected 35 in control grup and 35 case group. Inclusion criterias for case group were minimum 2 IVF failure, Inclusion criterias for control group were minimum 1 live birth without receiving any infertility treatment,

Participants/materials, setting, methods: Endometrial biopsies were taken 21 th or 24 th day of menstural cycle. Endometrial samples were stained with CD 56 antibodies (Novocastra Laboratories Ltd. NCL-L-CD56-1B6).

Main results and the role of chance: Mean age in control and case group were 34.4 and 33.5 respectively. There were no gravid, parity or abortus in case group. Mean parity, abortus were 3.7 and 1.7 respectively. There were significant positive correlation between abort number and uterine natural killer count in control group $p<0.005$. There significantly low uterine natural killer count in case group $p<0.005$.

Limitations, reasons for caution: Other surface antigens of uterine natural killer cells may be studied in further studies.

Wider implications of the findings: In literature studies reported that more natural killer cells in patients with habitual abortus but We observe lesser uterine natural killer cells in patients with IVF failure.

Trial registration number: not applicable.

P-414 The impact of serum estradiol level prior to progesterone administration on live birth rate in single frozen-thawed blastocyst transfer cycles

C. Celik[1], M.R. Asoglu[1], L.S. Karakis[1], F. Necati[1], G. Meral[1], C. Sabri[1], B. Mustafa[1]

[1]Bahceci Women's Health Center, Reproductive Endocrinology and Infertility, Istanbul, Turkey

Study question: Does serum estradiol (E2) level monitoring on the day of progesterone administration affect live birth rate for artificial frozen-thawed (FT) single blastocyst transfer cycles?

Summary answer: Serum E2 level monitoring on the day of progesterone administration does not appear to be predictive for live birth rate.

What is known already: Estradiol is critical to endometrial and placental development. However, excess E2 may adversely affect placentation and endometrial receptivity, which may result in decreased implantation rates.Although much work has focused on identifying the optimal duration of exogenous E2 use, its dosage and route of administration, only few studies have addressed the predictive value of serum E2 level on the day of progesterone initiation for live birth rates. No consensus has been reached on E2 level monitoring on the day of progesterone initiation and previous studies have provided conflicting results.

Study design, size, duration: This study analyzed 468 FT single blastocyst transfer cycles performed between January-2015 and January-2018. All FTs were performed in patients aged between 20-37 years with unexplained or tubal infertility who had a top quality embryo. We excluded patients with repeated implantation failure, diminished ovarian reserve, a known structural chromosomal abnormality, severe male factor, recurrent pregnancy loss, hydrosalpinx and/or any uterine factor and those with progesterone level>1.5ng/mL or endometrial thickness<7mm on the day of progesterone initiation.

Participants/materials, setting, methods: This study was conducted in Bahceci Women's Health Center in Istanbul in Turkey. The patient population was stratified into four groups based on the percentiles of E2 levels measured on the first day of progesterone administration; group 1 (<25th percentile), group 2 (25-50th percentile), group 3 (50-75th percentile) and group 4 (>75th percentile). The impact of E2 level percentiles on clinical pregnancy and live birth rates were analyzed.

Main results and the role of chance: A total of 468 patients were included in the study. Data was obtained from the first single top quality blastocyst transfers of these patients, and thus 468 FT embryo transfer cycles were included in all calculations. The patients' median age, median body mass index, and median duration of infertility (range) were 31 years (20-37), 25 kg/m^2 (18-38), and 3 years (1-9), respectively. On the day of progesterone initiation day, the patients' median endometrial thickness, median E2 level and median progesterone level (range) were 9.8mm (7-13), 257pg/mL (64-1560) and 0.2ng/mL (0.01-1.45), respectively. Based on E2 level percentiles measured on the first day of progesterone administration: group-1 (<25thpercentile), group-2 (25-50thpercentile), group-3 (50-75thpercentile) and group-4 (>75thpercentile) did not show statistically significant differences in terms of live birth rate, which were 51.6%, 55.1%, 54.9% and 56.4%, respectively. The groups also did not significantly differ in implantation and clinical pregnancy rates. To determine whether there is a threshold for E2 level to predict pregnancy or not, receiver operating characteristic (ROC) analysis was conducted. Based on ROC curves, the E2 level on the day of progesterone administration was not predictive for implantation (AUC: 0.490, p=0.98), clinical pregnancy (AUC: 0.507, p=0.80) and live birth (AUC: 0.514, p=0.60).

Limitations, reasons for caution: The study has the limitations inherent to its retrospective nature.

Wider implications of the findings: Our results suggest that serum E2 level measured on the day of progesterone initiation does not predict live birth rate in patients undergoing single frozen-thawed top quality blastocyst transfer in artificial endometrial preparation cycles. Thus, our data may provide guidance to physicians managing this group of patients.

Trial registration number: not applicable

P-415 Effect of levothyroxine treatment and prevalence of thyroid autoimmunity in a cohort of 1065 patients with recurrent pregnancy loss

Abstract withdrawn by the authors

P-416 Measuring serum progesterone level on the day of transfer can be an additional tool to maximize ongoing pregnancies in single euploid frozen blastocyst transfers.

F.K. Boynukalin[1], M. Gultomruk[2], S. Cavkaytar[3], B. Demir[4], D. Nagihan[5], N. Findikli[2], M. Bahceci[1]

[1]Bahceci Health Group, Bahceci Fulya IVF Center, Istanbul, Turkey
[2]Bahceci Health Group, Research and Development, Istanbul, Turkey
[3]Bahceci Health Group, Bahceci Umut IVF Center, Istanbul, Turkey
[4]Bahceci Health Group, Bahceci Ankara IVF Center, Ankara, Turkey
[5]Bahceci Health Group, Nursing Services, Istanbul, Turkey

Study question: Is there a relation between serum progesterone(P) levels on day of embryo transfer(ET) and ongoing pregnancy rates(OPR) ?

Summary answer: OPR is found to be significantly diminished in patients where serum P level is less than 14,6 ng/ml in single euploid vitrified-warmed blastocyst ET.

What is known already: Since contemporary comprehensive chromosomal screening (CCS) applications necessitate embryo cryopreservation at the blastocyst stage, number of euploid FBT cycles are steadily increasing worldwide. it has been reported that transfer of euploid blastocysts can result in high clinical and ongoing pregnancies. On the other hand, in nearly 30-35% of these cycles, a successful pregnancy can not occur.The role of monitorization of P levels on day of FBT in artificial cycle is controversial and the common practice is not to monitor. Studies in which an optimum serum P threshold or wiindow on ET day is evaluated for better pregnancy outcome are scarce.

Study design, size, duration: This prospective cohort study includes patients who underwent single euploid FBT between March and August 2018. All patients received HRT with estradiol valerate (EV) and 50 mg intra muscular (IM) P. Patients with uterine anomalies, pathologies and endometrial thickness <7 mm were excluded. In all cycles, only embryos that were biopsied on day 5 were utilized for FBT. Next generation sequencing (NGS) was used for comprehensive chromosomal analysis. The primary outcome measure was OPR.

Participants/materials, setting, methods: One hundred and sixty-eight patients undergoing euploid single FBT were analysed. Following 10-13 days of EV use, vaginal ultrasound examination was performed to confirm endometrial thickness >7 mm and serum progesterone level<1 ng/ml. FBT was scheduled 117-120 hours after starting 50 mg IM P. Serum P level was analysed 1 hour before the 6th day of P administration. For each pregnant patient, OPR was monitored by ultrasound at the end of 16th weeks of pregnancy.

Main results and the role of chance: Overall, OPR was 58.9%(99/168). In logistic regression analysis, ongoing pregnancy was taken as the dependent variable and female age(years), BMI(kg/m2), duration of infertility(years), number of previous cycles, previous pregnancy history, endometrial thickness(mm), P and estradiol level at the starting day of progesterone P, P level on the day of FBT, blastocyst morphology were taken as independent variables. BMI(p=0,041) and P level on the day of FBT(p=0.013) were found to be significant predictors of OP. Mean serum P on the day of FBT was 33.2±23.3 ng/ml (Percentiles 25, 14.6; 50, 24.7; 75, 54.4). OPRs according to serum P quartiles were Q1:26.2(11/42); Q2:74.4%(32/43); Q3:60.5%(26/43); Q4:75%(30/40). The OPR of Q1 was significantly lower than Q2–Q4: 26.2% versus 70.6%; p :0.007 RR (95%CI):0.28(0.11-0.69). Serum P levels on the day of FBT were found to be correlated only with BMI (rho:-0.013 p=0.001) and P level at the starting day of P (rho:0.258 p=0.001). The ROC curve showed a significant predictive value of serum P levels on the day of FBT for OPR, with an AUC (95%CI)=0.69(0.60-0.77). The optimal serum P threshold in which sensitivity and specificity for OPR were both >50% was 20.9 ng/ml (70.7% sensitivity, 55.1% specificity).

Limitations, reasons for caution: Patient population included only women with appropriate endometrial thickness and good quality euploid blastocysts transfer. Validation of P levels on different population should be extrapolated. The results needs to be confirmed in larger studies.

Wider implications of the findings: The study suggests a minimum threshold of serum P values on the day of FBT in artificial cycles to

optimize pregnancy rates. Large variations in P levels should be documented and evaluate. Individualization of progesterone dosage and optimal route especially in obese patients should be evaluated in further studies.

Trial registration number: None

P-417 An examination of density and clustering of four major immune cells in women with recurrent miscarriage in precisely timed endometrial samples compared with fertile controls

Y. Zhao[1], X. Chen[1], T. Zhang[1], L.K.Y. Chan[1], Y. Liu[1], J. Kwong[1], T.C. Li[1]

[1]The Chinese University of Hong Kong, Department of Obstetrics and Gynaecology-Faculty of Medicine, Hong Kong, China

Study question: Is there any difference in the density and infiltration level of four major endometrial immune cell types between women with recurrent miscarriage and fertile controls?

Summary answer: There was a significant increase in the density of CD3+, CD68+ and CD56+ cells and clustering between CD68+ and CD56+ cells in recurrent miscarriage women.

What is known already: Serval studies showed an increased uNK cell density on day LH+7 of women with recurrent miscarriage (Lash *et al*., 2016)(Chen *et al*., 2017). A few studies examined other endometrial immune cells (T cell/Macrophage/B cell) but with inconstant results (Mei *et al*., 2010)(Yin *et al*., 2012), partly because the specimens were not precisely timed. To better understand the contribution of different immune cells to recurrent miscarriage, it is necessary to simultaneously examine major immune cells in the same specimen to determine the relative magnitude of the cell density changes (if any) and the degree of clustering between two immune cell types.

Study design, size, duration: This was a retrospective study of archived endometrial specimens carried out in a university teaching hospital in Hong Kong between Aug. 2017 and Sep. 2018. A total of 30 women with unexplained recurrent miscarriage (three consecutive pregnancy losses) and 30 fertile controls were included in this study.

Participants/materials, setting, methods: Endometrial biopsies were collected precisely 7 days after LH surge. A multi-colour immunofluorescent method was used to simultaneously measure the density of CD3 for T cells, CD 20 for B cells, CD56 for uNK cells and CD 68 for macrophages in the same endometrial biopsy. The degree of clustering of different pairs of endometrial immune cells was measured by the infiltration level, using the spatial distribution toolbox 'spatstat' in R (Carstens *et al*., 2016).

Main results and the role of chance: The median CD3+/CD20+/CD68+/CD56+ cell density in the fertile controls was 1.3%, 0.4%, 2.8% and 7.1%, respectively; and for women with recurrent miscarriage was 2.7%, 0.5%, 4.3% and 11.9%. In women with recurrent miscarriage, there was a significant increase density ($p<0.05$) of CD3+ T cells (107.6%), CD56+ uNK cells (40.3%) and CD68+ macrophages (34.8%), with no significant increase in CD20+ B cell density. In addition, there was a significant infiltration level between CD56+ uNK cells and CD68+ macrophages, compared with fertile controls.

Limitations, reasons for caution: The prognostic value of the measurements has not been examined in this study.

Wider implications of the findings: Recurrent miscarriage is associated with alteration of multiple immune cells density in the endometrium and the degree of clustering between the different immune cell types.

Trial registration number: This work was supported by the Health and Medical Research Fund in Hong Kong (No. 04152786) and 2018 Hong Kong Obstetrical and Gynaecological Trust Fund.

P-418 Comparison of live birth rate between fresh embryo transfer and vitrified-thawed embryo transfer

T. Du[1,2], Q. Lyu[1], Y. Kuang[1]

[1]Shanghai 9th People's Hospital- Shanghai Jiao Tong University School of Medicine, Department of Assisted Reproduction, Shanghai, China

Study question: Does vitrified-thawed embryo transfer (VET) result in higher live birth rate (LBR) than fresh embryo transfer (ET) in women without polycystic ovary syndrome (PCOS)?

Summary answer: VET resulted in higher LBR than fresh ET in women without PCOS.

What is known already: Theoretically, VET may result in higher LBR than fresh ET due to a more favorable intrauterine environment for embryo implantation by avoiding the supraphysiologic condition that occurs after ovarian stimulation, and results from most previous studies of limited sample size did observe a higher LBR after VET. However, two recently published randomized clinical trials (RCTs) showed the LBR did not differ significantly between fresh ET and VET in women without PCOS.

Study design, size, duration: This was a retrospective cohort study involving a total of 28,672 transfer cycles (3,389 fresh ETs and 25,283 VETs) of in vitro fertilization/intracytoplasmic sperm injection from 2006 to 2014.

Participants/materials, setting, methods: LBR was compared by patient and treatment characteristics, including female age, BMI, infertility duration, gravidity, parity, previous full-term births, tubal-factor infertility, PCOS, endometriosis, male-factor infertility, ovary stimulation protocol, endometrial thickness on ET day, number of embryos transferred, treatment year, and transfer type. Thereafter, we used generalized estimated equation regression models to calculate unadjusted and adjusted ORs for the association between LBR and the aforementioned characteristics in the whole population and women without PCOS, respectively.

Main results and the role of chance: For the whole population studied, the overall LBR was 34.4% (9865/28672). VET was associated with a significantly higher LBR than fresh ET (35.6% vs. 25.5%, OR 1.67, 95% confidence interval [CI] 1.54-1.81, P<0.001). After adjusting for confounding factors, VET still had a significantly higher LBR compared with fresh ET (adjusted OR 1.28, 95% CI 1.15-1.41, P<0.001). For women without PCOS, the overall LBR was 33.8% (9143/27042). VET was also associated with a significantly higher LBR than fresh ET both in the unadjusted (35.0% vs. 25.1%, OR 1.61, 95% CI 1.48-1.75, P<0.001) and adjusted (adjusted OR 1.27, 95% CI 1.15-1.41, P<0.001) analyses.

Limitations, reasons for caution: This was a retrospective study based on data from a single center. Moreover, progesterone level on the day of trigger was not available, which limited our further comparison of LBR between fresh ET and VET under different progesterone subgroups.

Wider implications of the findings: VET resulted in higher LBR than fresh ET both in the general population and ovulatory women, which supports the hypothesis that VET can result in more favorable intrauterine environment for implantation. Transfer of fresh versus frozen embryos in ovulatory women should be further assessed in RCTs of large sample size.

Trial registration number: Not applicable.

P-419 Autologous Intrauterine Platelet-Rich Plasma Instillation for recurrent implantation failure: A Pilot Study

M. Alhalabi[1], S. Alsamawi[2], H. Deroubi[2], A. Taha[2], R. Doghouz[2], A. Alkhatib[3]

[1]Faculty of Medicine- Damascus University, Division of Reproductive Medicine-Embryology and Genetics, Damascus, Syria

[2]Orient Hospital, Assisted Reproduction Unit, Damascus, Syria

[3]Orient Hospital, Molecular Genetics Unit, Damascus, Syria

Study question: To evaluate the effects of intrauterine infusion of Autologous Platelet-Rich Plasma (PRP) on RIF regarding to implantation rates, clinical pregnancy rate and abortion rate.

Summary answer: The use of autologous PRP may increase clinical pregnancy and implantation rate in patients with recurrent implantation failure.

What is known already: Recurrent implantation failure (RIF) is defined as unsuccessful implantation after repeated transfers of at least 4 good quality embryos in a minimum of three fresh or frozen cycles in a woman under 40 years into a normal uterus. The definition of RIF is under constant scrutiny.

Study design, size, duration: 80 patients with the history of RIF from 01.01.2017 until 01.01.2018 were recruited in this Randomized control trial.

Participants/materials, setting, methods: PRP was administered at the day of oocyte puncture. Intrauterine instillation of autologous PRP was done in Forty patients as PRP group, and forty patients in control group.
Main results and the role of chance: The mean age for whole study group was 35.7±6.2 years (PRP 35.5±5.2, controls 35.4±4.7). 10/40 (25%) patients had a clinical pregnancy after embryo transfer in PRP group while 6/40 (15%) patients in control group. The implantation rate was 14.1% in PRP, 7.3% in control group.
Limitations, reasons for caution: Further research in the form of large scale randomized controlled trials is needed.
Wider implications of the findings: This study suggests that the use of autologous PRP holds promise in the treatment of women with Recurrent implantation failure.
Trial registration number: none

P-420 A comparison of expression of angiotensin II receptor type 1 in peri-implantation endometrium in women with RIF and fertile controls

R. QI[1]
[1]*IVF, Obstetrics and Gynaecology, Hong Kong, Hong Kong*

Study question: Does local renin angiotensin system play a role in peri-implantation endometrial vascularization and function?
Summary answer: The expression of angiotensin II receptor type I in women with recurrent implantation failure (RIF) was significantly lower than in fertile controls.
What is known already: Altered vascularization status in the endometrium around the time of embryo implantation may contribute to different implantation outcome. It is known that Angiotensin II promotes the growth and vascularization of the endometrial stroma. However, it is not known that if angiotensin pathway plays a role in implantation outcome.
Study design, size, duration: It was a prospective cohort study. A total of 33 women were recruited in the study, including 10 fertile women and 23 women withRIF. All endometrial biopsies were collected precisely on day LH+7.
Participants/materials, setting, methods: Endometrial biopsied tissue was collected and immunostained for Angiotensin II receptor type I(AT1)and Angiotensin (1-7) mas receptor Results was graded and calculated according to an H-score equation. The H scores were measured in luminal epithelium, glandular epithelium, and stroma separately.
Main results and the role of chance: The expression of AT1 was observed in all compartments in the peri-implantation endometrium, and a significantly lower expression in all compartments of the endometrium was observed in peri-implantation endometrium of women with RIF (luminal epithelium: 104±72 ; glandular epithelium: 97±66 ; stroma 76±50), compared with fertile control (luminal epithelium: 218±46 ; glandular epithelium: 191±50 ; stroma 151±54). Moreover, we found that the expression of Ang(1-7) mas receptor was confined in endometrial stromal compartment.
Limitations, reasons for caution: More components of renin angiotensin system components need to be confirmed (such as AT2, Angiotensin II, Renin, ACE), and a larger sample size need to be recruited to verify this novel finding in the future.
Wider implications of the findings: The renin angiotensin system may be involved in the endometrial vascularization. The role of renin angiotensin system in peri-implantation endometrium is worthy of further study.
Trial registration number: None

P-421 Endometrial receptivity analysis in recurrent implantation failure: A prospective study comparing benefits in own versus donor cycles.

P. Selvaraj[1], **K. Selvaraj**[1], **M. Sivakumar**[1], **R. Pathy**[2], **S. Balakrishnan**[1]
[1]*GG Fertility and Womens Speciality Hospital, G.G. Hospital, Chennai, India*
[2]*Vellore Institute of Technology, Biotechnology, Vellore, India*

Study question: To determine if endometrial receptivity analysis (ERA) is beneficial for universal application in recurrent implantation failure (RIF) or in select groups.
Summary answer: ERA was found to be more beneficial in RIF patients recruited in donor cycles when compared to those using own gametes.
What is known already: The factors affecting implantation potential are multi-factorial encompassing many different growth factors, cytokines and a plausible shift in implantation window during fresh IVF cycles following hyper-stimulation. ERA serves as a study of measurable RNA and 238 genes and found to be beneficial in cases of RIF, considering 25% have a shift of this window and another 12% are non-receptive at any given time. The testing allows personalized embryo transfers at the receptive phase thereby enhancing success rates to almost 67%. But is it universally applicable in all cases especially in donor programs remains to be seen.
Study design, size, duration: A prospective study was conducted from Oct 2013 - Dec 2018 with the sample size of 391 women with recurrent implantation failure undergoing assisted reproduction. The mean age of women was 34.66 ± 5.69 years. Recurrent implantation failure was defined as more than two IVF failures in self and donor programs. ERA was performed on day 21 of a hormone replacement cycle. The reports were generated as receptive, pre or post receptive endometrium.
Participants/materials, setting, methods: The study participants were divided into two groups. Group A (n= 91) comprised of women using own gametes and Group C (n= 92) comprised of women using donor gametes. Both groups were compared to their respective controls B (n=107) and D (n=101). ERA was performed on groups A and C following standard hormone replacement therapy protocol. Clinical pregnancy rates, fetal miscarriages and live birth rates were compared between study and respective control (non-ERA) groups.
Main results and the role of chance: In group A (ERA, own cycles) 65.93% of women had receptive endometrium, 27.45 % had pre receptive and 6.59% of women had post receptive endometrium. In group C (ERA, donor cycles) 68.48% of women had receptive endometrium, 17.39 % had pre receptive and 14.13% of women had post receptive endometrium.

There were no statistically significant differences with respect to clinical pregnancy (p=0.128) and fetal miscarriage rates (p=0.133) between groups A (ERA) and B (non-ERA) in RIF patients using own gametes. However there were statistically significant differences in clinical pregnancy (p=0.013), live birth (p=0.032) and fetal miscarriage rates (p=0.04) between groups C (ERA) and D (non-ERA) in RIF patients using donor gametes. This signifies the benefits of performing ERA in recurrent implantation failure patients who have failed despite using donor gametes, where poor response or poor embryo quality had previously been more of a deterrent than the endometrium per say.
Limitations, reasons for caution: A larger sample size would add more value to the study.
Wider implications of the findings: The study groups were demographically comparable to their respective control groups there by having fewer limitations and adding significance to performance of ERA in donor cycles where recurrent failure implicates an endometrial factor in implantation.
Trial registration number: N/A

P-422 The role of endometrial and circulating miRNAs in the recurrent implantation failure (RIF)

F. Azhari Zarnagh[1], **S. Pence**[1], **M.K. Hosseini**[2], **B. Karamustafaoglu Balci**[3], **N. Cevik**[4], **E. Bastu**[3], **T. Gunel**[2]
[1]*Institute of Aziz Sancar Experimental Medicine Research- Istanbul University, Molecular Medicine, Istanbul, Turkey*
[2]*Faculty of Science- Istanbul University, Molecular Biology and Genetic, Istanbul, Turkey*
[3]*Faculty of Medicine- Istanbul University, Obstetrics and Gynecology, Istanbul, Turkey*
[4]*Engineering- Architecture Faculty- Istanbul Arel University, Computer Engineering Department, Istanbul, Turkey*

Study question: Has the expression of endometrial and circulating miRNAs in two different phase of menstrual cycle significantly altered between RIF and the control group?
Summary answer: The study results showed that four selected miRNAs were significantly dysregulated in between RIF and control groups samples.
What is known already: In the menstrual cycle, it has been identified that endometrium specific miRNAs have different expression levels in endometrial tissues and maternal serum. A previous study has been suggested that miRNAs are related with mediating endometrial responses to maternal hormones and regulating the modulation from the proliferative into the secretory phase. Some Research demonstrated that endometrial miRNAs are altered in patients with

RIF, and suggested that they may be important regulators of endometrial receptivity and thus implantation success. Accordingly, these RIF-associated miRNAs might possibly be employed for diagnosis and treatment of embryo implantation failures.

Study design, size, duration: In this study, there are two groups; RIF and normal fertility samples which are collected as two blood and two endometrial biopsies in two different phase of mestural cycle. In first step, total RNAs are isolated from endometrium tissue and sera exosomes, next step is quantitative analyses of targeted miRNAs (hsa-miR-31, hsa-miR-30b, hsa-miR-145 and hsa-miR-23b) in samples and the last step is bioinformatic analysis of quantitative RT-PCR results. Study duration lasted from 2016 until 2019.

Participants/materials, setting, methods: In total, twelve RIF samples (age range, 25-38) and eight normal fertility samples (age range, 29-40) which were obtained as two peripheral blood and two endometrial biopsies; the proliferative phase (cycle day 7-10) and the secretory phase (cycle day 20-24). In this study, all of endometrial and serum miRNA exprassions are measured by quantitative real-time PCR (qRT-PCR) technique which is a high sensitive method for measures quantitatively expression of targeted miRNA in biological sample.

Main results and the role of chance: The significant feature of this study is the analysis of miRNA expression level in two different type of samples in same cases with colected sample in two varied menustral phase. In total, study results are dysregulated miRNAs selected by expression analyses in two different sample in RIF versus control groups. The statistical analysis showed that four selected miRNAs (hsa-miR-145, hsa-miR-23b, hsa-miR-31and hsa-miR-30b) were significant ($P<0.05$) up-regulated in proliferative phase and down-regulated in secretory phase of endometrium samples. In serum sample only two miRNA (hsa-miR-145 and hsa-miR-23b) was significantly down-regulated in both of proliferative phase and secretory phase. Target analysis for dysregulated miRNAs in different target scan databases (Target Scan, Miranda and Pictar) identified important, validated and predicted genes for implantation process. Pathway analysis of targeted genes showed critical pathways with $P<0.05$ which are related to cell important cell functions such as proliferation, apoptosis, invasion, adhesion and differentiation.

Limitations, reasons for caution: In this study, one of the challenge was endometrial biopsy step; the obtaining sample from normal fertile women in two different phase of menstrual cycle was difficult. Another challenge was exosomal RNA isolation step; the low concentrations of circulating RNAs limits the detection with Nanodrop (~2 ng/μL).

Wider implications of the findings: The findings of this study showed that selected miRNAs can be effective in the biological progression of the RIF. Finally, the results can create a basis for developing a new theory for the potential treatment of RIF and can be used for non-invasive molecular biomarkers in early diagnosis of RIF.

Trial registration number: This PhD thesis was supported by Istanbul University Scientific Research Projects Department (grant no. 20535)

P-423 RCT of the impact of the online lifestyle coaching platform 'Smarter Pregnancy' on modifying peri-conceptional behaviours in women presenting with subfertility or recurrent miscarriages.

K.Y.B. Ng[1], R. Steegers-Theunissen[2], S.P. Willemsen[3], S. Wellstead[1], Y. Cheong[1], N. Macklon[4]

[1]*University of Southampton Academic Unit of Human Health and Development, Princess Anne Hospital, Southampton, United Kingdom*

[2]*Erasmus MC, Department of Obstetrics and Gynaecology, Rotterdam, The Netherlands*

[3]*Erasmus MC, Department of Epidemiology, Rotterdam, The Netherlands*

[4]*London Women's Clinic, Fertility Clinic, London, United Kingdom*

Study question: Is the online lifestyle coaching platform 'Smarter Pregnancy' more effective at modifying peri-conceptional behaviours than standard advice offered by the UK National Health Service (NHS)?

Summary answer: This online lifestyle coaching platform is an effective alternative means of delivering lifestyle advice and modulating behaviours in women with reproductive failures.

What is known already: The impact of peri-conceptional lifestyle factors on fertility and pregnancy outcomes has been well described and clinical guidelines increasingly advise optimization of BMI, nutrition, smoking and other factors prior to attempting conception. The peri-conceptional intrauterine environment, which has been shown to be modulated by diet, is a determinant of early embryo development and programming. Modifiable lifestyle behaviours therefore have an impact on fertility, miscarriage risk, fetal development and on longer term health outcomes for future children. However, cost effective means of altering peri-conceptional lifestyle remain elusive. The use of an online personalized lifestyle coaching platform may address this challenge.

Study design, size, duration: Between June 2016 and August 2018, 400 women were recruited to a two centre randomised controlled trial comparing the impact of an online based, smartphone accessed personalised lifestyle coaching program to that of referral to an NHS provided information website.

Participants/materials, setting, methods: Women referred to two NHS clinics for treatment of subfertility or recurrent miscarriages who met the inclusion criteria were randomised to receive either the personalised online lifestyle coaching platform 'Smarter Pregnancy' or standard peri-conceptional advice provided by NHS websites. All participants were requested to complete a validated lifestyle questionnaire at baseline, 12 and 24 weeks. T-tests and chi-squared tests were used to compare differences in nutritional (vegetable and fruit) and folic-acid supplement intake between groups.

Main results and the role of chance: Of the 400 women recruited into the trial, 264 women were randomised (n=131 intervention group, n=133 control group). At baseline, for the intervention group, mean vegetable intake was 136.7g per day (standard deviation (s.d.) 83.0g) and mean fruit intake per day was 2.34 pieces per day (s.d.1.8 pieces/day). At baseline, for the control group, mean vegetable intake was 126.7g per day (s.d. 92.4g) and fruit intake was 1.96 pieces per day (s.d. 1.8 pieces/day). At 12 weeks, there was a significant difference in the mean fruit intake (intervention group 2.82 pieces per day (s.d.1.9 pieces/day) vs control group 2.02 pieces per day (s.d.1.7 pieces/day), p-value 0.001, 95% CI 0.33, 1.28), but no significant difference in the mean vegetable intake between the two groups was observed (intervention group 147.7g per day (s.d. 80.9g) vs control group 135.2g per day (s.d. 92.3g), p-value 0.28, 95% CI -10.2, 35.3) The folic acid intake was not significantly different between intervention and control groups at baseline, or 12 weeks after randomisation (At baseline: 91/124 for intervention group vs 96/130 for control group, p-value 0.58) and at 12 weeks: 79/108 for intervention group vs 91/116 for control group, p-value 0.44)

Limitations, reasons for caution: Although clinicians were blinded throughout, due to the nature of the study, it was not possible to blind women who were randomised. The women's diet and lifestyle were self reported through questionnaires and it was not possible to eliminate reporting biases.

Wider implications of the findings: This personalised online lifestyle coaching platform has the potential to be a useful adjunct to standard resources in modifying behaviours. It may represent an empowering and cost effective means of delivering peri-conceptional advice to women suffering from subfertility or recurrent miscarriages.

Trial registration number: ISRCTN 89523555

P-424 Rheumatic autoimmune diseases as a risk factor for primary ovarian failure - a case control study

M. Henes[1], S. Huebner[1], R. Katharina[1], J. Henes[2]

[1]*Universitats-Frauenklinik Tubingen, Department of Women's Health, Tübingen, Germany*

[2]*University Hospital Tuebingen, Centre for Interdisciplinary Clinical Immunology-Rheumatology and Auto-inflammatory Diseases, Tuebingen, Germany*

Study question: The objective of this study was to investigate the relation between premature ovarian failure (POF) and autoimmune diseases (AIDs).

Summary answer: We found a high prevalence of AIDs in patients with POF. Screening for AID should therefore be offered to every POF patient.

What is known already: Premature ovarian failure (POF) is defined as a hypergonadotropic amenorrhoea, persisting more than 4 months before the age of 40 years with elevated follicle stimulating hormone (FSH) and luteinizing hormone (LH) levels. This condition affects 0.3 - 1% of women

Study design, size, duration: This prospective study included patients with POF. Exclusion criteria were chromosomal abnormalities, chemo- or radiotherapy and ovarectomy. AMH was measured with electrochemiluminescence

(ECLIA; Roche diagnostics). The test measures concentrations between 0.01 – 23 ng/ml. Depending on age, normal values range from 0.77 – 9.49 ng/ml.
Participants/materials, setting, methods: From 2009 until 2017 52 consecutive women between the age of 18 to 40 years and POF were included and screened for AID at the department for rheumatology
Main results and the role of chance: In 40.4% (95% CI: 26.9-53.9%) of the patients at least one AID was detected. In more than half (57.1%) of the patients POF preceded the diagnosis of the AID. The average age for the first diagnosis for POF was 29.5 years (13-40 years). Most patients reported menopausal symptoms. All patients showed low AMH-values (Median: 0.05; 0.0-0.9 ng/ml). Without considering the quite common Hashimoto's disease, still 15.4% (95% CI: 7-28.1%) of the patients were diagnosed with a systemic AID like systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), psoriasis, Crohn's disease and celiac disease (both biopsy-confirmed), presenting with typical clinical symptoms and antibodies.
Limitations, reasons for caution: The relatively small number of patients in our study limits its significance, but up to now this is the biggest prospective study to show the high prevalence of AID in patients with POF. All our patients received the same standard diagnostic approach.
Wider implications of the findings: Autoimmune diseases can be found in around 40% of patients with primary ovarian failure and are associated with a poorer infertility treatment-outcome. Screening for autoimmune diseases therefore should be offered to all POF patients
Trial registration number: Ethics committee number:196/2009BO2

P-425 Endometrium epithelial cells from recurrent implantation failure (RIF) patients inhibit HTR8/SVneo cell proliferation, invasion, and promote apoptosis via exosomal pathway.

C. Liu[1]
[1]*Tongji Hospital- Tongji Medical College- Huazhong University of Science and Technology, Reproductive Medicine Center, Wuhan, China*

Study question: Could endometrial epithelial cell-derived exosomes of RIF patients impact embryonic development and implantation?
Summary answer: Exosomes derived from endometrial epithelial cell of RIF patients decreased embryo blastocyst formation rate, inhibited HTR8/SVneo cell proliferation, invasion, and induced apoptosis.
What is known already: Recurrent implantation failure is a clinical diagnosis which occurs in repeated good-embryo transfer without pregnancy. It is generally accepted that impaired endometrial receptivity and embryo-endometrium cross talk play significant roles in RIF. Exosomes, one of the extracellular vesicles, play important roles in mediating cell-cell communication. Recently, exosomes were identified within the uterine cavity of woman and they contributed to the implantation and embryonic development.
Study design, size, duration: Endometrial tissue samples in the late proliferative phase were obtained from women who undergone hysteroscope in two groups (RIF group: 14 women who underwent embryo transfer number at least 3 times without pregnancy; fertile group: 9 women who had a live birth or conceived in 2 years). Primary endometrial epithelial cells were isolated from samples and modulated by estrogen and progesterone to mimic the receptive-phase.
Participants/materials, setting, methods: Exosomes were isolated from the conditioned media by ultracentrifugation, and characterized by transmission electron microscopy and Western blot. Murine 2-cell embryos and HTR8/SVneo cells were treated by exosomes or PBS (control group). The blastocyst formation rate, hatching rate and blastomere count were counted. Exosomes labeled by 1,1-dioctadecyl-3,3,3'3'-tetramethylindotricarbocyanine-iodide fluorescent dye were tested endocytosis. HTR8/SVneo cell proliferation, apoptosis and invasion capacity were accessed by CCK8, immunofluorescence staining of caspase3 and transwell invasion assay.
Main results and the role of chance: The data showed that primary endometrial epithelial cells were able to secret exosomes with a biconcave morphological feature. Exosomes from RIF group significantly decreased the blastocyst formation rate (84.2%) compared to fertile group (97.1%) and control group (93.1%). Exosomes can be endocytosed by HTR8/SVneo cells. Compared to the control and fertile group, exosomes from RIF group inhibited HTR8/SVneo cell proliferation ($p<0.05$), invasion ($p<0.05$) and promoted apoptosis ($p<0.05$).
Limitations, reasons for caution: We used only in vitro methods to show the regulation of proliferation, apoptosis and invasion effects of exosomes. Thus, future studies should determine the mechanisms involved in this process.
Wider implications of the findings: This study found that endometrial epithelial cell derived exosomes participate in the regulation of embryonic development and implantation, especially in RIF patients. Inefficient maternal communication may be the pathology of RIF via exosome pathway.
Trial registration number: not applicable

P-426 Adjunction of paternal activated peripheral mononuclear cells (PBMCs) with autologous PBMCs to immune-modulate endometrium in cases of recurrent implantation failures (RIF).

H. Elloumi[1], **K. Mahmoud**[2], **S. Mnallah**[1], **M. Khrouf**[2], **M. Ben khelifa**[1], **F. Zhioua**[2], **M.H. Ben Aribia**[1], **K. Terras**[2], **L. Hamdoun**[2], **K. Neji**[2]
[1]*FERTILLIA, Laboratory of reproductive biology of the fertility center FERTILLIA, Tunis, Tunisia*
[2]*FERTILLIA, Gynecology departement of the fertility center FERTILLIA, Tunis, Tunisia*

Study question: Does intrauterine administration of co-cultured maternal and paternal PBMC improve pregnancy and implantation rates in patients with RIF?
Summary answer: Intrauterine administration of at least 2 millions of co-cultured maternal and paternal PBMC is an effective approach to improve embryo implantation in patients with RIF.
What is known already: The physiopathology of mechanism of RIF is not easy to define. Recently, immunological factors such as infammatory reaction, lymphocyte T helper 1/T helper 2 ratio and cytokines production have been proposed as the cause of endometrial receptivity defect.

Some studies suggested the role of endometrium immuno-modulation with maternal activated PBMC in implantation success. However, the effect of intra uterine insemination of mixed paternal and maternal activated PBMC before embyo transfer in RIF cases has not been studied enough. Indeed, paternal PBMC facilitate immune reactions including blocking antibodies.
Study design, size, duration: Prospective study conducted between February 2018 and January 2019. Thirty six couples with RIF were included.The patients were categorized into two groups with regard to their treatment type, autologous PBMC: group A (n=17) and co-cultured maternal and paternal PBMC: group B (n=19). Subgroups were defined according to the number of PBMC inseminated : $<$ 2 millions (Group A1 (n=8) and group B1 (n=9); and $\geq$ 2 millions (Group A2 (n=9) and group B2 (n=10).
Participants/materials, setting, methods: Mononuclear cells were isolated from patient's peripheral blood by density gradient centrifugation using commercially available lymphocyte preparation and then cultured for 3 days and transferred into the endometrium cavity prior to embryo transfer. All patients were selected on the following inclusion criteria: failure to achieve a pregnancy following a minimum of three IVF/ICSI cycles in which more than 5 high-grade embryos were transferred, age $<$40 years old, primary infertility and absence of uterine pathology
Main results and the role of chance: The median age of our patients was 36 years. Vitamin D level ranged from 15,3 to 78 ng/ml. The couples studied had a mean of 5 previous failed IVF cycles, and had been trying to conceive for a mean of 7 years. All patients had normal karyotype.

The pregnancy rates were significantly higher when at least 2 millions of co-cultured maternal and paternal PBMC were inseminated, group B2, (60%) in comparison respectively to group A1, A2 and B1 ((37,5%; 33%; 11%); ($p<0,05$). The implantation rate was also significantly higher in group B2 (35,3%) in comparison respectively to group A1, A2 and B1 ((18,7%; 26,6%; 8,7%); ($p<0,05$).

Main baseline characteristics and main ovarian stimulation outcomes had no statistically significant differences between groups A and B or between subgroups, nor did the number of embryo transferred per cycle.
Limitations, reasons for caution: Sample size must be increased and further studies are required to assess if ART outcome could be improved using our immunomodulation procedures in case of RIF.

In our study, sperm abnormalities patients were included which could not avoid the effect of sperm DNA fragmentation on implantation failure.

Wider implications of the findings: Further studies are needed to define other factors that may improve implantation rates in RIF cases.
Trial registration number: Not applicable

P-427 Hormonal stimulation modulating the expression of genes responsible for endometrial receptivity: an in vitro study

A. Luddi[1], V. Pavone[1], C. Marrocco[1], B. Semplici[1], L. Governini[1], V. De Leo[1], S. Luisi[1], P. Piomboni[1]
[1] *University of Siena, Molecular and Developmental Medicine, Siena, Italy*

Study question: To determine, in endometrial stromal cells, the impact of decidualization on the expression of genes involved in endometrial receptivity. Does hormonal hyperstimulation affect this profile?
Summary answer: *In vitro* decidualization affects the expression profile of genes involved in endometrial receptivity. Hormonal treatment mimicking ovarian hyperstimulation protocols seems to affect this specific fingerprinting
What is known already: Despite great progresses achieved by assisted reproductive techniques, the pregnancy rate still remains low, with implantation process representing one of the most crucial step. In this regard, endometrial receptivity is an essential prerequisite for a successful embryo implantation; alterations in development and maturation of the endometrium can cause implantation failure and infertility. Moreover, several evidences suggest that protocols of controlled ovarian hyperstimulation currently applied in assisted reproductive techniques may affect endometrial physiology, with possible negative effects on the embryo implantation
Study design, size, duration: We investigated the expression of 19 selected genes involved in endometrial receptivity using primary endometrial stromal cells (HESCs) isolated from endometrial tissue biopsies. Endometrial specimens have been obtained from healthy women who underwent surgical interventions starting from March to October2018 and signed an informed consent. Gene expression analysis of 19 genes involved in endometrial receptivity was carried out in primary HESCs, before and after decidualization, associated or not with FSH, LH, hCG treatment
Participants/materials, setting, methods: HESCs isolated from endometrial tissues collected from fertile women during implantation window have been exposed for 4 days to estrogen, progesterone and cAMP to mimic the decidualization process or with estrogen alone as a control. They have been treated for 24h with FSH alone or in combination with LH or hCG, reproducing the hormonal hyperstimulation conditions. mRNA extracted was subjected to qRT-PCR and the expression profiles of selected genes were evaluated by using precustomised array
Main results and the role of chance: Our results highlighted that most of the analysed genes, even if expressed in both decidualized and non-decidualized HESCs, are significantly modulated by *in vitro* decidualization process. The expression of several genes resulted to be significantly increased by decidualization: between others, *WNT4* and *SPP1*, genes codifying for proteins having role in cell-cell interactions, as well as *LIFR*, the LIF receptor. By contrast, *in vitro* decidualization significantly decrease the expression of *BMP2* and *IGF1*, genes encoding for multifactorial growth factors. Moreover, we observed that *in vitro* gonadotropins treatment significantly affects the gene expression profile of *WNT4* and *IGF1,* whose mRNA levels were reduced in both decidualized and non-decidualized HESCs. Interestingly, the treatment with FSH alone induced in non-decidualized cells an increase in WNT4 mRNA levels, and the treatment with FSH in combination with LH in IGF1 mRNA level in decidualized cells. *BMP2*, *SPP1*and *LIF* display an opposite trend of expression after the hyperstimulation treatment Before and after the decidualization process. Indeed, all hormonal treatments up-regulate LIFR mRNA levels.
Limitations, reasons for caution: The present results were obtained using primary endometrial stromal cells and *in vitro* decidualization protocols. In addition, different parameters may influence the response to hormonal hyperstimulation protocols, hence, further studies are necessary to elucidate whether these mechanisms operate similarly *in vivo*.
Wider implications of the findings: This approach allowed us to identify key genes whose expression is significantly modulated in decidualized compared to non-decidualized HESCs, also in response to hormonal hyperstimulation. This study, if replicated in a larger population, might contribute in understanding impact of the ovarian hyperstimulation protocols used in ART cycles
Trial registration number: Not applicable

P-428 Are endometrial receptivity assay results correlated with obstetrical outcomes and body mass index in patients undergoing embryo transfer in embryo transfer cycle immediately following assay

C. Mostisser, B.S.- M.D.[1], M. Pasternak[1], G. Schattman[2], Z. Rosenwaks[2]
[1] *Weill Cornell Medical College, Reproductive Medicine, New York, U.S.A.*
[2] *Cornell Weill Medical College, Reproductive Medicine, New York, U.S.A.*

Study question: Are pregnancy and live birth rates in the cycle subsequent to endometrial receptivity assay (ERA) increased, and is body-mass index (BMI) correlated with abnormal ERA.
Summary answer: There is a high rate of pregnancy and live birth in cycle subsequent to ERA for patients with adjusted and unadjusted embryo transfer (ET) cycles.
What is known already: The ERA test helps assess a woman's window of implantation (WOI) and optimize the time of ET. Up to 20-30% of women may have a displaced WOI, and for those who have failed previous ET with and without euploid blastocysts, this may be a useful tool to identify an individual's WOI and optimize ET timing. It is also possible that excessive adiposity leads to higher peripheral estrogen conversion, and thereby a higher rate of out-of-phase receptivity in the overweight/obese population due to an altered hormonal milieu.
Study design, size, duration: This is a retrospective observational study. Demographics of 35 patients undergoing ERA over an 18-month period were recorded. These patients had ERA performed due to failed implantation following multiple ART cycles.
Participants/materials, setting, methods: This is a single institution studyof patients who had undergone fresh ET cycles with high grade embryos, and/or frozen cycles with either genetically tested euploid blastocysts or untested high grade embryos. Patient age at ERA, BMI, and number and type of previous ET cycles were documented. Modifications to the subsequent ET cycle were performed when "non-receptive" test results were received. The correlation between ERA results and BMI was performed by chi-square analysis.
Main results and the role of chance: 43 ERA tests were performed for 35 patients; 8 patients had repeat biopsies during mock frozen ET cycles after hormonal/timing alterations due to non-receptive results. 22 patients had receptive results. Two patients had early/late receptive results, and subsequent adjustment by 12 hours of ET as recommended. 11 patients had pre- or post-receptive results, and subsequent ET cycles were adjusted accordingly. 25/35 patients proceeded with a subsequent frozen ET cycle subsequent to ERA. 22 patients achieved pregnancy in their next ET after ERA (88%); all 10 patients whose ET cycles were adjusted due to ERA results achieved pregnancy in their next cycle (100%), as did 12/15 (80%) with receptive ERA and unadjusted cycles. 13/22 pregnancies resulted in live birth (59.1%). 59% pregnancies occurred with euploid SET, and 41% with untested embryos. 11/35 patients had a BMI >25 (overweight or obese). 3/11 of patients with BMI>25 had abnormal ERA results (27%), while 8/24 women with BMI 19-25 had abnormal ERA results (33%) (p=0.36). As our sample population is 35 patients, the role of chance and possible regression to the mean in terms of success rates factors into our results
Limitations, reasons for caution: Our results did not confirm that BMI is related to endometrial receptivity, however, further investigation with a larger sample size is warranted to determine significance of our findings in terms of obstetrical outcomes, as well as the population to whom ERA is beneficial.
Wider implications of the findings: The high success rate in unadjusted ET cycles warrants further exploration as to whether the reason for success is related to changes in hormonal stimulation, or to the proximity of ERA and the endometrial effects of the biopsy on subsequent ET.
Trial registration number: N/A

P-429 Rnasequencing of trophectoderm cells biopsied from human blastocysts cultured in a new three-dimensional in vitro model reveal major pathways predicting implantation

W. Essahib[1], A. Aberkane[2], P. Verdyck[3], Y. Guns[4], C. Spits[5], I. Van Riet[6], S. Mackens[4], M. Debrucker[7], G. Verheyen[4], H. Tournaye[4], H. Van de velde[4]

[5]*Vrije Universiteit Brussel, Rege, Brussels, Belgium*
[6]*UZBrussels, Clinical Hematology, brussels, Belgium*
[7]*UZBrussels, gynecology, brussels, Belgium*

Study question: Can we use a three-dimensional *in vitro* model to study early human embryo implantation and do trophectoderm cells express predictive markers for embryo implantation potential?
Summary answer: This three-dimensional *in vitro* model sustains growth until day 14 of human embryo development. RNAsequencing of trophectoderm cells revealed key pathways decisive for embryo implantation.
What is known already: Successful implantation requires a receptive endometrium and a competent embryo, but little is known about the mechanisms regulating this crosstalk. Therefore understanding the first events of implantation is crucial. Identifying an objective criterium to select the embryo with the best implantation potential has been one of the most challenging aspect of artificial reproductive treatment. A number of models have been set up but so far only limited advancements have been achieved because of obvious ethical and technical restrictions (Teklenburg et al. 2009). Nevertheless studies have highlighted the crucial role of the trophectoderm cells during implantation (Ahlström et al. 2011).
Study design, size, duration: To set up the *in vitro* model 70 healthy oocyte donors were recruited. Between January 2014 and December 2018 they donated an endometrial biopsy on the day of pick-up. Day 5 good quality human blastocysts donated to research were warmed between 2014 and 2018 and cultured. Trophectoderm biopsies taken on day 6 were divided in two parts for (1) RNA sequencing and (2) DNA sequencing using Next Generation Sequencing (NGS). Twenty seven embryos were sequenced.
Participants/materials, setting, methods: This three-dimensional model was composed of decidualized stromal cells (using cAMP and Progesterone) embedded in Matrigel and a layer of Ishikawa cells. Day 6 biopsied human embryos were put in co-culture and after 48 hours the embryos were allocated to a group: "implantation" or "no implantation". Prolactine (PRL) and human Chorionic Gonadotropin (hCG) were analyzed by ELISA. Trophectoderm biopsies were analyzed with NGS using Illumina Hiseq and library preparation was obtained with SMARTseq.
Main results and the role of chance: To validate stromal cell decidualization PRL was measured in spent medium of the model after 72 hours of culture. Day 6 embryos were co-cultered in the three-dimensional model until day 14 of embryo development. Attachment and implantation were evaluated using the reaction of the embryos when pipetting the medium up and down. An invasion rate of 60% (16/27 blastocysts invaded) was achieved after 48 hours of co-culture. The invasion rate was confirmed with the measurement of hCG.

Trophectoderm biopsies obtained before co-culture were further matched to the fate of the embryos and allocated to the "implantation" or "no implantation" groups. DNA sequencing outcome (euploidy vs aneuploidy) could not be linked to the invasion capacity of the embryos. Unlike DNA, RNA sequencing with NGS revealed a number of pathways with differential expression in both groups such as WNT and epithelial-to- mesenchymal transition. Finally the presence of a number of miRNA's was specifically found in the "implantation" group.
Limitations, reasons for caution: Data from an *in vitro* model may not be extrapolated to the *in vivo* situation. The model is composed of Ishikawa cells showing similarities to primary epithelial cells but different mechanisms cannot be excluded. The absence of other cells present *in vivo*, like natural killer cells, may have an effect.
Wider implications of the findings: These findings support the role of trophectoderm cells during implantation and the capacity of the TE biospy to predict the pregnancy outcome. The pathways will lead to specific markers that could be used in the clinic to choose the best embryo and as a result reduce de time to pregnancy.

P-430 Anti-Müllerian Hormone levels after ovarian protection with gonadotropin-releasing hormone agonist during chemotherapy in breast cancer patients

Y.M. Choi[1,2], J.J. Shin[3], H. Kim[1], K.H. Lee[4], T.Y. Kim[4], W. Han[5], S.A. Im[4]

[1]*Seoul National University College of Medicine, Department of Obstetrics and Gynecology, Seoul, Korea- South*
[2]*Seoul National University College of Medicine, Medical Research Center- the Institute of Reproductive Medicine and Population, Seoul, Korea- South*
[3]*Heryoojae Women's Hospital, Fertility Center, Seoul, Korea- South*
[4]*Seoul National University College of Medicine, Department of Internal Medicine, Seoul, Korea- South*
[5]*Seoul National University College of Medicine, Department of Surgery, Seoul, Korea- South*

Study question: Is there is a difference in the ovarian protective effect among different administration timing of gonadotropin-releasing hormone (GnRH) agonist during chemotherapy in breast cancer patients?
Summary answer: There was no difference in ovarian protective effect among different timing of administration of GnRH agonist.
What is known already: GnRH agonists requires several days to achieve pituitary suppression. The effect of ovarian protection when chemotherapy has been administered before pituitary suppression is unknown.
Study design, size, duration: Prospective cohort study. Between October 2009 and August 2014, we included 93 breast cancer patients under age 40 who had their anti-Müllerian hormone (AMH) evaluated at least once after chemotherapy.
Participants/materials, setting, methods: Breast cancer patients received GnRH agonist at least one day prior to- and during chemotherapy. Serum AMH was measured before and 12 months and 24 months after completion of chemotherapy. The AMH value was compared among the three groups, divided by the date difference between the GnRH agonist start day and the chemotherapy start day: 1-6 days, 7-13 days, and 14 days or more
Main results and the role of chance: The mean age of subjects was 32.3 $\pm$ 4.7 years. There was no difference in the initial AMH levels among the three groups (5.4 $\pm$ 3.2 ng/ml, 5.3 $\pm$ 6.2 ng/ml, and 6.4 $\pm$ 3.8 ng/ml in the 1-6 days group, 7-13 days group, and 14 days or more groups, respectively, P = 0.23). Among the 93 women initially included, AMH value was available in 57 women at 12 months. The mean AMH levels at 12 months were 1.8 $\pm$ 2.2 ng/ml, 2.0 $\pm$ 2.5 ng/ml, and 1.6 $\pm$ 1.3 ng/ml in the three groups, respectively, and there was no statistically significant difference among them (P = 0.87). The AMH value was available in 38 patients at 24 months, and also did not show significant difference across groups (1.6 $\pm$ 1.7ng/ml, 1.5 $\pm$ 2.0 ng/ml, and 1.3 $\pm$ 0.9 ng/ml, respectively, P = 0.91).
Limitations, reasons for caution: Limited number of patients were available at 12 months'- and 24 months' follow up.
Wider implications of the findings: The action of GnRH agonist on ovarian protection, when administered at least one day prior the chemotherapy, works equally regardless of the timing of administration.
Trial registration number: None

P-431 A six-year experience of social freezing and IVF after warming oocytes

M.J. Lopez Martin[1], D. Garcia[1], R. Vassena[1], A. Ridríguez[1]

[1]*Clinica Eugin, Assisted reproduction, Barcelona, Spain*

Study question: Which are the current outcomes of social egg freezing?

Summary answer: Of all the women that vitrified their oocytes in a six-year period, 5.7% have returned to used them, with a 19% live birth rate.

What is known already: For several decades now, the mean age at which women have their first child has increased across developed countries. This has lead to a steady increase in age related sterility, as well as a demand of assisted reproduction techniques. The main reason given by women for their delayed motherhood is the lack of a suitable partner, over other reasons like accomplishment of education or career goals. Social oocyte vitrification has been proposed as an option for women who decide to postpone maternity due to sociodemographic changes, however, large studies on the outcomes of this technique are still lacking.

Study design, size, duration: Retrospective cohort study of women who underwent a social oocyte vitrification treatment, between 2011 and 2017, in one private fertility clinic**.**

Participants/materials, setting, methods: 1,519 women sought information to freeze their oocytes. Of these, 1,006 started a stimulation cycle, and 860 had their oocytes vitrified. As 197 women underwent stimulation more than once, 1284 vitrification cycles were performed in total.

Main results and the role of chance: The mean age at the time of vitrification was 37.5±3.17, with a steady and encouraging decrease in age at treatment, from 40 years in 2011 to 36.6 in 2017. The mean number of cumulus-oocyte complex (COC) and metaphase II (MII) obtained were 10.4±8.07 and 7.9±6.32, respectively. There were 12% (n=164) cancelled cycles and 0.3% (n=35) cases without any MII at ovum pick-up. On average, each woman underwent 1.26 stimulation and vitrification cycles. During this period, 67 ET were scheduled (from 57 patients), of which 63 were finally performed (2 fertilization failure after ICSI, 1 no survival after warming and 1 no ET due to PGT-A results). The mean age at the time of ET was 41.4 years (for these women, mean age at vitrification was 38.5 years). Of the women that came back to use their oocytes, 55.6% performed IVF with a male partner, while the others opted for donor semen. Biochemical, clinical, ongoing pregnancy and live birth rates were 30.2%, 23.4%, 23.4% and 19%, respectively.

Limitations, reasons for caution: Only 5% of women who vitrified their oocytes used them during the time of the study and mean age for these women was higher than average for the program. Therefore, IVF results of these women may not be representative of the population of women who vitrified oocytes**.**

Wider implications of the findings: Although the age of women who have vitrified their oocytes has been decreasing in the last years, more educational efforts are needed to further decrease the age at vitrification, in order to improve the reproductive results associated to this technique.

Trial registration number: not applicable

P-432 Oocyte cryopreservation for fertility preservation in women with ovarian endometriosis

S. Kim[1,2], S.K. Kim[1,2], J.R. Lee[1,2], C.S. Suh[1,2], S.H. Kim[2]

[1] *Seoul National University Bundang Hospital, Obstetrics and Gynecology, Seongnam, Korea- South*

[2] *Seoul National University College of Medicine, Obstetrics and Gynecology, Seoul, Korea- South*

Study question: Is the oocyte cryopreservation feasible fertility preservation (FP) option for women with ovarian endometriosis (endometrioma)?

Summary answer: In women with endometrioma, oocyte cryopreservation before ovarian cystectomy could be a feasible option for FP.

What is known already: Ovarian endometriosis by itself reduces the ovarian reserve by affecting ovarian physiology in the healthy ovarian tissue surrounding it. Ovarian cystectomy is a treatment option for endometrioma in most cases. However, ovarian cystectomy has been associated with a risk of diminished ovarian reserve. Women with endometrioma are at a higher risk of decreased ovarian reserves and are potential candidates for FP. However, there are few published papers on the topic of FP in endometriosis.

Study design, size, duration: This retrospective study was conducted at a tertiary university hospital. We performed controlled ovarian stimulation (COS) and oocyte cryopreservation in 26 women with endometrioma before a planned ovarian cystectomy between May 2016 and October 2018.

Participants/materials, setting, methods: Clinical characteristics and the COS results were analyzed in 26 women with endometrioma before a planned ovarian cystectomy. We compared COS outcomes of the first cycle in FP patients with endometrioma with the COS outcomes in infertile patients without endometrioma who underwent in vitro fertilization treatment (24 patients owing to male, tubal, or unexplained cause). We analyzed the number of oocytes cryopreserved in repeated COS cycles and evaluated the differences between the cycles.

Main results and the role of chance: The median [interquartile range] of endometrioma size was 5.3 [3.9, 7.1] cm. The median age and serum anti-Mullerian hormone (AMH) levels of the women were 30 [26, 38] years and 1.38 [1.00, 2.34] ng/mL, respectively. The number of oocytes retrieved and the number of oocytes cryopreserved were 5.0 [3.0, 8.0] and 4.0 [2.0, 7.0], respectively. Despite there being no difference in the AMH levels in patients with bilateral and unilateral endometriomas, the number of oocytes cryopreserved was lower in patients with bilateral endometrioma (5.5 [3.8, 8.3] vs. 3.0 [2.0, 6.0], p=0.044). Although the ages were similar, the AMH level was significantly lower in the FP patients with endometrioma compared to that in infertile patients without endometrioma (1.38 [1.00, 2.34] vs. 3.35 [2.14, 4.20] ng/mL, p<0.001) The number of oocytes retrieved was lower in the FP patients with endometrioma, but not statistically significant (4.0 [3.0, 8.0] vs. 7.0 [4.3, 11.0], p=0.069). Total 10 (38.5%) patients with endometrioma obtained more oocytes through more than one COS cycle. Retrieved oocyte number at the first, the second, and the third cycle were 3.0 [2.0, 6.0], 4.5 [2.0, 7.3], 3.0 [2.0, 7.5], respectively.

Limitations, reasons for caution: The retrospective study design and the small number of study subjects are limitations. We showed only the result of oocyte cryopreservation, and further studies are needed to evaluate the results after thawing.

Wider implications of the findings: Women with endometrioma should be counseled about oocyte cryopreservation for FP before surgery. The optimal number of oocytes for cryopreservation can be secured by repeated oocyte retrieval.

Trial registration number: not applicable

P-433 Is vitrification damaging oocytes? Results from 37.520 fresh and vitrified sibling donor oocytes

A. Rodriguez Aranda[1], D. Cornet-Bartolomé[1], D. García[1], M. Barragan[1], R. Vassena[1]

[1] *Eugin Euvitro SLU, Reproduction, Barcelona, Spain*

Study question: Are reproductive outcomes of IVF cycles with vitrified donor oocytes comparable to IVF cycles with fresh donor oocytes?

Summary answer: IVF with vitrified donor oocytes provides similar reproductive outcomes to fresh oocytes when the same number of oocytes is available for fertilization after warming.

What is known already: Oocyte vitrification is used to preserve the reproductive potential of oocytes. Several RCTs, carried out by highly trained and experienced groups have shown that this technique provides comparable reproductive outcomes to the use of fresh oocytes. However, large registries analyses have consistently reported lower live birth rates after using vitrified oocytes. It is not clear whether this decrease may be due to an inherent damage that vitrification causes to the oocytes or to the lower efficiency of the technique, as a variable proportion of the allocated oocytes (around 10% even in the best laboratory conditions) do not survive warming.

Study design, size, duration: Retrospective cohort analysis of 1,844 cycles of oocyte donation, each woman providing sibling oocytes for at least one recipient of fresh oocytes (2,562 cycles) and one other of vitrified oocytes (2,472 cycles), representing a total of 37.520 MII sibling oocytes included in this study. All recipient cycles (n=5,034) were carried out between 2011 and 2017 (embryo transfer date).

Participants/materials, setting, methods: Differences in reproductive outcomes between groups were evaluated using Chi^2 tests and regression analysis adjusted for recipient's age, BMI, sperm origin (patient/donor), sperm state (fresh/frozen), day of ET, morphological score and number of transferred embryos. In addition, we performed a subanalysis of 1,336 IVF cycles where the number of inseminated oocytes was the same for the recipients of fresh and vitrified oocytes to test whether vitrification/warming efficiency impacts reproductive results.

Main results and the role of chance: Baseline characteristics of recipients and number of inseminated and fertilized MII were comparable between groups. Overall, vitrified oocytes provided lower reproductive outcomes than their sibling fresh oocytes: ongoing pregnancy (32.4% vs 37.9%; p<0.001) and live birth (31% vs 36.2%; p<0.001). When the number of inseminated oocytes was the same for fresh and vitrified donor cycles, reproductive outcomes in recipients became comparable: ongoing pregnancy (33.5% vs 34.1%; p=0.82) and live birth rate (32.1% vs 32%; p=0.97), indicating that the efficiency of the vitrification process, rather than an intrinsic oocyte damage due to vitrification, affects the reproductive outcomes of oocytes. The multivariable analysis confirmed these results; the OR (95%CI) of vitrified vs fresh oocytes was 0.869 (0.764, 0.990) for ongoing pregnancy and 0.882 (0.773, 1.006) for live birth at the main analysis; and 1.110 (0.865, 1.425) for ongoing pregnancy and 1.150 (0.892, 1.483) once controlling for oocyte loss due to warming. In summary, when the allocation of oocytes to recipients provides the same number of oocytes after warming than would be allocated fresh, reproductive results up to live birth are comparable.
Limitations, reasons for caution: An open vitrification system was used for all cases, and oocyte vitrification/warming was performed by experienced embryologists with consistently high survival rates; caution must be exerted when extrapolating our results to closed vitrification systems or to IVF units with survival rates <90%.
Wider implications of the findings: This is the biggest cohort study comparing reproductive outcomes of vitrified and fresh sibling donor oocytes so far. Our results indicate that vitrification *per se* does not affect oocyte developmental competence; we recommend implementing strict indicators of vitrification/warming efficiency in clinics, and developing vitrification/warming protocols to maximize oocyte survival.
Trial registration number: not applicable

P-435 Isolation and in vitro maturation of immature oocytes from a small piece of ovarian tissue in fertility preservation treatments.

J.E. Dietrich[1], J. Liebenthron[2], J. Jauckus[1], S. Hoffmann[1], J. Liebscher[1], T. Strowitzki[1], A. Germeyer[1]
[1]*Heidelberg University Women's Hospital, Department of Gynecologic Endocrinology and Fertility Disorders, Heidelberg, Germany*
[2]*Universitäts-Frauenklinik Düsseldorf, Universitäre Cryobank für assistierte Reproduktionsmedizin und Fertilitätserhalt Düsseldorf, Düsseldorf, Germany*

Study question: Can immature oocytes retrieved during the ex-vivo preparation of ovarian tissue prior to cryopreservation be matured in vitro, fertilized and cryopreserved for future fertility treatments?
Summary answer: Immature oocytes can be successfully retrieved from ovarian tissue, matured in vitro, fertilized and cryopreserved for future fertility treatments.
What is known already: Fertility preservation in women prior to gonadotoxic therapies can be achieved by the cryopreservation of ovarian cortical tissue. Immature oocytes recovered during the preparation can be matured in vitro and lead to live births, thereby providing an additional option for fertility preservation (Fasano et al., 2017; Prasath et al). Here, the feasibility of this approach in a setting with unilateral biopsy of a small piece of ovarian tissue and minimal tissue preparation prior to shipment to an external cryo-bank was tested.
Study design, size, duration: Feasibility study at the University Women's Hospital Heidelberg (Germany) initiated in December 2017. Until December 2018 n= 9 patients requiring chemotherapy were recruited and provided written informed consent, of which n= 2 decided not to undergo ovarian tissue extraction. Unilateral biopsy of approx. 50% of ovarian tissue was performed on n= 7 patients. The tissue was minimally prepared by separation of the cortex from the medulla before shipment to an external cryo-bank.
Participants/materials, setting, methods: An unilateral biopsy of approx. 50% of the ovary was performed on n= 7 female patients. Immature oocytes were retrieved during minimal preparation of ovarian tissue before transport for cryopreservation in an external cryo-bank. In vitro maturation was performed as described previously (Roesner et al., 2017). Intracytoplasmic sperm injection (ICSI) was performed either directly or after vitrification of Metaphase II (MII) oocytes (Kitazato, 91171, 91182). Pronuclear stage oocytes were cryopreserved by slow freezing (Vitrolife, 10166).
Main results and the role of chance: The patient's age was 20 to 33 years (25.6 ± 5.0 years (mean ± stdev); n= 7). The anti-Müllerian hormone level (AMH) ranged from 0.65 to 8.15 ng/ml (4.1 ± 3.1 ng/ml (mean ± stdev)). The number of immature oocytes recovered was n= 23 (n= 1 – 8 (min. – max.); 3.3 ± 2.2 (mean ± stdev)). The maturation rate after 24 hours was 34.8% (n= 8/23). MII-oocytes were either vitrified (n= 3, n= 3 patients) or directly used for ICSI (n= 5, n= 3 patients) with a fertilization rate of 60.0% (n= 3/5). Pronuclear stage oocytes were cryopreserved (n= 3). Vitrified MII-oocytes were warmed (n= 2, n= 2 patients) with a post-warming vitality rate of 50.0% (n= 1/2) and used for ICSI with a fertilization rate of 0% (n= 0/1, n= 1 patient).
Limitations, reasons for caution: A limitation of this study is the small sample size. No embryo culture and transfers were performed so far because of fertility preservation purposes in cancer patients, therefore no conclusion on the oocyte's developmental potential and clinical outcomes can be drawn. Fertilization of vitrified MII-oocytes still needs to be shown.
Wider implications of the findings: This study shows that immature oocytes can be successfully recovered from small unilateral pieces of ovarian tissue during minimal preparation. In agreement with data from Fasano et al. (2017) these oocytes can be matured in vitro and fertilized, thereby contributing to the fertility preservation treatment offered to patients.
Trial registration number: The study was approved by the Ethics Committee of the Medical Faculty Heidelberg (S-222/2017) and registered at the DRKS (registration number DRKS00013170).

P-436 Key recommendations for high quality female oncofertility care based on international clinical practice guidelines

Ö. Baysal[1], M. Van den Berg[1], F. Beldman[1], D. Braat[1], W. Nelen[1], R. Hermens[2], C. Beerendonk[1]
[1]*Radboud university medical center, Obstetrics and Gynaecology, Nijmegen, The Netherlands*
[2]*Radboud University Medical Centre, IQ Healthcare, Nijmegen, The Netherlands*

Study question: Which guideline-based key recommendations can be selected for high quality female oncofertility care?
Summary answer: A set of eleven key recommendations for high quality female oncofertility care was selected to enable future oncofertility care monitoring and improvement.
What is known already: Young women scheduled to undergo gonadotoxic therapy are at risk to become infertile. To ensure the ability for biological children, care activities to preserve fertility are necessary. However, this oncofertility care is still suboptimal. Evidence based key recommendations (KRs) for high quality female oncofertility care have to be selected to identify and monitor the specific needs of improvement.
Study design, size, duration: To select a set of KRs for female oncofertility care, the Delphi method was used. First, recommendations from (inter)national clinical practice guidelines were selected in four domains: risk communication, referral, counselling and decision-making. Thereafter, they were scored, per domain, on their importance for high quality oncofertility care in two Delphi rounds. Finally, the selected KRs were presented for approval in a third round.
Participants/materials, setting, methods: A multidisciplinary, national oncofertility expert panel, consisting of patients, referrers, and counsellors, participated in the three online questionnaires' rounds. Differences in perspectives between subgroups of the expert panel were analysed.
Main results and the role of chance: The expert panel (N=86) selected eleven KRs for high quality female oncofertility care. KRs in the domains risk communication and referral focused on information provision and offering referral to a reproductive specialist to female cancer patients. Regarding the counselling domain, KRs focused on all aspects of counselling including different methods, safety, and pros and cons. In the decision-making domain, KRs focused on shared decision-making and supporting the decision with written information. The final set of selected KRs was approved by 91% of the experts. Differences in perspectives were found between subgroups, particularly patients found recommendations regarding decision-making and information provision more important than referrers and counsellors.

Limitations, reasons for caution: Expert panel's opinions were obtained through online questionnaires, which could have led to the lack of subtleties provided by a face-to-face discussion. However, by using online questionnaires, participants from all over the country could take part and they could not be influenced by the (strong) opinions of other participants.
Wider implications of the findings: After transcribing these KRs into quality indicators, these are well suited as a measuring tool for identifying problems and improving the quality of female oncofertility care and quality of life in survivors in the Netherlands and internationally.
Trial registration number: Not applicable

P-437 In vitro activation (IVA) of follicles: effective in human frozen-thawed ovarian tissue but influenced by the type of incubation medium and its volume

I. Virant - Klun[1], S. Frkovic-Grazio[1], V. Salamun[1], N. Jancar[1], E. Vrtacnik-Bokal[1]
[1]University Medical Centre Ljubljana, Department of Obstetrics and Gynaecology, Ljubljana, Slovenia

Study question: Does the type of culture medium and its volume affect the frozen-thawed ovarian tissue (follicles, stroma) during the in vitro activation of follicles?
Summary answer: In vitro activation of follicles is effective in the frozen-thawed ovarian tissue, but is affected by the type of culture medium and its volume.
What is known already: In vitro activation (IVA) of follicles in the ovarian tissue with PTEN inhibitor and phosphatidylinositol-3-kinase stimulator and re-transplantation is a promising method of assisted conception. During IVA procedure, the ovarian tissue is incubated in the medium with activators for 48 hours, which may impair the tissue (structure, vitality, and DNA fragmentation of follicles/oocytes) and success of subsequent transplantation. Therefore, the aim of this study was to elucidate whether the type of culture medium (simple, for IVF designed and tested Flushing Medium vs. complex DMEM-F12 medium) and its volume affect the quality of frozen-thawed ovarian fragments (follicles, stroma) treated with IVA.
Study design, size, duration: During two years, the ovarian tissue of one patient (female-to-male transgender surgery) was slowly frozen (25 cryotubes), thawed, sub-fragmented, and exposed to activators of follicles bpV(Hopic) and 740YP, diluted in two different culture media: complex DMEM-F12 and Flushing Medium of two volumes (1 and 5 ml). After thawing and 48-hour incubation in the medium with activators or without them, the ovarian fragments were compared in terms of histology, vitality, and DNA fragmentation of follicles/oocytes.
Participants/materials, setting, methods: The ovarian (cortex) fragments were frozen using the slow freezing with 1,2-propanediol and sucrose (Fabbri et al., 2010). After rapid thawing, they were treated with bpV(Hopic) and 740YP for 24 hours and with 740YP alone for another 24 hours in a complex DMEM-F12 (+$NaHCO_3$/glucose/L-glutamine/albumin) or Flushing medium (+HEPES; Origio). To evaluate the histology, vitality, and DNA fragmentation of tissue/follicles, the hematoxylin-eosin staining, vital stains (Trypan Blue, Neutral Red), and Roche DNA fragmentation kit were used.
Main results and the role of chance: Just after thawing, the histology of the ovarian tissue was quite comparable to the fresh tissue of the same patient. The IVA procedure significantly decreased the proportion of optimal – the best preserved follicles (oocyte nucleus/chromatin, follicular cells) and increased the proportion of vital but suboptimal (less preserved) follicles, and dead follicles in comparison to the tissue just after thawing regardless of the culture medium (7.5 %, 89.0 %, 3.5 % vs. 97.1 %, 2.9 %, 0 %; $P<0.01$, Chi-Square Test). In the ovarian fragments cultured in the DMEM-F12 and Flushing Medium there was a relatively high and comparable proportion of vital/alive follicles (98.0 % vs. 94.7 %) and more growing follicles after the IVA procedure, as revealed by histology and vital staining (Neutral Red, Trypan Blue). However, the incubation of ovarian fragments in the Flushing Medium resulted in a less-preserved stroma with a mass of pycnotic cells and a higher proportion of follicles/oocytes with DNA fragmentation. In the optimal DMEM-F12 medium the histology of ovarian tissue was favorable, with more optimal and less dead follicles, when cultured in a higher volume of medium (5 ml: 8.7 %, 0 % vs. 1 ml: 0 %, 3.9 %; $P < 0.05$).
Limitations, reasons for caution: To establish the optimal condition, different culture conditions were tested and analyses performed in the ovarian tissue of the same patient to avoid the bias due to heterogeneity of the ovarian tissue. In the next step, this procedure will be applied to the ovarian tissue of different patients.
Wider implications of the findings: In vitro activation of follicles is effective in the frozen-thawed ovarian tissue and is promising for oncological and infertile patients with cryopreserved ovarian tissue, when optimal. It allows the infertility treatment in women with severe ovarian infertility and residual follicles in their ovaries (e.g., premature ovarian failure, low ovarian reserve).
Trial registration number: Approved by the Slovenian Medical Ethical Committee: 0120-484/2017/4
Trial registration number not needed.

P-438 Systematic proposal of fertility preservation (FP) by oocyte freezing in patients with recurrent benign ovarian tumors (BOT)

L. Keller[1], Y. Dadoune[2], A.L. Barbotin[1,3], E. D'Orazio[2], P. Collinet[4], C. Rubod[5], C. Decanter[2,3]
[1]Lille University Hospital, Reproductive Biology Institute, Lille, France
[2]Lille University Hospital, Department of Gynecology and Reproductive Medecine, Lille, France
[3]Lille University, EA4308 gametogenesis and gamete quality, Lille, France
[4]Lille University Hospital, Department of gynecologic surgery, Lille, France
[5]Lille University Hospital, Department of gynaecologic surgery, Lille, France

Study question: How about COH outcomes in terms of mature oocytes number and risks-benefits balance in case of oocyte freezing for fertility preservation in patients with recurrent BOT ?
Summary answer: Oocyte accumulation is recommended in young patients with BOT to have sufficient frozen oocytes and further chances of pregnancy.
What is known already: Benign ovarian cysts are frequent during women's life. They are diagnosed with pelvic pain or fortuitously during an ultrasonographic exam. In some case, cysts are recurrent and multiple surgeries are needed leading to a significant risk of ovarian damage by follicular depletion. To date, there is no cohort study dedicated to fertility preservation by oocyte freezing in this specific subgroup of patients. An effective strategy of fertility preservation has to be evaluated and propose for these young patients.
Study design, size, duration: This is a prospective observational study performed from 2014 to 2018 at the IVF centre of the Lille University Hospital. All women, age between 18-35 years, with recurrent ovarian cysts were proposed to an oocyte accumulation program (1 to 3 ovarian stimulation cycles) to preserve their fertility. The primary endpoint is to evaluate the efficiency in terms of metaphase II oocytes number. The secondary end-point is to assess safety and compliance to the procedure.
Participants/materials, setting, methods: 54 patients were included and 81 FP cycles were analysed. COH was performed by using antagonist protocols after baseline ovarian reserve assessment (AMH measurement and sonographic antral follicle count). Triggering was achieved by hCG when at least 3 follicles reached a 18mm diameter. Mature oocyte vitrification was realized 2 hours after retrieval in a closed device. (Rapidl Kit Vitrolife®). Statistical analysis was performed with the SAS Software V9.3 by the Biostatistics Unit of Lille's Hospital.
Main results and the role of chance: 54 patients, 50% with endometriomas (endometriosic group) and 50% with dermoid/mucinous cysts (non-endometriosic group) were included with a mean age of 26.7 ± 4.9 years. Mean AMH levels were 12.4 ±9.2 pmol/L (2;43). The mean number of total retrieved oocytes per cycle was 6.9 ± 4.6 (0;19). The mean number of Metaphase II oocytes per cycle was 4.6 ± 3.7 (0;16). We found a high proportion of patients (37%) exhibiting a poor ovarian response (i.e. less than 4 mature oocytes) at the first cycle. To date, 21 patients achieved 2 or 3 cycles. After accumulation, a mean number of 8.8 M2 vitrified oocytes per patient were obtained. 54% of patients had more than 8 meta II oocytes frozen after accumulation. AMH levels were strongly correlated to the Meta II oocyte number but did not appear to be predictive according to the ROC curve analysis (AUC=0.75, sensibility = 0,63; specificity=0.75).

No difference was found between endometriosic and non-endometriosic groups.

No serious adverse events occurred and the procedure was well tolerated by patients.

Limitations, reasons for caution: Our results are preliminary. Long-term follow-up is needed in order to assess the efficiency, clinical relevance and cost-effectiveness of the procedure through the analysis of reutilization and further pregnancy rates.

Wider implications of the findings: The mean number of vitrified mature oocytes after only one COH cycle in young patients with history of recurrent ovarian cysts and surgery is too low to further provide good chances of pregnancy. Hence, oocyte accumulation may be proposed as it appears to be well-tolerated and safe for patients.

Trial registration number: not applicable

P-439 Predictors of oocyte yield in social egg freezing

J. Green[1], B. Jones[2], A. Petrie[3], G. Morris[4], R. Odia[5], P. Serhal[6], J. Ben-Nagi[6]

[1]*CRGH, Nursing, London, United Kingdom*

[2]*Imperial College London, Surgery and Cancer Institute of Reproductive & Developmental Biology, London, United Kingdom*

[3]*University College London, Department of Statistics, London, United Kingdom*

[4]*University College London Hospital, Reproductive Medicine Unit, London, United Kingdom*

[5]*The Centre for Reproductive & Genetic Health, Embryology, London, United Kingdom*

[6]*The Centre for Reproductive & Genetic Health, Clinical, London, United Kingdom*

Study question: Can oocyte yield in social egg freezers be predicted by clinical, biochemical and radiological markers?

Summary answer: Age and BMI, along with oestradiol level and number of follicles >12mm at trigger can help predict oocyte yield in Social Egg Freezing (SEF) cycles.

What is known already: SEF offers women the opportunity to preserve their reproductive potential prior to the inevitable decline in ovarian reserve. Extensive counselling is essential to ensure women are fully informed, including the possibility of unsuccessful treatment in the future with a finite number of stored eggs. To minimise this risk, the timing of vitrification and determination of how many oocytes to store is important. However, other than age, there is currently little evidence to determine other factors that predict the number of oocytes retrieved in SEF.

Study design, size, duration: This was a retrospective cohort study which included 315 SEF cycles in a single fertility clinic in the United Kingdom between 2008-2018.

Participants/materials, setting, methods: The number of oocytes retrieved from 315 SEF cycles was calculated. Clinical, biochemical and radiological data including age, body mass index (BMI), anti-Mullerian hormone (AMH), antral follicle count (AFC) and oestradiol level and total number of follicles >12mm at trigger were assessed. Numerical variables were summarised by the median and range. Multivariable Poisson regression was used to evaluate the impact of each variable, whilst adjusting for the other variables, on the number of oocytes retrieved.

Main results and the role of chance: The median (range) for the variables of interest were: total number of oocytes retrieved per cycle 7 (1-37); number of metaphase II oocytes 6 (1-23); age 38 (29-45) years; BMI 22 (17-34) kg/m2; baseline AMH 10.0 (0.7-98.3) pmol/l; AFC 11 (1-47); oestradiol level at trigger 6744 (557-23924) pmol/l; total number of follicles >12mm at trigger 9 (1-69). Multivariable Poisson regression demonstrated that an increase in age by one-year results in a statistically significant 4% decrease in yield after adjusting for all other variables (IRR 0.96; 95% CI 0.94-0.98; p< 0.001). BMI (IRR 1.02; 95% CI 1.00 -1.03; p=0.04), oestradiol level per 1000 pmol/l increase (IRR 1.05; 95% CI 1.04 -1.07; p<0.001) and the number of follicles >12mm at trigger (IRR 1.02; 95% CI 1.01-1.03; p<0.001) were all significant independent predictors of oocyte yield. There was no significant effect on oocyte yield of either AFC (IRR=1.00; 95% CI 0.99-1.02 p=0.43) or AMH (IRR 1.00; 95% CI 0.99 – 1.01; p=0.71).

Limitations, reasons for caution: The data from this study was retrospective and from a single centre.

Wider implications of the findings: Our data demonstrates that age, BMI, oestradiol level and number of follicles >12mm at trigger can all be used to help predict oocyte yield in SEF cycles. This information can be used to optimise counselling in SEF, help manage expectations and guide decisions over future treatment.

Trial registration number: Not applicable

P-440 Novel cryopreservation medium reduces post-thaw oxidative stress and improves viability/survival

S. Gupta[1], A. Agarwal[1], R. Sharma[1], M. Rana[1], M.K. Panner Selvam[1], R. Henkel[1,2]

[1]*Cleveland Clinic, American Center for Reproductive Medicine- Department of Urology, Cleveland, U.S.A.*

[2]*University of the Western Cape, Department of Medical Bioscience, Bellville, South Africa*

Study question: Does the new cryopreservation medium improve sperm parameters and provide better cryoprotection from injury and oxidative stress (OS) -induced damage compared with other sperm freezing media?

Summary answer: The novel sperm freezing medium preserves sperm vitality and confers protection from oxidative stress induced injury compared with established media for all subjects.

What is known already: Cryopreservation allows men to preserve their fertility. However, cryopreservation greatly reduces sperm parameters and increases DNA damage. The addition of cryopreservation-media maintains post-thaw sperm parameters including post-thaw motility. The use of glycerol, animal versus human protein, antioxidants, and other additives in cryomedia remains highly debatable. The use of egg yolk lacks clinical popularity due to its potential to elicit antibody production in the vaginal canal and its associated risk of prion disease. A novel media called Arctic sperm cryopreservation medium (ASCM) is free from animal protein and has a dual buffering capacity because of presence of HEPES and MOPS.

Study design, size, duration: Semen samples from 22 normozoospermic donors and 20 infertile men were examined for sperm concentration, motility, viability, oxidation-reduction potential (ORP), and sperm DNA fragmentation (SDF). ORP was measured using MiOXSYS system and SDF by TUNEL assay using bench flow cytometer. Identical freezing protocols were used using Arctic sperm cryopreservation medium ;ASCM and another competitive medium called Origio sperm freezing medium; OSFM) but with different dilution ratios (ASCM: 1:3 and OSFM: 1:1) as per manufacturer instructions.

Participants/materials, setting, methods: Samples were randomized for freezing with ASCM or OSFM. Pre-freeze and post-thaw sperm concentration, motility, ORP and SDF were measured. For cryopreservation, samples were cooled to 4°C for 10 minutes, placed in liquid nitrogen vapors for 60 minutes, and then submerged in liquid nitrogen for 24 hours. Samples were thawed and same pre-freeze parameters were measured post-thaw. Data was analyzed using independent t-test or Mann-Whitney Test and 95% confidence intervals (CI) were used.

Main results and the role of chance: The baseline pre-freeze and post-thaw semen parameters such as sperm concentration, motility, SDF and ORP were significantly better (P<0.0001) in all donors versus infertile patients. ASCM required less volume of the medium than OSFM [(0.53ml (95% CI: 0.39-0.93 vs. 1.50ml (95% CI: 1.10-2.04 p<0.0001)] and provided no significant differences in post-thaw motility in patients [(20.0 CI: 14.4-32.2 vs 18.0 CI: 13.0-20.6, p=0.64)]. The change in normalized ORP from pre-freeze (PF) (PF NORP) to post-thaw (PT) (PT NORP) was found to be significantly increased in OSFM compared to ASCM (2.05, CI 1.15 to 3.23 mV/10^6/mL, vs.1.01, CI 0.54 to 1.75 mV/10^6/mL, p=0.011). The overall decrease in viability was significantly higher in OSFM compared to ASCM (39.0(CI: 38.0-47), 26.5(CI: 22-28), P =0.0048). Overall, post-thaw SDF was comparable in both patients and donors for the 2 media (20.3 ± 12.2% vs 23.1 ± 8.7%, p=0.36).

Limitations, reasons for caution: Future controlled studies with larger sample size are needed to compare ASCM with the other established sperm freezing medium such as Test yolk buffer and Sperm freeze solution to validate the findings of this study.

Wider implications of the findings: The novel medium is a xeno-free medium with dual buffering capacity, economical and can be used for better viability preservation and protection from OS especially in abnormal patient samples.
Trial registration number: Not applicable

P-441 The effect of Letrozol or Tamoxifen co administraton in fertility preservation protocols for breast cancer patients

Y. SHULMAN[1], Y. Cohen[1], Y. Kalma[1], F. Azem[1], B. Almog[1]
[1]Sackler faculty of medicine- Tel-Aviv university., IVF unit- Lis Maternity hospital-Sourasky medical center Tel- Aviv., Tel-Aviv, Israel

Study question: Does co-administration of Letrozole or Tamoxifern during standard IVF protocols for fertility-preservation influence treatment outcomes?
Summary answer: Co-administration of Tamoxifen is associated with lower rates of top quality embryos, whereas co-administration of Letrozole is associated with higher rates of abnormal fertilizations.
What is known already: Ovarian hyperstimulation protocols for fertility-preservation in breast cancer patients, give rise to supra-physiological estradiol levels.

In order to reduce the exposure to high and potentially harmful estrogen levels, modifications to standard protocols have been made using: aromatase inhibitors (Letrozole, Femara) and selective estrogen receptor modulators, such as Tamoxifen. The alteration of the Estrogen/androgen balance in the follicle habitat may have an effect on its development and thus on the success of the fertility treatment. To date little is known about the effect of Letrozole and Tamoxifen administration on fertility outcomes.
Study design, size, duration: This is a retrospective cohort study. Data was retrieved from patients electronic records. The treatment outcomes of 118 breast cancer patients undergoing controlled ovarian hyperstimulation for fertility-preservation between the years 2009 -2017 were analyzed.
Participants/materials, setting, methods: All the patients received a standard IVF protocol for induction of ovulation.

The study groups received additionally Letrozole (n=36) or Tamoxifen (n=30). The control group (n=52) received standard protocol only. The main outcome measures were: number of oocyte retrieved, mature oocytes rate (MII oocyte), fertilization rate and top quality embryo rate. Secondary outcomes measures included: duration of stimulation, total amount of gonadotropin administered, peak estradiol (E2) levels and rate of abnormal fertilization (1PN+3PN).
Main results and the role of chance: The mean age of the patients in the three groups were similar (34.3±4.4, 34.5±4.8 and 34.5±4.5 years).

No differences were found in the numbers of oocyte retrieved, mature oocyte, and fertilization rate between the study groups and the controls.

The percentage of top quality embryos was lower for the Tamoxifen group compared to controls (25% vs 39.4%, p=0.034), but not for the Letrozole group (37.9% vs 39.4%, P=0.8083).

No differences were found in duration of stimulation and total amount of gonadotropin administered between the treatment groups and controls.

As expected Peak E2 levels were significantly lower in the Letrozole group compared to controls (mean 746.4 ±537 pg/ml vs 1745.6± 1068 pg/ml, P< 0.0001). No statistical difference was found between the tamoxifen group and controls (mean 1883.6 ± 1404.3 pg/ml vs 1745.6± 1068 pg/ml, P=0.997).

The rate of abnormal fertilization (1PN + 3PN fertilizations) was higher in both study groups when compared to controls, however only for the Letrozole group it achieved significance (7.8% vs 3.60%, P=0.0148). Stepwise logistic regression analysis revealed that Letrozole administration (OR 11.9; 95% CI 2.2-60.4, P= 0.0013) and Maximal E2 (OR 1.0007; 95% CI 1.0002-1.0013, P= 0.0017 per unit change) were significantly associated with abnormal fertilization.
Limitations, reasons for caution: Main limitations: 1.Retrospective study 2.Small study groups
Wider implications of the findings: Our data suggests that Letrozole and Tamoxifen may affect intra and extra cellular mechanism in the oocyte accounting for its ability to fertilize normally.
Trial registration number: not applicable

P-442 Fertility preservation (FP) by oocyte accumulation in patients with low and very low AMH levels: is it worth it?

A.L. Barbotin[1,2], A. Dumont[3], L. Keller[1], N. Ramdane[1], E. D'orazio[3], V. Mitchell[1,2], C. Decanter[2,3]
[1]Lille University Hospital, Reproductive Biology Institute, Lille, France
[2]Lille University Hospital, EA4308: Gametogenesis and gamete quality, Lille, France
[3]Lille University Hospital, Endocrine Gynaecology and Reproductive Medicine, Lille, France

Study question: *What are the results of FP in patients with low AMH levels? How many controlled ovarian stimulation are needed to offer real chances of pregnancy?*
Summary answer: *It is worth preserving and accumulating oocytes in women with low and even very low AMH levels, regardless the cause of the diminished ovarian reserve.*
What is known already: *Patients with low AMH levels have, by definition, a smaller number of antral follicles and therefore fewer metaphase 2 (M2) oocytes in controlled ovarian stimulation. In 2016, Cobo et al. showed that a minimum of 8 M2 oocytes were required to give real chances of pregnancy. No studies have analyzed so far the results of FP in patients with low and very low AMH levels. No studies compared the outcomes of FP depending on the etiology of the diminished ovarian reserve (DOR).*
Study design, size, duration: This is a retrospective study with data collected prospectively from 2011 to 2018, in the IVF Center of Lille University Hospital (France). 123 women with low AMH levels (<10 pmol/L) and undergoing FP for oocytes accumulation were included, resulting in 180 cycles. All patients were treated with an antagonist protocol, high doses of recombinant FSH and a trigger by recombinant HCG. Data were analyzed using the SAS software 9.4 (SAS Institute Inc, Cary, NC, USA).
Participants/materials, setting, methods: The main outcomes were the number of M2 oocytes vitrified following the first cycle, and the cumulative number after a maximum of 3 cycles. Patients were divided into 4 groups: pre-cancer (n=55), post-cancer (n=16), premature ovarian insufficiency (POI) (n=19) and history of ovarian surgery (n=33). The secondary outcomes were the number of M2 oocytes according to the serum AMH level (low 5-10 pmol/L or very low ≤5 pmol/L) and to the etiology of the DOR.
Main results and the role of chance: The mean number of M2 oocytes obtained after the first cycle of FP was 3.03 ± 2.69. This number increased to 5.48 ± 3.72 after a second retrieval (n=41) and to 8.53 ± 4.52 after a third cycle (n=15). 28 women (23%) had at least 8 M2 oocytes vitrified (10 after the 1st cycle, 12 after the 2nd cycle and 6 after the 3rd cycle). Women with low AMH obtained a higher number of M2 oocytes vitrified per cycle than women with very low AMH (3.39 ± 2.60 vs. 2.43 ± 2.76, p=0.001 respectively). 11,8 % of the women with very low serum AMH levels (8/68) had at least 8 M2 vitrified. After controlling for confounders in logistic regression analysis, the mean number of M2 oocytes per cycle did not differ significantly regarding the indication (3.25 ± 3.03 in pre-cancer, 2.83 ± 3.38 in post-cancer, 2.78 ± 1.71 in POI and 3.04 ± 2.41 in women with ovarian surgery history, p=0.47). The maturation rate was similar between the four groups. Lastly, only AMH level and estradiol level on trigger day were correlated with the number of M2 oocytes obtained.
Limitations, reasons for caution: In addition to the retrospective nature of this study, the specific topic and the inclusion criteria resulted in a small population size, which subsequently decreased the power of our study.
Wider implications of the findings: A low serum AMH level should not be an argument against FP and oocyte accumulation in patients with DOR, regardless of the etiology. Long term follow-up is needed to assess the efficiency, clinical relevance and cost-effectiveness of the procedure through the analysis of the reutilization and further pregnancy rates.
Trial registration number: not applicable

P-443 Perceptions, outcomes and regret following social egg freezing in the UK

B. Jones[1,2], M. Jalmbrant[3], G. Norris[4], R. Odia[5], J. Green[6], S. Saso[1,2], P. Serhal[7], J. Ben Nagi[7]
[1]Imperial College London, Department of Surgery and Cancer, London, United Kingdom
[2]Hammersmith Hospital- Imperial College NHS Trust, Department of gynaecology, London, United Kingdom

[3]Hammersmith Hospital- Imperial College NHS Trust, Clinical Psychologist, London, United Kingdom
[4]University College Hospital, Department of gynaecology, London, United Kingdom
[5]The Centre for Reproductive & Genetic Health, Department of embryology, London, United Kingdom
[6]The Centre for Reproductive & Genetic Health, Department of nursing, London, United Kingdom
[7]The Centre for Reproductive & Genetic Health, Clinical department, London, United Kingdom

Study question: Why do women undergo social egg freezing (SEF) in the UK, and what are their perceptions and attitudes towards SEF after undergoing the process?
Summary answer: Women mostly undergo SEF because they do not have a partner. The majority of women are satisfied after SEF with less than 10% experiencing regret.
What is known already: Social egg freezing (SEF) enhances reproductive autonomy by empowering women with the capacity to delay their childbearing years. However age-related obstetric complications, economic implications and the risk of unsuccessful future treatment make it a controversial option. Some women have no reasonable alternative, such as single women approaching the inevitable physiological decline in their ovarian reserve. Despite the upward trend in women electively cryopreserving their eggs, there is little data about the women's perceptions and experiences, having undergone the process.
Study design, size, duration: This was a cross sectional survey which included 75 women who underwent SEF in a single fertility clinic in the UK between 2010-2018.
Participants/materials, setting, methods: An online questionnaire, utilising a 5-point Likert scale, was created to assess reproductive plans, motivations for SEF, perceptions to their fertility and SEF, along with attitudes to the treatment they received, specifically including regret.
Main results and the role of chance: 71 women responded. At the time of SEF, the majority (93.3%; n=65) were worried about their declining fertility. The predominant motivation was not having a partner with more than three quarters (n=55; 77.5%) saying it influenced their decision. Conversely, just 9.9% and 2.8% attributed career or education to impact their decision. Most intended to store their eggs for 3-4 years (n=25; 35%). However, 11.3% of women planned to store their eggs for >10 years, which is longer than current legal limits in the UK.The majority (81.7%; n=58) understood there was a chance of future treatment failure and that a livebirth could not be guaranteed. Whilst 49 women (69%) were aware that becoming pregnant at advanced maternal age was associated with increased pregnancy risk, 31% (n=22) were not. 19.4% (n=12) have successfully had a baby since SEF and two (2.8%) are currently pregnant. The majority (n=10; 71.4%) were naturally conceived, while the remainder (n=4; 28.6%) conceived using their stored eggs. Overall 90.1% (n=64) had no regrets over electively freezing their eggs. Of those who felt regret, the vast majority described it as 'a little' (n=6; 85.7%). None of the women who underwent SEF and subsequently became pregnant naturally experienced regret.
Limitations, reasons for caution: The data from this study was retrospective and from a single centre.
Wider implications of the findings: Despite significant physical, psychological and financial burden, with no guarantee of a livebirth, only a small minority of women experience regret after SEF. The suboptimal perceptions of associated risks demonstrated herein highlights the need for individualised extensive counselling to ensure women are fully informed including awareness of storage limits.
Trial registration number: Not applicable

P-444 THE 9 YEARS-EXPERIENCE OF FERTILITY PRESERVATION FOR BREAST CANCER PATIENTS AT ADVANCED FERTILITY PRESERVATION CENTER IN JAPAN.

K. Nakamura[1], S. Takae[1], E. Shiraishi[1], Y. Horage[1], K. Uwajima[1], Y. Suzuki[1], S. Sawada[1], H. Iwahata[1], Y. Sugishita[1], N. Suzuki[1]

[1]St. Marianna University School of Medicine, Obstetrics and Gynecology, Kawasaki-Kanagawa, Japan

Study question: How effective we could provide fertility preservation (FP) for breast cancer patients at fertility preservation center with advanced role in Japan?
Summary answer: We have provided effective and safe FP care for 424 of breast cancer patients through 9 years, based on closed collaboration with multidisciplinary medical professions.
What is known already: Improvement in early cancer detection and multidisciplinary treatment have enabled survival rates of cancer patients to increase, loss of fertility known as the effects of cancer treatment has been focused. Breast cancer is most popular disease for FP. Embryo or oocyte cryopreservation after controlled ovarian stimulation with aromatase inhibitor is one of FP procedure for breast cancer patients who have Estrogen receptor positive (Luminal type) cancer. Also, there are no evidence that fertility preservation was associated with an increased risk of recurrence. And the long-term safety of pregnancy in breast cancer survivors is demonstrated including those with Luminal type cancer.
Study design, size, duration: Data were retrospectively obtained from the clinical records of 424 breast cancer patients who were referred to the Fertility Preservation Unit at the Center for Reproductive Medicine of St. Marianna University Hospital from 2010 to December 2018.
Participants/materials, setting, methods: The breast cancer patients who hope to preserve own fertility were received the oocyte, embryo, or ovarian cryopreservation. We investigated the clinical records of patients and figured out their backgrounds, kinds of FP option, outcome of FP, reproductive outcome using embryo or oocyte or ovarian tissues, and subsequent outcome in terms of cancer recurrence.
Main results and the role of chance: The total numbers of patients who visited for FP was 569, and 424 of them had breast cancer. Result in provision of information, 177 of 424 didn't receive FP treatment (only consultation). Also, 26 of 424 were not applicable cases for FP due to severity of primary disease. To develop safety and efficacy of FP treatment, we have established the closed collaboration with breast surgeons since 2014 (Breast-Obgyn: BROG conference). The members of BROG conference consists of the breast surgeons and the reproductive specialists, and nurse staffs and psychologists. At the BROG conference, we can determine the eligibility for FP treatment, and consecutive time course of FP to cancer treatment with multidisciplinary specialists. After establishment of BROG conference, the FP treatment details were 43 cases of oocyte cryopreservation, and 64 cases of embryo cryopreservation, and 31 cases of ovarian tissue cryopreservation (total 134, 4 were combined treatment). After FP treatment, 11 of 138 finished cancer treatment and restarted fertility treatment. Six of 11 received embryo transfer which used embryo which were preserved before cancer treatment, and 4 of them got pregnant. And one of 11 got pregnant naturally. In addition, 3 patients had a recurrence and 2 of them died.
Limitations, reasons for caution: To determine the efficacy and safety of our fertility preservation treatment, we need to follow up for long period after fertility preservation including perinatal outcome. Also, psychological care for patients who gave up FP is important to achieve high quality FP care.
Wider implications of the findings: Present investigation outcome demonstrated the efficacy and safety of FP for breast cancer patients, based on closed collaboration with multidisciplinary medical professions. Such collaboration may improve the quality of FP.
Trial registration number: This study received Institutional Review Board approval from St. Marianna University of Medicine. (approval No[S1] . 2973, 3464)

P-445 How rapid freezing affects active mitochondria, DNA integrity and seminal parameters of human sperm?

P. Pinto de Pinho[1,2], R. Arantes-Rodrigues[1,3], I. Gaivão[2,4], Z. Gomes[5], M. Brito[5], O. Moutinho[5], B. Colaço[3], R. Pinto-Leite[1]

[3]Centre for the Research and Technology of Agro-environmental and Biological Sciences CITAB, University of Trás-os-Montes and Alto Douro, Vila Real, Portugal
[4]Animal and Veterinary Research Centre CECAV, University of Trás-os-Montes and Alto Douro, Vila Real, Portugal
[5]Hospital Centre of Trás-os-Montes and Alto Douro, Department of Obstetrics and Gynecology, Vila Real, Portugal

Study question: What is the impact of rapid freezing with cryoprotectant on mitochondrial activity, DNA damage, as well as on motility, vitality, morphology and sperm concentration, and how the parameters are correlated?
Summary answer: Cryopreservation has been found to lead to a significant decrease of the spermatic quality.
What is known already: Infertility affects approximately 15% of all couples trying to conceive. Mitochondria are an important source of energy for spermatozoa necessary for both sperm motility and fertilization. Thus, plasma and mitochondrial membranes must remain intact to allow cell competence. The DNA damage has also been related to male infertility and reduced fertilization rates. Although several studies report a spermatic quality decrease with cryopreservation, the impact of freezing on sperm human cells is still controversial. Therefore, it is important to evaluate the impact of current freezing protocols on several spermatic characteristics.
Study design, size, duration: This study was performed on 26 anonymous semen samples provided by 26 adult men (22-46 years old), who attended the Fertility Support Centre consultations, at the Hospital Center of Trás-os-Montes and Alto Douro, between January and May 2018. The semen samples were cryopreserved with cryoprotectant by a rapid freezing protocol, and the percentage of sperm with active mitochondria, the DNA damage and the spermatic parameters obtained before and after 1 month of cryopreservation were compared.
Participants/materials, setting, methods: The percentage of sperm with active mitochondria (MitoTrackerTM Red FM dye), the DNA damage (assessed by Alkaline Comet assay and TUNEL assay) and the semen analysis (according to WHO, 2010) were assessed on fresh samples and after cryopreservation.

All samples were cryopreserved on cryovials, with Sperm Freezing Medium, on liquid nitrogen vapors and then plunged into liquid nitrogen.

The statistical analysis was performed (IBM SPSS Statistics 25 software) and p-values $<0,05$ were considered statistically significant.
Main results and the role of chance: The percentage of spermatozoa with active mitochondria decreased by 68% with cryopreservation (from 66% to 21%, p=0,001). The DNA damage increased from 88 arbitrary units (AU) to 172 AU ($p<0,001$) and the percentage of spermatozoa with fragmented DNA was similar before and after freezing (from 6% to 10%, $p>0,05$). The spermatic parameters were significantly worse ($p<0,05$) after cryopreservation. The motility was the most affected parameter, decreasing from 70% to 24%, and in particularly the progressive motility that decreased by 78% (from 58% to 13%). Vitality decreased from 77% to 27%, morphologically normal spermatozoa decreased from 4% to 2% and sperm concentration decreased from $81x10^6$ SPZ/mL to $42x10^6$ SPZ/mL. A strong positive correlation between mitochondrial activity and motility/vitality was also observed ($p<0,01$).

To our knowledge, few studies have compared and evaluated the impact of a current freezing protocol on mitochondrial activity, DNA damage, motility, vitality, morphology and sperm concentration simultaneously.

Limitations, reasons for caution:

- The small number of samples.
- This study was conducted among patients from fertility support consultations, thus it doesn't represent a broadest population.

Wider implications of the findings: The results are consistent with the literature and since cryopreservation is currently used for assisted reproduction, it´s urgent to enhance the efficiency of freezing systems, testing other protocols with different cooling/thawing rates.
Trial registration number: Not applicable.

P-446 LH in vitro treatment promotes DNA repair of mouse apoptotic follicles damaged by alkylating agents.

L.M. Castillo[1,2], A. Buigues[1,2], M. Marchante[1,2], V. Rossi[3], J. Martinez[1,2], F.G. Klinger[3], A. Pellicer[4,5], S. Herraiz[1,5]

[2]University of Valencia, Department of Pediatrics- Obstetrics and Gynecology, Valencia, Spain
[3]University of Rome Tor Vergata, Departament of Biomedicine and Prevention, Rome, Italy
[4]IVI-RMA, IVI Rome, Rome, Italy
[5]IIS La Fe, Reproductive Medicine, Valencia, Spain

Study question: Does luteinizing hormone (LH) incubation protect mouse follicles against chemotherapy-induced apoptosis by promoting DNA repair during exposure to alkylating agents?
Summary answer: LH promoted the homologous recombination mechanism allowing DNA repair to avoid follicle apoptosis in adult mouse ovaries cultured in vitro with alkylating drugs.
What is known already: High-dose chemotherapy treatment with alkylating agents in female patients may impose deleterious effects on the ovary. The follicular pool can be destroyed by the induction of DNA damage leading follicles to atresia, if cells are not able to repair it. In oocytes, the homologous recombination via ataxia telangiectasia-mutated (ATM) pathway is a main mechanism for DNA damage response.

Previous studies suggested that LH incubation preserves the ovarian reserve against follicular depletion induced by chemotherapy in mouse models. We aim to elucidate if LH in vitro treatment protects follicles or promotes DNA repair mechanisms after ovarian exposure to alkylating agents.
Study design, size, duration: Experimental in vitro study with 32 ovarian fragments obtained from eight 10 week-old CD1 mice. Ovarian fragments were randomly allocated to four experimental conditions (n=8/group): Control, Chemotherapy (ChT), ChT+LH-1IU and ChT+LH-5IU. Samples were conditioned with basal media for 24 hours before treatment. Tissue was pre-incubated with LH and one hour after, the ChT-treated groups were supplemented with alkylating drugs. Samples were recovered at 12 and 24 hours after treatments.
Participants/materials, setting, methods: Ovarian fragments were in vitro cultured with α-MEM basal media (37°C-5%CO_2) After 24 hours medium was renewed, and treatments added. LH supplementation was performed 1h before treatment by adding 1 or 5IU of LH. Then, controls and ChT treated groups were supplemented with Vehicle or 1.2µM of busulfan +12µM of 4-Hidroperoxiclyclophosphamide, respectively. Fragments were collected at 12 and 24h and analysed for follicle counts, TUNEL, apoptosis and DNA repair markers by western blot.
Main results and the role of chance: LH incubation, especially at 5IU, reduced the number of TUNEL-positive-oocyte follicles (C: 74.2±17.2%; ChT: 90.4±6.7%; ChT+LH-1IU: 86.7±23.1%; ChT+LH-5IU: 63.1±16.5%, p=0.03) and the percentage of follicles with >20% of TUNEL-positive granulosa cells (C:68.1±40.8%; ChT:96.9±50.3%; ChT+LH-1IU:68.6±30.8%; ChT+LH-5IU:37.6±21.1%, p=0.04) already damaged after 24h of exposure to alkylating drugs. These decreases appeared during the first 12h of incubation although not statistically significant. Furthermore, both LH dosages reduced the percentage of apoptotic cells by follicle at all examined timepoints (12h exposure; C:56.3±6.3%; ChT:71.1±33.5%; ChT+LH-1IU:26.8±22.2%; ChT+LH-5IU:45.6±15.9% and 24h exposure C: 25.8±21.1%; ChT: 70.0±11.6%; ChT+LH-1IU: 61.9±29.2%; ChT+LH-5IU: 27.7±17.0%). The expression levels of the antiapoptotic protein Bcl2 were also quantified in all samples. LH incubation increased the levels of Bcl2 at 12h (C:0.2; ChT: 0.5; ChT+LH-1IU: 0.8; ChT+LH-5IU: 2.1) and 24h (C:1.1; ChT: 0.6; ChT+LH-1IU: 1.3; ChT+LH-5IU: 0.9).

In order to evaluate if the LH protective effect was mediated by DNA damage repair systems, ATM pathway proteins were examined. We found that both LH treatments increased levels of ATM (C:0.3; ChT: 1.1; ChT+LH-1IU: 1.9; ChT+LH-5IU: 2.1), BRCA1 (C:1.0; ChT: 1.3; ChT+LH-1IU: 2.2; ChT+LH-5IU: 1.5) and Rad51 (C:0.7; ChT: 1.3; ChT+LH-1IU: 2.0; ChT+LH-5IU: 1.3) from the first 12h of incubation.
Limitations, reasons for caution: This is an in vitro study performed with mouse ovaries that should be confirmed in a preclinical study with a larger population of human samples prior to be proposed as a suitable clinical alternative to preserve fertility in cancer women.
Wider implications of the findings: LH administration promotes follicle recovery by inducing DNA repair via the expression of proteins involved in the ATM pathway. To elucidate mechanisms and promote repairing might be crucial,

as otherwise damaged follicles underwent atresia leading to follicular depletion and to ovarian failure.
Trial registration number: Not applicable

P-447 Fertility preservation for prepubertal boys: evaluation of controlled slow freezing of testicular prepubertal tissues

M. Safrai[1], D. Kabiri[1], M. Gropp[2], T. Mordechai Daniel[3], G. Hidas[4], T. Imbar[3], B. Reubinoff[5]
[1]Hadassah-Hebrew University Medical Center- Ein-Kerem, Obstetrics and Gynecology, Jerusalem, Israel
[2]Hadassah-Hebrew University Medical Center- Ein-Kerem, The Sidney and Judy Swartz Embryonic Stem Cell Research Center of The Goldyne Savad Institute of Gene Therapy, Jerusalem, Israel
[3]Hadassah-Hebrew University Medical Center- Ein-Kerem, Infertility and IVF Unit, Jerusalem, Israel
[4]Hadassah-Hebrew University Medical Center- Ein-Kerem, Department of pediatric Urology, Jerusalem, Israel
[5]Hadassah-Hebrew University Medical Center- Ein-Kerem, Department of Obstetrics & Gynecology & The Sidney and Judy Swartz Embryonic Stem Cell Research Center of The Goldyne Savad Institute of Gene Therapy, Jerusalem, Israel

Study question: Does Controlled Slow Freezing (CSF) of prepubertal testicular tissues enable the survival of Spermatogonial Stem Cells (SSCs) and maintain the integrity of the testicular niche?
Summary answer: CSF of prepubertal testicular tissues allows the survival of both SSCs and Sertoli cells and maintains the integrity of the testicular niche.
What is known already: Late onset effects of pediatric cancer treatments may include infertility. Fertility preservation options for prepubertal boys are very limited. Testicular tissues containing SSCs and testicular niche cells can be cryopreserved for potential future use. Cryopreservation using CSF may be an acceptable option for cryopreserving prepubertal testicular tissue.
Study design, size, duration: After approval by our institution review board, testicular tissue cryopreservation is offered as an experimental procedure to young prepubertal boys prior to gonadotoxic treatment. Informed consent is obtained from their parents. Following testicular biopsies, testicular tissues are cryopreserved by CSF. Some of the tissues are thawed and analyzed by H&E staining and immunostaining for MAGE-A4 - a marker of SSCs, and vimentin –a mesenchymal marker expressed by Sertoli cells.
Participants/materials, setting, methods: Five cancer-affected prepubertal boys (aged 6 to 14) before and after gonadotoxic treatment underwent the procedure. Following testicular biopsies, one testicular fragment was immediately fixed in 4% PFA and served as a control. The remaining fragments were cryopreserved by CSF. After thawing, fixing and embedding in paraffin, sections from various parts of the testis were immunostained for MAGE-A4 and vimentin. Testicular tubules were counted and evaluated for the presence of these markers.
Main results and the role of chance: Histopathological analysis of the tissues by H&E staining did not reveal any significant differences between control and thawed post-CSF testicular sections. Specifically, there were no significant differences in the number of tubules per section, tissue architecture, and structural integrity between the samples. Immunostaining for the vimentin, showed similar positive staining of the Sertoli cells in all tubules. No significant difference was observed in MAGE-A4 stained SSCs, between control and cryopreserved samples. The immunostaining demonstrated a clear difference between the testicular tissues of children who had been previously treated with chemotherapy: the overall number of SSCs in the sample was significantly lower. Interestingly, prior chemotherapy treatment did not affect the survival of the Sertoli cells. These results demonstrated that CSF of testicular tissue pieces from prepubertal boys preserved both the SSCs and the testicular niche. Moreover, testicular tissues exhibited a profound damage to the SSC caused by chemotherapy in the prepubertal boys, re-emphasizing the importance of fertility preservation prior to gonadotoxic treatment.
Limitations, reasons for caution: Due to low numbers of suitable donors, this study thus far includes few samples. As the reported study is ongoing, more samples will be collected and analyzed. More markers for the different components of the testicular tissue are needed. Differentiation between different chemotherapeutic regimen and doses should also be examined.
Wider implications of the findings: This study demonstrates that CSF presents a suitable option for cryopreserving prepubertal testicular tissues. It highlights the significance of cryopreservation of the testicular tissues prior to gonadotoxic treatments. CSF is a feasible and affordable cryopreservation method. It may, therefore, advance the possibility of future fertility restoration for cancer-affected prepubertal boys.

[4]Goethe-Universität Frankfurt am Main, Buchmann Institute for Molecular Life Sciences- Goethe-Universität Frankfurt am Main, Frankfurt, Germany
[5]University of Edinburgh, MRC Centre for Reproductive Health, Edinburgh, United Kingdom

Study question: Are pharmacological kinase inhibitors able to protect the ovary against cisplatin-induced damage and by which pathways?
Summary answer: GSK3b inhibitors significantly protect oocytes from cell death induced by cisplatin *in vitro* through TAp63a inhibition
What is known already: Advances in cancer therapies have increased survival rates, but there is a risk of premature ovarian insufficiency (POI) for female patients. Several recent studies have demonstrated a key role of kinases in oocyte death induced by cisplatin (Cs). Furthermore, Cs resistance in some cell types is attributable to reduced activity of certain kinases. In the ovary, it is known that inhibition of kinases CK1 and CHK2 protects primary oocytes from both Cs and g-irradiation, by blocking the tetramerization/activation of TAp63a, a pivot protein involved in programmed cell death of oocytes
Study design, size, duration: A GlaxoSmithKline library containing 341 new inhibitors against 14 different kinase pathways was tested for their protective action in vitro against Cs-induced damage on ovarian fragments obtained from postnatal day 4 (P4) mice (GFP/c-Kit and CD1 strains). Analyses were performed after T0h and T24h compound exposure. Whole ovaries from P8 CD1 mice were also treated *in vitro*, with analysis time points: T0h, T16h, T24h, T5days. iGSK3bwas tested against g-irradiation on P4 GFP/c-Kit ovarian fragments.
Participants/materials, setting, methods: Ovarian fragments were pretreated (T0) increasing concentration of inhibitors (0,003mM-3mM), before Cs(10mM) or g-irradiation(0.2Gy)treatment, and cultured for 24h. For each condition, GFP/c-kit positive and trypan blue negative healthy follicles were scored at T0 and T24h.

P8 whole ovaries cultured with Cs+iGSK3bwere analysed at different time points for apoptotic and DNA damage markers (cleaved-caspase3/Bax/g-H2AX) by SDS-page and immunofluorescence analysis. Native-page and in vitro assay were usedto verify the inhibition of TAp63aactivation.
Main results and the role of chance: At least two inhibitors from 14 different pathways were tested. Inhibitors of GSK3b were able to preserve follicles against Cs-induced damage in both type of analysis (survival rate 55% vs 25%; $P<0.05$). We used a commercial inhibitor of GSK3b (CHIR99021) to study the molecular pathways involved in this protection. WB analysis on whole P8 ovaries treated with inhibitor and Cs showed that iGSK3bdecreased protein expression levels of BAX and gamma-H2AX. Histological and immunofluorescent analysis of ovaries treated with iGSK3b and Cs vs only Cs showed a higher percentage of primordial follicles [AR1] (24h, Cs: 42.6±4.5 vs Cs+iGSK3b: 73.3±5.7; 5days, Cs: 15.6±4.1 vs Cs+iGSK3b: 66.5±7.3; $P<0.05$) and a decrease in cleaved-caspase3 (24h, Ctrl: 0.7[AR2] ; Cs+iGSK3b: 1.0; Cs: 2.6) In addition, we demonstrated by SDS- and native page, that iGSK3b inhibited the phosphorylation and consequent tetramerization/activation of TAp63a induced by Cs. I*n vitro* analysis showed that GSK3b was not able to phosphorylate TAp63a directly.

Survival analysis on ovarian fragments also showed that iGSK3b protected oocytes from g-irradiation (0.2Gy = 17±7; iGSK3b+0.2 Gy =49.5±13; $P<0.05$).

Limitations, reasons for caution: This study has been performed using short term in vitro assays in mice, thus the results need to be confirmed in vivo and at least in vitro in human and against other chemotherapy drugs. The molecular mechanisms underlying GSK3 protection against Cs is not known.

Wider implications of the findings: These results confirm the value of this culture system for rapid and simple drug screening effects on ovarian follicles. The use of GSK pathway inhibitors may provide a novel approach to protect female fertility against chemotherapy.

Trial registration number: Not applicable

P-449 Effect of sphingosine-1-phosphate on activation of dormant follicles in ovarian tissue from mouse and human

S.E. Pors[1], L. Harðardóttir[1], S.G. Kristensen[1], C.Y. Andersen[1]

[1] *Rigshospitalet, Laboratory of Reproductive Biology, Copenhagen, Denmark*

Study question: Can sphingosine-1-phosphate enhance the number of activated follicles in ovarian tissue?

Summary answer: Sphingosine-1-phosphate upregulates the expression of genes downstream of the Hippo pathway, increases the number of activated follicles and promotes the survival of follicles

What is known already: The development from primordial follicle to a mature oocyte is a complicated and not fully understood process. Multiple signalling pathways are involved in maintaining dormancy of follicles. Activation of non-growing follicles in vitro is a novel approach to treat infertile women that cannot generate sufficient number of mature oocytes. The compound sphingosine-1-phosphate has been shown to promote follicle growth, in addition to having an anti-apoptotic effect on follicles. The aim of the study was to evaluate sphingosine-1-phosphate as a growth promoting agent in both murine and human ovarian tissue.

Study design, size, duration: The material consisted of donated human ovarian tissue and isolated preantral follicles from women undergoing ovarian tissue cryopreservation for fertility preservation. In addition ovaries and follicles isolated from juvenile mice (2-10 days old) were used. Culture of both human and murine ovarian tissue were done with or without a following xenotransplantation into immunodeficient mice. Isolated murine and human follicles were cultured.

Participants/materials, setting, methods: Human ovarian cortex (six patients) were cultured with sphingosine-1-phosphate for 24 hours, prior to xenotransplantation for six weeks. Follicle growth was evaluated by histology with counting and classification. Ovaries from juvenile mice were cultured with sphingosine-1-phosphate for 1-4 days. The ovaries where then used for analysis of gene expression, histology or xenotransplantation. Isolated human and murine follicles were cultured with sphingosine-1-phosphate and then evaluated for expression of genes in the Hippo signalling pathway.

Main results and the role of chance: A significantly higher expression of the downstream effector gene in the Hippo pathway, CCN2, was found in both murine and human follicles. Thereby, showing that sphingosine-1-phosphate induces a disruption of the Hippo signaling pathway and potential growth activation. For both sphingosine-1-phosphate treated mouse ovaries and grafted human ovarian cortex pieces, the treatment with sphingosine-1-phosphate increased transition of primordial follicles to the primary stage, but it did not seem to induce further growth compared to control. The results suggest that there is an increased shift from the primordial stage to the primary stage after sphingosine-1-phosphate treatment in both mouse ovaries and human ovarian cortex, but further growth was not evident. Interestingly, the human ovarian cortex study indicates an increase in follicle survival after sphingosine-1-phosphate treatment, compared to control.

Limitations, reasons for caution: Further studies are needed to describe the impact of sphingosine-1-phosphate on the further follicle growth and maturation. Additionally, the impact on the specific signalling pathways should be described in further details.

Wider implications of the findings: As the in vitro activation method needs to be optimized for increased success rate, new compounds that promote follicle growth, in addition to exerting further positive effects on follicles, are needed. The results indicate that sphingosine-1-phosphate may promote follicle growth and increase the survival rate of ovarian follicles.

Trial registration number: Not applicable

P-450 Why the differences in the oocyte survival rate in a donor vitrified program?

S. Cortés Gallego[1], A. Guijarro Ponce[2], A. Rodrigo Carbajosa[1], C. Andrés Santé[1], C. Cordero Rosales[1], R. Pandolfi[1], M. Saladino[2], J. Muñoz Ramirez[1]

[1] *Clínica Tambre, Madrid, Madrid, Spain*

[2] *Clínica Tambre, Cuenca, Cuenca, Spain*

Study question: What´s the cause of success in a vitrified donor program? The know-how of the embryologists, the number of oocytes retrieved or the donor herself?

Summary answer: The main factor influencing the survival rates in a thawing cycle is the donor's characteristics; not the embriologyst or the number of mature oocytes.

What is known already: Some studies have found differences on the survival rate depending on the vitrification experience of the operary. Furthermore, differences have also been found regarding the origin of the oocytes. Survival rates in donor oocytes were better than in non-donor oocytes.

To our knowledge, there are no studies which assess if, within the pool of donors which normally have good ovarian response, there is a subgroup which systematically have lower survival rates after oocyte warming.

Study design, size, duration: Retrospective study over donors who underwent at least five vitrification cycles and their corresponding thawing. Data compiled from 2012 to 2018 involving 39 cycles from seven donors. Survival rate was analyzed as dependent variable. The embryologist who vitrified and thawed the oocytes and, considering as a different dichotomic variable, if he performed both were independent variables. Personal experience was considered as the number of thawing cycles performed together with the oocytes thawed per cycle.

Participants/materials, setting, methods: All oocytes were vitrified and thawed using Kitazato media following their protocols strictly. Eight different embryologists with varied laboratory and thawing experience were analyzed. Each thawing cycle had a mean of 6,92 mature oocytes (95%IC:5,76-8,12) SPSS V20.0 was used for the statistical analysis ANOVA, the average comparison by t-student analysis as well as the Pearson correlation coefficient. Whilst, MANOVA was calculated using STATA v15.1

Main results and the role of chance: The survival rate per cycle was between 12,5 and 100%, with a mean of 81,56% (95%IC:73,71-89,41%) and median of 100%.

On ANOVA no statistical differences were observed concerning the embryologists who vitrified (p:0,452) or thawed the oocytes (p:0,439), neither differences were found on the means by T-Student testing to analyze if there is an effect if the embryologist was the same or not on both processes (p:0.947). Pearson testing didn't show any significant correlation between survival rates and the number of mature oocytes (p:0,568) nor with the embryologist's experience (p:0,408).

The use of one-way ANOVA to compare survival rates between the different donors revealed significant differences, being the survival rate means on their 5-6 cycles from 62,65 to 100% (F:4,46 p:0,002).

By a Multiple-way ANOVA we determined that the correlation is independent from previous confounders. MANOVA model with inclusion of these six variables was significant (p:0,0193) and therefore the donor is the only factor which showed influence on survival rates (p:0,0006) regardless of other five confounding factors.

Limitations, reasons for caution: The main limitation of our study is the small number of participants. The results observed in this study should be further confirmed with a larger sample number.

Wider implications of the findings: Standardization of vitrification-thawing protocols reduces the impact of the experience from each embryologist on the survival rates and variability of the results. The intrinsic characteristics of each donor may have a major effect over the survival rate. However, the causes remain unknown.

Trial registration number: Not applicable

P-451 A survey of French Gynecologist knowledge and attitudes toward fertility preservation (FP) in young patients with endometrial cancer (EC) or endometrial atypical hyperplasia (AH)

M. Peigné[1], L. Maumy[1], M. Koskas[1]

[1]*Bichat Claude Bernard Hospital - AP-HP, Department of Gynecology-Obstetrics and Reproductive Medicine, Paris, France*

Study question: What are current knowledge and attitudes toward fertility preservation in patients with AH or EC among gynaecologists in France?

Summary answer: Score of knowledge of FP in EC/AH was low; most physicians were not comfortable with conservative treatment for FP in EC/AH.

What is known already: The safety of FP in AH or grade 1 EC has been reported in various studies. Although, no clear guidelines have been established. Patients are often diagnosed with endometrial malignant or premalignant disease during infertility explorations. Remission is obtained using antigonadotropic treatment in approximately 80% of the cases, more frequently in AH than in EC. However, the extent to which this conservative management of AH or EC for FP is being implemented in practice is unclear. Despite a legal obligation and technical progress, there is a lack of information about FP given to French patients treated for cancer.

Study design, size, duration: Based on previous studies, one specific questionnaire was developed with one common and two specific parts: one for Gynecological Surgeon (GS) and one for specialists in Reproductive Medicine (SRM). Questionnaires were sent via email or given directly during congresses from April 2017 to April 2018. GS were members of the French Society of Gynecologic and Pelvic Surgery (N=434) and SRM belonged to Reproductive Medicine Society or French Study group on Fertility (N ~ 500).

Participants/materials, setting, methods: 140 physicians answered the survey, 87 GS and 53 SRM. Demographic, medical training and practice information were collected. FP knowledge in EC/AH was evaluated with a "score of knowledge" coding results of a four-point Likert scale. To evaluate attitudes toward FP, a five-point Likert scale was used coding a "score of attitudes". GS practice behaviors evaluation was FP information provided to patients. SRM were asked about their management of fertility after FP.

Main results and the role of chance: Knowledge score was low, 59.3 % of participants having a medium/low score. It was significantly higher for GS than SRM and for physicians working in a centre accredited for FP, with a significant EC/AH activity or in university hospitals. The two better known treatments were oral progestins and hysteroscopic resection. Among the 97 participants confronting EC/AH, 52.6% found "difficult" to take care of these patients and 61.8% regretted the lack of official recommendations.

Most physicians felt the upper age limit for FP was 42 or under; the SRM being stricter: 71.6% said '38' or '40' versus 52.9% for GS.

Most physicians seemed not very supportive and/or comfortable with FP in EC/AH, 57.2% having an 'attitude toward FP score' below 11/20. Physicians with a shorter time of practice (<10y), working in a centre performing FP or in a university hospital were more supportive. A significant positive correlation was found between knowledge and attitude scores.

GS "usually" or "always" give advice to patients about FP before EC/AH treatment. 56.6% of SRM wait for spontaneous pregnancy, maximum 3/6 months. If a fertility treatment is planned, 56.6% chose IVF to reduce time to pregnancy. 15.1% chose a mild stimulation to avoid hyperestrogenism.

Limitations, reasons for caution: Small sample size with only 20 % and 10% of response respectively in both populations (GS and SRM), may be inducing a bias. In addition, we asked only members of academic societies maybe more aware of FP options and management in EC/AH.

Wider implications of the findings: Despite reassuring results in the literature, French gynecologists are not very comfortable with FP by conservative management of EC/AH, probably due to a lack of confident knowledge. Specific guidelines are needed to help physicians to manage these young patients with EC/AH and their fertility.

Trial registration number: NA

P-452 Freezing for future fertility: does the Australian public support oocyte cryopreservation?

M. Johnston[1], N. Richings[1], S. Catt[1], G. Fuscaldo[2]

[1]*Monash University, Obstetrics & Gynaecology, Clayton, Australia*

[2]*Barwon Health, University Hospital, Geelong, Australia*

Study question: What are the attitudes of the public towards medical and planned oocyte cryopreservation (OC)?

Summary answer: There is widespread support for medical OC but less support for the uptake and funding of OC to mitigate age-related infertility.

What is known already: Improvements in OC technology and outcomes have resulted in a significant increase in the uptake of OC; growing by almost 500% in the UK, and by almost 600% in Australia/New Zealand over the last 7 years. However, technical progress has outpaced policy development and ethical analysis, and there is a lack of clear or consistent policy guiding access to and funding for OC. Surveys on public attitudes from Europe and the US suggest using OC to manage the risk of age-related infertility (planned OC) is viewed more negatively than medical OC, however little is known about public attitudes in Australia.

Study design, size, duration: An online, cross-sectional survey was conducted in Australia between April 2018 and May 2018, open to members of the general public. Participants were asked to respond to multiple choice, 5-point Likert scale, and open-ended questions. The aim of the survey was to investigate the public's view about access to and funding for OC and whether policies should distinguish between medical and planned OC.

Participants/materials, setting, methods: This was a nationwide study that invited men and women aged between 18 and 60 years to give their views on both medical and planned OC. A total of 1,127 individuals initiated the survey: 89% female, 10% male and 1% identified as transgender or other. The data were analysed with descriptive statistics and multiple regression analyses.

Main results and the role of chance: This study surveyed the general public through a number of online fora and therefore an accurate response rate cannot be given. The median age of the participants was 29 years, 82% were <40 years old and 18% were ≥ 40 years old. There was almost unanimous support (agree/strongly agree) for the use of medical OC when treatments threaten fertility (*e.g.* chemotherapy) or for when medical illnesses threaten fertility (97.5% and 97.3%, respectively). Among the reasons for accessing planned OC, lack of suitable partner was the most supported (76%), followed by financial inability to raise a child (72.9%) and delaying childbearing for career/educational advancement (65.6%). Respondents ≥40 years was the only demographic group less supportive of planned OC for all reasons; *no partner* (OR: 0.41, 95% CI: 0.25 – 0.70, p<0.005), *financial* (OR: 0.34, 95% CI: 0.22 – 0.52, p<0.005) and *career* (OR: 0.31, 95% CI: 0.21 – 0.47, p<0.005). Although 82% of participants identified the costs of OC as a concern, <50% of participants agreed that medical OC should be publicly funded, and only 7% of participants supported public funding for planned OC, with higher support for self-funded (32%) or coverage through private health insurances (24.3%).

Limitations, reasons for caution: Given that people interested in, or experienced with, infertility are more likely to respond positively to new ARTs it is possible that results contain a selection bias in favour of OC. Furthermore, access to the survey was limited to the online format, therefore the findings may not apply more broadly.

Wider implications of the findings: This study contributes Australian findings to the limited data on public attitudes to OC and informs a critical review of the current fertility preservation policies in Australia. Our findings reiterate the perceived distinction between medical and planned OC, which raises difficult questions for policy and equity of access.

P-453 The role of Akt and mTOR pathways in follicle activation after grafting of human ovarian tissue

R. Masciangelo[1], C. Hossay[1], M.C. Chiti[1], D.D. Manavella[1], C.A. Amorim[1], M.M. Dolmans[2]

[1]*Université Catholique de Louvain, Pôle de Recherche en Gynécologie- Institut de Recherche Expérimentale et Clinique, Bruxelles, Belgium*

[2]*Cliniques Universitaires St. Luc, Département de Gynécologie, Bruxelles, Belgium*

Study question: What is the role of the Akt/FOXO1 and mTOR signaling pathways in follicle activation after ovarian tissue transplantation and burnout of the ovarian reserve?

Summary answer: Increased Akt phosphorylation and FOXO1 nuclear extrusion were observed in primordial follicles 3 days post-grafting. No change in mTOR was detected in primordial follicles post-transplantation.

What is known already: Ovarian tissue transplantation leads to massive loss of primordial follicles, together with an increase in the growing follicle population. This suggests that a double mechanisms is responsible for this event: follicle death and follicle activation. Follicle activation is irreversible and, once activated, follicles that are not selected to develop further will undergo atresia. Consequently, early exhaustion of the follicle pool and a shortened lifespan of ovarian grafts will occur. The Akt/FOXO1 and mTOR pathways have been extensively studied in animals and their role in follicle activation widely elucidated, nevertheless, no conclusive proof exists in the activation of human primordial follicles.

Study design, size, duration: Frozen-thawed ovarian tissue from six different patients was divided into 4 fragments, each measuring approximately 5×8×1.5 mm3: one to be used as non-grafted control and three to be grafted to SCID mice. Three grafting durations were evaluated: 3, 7 and 21 days.

Participants/materials, setting, methods: The ovarian tissue was collected from patients who underwent surgery for non-ovarian pathologies (age 25-35 years). The ovarian tissue and grafts after recovery were processed for hematoxylin and eosin (H&E) staining and immunohistochemistry. Follicle classification, growth by Ki67 analysis and and atresia by H&E and TUNEL analysis were analyzed, as well as, Akt and mTOR phosphorylation, and FOXO1 cytoplasmic localization.

Main results and the role of chance: At H&E staining, a significant decrease in primordial follicles and significant increase in growing follicles were detected after transplantation and more than 50% of follicles were atretic after 3 days, with a further 50% after 7 days of grafting. These results were confirmed by Ki-67 and TUNEL analysis, respectively. Moreover, extensive stromal cell death was also shown by TUNEL analysis. Akt phosphorylation significantly increased in primordial follicles after 3 days of grafting. No change in mTOR was observed in primordial follicles post-transplantation, but a significant upturn was recorded in growing follicles compared to primordial follicles, regardless of grafting time. We also found a higher percentage of primordial follicles with FOXO1 in the cytoplasm after 3 days of transplantation than in non-grafted controls.

Limitations, reasons for caution: Our study addresses Akt and mTOR phosphorylation and FOXO1 cellular localization, but animal studies also report the existence of other pathways involved in follicle activation.

Wider implications of the findings: We confirmed that primordial follicle activation is an early event post-grafting, and significant follicle death also contributes to burnout, eventually resulting in early depletion of the ovarian reserve. We evaluated for the first time that the Akt/FOXO1 and mTOR pathways in human ovarian tissue and documented their role in burnout.

Trial registration number: Not applicable

P-454 The evaluation of the role of patient navigators in female oncofertility care in a tertiary medical centre

M. Van den Berg[1], S. Nadesapillai[1], D. Braat[1], R. Hermens[2], C. Beerendonk[1]

[1]Radboud University Medical Centre, Obstetrics and Gynaecology, Nijmegen, The Netherlands

[2]Radboud University Medical Centre, IQ Healthcare, Nijmegen, The Netherlands

Study question: What are patients' and healthcare professionals' experiences with patient navigators in female oncofertility care and their recommendations for improvement?

Summary answer: Patients and healthcare professionals were satisfied about the supportive role of patient navigators. They added value as they became 'familiar faces' and provided personal care.

What is known already: Cancer treatment can cause infertility in young female cancer patients. Therefore, patients have to make a decision whether they want to undergo treatment to preserve their fertility in the stressful period of being diagnosed with cancer. Patients indicate that it is important to receive personal care, emotional support and information about the available options. However, many of these items remain unaddressed in current healthcare practice. To meet these needs and to provide additional support, two fertility nurses were assigned as patient navigators at the Radboud university medical centre fertility department.

Study design, size, duration: To explore patients' and healthcare professionals' experiences and recommendations for improvement, semi-structured in-depth interviews were conducted within nine patients and six professionals between July and September 2016.

Participants/materials, setting, methods: Participants were recruited from a tertiary academic centre, Radboudumc, which serves as a referral clinic for female fertility preservation care. The structure of the in-depth interviews was based on two separate topic lists. Interviews were independently coded and analysed by two authors using a method based on the concepts of grounded theory.

Main results and the role of chance: Patients were satisfied about the supportive role of the patient navigator in their fertility preservation process. They added value as they became 'familiar faces' who were easy to approach, aware of the process, and provided personal care and information in the process. Patient navigators reduced professionals' workload by taking over tasks and by being flexible about seeing patients outside regular consultation hours. To improve their role, both groups suggested that the patient navigator should always be present in fertility preservation counselling. Furthermore, attention should be paid to their availability to improve continuity of care.

Limitations, reasons for caution: Bias could have occurred, because most interviewed patients were diagnosed with breast cancer. Patients with other cancer types may have different experiences with patient navigators. However, the representation of breast cancer patients can be explained by the relatively high incidence of breast cancer in women of reproductive age.

Wider implications of the findings: Recommendations for improvement can be used to improve patient navigators' role in the future to ultimately improve female oncofertility care. Furthermore, the presented overview could be assessed by other centres when considering implementing patient navigators.

Trial registration number: Not applicable

P-455 Adipose tissue-derived stem cells boost vascularization in grafted human ovarian tissue by differentiation into endothelial cell lineages, yielding improved follicle survival rates

D.D. Manavella[1], L. Cacciottola[1], V.L. Payen[2], C.A. Amorim[1], J. Donnez[3], M.M. Dolmans[1]

[1]Pole of research in gynecology, Institut de Recherche Expérimentale et Clinique IREC, Brussels, Belgium

[2]Pole of research in pediatry, Institut de Recherche Expérimentale et Clinique IREC, Brussels, Belgium

[3]Society for Research into Fertility, Av. Grandchamp 143, Brussels, Belgium

Study question: What are the mechanisms by which adipose tissue-derived stem cells (ASCs) enhance vascularization and follicle survival in xenografted human ovarian tissue using a two-step transplantation approach?

Summary answer: Increased oxygenation, vascularization, proangiogenic growth factor secretion and follicle survival rates were observed in grafted human ovarian tissue supplemented with ASCs.

What is known already: Ovarian tissue cryopreservation and transplantation has gained ground as a valid fertility preservation and restoration approach thanks to its established effectiveness. However, there are still issues arising from the avascular nature of the grafting procedure, as up to 80% of follicles may be lost due to hypoxia. Shortening the hypoxic/ischemic post-grafting period is therefore paramount. Our team has recently developed a new transplantation technique using ASCs to improve follicle survival rates. ASCs have multilineage differentiation potential and proangiogenic properties, and have been shown to enhance vascularization in xenografted human ovarian tissue.

Study design, size, duration: Ten severe combined immunodeficient (SCID) mice were grafted with frozen-thawed human ovarian tissue from 5 patients. ASCs were labeled by lentiviral transfection for expression of enhanced green fluorescent protein (eGFP) to enable cell tracking. They were then transferred to peritoneum inside a fibrin implant 14 days prior to ovarian tissue grafting (n=5 mice). In the control group (n=5 mice), ovarian tissue was transplanted using the standard one-step approach. Ovarian grafts were collected on day 7.

Participants/materials, setting, methods: Prospective experimental study conducted in an academic gynecology research laboratory. Human ovarian tissue xenografts were analyzed by histology, immunohistochemistry,

immunofluorescence and real-time reverse transcription polymerase chain reaction (RT-qPCR), to assess proangiogenic factor secretion by ASCs (anti-human vascular endothelial growth factor [VEGF]). Immunofluorescence was also applied to investigate ASC differentiation into endothelial cell lineages and graft vascularization (eGFP, CD34 and CD31 for labeled ASCs and human endothelial cell lineages respectively).

Main results and the role of chance: The eGFP antigen revealed ASCs surrounding and infiltrating ovarian tissue grafts. Significantly higher vessel density was observed in the ASC group (p=0.0182) on day 7. Among human vessels, 12.15 ± 3.16% exhibited co-expression of both eGFP and CD34 antigens, confirming ASC differentiation into human endothelial cell lineages. RT-qPCR showed significantly higher expression of VEGF in the ASC group (p=0.0182), as did immunohistochemistry targeting anti-human VEGF (p=0.033). VEGF and eGFP immunofluorescence also displayed higher growth factor expression in areas surrounding ASCs, demonstrating co-expression.

Limitations, reasons for caution: Long-term studies should be carried out to investigate ASC safety and efficacy, with a view to future clinical application in patients undergoing ovarian tissue transplantation.

Wider implications of the findings: This is a promising step towards potentially improving ovarian tissue quality and lifespan, and extending ASC use in regenerative medicine. The present study provides further insights into the mechanism of action underlying the beneficial effects of ASCs in grafted ovarian tissue.

Trial registration number: no

P-456 The chronology of sperm sample storage and use in patients attending a national fertility preservation centre

L. Powis[1], D. Sanders[1], P. Knaggs[1]

[1]*University Hospital of Wales, Wales Fertility Institute, Cardiff, United Kingdom*

Study question: Are there patterns of storage and use of sperm samples from patients about to undergo oncology treatment?

Summary answer: 6% of patients died before using their samples and 2% returned for treatment which gave a 14% pregnancy rate and a 7% live birth rate.

What is known already: It is thought that there is a low return rate on stored sperm. The number of oncology patients that are referred and attend for sperm storage is much higher than the number that return for fertility treatment. Currently there are 585 oncology patients that have sperm samples stored at this clinic.

Study design, size, duration: Retrospective study looking back at 5 years of data.

Participants/materials, setting, methods: All oncology storage patients were included in this study. Methods included reviewing sperm storage and fertility treatment data.

Main results and the role of chance: On average this clinic stores for 47 oncology patients a year. Currently there are 585 oncology patients that have sperm samples in storage. Since 2014, 14 patients have returned to use their stored samples in fertility treatment meaning only approximately 2% of oncology patients that have stored prior to their treatment have returned to use their samples. Two patients also returned for a second cycle using stored samples. The median age of patients at storage date is 31 and at thaw date is 40. The interval between freeze date and thaw rages between 1 and 23 years. Of the 14 patients that received treatment there were two positive hCG tests however only 1 resulted in a live birth. It was also noticed that 13 patients have exported samples to other clinics, so it would be assumed that their intentions were to be treated elsewhere.

Limitations, reasons for caution: Data collected for treatment was from the last 5 years however the life of the storage data is much longer. Includes newly stored patients potentially still undergoing treatment and some are still too young to be considering starting a family. Outcome data for exported samples was not included.

Wider implications of the findings: Improved management of oncology patients that have stored within the service is required. This may assist with managing patient's expectations when they store as it suggests that there is a possibility that a large number of patients are still able to conceive naturally after their treatment.

Trial registration number: not applicable

P-457 The developmental potential of the in vitro matured oocytes recovered from excised ovaries in oncology patients: a pilot study

E. Petrova[1], A. Kirillova[1], N. Kamaletdinov[1], E. Bunyaeva[1], G. Khabas[2], N. Mishieva[1], T. Nazarenko[3], A. Abubakirov[1]

[1]*National Medical Research Center for Obstetrics- Gynecology and Perinatology n.a. ac. V.I. Kulakov, The department of preservation and restoration of reproductive function, Moscow, Russia C.I.S.*

[2]*National Medical Research Center for Obstetrics- Gynecology and Perinatology n.a. ac. V.I. Kulakov, The department of innovative oncology and gynecology, Moscow, Russia C.I.S.*

[3]*National Medical Research Center for Obstetrics- Gynecology and Perinatology n.a. ac. V.I. Kulakov, The institute of reproductive medicine, Moscow, Russia C.I.S.*

Study question: Do the oocytes recovered ex vivo and matured in vitro have the potential for fertilization and further successful development?

Summary answer: Ex vivo retrieved oocytes from oncology patients have lower potential for fertilization and development, however, in rare cases good quality blastocysts can be obtained.

What is known already: Immature oocytes could be identified during most cases of ovary preparation for cryopreservation and can serve as an additional option for fertility preservation. However, only several cases of fertilization and embryo development from such oocytes have been reported, and most of them are presented as case reports. The published in vitro maturation (IVM) rates of ex vivo retrieved oocytes range from 3 to 100. Only three pregnancies after transfer of frozen-thawed day 2-3 embryos obtained from such oocytes were reported. Two of them resulted in life births.

Study design, size, duration: This study included 14 cancer patients aged 16-42 who underwent oophorectomy in the tertiary referral hospital from July 2018 to January 2019 for fertility preservation. In 12 patients ovarian tissue was frozen along with IVM, and in 2 patients due to nosology only IVM was performed. The main outcome measures were: maturation rate, fertilization rate, cleavage rate and blastocyst formation rate.

Participants/materials, setting, methods: The cumulus oocyte complexes (COCs) were retrieved from visible follicles by aspiration and from the remained fluid after ovarian tissue dissection. COCs were cultured in the IVM medium (Sage, CooperSurgical) supplemented with 0,75 IU/ml HP-hMG (Menopur, Ferring) for 48-72 hours. All matured oocytes were vitrified or fertilized with the husband's or donor's sperm. All normally fertilized zygotes were cultured until day 7.

Main results and the role of chance: In total 212 COCs from 13 patients were retrieved. The mean number of oocytes obtained per patient was 15 (from 1 to 77 COCs per patient). Oocytes were not retrieved from one patient. 60 oocytes (28,3%) matured in 48 hours, 28 oocytes (13,2%) - in 72 hours. The total maturation rate was 41,5% (88/212), and 31,6% of oocytes degenerated (67/212). After denudation 3 oocytes had 1 or 2 visible pronuclei, and 6 were found on the cleavage stage. Remaining 48 oocytes (22,6%) arrested at the germinal vesicle or MI stage. 32 mature oocytes were vitrified according to the patients' will. 55 mature oocytes were fertilized by ICSI. 18 hours after fertilization 11 zygotes (20%) had 2PN, 11 (20%) had 1 or 3PN, the remaining oocytes had no signs of fertilization or cleaved early. The cleavage rate was 100% (11/11), and the blastocyst formation rate was 27% (3/11). All 3 blastocysts were obtained from 1 patient and had 5BB, 5BB, and 3CC score accordingly to Gardner criteria).

Limitations, reasons for caution: Larger study is needed in order to determine whether the oocytes potential is compromised by the patient's nosology, the method of oocyte retrieval or the maturation protocol. None of the vitrified blastocysts have been thawed and their viability remains unknown.

Wider implications of the findings: This pilot study showed that immature oocytes can be harvested from excised ovaries and matured in vitro. However, such oocytes have low potential for fertilization and blastocyst formation. New modified protocol of IVM should be developed and strict criteria for patients who can benefit from such procedure should be set.

Trial registration number: n/a

P-458 Interactions between PI3K/Akt and Hippo signaling pathways during in vitro spontaneous and chemotherapy-induced follicular activation in mouse ovaries

M. Devos[1], J. Grosbois[1], I. Demeestere[1]
[1]*Université Libre de Bruxelles ULB, Faculty of Medicine- Research Laboratory on Human Reproduction, Bruxelles, Belgium*

Study question: Do PI3K/Akt/mTOR and Hippo signaling pathways interact during spontaneous and chemotherapy-induced follicular activation in vitro?
Summary answer: PI3K/Akt/mTOR and Hippo signaling are involved in follicular activation. The inhibition of mTORC1 also affected the Hippo pathway, suggesting an interaction between the two pathways.
What is known already: The development of a complete in vitro culture system supporting follicular growth is an attractive option for restoring fertility using cryopreserved ovarian tissue in cancer patients. However, one of the remaining challenges is the massive follicular activation (FA) that occurs in vitro. FA is also part of the mechanism involved in chemotherapy-induced follicular depletion. Previous studies showed that PI3K/Akt/mTOR is a crucial pathway involved in FA. Moreover, disruption of the Hippo pathway after ovarian sectioning also induces FA. Here, we addressed the involvement of both PI3K/Akt/mTOR and Hippo signaling pathways in in vitro spontaneous and induced FA.
Study design, size, duration: Postnatal-day 3 (PND3) mouse ovaries were used as a model because they contain mainly primordial follicles that represent the follicular reserve. Whole ovaries were cultured in control medium (Dspontaneous activation) or exposed to 4-hydroperoxycyclophosphamide (4HC, 3µM or 20µM for 4h or 24h- chemotherapy-induced FA) with or without mTORC1 inhibitor (Everolimus 100nM- EVE). Ovaries were analyzed after 4 or 48 hours of culture in the different conditions. Each experiment was performed at least three times.
Participants/materials, setting, methods: The involvement of PI3K/Akt/mTOR and Hippo pathways during spontaneous and chemotherapy-induced FA was assessed after 0, 4 and 48 hours of culture by qPCR (gene expression) and Western Blot (protein analyses). Histological analyses were performed after 48h of culture. FA and apoptosis were evaluated by follicular counting and TUNEL staining.
Main results and the role of chance: Although PI3K/Akt/mTOR pathway gene expression was not modified during in vitro spontaneous activation, the protein levels of P-Akt were decreased compared to fresh ovaries as the medium did not contain any growth factors. In contrast, the expression levels of CCN2 and c-myc, genes regulated by the Hippo pathway, were increased after 4 hours of culture, despite the absence of ovarian fragmentation before culture. The proportion of growing follicles increased after 48h of culture in all conditions, irrespective of chemotherapy exposure. Nevertheless, a dose-dependent increase in apoptosis and morphological abnormalities was observed after 24 hours of 4HC exposure. Chemotherapy exposure induced an increase in PI3K pathway phosphorylated protein levels, such as P-Akt and P-rps6, at 4 and 48 hours of culture. The Hippo pathway was also affected by chemotherapy at both concentrations, 3µM and 20µM, with an increase in CNN2 expression after 48h of culture. As expected, the inhibition of mTORC1 by EVE significantly decreased P-rps6 levels but not P-Akt levels. Surprisingly, EVE also prevented the increase in CCN2 expression after 4HC exposure at 48 hours of culture. Therefore, EVE was able to reduce both spontaneous and chemotherapy-induced FA.
Limitations, reasons for caution: This study was limited to the evaluation of the two major signaling pathways. The PND3 model was chosen to evaluate a homogeneous population of early stage follicles but did not take into account the follicular interactions between growing and resting follicles occurring in adult ovaries.
Wider implications of the findings: Spontaneous and chemotherapy-induced follicular activation in vitro involves both the PI3K/Akt/mTOR and Hippo pathways. mTORC1 inhibition acts on both pathways to reduce follicular activation, suggesting cross-talk between the PI3K/Akt/mTOR and Hippo pathways. This represents an interesting approach to regulating follicular activation in vitro and reducing the chemotherapy-induced "burn out effect".
Trial registration number: not applicable

P-459 Inhibithion of Sirt1 protects ovarian primordial follicles from the gonadotoxic action of cyclophosphamide

R. Gualtieri[1], V. Costanzo[1], M. Di Nardo[1], V. Barbato[1], G. Di Emidio[2], C. Tatone[2], R. Talevi[1]
[1]*University of Naples Federico II, Biology, Naples, Italy*
[2]*University of L'Aquila, Life- Health and Environmental Sciences, L'Aquila, Italy*

Study question: Does inhibition of SIRT1 activity protect ovarian primordial follicles (PF) from gonadotoxic action of cyclophosphamide (CPM), one of the most used anticancer drugs?
Summary answer: SIRT1 inhibition *in vitro* prevents PF activation induced by the active CPM metabolite phosphoramide mustard (PM) without compromising follicle viability and ability to resume growth.
What is known already: CPM gonadotoxicity is related to follicle apoptotic damage and disturbance of PF activation. Use of fertoprotective strategies has helped in understanding these mechanisms. Physiologically, SIRT1, a NAD^+-dependent deacetylase, is essential for follicle homoeostasis. A possible role for SIRT1 during the PF activation has been suggested based on increased nuclear expression of SIRT1 in primordial oocytes during transition to primary follicle and decrease of NADH/NAD^+ nuclear ratio. Moreover, increased SIRT1 expression is part of the early adaptive response of mouse ovaries to *in vivo* administration of CPM provoking 60% loss of PFs (Tatone et al., 2018).
Study design, size, duration: Cortical strips of bovine ovarian tissue 1×1×0.5mm were cultured in gas-permeable dishes (PD) for 6 days. Experiment 1: aimed to evaluate possible protective effects of the SIRT1 inhibitor Ex527 (control, treated with PM or with Ex527 alone, or in combination). Experiment 2: aimed to understand whether protected PFs were able to resume growth (control day 3 and 6, PM+Ex527 day 3, PM+Ex527 3 days + medium alone for the next 3 days).
Participants/materials, setting, methods: Bovine ovaries were minced through a tissue chopper and cultured in PD in alpha-MEM plus supplements at 38.8 °C, 5% CO_2 and 95% humidity in air. Strips were incubated in medium alone, with PM 10µM or with EX527 10µM alone or in combination. Follicle quality, stage and viability of fresh and cultured strips were analyzed through histology and after live/dead assay through confocal microscopy.
Main results and the role of chance: Experiment 1 (956 follicles): At day 0, most follicles were at the primordial stage (primordial, 57.7; primary, 26.9; secondary, 15.4%). At day 6, culture with PM promoted a higher follicle activation and growth compared to control (primordial, 18.9 vs 26.2; secondary, 40.4 vs 26.8%; $p<0.01$). EX527 prevents follicle activation and growth compared to control (primordial, 47.3 vs 18.9; secondary, 12.5 vs 40.4%; $P<0.01$). EX527+PM prevents follicle activation and growth compared to PM alone (primordial, 53.2 vs 18.9; secondary, 11.5 vs 40.4%; $P<0.01$). Follicle viability was not affected by treatments except for Ex527 alone (control 71.5 vs Ex527 38.7%; $P<0.01$). Experiment 2 (990 follicles): At day 3, Ex527+PM prevents PF activation and growth compared to control (primordial, 79.6 vs 61.8; secondary, 5.4 vs 9.6%). Follicles in samples exposed to Ex527+PM for 3 days followed by culture in medium alone for the next 3 days are able to resume activation and growth reaching values similar to control (primordial, 58.1 vs 55.4; secondary, 12.4 vs 11.3%; NS). Follicle viability was not affected by treatments. Overall, PM accelerates follicle activation and growth and its effect can be prevented by Ex527 without compromising follicle viability and their subsequent ability to resume growth.
Limitations, reasons for caution: This is an in vitro study in an animal model.
Wider implications of the findings: Understanding the mechanisms underlying PF activation induced by the gonadotoxic action of CPM may contribute to build up strategies aimed to protect the ovarian reserve to preserve the fertility potential of female oncological patients.
Trial registration number: not applicable

P-460 Dynamic culture of human ovarian cortical tissue enhances follicle health, growth, and steroids secretion

R. Talevi[1], G. Catapano[2], M. Di Nardo[3], V. Costanzo[1], V. Barbato[1], M. Ruggiero[4], A. Ferraro[5], S. Adiga[6], R. Gualtieri[1]
[1]*Università degli studi di Napoli Federico II, Dipartimento di Biologia, Napoli, Italy*
[2]*University of Calabria, Environmental & Chemical Engineering-, Cosenza, Italy*

[3]Università degli studi di Napoli Federico II, Dipartimento di Biologia-, Napoli, Italy
[4]Università degli studi di Napoli Federico II- Dipartimento di Biologia- Napoli- Italy, Dipartimento di Biologia, Napoli, Italy
[5]Iatropolis, -Centro Genesis, Caserta, Italy
[6]Kasturba Medical College . Manipal Academy of Higher Education-, Department of Clinical Embryology, Manipal, India

Study question: Does dynamic in vitro culture of human ovarian cortical tissue improve follicle growth and health?
Summary answer: Dynamicin vitro culture of human ovarian tissue in perfusion bioreactors (PB) does improve follicle health, progression to the secondary stage and steroids secretion.
What is known already: In vitro culture of human ovarian cortical strips in gas-permeable dishes (PD) enhances follicular health and secondary follicle growth over conventional dishes by improving oxygen availability in situ. However, the static culture systems adopted so far lack physiological biomechanical cues and generate stagnant media layers around the tissue with a consequent deprivation of nutrients and accumulation of catabolites. Dynamic culture in continuous perfusion bioreactors enables disruption of solutes concentration gradients and application of physiological fluid mechanic stresses on tissue and may improve ovarian cortical tissue culture.
Study design, size, duration: Biopsies of human ovarian tissue (HOB) were cut into 1×1×0.5mm strips and cultured in PD and in PB (ten strips each) for 6 days. At the end of culture, the following endpoints were assessed: 1) follicle health and stage; 2) follicle viability; 3) estradiol (E2) and progesterone (P4) levels in spent media. This study was approved by the ethical committee.
Participants/materials, setting, methods: HOBs were obtained from five consenting patients (age 24.8±6.4)during laparoscopic surgery for benign gynecologic conditions, minced into strips using a tissue chopper and cultured for 6 days in PD and PB. Fresh and cultured strips were fixed and stained for histological analysis of follicle health and stage, labelled with live-dead far red and Hoechst 33342 for viability assessment by confocal microscopy, and day 6 spent media were analysed for E2 and P4 levels.
Main results and the role of chance: Overall, 1696 follicles were analyzed. At day 0 most follicles were primordial (primordial, 75.6%; primary, 21.1%; secondary, 3.3%), with high viability (78.4%) and good quality (grade 1, 41%; grade 2, 31.6%; grade 3, 27.2%). At day 6, PB culture was superior to PD culture in terms of follicle progression (primordial, 31.5% vs 17.3%; primary, 51.3% vs 54.5%; secondary, 17.2% vs 28.2%; $p<0.01$) and health (grade 1, 27.1% vs 33.9%; grade 2, 33% vs 38.2%; grade 3, 39.9% vs 27.9%; $p<0.01$). Viability was not significantly different between samples. E2 secreted by the tissue in spent media at day 6 was higher in PB (2.5pg in PD vs PB, 4.2pg in PB), whereas P4 remarkably increased in PD (16.8ng in PD vs 1.1ng in PB). Overall, culture in PB provided the best conditions yielding a higher proportion of healthy secondary follicles, and an increased ratio between estradiol and progesterone levels (E2/P4: 0.0002 in PD; 0.004 in PB).
Limitations, reasons for caution: This is a preliminary study and should be validated on a larger cohort of patients.
Wider implications of the findings: Culture in a dynamic system permits the disruption of stagnant media layers and the application of shear stress, and improves ovarian cortical tissue culture. Use of a dynamic system yielding enhanced number and health of secondary follicles could represent a valuable tool for multistep in vitro folliculogenesis.
Trial registration number: none

P-461 Cumulus growth pattern of in-vitro matured cumulus-oocyte-complexes (COC) of transgender persons obtained during cryopreservation of ovarian tissue correlates with the maturation status.

S. Lierman[1], P. De Sutter[1], K. Tilleman[1]
[1]Ghent University Hospital Ghent Fertility and Stem cell Team, Department for Reproductive Medicine, Gent, Belgium

Study question: Is the morphology growth pattern of COCs from female-to-male (FtM) transgender persons during *in-vitro* maturation (IVM) an indicator for oocyte meiotic competence?
Summary answer: The growth pattern of the cumulus cells is a significant predictor for maturity of ex-vivo *in-vitro* matured oocytes in FtM transgenders.
What is known already: It has been shown that during ovarian tissue processing and cortex freezing, COCs can be found in the remaining medulla suspension. These COCs can be in-vitro matured for 44-48 hours until they reach metaphase II stage. This has been described for fertility preservation programs for oncology patients (Kristensen, *et al.* 2011, Wilken-Jensen, *et al.* 2013) and by our group for transgender persons (De Roo et al. 2017). During the IVM culture, the cumulus cell morphology pattern changes and can be a useful tool for predicting the maturation status of the oocyte (Smitz J. et al., 2004).
Study design, size, duration: At the moment of cryopreservation of ovarian tissue (OT), the COC's were collected and cultured for 44-48h in a commercial IVM medium (Origio). Cumulus mass (CM); cumulus expansion (CE) and contact between CC and the oocyte (CO) were scored according to Smitz J.(2004). The size of the expansion was measured and calculated on day0 (collection date) and day2 (after 44-48h IVM) after which denudation took place and the maturation status of the oocyte was assessed.
Participants/materials, setting, methods: Total of 1934 COCs were collected at time of transition surgery from 91 FtMs (23.3±5.9y). All participants were on testosterone treatment prior to OT preservation. Combinations of CM,CE and CO were established and mixed logistic regression was applied with patient as random factor, the combination categories as fixed predictor and vitrification as outcome variable. Separate models were applied for day0 and day2. Model based estimated proportions of vitrification per category are reported with their 95%CI.
Main results and the role of chance: On day 0 the highest estimated proportion of matured MII oocytes were for the COCs which were fully enclosed, with moderate expansion of 10 or more layers of cumulus cells. The estimated proportion of matured MII oocytes was 43.3% (95% CI: 33.6% to 53.6%). The lowest estimated proportion of matured MII oocytes on day 0 were COCs that were fully enclosed, with tight dense cells of 10 or more layers of cumulus cells. The estimated proportion of matured MII oocytes was 12.9% (95% CI: 10.7% to 15.6%).

On day 2 the highest estimated proportion of matured MII oocytes were those COCs that lost their tight dense connection between oocyte and cumulus cell layers, also called naked oocytes after 44-48h IVM. The estimated proportion of matured MII for those COCs was 42.5% (95% CI: 36.1% to 49.3%). The lowest estimated proportion of matured MII oocytes on day 2 were COCs that were fully enclosed, with tight dense cells of 3 to 10 layers of cumulus cells. The estimated proportion of matured MII oocytes was 4.3% (95% CI: 0.6% to 25.3%).
Limitations, reasons for caution: This study is based on material donated from FtM transgender persons which were under testosterone treatment at the time of OT cryopreservation and COC collection. We couldn't compare this data with literature nor with data from oncology patients in our center, because we do not have the same large dataset.
Wider implications of the findings: The morphological growth pattern during maturation can help us to study the maturation competence of these COCs that are obtained during the ovarian tissue cryopreservation under testosterone treatment. This cohort of COCs makes it possible to design a prognostic model for clinical use in fertility preservation programs for transgender persons.
Trial registration number: This research is conducted with the approval of the local ethics committee
(2015/0124 – B670201523543).

P-462 Prospective assessment of clinical and oocyte morphological quality in oncological fertility preservation in comparison with matched-age social fertility preservation patients.

M. Chehin[1], R. Mazetto[2], B.C. Barros[2], M. Cavagnoli[3], L. Munhoz[3], A.R. Lorenzon[4], E.L.A. Motta[5]
[1]Huntington Medicina Reprodutiva/Santo Amaro University, Clinical Coordinator / Assistant Professor, São Paulo, Brazil
[2]Huntington Medicina Reprodutiva, Embryology, São Paulo, Brazil

[3]Huntington Medicina Reprodutiva, Clinical Medicine Department, São Paulo, Brazil
[4]Huntington Medicina Reprodutiva, Scientific Coordinator, São Paulo, Brazil
[5]Huntington Medicina Reprodutiva/Federal University of São Paulo, Clinical Medicine Department/Department of Gynecology, São Paulo, Brazil

Study question: Are clinical/oocyte quality parameters in oncological fertility preservation (FP) patients, and in breast cancer subgroup (Letrozol effect), altered in comparison to social FP patients?

Summary answer: Oncological FP have more morphological oocyte alterations and lower AFC compared to social FP. Letrozol subgroup (Breast cancer) does not differ from other cancer types.

What is known already: Advances in oncological treatments have increased life expectancy but the risks for reproductive potential is uncertain. Fertility preservation for oncological patients in reproductive age represents hope to them reach maternity in the future. Oocyte vitrification, an effective technique for FP, is a establish option for these patients. Follicular environment – follicular fluid, cumulus complex - is responsible to support oocyte development. When follicular environment is unbalanced by inflammation, such as in PCOS, oocyte quality is decreased. In oncological patients, inflammation reaches a systemic level, but inflammatory status in follicular environment and the oocyte morphological alteration have not been explored yet.

Study design, size, duration: Prospective, non-interventional study; oncological and social fertility preservation patients were monitored between 2014 and 2018 at Huntington Medicina Reprodutiva clinic, Brazil. Patients under treatment for social FP (n=105 patients/105 cycles) and oncological FP (n=77 patients/86 cycles; in which n=54 patients/59 cycles were diagnostic with breast cancer) were included in this study. In oncological patients, reproductive-associated tumors represented 78% of cycles (69% breast, 7% uterine, 7% ovary tumors).

Participants/materials, setting, methods: Social and oncological FP patients under treatment with antagonist cycle and agonist trigger were included. Breast cancer patients also used Letrozol. Clinical parameters such as type of tumor, antral follicular count, number of follicles ≥15mm and total gonadotrophins dose were analyzed. Laboratory parameters such as number of oocytes retrieved, number of mature oocytes (MII) and oocytes alteration (shape, cytoplasm, extra-cytoplasmic) were compared between groups. Student's T-test and Fisher's exacted test were used as appropriate.

Main results and the role of chance: Social FP mean age was 31.22±4.98 and oncological FP 32.37±4.10 years old (p=0.24). Breast cancer patients were older (33.06±3.60) when compared with other tumor types (29.64±5.90), p=0.0042. Antral follicular count mean in social FP was higher than in oncological FP (14.9±6.76 vs 12.41±7.83, p=0.0005), but no difference was observed between breast cancer vs other tumors (12.23±7.83 vs 12.425±8.05, p=0.70). Number of follicles ≥15mm during ovary stimulation and total gonadotrophins used were not different between social and oncological FP (13.78±7.63 vs 12.78±8.46, p=0.20; 3042.86±776.70 vs 2996.22±877.72, p=0.94), neither between breast cancer vs other tumors (12.5±8.9 vs 12.08±9.29, p=0.37; 3029.82±819.86 vs 3064.42±930.25, p=0.96). Number of oocytes retrieved, number of MII and %MII were not different between social and oncological FP (17.5±7.69 vs 17±11.07, p=0.19; 12.08±5.58 vs 12.4±9.32, p=0.37; 70.27% vs 72.37%, p=0.31), neither between breast cancer and other cancer types (17.58±10.64 vs 15.74±12.07, p=0.32; 12.85±9.15 vs 11.26±9.63, p=0.16; 72.30%±0.18 vs 72.53%±0.21, p=0.91). The number of cycles with oocyte alterations were higher in oncological than social FP (77% vs 55%, p= 0.0072), but were not different between breast cancer and other tumors (78% vs 70%, p=0.54). Frequency of oocyte alterations by type – shape, cytoplasmic and extra-cytoplasmic – was not different between groups.

Limitations, reasons for caution: Low number of patients of both social and oncological FP have requested the use of preserved oocytes, what difficult the evaluation on procedure efficacy and the implication of oocyte alterations in reproductive outcome. Oncological patients were not tested for inflammatory markers.

Wider implications of the findings: Although clinical parameters did not differ, lower AFC and increased oocyte morphological alterations in oncological FP highlight the need of studies regarding the alterations on follicular environment in response to cancer pathophysiology. Implication of these oocyte alterations should be investigated/punctuated for the potential use of these cells in the future.

Trial registration number: Not applicable.

P-463 Fertility preservation in breast cancer patients: clinical experience and outcomes

S. Lavery[1], B. Kim[2], G. Christopoulos[2], M. Das[3], A. Carby[4], S. Khanjani[2]
[1]Hammersmith Hospital, IVF Unit, London, United Kingdom
[2]Imperial College, Obstetrics and Gynaecology, London, United Kingdom
[3]Chelsea and Westminster Hospital, Obstetrics and Gynaecology, London, United Kingdom
[4]CARE London, Obstetrics and Gynaecology, London, United Kingdom

Study question: What are the short and long-term outcomes of fertility preservation in breast cancer patients- do they respond differently to ovarian stimulation?

Summary answer: Patients show a high return rate with good clinical pregnancy rates. Response to ovarian stimulation is similar to matched non-cancer infertile controls.

What is known already: Breast cancer can often affect young women of childbearing age. Whilst treatments such as chemotherapy and long-term endocrine medication are proving to be effective interventions, they can have a significant adverse impact on fertility. Whilst more women are choosing to have oocyte or embryo cryopreservation- there remains little data on short and long-term outcomes. Moreover, data that compares response to IVF in these patients as compared with matched controls are limited.

Study design, size, duration: We retrospectively analysed a matched, cohort of 152 breast cancer patients who proceeded with oocyte or embryo cryopreservation at the Hammersmith Hospital IVF unit between 2002 and 2018. The primary aims were controlled ovarian hyperstimulation outcomes, including oocyte retrieval and maturity number and percentage, total dose and duration of gonadotrophin stimulation, number and percentage of zygotes created, peak serum oestradiol and incidence of complications.

Participants/materials, setting, methods: Fertility preservation patients were matched for age, suppression protocol, gonadotrophin starting dose and antral follicle count. Total dose and duration of gonadotrophin stimulation, oocyte number, zygote number and peak serum oestradiol were compared. Mann-Whitney U test and independent t-tests were performed to demonstrate statistical difference between breast cancer patients and controls. We also report long-term return results of patients with breast cancer who had IVF and compare cycle outcomes of this cohort to matched controls.

Main results and the role of chance: No statistical significance was seen in any of the cycle outcomes compared between breast cancer and non-cancer infertile patients. Furthermore, letrozole had no impact on immediate cycle outcomes. 21 patients returned for 30 cycles of frozen embryo transfer (FET). 51 successfully thawed embryos were transferred. This resulted in 16 clinical pregnancies (31.4% per embryo transferred); 2 were ectopic (3.9%), 8 resulted in miscarriage (15.7%) and 6 pregnancies were carried to term and produced healthy babies (11.8%). A further 11 patients achieved 13 spontaneous pregnancies; 10 of which were carried to term, one miscarriage and two terminations due to continued tamoxifen use.

Limitations, reasons for caution: Although we work in a busy fertility preservation unit the overall number of patients remains small, and outcomes should remain viewed with some caution. The significant number of patients conceiving naturally is an important outcome and should be considered by patients and doctors during decision making.

Wider implications of the findings: Long-term follow-up shows a high return rate with good clinical pregnancy rates. Similarities in response between cohort and control groups suggest comparable efficacy of IVF in breast cancer patients. Further large studies are required to make meaningful comparisons of FET outcomes in cancer patients to non-cancer patients.

Trial registration number: N/A

P-464 Combining fertility preservation procedures to spread the eggs across different baskets: a retrospective single-centre cohort study

S. Delattre[1], I. Segers[1], E. Van Moer[1], I. Mateizel[1], S. Van Ginderdeuren[1], L. Enghels[2], H. Tournaye[1], M. De Vos[1]

[1]UZ Brussel, Centre for reproductive medicine - Centrum voor reproductieve geneeskunde, Jette, Belgium
[2]VUB, Medicine, Brussels, Belgium

Study question: What is the reproductive potential of combining ovarian stimulation, in vitro maturation (IVM) and ovarian tissue cryopreservation in female patients seeking fertility preservation (FP)?
Summary answer: In selected patients, combining different FP procedures is a feasible approach. Reproductive outcomes following FP in patients who return to attempt pregnancy are promising.
What is known already: Fertility preservation is increasingly performed in infertility clinics but an algorithm to select the most suitable FP procedure according to patient characteristics and available timeframe is currently lacking. Vitrification of mature oocytes and ovarian tissue cryopreservation (OTC) are most commonly performed, although in some clinical scenarios a combination of procedures, including IVM, to spread the sources of gametes may be considered with the goal of enhancing options for the future.
Study design, size, duration: Retrospective, observational study in a university-based, tertiary infertility center involving all female patients who underwent urgent medical FP between January 2012 and December 2018. Descriptive analysis of various FP procedures, either stand-alone or combined, was performed, and reproductive outcomes of patients who attempted pregnancy in the follow-up period were recorded.
Participants/materials, setting, methods: 207 patients (between 0 and 42 years of age) were referred to our centre for medical or oncological fertility preservation. Patient-tailored strategies and procedures were selected after multidisciplinary discussions. When deemed feasible, fertility preservation procedures were combined to cryopreserve different types of reproductive tissue and to enhance future reproductive potential. The main outcome measure was the number of mature oocytes. Live birth rates (LBR) were analysed in patients who returned for reproductive treatment.
Main results and the role of chance: Among patients seeking FP, 95/207 (46%) had breast cancer, 43/207 (21%) had haematological, and 31/207 (15%) had gynaecological tumours. Mean age was 27 +/- 8.3 years.

Eighty-four (40.8%) patients underwent controlled ovarian stimulation (COS), yielding 10.8 +/- 7.1 metaphase II (MII) oocytes. Eleven (5.34 %) patients had multiple COS cycles. Transvaginal oocyte retrieval for IVM was performed in 17 (8.3%) patients, yielding 8.9 +/- 10.5 MII oocytes. Thirty-one (15.0%) patients underwent OTC combined with ex-vivo IVM, yielding 4.0 +/-4.3 MII oocytes in addition to ovarian fragments. Sixteen (7.8%) patients had OTC combined with ex-vivo IVM and transvaginal retrieval of oocytes from the contralateral ovary for IVM, resulting in 12.6 +/-9.3 MII oocytes. In 13 (6.3%) patients, OTC with ex-vivo IVM was followed by stimulation of the contralateral ovary, yielding 11.3 +/-6.6 MII oocytes in total.

So far, 28/207 (14%) patients have returned. Of those, nine (32.1%) patients had preserved ovarian function conducive to ART treatment with fresh oocytes, resulting in five (55.6%) live births (LB) and two ongoing pregnancies. The remaining 19 (67.9%) patients had their cryopreserved potential thawed. Of those, eight (42.1%) patients had a LB, of whom three after ex-vivo IVM. To date, 5/207 patients achieved a spontaneous pregnancy.
Limitations, reasons for caution: The FP program in our centre is based on a patient-tailored approach rather than based on an efficiency-driven algorithm. The data presented are descriptive, which precludes firm conclusions.
Wider implications of the findings: Combining different FP procedures has the potential to enhance the reproductive competence of patients undergoing gonadotoxic treatment, but our data need confirmation in larger follow-up studies. Live birth rates are promising in patients who return after FP to undergo ART, whether or not they present with ovarian insufficiency.
Trial registration number: Not applicable

P-465 Knowledge, attitudes, and practices regarding fertility preservation among oncologists and healthcare providers in China

Q. Li[1], H. Chuan[2], L. Qiongyu[1], L. Anwen[1]

[1]the Second Affiliated Hospital of Nanchang University, Department of Oncology, Nanchang, China
[2]The Reproductive & Genetic Hospital of CITIC-XIANGYA, sperm bank, Changsha, China

Study question: What is the knowledge level, attitude, and practice towards fertility preservation in cancer patients among Chinese oncologists and healthcare providers?
Summary answer: Chinese oncologists and healthcare providers exhibited positive attitude towards fertility preservation in cancer patients, although the knowledge of the techniques and institutes specializing was insufficient.
What is known already: As cancer treatment can potentially affect patient fertility, fertility preservation prior to tumor treatment is an effective method for preserving patients' fertility. However, the knowledge, attitude, and clinical practice regarding to this topic among Chinese healthcare providers remains unclear. Awareness of guideline and multi-disciplinary discussion including oncology, reproductive medicine and other healthcare providers are important to ensure they provide patients with effective and timely information on fertility preservation.
Study design, size, duration: In this cross-sectional study conducted at community oncology practicer in China, we anonymously surveyed 1,532 oncologists and healthcare providers from September 2017 to February 2018.
Participants/materials, setting, methods: The study used a cross-sectional design to evaluate the knowledge, attitudes, and practices of FP among oncologists and clinical healthcare providers in China. This survey consisted of 20 questions. Oncologists and healthcare providers who worked in the fields of clinical oncology, internal medicine, surgery, gynecology, and pediatrics in hospitals in China were surveyed using this questionnaire.
Main results and the role of chance: Among the 1,532 healthcare providers (mean [standard deviation] age, 34.3 [7.2] years; 38.4% male and 61.6% female), 1,372 (89.56%) believed it was necessary to recommend fertility preservation to cancer patients. With regard to male and female fertility preservation, 1,017 (66.38%) and 989 (64.56%) respondents were aware of the topic, and 217 (14.16%) and 213 (13.90%) were aware of correct institutes, respectively. Age, department, area, hospital grade, professional qualifications, and educational background ($P<0.01$) of the healthcare providers affected the practice of recommending fertility preservation to their patients. "I think the patient is not suitable for childbirth" (28.39%), "I am unaware of fertility preservation" (28.13%), and "lack of information regarding the institutes/departments providing fertility preservation" (26.37%) were the 3 main reasons for non-recommendation of fertility preservation for cancer patients among healthcare providers.
Limitations, reasons for caution: The present study has certain limitations such as the unbalanced sample size. The sample size in some provinces was relatively small, hence the findings might not represent the views of all clinicians. Moreover, we were unable to examine the specific conditions under which healthcare providers recommend FP to their patients.
Wider implications of the findings: It is necessary to include fertility preservation in physician education to increase knowledge and awareness of this topic among oncologists and other healthcare providers in China.
Trial registration number: N/A

P-466 Differential mouse-oocyte radiosensitivity as a function of the follicle stage

V. Puy[1,2], S. Messiaen[2], D. Moison[2], V. Menard[3], V. Barroca[3], E. Martini[2], N. Frydman[1,2], G. Livera[2]

[1]University hospital Antoine-Béclère- AP-HP, Reproductive Biology Unit, Clamart- F-92140, France
[2]CEA- Universities Paris Diderot and Paris Saclay, Laboratory of Development of the Gonads - UMR Genetic stability- Stem cells & Radiation, Fontenay aux Roses- F-92265, France
[3]CEA- Universities Paris Diderot and Paris Saclay, Animal experimentation platform - UMR Genetic stability- Stem cells & Radiation- INSERM, Fontenay aux Roses- F-92265, France

Study question: What is the quantitative and qualitative impact of X and γ irradiations on oogenesis in the mouse?

Summary answer: Irradiations trigger oocyte death in a dose dependent manner in primordial follicles. Strikingly, there is little impact on oocytes survival in growing follicles.

What is known already: During the last decades, the use of irradiations for medical purposes increased tremendously. It is therefore of great importance to determine the consequences of these expositions on female fertility. Human data were so far collected from women who were irradiated years ago under highly variable conditions. Moreover, such approaches did not allow the study of the quality of the surviving oocytes and were performed with high doses of radiations. We know that low-dose irradiation alters the integrity of human somatic cells. These low doses are used for medical imaging pointing the importance to study their effect on female fertility.

Study design, size, duration: This prospective experimental study conducted from 2018 to 2019 aimed to quantify the number of oocytes and DNA damages induced by various types (X and γ) and doses of irradiations in a murine model.

Participants/materials, setting, methods: Irradiations were performed using GSRD Ce137 and X LINAC irradiators on NMRI prepubertal mice at 8 days post partum (dpp). Non irradiated and irradiated mice (0.02 Gy, 0.1 Gy, 0.5 Gy, 2 Gy) were sacrificed at 10 dpp to determine oocytes survival after ovarian histological analysis of each group (n=3). DNA damages were quantified at 4 hours post irradiations using γH2AX labeling.

Main results and the role of chance: We observed a difference of radiosensitivity between primordial and growing follicles. At the dose of 0.1 Gy the number of oocytes from primordial follicles was significantly decreased by half (average of 1150 per ovary) and tended to disappear at 0.5Gy compared to non irradiated mice. Oocytes from growing follicles were radioresistant as their average number was similar to control (350 oocytes per ovary). These results were similar between X and γ irradiations sources. Quantification of γH2AX labeling revealed an important increased of DNA damages with an average of 12 nuclear foci per oocyte at 4 hours post irradiation time compared to control ($p<0.0001$). This increase was not significantly different between primordial and growing follicles ($p=0.78$) suggesting similar initial DNA damages.

Limitations, reasons for caution: The murine model allows experimental flexibility to perform histological and immunolocalization approaches but our preliminary results will require further consolidation with human follicles.

Wider implications of the findings: The data of this work should allow us to improve female fertility preservation, estimate the risks of giving birth with irradiated oocytes and later develop new technics of radioprotection of human oocytes.

Trial registration number: Not applicable.

P-467 Fertility preservation and oocyte quality in young cancer women: a prospective analytical study.

E. Licata[1], C. Fabiani[1], G. Paciotti[1], C. Meneghini[1], R. Rago[1]

[1] *Sandro Pertini Hospital, UOSD Fisiopatologia della Riproduzione e Andrologia, Rome, Italy*

Study question: Does cancer disease influence on the oocyte quality and ovarian stimulation outcomes in female oncology patients?

Summary answer: The number of dysmorphic oocytes is similar between two groups, even if a particular abnormality was observed in the study group.

What is known already: Fertility preservation (FP) has become an important component in cancer management. Oocyte vitrification is no longer experimental and this option is elective for FP in young women. In assisted reproduction vitrified oocyte give results nearly similar to those of fresh oocyte. While it is known that cancer treatments can impair fertility in women, it is not yet clear whether oncological diseases have an impact on ovarian reserve and oocyte quality influencing ovarian stimulation outcomes, mainly metaphase II (MII)-total oocyte ratio and dysmorphic oocyte ratio after retrieval in cancer patients.

Study design, size, duration: This is a prospective analytical study performed in the IVF laboratory at the Sandro Pertini Hospital in Rome between 2016 and 2018. The aim of this study is to determine the effect of cancer diseases on number, above all on quality of oocyte in oncology patients and to define if there is a typical pattern of dysmorphic oocyte in cancer women compared to women age-matched who undergone ICSI treatment for tubal or male factor infertility.

Participants/materials, setting, methods: A total of 48 patients recently diagnosed with cancer underwent ovarian stimulation for oocyte cryopreservation is the study group (Group A). A total of 50 patients under 38 age underwent ICSI treatment for tubal or male infertility is the control group (Group B). Baseline characteristics are age, body mass index (BMI) and antimulleran hormone (AMH) value. The primary outcome was number and quality of retrievd oocyte from ovarian pick-up (OPU).

Main results and the role of chance: Baseline characteristic are comparable. Despite similar ovarian stimulation protocol, similar recombinant FSH total dose (Group A: 2258,33 U.I.; Group B: 1604,72 U.I.), similar mean stimulation duration (Group A: 11,31 days; Group B: 11,45 days), similar oestradiol peak at triggering (Group A: 1127,12; Group B: 932,02) patients from Group A had lower number of MII ($P<<0.01$)and higher number of immature oocytes than Group B ($P<<0.01$) . There are no differences in the ratio of dysmorphic oocyte though in Group A dysmorphic analyzed oocyte have a particular abnormality: a perivitelline space (SPV) with granularity.

Limitations, reasons for caution: Limitations concern the paucity of groups and the fact that we haven't a follow up to evaluate the competence of vitrified MII oocytes for oncology patients. Also it was not possible to stratify the study group according to the cancer diagnosis to discriminate ovarian tumors one.

Wider implications of the findings: There are few studies about fertility preservation that investigate oocyte quality and not only quantitative parameters of ovarian stimulation. This allows a more exhaustive counseling to oncology patient and an optimized treatment for FP.

Trial registration number: Not applicable

P-468 AMH, AFC and FSH long term follow up before and after chemotherapy in patients undergoing temporary ovarian suppression with GnRH analogs

L. Cipriani[1], E. Porcu[1], G. Damiano[1], F. Sacilotto[1], G.M. Cillo[1], I. Roncarati[1], F. Vergine[2]

[1] *Bologna University, Infertility and IVF Center, Bologna, Italy*

[2] *Pisa University, Infertility and IVF Center, Pisa, Italy*

Study question: Is there a difference in long-term fertility outcomes after chemotherapy among patients suffering from hematologic, breast or ovarian cancer undergoing temporary ovarian suppression with GnRHa?

Summary answer: There is a clinical difference in AMH, FSH, AFC decrease rate and recovery time among the three groups.

What is known already: The increase in cancer survival rates changed survivors attitude about reproductive options and desires.

Premature ovarian failure (POI) is a well-recognized consequence of chemotherapy, leading to infertility and menopausal symptoms. Temporary ovarian suppression with GnRH agonist during chemotherapy is a strategy to reduce the gonadotoxic impact and incidence of POI. Chemotherapy induces apoptosis of the granulosa cells in the growing follicles and the subsequent increase of FSH stimulate the proliferation of granulosa cells increasing their sensitivity to chemotherapy. GnRHa co-treatment decreases FSH levels suppressing ovarian function and reducing the gonadotoxic effect of chemotherapy.

Study design, size, duration: Prospective study including 201 oncological patients with a pending gonadotoxic treatments, aged 18 to 45 (mean age 29,2±4,3), enrolled from 1997 to 2018 at the Bologna University IVF and infertility Center.99 had hematologic neoplasms, 64 had breast cancer, 36 had pelvic-related (ovarian and cervical) cancer, 2 had colorectal cancer.

Participants/materials, setting, methods: All the patients started GnRH agonist treatment before and continued it during chemotherapy. AFC, FSH and AMH basal levels were previously measured. A complete follow up of AFC, FSH and AMH levels during chemotherapy and 6 and 12 months after the end of therapies was recorded. Menses resumption and spontaneous pregnancy after treatment were also investigated. T-student test was used to analyze the data.

Main results and the role of chance: The overall results of the study reported a significant decrease in AMH and AFC when comparing basal and during-chemotherapy levels, followed by a significant increase at 6 and at 12 months after the end of antineoplastic therapy. Similarly, FSH increased significantly during chemotherapy and then significantly diminished 6 months after the end of treatments. 52 (59,4%) patients experienced a menstrual resumption.

Considering the 99 patients suffering hematologic neoplasm, 28/44(63%) resumed regular menses and 3/28(10.7%) had a spontaneous pregnancy. Out of the 66 breast cancer patients, 24 (36%) resumed menstrual cycles and 1 (1.5%) had a spontaneous pregnancy. Of the 36 patients with ovarian cancer 12/19 (62%) had menses resumption and 3(25%) of them got pregnant spontaneously.

The results of the study, in agreement with the literature, confirm that GnRH agonist during chemotherapy should be suggested in all cancer patients that desire to preserve their fertility. GnRH should be started one week before the beginning of therapies and prolonged until the end of chemotherapic cycles.

Limitations, reasons for caution: The main weakness of the research is that a small number of patients who attended the center completed the whole follow up. Furthermore the monocentric nature of the study could create a bias in the interpretation of the data.

Wider implications of the findings: In all cancer patients with a scheduled chemotherapic treatment and the desire to preserve their ovarian function, GnRH agonist should be always recommended, alone or in combination to other fertility preservation techniques.

Trial registration number: /

P-469 Feasibility of follicle isolation, culture and oocyte maturation from ovaries recently gonadotropin-stimulated for IVF. A proof of concept study using an experimental mouse model

X. Hao [1,2], A. Anastacio [1,2], K. A. Rodriguez-Wallberg [1,2,3]

[1] *Karolinska Institutet, Department of Oncology and Pathology, Stockholm, Sweden*
[2] *Cancer Center Karolinska CCK, Laboratory of Translational Fertility Preservation, Stockholm, Sweden*
[3] *Karolinska University Hospital, Department of Reproductive Medicine, Stockholm, Sweden*

Study question: Is it feasible to isolate and culture secondary follicles up to oocyte maturation from ovaries recently stimulated with gonadotropins for in vitro fertilization (IVF)?

Summary answer: Secondary follicle isolation, culture and oocyte maturation were feasible, percentage of follicles fulfilling IVM conditions and ratio of MII oocytes were similar to non-stimulated control.

What is known already: Mature oocyte cryopreservation is an established option to preserve fertility of cancer patients, while in certain cases, only a few or no mature oocytes can be collected after controlled ovarian hyperstimulation (COH). We designed a study to investigate if ovaries recently treated with COH could provide secondary follicles that could grow and mature in culture, as an additional source of mature oocytes for fertility preservation.

Study design, size, duration: Controlled experimental study. Ovaries from five female mice C57Bl/6J 3-4-weeks old were obtained after completion of hormonal stimulation and egg retrieval as in COH for IVF and five non-stimulated mice served as controls. Secondary follicles were isolated and cultured for 12 days and matured in vitro according to the method of R.Cortvrindt (1996).

Participants/materials, setting, methods: Pregnant mare serum and human chorionic gonadotrophin (hCG) were administered by intraperitoneal (i.p.) injection to the mice and the ovaries were collected 13.5 hours after hCG injection. Secondary follicles were isolated and cultured. Follicle growth was recorded daily. On day 12, follicles that reached at least 500 mm of diameter were matured by adding hCG and epidermal growth factor (EGF) to the culture medium. Oocyte maturation status was evaluated after 16-20 h.

Main results and the role of chance: Comparable numbers of isolated secondary follicles per ovary were obtained from non-stimulated (n=9.9±4.20) and stimulated ovaries (n=9.7±2.03). During the 12-day culture, follicles from both groups showed similar growth curves. In the non-stimulated group 86.1% of 79 cultured follicles reached day 12 whereas only 54.4% of 68 cultured follicles grew till day 12 in the stimulated group ($p<0.001$). Despite this it was possible to obtain similar percentages of follicles fulfilling the conditions of in vitro maturation (IVM) (59.5% in the stimulated group vs 66.2% in the non-stimulated group, p=0.68) and similar ratios of metaphase II-stage (MII) oocytes in both groups, 51.1% in the non-stimulated group and 36.4% in the stimulated group, p=0.38).

Limitations, reasons for caution: This study was performed in animal model in which secondary follicle isolation and culture have been established and are less challenging compared to large mammals or human. The further confirmation of our findings in ovaries of larger mammals is suitable.

Wider implications of the findings: Our results show that isolation of secondary follicles from IVF-stimulated ovarian tissue is feasible and that mature oocytes can be obtained in culture. Additionally, similar percentages of follicles fulfilling IVM conditions and similar ratios of MII oocytes can be achieved comparing to non-stimulated ovaries.

Trial registration number: not applicable

P-470 Primordial Follicle Viability Following Culture in to the Decellularized Ovarian Scaffold in vitro

H. Nikniaz[1], B. Jameie[2], Z. Zandieh[1], M. Nouri[3], R. Aflatoonian[4]

[1] *Iran University of Medical Sciences, Anatomy, Tehran, Iran*
[2] *Iran University of Medical Sciences, Biochemistry, Tehran, Iran*
[3] *Tabriz University of Medical Sciences, Medical Biotechnology, Tabriz, Iran*
[4] *Royan, Endocrinology and Female Infertility at Reproductive Biomedicine Research Center, Tehran, Iran*

Study question: What is the effect of decellularized scaffold on viability of cultured mice ovarian follicles?

Summary answer: Mice ovarian follicles can be viable and seed into the acellular scaffold.

What is known already: Decellularization is a novel technique in regenerative medicine. Recently decellularized ovarian cortex introduced as a scaffold in the field of human fertility preservation. Studies demonstrated that follicle growth and the survival rate are depend on type, structure, and rigidity of the scaffold, so scientific groups attempt to find ideal scaffold to support follicle development. Acellular ovarian cortex due to its high resemblance to the origin niche of the follicles, can ensure their growth and development.

Study design, size, duration: In the present study bovine ovarian cortical fragments (2 × 2mm) were prepared and divided in to two groups (SDS and SDS-Triton-Ammonium). 120 primordial follicles from two 14 days old NMRI mice were isolated and put into the SDS-Triton-Ammonium decellularized scaffold (n= 30/ 4 scaffold) then cultured for 4 days at 5% CO_2 and 37 °C.

Participants/materials, setting, methods: SDS group was decellularized with 0.1% SDS for 24 hours and SDS-Triton-Ammonium group was decellularized with 0.5% SDS for 2 hours and 1% Triton-0.1% ammonium for 22 hours.

H&E and DAPI staining **were** applied to prove decellularization. Orcein and Masson's trichrome staining was carried out to evaluate the presence of elastin and collagen fibers respectively. For evaluating scaffold's cytocompatibility, MTT test was done. Follicles viability and seeding were tested by H&E staining and SEM analysis.

Main results and the role of chance: According to the H&E staining results, the bovine ovarian cortex was decellularized in both groups. No residual nuclei were observed by DAPI staining.

Elastic and collagen fibers were kept after the decellularization process in both groups.

OD values of eluted formazan of MTT test showed that the SDS-Triton-Ammonium decellularized scaffolds were cytocompatible than SDS group.

The results of the in vitro culture showed that after 4 days 111/120 follicles were viable (92.2%) and seeded into the scaffold.

Limitations, reasons for caution: The study was performed in vitro just for 4 days so long term culture and extra analysis such as maturation of oocyte and grafting in ovariectomized mice are needed.

Wider implications of the findings: We showed for the first time follicles can survive and seed in to the acellular matrix and decellularization of ovarian cortex with SDS-Triton-Ammonium has satisfactory results.

Trial registration number: -

P-471 return rate and utilization rate of oocytes and embryos after fertility preservation

N. Klijn[1], H. Verburg[1], L. Van der Westerlaken[1]

[1]Leiden University Medical Center, Gynecology- H3-P, Leiden, The Netherlands

Study question: What is the return rate and utilization rate of cryopreserved oocytes and embryos after fertility preservation (FP) for patients with malignant disease?

Summary answer: Of patients that underwent FP prior to cancer treatment 52.7% returned with questions concerning their fertility. Cryopreserved material was used in 23.7% of all patients.

What is known already: Cancer therapy can lead to loss of fertility due to primary ovarian insufficiency (POI). FP prior to cancer treatment can give additional chances to conceive after the gonadotoxic treatment, especially in case of POI. Because infertility is known to have a negative effect on quality of life, referral to a fertility specialist for FP has become more routinely imbedded in cancer therapy. Although the number of patients that go through FP prior to cancer treatment has increased, not much data have been published about the use of this cryopreserved material.

Study design, size, duration: A single center retrospective study of patients who were counseled for FP between 2002 and 2012. In this timeframe 178 patients were counseled and 93 patients went through FP. Follow up was collected up to 2017.

Participants/materials, setting, methods: All patients counseled for FP in means of vitrification of oocytes or cryopreservation of embryos were included. Retrospective data were collected from medical records.

Main results and the role of chance: Between 2002 and 2012 a total of 178 patients with malignant disease were counseled in our clinic for oocyte vitrification and embryo cryopreservation. 93 patients (52,2%) underwent at least one cycle of FP prior to the cancer treatment. Of those 49 (52.7%) returned for information about their fertility up to 2017. 22 of the returned patients (23.7% of all the FP patients) used their cryopreserved material, which resulted in an overall pregnancy rate of 45.5% and birth rate of 36.4%.

Of the patients that underwent FP 47.3% did not return, 5.4% had passed away and in 7.6% frozen embryos were discarded because their relationship had ended. Information about the other patients is missing.

Not in all patients that did return after FP ovarian reserve was compromised. Those with normal ovarian reserve were advised to pursue natural conception and 34.7% did conceive naturally. This explains the relatively low utilization rate (23.7%) of the cryopreserved material.

Limitations, reasons for caution: The study size is relatively low. Follow up data of patients that did not return is incomplete. Time to follow up is at least 5 years, but patients might not be ready to try to conceive yet and utilization rate might be underestimated.

Wider implications of the findings: FP prior to a gonadotoxic treatment is increasing. This study shows that the utilization rate of the stored material is relatively low. Discussion is needed to determine the indications of FP and whether it is performed too often.

Trial registration number: Not applicable

P-472 Oocyte vitrification negatively affects the Ca2+-releasing pattern and oocyte activation potential of mouse oocytes

D. Bonte[1], V. Thys[2], A. Boel[2], L. Leybaert[3], P. De Sutter[2], B. Heindryckx[2]

[1]Ghent University Hospital Ghent Fertility and Stem cell Team, Reproductive Medicine, Gent, Belgium

[2]Ghent University Hospital Ghent Fertility and Stem cell Team, Department for Reproductive Medicine, Gent, Belgium

[3]Physiology Group, Department of Basic and Applied Medical Sciences, Gent, Belgium

Study question: Can vitrified-thawed instead of fresh mouse oocytes be used to determine the oocyte activation potential of human spermatozoa?

Summary answer: Vitrified-thawed mouse oocytes display reduced Ca2+-releasing potential, necessitating adapted classification criteria in order to be used for assessing the activation potential of human spermatozoa.

What is known already: Mouse oocyte Ca2+ analysis (MOCA) is a diagnostic test whereby a patient's sperm is injected into mouse oocytes to investigate its ability to induce Ca2+ oscillations and assess the oocyte activation capacity. To facilitate large-scale diagnostic testing and decrease dependency of live mouse availability, the creation of a mouse oocyte bank with vitrified oocytes would be beneficial. However, vitrification-thawing might negatively impact oocyte activation by itself (i.e. the Ca2+-releasing machinery), or compromise embryonic development.

Study design, size, duration: Mouse oocytes were randomized into fresh or vitrified-thawed groups (each ≥ 15 oocytes) for further experimental investigations. Oocytes were injected with spermatozoa or parthenogenetically activated and checked for Ca2+ pattern analysis and developmental competence. Each experiment was repeated 3 times. We analysed the mean amplitude, frequency, and full width at half maximum (FWHM) of the Ca2+ peaks, as well as the area under the curve (AUC). For development, fertilization and blastocyst rates were observed.

Participants/materials, setting, methods: First, fresh and vitrified-thawed mouse oocytes (B6D2F1, 7-12 weeks old) were injected with frozen-thawed control human sperm. Secondly, mouse oocytes were exposed to SrCl2, or to a single or twice repeated (30 min time interval) ionomycin exposure, and monitored for their fertilization potential and Ca2+ patterns. Finally, oocytes were exposed to thapsigargin to evaluate the intracellular Ca2+ store content. Intracellular Ca^{2+} levels were measured by fluorescence microscopy using leakage-resistant FURA-2 AM as a Ca2+ indicator.

Main results and the role of chance: MOCA-test evaluation of sperm-injected vitrified-thawed oocytes (n=58) displayed a significantly lower amplitude ($p<0.001$) and AUC ($p<0.05$) of the induced Ca2+ pattern compared to fresh oocytes (n=44). The amplitude and FWHM of the Ca2+ peaks, as well as the AUC, were significantly lower and frequency significantly higher in vitrified-thawed SrCl2-exposed oocytes (n=60) compared to fresh oocytes (n=69) ($p<0.001$). The first ionomycin exposure resulted in a significantly lower amplitude, FWHM, and AUC in vitrified-thawed oocytes (n=48) compared to fresh oocytes (n=60) ($p<0.001$). The second ionomycin exposure also resulted in a lower amplitude ($p<0.001$), FWHM ($p=0.11$), and AUC ($p<0.001$) in vitrified-thawed oocytes. Fertilization rates after SrCl2 activation were similar between both groups (fresh 95.4%;n=87 and vitrified-thawed 94.4%;n=89; $p=0.76$). However, activation rates after a single or double ionomycin exposure were significantly lower in vitrified-thawed oocytes (43.2%;n=111 and 78.4%;n=51) compared to fresh oocytes (73.0%;n=100 and 100.0%;n=50) ($p<0.001$). By contrast, blastocyst rates did not differ between both groups. Thapsigargin exposure of vitrified-thawed oocytes (n=72) demonstrated oscillatory Ca2+ changes which were not observed in fresh oocytes which displayed a single transient Ca2+ increase (n=60) ($p<0.001$). The first peak showed a significantly lower amplitude and AUC in vitrified-thawed oocytes ($p<0.001$), indicating decreased Ca2+ store content after vitrification-thawing.

Limitations, reasons for caution: Oocyte vitrification negatively affects the Ca2+-releasing potential. Therefore, we cannot extrapolate results obtained in vitrified-thawed oocytes to fresh oocytes. Adapted, new classification criteria need to be established to correctly interpret MOCA results. Also, more research in human is recommended for gaining information about the Ca2+-signalling machinery in vitrified-thawed human oocytes.

Wider implications of the findings: When creating new classification criteria, we can perform large-scale diagnostic testing and decrease dependency of live mouse availability by using vitrified-thawed oocytes. Furthermore, one has to take in mind the reduced Ca2+-releasing potential of vitrified-thawed oocytes, especially when performing assisted oocyte activation on human vitrified-thawed oocytes in the IVF clinic.

Trial registration number: not applicable

P-473 Letrozole and fertility preservation in women with breast cancer

S. AMARI[1]

[1]Tunis, Tunis, Tunis, Tunisia

Study question: The question is to investigate whether the use of letrozole is effective in fertility preservation for patients presenting with breast cancer ?

Summary answer: The use of letrozole in PF is effective because it does not reduce the average number of oocytes or embryos collected.

What is known already: Ovarian stimulation with exogenous gonadotropins leads to a significant rise in circulating estrogen levels. This could aggravate these particular patients' condition and even cause the spread of the disease. The use of anti aromatase agents such as letrozole could prevent this elevation

and protect the patients while remaining effective in terms controlled ovarian stimulation , as well as oocyte retrieval and overall outcome.

Study design, size, duration: We conducted a prospective comparative study from January 2015 to October 2018 and which involved 143 cycles for fertility preservation. We have compared the number of mature oocytes obtained between patients with breast cancer (Groupe 1) and patients with other types of cancer (group 2).

Participants/materials, setting, methods: Patients were referred by their treating physician. A FP consultation is provided by a gynecologist and a biologist. The evaluation of the ovarian reserve is done by Antral Follicle Count (AFC) ultrasound and AMH dosage.

The stimulation is conducted by antagonist protocol with random start and GnRH agonist triggering. For patients with breast cancer, the adjunction of letrozole 5mg/day was started the first day of the ovarian stimulation and continued 7 days after oocyte pick up.

Main results and the role of chance: 171 patients were referred to our FP visits, of which 143 patients had fertility preservation (oocyte/embryo vitrification) and 75 amongst them had breast cancer.

The average age of patients (year) in group 1 was 30.3 +/- 3.7 and 26.9 +/- 6.7 and the difference was not significant (p=0.73). The ovarian reserve was not statistically different : AFC (12.3 +/- 6.2 vs 13.9 +/- 6.4; p = 0.7) and AMH (2.43 +/- 2.3 ng/ml vs 2.8 +/- 2.45 ng/ml, p = 0.5).

The duration of the ovarian stimulation was not different : 10.2 +/- 2.3 days vs 11.8 +/- 3.1 days; p = 0.5).

The estradiol level on the day of ovulation triggering was 479 +/- 323 pg/ml in the breast cancer group versus 1701 +/- 682 pg/ml in the other group with a significant difference (p = 0.02) The number of CCOs obtained in the breast cancer group was 10.76 +/- 8.39 compared with 9.11 +/- 6.81 in the group 2 and the difference was not significant (p=1.83)

The mean number of mature metaphase II oocytes collected in the breast cancer group was 7.38 +/- 6.11 oocytes versus 6.09 +/- 4.72 oocytes in the group 2 and the difference was not statistically significant (p=1.33)

Limitations, reasons for caution: Amongst the limitations, some patients did not undergo FP upon fertility, because they could not afford the gonadotropins and were not included in the program unfortunately.

Wider implications of the findings: Letrozole would provide much ease and safety when stimulating women with breast cancer, as it a very frequent malignancy.

P-474 Discontinuation before even starting fertility treatment: prevalence and prediction

L. Dias[1], P. De Loecker[2], S. Lie Fong[3], U. Van den Broeck[3], K. Peeraer[3], E. Dancet[1]

[1]*KU Leuven, Regeneration and development, Leuven, Belgium*
[2]*GZA Ziekenhuizen campus Sint-Augustinus, Obstetrics and gynaecology, Wilrijk, Belgium*
[3]*UZ Leuven, Vrouw en kind, Leuven, Belgium*

Study question: How common is discontinuation prior to starting fertility treatment and can this be predicted by women's or their partner's medical chart factors or infertility-specific distress?

Summary answer: One in five couples discontinued the fertility clinic trajectory before even starting treatment, most commonly between diagnostic tests, but no predictors were identified.

What is known already: 'Discontinuation' is the decision of a couple to opt out from the fertility clinic trajectory without being advised to stop by the clinic, without financial reasons and without having fulfilled their wish for a pregnancy or child. Most studies on discontinuation and infertility-specific distress focus on patients in treatment. Surprisingly, two studies reported rates of discontinuation prior to treatment ranging between 8-13% and identified women's higher age, lower education level and symptoms of depression as risk factors. To help couples achieve parenthood, more research into discontinuation and infertility-specific distress prior to starting fertility treatment is needed.

Study design, size, duration: This longitudinal study asked 104 couples first consulting a fertility clinic between March 2017 and July 2019 to fill out a questionnaire. Medical charts of couples were followed up for six months to assess 'discontinuation prior to treatment'. More specifically, we followed up how many couples did not start treatment, within six months after first consulting the clinic without reporting a pregnancy or having been advised by the clinic to delay their diagnosis or treatment.

Participants/materials, setting, methods: Heterosexual couples consulting a fertility clinic for the first time were eligible. Discontinuation, pregnancy, clinic censoring, and potential predictors (i.e. age and duration of infertility) were extracted from medical charts. Infertility-specific distress was assessed with the reliable Infertility-Distress-Scale questionnaire (IDS; range: 8-40; the higher, the more distress; Cronbach's α = 0.80). T-tests examined associations between discontinuation and the infertility-specific distress and age of both partners and couple's duration of infertility.

Main results and the role of chance: A total of 65 couples gave their consent and filled out the IDS-questionnaire (response rate=63%). Eleven couples were excluded due to spontaneous pregnancy (n=7) or due to clinic censoring to delay diagnosis and/or treatment (n=4; i.e. mainly because of obesity). Of our final 54 participating couples, ten discontinued the fertility work-up (19%). Most of them (n=7/10) discontinued in between diagnostic tests rather than not starting treatment after having received a fertility diagnosis (n=3/10). Participating women and men were on average, respectively, 31.1 (+/- 4.2) and 33.6 (+/- 4.9) years old. The couples had an average duration of infertility of no less than 18.5 (+/- 9.9) months. On the day of their first fertility clinic visit, the IDS showed considerable stress in both partners. Women's level of infertility-specific distress (mean=23.9; +/- 4.7) was significantly higher than their partner's (mean=21.0; +/- 4.9; paired difference=2.9 +/- 4.9; p<0.001). However, infertility-specific distress did not significantly predict discontinuation regardless of gender (women p=0.771; men p=0.595). Also women's (p=0.658) and men's age (p=0.501) were not predictive. Interestingly, a positive trend was observed between discontinuation and couple's duration of infertility (p=0.087); this can be re-examined in our final sample.

Limitations, reasons for caution: Our current sample size only allowed detecting medium effect sizes for potential numerical predictors (ES d=0.55; power=0.80, alpha=0.05; t-test). As recruitment is ongoing, we will report on a larger sample size and be able to detect smaller effect sizes for numerical predictors and include potential categorical predictors (e.g. education).

Wider implications of the findings: Before even starting treatment, women and men have considerable distress and a considerable proportion of couples discontinues fertility treatment. As research showed that many discontinuers still want children and regret discontinuation, clinics need to devote attention to the prevention of discontinuation and do so from patient's first clinic visit on.

Trial registration number: not applicable

P-475 An overview of the nursing management and pathway of patients undergoing Intravenous Immunoglobulin infusion therapy (IVIg)

F. Steyn[1], W. Saab[2], V. Seshadri[2], P. Serhal[2], K.L. Wright[1]

[1]*The Centre for Reproductive and Genetic Health, Nursing, London, United Kingdom*
[2]*The Centre for Reproductive and Genetic Health, Clinical, London, United Kingdom*

Study question: Intravenous immunoglobulin therapy is being prescribed as an additional treatment option to patients undergoing fertility treatment. Is there a need to implement a specialist nursing service to manage these patients?

Summary answer: Fertility nurses are well placed to manage the care of patients receiving Immunoglobulin therapy as part of their treatment.

What is known already: Intravenous Immunoglobulin therapy is a non evidence based treatment that is offered to some patients undergoing fertility treatment when they meet the criteria for the therapy. IVIg is concentrated and highly purified human immunoglobulins (antibodies) primarily IgG (immunoglobulin G). IVIg is prepared from pooled human blood donors. The immunoglobulin

therapy can be associated with a number of side effects including pain at infusion site, muscle pain, fever and low blood pressure. Chest tightness and blood clotting has also been associated with the therapy. Patients undergoing IVIg need to be monitored and observed both closely and cautiously throughout the infusion.

Study design, size, duration: Fertility nurses who are competent in the administration and information provision on the use of IVIg, manage the pathway and oversee the patients undergoing IVIg. The head of Nursing, clinical lead and theatre lead initiated the programme and devised a patient information and consent leaflet, clinical protocol and post infusion instructions in order to ensure that the patient is managed both safely and effectively pre, during and post infusion. The programme began in 2017.

Participants/materials, setting, methods: The programme consists of A clinical lead, head of nursing, senior fertility nurse and a theatre nurse. Evidence and research supporting the use of IVIg was reviewed and discussed at a preliminary meeting with the team. The protocols were devised and a log initiated to record the patients that meet the criteria of IVIg. Each member of the group were responsible for initiating the protocol and pathway.

Main results and the role of chance:

The HFEA, the Royal College of Obstetricians and Gynaecologists (RCOG), Science Advisory Committee and the American Society of Reproductive Medicine (ASRM) all agree that there is no strong evidence at the moment to justify immune testing and treatment in the context of fertility failure and recurrent miscarriages. However, if a patient is appropriately counselled on the use and given the opportunity to make an informed decision, safe protocols and pathways for the use of IVIg can be developed and managed by informed and competent staff in the delivery of the programme. Fertility nurses who are trained in the administration and use of the medication are able to deliver effective nursing care and manage the pathway for those receiving intravenous immunoglobulin infusions. It is crucial for these patients to be managed safely and to be well informed of all potential outcomes or adverse reactions and the fertility nurse is well placed to do this in accordance with the NMC Code 2018 - preserving safety, practising effectively, prioritising people and promoting professionalism and trust.

Limitations, reasons for caution: This project serves as a reminder that anyone providing care should not undertake a procedure unless competent to do so, whilst considering how they can best ensure competence and confidence to carry out activities that expands their scope of practice.

Wider implications of the findings: IVIg is non evidence based and there is division in the opinion of professionals that Immunoglobulin's are effective in the outcome of patients undergoing fertility treatment, IVIg is derived from a blood product so extreme caution should be taken when administering the infusion and nurses should receive further training.

Trial registration number: not applicable

P-476 Effectiveness of a spousal support program in improving the quality of life of infertile men in Japan: a pilot study

K. Asazawa[1], M. Jitsuzaki[2], A. Mori[3], T. Ichikawa[4], K. Shinozaki[5]

[1]*Tokyo Healthcare University, Department of Nursing, Tokyo, Japan*

[2]*University of Occupational and Environmental Health, Department of Nursing, Fukuoka, Japan*

[3]*St. Luke's International University, Women's Health and Midwifery- Graduate School, Tokyo, Japan*

[4]*Chiba University, Graduate School of Medicine, Chiba, Japan*

[5]*International University of Health and Welfare, Graduate School of Health and Welfare Science, Fukuoka, Japan*

Study question: What is the effect of a spousal support program on improvement of the quality of life (QOL) of male patients with infertility of various causes?

Summary answer: The spousal support program had a positive effect in terms of increasing the scores of the Relational and Emotional subscales of QOL.

What is known already: Infertile men experience infertility-specific anxiety, and socially isolated infertile men are more vulnerable to severe anxiety (Fisher & Hammarberg, 2011). Counseling and an educational program reportedly reduce stress in female patients but not in male patients undergoing infertility treatment (Boivin, 2003; Asazawa, 2015). The major predictors of the QOL of men undergoing infertility treatment are lack of spousal support, prolonged infertility period, and male factor (Asazawa, 2018). Therefore, a spousal support program for men with infertility from various causes and a short infertility period is needed.

Study design, size, duration: This a non-randomized controlled study involving a quasi-experimental one-group pretest posttest design to evaluate the preintervention and postintervention QOL and Distress scores. The program which aimed to obtain spousal support was conducted on a purposive sample of 38 couples of infertility patients in Tokyo, Japan, from April to August 2018. The sample size calculation involved a significance level of alpha = 0.05, power = 0.80, effect size to γ = 0.80, dropout rate = 35%.

Participants/materials, setting, methods: A single spousal support program provided information and used a participatory–interactive approach to enhance understanding and cooperation between couples undergoing fertility treatment. Interventions were performed for the couples, and surveys were conducted only in men. QOL and Distress were measured using self-administered valid and reliable questionnaires. The paired t-test was used to analyze preintervention and postintervention data.

Main results and the role of chance: During the study, 38 questionnaires were distributed to eligible men. Data from 31 questionnaires were usable for analysis, with a response rate of 81.6%. The mean age (± SD) was 38.6 (± 7.0) years. The causes of infertility were a low sperm concentration (i.e., oligospermia) of 61.3% and a poor sperm motility (i.e., asthenospermia) of 38.7%. There were no significant differences between the pretest-posttest scores in the three scales of QOL, Distress, and Spousal Support based on the paired t-test. The paired t-test was conducted for the QOL subscales. There were significant differences between the pretest-posttest scores of the Relational and Emotional subscales of QOL. The t-test showed that the posttest Emotional score (66.9 ± 16.9) was significantly higher than the pretest Emotional score (58.5 ± 13.5; $t(30) = 2.2$, $p < 0.05$). The posttest Relational score (71.2 ± 21.6) was significantly higher than pretest Relational score (60.8 ± 13.7; $t(30) = 2.3$, $p < 0.05$). In the high age group, there were significant differences between the pretest-posttest scores of the QOL ($p < 0.05$) and Distress ($p < 0.01$) scales based on the Wilcoxon signed-rank test. The majority of the participants (74.2%) were satisfied with the program.

Limitations, reasons for caution: This study involved a single group pretest-posttest design. The internal validity of the intervention effect was weaker. As this study had a small sample size and data were collected only from a single clinic, there is limited generalizability and potential bias.

Wider implications of the findings: The spousal support program was well received and had significantly improved part of the QOL of men with infertility from various causes. Therefore, a larger study using a pretest-posttest randomized controlled trial is recommended.

Trial registration number: noting.

P-477 Worlds Apart or Two Sides of the Same Coin? Attitudes, Perceptions and Motives of Potential Oocyte and Sperm Donors in Austria

B. Boettcher[1], M. Flatscher- Thoeni[2], W. Geser[3], A. Lampe[4], G. Werner- Felmayer[5], C. Voithofer[6], C. Schusterschitz[7]

[5]*Medical University of Innsbruck, Division of Biological Chemistry - Biocentre-, Innsbruck, Austria*

[6]*University Innsbruck, Department of Civil Law-, Innsbruck, Austria*

[7]*University for Health Sciences- Medical Informatics and Technology, Department of Psychology and Medical Sciences, Hall in Tirol, Austria*

Study question: This study analyses the willingness to donate oocyte or sperm and focuses on differences between potential female and male donors in attitudes, perceptions and motives.
Summary answer: Significant differences between the donor groups "doubtful", "potential" and "non-donors" as well as significant sex differences with respect to attitudes, perceptions and motives are evident.
What is known already: Oocyte and sperm donors have been explored previously, mostly focusing on post-donation scenarios (Hershberger, 2004; Purewal and van den Akker, 2009; Sydsjö et al., 2012; Van den Broeck et al., 2013; Bracewell-Milnes et al., 2016, Thijssen et al., 2017, Provoost et al., 2018). Main issues of these empirical studies are characteristics, experiences, motivations, attitudes, disclosure, health risks, and the willingness to donate. Up to our knowledge we present the first pre-donation study of potential oocyte and sperm donors focusing on sex differences against the background of the literature-based variables attitudes, perceptions and motives.
Study design, size, duration: An electronic anonymous survey was conducted between April and June 2017. In total 556 students completed the questionnaire online. To allow the comparison between men and women regarding their attitudes, perceptions and motives as well as regarding their willingness to donate gametes we designed two separate questionnaires. Both generally consist of the same 44 items whereby the questionnaire for female respondents exclusively refers to oocyte donation and the male version exclusively focuses on sperm donation.
Participants/materials, setting, methods: Students from three Austrian universities received an email-invitation with a study description and a link directly leading to the online survey. Instructions on how to fill out the questionnaire were given online after participants had signed the informed consent form. Chi-square tests, two-way analyses of variance, and subsequent one-way analyses of variance with post-hoc tests (Scheffé) were used to analyse differences between the three donor groups and sex differences in the variables of interest.
Main results and the role of chance: Based on an item, concerning participants' willingness to donate oocytes/sperm at some point in the future, the study sample was subdivided in three groups: potential donors (n=133; 24%; women: 48%, man: 52%), doubtful donors (n=207; 37%; women: 76%, man: 24%) and non-donors (n=215; 39%; women: 68%, man: 32%). Results show that, compared with male potential donors (39%), the group of female potential donors (17%) is significantly smaller, while the groups of female non- (41%) and doubtful donors (42%) are significantly larger than the groups of male non- (28%) and doubtful donors (32%).

We can also provide evidence for sex differences and/or differences between doubtful and potential donors in motives for gamete donation. Doubtful donors differ significantly from potential donors in the role that altruism, passing on one's genes, and enhancing one's self-worth play with respect to the willingness to donate. Altruism is more important to doubtful than to potential donors, while passing on one's genes and enhancing one's self-worth is more important to potential than to doubtful donors. Beyond that altruism and the motive of passing on one's genes seem more relevant to men than to women. For the self-enhancement motive, we find no significant sex differences.
Limitations, reasons for caution: The study focuses on students of three Austrian universities, a non-representative study sample. Hence, we cannot generalize our results to all university students nor to the general population who would qualify as oocyte and sperm donors. Moreover, social desirability may have had an influence.
Wider implications of the findings: The study at hand presents relevant findings on the general perception of sperm and oocyte donation and especially focuses on the potential donors' perspective. Gaining a better understanding of potential donors in the existing donation framework helps to evaluate the given regimes in light of designing improved ones.
Trial registration number: not applicable

P-478 Women's reports of barriers to and facilitators of oral medication adherence during controlled ovarian hyperstimulation: A mixed methods study

D. Mahoney[1], C. Russell[2]
[1]*University of Kansas, School of Nursing, Kansas City, U.S.A.*
[2]*University of Missouri-Kansas City, School of Nursing and Health Studies, Kansas City, U.S.A.*

Study question: What are women's perceived barriers to and facilitators of oral medication adherence during controlled ovarian hyperstimulation cycles?
Summary answer: This study has identified multifaceted barriers and facilitators that could power new interventions tailored to optimize adherence behaviors in future trials and clinical practice.
What is known already: Adherence to lifestyle modification recommendations remain problematic for women undergoing fertility treatment raising concerns about the extent to which women adhere to prescribed medication regimens. There is a scarcity of research assessing mediation adherence during fertility treatment clinical trials although limited data have shown suboptimal oral medication adherence rates of 19%-74%. Yet, researchers have not established a systematic process to investigate medication-taking behaviors while women undergo controlled ovarian hyperstimulation to determine if interventions are needed to optimize adherence. Exploring barriers to and facilitators of medication adherence during fertility treatment cycles is a novel approach to understand women's perspectives on adherence.
Study design, size, duration: A prospective, cross-sectional, non-interventional, single-visit, mixed methods study was conducted among a sample of 30 women who were actively taking either letrozole or clomiphene citrate for ovarian hyperstimulation in conjunction with undergoing intrauterine insemination cycles. The study duration was 4 months.
Participants/materials, setting, methods: Women recruited were patients of a reproductive endocrinology and infertility center located in the Midwestern region of the United States of America. Medication adherence barriers were measured using a 20-item adherence barrier questionnaire. Medication adherence facilitators were assessed with structured interviews. The interviews were audiotaped, transcribed, and data coded using a thematic approach. The relationship between barriers, facilitators, and demographic variables were tested. Analysis included Pearson $\square^2$ or Fisher exact test.
Main results and the role of chance: Reported barriers included recently feeling sad, down, or blue (53%), taking medication more than once per day (40%), worrying if the medication would affect sexual health (17%), and forgetting to take medication (10%). Women also reported not having the medication with them when it was time to take it (47%), taking medication more or less than prescribed (27%), and having skipped or stopped taking a medication because it made them feel bad (20%). Race was significantly associated with having attitudes and beliefs related barriers ($p < .05$) and physical related barriers ($p < .05$). Facilitators included using physical aides as reminders (60%), establishing a daily routine (50%), social support (43%), motivation (27%), hoping the medication works (20%), relationship with healthcare provider (17%) , and remembering to take medication (10%). Level of infertility insurance coverage was significantly associated with having social support related facilitators ($p < .05$). Race ($p < .01$) and ethnicity ($p < .01$) were significantly associated with having knowledge related facilitators. Number of prior failed treatment cycles were significantly associated with having attitudes and beliefs related ($p < .05$) and motivation related facilitators ($p < .05$). Highest level of education was significantly associated with having cognitive related facilitators ($p < .01$).
Limitations, reasons for caution: This study was conducted at a single site fertility center and the sample size was small. The study participants were married (100%) primarily white (83%), college educated (87%), had a household annual income of at least $100,00 (57%), and lived in a suburban community (83%) which limited generalizability.
Wider implications of the findings: The dynamic interplay between perceived barriers and facilitators and women's medication-taking patterns could influence whether or not medication regimens are followed correctly. These study findings provide important implications for researchers to explore the relationship between medication adherence and reproductive outcomes in future clinical trials involving fertility medications.
Trial registration number: Not applicable

POSTER VIEWING

PSYCHOLOGY AND COUNSELLING

P-479 Identification of research priorities in infertility and assisted reproduction: a multicenter study in partnership with patients

D. Garcia Garcia[1], S. Brazal[1], F. Lindenberg[2], E. Toft[2], A. La Marca[3], R. Borras[4], A. Lorenzon[5], M. B. Chehin[5], M. Ripero[6], I. Madero[7], M. Ricardo[8], A. Bolivar[9], A. Rodriguez[1], R. Vassena[1]

[1]*Clinica Eugin, Assisted reproduction, Barcelona, Spain*
[2]*Copenhagen Fertility Center, Assisted reproduction, Copenhagen, Denmark*
[3]*Eugin Modena, Assisted reproduction, Modena, Italy*
[4]*CIRH, Assited reproduction, Barcelona, Spain*
[5]*Huntington, Assisted reproduction, São Paulo, Brazil*
[6]*Fecunmed, Assisted reproduction, Barcelona, Spain*
[7]*Eugin Colombia, Assisted reproduction, Bogotá, Colombia*
[8]*Pró-CRIAR, Assisted reproduction, Belo Horizonte, Brazil*
[9]*Eugin Madrid, Assisted reproduction, Madrid, Spain*

Study question: Which are the main research interests among assisted reproduction (ART) patients?

Summary answer: Patients identified as research priority the areas of: ART side-effects and health, coping resources, diet and exercise, success rates, oocytes quantity/quality, and genetics of infertility.

What is known already: The involvement of patients and caregivers in setting research agendas in medicine has gathered significant momentum in the last decade. Patient involvement in setting research priorities offers several benefits: improved patient awareness and knowledge of their condition; greater understanding of the medical professionals of the impact of the condition on patients' quality of life; reduce costs associated with redundant research activities. This is may be also applicable to research in infertility and ART, where patients' interests have never been explored before.

Study design, size, duration: Cross-sectional study; an anonymous online survey was sent up to three times to patients from 8 fertility centers in 5 countries between January-November 2018. The study was based in the James Lind Alliance priority setting partnership model that comprises four phases: 1) exploration: identification of patients groups; 2) consultation and prioritization: analysis of the research agenda; 3) integration: analysis of collected data and identification of priorities; 4) follow-up: analysis of patients' views' contribution into recommendations.

Participants/materials, setting, methods: Overall, 2112 patients were contacted, and 945 surveys were answered (RR: 44.7%). Female (845, 89.4%) and male (100, 10.6%) patients were included. In the first part of the survey, patients were asked about their experience living with infertility. In the second part they were asked to identify research questions in this are relevant to them. Answers were categorized in topics and ranked by frequency. A shortlist of the Top-10 research questions is presented.

Main results and the role of chance: Mean age of patients was 37.8 (SD 1.74). Most of the patients did not have children at the time of the survey (523, 59%), while 51 (5.7%) were pregnant. Sixty (6.3%) patients did not start treatment, 579 (61.3%) performed a treatment with their own gametes and 304 (32.2%) recurred to gametes donation.

Patients were mainly interested in the effectiveness of ART and side effects of drugs, protection of fertility, prevention of infertility, and psychological aspects. The top-10 research priorities identified were: 1) What are the side-effects of ART treatments? (41.6%); 2) What are the most effective methods to cope with infertility from the psychological point of view? (37.2%); 3) What effects could the diet have on fertility? (25.9%); 4) What are ART success rates per clinical profile? (25.9%); 5) Are there healthy habits and lifestyle that could prevent infertility? (20.0%); 6) What are the long term risks associated to ART? (18.5%); 7) Are alternative therapies as acupuncture, yoga and meditation effective to treat/prevent infertility? (18.5%); 8) What is the impact of exercise on fertility? (15.4%); 9) How does oocytes quantity and quality affect fertility? (9.5%); 10) What are the genetic patterns or hereditary conditions causing/related to infertility? (9.5%).

Limitations, reasons for caution: Although all respondents had attended a fertility center, not all had started treatment at the time of response, while a few were pregnant; their priorities for research might have been informed by their infertility journey. Participants came from private fertility centers; areas of interest may be different in public settings.

Wider implications of the findings: Researchers and clinicians should keep in mind that, in addition to improvement of treatments' success rates and side-effects, patients greatly value research on causes, prevention and emotional aspects of infertility. As their views might differ from those of medical professionals, patients' voices should be incorporated in setting infertility research priorities.

Trial registration number: not applicable

P-480 Experience of and coping with recurrent miscarriages: Risk for depression, anxiety and restricted social support

R.J. Kuon[1], P. Voss[1], B. Ditzen[2], T. Strowitzki[1], T. Wischmann[2], M. Schick[2]

[1]*University Hospital, Department of Gynecological Endocrinology and Fertility Disorders, Heidelberg, Germany*
[2]*University Hospital, Institute of Medical Psychology- Centre for Psychosocial Medicine, Heidelberg, Germany*

Study question: Aim of the study was to identify the psychological risk and protective factors in couples with recurrent miscarriages and to derive the required professional support.

Summary answer: Already having a child increases anxiety and decreases depression in both partners. A high number of miscarriages correlate with low social support.

What is known already: Recurrent miscarriages are defined by the WHO as at least three consecutive losses of pregnancy before the 20th week of gestation. Anxiety, mourning and depression occur more frequently in women with recurrent than singular miscarriages. In one study a clinical relevant depression was found in 17% of the women and anxiety in 21%. A stable social network facilitates successful coping processes. Explicit statements about the emotional experience of the male partners are missing yet.

Study design, size, duration: A quantitative and qualitative questionnaire study was devised, approved by the Ethics Committee of the Heidelberg Medical Faculty. The ongoing study started in September 2018 and includes N=52 participants (25 couples, 2 women) so far. All women and their partners consulting the clinic for recurrent miscarriages at Heidelberg University Women's Hospital were invited to participate in the study.

Participants/materials, setting, methods: Participants completed a questionnaire with items regarding risk factors towards anxiety, depression and restricted social support (measured by the Screen-IVF), experience of miscarriages, coping (modified questionnaire on coping behaviour), impact on partnership, personal and social factors (COMPI Fertility Problem Stress Scales), attitudes towards treatment, need for support and sociodemographic variables. Data were analysed using chi square test, independent t-test analysis and ANOVA.

Main results and the role of chance: Questionnaires were handed out to 62 patients, whereof 52 completed the full assessment (response rate: 83.9%). In total, N=27 women (mean age: 35.1 years) and N=25 men (mean age: 36.2 years) have participated in the study so far. Of all subjects, 72.6% hold a high school or university degree. 40.4% of all participants already had one child in the current relationship. In the ScreenIVF, 84% of all participants showed at least one psychological risk factor. Overall, 66.7% revealed a risk for anxiety, 34.6% a risk for depression and 23.5% a risk for restricted social support. The risk for depression differs significantly between men and women with 48.1% for women and 20% for their partners (p=0.033). Having at least one child together decreases the depression risk in both women (p=0.043) and men (p=0.014), but increases the risk for anxiety in the whole group (p=0.033). A high number of miscarriages correlates with perceived restricted social support in the whole group (p=0.009).

Limitations, reasons for caution: Despite the high response rate, the generalizability of our findings is limited due to the small sample size. Furthermore, the participants in this sample showed an above-average high educational background.

Wider implications of the findings: Regarding the needs for emotional support, the study shows two results. Psychological counselling of couples with recurrent miscarriages and previous successful pregnancy should focus on anxiety rather than on depression. Couples with a high number of miscarriages should be encouraged to make demands on their social network.

Trial registration number: not applicable

P-481 Even in a population of patients satisfied of their medical care, ART burden remains an important issue to be addressed

B. Courbière[1], M. Grynberg[2], A. Grelat[3], V. Rio[4], C. Solignac[5], E. Arbo[5]
[1]Hôpital de la Conception- AP-HM, Department of Reproductive Medicine, Marseille, France
[2]Hôpital Antoine-Béclère, Department of Reproductive Medicine & Fertility Preservation, Clamart, France
[3]Clinique Pasteur, Centre Mistral, Guilherand-Granges, France
[4]Collectif BAMP, Association de patients de l'AMP et de personnes infertiles, Quincy sous Sénart, France
[5]Gedeon Richter France, Medical Department, Paris, France

Study question: What is the perception and impact on quality of life among infertile French women and men having undergone assisted reproduction technologies (ART)?
Summary answer: Despite an overall high level of satisfaction concerning the treatment received, we observed the burden of infertility and treatments on most of the aspects investigated.
What is known already: Impact of infertility and ART on quality of life is well established. However, data focused on both women and men, their feeling, their main questions and preoccupations as well as the consequences of ART on their daily life are still lacking.
Study design, size, duration: We performed a cross-sectional study, from October 7, 2018 to October 28, 2018 in France. First, we screened 2,003 people aged 18 years or older, from a large panel representative of national population. From these, 1 045 patients (355 men; 690 women) had already undergone ART and accepted to answer to the online survey.
Participants/materials, setting, methods: The questionnaire included 56 questions on several domains: global feelings, treatment burden, rapport with medical staff, expectations… Respondents were divided into three groups: people who succeed to have a baby following ART (n= 523), those currently undergoing ART (n =199) and people having terminate the ART process without a baby (n = 219). Results are descriptive and are presented in percentage or by their mean ± standard deviation.
Main results and the role of chance: Respondents had already experienced 3.6±4.2 cycles of ART on average. The two main concerns prior to starting ART were the possibility of never become a parent (57%) and self-questioning about their own accountability in prior failure of getting pregnant (46%). For 470 patients (45%), the first specialized consultation occurred less than 12 months after the start of natural attempts. Patients had started their reproductive project 3.8±3.6 years before participating to the survey. Satisfaction rates regarding medical care are above 80% for most items: quality of care (88%), amenities (86%), adequate answers to their questions (85%), availability of medical staff (83%), medical information (83%) and involvement of medical staff (83%). Overall, 77% of respondents reported that examinations needed for monitoring were burdensome or very burdensome. The most prominent feeling in case of ART failure were discouragement (65%), and the most frequent psychological consequences were fatigue (65%), distress (59%), and feeling of unfairness (53%). Important impact on sexual life was reported by 57% of respondents. They pointed out the lack of information about non-medical support (42%), treatments options and modalities (24%), criteria for medical care access and reimbursement (23%).
Limitations, reasons for caution: This was an online survey, potentially biased by the representativeness of study sample. Also, data are only descriptive, and the single-country nature of the study limits the generalization of these findings.
Wider implications of the findings: These findings showed high overall level of satisfaction regarding the medical care received. Nevertheless, the burden of infertility and of ART are not negligible and should be considered. ART units should be encouraged to develop non-medical support for all patients.
Trial registration number: not applicable

P-482 Working conditions and fertility quality of life (FertiQoL): a cross-sectional study in Japan

E. Maeda[1], O. Hiraike[2], K. Murata[1], H. Sugimori[3], Y. Osuga[2]
[1]Akita University Graduate School of Medicine, Environmental Health Sciences, Akita, Japan
[2]The University of Tokyo, Department of Obstetrics and Gynecology, Tokyo, Japan
[3]Daito Bunka Univerisity, Department of Nursing, Tokyo, Japan

Study question: Is there an association between working conditions and quality of life among women undergoing fertility care?
Summary answer: Working conditions for both women and their partners, such as the ease of taking days off, are significantly associated with fertility quality of life.
What is known already: More than 20% of Japanese women undergoing fertility treatment were reported to have resigned from their jobs due to difficulty in coping with work and fertility treatment. However, studies examining the impact of working conditions on fertility quality of life are lacking.
Study design, size, duration: We conducted a cross-sectional survey in Japan in January 2019. Participants were 721 women recruited via an online social research panel.
Participants/materials, setting, methods: Participants included women aged 25-44 years, having paid employment, and undergoing fertility diagnosis and/or treatment. They completed questionnaires to assess fertility quality of life (FertiQoL), job stress based on the demand-control-support model (Brief Job Stress Questionnaire, BJSQ), and working conditions of participants and their partners (e.g., working hours per week, ease of taking work days off rated on 5-point scale). They rated their partner's cooperation during fertility treatment and provided clinical and socio-demographic data.
Main results and the role of chance: Of the 1,223 eligible people, we sent recruitment emails to 958, and 721 completed the survey (75% participation rate). Twenty-nine percent of the participants reported that it was difficult (i.e., very difficult or difficult) to take days off for themselves and 58% reported it was difficult for their partners. The mean (SD) total score on the FertiQoL increased linearly with a higher level of ease to take days off: from 39.3 (15.7) to 57.1 (15.1) for the participants' time-off, and from 47.3 (15.4) to 57.2 (17.6) for their partners' time-off. The proportion of those who received high support from co-workers on the BJSQ was 12%. Multiple regression analysis showed that total FertiQoL score was significantly associated with the following work factors: self-employed (β = 0.10, compared with regular employees), high job demand (β = –0.13), high support from co-workers (β = 0.07), easy to take days off (β = 0.24), easy for partners to take days off (β = 0.10), partner works $\geq$ 50 hours per week (β = –0.08), after adjusting for partner's cooperation (β = 0.23), clinical (e.g., etiology, treatment stage), and socioeconomic factors. The association was evident especially in the Mind-Body, Social, and Treatment Tolerability domains.
Limitations, reasons for caution: We cannot infer causality due to the cross-sectional study design. The use of a social research panel and possible volunteer bias may limit the generalizability of the findings.
Wider implications of the findings: Flexible work arrangements and restrictions on long working hours would improve fertility quality of life, which might help employees balance work and fertility treatment. Considering the low proportion of participants receiving support from co-workers, social support at workplaces could assist women with fertility problem who tend to be psychologically isolated.
Trial registration number: Not applicable.

P-483 Psychological stress at the time of transvaginal ultrasound guided oocyte retrieval does not adversely affect in-vitro fertilization outcomes: A prospective observational study

W.C. Cheung[1], P.S. Chan[1], J.P.W. Chung[1], T.C. Li[1]
[1]The Chinese University of Hong Kong, Department of obstetrics and Gynaecology, Shatin- New Territories, Hong Kong

Study question: Does psychological stress at the time of transvaginal ultrasound guided oocyte retrieval (TUGOR) adversely affect in-vitro fertilization (IVF) outcomes?
Summary answer: Infertile women experienced stress during TUOGR, however psychological stress did not adversely affect the IVF outcomes.
What is known already: Women felt most stressful during TUGOR in the whole IVF treatment, because of the uncertainty and the pain experienced at the time of the procedure. However, it is unclear

whether physical and psychological stress would adversely affect the IVF outcomes. The majority of past studies measured stress level by the use of questionnaires; the use of stress biomarkers such as salivary alpha amylase (sAA) and salivary cortisol (sCort) may provide additional, objective assessment of the body's response towards stress.
Study design, size, duration: This prospective observational study took place in a university based hospital over a 12 month period. A total of 209 women undergoing TUGOR were recruited.
Participants/materials, setting, methods: Participants were asked to (1) complete two psychological questionnaires (Beck depression inventory-BDI; general health questionnaire-GHQ) before TUGOR, (2) fill in a questionnaire (State trait anxiety inventory–STAI) and collect saliva samples before and after TUGOR, and (3) rate the pain score by visual analogue scale (VAS-P) immediately after TUGOR. Results above the 75 th centile for each measurement were considered to represent high score. The psychological and biochemical stress scores in women with different outcomes were compared.
Main results and the role of chance: The median (25 – 75 percentile) of STAI scores (65, 56 – 71), sAA level (0.9 x 10^5, 0.5 x 10^5– 1.8 x 10^5) and sCort level (10, 7 - 14) after TUGOR were significantly (p = 0.001, p = 0.017 and p = 0.001 respectively) higher than those before TUGOR (56, 49 – 61; 0.8 x 10^5 , 0.5 x 10^5 – 1.3 x 10^5; 7, 5 – 9.8 respectively). There was no differences in age, body mass index, basal follicle-stimulating hormone, the duration of infertility and endometrial thickness between the various groups of subjects (non-conception, conception, miscarriage and live birth group). There was no significant differences in in sAA, sCort, VAS-P, STAI, GHQ, BDI scores between non-conception and conception group, and between live birth and miscarriage group. In additional, there was no differences in the number of oocytes retrieved, mature oocytes recovered and viable embryo produced between women with high or low stress score.
Limitations, reasons for caution: The high stress scores in this study represented only modest increase in stress level; it does not rule out the possibility that more marked increase in stress level could have an adverse effect.
Wider implications of the findings: Although women do find the TUGOR procedure painful and stressful, they should be reassured that a modest increase in the amount of stress does not appear to affect the IVF outcomes.
Trial registration number: Not applicable

P-484 Development of a measure to assess Infertility-related external and internal shame

M. Moura-Ramos[1,2], C. Ferreira[2,3], M. Matos[2,3], A. Galhardo[2,4]
[1]*Centro Hospitalar e Universitário de Coimbra, Serviço de Reprodução Humana, Coimbra, Portugal*
[2]*University of Coimbra, Center for Research in Neuropsychology and Cognitive and Behavioral Intervention, Coimbra, Portugal*
[3]*University of Coimbra, Faculty of Psychology and Educational Sciences, Coimbra, Portugal*
[4]*Instituto Superior Miguel Torga, Psychology, Coimbra, Portugal*

Study question: Is there any short, valid and reliable measure to assess the experience of infertility-related shame?
Summary answer: The Infertility external and internal shame scale (I-EISS) is a short, valid and reliable tool to assess the experience infertility-related shame in men and women.
What is known already: Shame is a universal human emotion that plays a critical role in psychosocial functioning and development. Shame can be painful and incapacitating as it involves feelings of inferiority, defectiveness, uselessness and isolation, and has been associated with depressive symptoms in a wide range of populations. Studies on emotional aspects of the infertility experience have often documented that shame is associated with infertility. Indeed, men and women with infertility often report feelings of defectiveness, unworthiness and low self-esteem or inferiority and social isolation, which often leads to difficulties in disclosing their infertility experience.
Study design, size, duration: Cross sectional study. Data was collected through self-report measures using online and paper-and-pencil methods. Inclusion criteria were age (18 years or older), and having an infertility diagnosis. A 8-item questionnaire assessing external (4 items) and internal shame (4 items) was developed to specifically assess infertility related shame, based upon a questionnaire developed by the same research team to assess general external and internal shame.
Participants/materials, setting, methods: Participants (*N*=245) are men (*n*=75, 30.6%)) and women (*n*=170, 69.4%) diagnosed with infertility. Of these, 98 were recruited online (40%) and 147 (60%) were recruited in the Reproductive Medicine Unit of an Universitary Hospital. Mean age is 34.88 (*SD*=0.32) for women and 35.74 (*SD*=0.50) for men. Self-report questionnaires were used to assess external and internal shame, Infertility related stress, depression, and shame. A confirmatory factor analysis was conducted to test factor model of the I-EISS.
Main results and the role of chance: Regarding the factor structure of the measure, a confirmatory factor analysis in a two-factor model was tested. This model revealed an very good fit to the data, with χ^2 (19) = 40.57; p =.003; CFI = .97; RMSEA = .08, SRMR = .04. Reliability was also high (α= 85 for external shame and .91 for internal shame). Criterion validity was assessed examining the correlations of the I-EISS subscale and other measure assessing general shame and results were of r = 0.60, p<0.001 for both subscales. We also tested the association of I-EISS subscales and the Fertility Problem inventory subscales assessing Social concerns (SocC), sexual concerns (SexC) and relationship concerns. External and internal shame were highly correlated with social concerns (r=0.65 and r=0.70, both p < 0.001), sexual concerns (r=0.43 and r=0.63, both p < 0.001) and marital concerns (r=0.42 and r=0.52, both p < 0.001). These results allowed us to establish the concurrent validity of the I-EISS with infertility-related emotional outcomes, namely infertility-related stress.
Limitations, reasons for caution: Due to the small sample size and the cross-sectional design, the results must be analysed with caution. Because sample was self-selected, patients with higher experience of shame may have preclude themselves from participating in the survey and therefore participants may not be representative.
Wider implications of the findings: The I-EISS can be used in research and clinical contexts to assess infertility related-shame and identify patients at risk of psychological malfunctioning. I-EISS holds potential interest for researchers and clinicians being a brief and reliable tool for assessment of a specific emotion that seems particularly relevant in infertility-related psychological adjustment.
Trial registration number: not applicable

P-485 Cycle Apps – help or confusion? Understanding women's perception towards cycle tracking apps

S. Bench-Capon[1], S. Bond[1], S. Johnson[1], S. Weddell [1]
[1]*SPD Development Company Ltd, Clinical Affairs, Bedford, United Kingdom*

Study question: How do women perceive the fertility predictions that are provided through calendar-based cycle tracking apps?
Summary answer: Women did not know the accuracy of fertility apps, with some believing calendar app predictions. This led them to question their fertility causing unnecessary stress.
What is known already: Monitoring lifestyle and health factors on their smartphones is now commonplace. Women looking for ways to reduce their time to pregnancy often turn to calendar-based fertility apps when trying to conceive.

Studies have shown that the day of ovulation can vary between women with the same cycle length which means that predictions of apps solely using cycle length are often found to be inaccurate or imprecise. Information on the accuracy of these apps is scarce, making it hard for women to make an informed decision on their use.
Study design, size, duration: This study was a qualitative component of a larger mixed methods study examining the efficacy of the Clearblue Connected Ovulation Test System. We performed 38 qualitative in-depth interviews on women randomly sampled from both study arms and all study outcomes (conceived after 1 or 2 cycles, or did not conceive). All women were provided ovulation tests either during or after study completion. Interviews were conducted May – September 2018.

Participants/materials, setting, methods: Women aged 18-40 who had a smartphone and were actively trying to conceive were recruited from across the UK. Telephone interviews were conducted to discuss their views and experience of trying to conceive. Data was transcribed and analysed by thematic framework analysis. Ethical approval was given from the internal review board.
Main results and the role of chance: The initial trust in calendar-based apps varied, from believing that they would not be on the market if they didn't work, to others using them as a guide or record. Some women did understand their limitations with one saying "I'm wanting to not work off estimations, I want to work on something that is more accurate and more specific to me".

When using ovulation tests women found the results did not always correlate with predictions from calendar-based apps. Comments included ". . .obviously it is incorrect. . .. . .because I was ovulating weeks later", ". . .my fertile time [from the ovulation test] started when the other [calendar-based] app said it would have finished".

Querying the impact of inaccurate predictions women mentioned they would have queried their body rather than the app, "I think I probably would have questioned myself before I questioned an app, it's hard to question technology really, isn't it? Because you think it's got the answers to everything". This may have resulted in delays to pregnancy ". . .would've taken a hell of a lot longer for me to conceive if I had just used the app." "If I hadn't have used the ovulation kit, I don't think I would be pregnant...".
Limitations, reasons for caution: Due to recruiting online, participants were self-selecting and the data reflects those who applied to the study.
Wider implications of the findings: Some women question their bodies before fertility apps. Following incorrect advice from calendar-based apps could prolong their time to pregnancy and cause unnecessary stress. We would recommend that fertility apps provide more information on their accuracy, so women can make an informed choice on how to use them.
Trial registration number: NCT03424590

P-486 Does socioeconomic status (SES) affect anxiety/depression in women undergoing assisted reproduction treatment?

L. Leis [1], R. Wonchockier [2], C. Eduardo Busso [3], A. Neves Ribeiro [2], S. Glina [3], N. Eduardo Busso [4]
[1]Projeto Alfa- Reproduction Medicine, Psychology, São Paulo, Brazil
[2]Projeto Alfa- Reproduction Medicine, Embriology, São Paulo, Brazil
[3]Projeto Alfa- Reproduction Medicine, Human Reproduction Medicine, São Paulo, Brazil
[4]Projeto Alfa- Reproduction Meducine, Human Reproduction Medicine, São Paulo, Brazil

Study question:

The aim of the study was to investigate whether SES is associated with higher levels of anxiety/depression in women undergoing assisted reproduction treatment.

Summary answer: We found no correlation between SES and anxiety/depression levels among subjects studied.
What is known already: SES affects overall human functioning, including physical and mental health. Financial burden due to fertility treatment contributes to worsening of quality of life and treatment dropout. There are no studies correlating SES and anxiety/depression levels in assisted reproduction patients.
Study design, size, duration: Cross-sectional study conducted between April-December 2018.
Participants/materials, setting, methods:

127 women undergoing fertility treatment in a private clinic were included. They underwent SES evaluation and were divided in 4 groups according to family income. All fulfilled a questionnaire on demographic data, period of infertility, previous treatments. Subjects also fulfilled IDATE anxiety test and Beck Depression Inventory.
Main results and the role of chance: There was no significant association between SES and depression (p=0,39) or anxiety (p=0,67). There was no significant association between number of previous attempts and depression (p=0, 06) or anxiety (p=0,74). However, we found a statistically significant association between period of infertility and depression (p=0,02).
Limitations, reasons for caution: Considering our sample size, more studies are required to confirm these findings.
Wider implications of the findings: To wait for a child in the context of infertility seems to be the most important factor leading to anguish and depression, overcoming the need of successive treatments or financial issues.
Trial registration number: Not aplicable

P-487 Cross-border reproductive care from the Netherlands to Belgium explained by shared-decision-making

J. Devroe[1], W. Ombelet[2], D. De Neubourg[3], N. Nieuborg[1], K. Vandenborne[2], K. Peeraer[1], S. Vereeck[3], C. Meuleman[1], E. Dancet[1]
[1]Leuven University Hospital, Gynaecology, Leuven, Belgium
[2]Ziekenhuis Oost-Limburg, Fertility clinic, Genk, Belgium
[3]University Hospital Antwerp, Centrum voor Reproductieve Geneeskunde, Antwerp, Belgium

Study question: Can the cross-border movement from Dutch IVF-patients to Belgian clinics be explained by a difference in shared decision-making?
Summary answer: Most Dutch patients travelled to Belgium for shared decision-making (SDM) and experienced SDM on IVF was indeed higher in Belgium as compared to the Netherlands.
What is known already: Dutch patients travel to the Dutch speaking part of Belgium for Cross-Border Reproductive Care (CBRC). Belgian and Dutch clinics offer Dutch patients equally successful reimbursed in vitro fertilisation (IVF). Quantitative research clarified that Dutch patient's most cited reason for traveling is 'higher quality care' (Shenfield et al., Hum Reprod, 2010). Dutch patients clarified in interviews and on internet fora that they expected and experienced more shared decision-making (SDM) in Belgium (Van Hoof et al, Facts Views Vis Obgyn 2014). Dutch patient's expectations and experienced level of SDM in Belgium and the Netherlands had yet to be quantified and compared.
Study design, size, duration: Last winter (2017-2018), we conducted a multicenter retrospective survey on the motivations and experiences of 320 heterosexual couples living in the Netherlands and having traveled to Belgium for IVF between September 2015 and September 2017.
Participants/materials, setting, methods: In total 104 couples completed minimally half of the questions send out by three Belgian IVF-clinics. Two dichotomous questions assessed whether expected SDM and informed decision-making (IDM) motivated couples to travel. The valid and reliable 'SDM-Q9' questionnaire (Kriston et al, Patient Educ Couns, 2010), assessed the levels of experienced SDM (0-45) and IDM on IVF (0-27; the higher, the better). Paired and independent sample t-tests assessed within and between participant differences in SDM and IDM.
Main results and the role of chance: Of the 104 participating Dutch couples (participation rate=33%) having IVF in Belgium, only 32 previously had IVF in the Netherlands (30%). Most couples (n=53/104) travelled because they expected more SDM and/or more IDM in Belgium. The SDM-Q9 reliably assessed the levels of experienced SDM and IDM in our sample (respectively: Cronbach-alpha=0.89 & 0.78; Item Total Correlation $\geq$0.36 & $\geq$0.49). Experienced SDM and IDM on IVF in Belgium, did not differ between the three Belgian clinics (respectively: p=0.904; p=0.627). Dutch patients treated with IVF in both countries (n=32) experienced more SDM and more IDM on IVF in Belgium as compared to the Netherlands (respectively: paired difference=7.1 +/-9.5; p<0.001 & paired difference= 2.0 +/-3.5; p=0.003). Neither of these differences seem due to second rather than first opinion seeking in Belgium, as having had IVF in the Netherlands (n=32) or not (n=72) did not affect the experienced level of SDM or IDM on IVF in Belgium (respectively: 31.8+/- 8.3 vs 34.0 +/- 8.3; p=0.21 & 10.9+/- 2.9 vs 11.9 +/- 2.8; p=0.12).
Limitations, reasons for caution: What drove participation might also drive expectations and experiences of SDM. Focussing on couples who had IVF in both countries, ensured that SDM and not accessibility was compared. Paired t-tests rather than multilevel modelling were appropriate as Belgian clinics did not differ but numbers per Dutch clinic were too small.
Wider implications of the findings: This study proves that SDM rightfully drives clinic surfing across national borders. This novel finding implies that SDM can affect clinic's market share. Whether clinic's ability to provide SDM

also drives national IVF-clinic surfing and even IVF-discontinuation should be examined.

Trial registration number: Not applicable

P-488 Evaluation of depression and anxiety levels in IVF / ICSI cycles of patients with endometriosis; a prospective study

M.U. Ceran[1], N. Yilmaz[2], E.N. Ugurlu[3], N. Erkal[4], A.S. Ozgu Erdinc[2], Y. Tasci[2], H. Gulerman[2], Y. Ustun[2]

[1]*Baskent University, Gynecology and obstetrics, Konya, Turkey*

[2]*Health Science University Zekai Tahir Burak Women's Health- Education and Research Hospital, Department of Reproductive Endocrinology-, Ankara, Turkey*

[3]*Medical Park Health Group, Department of Gynecology and Obstetrics-, Mersin, Turkey*

[4]*Health Science University Antalya Education and Research Hospital, Department of Gynecology and Obstetry, Antalya, Turkey*

Study question: Can psychological health levels and scales be important in endometriosis patients during ART ?

Summary answer: Although the depression level is higher in endometriosis patients, it does not cause any changes in pregnancy rates in ART cycles.

What is known already: Pelvic endometriosis negatively affected the quality of life of women and caused significant depressive and anxiety symptoms. Controlled trials have shown that endometriosis can adversely affect women's psychological health and overall quality of life. Although several studies on IVF treatment have shown that psychological distress before and during the treatment did not affect the likelihood of pregnancy, there are not enough studies examining the effect of psychological health levels on the ART cycle in patients with endometriosis.

Study design, size, duration: This study was designed prospectively. A total of 93 women in the IVF/ICSI program at the educational research hospital between October 2017 and March 2018 agreed to participate in the study. Patients were divided into two groups as endometriosis (n:37) and non-endometriosis (n:57) group. Patients were included in the study regardless of ART indication. But the presence of psychopathological disease and chronic systemic disease was defined as exclusion criteria.

Participants/materials, setting, methods: The WHOQOL-BREF short-form quality of life questionnaire, the Beck Depression Inventory (BDI) and the Beck Anxiety Inventory (BAI) scale were used to determine the psychological health levels before IVF treatment. Psychological health levels were defined as percentiles, and depression and anxiety scales were categorized through the scores (normal, mild, moderate-severe). In addition, demographic features, stimulation parameters, oocyte-embryo quality, and clinical pregnancy outcomes were recorded. SPSS 25 program was used in the analysis.

Main results and the role of chance: Ninety-three infertile patients underwent IVF treatment and 26 positive pregnancies are achieved. No statistically significant difference was observed between the two groups in terms of age, body mass index, day two FSH, LH and estradiol levels, antral follicle count and infertility reasons (p> 0,05). Moderate-high depression was 8,9 percent in non-endometriosis group and 37,8 percent in endometriosis group. A significant difference was found between endometriosis and non-endometriosis groups in depression scores (p <0,01), but no significant difference in psychological health levels and anxiety (p: 0,897, p:0,058,respectively). A significant correlation was observed between depression and endometriosis (CC: 0,435, p<0,01) In terms of stimulation parameters no significant difference was observed between two groups, except total gonadotropin dose. Total and MII oocyte counts, number of embryos and pregnancy outcome were similar in both groups (p> 0.05).When the effects of psychological health, depression and anxiety scores on pregnancy outcomes were examined, no significant relationship was found.

Limitations, reasons for caution: We can say that one of our limitations is the number of patients. Increasing the number of patients can prevent errors that we cannot foresee.Another issue is that the study was designed as a single center.

Wider implications of the findings: We observed a relationship between endometriosis and depression scores similar to the literature. With wider studies in future, we think that the role of psychological factors in IVF treatment and its relationship with endometriosis can be elucidated.

Trial registration number: not applicable

P-489 The impact of a 12-hour mindfulness-based wellness curriculum on obstetrician/gynecologists (OB/GYN) residents' burnout, mindfulness, and self-compassion.

B. Peterson[1], L. Fitzmaurice[2], J. Boehm[3], J.M. Place[4]

[1]*Chapman University, Crean College of Health and Behavioral Sciences, Orange- CA, U.S.A.*

[2]*University of California Irvine- Residency Program Director, Department of Obstetrics and Gynecology, Orange, U.S.A.*

[3]*Chapman University, Department of Psychology, Orange, U.S.A.*

[4]*Ball State University, Department of Nutrition and Health Science, Munice, U.S.A.*

Study question: Does participation in a 12-hour mindfulness-based wellness curriculum decrease burnout, increase mindfulness, and improve self-compassion in a group of OB/GYN residents?

Summary answer: Overall self-reported levels of mindfulness and self-compassion increased at a 6-9 month follow-up assessment, but burnout did not change.

What is known already: A lack of physician wellness due to burnout is a serious problem impacting over half of obstetrician/gynecologists (OB/GYN) in the United States. Efforts to reduce burnout in medical training and post-graduate practice settings have focused on increasing resilience through mindfulness and compassion-based programs, as mindfulness and self-compassion are positively correlated with well-being in the general population. There is some evidence that these programs reduce burnout. However, effectively reducing burnout in residency training programs may be limited by inflexible institutional factors such as demanding rotations, extended work hours, stigma associated with admitting burnout symptoms, and limited time for social support.

Study design, size, duration: Fourteen 1st year OB/GYN residents (n=7 in two separate cohorts) completed a 12-hour, in-person mindfulness-based resilience curriculum over a 3-month period that emphasized meditation training, emotional awareness, empathic patient communication, self-compassion, gratitude and value-based living. The curriculum included didactic and experiential components, along with home-based exercises in meditation, gratitude, and value-clarification. The curriculum was implemented at a California medical school between January 2017 and May 2018.

Participants/materials, setting, methods: Assessments occurred prior to the start of the curriculum (T1), at the end of the curriculum (T2), and 6-9 months later (T3). Participants completed the Maslach Burnout Inventory (MBI), the Five Facet Mindfulness Questionnaire (FFMQ), and the Self-Compassion Scale (SCS) during each assessment period. Qualitative focus groups were also conducted with both cohorts of residents following the conclusion of the programs (July 2017, August 2018) and themes were analyzed using a grounded theory approach.

Main results and the role of chance: Paired samples t-tests examined changes in scores from T1 to T2 and T3. Levels of burnout did not change significantly from T1 to T2 or T3. However, overall self-reported levels of mindfulness increased from T1 to T3 ($p<.05$), as did the mindfulness subscale of non-judging inner experiences ($p<.01$). Overall levels of self-compassion also increased from T1 to T3 ($p<.05$), with the specific subscales of self-kindness and self-judgment showing improvements from T1 to T3 (both $p<.05$). Levels of isolation (a subscale on the SCS) significantly decreased from T1 to T2 ($p<.01$), however, no other significant changes from T1 to T2 were observed for mindfulness or self-compassion. Thus, the vast majority of improvements were evident only at the 6-9 month follow-up. The delayed nature of improved mindfulness and self-compassion may indicate a developmental process of skill building that equated to lasting change. It may also be indicative of adjustment to the demands of residency training as residents were now in the second year with more experience and more effective coping strategies. Qualitative reports indicated that increased emotional awareness could make stress worse in the short-term, however, residents also commented that mindfulness training may become more valuable over time.

Limitations, reasons for caution: Due to the small sample size, caution is warranted in generalizing findings. Qualitative focus-groups indicated that increasing emotional awareness could increase short-term stress and burnout. Furthermore, unchanging institutional factors in residency training program (mandatory challenging rotations, inflexible work hours) may obscure the impact of mindfulness-based resilience training on resident burnout.

Wider implications of the findings: This pilot study provides preliminary support that a mindfulness-based resilience curriculum may improve overall levels of mindfulness and self-compassion in 1st year OB/GYN residents. As these traits are related to decreased psychological stress and increased wellness in other populations, larger scale studies to further examine this issue are warranted.
Trial registration number: not applicable

P-490 2018 study of 2,013 donor-conceived people

W. Kramer[1]
[1] *Donor Sibling Registry, Research, Nederland- Colorado, U.S.A.*

Study question: What are the experiences, desires, and needs of the donor-conceived community?
Summary answer: Donor-conceived people desire to know about their origins and to connect with their donor relatives.
What is known already: The Donor Sibling Registry has been connecting, supporting, counseling and studying donor-conceived people for more than 18 years. We know that many donor offspring desire to know more about their ancestry, medical backgrounds, and about their first and second-degree genetic relatives.
Study design, size, duration: In 2009 and again for three weeks in October of 2018 surveys with both quantitative and qualitative questions were collected reporting on the experiences of being a donor-conceived person, including disclosure, terminology, anonymity, missing father/male figure, feelings about being donor-conceived, and curiosity about and contact with previously unknown genetic (donor) relatives.

Participants in 2018 were asked to *not* take the survey again if they already had in 2009. Each participant is, therefore, a unique case.
Participants/materials, setting, methods: 1268 individuals responded to the survey designed for donor-conceived people raised in non-LGBTQ households (HET) (467 in 2009 and 801 in 2018).

745 individuals responded to the survey designed for donor-conceived people raised in LGBTQ households (LGBT) (287 in 2009 and 458 in 2018).

64% of LGBT and 74% of HET respondents were female. 14 LGBT and 69 HET respondents were conceived using an egg donor and the balance were conceived with a sperm donor.
Main results and the role of chance:
Disclosure

69% of LGBT offspring and 32% of HET offspring indicate that they have "always known" about being donor conceived.

In the HET families, over 50% of those under 18 have "always known." This number is considerably less for older cohorts.
Terminology

"How do you refer to the donor? LGBT Sperm Donor Offspring: 53% Donor, 30% Sperm Donor, 18% Biological Father, 14% Donor Dad, 8% Father, 2% Genetic Father, 10% Other

HET Sperm Donor Offspring: 41% Biological Father, 41% Donor, 39% Sperm Donor, 12% Donor Dad, 7% Father, 6% Genetic Father, 8% Other
Anonymity

87% of HET offspring, 69% of LGBT offspring said that their parents used an anonymous donor.

"If your donor is anonymous, do you wish that your parent(s) would have used a willing-to-be-known or known donor?"

59% of LGBT offspring and 73% of HET offspring answered "Yes".
Missing Father/Male Figure

"If you are conceived via sperm donation, and have been raised by a single mom, have you felt something missing from your not being parented by a father/male figure?"

52.6% HET offspring answered yes, 37% LGBT offspring answered yes.
Limitations, reasons for caution: 52% of respondents to the HET survey and 42% respondents of the LGBT survey reported that they are Donor Sibling Registry members.

The data is, therefore, representative of both Donor Sibling Registry members and non-members.
Wider implications of the findings: The reproductive medicine industry can better serve the needs of the donor-offspring community by better understanding their experiences and desires to know more about their origins and to connect with their close relatives.
Trial registration number: None

P-491 Assessing pain-related psychological inflexibility in endometriosis

A. Galhardo[1,2], **C. Ferreirinha**[1], **M. Cunha**[1,3], **I. Massano-Cardoso**[1,4,5]
[1] *Instituto Superior Miguel Torga, Psychology, Coimbra, Portugal*
[2] *Faculty of Psychology and Educational Sciences of the University of Coimbra, Cinneic, Coimbra, Portugal*
[3] *Faculty of Psychology and Educational Sciences of the University of Coimbra, Cineicc, Coimbra, Portugal*
[4] *Faculty of Economics of the University of Coimbra, Ceisuc, Coimbra, Portugal*
[5] *Faculty of Medicine of the University of Coimbra, Public Health, Coimbra, Portugal*

Study question: Is the Psychological Inflexibility in Pain Scale (PIPS) adequate for the assessment of psychological inflexibility in women facing a diagnosis of endometriosis?
Summary answer: Results suggest that the Portuguese version of the PIPS is a valid and reliable instrument for the assessment of psychological inflexibility in women with endometriosis.
What is known already: Endometriosis is a chronic, incapacitating condition which may involve experiencing chronic pain. Assessment instruments addressing emotion regulation processes, such as avoidance of pain and cognitive fusion with pain, which are components of psychological inflexibility, in this population are scarce. ThePsychological Inflexibility in Pain Scale was developed to assess these processes related to chronic pain and its psychometrics properties have been tested in other medical conditions implicating chronic pain such as whiplash associated disorders, fibromyalgia and back pain. Assessing these emotion regulation mechanisms allows the identification of relevant targets for psychological intervention with women dealing with endometriosis-related pain.
Study design, size, duration: Participants were recruited through the Associação Portuguesa de Apoio a Mulheres com Endometriose and the Associação Portuguesa de Fertilidade (endometriosis and infertility patients' associations). Inclusion criteria were age (18 years or older) and an endometriosis medical diagnosis. Data were collected online through self-report instruments between February 2018 and May 2018. A sub-sample of 88 participants also completed the PIPS-PT 4 week later to the first administration.
Participants/materials, setting, methods: A sample comprising 209 women with an endometriosis diagnosis completed online a sociodemographic questionnaire, the PIPS-PT, the Numeric Pain Rating Scale (NPRS), the Depression, Anxiety and Stress Scales (DASS – 21), the Chronic Pain Acceptance Questionnaire (CPAQ) and the Acceptance and Action Questionnaire - II (AAQ-II). A confirmatory factor analysis was conducted, as well as reliability, and relationship of the PIPS-PT with others measures.
Main results and the role of chance: The PIPS-PT two factor model: (1) avoidance of pain and (2) cognitive fusion, showed the following adjustment indices: $\chi 2/gl = 2.72$, CFI = .92, GFI = .86, TLI = .91, RMSEA = .091, MECVI = 1.68. As for the Cronbach alpha values .94 was observed for the total scale,.94 for the pain avoidance subscale and of .82 for the cognitive fusion subscale. The composite reliability (CR) revealed a value of .95 for the total scale, of .93 for the pain avoidance subscale and of .82 for the cognitive fusion subscale. Test retest reliability showed a correlation of .75 ($p < .001$). The correlation between the two PIPS-PT subscales was of .69 ($p < .001$). The PIPS-PT showed positive correlations with the AAQ-II ($r = .49$; $p < .001$), the Numeric Pain Rating Scale ($r = .51$, $p < .001$), the depression scale ($r = .45$; $p < .001$), the anxiety scale ($r = .38$; $p < .001$) and the stress scale ($r = .43$; $p < .001$) and a negative correlation with the CPAQ ($r = -.60$; $p < .001$).
Limitations, reasons for caution: The online recruitment tends to recruit more educated participants, with easy access to online platforms. Participants diagnosis of endometriosis was self-reported, there was no consulting of medical records.
Wider implications of the findings: The PIPS-PT proved to be a valid and reliable measure for psychological inflexibility related to chronic pain for women with endometriosis. Women with endometriosis-related pain show a high prevalence of psychiatric disorders. The PIPS-PT allows to assess relevant psychological intervention targets. It can be used in clinical and research settings.
Trial registration number: N/A.

P-492 Participant experiences with an evidence-based diet and lifestyle group educational and support program: a feasibility study

Z. Uraz[1], K. Cooley[2], A. Vu[1], L. Sanders[3], T. Hannam[4], P. Raina[3]

[1]*The Canadian College of Naturopathic Medicine, Clinical Education, Toronto, Canada*

[2]*The Canadian College of Naturopathic Medicine, Research, Toronto, Canada*

[3]*Hannam Fertility Centre, Research, Toronto, Canada*

[4]*Hannam Fertility Centre, Clinical Care, Toronto, Canada*

Study question: What are the experiences of participants in a group educational health information program on diet, lifestyle and stress management for fertility?

Summary answer: Overall positive experiences were noted among participants. Themes of trust, the nature of content, group dynamic, commitment, and facilitator expertise emerged as key common experiences.

What is known already: Individuals undergoing fertility treatment often make lifestyle choices that negatively impact their fertility success rates. The experience of infertility can increase psychological, physical, and financial stress on an individual/couple. Recent studies on mindfulness and cognitive behavioural therapy-based interventions, and group-based interventions are of benefit to patients. Given the complex psychosocial and emotional impact that infertility can have on individuals, there is the likelihood that an evidence-based diet, lifestyle and stress-reduction group-based, educational program would be beneficial to participants. The purpose of the current study was to examine the impact of a diet, lifestyle and stress-reduction group-based, educational model of care.

Study design, size, duration: Nineteen participants were enrolled in a 6-week evidence-based educational pilot program providing support related to healthy diet, lifestyle and stress-reduction behaviours in a group setting. Participants were provided information in a lecture-style format and were trained on stress reduction techniques including deep breathing and mindfulness exercises. Participants completed pre and post standardized questionnaires including open –ended options assessing satisfaction, challenges and adherence to different program components provided a framework for program evaluation and participant experiences.

Participants/materials, setting, methods: Participants were current patients of an urban fertility clinic in Toronto where the sessions took place. Of the 19 participants, 13 were female and 6 were male. Twelve participants attended as a couple and 7 attended individually. On completion of the 6-week program participants were asked complete evaluation of the program. Results were analyzed using descriptive statistics (quantitative data) and thematic analysis (qualitative data).

Main results and the role of chance: Survey data was collected from 15 of the 19 participants at the end of the program. Participants attended anywhere from 2-6 sessions; open-ended feedback states that despite commitment to the program, travel and scheduling posed a logistical inconvenience, in some cases adding additional stress. Many responses included different suggestions for scheduling, and number of sessions. Most participants indicated that they were hoping to learn about dietary and lifestyle strategies, including stress reduction techniques to improve their overall health and fertility. Participants rated the material as being very useful (average 4.67 out of 5), and when asked how many of the diet and lifestyle strategies they were able to implement (0=none - 5=all) the median response was 3 (IQR=3-4). Most participants (86.6%) enjoyed the group format of the sessions, although some mentioned that they were apprehensive about this at first; feedback shows that trust in facilitators as well as co-attendees was critical in creating a safe and supportive dynamic. Participants were also exceptionally likely to recommend this program to others (median=5, IQR=5). All appreciated the knowledge and expertise of the facilitators, although divergent views and preferences on the quantity of topics and depth of content were exhibited.

Limitations, reasons for caution: Limitations of the study's findings include;

1. Small sample size
2. 21% loss to follow-up
3. The facilitators and co-participants were likely to influence each participants experience
4. There were no matched controls and no long-term pregnancy follow-up, all of which add elements of bias and subjectivity to the findings

Wider implications of the findings: This feasibility study indicates that participants who are patients of a fertility clinic are willing to participate, and are satisfied with a 6-week group program to learn how to implement positive diet, lifestyle and stress-modification behaviours. This allows for a starting point for future research on this model of care.

Trial registration number: N/A

P-493 A novel and easy method for implementation of donor selection: a new useful algorithm

L. Arenaz[1]

[1]*Fenomatch, Reproduction Data Research, Zaragoza, Spain*

Study question: How can we improve the donor selection to increase the resemblance between receptors and their offspring?.

Summary answer: It's necessary to implement new algorithms including biometry distance measurements across family generations to improve donor selection according to the facial resemblance.

What is known already: In addition to the essential medical criteria in donor selection, there are basic criteria in facial resemblances, such as eyes and hair colour.

In order to improve this focus including facial biometric algorithms, several R and Phyton packages are available based on facial recognition and the probability of being the same person. Unfortunately, this approach is not valid as sorting images by biometric distances is needed to lead to a scientifically verified result. So, a new Data Scientist approach using specific and innovating methodologies with Big Data and Artificial Vision Technologies is required.

Study design, size, duration: During the last two years, a Data Science study based on biometry distances, artificial vision technologies and neuronal net algorithms has been developed.

Creation of the new algorithm was based on the study of family trees (n = 108), with an innovative approach using pre-ponderation of facial biometry distances (12,208) and allow establishing measurements on results.

In addition, the new algorithm was compared to the pre-existing facial recognition approach.

Participants/materials, setting, methods: A total of 864 subjects (age 18-60) from 108 families were included with their participant agreement (73% training - 27% validation). All images correspond to 21-50 years old subjects, with a gender distribution 1:1. Several scripts in Python and R were developed to classify 12,208 facial distances of each picture using K-means algorithms to study facial similarity objects. 80 Gb RAM and 60 computing processors were used intensively. Artificial Neural Networks methodologies were used.

Main results and the role of chance: The new algorithm is stable and can reproduce results when iterating validation data. The new prediction model based on biometric distances results is 86,66%(σ2 47.88) if we require all images must be in the right order to get a positive result. The accuracy results improve performance up to 96% when the right order is just required in the 5 images with more resemblance. Comparison between images is independent of the subject gender providing same accuracy results for gender-crossed images as for same-gender.

As final extra testing, when the test was made by the computational algorithm and also by a human team (10 individuals with a majority vote criteria), humans results are 98% in line with the new algorithm.

When doing the same testing with the two most used existing open python scripts based on facial recognition average results provide 56.88% of accuracy(σ2 638.98) in ordering subjects right. When comparing gender-crossed images test shows just a 23.38%(σ2 89.23) of accuracy.

We can conclude that the new algorithm is valid as it has great accuracy in its results and it has widely improved results in the current state of the art.

Limitations, reasons for caution: The algorithm should be used as a decision support application that helps the medical team decide on a donor from among those who already meet the medical and genetic criteria in order to guarantee to find the donor that most resembles the receptor's family.

Wider implications of the findings: This application provides more confidence and reduces receptor stress caused when addressing the decision of accepting a gamete's donation.

The new findings in Artificial Vision when locating objects in images may serve in new time-lapse technology studies of embryos.

Trial registration number: not applicable

P-494 Fertility knowledge and beliefs about fertility: findings from a cross-sectional survey in Tunisia

S. Daoud[1], A. Mnif[2], A. Sellami[1], N. Chakroun[1], F. Hammami[1], M. Ben Amor[1], L. Keskes[1], T. Rebai[1]

[1]*Medical School of Sfax, Labporatory of Histology-Embryology & Biology of reproduction, Sfax, Tunisia*

[2]*Habib Bourguiba Hospital, Department of oncology, Sfax, Tunisia*

Study question: The aim of this study was to evaluate the level of fertility knowledge among the reproductive-aged population.

Summary answer: We evidenced a lack of knowledge with regards to fertility issues in our study population.

What is known already: Fertility knowledge is an important factor that can influence individual and couple's fertility behavior. Numerous reports have highlighted a lack of information about fertility in the general population, especially in relation to risk factors for infertility and treatment beliefs. However, few data are available about such issues among Tunisian population, and Arabic-speaking countries in general.

Study design, size, duration: A 14-items questionnaire on the knowledge of infertility demography (2 items), risk factors (10 items) and treatments (2 items) was completed by a cross-sectional sample, over a period of 3 months.

Participants/materials, setting, methods: The sample (n=150) consisted of 83 female and 67 male with an average age of 32.5±9 years and 45.8±14 years, respectively. Knowledge scores were based on responses to the questionnaire. The validity and reliability of the questionnaire were previously tested. Questionnaires were completed online (74%) and in our fertility testing department (26%).

Main results and the role of chance: Average knowledge score per participant, corresponding to the mean percentage of correct answers on all 14 questions, was 48.9 ± 2% ranging from 0 to 85.7%. The majority of respondents (n = 96, 64%) had a knowledge score between 34 and 66%. The lowest scores were for questions related to infertility prevalence (7%) and to health insurance coverage of fertility treatments (7%). Questions related to the impact of stress and smoking on fertility have had the highest scores (87% and 81%, respectively). Only 36% of respondents have correctly identified the age of fertility decline among women. The score was even lower for age-related fertility decline in men (21%).

Limitations, reasons for caution: The majority of participants have responded online which could indicate a better level of education and thus lead to an overestimated score of knowledge.

Wider implications of the findings: A wider implementation of the questionnaire will allow us to improve its reliability and to identify the major knowledge gaps that have to be especially considered while developing population education programmes.

Trial registration number: No trial registration number

P-495 Consideration of a multi-method assessment approach to the psychological evaluation of gestational surrogates

M. Riddle, Ph.D.[1], S. Jenkins, Ph.D.[2]

[1]*The Pennsylvania State University, Psychology Department, University Park PA, U.S.A.*

[2]*University of North Texas, Psychology Department, Denton TX, U.S.A.*

Study question: What is the utility of a multi-method assessment approach to screening gestational surrogates (GS) for determining both psychological appropriateness and for pre-surrogacy implications counseling?

Summary answer: Utilizing multiple assessment methods can give more specific information about psychological vulnerabilities that are important to address during implications counseling prior to a surrogacy pregnancy.

What is known already: Psychological assessment of GS candidates requires consideration of complex factors in determining their psychological appropriateness to proceed with mental health professionals often placed in gate-keeping roles. ASRM guidelines recommend psychosocial consultations and psychological testing (where deemed appropriate), but there are no uniform interpretations of these guidelines. Using a single, broad-band self-report measure (such as the MMPI-2 or PAI) is the most common practice among mental health professionals asked to assess commercial arrangements in the US. However, recent research suggests that surrogates consistently underreport and deny problems and their MMPI-2 and PAI profiles are often defensive and difficult to interpret.

Study design, size, duration: This retrospective chart review examined psychological test data from women screened and accepted to become GSs (n = 33) between January, 2010 and March, 2018. Data from two psychological tests were scored and entered into SPSS software. GS test data from these tests were compared as measures of the psychological constructs most important in consideration of a potential surrogate, including Self-Esteem. Resiliency, Self-Efficacy, Problem-Solving/Coping, and Interpersonal Relationships.

Participants/materials, setting, methods: 33 women seen in private practice and psychologically evaluated for consideration as surrogates were administered the Personality Assessment Inventory (PAI) and an abbreviated protocol of the Thematic Apperception Test (TAT) (Cards 1, 2, 3GF, and 13MF). Data were scored using well validated scoring systems. Analyses (t-test and chi-square) examined both their measurement of the psychological constructs of interest and comparison to published normative data. .

Main results and the role of chance: PAI Positive Impression Management (PIM) scores between 44T-56T reflect a respondent presenting themselves realistically. Therefore, PAI profiles deemed least defensive (PIM $\leq$ 56; n = 19) are reported here. Corresponding TATs didn't show significant differences between groups, so all (n = 33) are reported here. Lower Self-Esteem was reflected in PAI Aggression scale scores with the majority (65%) of scores $\leq$ 44, suggesting meekness and difficulties with assertiveness. Likewise, lower Self-Esteem on the TAT (n = 33) was reflected both in Emotional Tone on Card 1 reflecting sadder themes than the normative population ($p < .001$) and "Inferiority" and "Depression" endorsed at the highest rate on Fine's Scoring Scheme. Interpersonal relations were reflected on the PAI Warmth scale, with 32% (n = 6) having t-scores $\geq$ 60. Although this suggests a warm and sympathetic personality style, it reflects potential difficulties with confrontation and conflict. 79% of PAI Treatment Rejection Scale scores were > 50. Scores > 60 (n = 6) reflect individuals who are rejecting of intervention, which might reflect higher levels of self-efficacy but create potential difficulties with implications counseling. Tendencies towards denial of card pull and task demand/difficulty may reflect magical thinking impacting both resiliency and problem-solving skills.

Limitations, reasons for caution: This is a retrospective chart review and TAT scores obtained for present research were not considered in the acceptance or rejection of the GSs in this sample. Statistical analyses were based on the theoretical assumption that published norms represented the general non-patient population and deviations from this assumption are unknown.

Wider implications of the findings: Multi-method assessment may address limitations posed by single measure assessment, particularly given the defensive profiles often seen on self-report measures. Combined analyses may also help clarify psychological vulnerabilities that should be addressed during implications counseling prior to a surrogacy pregnancy to protect the psychological well-being of a gestational surrogate.

Trial registration number: not applicable

P-496 Out of sync: A qualitative examination of male and female partners' role in decision-making in in vitro fertilization (IVF)

Y.K.G. So[1], C.H.Y. Chan[1], D.Y. Guo[1], Y.L. Fung[1], B.H.P. Lau[2], X.C. Yin[1]

[1]*University of Hong Kong, Department of Social Work and Social Administration, Hong Kong, Hong Kong*

[2]*Hong Kong Shue Yan University, Department of Counselling & Psychology, Hong Kong, Hong Kong*

Study question: What role do male and female partners play in the process of reproductive decision-making and how aligned are their expectations?

Summary answer: In most cases, male and female partners hold disparate views on whether treatment decisions should be made jointly or by women alone.

What is known already: Couples face multiple, significant decisions in IVF. However, people's capacity to make decisions decreases in stressful situations. In this scenario, the provision of accurate information and support from clinicians may empower couples to make informed treatment decisions. Active involvement of patients in decision-making is highly desirable, and is predictive of treatment compliance and better psychosocial adjustment. However, most research on reproductive decision-making is conducted with women, rather than men or the couple, as the unit of analysis. This risks overlooking the role and preferences of male partners, as well as couple-level factors that might influence the course of treatment.

Study design, size, duration: Participants were infertile couples who received at least one cycle of IVF recruited from a local fertility clinic in Hong Kong. Two two-hour parallel focus group interviews were conducted with male and female partners separately.

Participants/materials, setting, methods: Focus group interviews were conducted with five couples (*n*=9; one woman attended without partner). The age range of participants is 32-39 for women and 37-41 for men. Two couples report male factor as the cause of infertility, two couples report female factor, and one couple report mixed factors. The number of previous ART cycles performed ranged between zero and seven. Interviews were tape-recorded and transcribed. Verbatim transcripts were analyzed using a thematic, inductive approach.

Main results and the role of chance: Our analysis revealed two major findings. First, whilst men often willingly hand over the right to make important decisions to their partner, women expect men to involve actively and to make decisions jointly as a couple. Second, and consistent with existing knowledge, the physical and emotional needs of women constantly take precedence over that of men. Couples, especially women, think it is desirable when they are 'on the same page' with their partner when making treatment decisions. However, joint decision-making in treatment may be difficult if partners are not aligned in one of four main areas, which are summarised as, strategies used to arrive at decision, perceived importance of childbearing, emotional investment in fertility treatment, and acquiring fertility-related information.

Limitations, reasons for caution: Participants were recruited from one fertility clinic through self-selection. The low response rate, especially for male partners, means our sample may principally comprise couples who have stronger marital relationship, find IVF more palatable, and who are less concerned about disclosure.

Wider implications of the findings: Educational programs should be directed at increasing men's self-efficacy in making informed treatment decisions. Reproductive counselors should better address men's perceived barriers in decision-making and facilitate joint decision-making with the couple as a unit.

Trial registration number: Not applicable.

P-497 What about decisional regret regarding fertility preservation one year after diagnosis? A randomized controlled trial of a decision aid for female cancer patients

V. Ehrbar[1], C. Urech[1], C. Rochlitz[2], R. Zanetti Dällenbach[3], R. Moffat[1], R. Stiller[4], A. Germeyer[5], F. Nawroth[6], A. Dangel[6], S. Findeklee[7], S. Tschudin[1]

[1]*University Hospital Basel, Gynaecology and Obstetrics, Basel, Switzerland*
[2]*University Hospital Basel, Medical Oncology, Basel, Switzerland*
[3]*St. Claraspital, Gynecology and Gynaecologic Oncology, Basel, Switzerland*
[4]*University Hospital Zurich, Gynaecology and Obstetrics, Zürich, Switzerland*
[5]*University Women's Hospital of Heidelberg, Division of Gynaecological Endocrinology and Reproductive Medicine, Heidelberg, Germany*
[6]*Centre for Infertility- amedes experts-, Prenatal Medicine- Endocrinology and Osteology, Hamburg, Germany*
[7]*University Women's Hospital Saarland, Obstetrics and Reproductive Medicine, Homburg, Germany*

Study question: Does the use of an online decision aid in addition to counseling with a reproductive specialist have an impact on decisional regret?

Summary answer: Decisional regret was low in both groups. The intervention group showed a decrease, whereas the control group showed an increase in decisional regret over time.

What is known already: Female cancer patients perceive deciding whether to opt for fertility preservation (FP) or not as very difficult and emotionally challenging. They report decisional conflict and decisional regret and express the need for more support. Information provision and being aware of their own values is associated with lower decisional conflict and regret. We could demonstrate that the use of our online decision aid (DA), in addition to fertility counseling, lowers decisional conflict and patients show high satisfaction with the additional support.

Study design, size, duration: The study was a randomized-controlled trial including women, who were referred to one of the participating fertility centers after having been diagnosed with cancer. Participants were either assigned to the control group (counseling only) or to the intervention group (counseling and additional use of the online DA immediately after counseling). Recruitment was ongoing for 18 months at eight fertility centers in Switzerland and Germany.

Participants/materials, setting, methods: The online DA was developed by an interdisciplinary team of reproductive specialists, gynecologists and psychologists. Participants were asked to complete an online questionnaire at three time points: after counselling (control group) or after counseling and the use of the DA (intervention group) (T1) as well as one month (T2) and 12 months later (T3). The survey comprised questions about fertility-related knowledge, decisional conflict, decisional regret, attitude towards FP, willingness to undergo FP and socio-demographic data.

Main results and the role of chance: Whereas the main outcome measure of this RCT was decisional conflict, this abstract focuses on one of the second outcome measures, i.e. decisional regret over the course of time (T2 to T3) in those participants with follow-up until one year after diagnosis (N=37).

Both groups showed low scores on the decisional regret scale (from 0 min. to 100 max.) at both time points (T2 and T3), whereby the intervention group consistently reported lower scores compared to the control group. The control group showed an increase of decisional regret from T2 (Mean: 19.00, SD: 13.24) to T3 (Mean 22.00, SD: 20.67). The intervention group, however, showed a decrease of decisional regret from T2 (Mean: 14.12, SD: 11.07) to T3 (Mean: 12.94, SD: 13.24).

Neither at T2 (p=0.113) nor at T3 (p=0.129) the group differences reached statistical significance. The difference in the change over the course of time of each group almost reached significance (p=0.078).

Limitations, reasons for caution: The study included 51 participants at T1, however until the end of all follow-up analysis, there were 14 dropouts to note. Decisional regret is a second measure outcome of this study, as a consequence statistical significant differences could not be expected. Therefore, the results can only be interpreted with caution.

Wider implications of the findings: These longitudinal data complement our previous results that showed a beneficial short-term effect of the DA regarding decisional conflict. The use of the online DA seemed to support patients also regarding decisional regret. The findings all together reinforce the qualification of the DA to be implemented into clinical practice.

Trial registration number: NCT02404883 (clinicaltrials.gov)

P-498 Same-donor offspring networks: Donor-conceived people's experiences with making contact, through group meetings, with same-donor offspring

S. Bolt[1], A.J.B.M. Maas[2], A.M.K. Indekeu[3]

[1]*Fiom, Research Department, 's Hertogenbosch, The Netherlands*
[2]*Fiom, Policy Donor Conception, 's-Hertogenbosch, The Netherlands*
[3]*Fiom, Research Department and Policy Donor Conception, 's-Hertogenbosch, The Netherlands*

Study question: What are the experiences of donor-conceived people with making contact, through group meetings, with same-donor offspring?

Summary answer: While relationships with same-donor offspring are viewed as beneficial, they can cause confusion and questions about how to integrate them into one's life.

What is known already: A recent phenomenon is the contact of donor-conceived people with offspring of the same donor, partly enabled by more openness regarding donor conception, online searches, social media, donor

registers and (online) DNA testing. The relationships of same-donor offspring are commonly viewed as generally more beneficial than connecting with a donor. Yet donor-conceived people can find large numbers of same-donor offspring. So far, the impact of meeting large numbers of same-donor offspring has not been explored.

Study design, size, duration: Qualitative semi-structured interviews with 19 donor-conceived people, registered in the Fiom KID-DNA Database, were conducted between April and June 2018. Participants were recruited from same-donor offspring group meetings (*n*=6) that were organised by Fiom counsellors between May 2017 and February 2018. A total of 82 donor-conceived persons were present at the meetings (30% male, 70% female). 74 persons were contacted by e-mail, 22 wanted to participate in the study of whom 19 persons were interviewed.

Participants/materials, setting, methods: Participants were female, 15-42 years old (*M*= 30; *SD*=8.6), born into a hetero (*n*=12), single (*n*=3) or lesbian (*n*=4) household. The groups of same-donor offspring consisted of 7-18 donor-offspring at time of group meetings, extending to 8-31 at time of interviews. Participants were interviewed about: (1) their motives for searching same-donor offspring, (2) their expectations about the contact and (3) their feelings prior, during and after the group meeting. Interviews were analysed using MAXQDA.

Main results and the role of chance: Most participants (*n*=13) started searching for their donor and had not thought about same-donor offspring upfront, others (*n*=4) were solely interested in contact with same-donor offspring, or (*n*=2) wanted to know if their sisters were full-genetic siblings. The three main motivations to search were: curiosity (*n*=19), the wish to receive medical information (*n*=11), and to the wish to extend their family, arising from feeling different (*n*=5) or missing family (*n*=7). All participants (*n*=19) expected to find resemblances (physically and/or personality-wise), but not all found them (*n*=2). Meetings went together with various emotions: shock and feeling overwhelmed (*n*=14) of being confronted with so many half-siblings; tension (*n*=17) due to insecurity, the unknown and uncomfortable feelings; restless feelings (*n*=12) due to the lack of a framework how and where to situate these new relationships; and satisfaction and excitement (*n*=18). Specific challenges concerned the continuous expansion of the group; and differences in privacy boundaries and information sharing (about the donor). This data shows that while relationships with same-donor offspring are commonly viewed as generally more beneficial than connecting with a donor, they can cause confusion and leave questions about how to integrate these new relations into their lives, as family, kinship, and/or friendship.

Limitations, reasons for caution: Participants are self-selected, and we do not know the reason for non-participation of the other donor-conceived people who participated in the group meetings and if they have similar or different experiences of study participants. All participants were female. Donor-related information is lacking, although 30% of group sessions participants were male.

Wider implications of the findings: These findings may be a starting point for developing needs-orientated counselling for donor-conceived people searching for same-donor offspring. This study identifies issues for further research to explore the meanings of genetic networks: are they family, kinship and/or friendship? These data are important in debates about the offspring limit per donor.

Trial registration number: not applicable.

P-499 Five Country Study of women's attitudes and knowledge regarding fertility

F. Clancy[1], L. Foster[2], G. Zanzi[2], C. Mollard[3], S. Johnson[4]

[1]*SPD Development Company Ltd, Medical Affairs, Bedford, United Kingdom*
[2]*SPD Swiss Precision Diagnostics GmbH, Marketing, Geneva, Switzerland*
[3]*IPSOS Suisse SA, Marketing, Geneva, Switzerland*
[4]*SPD Development Company Ltd, Clinical Affairs, Bedford, United Kingdom*

Study question: What are women's attitudes towards becoming pregnant, how good is their fertility knowledge and does it vary between countries?

Summary answer: Fertility knowledge was poor amongst women in all countries surveyed. US and Chinese women were more focused on trying to maximise pregnancy chances.

What is known already: The demographics of women seeking to conceive has changed, with many women now seeking pregnancy when older. When unsuccessful, this can lead to disappointment, with the sentiment "I wish I had known more about fertility" often given, indicating basic knowledge on fertility is missing. Having a life-plan and a expecting a high degree of control over major events in life is now prevalent and extends to pregnancy planning.

Study design, size, duration: On behalf of SPD, Ipsos Suisse SA surveyed a minimum of 1,000 women in each of five countries: US, UK, Germany, Italy and China. The survey took place between 27th of July to 7th of August 2018 and covered a broad range of fertility and pregnancy themes, including knowledge and attitudes.

Participants/materials, setting, methods: Participants were women aged 20-45 years old who were able to have children and who chose to take part in our survey from Ipsos Panel. Interviews were conducted online.

Main results and the role of chance: Fertility knowledge varied between countries; when choosing the most accurate description of a menstrual cycle from five options, only 14% (U.S), 23% (U.K) 41% (Germany), 26% (Italy) 37% (China) selected the correct answer (first day of bleeding to the day before the next bleeding start. Only 20% (US), 25% (UK), 39% (Germany), 25% (Italy) 19% (China) of participants correctly knew there were 3-6 fertile days when women are able to get pregnant during a menstrual cycle. It was interesting that at least a quarter of women in the UK (29%) and US (25%) thought intercourse on any cycle day could lead to pregnancy; the proportion was lower for Germany (14%), Italy (14%) and China (8%).

Attitudes to becoming pregnant were assessed by asking women currently trying or planning pregnancy, which statement reflected their opinion best "I want to maximise my chance of getting pregnant as soon as possible (using methods to identify my most fertile days, taking supplements, etc)" or "prefer to let nature take its course and wait". US (74%) and Chinese (61%) were more likely to want to maximise chances than UK (55%), Germany (54%) and Italy (54%).

Limitations, reasons for caution: Participants were selected from the Ipsos on-line panel. Given the sample composition, the findings cannot be considered truly representative of this target audience. In China, the majority of participants resided in East (33%) and South Central China (32%) who are more affluent that the general population of this country.

Wider implications of the findings: There is a basic gap in the fertility knowledge among many women. Especially worrying was the proportion of women who believed that pregnancy was possible following intercourse on any day of the cycle, as this could lead to mistiming of intercourse when trying for a baby, and failure to conceive.

Trial registration number: Not applicable

P-500 Psychosocial, medical and practical factors affecting patients' fertility experience in a NHS setting. The importance of counsellors exploring beyond emotional factors

C. Dennehy[1]

[1]*University College Hospital London NHS Foundation Trust, Reproductive Medicine Unit, London, United Kingdom*

Study question: What were the patients difficulties, as expressed to the counsellor, in relation to the impact of, the rigours of treatment, physical health, practical life management, relationship issues and emotional wellbeing.

Summary answer: 50% of respondents reported their work/lifestyle and relationships were impacted adversely. Whereas treatment funding, waiting times, uncertainty, tiredness, sleep and sexual problems ranged between 25-30%.

What is known already: Distress, stress and the physical burden of fertility related issues are well known. In addition, there is increasing awareness of psychosocial and relationship pressures which can impact on patients quality of life (QOL). In promoting QOL in patients we need a deep understanding of their difficulties from different aspects. However there is little knowledge into what kind of psychological approach, specialist training and understanding, duration of therapy, can best benefit patients with reproductive problems.

Study design, size, duration: A retrospective analysis of fertility patients' experience was undertaken from January 2013 to December 2018. At the end of each year all patients seen by the counsellor were posted a client experience form. A stamped addressed envelope was included. A total of 1,388 were posted to 972 addresses, 60% responded totalling 843 questionnaires. As 43%

attended as a couple two forms were sent to the same address. The remaining respondents' had one form posted.

Participants/materials, setting, methods: The 'patient experience questionnaire' was adapted from the American Cancer Society (ACS). All of the sample were National Health Service (NHS) patients who had been seen by a member of the medical team in reproductive medicine. Responses were anonymous and sent, not to the counsellor, but to an administrator within the department. All questionnaires were sent with a stamped address envelope. The data was imported onto an Excel data base by an administrator.

Main results and the role of chance: The main difficulties reported were in areas of work/lifestyle and relationships; which impacted 50% of the respondents. The findings also highlighted sleep and sexual problems. Furthermore treatment funding, waiting times, uncertainty, tiredness, ranged between 25-30%. Of these respondents 52% were undergoing fertility treatment, 15% were suffering from/had been diagnosed with premature ovarian insufficiency, 10% had experienced recurrent miscarriage, less than 7% were pursuing gamete donation, undergoing fertility preservation, suffered from Turners Syndrome or had male factor issues. The respondents' emotional feedback reflected 15% stress, fears/worries and sadness versus 10% reported either low mood, feelings of being out of control and frustration, 7% reported lowered confidence and increased anger and finally 5% felt a lack of support, shame and low concentration.The referral source was 74% by a doctor, 10% made a self referral, 8% nurse, 6% other and 2% by an Andrologist.

In conclusion, fertility counsellors adopting an eclectic approach beyond the emotional factors may have far a reaching benefits to patients'.

Limitations, reasons for caution: The questionnaire adapted was from American Cancer Society from a different patient population and was not validated for fertility patients.

Wider implications of the findings: The high numbers of the sample reporting relationship and sexual concerns might indicate a place for fertility counsellors to be trained in couples' work and/or psychosexual awareness. Counsellors need increased awareness and skills with helping patients' reduce stress and manage work/lifestyle. In addition, sleeping difficulties might usefully be addressed.

Trial registration number: Not applicable.

P-501 Psychological impact and functional recovery after a Spontaneous Hemoperitoneum in Pregnancy (SHiP) in women with endometriosis.

A. Schreurs[1], M. Lier[1], D. Koning[1], C. Brals[2], E. Collette[2], M. De Boer[3], C. Lambalk[1], V. Mijatovic[1]

[1]Amsterdam UMC- Vrije Universiteit van Amsterdam, Department of Reproductive Medicine, Amsterdam, The Netherlands

[2]Amsterdam UMC- Vrije Universiteit van Amsterdam, Department of Medical Psychology, Amsterdam, The Netherlands

[3]Amsterdam UMC- Vrije Universiteit van Amsterdam, Department of Obstetrics and Gynecology, Amsterdam, The Netherlands

Study question: What is the psychological impact and functional recovery of a Spontaneous Hemoperitoneum in Pregnancy (SHiP) event?

Summary answer: SHiP had an impact on daily life. All women received psychological help. Lower scores on social functioning, vitality, pain and general health perception were found.

What is known already: Spontaneous Hemoperitoneum in Pregnancy (SHiP) is a rare, but life-threatening complication of pregnancy. SHiP occurs predominantly in the third trimester of pregnancy and is associated with adverse pregnancy outcomes (Brosens et al., 2012). Although the exact etiology is still unknown, endometriosis seems to be the major risk factor for SHiP. Recently the largest case series in literature was published (Lier et al., 2017) describing 11 Dutch cases of SHiP between 2010 and 2015. All women with SHiP were diagnosed with endometriosis. No previous studies have investigated the psychological impact and functional recovery of women after SHiP.

Study design, size, duration: An observational, prospective, follow-up study of our case series (Lier et al.,2017) was performed. Informed consent was obtained from nine patients. Interviews were conducted and questionnaires were completed in 2016 and 2017.

Participants/materials, setting, methods: Inclusion criteria were a history of SHiP. Participants completed three questionnaires (Utrecht Coping List (UCL), Impact of Event Scale (IES) and RAND-36 and had a semi-structured face-to-face in-depth interview which was audiotape recorded. Quality of life was described through an interview (focusing on psychological and functional aspects) and measured with a quality of life questionnaire (RAND-36). Quantitative data were analyzed by using descriptive statistics and interviews were analyzed thematically with a framework approach.

Main results and the role of chance: Seven women were interviewed individually and eight women completed the questionnaires. Saturation in the interviews was achieved meaning that no new information was gathered in the last available interviews. In the interviews women either described an anxious reaction (n=2) or a survival mode mindset (n=5) at moment of the SHiP event. In the period after SHiP one woman experienced problems with attachment to her child, however at the moment of interviewing all women bonded with their child adequately. SHiP had a major impact on daily life for all women (RAND-36). All women received psychological help after the SHiP event. Two women quitted their job and two other women did not work for almost a year. Three women were temporarily limited in daily activities after the event. At moment of interviewing, two women still had functional limitations of the SHiP event. They are both tired quickly. Coping strategies described by the women in the interviews correlate well with the answers of the UCL, except for one woman. The SHiP event developed a new perspective on the important things in life (benefit-finding) in two cases and one woman refrained from conceiving again after the SHiP event.

Limitations, reasons for caution: As SHiP events are rare, the available research population is small. However, saturation was achieved in the in-depth interviews. There could be participation bias. All questionnaires were analyzed through descriptive analysis because of the limited population. The analysis of the interviews were based on researchers interpretations.

Wider implications of the findings: By using these results, better support and follow up after SHiP can be given. The results may contribute to appropriate counseling concerning the psychological and functional impact of SHiP and could lead to a more extensive follow up to recognize the need for psychological help.

Trial registration number: not applicable

P-502 The use of generalized estimating equation model in the analysis of the correlation between life quality and pregnancy outcomes during IVF treatment

M.H. Wu[1], H.T. Ou[2], P.F. Su[3], G.H. New[1], C.W. Lin[1], W.Y. Chu[3], C.Y. Lin[4]

[1]College of Medicine and Hospital- National Cheng Kung University, Department of Obstetrics and Gynecology, Tainan City, Taiwan R.O.C.

[2]College of Medicine and Hospital- National Cheng Kung University, Department of Pharmacy, Tainan City, Taiwan R.O.C.

[3]National Cheng Kung University, Department of Statistics, Tainan City, Taiwan R.O.C.

[4]The Hong Kong Polytechnic University, Department of Rehabilitation Sciences-Faculty of Health and Social Sciences, Hung Hom, Hong Kong

Study question: If there is any association between quality of life and pregnancy outcomes among embryo transfer cycles of infertile women?

Summary answer: Generalized estimating equation analyses can prospectively evaluate the association between quality of life and IVF pregnancy outcomes among infertile women.

What is known already: Generalized Estimating Equations models with adjustment for the correlation among repeated measures (quality of life and pregnancy) can minimize the potential biases commonly seen in longitudinal cohort studies, especially for analyzing IVF data with multiple cycles.

Study design, size, duration: This longitudinal cohort study included 686 infertility women with 1,205 embryo transfer cycles from 2012 to 2017.

Participants/materials, setting, methods: Quality of life was measured using FertiQoL tool before embryo transfer procedure. The context of FertiQoL includes a Core module (mind/body, emotional, relational, and social domains) and a Treatment module (treatment environment and tolerability domains). The higher scores of FertiQoL indicate better quality of life. Generalized estimating

equation analyses were used to assess the association between FertiQoL scores and IVF outcomes, with various factor adjustments across multiple embryo transfers for an individual person.
Main results and the role of chance: The lowest scores were noted in the emotional domain of the core module and the tolerability domain of the Treatment module. Univariate generalized estimating equation analyses showed increased pregnancy rates are associated with higher FertiQoL scores. Multivariate generalized estimating equation analyses found when one unit score increases in the emotional domain, the ongoing pregnancy and live birth rates significantly increased by 2.4% and 2.6%, respectively ($p < 0.05$).
Limitations, reasons for caution: Because we did not manipulate the impact of emotional change before embryo transfer procedure for the prediction of subsequent pregnancy outcomes, randomized control trial is recommended to confirm the results of this study.
Wider implications of the findings: These results demonstrate that FeriQoL score, especially emotional domain before embryo transfer, is useful in clinical practice to predict subsequent pregnancy outcomes among women undergoing embryo transfer cycles.
Trial registration number: not applicable

P-503 The impact of unsuccessful PGT-HLA treatment(s) on the family and the ill child.

J. Nekkebroeck[1], C. Winter[1], E. Buyse[1], F. Belva[1], A. Buysse[1], M. De Rycke[1], A. De Vos[2], W. Verpoest[2], M. Bonduelle[1], I. Liebaers[1]
[1]UZ Brussel, Centre for Medical Genetics, Jette- Brussels, Belgium
[2]UZ Brussel, Centre for Reproductive Medecine, Jette- Brussels, Belgium

Study question: How are families doing after failed PGT-HLA and how do they look back on the PGT-HLA experience?
Summary answer: For all children an alternative treatment was found. Despite PGT-HLA failure, the treatment was empowering because parents felt they tried everything to save their child.
What is known already: The intention of people who apply for PGT-HLA (Preimplantation Genetic Testing combined with Human Leukocyte Antigen) is to save their ill child by means of a transplantation using haemotopoietic stem cells retrieved from the umbilical cord blood of the compatible newborn sibling. This new application of PGT-HLA raised numerous questions. While health and psychological well-being of children born after PGT is generally reassuring, little is known about families who experience an unsuccessful trajectory and are not able to save their ill child through PGT-HLA. Therefore, a semi- structured interview was applied to the couples in this situation.
Study design, size, duration: This study is part of a follow-up study of 162 couples treated with PGT-HLA in our centre between 2000-2016, 104 couples ended up without a PGT-HLA child.

Between September 2018 and January 2019, 61/104 families with an unsuccessful PGT-HLA treatment were approached by phone. 23 couples were lost to follow-up, 16 couples did not respond even after leaving several messages. Until now, only 22/61 (36%) couples were actually reached.
Participants/materials, setting, methods: Information was obtained by means of a semi-structured interview applied to the couple and with the following topics: the health-status of the ill child, experience of the PGT-HLA treatment, the impact on the partner-relationship, reasons for quitting with the PGT-HLA treatment and openness towards the ill child. In 2 cases the father instead of the mother was the interviewee. In one of these cases the mother had deceased and further details could not be gathered.
Main results and the role of chance: As to the **experience of PGT-HLA treatment,** only in 2/21 cases the financial burden was mentioned as the most stressful aspect. The practical and logistical aspects were mentioned 6 times and in 1 case the couple got relational problems during treatment. The foremost disturbing treatment aspects were however the psychological (76%) (e.g. fears about low success rates, waiting period between oocyte pick-up and embryo-transfer and pregnancy notification) and the physical impact (62%).

On average, PGT-HLA treatment was ceased after 3.09 times (range 1-6). The reasons to **stop treatment** were: psychological (43%) and physical (38%) burden, maternal medical reasons (38%) in combination with an alternative treatment for the ill child (48%). Four couples mentioned their relational issues (break-up, partner not allowing a subsequent treatment) as a reason to cease treatment.

Fifty-two percent of the children were aware of the PGT-HLA trajectory of their parents. According to the parent(s), children were able to recognize efforts that were made by the mother/parents and none of them expressed any problems with parents having ceased treatment. In most cases mothers felt they did everything they could to help their child. None of the parents expressed any regrets and 81% would recommend treatment to others.
Limitations, reasons for caution: Given that only a small number of families were interviewed in this study, the generalizability of these preliminary findings is limited.
Wider implications of the findings: People applying for PGT-HLA have high hopes on saving their ill child. Unfortunately, in most cases, the treatment will not succeed. Nonetheless, PGT-HLA was regarded as a positive, empowering experience generating a feeling of having tried the maximum to help their child. This information should be integrated in PGT-HLA counselling.
Trial registration number: Not applicable

P-504 Mediemo App - is tracking the emotional signature of patients undergoing IVF treatment useful?.

Y. Cheong[1], E. Halpin[2], N. Macklon[3], J. Boivin[4], B. Ng[1]
[1]University of Southampton Academic Unit of Human Health and Development, Complete Fertility Ltd, Southampton, United Kingdom
[2]Horizon strategic partnership ltd, Mediemo, Leeds, United Kingdom
[3]London Womens Clinic, Fertility, London, United Kingdom
[4]Cardiff university, Cardiff Fertility Studies Research Group, Cardiff, United Kingdom

Study question: Can we use a medical app to ascertain the emotional signatures of patients undergoing IVF cycles?
Summary answer: Through mobile technology, women undergoing IVF are empowered and willing to share their mood, allowing effective and low cost retrieval of vast emotional data.
What is known already: Infertility affects 1 in 6 couples; every year, over 60,000 cycles of IVF or ISCI performed in the UK. Assisted reproductive technologies (ART) are complex and stressful for patients, with 30% of couples ending treatment prematurely because of psychological burden. The period of waiting for the outcome of a pregnancy test further amplifies the stress and anxiety. Although ART is becoming increasingly prevalent, factors to address psychological burden or even harm within IVF units is limited. The use of medical technology in empowering women to record mood data and to further develop targeted coping strategies has not yet been explored.
Study design, size, duration: This was a prospective longitudinal study from May 2017 to December 2018. Every patient undergoing IVF/ICSI treatment at the Complete Fertility centre were offered the use of the Mediemo app as part of their care plan. Data was collated from all women who participated in using the Mediemo app.
Participants/materials, setting, methods: From May 2017 to December 2018, all women undergoing IVF (fresh or frozen embryo transfer) or IUI at the Complete Fertility Centre in Southampton, UK were given the opportunity to download and use the MediEmo mobile phone application. The application has a main feature known as 'medication timeline', an interface that allows patients to be reminded of their medication doses and timing. An additional component of MediEmo application allows patients to record their daily mood
Main results and the role of chance: Women during an IVF or IUI cycle are engaged in the MediEmo app and are voluntarily sharing their state of mind and mood, during potential episodes of stress. Over 30,000 mood samples have been recorded for women undergoing IVF at Complete Fertility. 43.4% of mood data was entered during the stimulation phase, 20.1% were entered in the 'luteal phase' (period after oocyte retrieval) and 34.1% were recorded either prior to or after the IVF treatment cycle. Further analysis is underway to delineate the key characteristics that influence the uptake of the app and the relevance of the emotional signature in relation to the clinical outcome.
Limitations, reasons for caution: The MediEmo application was only made available to women undergoing IVF/IUI treatment and so only women's and not the partner's mood has been recorded. However, we recognise the importance in the emotional state of the partner.
Wider implications of the findings: We have shown feasibility in the use of a medical mobile application in monitoring mood amongst women undergoing

IVF. This allows the development of targeted coping strategies deliverable through the medical app to help support patients through a potentially psychologically harmful IVF process.
Trial registration number: NA

P-505 Fertility Awareness among Malay women in KualaTerengganu: a cross sectional study

N. Yaacob[1], S.N. Ab Rahman[1]
[1]MOH Malaysia, Reproductive Services Unit- Hospital Sultanah Nur Zahirah, Kuala Terengganu, Malaysia

Study question: What is the quality of knowledge towards fertility awareness among laywomen in comparison to healthcare worker (HCW)?
Summary answer: Level of fertility awareness knowledge was comparable between both groups but higher in HCW (67.9% and 68%) than laywomen (65.2% and 59.7%).
What is known already: It has been observed that delayed childbearing has lead to increasing incidence of infertility. Although there has been increasing awareness to seek treatment, there is limited data on the level of knowledge in fertility awareness and affecting factors.
Study design, size, duration: A cross-sectional study conducted in 2016, that included laywomen attending public health education exhibition and a cohort of HCW that comprised doctors and nurses working in our department of O&G.
Participants/materials, setting, methods: Self-Administered questionnaires were distributed after consent to participate was obtained. Information on age and fertility, lifestyle factors influencing fertility and knowledge on fertility and treatments of infertility were recorded from 150 laywomen and 200 HCW. Results were analysed in each sections of age factor, lifestyles and fertility knowledge then further comparison between both groups were made.
Main results and the role of chance: Main ResultsMajority of the respondents were adults between age of 26-35(58.7%) with background education at diploma/degree level. Half (51.4%) of both groups agreed that increasing age negatively affect fertility. Majority (66.7%) of women studied were aware of lifestyle factors influencing fertility. More than two-thirds (66%) demonstrated knowledge about fertility and its treatment. Less than half (44%) of both groups of women were aware that fertility assessment may be initiated after 12 months of trying to conceive. 54% of laywomen were aware of their fertile periods as compared to 71.5% of HCW.
Limitations, reasons for caution: Laerger study including diverse group of respindents including infertility patients is required to further assess population's fertility awareness.
Wider implications of the findings: There is already considerable knowledge of fertility awareness amongst laywomen and healthcare provider. Further knowledge update and capacity building among healthcare provider is essential to further equip them to incrrease fertility awareness among laywomen to reduce infertility related to lack of fertiltiy awareness.
Trial registration number: Not applicable

P-506 The role of genetic counselling in reproductive decision making: an overview of the literature

I. Slegers[1], E. Buyse[1], J. Nekkebroeck[1], C. Winter[1], F. Belva[1], F. Hes[1], M. Bonduelle[1]
[1]University hospital Brussels UZB, Medical genetics, Brussel, Belgium

Study question: What is the impact of genetic counselling on reproductive decision making?
Summary answer: Genetic counselors play an important role in reproductive decision making and can be involved in different ways.
What is known already: The National Society of Genetic Counselors defines genetic counseling as *the process of helping people understand and adapt to the medical, psychological and familial implications of genetic contributions to disease. This process integrates the interpretation of family and medical histories, the education about inheritance, testing, management, prevention, resources and research and counseling to promote informed choices and adaptation to the risk or condition*. While genetic counseling was primarily conceptualized as a form of reproductive counseling, genetic counselors have now extended their experience to other non-reproductive areas such as cardiology and oncology (Resta, 2018).
Study design, size, duration: This poster provides a review of the current available literature regarding the role of genetic counseling in reproductive decision making. The Science Direct database was searched using 'genetic counselling', 'reproduction' and variant spellings. Only studies in English and published between 2008 and 2019 were included. Articles were screened to ensure they were peer reviewed and published in an academic journal.
Participants/materials, setting, methods: In total 2623 studies met the inclusion criteria, further selection of only review, research and data articles led to 1310 studies. An initial review of these abstracts resulted in a selection of a small number of articles.
Main results and the role of chance: It is well known that reproductive disorders are an important component of human diseases, affecting 10-15 % of couples both men and women. The main genetic factors in human reproductive disorders are the chromosome abnormalities (Cozaru et al., 2012). The negative psychosocial impact of reproductive disorders has been repeatedly described. Stanhiser and Steiner (2018) state that infertility and miscarriages are associated with a significant psychological burden. Furthermore, LoGiudice & Massaro (2018) state that an in vitro fertilization (IVF) treatment is a stressful process which often has a negative impact on woman's psychological health. Women undergoing such a treatment experience often feelings of anxiety, depression and distress (Kahyaoglu Sut & Balkanli Kaplan, 2015).

Despite this negative psychosocial impact, research has shown the positive impact of genetic counseling. Two reviews of genetic outcome studies from Madlensky et al. (2017) and Athens et al. (2017) concluded that patients can benefit from receiving genetic counseling. Genetic counselling can lead to an increase of knowledge, perceived personal control, positive health behaviors and patient satisfaction. Moreover, it can result in a decrease of anxiety, worries and decisional conflict.
Limitations, reasons for caution: Caution is indicated since recent genetic counseling outcome studies have mainly focused on cancer genetic counseling. Furthermore, many of the studies included in these described reviews lack rigorous methodologies and use different scales or other assessments for the same outcome (Resta, 2018).
Wider implications of the findings: These limitations suggest that further genetic outcome studies are needed, specifically in the reproductive field. Furthermore, genetic technologies are evolving leading to an expansion of applications in the reproductive field. Genetic counselors can play an important role in preconception family history evaluation, donor screening, preimplantation genetic diagnosis/screening and carrier screening.
Trial registration number: not applicable

P-507 Stress and the impact on assisted reproductive technology (ART) outcomes

M. Geisler[1], S. Meaney[2], J. Waterstone[1], K. O'Donoghue[3]
[1]Waterstone Clinic, Reproductive Medicine, Cork, Ireland
[2]Cork University Maternity Hospital, National Perinatal Epidemiology Centre, Cork, Ireland
[3]Cork Univarsity Maternity Hospital, INFANT centre, Cork, Ireland

Study question: To determine if psychological stressors had an impact on IVF/ICSI treatment cycle outcomes including miscarriage rates.
Summary answer: This study suggests that stressors do not impact greatly on the chance of conception from ART but may be implicated in increased rates of miscarriage.
What is known already: There is a small number of studies assessing the effect of stress on ART outcomes. A meta-analysis by Matthiesen et al found a small but significant effect of stress and anxiety on clinical pregnancy rates, but not for livebirth rates. There is more robust data however on the effect of stress on early pregnancy success. There is evidence to suggest the high perceived stress in early pregnancy is associated with increased rates of miscarriage. Immunological imbalances have been linked to miscarriage in those who reported high perceived stress.
Study design, size, duration: A survey-based study of 320 women recruited prior to commencing ART and followed prospectively for treatment outcome during the study period 2013- 2015. The survey on emotional/psychological wellbeing to measure specifically perceived stress, emotional well-being, maternal social support and outlook. The women were asked to grade their responses according to a specified scale.

Participants/materials, setting, methods: Women attending Waterstone Clinic, Cork, were invited to complete the survey in advance of treatment. A paper- based study was distributed to women attending the clinic and a further group of women were invited to complete an online version of the survey in advance of commencing their IVF/ICSI cycle. The reposes were collated and assessed according to outcome which included negative pregnancy test, positive pregnancy test and first trimester miscarriage.

Main results and the role of chance: 320 women completed the survey with a mean age of 36 years ± 3.4 years.

290 (90%, 290/320) proceeded to ART treatment of which 58.2% (n=169/290) conceived. Analysis of individual life stressors in the preceding 12 months, including job stress or serious financial problems did not reveal significance in terms of conception. A small number had experienced serious illness in the preceding 12 months which demonstrated significance in terms of not achieving pregnancy.

Overall, there were high rates of emotional wellbeing, very high rates of maternal support and medium to low levels of perceived stress and this did not differ amongst those who conceived and failed to conceive from treatment.

The women were further analysed according to livebirth and pregnancy loss (biochemical pregnancy and miscarriage). Individual life stressors revealed a higher rate of pregnancy loss amongst those who reported a stressful/demanding job ($p < 0.05$). A number of patients reported non-specified stressful life events and separation/divorce in higher numbers amongst the pregnancy loss group, reaching statistical significance, however the numbers are small thus limiting interpretation.

Psychological factors had no impact on the risk of pregnancy loss amongst the group. Those who achieved livebirth were less likely to have higher perceived stress.

Limitations, reasons for caution: The limitations of the study are the small numbers in some of the positive findings, thus limiting interpretation. Stress is multifactorial and therefore difficult to measure objectively.

Wider implications of the findings: There is evidence from the fertility cohort that stress, particularly job-related stress, is associated with higher chance of pregnancy loss. Conversely, those who achieve livebirth are less likely to report high perceived stress. This suggests that there may be a role for stress management in early pregnancy.

P-508 Chromosomal abnormalities occurrence in human blastocysts and detail

K. Kido[1], E. Otsu[1], A. Kanda[1], Y. Kumasako[1], Y. Kai[2], T. Utsunomiya[2]

[1] *St. Luke Clinic, Laboratory, Oita, Japan*

[2] *St. Luke Clinic, Dept. of Ob/Gyn, Oita, Japan*

Study question: What is the incidence of whole and segmental aneuploidies in human blastocysts?

Summary answer: Among abnormal blastocysts, almost all chromosomes had either trisomy or monosomy. The frequency of segmental aneuploidy was less than whole aneuploidy.

What is known already: Human blastocysts have a high frequency of aneuploidy and cannot be identified by traditional morphological methods. In recent years, it has been found that chromosomal abnormalities also occur when there is segmental gain or loss.

Study design, size, duration: This study was conducted between September 2017 and November 2018. Chromosomal copy number data was obtained from 42 blastocysts of 13 IVF patients, who requested chromosome testing for aneuploidy due to repeated implantation failure and/or recurrent pregnancy loss.

Participants/materials, setting, methods: Whole genome amplification was performed on TE biopsied from day5 or day6 blastocysts of IVF patients who requested chromosome testing for aneuploidy. The samples were processed and analyzed for their chromosome composition using microarray comparative genomic hybridization (aCGH).

Main results and the role of chance: Chromosomal abnormalities were detected in 69.0% of the analyzed samples. Among the chromosomal abnormalities, 39.3% involved a single chromosome, 35.7% two chromosomes, and 10.7% three and more chromosomes (maximum 6). Among the abnormal blastocysts, almost all of the chromosomes had either trisomy or monosomy. The trisomy/monosomy ratio approximated 1:1. Additionally, 21.4% of blastocysts also involved segmental aneuploidies.

Limitations, reasons for caution: Cytogenetic analysis was performed on TE biopsied from blastocysts. However, it is unclear as to whether the biopsied sample is representative of the true incidence of whole and segmental aneuploidy of the entire blastocyst.

Wider implications of the findings: This data shows details of the chromosomal abnormalities in repeated implantation failure and recurrent pregnancy loss. This data is useful for providing information on patient's future treatment options.

Trial registration number: non

P-509 Chromosomal analysis of early fetal losses in relation to embryonic heart rate on day 27-29 following in vitro fertilization-embryo transfer

Y. Ouyang[1], X. Li[1], Y. Tan[2], Y. Wen[1], G. Lin[3]

[1] *Reproductive and genetic hospital of Citic-Xlangya, Imaging Department, Changsha, China*

[2] *Reproductive and genetic hospital of Citic-Xlangya, Genetic Department, Changsha, China*

[3] *Reproductive and genetic hospital of Citic-Xlangya, Reproductive Department, Changsha, China*

Study question: Do early pregnancy losses (EPLs) with different karyotypes differ in embryonic heart rate (EHR) on day 27-29 following in vitro fertilization-embryo transfer (IVF-ET)?

Summary answer: The EHR differs significantly among EPLs with different karyotypes. When a slow EHR is detected, there is a higher likelihood of abnormal karyotype.

What is known already: Approximately 15% of all clinically recognized pregnancies end in miscarriage during the first trimester. Even after EHR is detected, the pregnancy loss rate remains 3–4%. Chromosomal abnormalities cause more than half of EPLs. Transvaginal sonography (TVS) enables us to identify the EHR to document fetal viability at very early time points. The first TVS examination is routinely arranged on day 27-29 after IVF-ET, and the EHR could be detected in most normal cases. The EHR, whether absent or slow, has been shown to have associations with EPLs. But the relationship between EHR and different karyotypes were seldom studied.

Study design, size, duration: The chromosomal data of 159 women who underwent dilation and curettage (D&C) from January 2012 to December 2016 for missed abortion were analyzed retrospectively. Chromosomal analyses were performed with chorionic villus. Written informed consent was obtained from all participants before D&C and cytogenetic tests. The absence or presence of embryonic cardiac activity and its rate were recorded during TVS examination in each patient.

Participants/materials, setting, methods: All included patients experienced singleton EPLs and underwent TVS examination on day 27-29 after ET. According to the karyotype results, the EPLs were divided into normal karyotype group (A, n=76) and abnormal karyotype group (B, n=83). The EHR was recorded by the M-mode imaging and was calculated using the software of ultrasound machine. The EHR and its distribution in EPLs were compared between 2 groups. The EHR of EPLs with different karyotype were also analyzed.

Main results and the role of chance: Except the maternal age of group B was significantly higher (31.1 ± 4.9 vs. 33.2 ± 5.6, $p = 0.014$), other characteristics were similar between 2 groups ($P > 0.05$). The EHR was markedly lower in group B compared to group A (106.2 ± 14.8 vs. 101.1 ± 16.2 bpm, $p = 0.044$). The 2 groups were similar regarding EHR distribution ($p = 0.313$). However, most cases in group A (32.9%) had an EHR among 111-120 bpm, while 101-110 bpm was more common in group B (31.3%) . Autosomal trisomy was the most common abnormality in group

B. Trisomy 15 (12.0%), trisomy 14 (9.6%) and monosomy X (9.6%) were the top 3 abnormalities. The EHR differs significantly among EPLs with different karyotypes (P = 0.003). Trisomy 13 (115.7 ± 8.7 bpm) and normal karyotype (115.5 ± 7.0 bpm) had the fastest EHR, while trisomy 8 (72.5 ± 10.1 bpm) with the lowest EHR. 82. 6% cases with viable abnormal karyotype had an EHR over 100 bpm. Additionally, the EHR in EPLs with viable abnormal karyotype was significantly higher than those with non-viable karyotype (107. 7 ± 13. 4 vs. 98. 6 ± 16. 7 bpm, P = 0. 022).

Limitations, reasons for caution: Maternal cell contamination is a major problem. We didn't exclude the female losses due to the sample size was not large enough and there were limited cases of some rare chromosomal abnormalities. Additionally, other variables associated with EPLs such as embryo and yolk sac were not studied here.

Wider implications of the findings: The findings suggest that an early slow EHR might be included as an additional parameter in the screening for chromosomal abnormalities. It might be useful in clinical practice for providing miscarriage clues and guidance for future pregnancies. However, additional studies involving larger patient populations are needed to further corroborate it.

Trial registration number: None

P-510 determination of mitochondrial DNA levels in human blastocysts as a predictor for embryonic implantation potential

A. Korolkova[1], N. Mishieva[1], B. Martazanova[1], M. Veykova[1], A. Kirillova[1], O. Bourmenskay[2], A. Ekimov[2], A. Abubakirov[1]

[1]Kulakovs National Medical Research Center of Obstetrics- Gynecology- and Perinatology- Ministry of Health of Russia, Department of preservation and restoration of reproductive function, Moscow, Russia C.I.S.

[2]Kulakovs National Medical Research Center of Obstetrics- Gynecology- and Perinatology- Ministry of Health of Russia, Laboratory of Molecular Genetic Techniques, Moscow, Russia C.I.S.

Study question: Is there correlation between the quantity of mitochondrial DNA (mtDNA) in trophectoderm (TE) biopsy samples and female age, embryo morphology, ploidy and blastocyst implantation rate?

Summary answer: Elevated mtDNA levels, above a threshold (0,004), are associated with the advanced reproductive age, embryonic aneuploidy and implantation failure.

What is known already: At present, even the transfer of euploid embryos with high morphological grade cannot guarantee pregnancy achievement. Therefore, it is necessary to find better methods of embryo selection leading to the improvement of ART outcomes. Recently it has been proposed, that the quantity of mtDNA in TE cells can serve as a new biomarker of embryo viability. For instance, was founded statistically significant increase mtDNA copy number in advanced reproductive age and aneuploid blastocysts, also higher mtDNA quantity associated with reduced implantation potential. However, for better understanding of mitochondrial biogenesis the subsequent randomized controlled trials are needed.

Study design, size, duration: This prospective cohort study involves the analysis of relative mtDNA levels in 106 blastocysts obtained from 50 couples undergoing preimplantation genetic testing for aneuploidy. The patients included in the study were divided into 2 groups: I- average female age 32±2.8 years (25-34 years), II – 38.6 ±3.6 years (35-45 years). The study performed from February to November 2018.

Participants/materials, setting, methods: DNA from the trophectoderm samples were amplified and subjected to aneuploidy analysis using array comparative genomic hybridization. MtDNA was assessed in the same whole genome amplification products using quantitative PCR.

Main results and the role of chance: Out of the 106 obtained blastocysts 38 embryos were diagnosed as aneuploid, and 68 as euploid. The aneuploid blastocysts (n = 38) contained significantly higher levels of mtDNA in all age groups, vs. euploid embryos (n = 68) (P = 0.003). A positive correlation of the relative level of mtDNA in the trophectoderm of embryos with the patients' age (P = 0.0038) was revealed. The ROC analysis allowed to establish a threshold value for the mtDNA level - 0.004, exceeding of the threshold predict implantation failure with a sensitivity of 76.8% and specificity of 74.9%. The 41 euploid blastocysts had been transferred, 27 led to ongoing pregnancies, an overall implantation rate was 65.8% (27 / 41). Out of the transferred embryos, 32 blastocysts contained levels of mtDNA in the normal range, thus the implantation rate for the euploid embryos with a subthreshold mtDNA level was 84.4% (27/32). The remaining 9 blastocysts contained mtDNA quantities above the threshold value and none of these led to a pregnancy (9/41). The difference between the implantation rates for embryos with normal/low and elevated mtDNA quantity was statisticaly significant (P < 0.0001).

Limitations, reasons for caution: Our study was carried out in a relatively small subset of participants and obtained embryos. Therefore, the results obtained cannot be readily extrapolated on other groups of patients and need to be confirmed in larger trials.

Wider implications of the findings: This study showed that mtDNA quantification can serve as an independent biomarker and predict the implantation potential of euploid blastocyst, hereby, allows to increase the effectiveness of IVF treatment, including treatment in advancing female age group.

Trial registration number: N/A

P-511 Examination of the Relationship between Mitochondrial DNA (mtDNA) Content Analysis using Next-Generation Sequencing (NGS) and the Morphological Assessment of Embryos and Aneuploidy

K. Takeuchi[1], H. Setoyama[2], Y. Kuroki[2], Y. Kuwatsuru[2], Y. Fukumoto[2], T. Iwakawa[1], M. Takeuchi[1], T. Kato[3], H. Kurahashi[3]

[1]Takeuchi Ladies Clinic / Infertility Center, Infertility, Aira-shi- Kagoshima-, Japan

[2]Takeuchi Ladies Clinic / Infertility Center, laboratory, Aira-shi-Kagoshima, Japan

[3]Fujita Health University, Division of Molecular Genetics. Institute for Comprehensive Medical Science., Toyoake-shi- Aichi, Japan

Study question: We examined whether the mtDNA read count obtained, along with the NGS result, could be used as a more reliable index of embryo for transfer.

Summary answer: There was no difference in mtDNA content based on age, aneuploidy or pregnancy outcome; there was a significant difference based on embryo morphological assessment (P<0.05).

What is known already: Recently, mtDNA content has been reported to be related to patient age, morphological assessment of embryos, euploid and implantation rate. In our hospital, NGS has also been used in preimplantation genetic testing (PGT). The data on mtDNA content was analyzed in this study.

Study design, size, duration: The data on 150 embryos were obtained from 15 patients who underwent PGT between 2014 and November 2018. The mean age of patients at the time of oocyte collection was 35.8±3.01 years. Embryo transfer was performed in 23 cycles in 14 patients after PGT.

Participants/materials, setting, methods: Mitochondria score (Ms) (mtDNA read count/total chromosome read count×10000) was calculated from total chromosome read count and mtDNA read count obtained by NGS. Correlation between patient age, embryo morphological assessment, chromosomal abnormalities, pregnancy and Ms was examined by median testing. In embryo assessment via Gardner grading, those with morphological grading better than/equal to 4BB were regarded good embryos. Pregnancy judged positive if a gestational sac (GS) was confirmed after embryo transfer.

Main results and the role of chance: There was no difference noted between a group of patients under 37 years (<37 years, n=104, median=9.91) and a group of patients aged 38 years or more (≧38 years, n=46, median=10.32). There was no difference between a group of patients with chromosomal abnormalities (n=91, median=10.98) and a group of patients without chromosomal abnormalities (n=59, median=9.76). When patients were categorized according to pregnancy outcome after embryo transfer, there was no difference between those who became pregnant (n=13, median=10.03) and those who did not (n=10, median=8.54). When embryos were categorized according to morphological assessment, there was a significant difference between good embryos (n=129, median=9.82) and poor embryos (n=21, median=13.01) (P<0.05).

Limitations, reasons for caution: There were no reasons for caution or limitations.

Wider implications of the findings: In this study, it was suggested that Ms might be correlated to the morphological assessment of embryos. There was no correlation between Ms and pregnancy. Because of the scarcity of data, we should accumulate more data and reexamine the results in the future.

Trial registration number: None

P-512 Mosaic embryo rate decreases with maternal age but mitotic error remains constant in embryos derived from euploid oocytes.

V. Montalvo[1], S. Novo[1], J. Massó[1], B. Freijomil[1], M. Solans[1], C. Castelló[1], M. Lopez-Teijon[1]
[1]*Institut Marques, Reproductive Medicine Service, Barcelona, Spain*

Study question: Which is the true incidence of the different types of embryo mosaicism (euploid and aneuploid) and how does it correlate with maternal age?

Summary answer: Euploid-mosaic rate decreases with age, but remains constant relatively to euploid rate. Instead, the aneuploid-mosaic rate is constant, but drops with regard to aneuploid rate.

What is known already: One of the main consequences of next generation sequencing (NGS) implementation is the greatest power to detect mosaic samples. It is well known that mosaicism arises from chromosome segregation mistakes during mitotic divisions. Several studies about the relationship between age and mosaicism indicates that, even though incidence of euploid mosaicism varies with age, mitotic errors are constant. Thus, the total mosaicism rate (euploid and aneuploid) is theoretically always the same and non-correlated with oocyte age. However, this argument is based on the hypothesis that euploid and aneuploid oocytes have an identical behaviour related to mitotic errors during their aging.

Study design, size, duration: This is a retrospective study that includes 899 blastocyst stage embryos from 252 preimplantation genetic testing cycles (PGT) performed between July of 2017 and December of 2018 and analysed through NGS. All these embryos were cultured under the same conditions, with the same one-step media and in a time-lapse incubator.

Participants/materials, setting, methods: After PGT-A results, the embryos were classified in four groups: euploid; aneuploid; euploid-mosaic (embryo with at least two cell lines, one euploid); and aneuploid-mosaic (embryo with at least two different aneuploid cell lines).

Cases were clustered according to maternal age, following the recommendations of the *Society for Assisted Reproduction Technology*: Egg donor (<35), <35, 35-37, 38-40, and >40 years old. Chi-square test was performed to compare the mosaicism rates between the different age groups.

Main results and the role of chance: Our data show that euploid-mosaicism rate decreases while oocyte age increases (egg donor= 26.9%, <35= 21.9%, 35-37= 24.5%, 38-40= 16.5%, >40= 3.3%), being statistically significant above 40 years old ($p<0.05$). Nevertheless, if we consider that euploid-mosaic and euploid embryos have the same origin (euploid egg), the mosaicism rate of them remains invariable through all age groups (33.7±7.6%; p= 0.323). Otherwise, the aneuploid-mosaic rate of embryos derived mainly from aneuploid oocytes decreases with age (egg donor= 22.9%, <35= 23.1%, 35-37= 17.2%, 38-40= 12.0%, >40= 4.9%), being statistically significant above 40 years old ($p<0.05$).

These results make us think that mitotic errors happen differently depending on ploidy and age of the oocytes. While embryos arising from euploid oocytes have always the same mitotic errors, embryos originated from aneuploid oocytes are more susceptible to mitotic errors the younger the egg is. Another plausible reason could be that aneuploid mosaic embryos are less able to achieve a biopsiable stage the older the oocyte from which they come.

Confronting previous publications, this study proves that embryonic mosaicism have different behaviour depending on the ploidy and the age of the oocyte.

Limitations, reasons for caution: This study is based on the capacity to detect mosaicism in 4 to 8 cells of trophoectoderm biopsy. Therefore, the representativity of the embryo biopsy is limited, and we could be underestimating the real incidence of mosaicism.

Wider implications of the findings: Our results demonstrate that mitotic error remains invariable in embryos derived from euploid oocytes. Thus, mosaicism in embryos that can be transferred is not correlated with age. However, a different age-depending dynamic of euploid and aneuploid mosaicism has been detected, so they should not be grouped.

Trial registration number: Not applicable

P-513 Optimizing clinical exome design for recessive genetic conditions in preconception carrier screening: insights from 14,125 exomes

A. Capalbo[1], R. Alonso[2], J. Jimenez-Almazan[2], M. Fabiani[1], P. Mir Pardo[2], V. Romanelli[1], D. Jiménez[2], C. Simón[2,3,4,5], J. Martin[2]
[1]*Igenomix, Reproductive Genetics, Marostica, Italy*
[2]*Igenomix, Reproductive Genetics, Valencia, Spain*
[3]*Baylor College of Medicine, Department of Ob/Gyn, Houston- TX, U.S.A.*
[4]*Stanford University, Department of Ob/Gyn, Stanford CA, U.S.A.*
[5]*Valencia University, Obstetrics & Gynecology, Valencia, Spain*

Study question: It is possible to define the optimal preconception carrier screening (PCS) panel based on disease prevalence, severity and penetrance using a large data set of 14,125 exomes?

Summary answer: Exome sequencing achieves high sensitivity in the detection of highly penetrant childhood-onset recessive disorders and provides useful data for developing preconception carrier screening (PCS) programs.

What is known already: Approximately 30 in 10,000 children suffer from one of the 1,300 known recessive genetic conditions. These data suggest that 1-2% of couples are at high risk of having an affected child. PCS aims at revealing recessive genetic conditions in healthy individuals in order to provide them with genetic risk information and assist them with reproductive decision-making. Current debate on PCS application focuses on which gene/mutation panel maximises clinical sensitivity and cost-effectiveness while minimising counterproductive effects. Lack of large translational research data from genomic sequencing hinders proper evaluation of reproductive risk in healthy individuals and optimization of PCS gene-panel design.

Study design, size, duration: De-identified ES data from 14,125 samples were used to define gene-condition level and aggregate fetal risk. Gene-condition pairs were included based on severity, penetrance, inheritance pattern, age of onset, and strength of gene-disease association according to ClinGen framework. Modelled disease fetal risk (MDFR) was based on specific inheritance pattern and simulated parental populations. Conditions with MFDR >1 per million were included. The diagnostic impact of actionable secondary findings (SF) detection (ACMGv2-recommended genes) was investigated.

Participants/materials, setting, methods: Clinical ES was performed on gamete donors (5,845) and infertile couples (8,280) without any known family history of inheritable genetic conditions. 4,813 genes were analysed using TruSight One Sequencing Panel (Illumina). Variants were classified as pathogenic (P); likely pathogenic (LP); uncertain significance (VUS); likely benign (LB); or benign (B) based on ClinVAr records. Multiple methodologies were employed to detect pathogenic variants undetectable with sequencing (HBA, SMA, GBA, GJB2; DMD and X-Fragile for females only).

Main results and the role of chance: Among the 14,125 samples analysed, 52.3% showed at least one positive carrier result. The average number of P/LP variants was 0.74 per individual, ranging between 0 and 7 variants. Donors and patients, as well as male and females, showed similar carrier burden (P=NS), suggesting that recessive genes causing severe and early onset diseases are not related to fertility. ES achieved high clinical sensitivity for highly penetrant childhood-onset disorders (1 out 280 conceptions) through the analysis of 127 selected gene-condition pairs. Significant contributions to MDFR were observed from rare (carrier rate <1:100) and X-linked conditions (15.4% and 52.2% of total MDFR, respectively). Subgroup analysis identified 32 of 776 couples at increased risk (4.1%; 95%CI=2.8-5.8) for one of the 127 conditions analyzed. Two additional couples were found at increased risk for very rare conditions beyond 1 in a million of prevalence (Adenylosuccinate lyase deficiency MIM: 103050 and Microcephaly, epilepsy, and diabetes syndrome MIM: 614231) when both members of a parental pair were treated as a unit and the search for reproductive risk was extended to the entire exome content. Finally, 7.8% of the participants showed at least one pathogenic variant for genes included in the updated ACMGv2 list of medically actionable SF.

Limitations, reasons for caution: One major limitation to our conclusions involves the lack of ethnic diversity in our large cohort (mainly of Caucasian). However, the disease-specific frequencies provided should allow comparison with ES data collected in other preconception populations with different ethnicities. The current ES protocol lacks CNVs and non-coding pathogenic variants analysis.

Wider implications of the findings: Our results support the use of ES for PCS, which maximises clinical sensitivity especially when aiming at providing a test applicable to a broad population with different ethnicities or in consanguineous relationships. Future studies are required to investigate the clinical impact of reporting of SF in reproductive medicine practice.
Trial registration number: none.

P-514 46,XX male? Reality, PGT-A misdiagnosis or laboratory quality management error?

M.C. Schiewe[1], N.L. Nugent[1], C.M. Rios[2], S. Zozula[1], S. Shahbazian[1], J.B. Whitney[1], R.E. Anderson[3]
[1]Ovation Fertility, ART Lab, Newport Beach- CA, U.S.A.
[2]Ovation Genetics, NGS Lab, Henderson- NV, U.S.A.
[3]SCCRM, Clinic, Newport Beach- CA, U.S.A.

Study question: Does a mid-term ultrasound of a confirmed male fetus derived from a single non-mosaic euploid 46,XX blastocyst transfer definitely imply a laboratory error occurred?
Summary answer: Sex determination errors from non-mosaic embryos are rare, but not when random meiotic X translocations of a SRY gene causes an uncommon XX male syndrome.
What is known already: Blastocyst biopsy (BL-Bx)/preimplantation genetic aneuploidy testing (PGT-A) have been shown to be subject to false-negative diagnosis due to mosaicism. We have previously shown that the BL-Bx technique can contribute to mosaic diagnoses. Wrong sex determinations are extremely rare based on the precision of NGS tests. Errors in the sex of offspring are typically associated with a laboratory handling/identification error. Conversely, viable aneuploidy of sex chromosomes is not unusual as it pertains to Klinefelter(<1:1000) or Turner's syndrome(<1:5000). Less common(1:20,000) is the random meiotic translocation of the SRY gene onto the sperms' X chromosome, causing a female to be born biologically male.
Study design, size, duration: Following a "wrong sex" ultrasound confirmation at 18-20 weeks, a retrospective case study analysis was performed. All aspects of embryo handling in the patients IVF/ICSI cycle and subsequent thaw/biopsy ("thawopsy") procedure were evaluated for potential error and confirmation of witness identification. Furthermore, the timing and procedural order/paperwork of other same day, BL-Bx/vitrification/FET cases was scrutinized for possible embryo mix-up. In addition, the patients' NGS tests were reviewed and rerun to assess accuracy of outcome.
Participants/materials, setting, methods: An infertility couple performed an ICSI cycle with blastocyst vitrification in May 2013. A successful term male birth followed and in May 2018 the couple chose to perform a thawopsy of their residual embryos. In June 2018 they performed a single euploid ET using a 6AA Day 6 46,XX blastocyst with a non-mosaic NGS profile. During the second trimester of pregnancy, a perinatologist performed ultrasound exams of the fetus and additional genetic testing (NIPT, amniocentesis).
Main results and the role of chance: A 35 year old patient entered her second trimester with a predetermined female pregnancy, only to be told and shown at 20 weeks, that the fetus had a penis. The distraught patient contacted the REI physician, whom informed the IVF Lab looking for answers to how such an error could occur. A detailed investigation of patient records revealed that the initial cycle produced 25 mature oocytes, 21 zygotes and 13 blastocysts (1 transferred and 12 vitrified) and that all embryo handling events had been witnessed, as were the subsequent thawopsy procedures. Of the 7 embryos re-biopsied/re-vitrified, 5 euploid (2-46,XY and 3-46,XX) blastocysts were confirmed. In retrospect, the only fact not fully detailed to alleviate any doubt in potentially mishandling another patients' male embryo post-biopsy was the exact time of vitrification. As we typically vitrify within 45 min post-biopsy, we had confidence that the prospects of a mix-up 90 min later was highly doubtful. Post-repeated ultrasound, the NIPT outcome was "inconclusive", which we assumed meant it did not support the ultrasound scan findings. Finally, in October 2018, the amniocentesis finding was conclusive revealing the rare XX male syndrome condition.
Limitations, reasons for caution: It is imperative that laboratories implement strict quality management practices involving witness verification and time/date details for all embryo handling/movement events to confidently assess and troubleshoot potential lab errors. As we integrate routine genetic testing, we must inform patients about the risks of potential rare events, besides issues of mosaicism.
Wider implications of the findings: When faced with a potential misdiagnosis, it is comforting to everyone when quality management efforts effectively confirm the elimination of lab error. Furthermore, we must anticipate incorrect mosaic profile interpretations, as well as unusual/rare developmental events to best inform and support our patients.
Trial registration number: None

P-515 Embryo culturing conditions and non-invasive preimplantation genetic testing for aneuploidy detection (NI-PGT-A); an observational study

M. Jasper[1], C. Robinson[1]
[1]PerkinElmer Health Sciences Australia Pty Ltd, PerkinElmer Health Sciences Australia Pty Ltd, Adelaide, Australia

Study question: Do embryo culturing conditions during IVF impact results obtained for non-invasive preimplantation genetic testing for aneuploidy (NI-PGT-A) of spent embryo culture media?
Summary answer: Replacing culture media during IVF improves overall concordance rates between the embryo biopsy and spent embryo culture media for NI-PGT-A.
What is known already: Challenges to the use of NI-PGT-A include achieving high concordance between the spent embryo culture media and embryo biopsy results, and also the ability to distinguish contaminating maternal DNA from the embryonic DNA. Variable rates of concordance have been reported to-date, but this may stem from the absence of standardized culturing conditions or molecular testing methodologies. Optimisation of either or both components will likely result in the highest accuracy of NI-PGT-A. The accumulation of embryonic and contaminating DNA in spent embryo culture media will be determined by culture conditions, however a robust amplification technology will be crucial for NI-PGT-A.
Study design, size, duration: Spent embryo culture media was collected and stored at -20°C by clinics (under their ethics approval) from single embryo culture droplets following biopsy of the embryo for PGT-A. Specific culturing conditions, including droplet size, day of biopsy, and whether the media was changed, were disclosed along with the biopsy PGT-A result at the time of sample processing. All samples were processed by a single laboratory.
Participants/materials, setting, methods: Spent embryo culture media samples (n=170) from 10ul-60ul culture droplets were whole genome amplified (WGA) using DOPlify® kit reagents (PerkinElmer). Next generation sequencing libraries and sequencing was performed according to the standard PG-Seq™ kit 48 sample protocol on a MiSeq sequencer (Illumina). Data was bioinformatically aligned to hg19 and analysed using PG-Seq™ kit software. WGA DNA yield, NGS metrics, and whole chromosome aneuploidy concordance with the PGT-A result for the embryo biopsy were determined.
Main results and the role of chance: Results were collated for each set of culturing conditions. Whole genome amplification using DOPlify® kit reagents resulted in the amplification of 78-100% of spent embryo culture media samples (WGA failure rate 0-22%). Ploidy concordance with the embryo biopsy ranged from 33-55% for autosomal chromosomes and 47-53% for sex chromosomes using a continuous culturing system (n=3 protocols), compared with concordance rates of 60-95% and 50-97% respectively when media was changed during the 5 day culturing period (n=4 protocols).
Limitations, reasons for caution: Limited numbers of media samples were available for each individual culturing protocol and researchers performing the data analysis were not blind to the culturing conditions or PGT-A biopsy results. Maternal DNA contamination of media may be underestimated, as it can only be detected when the embryo in culture was male.
Wider implications of the findings: Specific embryo culturing protocols and/or technology to determine the level of external DNA contamination are likely to improve concordance for NI-PGT-A. A subsequent study using DOPlify® kit reagents (PerkinElmer) is planned to be undertaken with researchers blind to the embryo culturing conditions and PGT-A results.

P-516 Prevalence and properties of copy number variation (1-10 Mb) in preimplantation blastocysts

P. Xie[1], D. Chen[2], S. Zhou[1], P. Liu[2], L. Hu[1], Y. Tan[1], G. Lu[1], G. Lin[1]
[1]1National Engineering and Research Center of Human Stem Cell- Changsha 410078- China 2Institute of Reproduction and Stem Cell Engineering- Central South University- Changsha- Hunan 410078- China- 3Reproductive and Genetic Hospital of Citic-Xiangya- Ch, ,
[2]MGI- Shenzhen- 518083- China, research, Shenzhen, China

Study question: Can next generation sequencing (NGS) accurately detect small segmental aneuploidy ((1-10Mb) using 3-5 cells and what is the prevalence and properties of SSA in human preimplantation blastocysts?
Summary answer: Our method can effectively detect SSA, the incidence of SSA was about 4.7% and a certain frequency was pathogenic in human preimplantation blastocysts.
What is known already: Copy number variations (CNVs) are a major contribution to the genome variability and can be either benign or pathogenic, depending on their location and genetic content et al. Pathogenic CNVs including microduplication and microdeletion syndromes are frequently associated with intellectual disability, multiple congenital autistic spectrum disorders and other phenotypic findings. Previous studies have indicated NGS-based method for preimplantation genetic testing (PGT) could accurately detect chromosome aneuploidy and segmental aneuploidy above 10 Mb. However, little is known about the NGS-based SSA detection of human preimplantation blastocysts.
Study design, size, duration: Six human embryonic stem cell lines with known CNV < 10 Mb and 158 preimplantation genetic testing for structure recombinant (PGT-SR) blastocysts from 35 patients were used to build and evaluate methodology. 4212 blastocysts from 1735 patients who requested PGT for aneuploidy(PGT-A)were used to evaluate prevalence and properties. The study was approved by the ethics committee (LL-SC-SG-2014-011).
Participants/materials, setting, methods: limited stem cells and biopsy samples were subjected to PicoPLEX WGA amplification and low-coverage sequencing were performed using the BGISEQ-500 sequencing platform. An average of 20 million reads were obtained for each sample. Further, genome-wide CNV analysis of the parental genomic DNA were performed to determine whether SSA were inherited or de-novo. The Clinical interpretation of the detected CNVs was based on the guidelines of American College of Medical Genetics and Genomics.
Main results and the role of chance: Using improved bioinformatic methodology, the picoPLEX WGA combined NGS can accurately detect SSA > 1Mb, the sensitivity and specificity were more than 90%.

From 4212 blastocysts from 1735 PGT-A cycles, 191 blastocysts were seen to carry 196 SSA (47 were 4-10Mb and 149 were 1-4Mb). Among 47 4-10Mb SSA, 28 were loss and 19 were gain. All 28 4-10Mb loss were de-novo CNV and pathogenic or likely pathogenic CNV(PCNV), all located the end of the chromosome. Among 19 4-10Mb gain, five from two couples were inherited from parents and were classified as variants of uncertain significance (VOUS), the remaining 14 4-10Mb gain, 11 were PCNV and 3 were classified as VOUS CNV. Among 149 1-4Mb CNV, 60 were loss and 89 were gain. 116 parental gDNA available were used to determine inherited or de-novo. The results suggested 45 (38.8%) were de-novo and 71(61.2%) were inherited from parents. Among 71 inherited 1-4Mb SSA, 27 were loss and 44 were gain. 29.6% (8/27) inherited 1-4Mb loss were PCNV, however, most inherited 1-4Mb gain were VOUS or benign. Refer to 45 de-novo 1-4Mb SSA, 18 loss out of 26 were PCNV and only 3 gains out of 19 were classified as PCNV.
Limitations, reasons for caution:

The de-novo SSA needed further confirmed using other credible methods. The clinical interpretation of the SSA was challenge,especially the de-novo SSA, as the phenotypic consequences of some SCNVs were quite variable and their impact on human health depends on factors that are not yet known.
Wider implications of the findings: Increasing the detection resolution to 1Mb is valuable for excluding the transfer of blastocysts with PCNV and non-priority transfer the blastocysts with VOUS-CNVs.
Trial registration number: not applicable

P-517 Efficacy of nuclear transfer to prevent the inherited mitochondrial pathology

D. Mykytenko[1], P. Mazur[2], L. Dyachenko[2], M. Borisov[3], Y. Masliy[3], V. Lamtyeva[1], K. Lavrova[1], T. Chernega[1], V. Zukin[4]
[1]Clinic of Reproductive Medicine 'NADIYA', Molecular Diagnostics Laboratory, Kiev, Ukraine
[2]Clinic of Reproductive Medicine 'NADIYA', Laboratory of embryology, Kiev, Ukraine
[3]Clinic of Reproductive Medicine 'NADIYA', IVF dpt, Kiev, Ukraine
[4]Clinic of Reproductive Medicine 'NADIYA', Administration, Kiev, Ukraine

Study question: Can mitochondrial transfer in ART provide embryos without the risk of mitochondrial pathology?
Summary answer: Nuclear transfer procedures showed high efficiency in describes case. But further investigations and long term follow up of children is required.
What is known already: Mitochondrial pathology is characterized by maternal inheritance. Women may be hidden mutation carriers, but in some cases the risk for descendants may reach up to 100%. Due to the uneven distribution of mitochondria during cell division, the practice of preimplantation testing of embryos has significant limitations, and prenatal diagnosis may be unacceptable. The first baby after nuclear transfer procedures was born in 2016 (J. Zhang et al., 2017).
Study design, size, duration: The study included a married couple with a confirmed hidden woman's carriage of Leigh syndrome mutation (37 years old). The couple had a history of birth of a girl with Leigh syndrome. For ethical reasons, prenatal diagnosis and donation of oocytes were not considered for further childbirth.
Participants/materials, setting, methods: The patient's mutation carrier status has been confirmed in independent laboratories (mtDNA 9176 T>C, Heteroplasmy ~ 40%). The child was diagnosed with confirmed Leigh syndrome (Homoplasmy 99.4%). The couple had 2 controlled ovarian stimulations followed by nuclear transfer procedures. Embryo biopsy was performed on Days 5-6 of development. Preimplantation genetic embryo testing PGT-A (NGS: Veriseq, Illumina) and heteroplasmy testing of pathological mutation (NGS, coverage of >1000x) were performed.
Main results and the role of chance: During the first stimulation, 3 blastocysts (euploid female embryo and two aneuploid embryos) were obtained. After consultation with the patients, it was decided not to use the female embryo for the embryo transfer. During the second stimulation, 6 blastocysts, incl. 3 aneuploid and 3 euploid (males) were obtained. Heteroplasmy of euploid embryos for pathological mutations: 0.51 ± 0.02%, 2.96 ± 0.05 and 3.32 ± 0.06%. The embryos obtained during ART from a patient with a mtDNA mutation carrier status were characterized by a low level of heteroplasmy of mtDNA mutation and had a low risk of mitochondrial pathology development. The patient is preparing for embryo transfer.
Limitations, reasons for caution: Nuclear transplantation in human is still experimental and highly controversial procedure. Further investigations and long term follow up of children is required.
Wider implications of the findings: Nuclear transplantation could be used in prevention of mitochondrial diseases, preimplantation embryonic lethality, repeated implantation failure and in investigation of nuclear-cytoplasmic interactions.
Trial registration number: Clinical trial is registered by Shupyk National Medical Academy of Postgraduate Education of Ukraine. Registration number: is not used.

P-518 Segmental insertions and monosomies are linked to developmental arrest.

N. De Munck[1], A. Bayram[1], I. Elkhatib[1], A. Liñán[2], A. Arnanz[1], B. Lawrenz[1], H.M. Fatemi[1]
[1]IVIRMA, IVI Middle East Fertility Clinic, Abu Dhabi, United Arab Emirates
[2]IVIRMA, IVI Middle East Fertility Clinic, Muscat, Oman

Study question: Which genetic abnormalities will prevent blastocyst formation?
Summary answer: Embryos from which the day 3 cleavage stage blastomeres have segmental insertions or monosomies, have a significantly decreased chance to reach the blastocyst stage.

What is known already: A major negative selection against aneuploid cells happens during the transition from the morula to the blastocyst stage. When analyzing different morphological or time-lapse parameters, they do not allow us to discriminate between euploid and aneuploid blastocysts. Besides the morphokinetic parameters, chromosomal abnormalities of day 3 cleavage stage embryos have been analyzed for their detrimental effect on development. After fluorescence in situ hybridization (FISH) for a selected number of chromosomes, it was noted that trisomies, extensive mosaicism and monosomy X or 21 reach the blastocyst stage more often.
Study design, size, duration: A single center retrospective study was performed between April 2016 and January 2017. Patients requiring Preimplantation Genetic Testing for Aneuploidies (PGT-A) by Next Generation Sequencing (NGS) were included. All embryos were cultured in a time-lapse imaging system and biopsy was performed on day 3 of development, which allowed us to perform a fresh embryo transfer as embryo vitrification is prohibited. Segmental or whole chromosome insertions and deletions were registered.
Participants/materials, setting, methods: Of the 285 embryos biopsied on day 3, the embryo arrest was defined at the blastocyst stage if the embryo failed to cavitate 118 hours post-injection. A logistic regression model was applied using the time to cavitate as the response variable and the different mutations as the explanatory variables, and a p-value <0.05 was considered significant. The reliability of the model was tested by plotting the sensitivity and specificity in a ROC curve.
Main results and the role of chance: After single blastomere biopsy, the 285 cleavage stage embryos were further cultured until day 5 of development. A total of 103 (36.1%) embryos were euploid and 182 (63.9%) were aneuploid. There was a significant difference in the developmental arrest between euploid and aneuploid embryos (8.7% versus 42.9%; p=0.0001). Segmental insertions and monosomies were found to have a statistically and clinically significant effect on developmental arrest (p=0.0163 and p=0.0075), while chromosomal insertions and segmental deletions were not found to have a statistically significant effect on developmental arrest. In case of segmental insertions, an increase of one extra segmental insertion in any given chromosome increases the odd of arrest by 159%. For chromosomal monosomies, the odd will only increase by 29% for every extra chromosomal monosomy. The area under the ROC curve, indicating the ability of our model to correctly classify embryos with arrest based on their chromosomes, was 0.6573.
Limitations, reasons for caution: Besides the retrospective design of the study, a higher number of embryos is needed to detect which individual chromosomes show a more pronounced effect on developmental arrest.
Wider implications of the findings: The results of this study reinforce the use of day 5 biopsy. Not only will euploid embryos have a higher chance to develop to the blastocyst stage, the genetic result obtained with trophectoderm samples is also more reliable as compared to day 3 cleavage stage biopsies.
Trial registration number: Not Applicable

P-519 Clinical outcomes of comprehensive 24-chromosome preimplantation Genetic testing in couples with balanced reciprocal or Robertsonian translocations

L. Yang[1,2], P. Xie[2,3], L. Hu[1,2,3,4], Y. Tan[1,2,3,4], K. Luo[1,2], F. Gong[1,2,3,4], G. Lu[1,2,3,4], G. Lin[1,2,3,4]

[1]*Reproductive and Genetic Hospital of Citic-Xiangya, Reproductive Center, Changsha, China*
[2]*Key Laboratory of Stem Cells and Reproductive Engineering- Ministry of Health, Research and Development Department, Changsha, China*
[3]*National Engineering and Research Center of Human Stem Cell, Research and Development Department, Changsha, China*
[4]*Institute of Reproduction and Stem Cell Engineering- Central South University, Basic medicine, Changsha, China*

Study question: To determine the clinical value of comprehensive 24-chromosome preimplantation Genetic testing (PGT) in couple with balanced reciprocal or Robertsonian translocation.
Summary answer: PGT for Male carriers had better clinical outcomes than the female carriers in both balanced reciprocal or Robertsonian translocation.
What is known already: Balanced translocation is one of the more common structural rearrangements of chromosomes. The two most common types are Robertsonian translocation and reciprocal translocation, which are associated with reproductive risks, such as infertility, spontaneous abortion and the delivery of babies with mental retardation or developmental delay. There is controversy over whether PGT can improve the pregnancy outcome.Some studies suggested the transfer of chromosomally normal/balanced embryos following PGT significantly reduce the risk of an affected pregnancy and decrease the risk of miscarriage. However, some research demonstrates that natural conception offers similar pregnancy outcomes compared with IVF-PGT.
Study design, size, duration: A retrospective study from October 2011 to October 2018, a total of 12338 blastocysts originating from 3076(2917) oocyte retrieval cycles from 2568(2410) couples with one of the partners carrying reciprocal or Robertsonian translocations were investigated (2263 reciprocal translocations cycles and 654 Robertsonian translocations cycles). The mean maternal age was 30.3±4.1 years (20 –47years).
Participants/materials, setting, methods: Trophectoderm biopsy of blastocysts was performed on the 5th or 6th day of development. Whole genome amplification (WGA) was performed on all samples, and the WGA was analyzed with SNP array or NGS. The euploid embryo and unbalanced embryo rate were analyzed according to the translocation pattern, the carrier's gender and maternal age.
Main results and the role of chance: Of the 3075 oocyte retrieval cycles, 188 cycles had no embryos to biopsy. Among 2910 biopsied cycles, the average biopsied blastocysts number was 4.2 and 2099 cycle resulted in one or more euploid embryos. We calculated the rate of euploid and unbalanced translocation in male and female carriers respectively. For reciprocal translocations, 32.0% (1475/4610) embryos in female and 37.5% (1476/3941) in male was euploid ($p<0.01$). The Rates for unbalanced translocation was 56.6% (2599/4610) and 49.9% (1967/3941) respectively in female and male carriers, ($p<0.01$). For Robertsonian translocations, the euploid embryos rate was 42.9% (542/1262) and 57.9% (666/1144) in in female and male carriers, The Rates for unbalanced translocation was 40.2% (507/1262) and 17.2% (197/1144) in female and male carriers, with significant difference ($p<0.01$). Further, we compared the results between maternal age$\leq$35 years and >35 years,>35 years group had less biopsied blastocysts(4.4 vs 2.9) and higher risk(25.6% vs 45.3%)of no euploid embryo compared with the $\leq$35 group ($p<0.01$). So far, out of 1590 ET cycles, the clinical pregnancy rate, miscarriage rate and live birth rates (LBR) per ET was 63.0% (1001/1590), 18.2% (182/1001) and 51.2% (814/1590) respectively.
Limitations, reasons for caution: About 30% oocyte retrieval cycles had no ET especially in women >35 years and reciprocal translocation.
Wider implications of the findings: Male carriers had better clinical outcomes than the female carriers both in balanced reciprocal or Robertsonian translocation. Patients should be aware of the high risk of no embryos ET, particularly in women >35 years and reciprocal translocation. This study may provide data for genetic counseling of balanced translocation carriers.
Trial registration number: This study was supported by the National Key R&D Program of China (2018YFC1003100).

P-520 Whole genome amplification (WGA) allowing combined PGT-A and PGT-M for detection of heteroplasmy and estimation of mtDNA mutation load in embryos.

S. Anthony[1], M. Jasper[1]

[1]*Perkin Elmer Health Sciences Ltd, Perkin Elmer Health Sciences Ltd, Adelaide, Australia*

Study question: Can data generated from embryos biopsied for PGT-A provide genetic information for the detection of heteroplasmy and estimation of mutation load at mitochondrial disease sites?
Summary answer: The PG-Seq^{TM} kit allows for excellent coverage of the mtDNA in biopsy samples from embryos and allows detailed calculations of heteroplasmy to be performed.
What is known already: A large number of pathogenic mitochondrial DNA (mtDNA) mutations have been implicated in a variety of diseases. As mtDNA is maternally inherited, women with pathogenic mtDNA mutations are likely to have affected children, the severity depending on the heteroplasmy proportion. A systematic meta-analysis showed that there is a $\geq$ 95% chance of being unaffected at a mutant level of $\leq$ 18% (Hellebrekers et al, 2012). PGT-M can be used to identify embryos with mutation loads below this phenotypic

threshold. The PG-Seq™ kit yields superior coverage of mtDNA and may allow combined PGT-A and PGT-M for mtDNA diseases from single biopsies.
Study design, size, duration: Two cell lines, a reference and "mutant", with mitochondrial single nucleotide variants (SNV) were selected. Six 5-cell samples from each cell line were whole genome amplified (WGA). The replicates were pooled before the cell lines were mixed in proportions ranging from 0% to 100% (mutant), in increments of 10%. Libraries were prepared for each of the pools prior to sequencing using the MiSeq instrument (Illumina).
Participants/materials, setting, methods: SNV sites with < 10x depth across all samples were removed, leaving 31 SNV sites. The proportion of mutant SNV at each site was calculated and analysed. The data were corrected for variance introduced by pipetting error in pooling. These corrections were only applied to samples with proportions of 40%, 50%, and 60%, and subsequent analyses were restricted to these data. To model data at different read depths we combined data across sites.
Main results and the role of chance: The average (± sd) mitochondrial read count for cell line samples was 5037 (± 1083). After filtering, the average (± sd) depth of coverage for the cell line samples at the SNV sites was 25.8x (± 12.5). Combining SNV data to achieve a read depth typical of a standard PG-Seq™ kit 48 sample run using a single embryo biopsy (500,000 reads), the observed SNV proportion was within 25% of the expected proportion in all cases. Combining SNV data to achieve a read depth of 5x a standard PG-Seq™ kit 48 sample run, the observed SNV proportion was within 11% of the expected proportion in all cases. This means that in any case where a heteroplasmy is detected at 7% or lower, including no detection, the mutant load should be below the phenotype threshold. In summary, the PG-Seq™ kit has the potential to be used for combined PGT-A and PGT-M for mtDNA diseases, although accuracy is dependent on read depth. Read depth at mtDNA can be increased by increasing sequencing throughput or by alternate means such as using PerkinElmer's Target Sequence Enrichment protocol.
Limitations, reasons for caution: Estimates of accuracy with increased depth were based on modelled data rather than experimental data; experimental data is needed for validation. Due to variable but consistent depth of coverage across the mtDNA, some sites will be more suited for analysis by this method than others.
Wider implications of the findings: The superior amplification of mtDNA achieved by the PG-Seq™ kit may allow combined PGT-A and PGT-M for mtDNA disease analysis. Combining PGT-A and PGT-M in this novel way would streamline a laboratory testing workflow. Further enrichment of mtDNA could be achieved using PerkinElmer's Target Sequence Enrichment protocol.
Trial registration number: -

P-521 Comparative proteomics of Seminal Exosomes reveal deregulation of cell signalling and defects in chromatin remodelling in Recurrent Pregnancy Loss Patients

S.R. JENA[1], G. Mohanty[1], J. Nayak[1], S. Kar[2], L. Samanta[1]
[1]*RAVENSHAW UNIVERSITY, DEPARTMENT OF ZOOLOGY, CUTTACK, India*
[2]*Kar Clinic and Hospital Private Limited, Department of Obstetrics and Gynaecology, Bhubaneswar, India*

Study question: Do seminal exosomal proteins hold an answer to anomalous sperm maturation leading to aberrant embryo formation as a cause of recurrent pregnancy loss (RPL)?
Summary answer: Compromised exosomal proteome expression involved in sperm maturation may be responsible for failed paternal gene expression leading to aberrant embryo formation and miscarriage in RPL.
What is known already: Spontaneous recurrent pregnancy loss (RPL) most often investigated from the women's perspective. However, recent evidences show the involvement of male factor as a plausible cause particularly in idiopathic RPL. Exosomes are vesicles derived from cells. Seminal exosomes derived from epididymis and prostate carry a distinct repertoire of regulatory RNAs and proteins necessary for sperm maturation and function. Though exosomes are known to carry proteins involved in energy pathways, protein metabolism, cell growth and maintenance, there is paucity of data on the role of seminal exosomal proteins in spermatozoa in general and RPL patients in particular.
Study design, size, duration: This prospective study consisted of male partners of RPL patients (n=21) with no female factor abnormality as revealed by gynaecologic investigation including karyotyping; and age matched fertile healthy volunteers (n=21). All samples were collected during 2016-2018 after getting institutional ethical approval and written consent from the participants.
Participants/materials, setting, methods: Seminal ejaculates were collected by masturbation after 2-3 days of sexual abstinence and analysed according to World Health Organization criteria. Exosome were isolated by ultracentrifugation and characterized by western blot, transmission electron microscopy, and nanoparticle tracking analysis followed by LC-MS/MS analysis. The expression profile of proteins present in exosomes was further examined using bioinformatics tools to elucidate the possible regulatory pathways.
Main results and the role of chance: Of the 998 proteins detected in the proteomic data set, 939 were from control and 935 from RPL group. A total of 447 differentially expressed proteins were detected of which 385 under expressed and 62 over expressed in RPL while 63 were exclusive to control and 59 exclusive to RPL. STRING protein-protein interaction analysis revealed that the major pathways dysregulated in RPL are immune response (HSA:168256 ; false discover rate p=2.67e-28), signalling proteins (HSA:376176 ; false discover rate p=3.04e-22), chromatin packaging and remodelling (GO:0031497; false discover rate p=2.78e-05), protein folding and apoptosis (HSA:109581; false discover rate p=5.93e-06). The present findings thus corroborate the previous idea with relation to immune dysfunction and DNA fragmentation in RPL that needs to be validated through Western Blotting and compared with proteome profile of spermatozoa to elucidate plausible biomarkers of male factors of RPL.
Limitations, reasons for caution: The validation of identified DEPs was not done as well as analysis of spermatozoa proteome. Further, the non-coding regulatory RNAs in the exosomes were not analysed.
Wider implications of the findings: The result of this pilot study implies the importance of exosomes in sperm maturation and function, particularly in RPL. Further validation may lead to identification of candidate biomarkers for determination of male factors in idiopathic RPL.
Trial registration number: Not applicable

P-522 TGFβ/SMAD signaling regulates transzonal projection (TZP) formation in growing follicles of the mouse ovary

S. Granados Aparici[1], Q. Yang[1], H. Clarke[1]
[1]*Research Institute - McGill University Health Centre- McGill University, Obstetrics and Gynecology, Montreal, Canada*

Study question: Do TGFβ signalling mediators SMAD3/4 regulate TZP formation by the granulosa cells during follicular development?
Summary answer: SMAD4 regulates the number of TZPs, whereas SMAD3 regulates expression of genes encoding proteins implicated in formation of filopodia.
What is known already: Shortly after the initiation of follicular development, the generation of an extracellular layer called the zona pellucida (ZP) physically separates the oocyte from the proliferating granulosa cells (GCs) that surround it. Since GC-oocyte contact-dependent communication is essential for oocyte development, GCs generate filopodia, termed transzonal projections (TZPs), which penetrate the ZP and establish contact with the oocyte plasma membrane. Growth-differentiation factor (GDF) 9, an oocyte-secreted TGFβ-family ligand, increases TZP number as well as the steady-state levels of *Myo10* and *Fscn1*, which encode proteins implicated in filopodial assembly. However, the mechanism by which GDF9 acts is not known
Study design, size, duration: Ovaries obtained from day-4 and day-12 mice (enriched in early and mid-growth follicles, respectively) were used for the quantification and localisation of SMAD-pathway and TZP-related factors during follicular development. The tamoxifen-inducible *Cre-ER*/floxed *Smad4*$^{+/+}$ knockout (KO) system was used in 4-day ovaries and 12-day granulosa-cell oocyte complexes (GOCs) in culture to delete the *Smad4* gene.
Participants/materials, setting, methods: Quantitative RT-PCR and immunofluorescent staining of ovarian histological sections were used to measure relative mRNA and protein levels. ChIP-qPCR was used to detect SMAD3 and SMAD4 binding to *Myo10* and *Fscn1* promoter regions. Following tamoxifen (1 µg/ml) treatment in *Cre-ER*/floxed *Smad4*+/+ KO ovaries and GOCs and subsequent incubation, western blotting to measure the protein levels of SMAD4, SMAD3, MYO10 and FSCN1; Image J software was used to quantify TZP number, GC number and oocyte diameter
Main results and the role of chance: Quantitative RT-PCR and immunofluorescent histological sections of ovaries revealed a significant increase in relative

mRNA and protein levels of Fscn1 and Myo10 between day-4 and day-12 of age. SMAD4 protein was depleted by ~50% in the tamoxifen-treated *Cre+/floxed Smad4* neonatal ovaries and GOC cultures. This was accompanied by a striking decrease in the number of TZPs in both early-growth follicles of day-4 ovaries and GOCs of day-12 ovaries, although oocyte diameter was unchanged. In contrast, MYO10 and FSCN1 protein levels were not significantly altered. Consistent with this, ChIP-qPCR revealed that SMAD3, but not SMAD4, bound to the promoter region of Fscn1 and Myo10, suggesting that SMAD3 may play regulate Fscn1 and Myo10 expression in GCs independently of SMAD4.

Limitations, reasons for caution: Experiments were performed using ovaries and GOCs maintained *in vitro*, which may not reproduce the physiological conditions *in vivo*. Deletion of the Smad4 gene did not occur in all cells. All experiments were performed using mouse,therefore further work is required to determine whether the same mechanisms operate in other species.

Wider implications of the findings: These results identify part of the mechanism by which the growing oocyte induces neighbouring granulosa cells to generate new TZPs. Understanding the molecular pathways regulating TZP formation may help identify novel markers of follicle/oocyte quality and provide insight about the causes of age-related and age-independent infertility.

Trial registration number: Not applicable

P-523 Paternal Age Has No Impact on Aneuploidy Rate in Embryos Derived from Young Egg Donors

D. Michal[1,2], S. Madjunkova[3], R. Antes[3], R. Abramov[3], S. Chen[3], M. Albar[2], A. Koziarz[4], J. Mashiach[1,2], S. Moskovtsev[2,5], I. Kuznyetsova[6], C. Librach[2,7,8,9,10]

[6]*CReATe Fertility Centre, IVF laboratory, Toronto, Canada*
[7]*CReATe Fertility Centre, Clinic Director, Toronto, Canada*
[8]*University of Toronto, Institute of Medical Sciences, Toronto, Canada*
[9]*University of Toronto, Department of Physiology, Toronto, Canada*
[10]*Women's College Hospital, Department of Gynecology, Toronto, Canada*

Study question: Is there a correlation between paternal age and the frequency of chromosomal aberrations in embryos derived from young oocyte donors?

Summary answer: There was no association between paternal age and aneuploidy rates in embryos derived from donated oocytes after adjusting for donor, sperm, and IVF cycle characteristics.

What is known already: Embryo aneuploidy is among the major factors contributing to poor in vitro fertilization (IVF) outcomes. The incidence of aneuploid embryos increases with maternal age. Oocyte donation overcomes the effect of maternal age on embryo aneuploidy. There is controversy regarding the impact of paternal age on embryo aneuploidy. Several studies have reported higher percentages of aneuploidy than expected in embryos derived from young oocyte donors. This ranges from 4-59% in published studies. Whether this higher than expected prevalence is related to advanced paternal age is still uncertain.

Study design, size, duration: A retrospective cohort study performed at the CReATe Fertility Centre, Toronto, Canada, between January-December,2017. Clinical and demographic data from 201 egg donation cycles for 246 patients, where preimplantation genetic testing for aneuploidy (PGT-A) was performed, was obtained. A total of 1248 blastocysts from these cycles were analyzed. PGT-A results from d5/6 trophectoderm biopsy obtained by next-generation sequencing(NGS) were available for 1185(98%) of embryos. Cycles using donors >33 years were excluded from the final analysis (n=30).

Participants/materials, setting, methods: Embryos from IVF-PGT-A ovum donor antagonist cycles were allocated to three groups according to paternal age: Group A 27-39 years (n=592); Group B 40-49 years (n=496); Group C ≥50 years (n=97). Multiple logistic or ordinal regressions were conducted to evaluate euploidy, aneuploidy, mosaicism, and blastocyst formation rates between paternal age groups where statistically appropriate. Analyses were adjusted for oocyte donor age, AMH, number of oocytes retrieved, semen characteristics, and number of embryos per patient.

Main results and the role of chance: 1185 embryos from 246 male patients included in the analysis had PGT-A results classifying them as euploid, aneuploid or mosaic (10Mb resolution; 30%-70% mosaicism). Fresh sperm was used in 51%, while frozen in 49% of patients. None of the patients had a male factor infertility diagnosis and there was no difference in semen parameters (concentration and motility) and stimulation protocol between the study groups.

No significant differences between paternal age groups A, B and C were found in euploidy rates (67.06%, 68.7%, 69.07%, respectively; p=0.812), aneuploidy rates (13.6%, 13.3%, 14.4%, respectively; p=0.953) or mosaicism rates (19.2%, 17.9%, 16.4%; respectively, p=0.749). Similar results were found when the rates of euploidy, aneuploidy and mosaicism in the three paternal age groups were analyzed at the level of treatment cycle (batch of embryos/patient cycle). Multiple regression analyses for embryos found older oocyte donor age to be significantly associated with mosaicism (OR 1.06, 95% CI 1.002-1.11; p=0.04). AMH levels of 20-80 pmol/L were found to be significantly associated with blastulation rate (OR 1.04, 95% CI 1.01-1.07; p=0.008). Analyses at the treatment cycle level demonstrated AMH levels >80 pmol/L to be significantly associated with both mosaicism (p=0.038) and aneuploidy (p=0.042) (n=172).

Limitations, reasons for caution: The main limitation is the retrospective nature of this study; however, multiple regression analyses were conducted to limit potential bias by adjusting for donor, sperm, and oocyte characteristics.

Wider implications of the findings: The results of the study may assist medical fertility practitioners when providing preconception counseling to patients using oocyte donation and their male partners, particularly for couples in which the male partner belongs to an older age group.

Trial registration number: not applicable

P-524 Genetics of infertility: Diagnostic interests of a custom designed panel for the analysis of 51 genes involved in non-syndromic human infertility

O. Okutman[1,2], J. Tarabeux[3], J. Muller[3,4], S. Viville[1,2]

[1]*Hôpitaux Universitaires de Strasbourg- Nouvel hôpital civil, Laboratoire de diagnostic génétique- UF3472 Infertilité, Strasbourg, France*
[2]*IPPTS, Université de Strasbourg, Strasbourg, France*
[3]*Laboratoire de Diagnostic Génétique, Hôpitaux Universitaires se Strasbourg, Strasbourg, France*
[4]*Laboratoire de Génétique Médicale, Universite de Strasbourg, Strasbourg, France*

Study question: Panels of infertility genes are now available. What is the relevance to offer them as a diagnostic tool for infertility patients?

Summary answer: According to our preliminary results, it is possible to define precisely the causative mutation for the defined phenotype by using custom designed panel.

What is known already: Infertility is a global healthcare problem which affects men and women equally. In research, the focus has shifted from single gene mutation studies to genome wide analyses. This has allowed, during the last decade, to identify a fast growing up list of human genes involved in infertility. However with the exception of few genes, the described mutations are rarely detected, most of them stayed as a familial mutation or individual cases. Therefore, the impact on human fertility still needs to be confirmed for the majority of these genes. Furthermore the prevalence of these mutations in specific population is unknown.

Study design, size, duration: In order to scan the 51 identified genes involved in different form of non-syndromic infertility, a genetic diagnostic test based on high throughput sequencing technology has been designed. The panel encloses 35 genes for male infertility, 16 genes for female infertility and 6 common control SNPs . As an initial study, a cohort of 125 French patients, with a well-defined infertility phenotype, has been planned to study.

Participants/materials, setting, methods: Male patients identified with teratozoospermia, asthenozoospermia, spermatogenic failure or total fertilization failures were recruited. For female infertility, women diagnosed with premature ovarian insufficiency/ failure (POI/POF) or with oocyte maturation arrest were included in the study. DNA was extracted from peripheral blood

and library was prepared using SureSelectQXT Target Enrichment system. Multiplex sequencing has been performed on Illumina NextSeq 550 with 2x150bp reads for total 51 genes. Variant analysis has been achieved using VaRank tool.

Main results and the role of chance: The panel size is 187 kb comprising 883 regions . Control SNPs were used to confirm identity of each patient. So far, 38 males and 4 females were analyzed after sequencing. Mean coverage was 495X and 99.4% of target bases were succesfully sequenced for >30X . Results revealed de nevo mutations in two genes related to defined infertility phenotype in three patients which were confirmed by Sanger sequencing. However two genes in the panel, one of them identified for female infertility and the other for male infertility, shows unexpectedly high amount of variations for unrelated phenotypes. This puts a question mark on the implication of these two genes in human infertility with the specific phenotype for which they have been identified.

Limitations, reasons for caution: The main limitation is the number of patients' analyzed so far. In order to challenge the clinical interest of such diagnostic tool, a larger group of patients need to be analyzed. Further works on the two genes for which lots of variations have been found has to be done.

Wider implications of the findings: The precise diagnostic is important for adapting the best treatment and counsel not only to patients but to their spouse and relatives. This study allows us to designate gene mutations which have significant impact on specific infertility phenotype on a restricted cohort of French patients.

Trial registration number: Not applicable

P-525 Thaw, biopsy and refreeze procedure for PGT-A analysis of previously cryopreserved embryos

M. Wilding[1], M. Terribile[1], I. Parisi[1], G. Nargund[1]
[1] *Create fertility, Embryology, London, United Kingdom*

Study question: To compare the clinical pregnancies after thaw, biopsy and refreeze (TBR) procedure versus biopsy of fresh embryos for PGT-A analysis.

Summary answer: Our data show that previously cryopreserved embryos can be screened with the PGT-A procedure after thaw, trophectoderm biopsy and refreezing with vitrification.

What is known already: Patients with cryopreserved embryos have not been able to access embryo screening techniques due to the poor survival rates after refreezing with the slow-freeze protocol. In recent years, the vitrification procedure has become widely used in assisted reproduction procedures. Vitrification has enormous advantages over slow-freeze techniques due to the high efficiency, reliability and excellent pregnancy rates after thaw. Vitrification of embryos also appears to be suitable for the refreezing of embryos previously thawed, although there is little data on this subject. In this work, we have tested whether the refreeze technique is suitable for screening cryopreserved embryos for PGT-A.

Study design, size, duration: The study is a retrospective analysis of data between 2016 and 2017. Group A patients had previously cryopreserved embryos were treated with the TBR procedure. Group B patients elected for PGT-A on fresh embryos in the same period (group B).

Participants/materials, setting, methods: Patients aged between 20 and 50 years old, with a body mass index between 19 and 30 were included. Embryos were created with either IVF or ICSI. Cryopreserved and fresh embryos were biopsied and frozen on day 5 or 6, with a minimum quality of 3Cc required (Gardner criteria). Vitrification and thaw of embryos followed Kitazato protocols. Chi-squared test was used for statistical analysis with $P<0.01$ considered significant.

Main results and the role of chance: Overall, 24 cycles of thaw biopsy and refreeze were performed (group A). 126 cycles of PGT-A were performed in group B. A total of 85 embryos were analysed in group A (TBP procedure). 25 of these (29.4%) were normoploid after PGT-A, 57 were aneuploid (67.0%) and 3 had no result obtained (3.5%). In group B, 453 embryos were analysed of which 168 were normoploid (37.1%), 271 aneuploid (59.8%) and 14 had no result obtained (3.0%). After receiving results, 7 patients had embryo transfer in group A and 5 clinical pregnancies (71.4%) were obtained. Of these, 4 achieved a live birth. In group B, 22 cycles of frozen embryo transfer were performed after results were obtained and 7 clinical pregnancies resulted from these transfers (31.8%), with 6 live births. Our results show that the thaw biopsy and refreeze approach is efficient and safe to be applied for previously cryopreserved, undiagnosed blastocysts, as it ultimately allows the transfer of euploid blastocysts and good clinical outcomes.

Limitations, reasons for caution: This study was limited by the retrospective nature of the study, and its small group size. Prospective data on the outcomes of embryo transfers is needed to determine the true efficiency of the technique.

Wider implications of the findings: This study demonstrates that the thaw biopsy and refreeze protocol is suitable for the PGT-A analysis of patients with previously cryopreserved embryos.

Trial registration number: None

P-526 Impact of semen quality on blastocyst mosaicism in preimplantation genetic testing for aneuploidy

N. Tarozzi[1], G. Coticchio[1], M. Nadalini[1], C. Lagalla[1], A. Borini[1]
[1] *9.Baby, Family and Fertility Center, Bologna, Italy*

Study question: Does semen quality impact the rate of mosaic blastocysts in preimplantation genetic testing for aneuploidy (PGT-A) cycles?

Summary answer: Compromised sperm quality is positively associated with increased rates of mosaic blastocysts analyzed in PGT-A cycles.

What is known already: PGT-A has long been proposed as an approach for selection of euploid and viable embryos in order to improve treatment efficiency and reduce time to pregnancy. The origins of embryo aneuploidy are well understood, in the large majority of cases being derived from chromosome segregation errors during maternal meiosis. Much less is known on possible intrinsic (inherent to reproductive cells) or extrinsic (e.g. in vitro manipulation) factors that may be responsible for embryo mosaicism. Understanding the causes of embryo mosaicism would be therefore beneficial to formulate more precise prognoses and potentially to better preserve embryo quality.

Study design, size, duration: Retrospective observational study carried out between May 2013 and December 2017, on 340 PGT-A cycles. Study groups were identified according to semen quality: i) severe male factor (SMF), (post-preparation total count <0.1 M/ml sperm); ii) ICSI (sub-optimal post preparation semen characteristics: total motile spermatozoa <2 M/ml; total sperm motility <70%; total sperm rapid motility < 20%, normal sperm morphology <30%); iii) non-male factor (NMF). Performance and rate of mosaic blastocysts of different groups were compared.

Participants/materials, setting, methods: Irrespective of semen quality, all available oocytes were fertilized by ICSI to prevent contamination of biopsied cells by non-embryonic material (cumulus cells, non-fertilizing sperm attached to the zona pellucida). Embryos were cultured to the blastocyst stage (day 5-6) and, where possible, subject to biopsy to collect 3-7 trophectoderm cells to be analyzed for PGT-A. Genetic testing was carried out by array comparative genomic hybridization (aCGH).

Main results and the role of chance: Twenty-two, 173 and 146 cycles were responded to the criteria of the SMF, ICSI and NMF groups, respectively. Age differences between embryo transfer (ET) cycles were not statistically significant. Cycles with blastocysts suitable for genetic testing were 17, 110 and 87 for the same groups, respectively. The rate of euploid blastocysts was 48.1%, 45.9% and 42.9%, respectively ($P>0.05$). Implantation rates of euploid embryos were 30.8%, 30.1% and 39.0%, respectively ($P>0.05$). Live birth rates per treatment cycle were 58.3%, 40.5% and 48.8% in the SMF, ICSI and NMF groups, respectively ($P>0.05$).

Importantly, the rates of mosaic blastocysts were inversely associated with sperm quality being 7.7%, 3.6% and 0.5% in the SMF, ICSI and NMF groups, respectively (SMF vs. NMF, $P=0.0012$; ICSI vs. NMF, $P=0.03$). A significantly higher mosaicism rate in the SMF group was also observed in comparison with all other cycles taken together ($P=0.008$).

Limitations, reasons for caution: The retrospective design and limited numerosity of the study call for more extensive investigations.

Wider implications of the findings: The results indicate that compromised sperm quality is positively associated with increased rates of mosaic blastocysts. This is in line with the hypothesis that sub-optimal characteristics of fertilizing sperm impact the fidelity of chromosome segregation. Sperm assessment appears therefore relevant to a more precise prognostic assessment in PGT-A cases.

Trial registration number: None.

P-527 To examine concordance and mosaicism in oocytes and embryos

K. Berrisford[1], S. Fishel[1], E. Armstrong[2], L. Davies[1], C. Miralles[3]
[1]*CARE, Embryology, Nottingham, United Kingdom*
[2]*CARE, Embryology, Birmingham, United Kingdom*
[3]*CARE, Embryology, Northampton, United Kingdom*

Study question: Analysing concordance and mosaicism in oocytes and embryos to predict the optimal stage of development to perform biopsy to maximise clinical outcome in a PGT-A program

Summary answer: Biopsy for PGT-A assessment most accurately predicts embryo ploidy when done at the blastocyst stage

What is known already: ESHRE PGD Consortium best practice guidelines 2005 found biopsy of polar body (PB) 1 to be acceptable, PB1 and 2 combined to be recommended, blastomere in cleavage stage embryos (day 3) recommended and trophectoderm cells in blastocyst (day 5/6) acceptable. Updated guidelines in 2011, found that due to evolving technologies/techniques and increasing knowledge of mosaicism, biopsy at the day 3 stage was no longer recommended.

HFEA Code of Practice published January 2019, there is no evidence that blastomere biopsy on cleavage stage embryos is safe and effective, trophectoderm biopsy on blastocysts shows conflicting evidence and further research is required

Study design, size, duration:

1. Oocyte donors (5) had oocytes collected and PB1 biopsy from mature oocytes. ICSI performed using donor sperm and PB2 biopsy from zygotes. Embryos were cultured to day 3 and disaggregated.
2. Frozen/vitrified day 3 embryos (34) and blastocysts (21) were thawed/warmed. Blastomere biopsy (day 3 embryos) mural/polar trophectoderm biopsies (blastocysts developed from day 3 embryos and warmed blastocysts) were performed. The ICM was isolated via immunosurgery.

Biopsies, blastomeres and ICM's were sent for genetic testing

Participants/materials, setting, methods: Oocyte and sperm donors were recruited for this project, which was approved and licensed by the HFEA. Oocyte collection, ICSI and biopsy/tubing were carried out as per clinical protocols.

Disaggregation was performed by laser ablation of the Zona Pellucida to release the blastomeres.

Thawing/warming and biopsy/tubing were carried out as per clinical protocols. Immunosurgery using anti-trophoblast antibody and baby rabbit complement isolated the ICM.

Genetic testing was performed by aCGH or NGS

Main results and the role of chance:

1. 65 oocytes collected, maturity rate 92% (60) and fertilisation rate 40% (24). All 24 embryos had PB1 and 2 biopsy and were disaggregated on day 3.
2. Amplification rates for PB1 were 95.8% (23), PB2 79.2% (19) and disaggregation 96% (191).
3. 18 embryos included in concordance analysis. PB1 and 2 concordance rate was 44% (8), 3 aneuploid and 5 euploid. The non concordance was aneuploid:euploid (4) and euploid:aneuploid (6).
4. 16 embryos included in PB1 to blastomere concordance analysis (where >= 70% blastomere concordance). Concordance rate was 56.3% (9). 31.3% (5) were euploid:aneuploid non concordant.
5. Mosaicism was 87.5% (21) with 48% (10) being aneuploid/euploid.
6. The thawing/warming survival rate was 76.5% (26) for day 3 embryos and 71% (15) for blastocysts. 38.5% (10) of the day 3 embryos developed into blastocysts.
7. 19 embryos had a complete set of tubed samples (+- blastomere, mural/polar trophectoderm and ICM) analysed.
8. Amplification rates for blastomeres were 0 (4), mural trophectoderm 42% (8), polar trophectoderm 68% (13) and ICM 63.2% (12).
9. 6 blastocysts were included in the concordance analysis.

Concordance rate was 100% (for mural/polar trophectoderm and ICM). With 50% (3) showing euploid concordance and 50% showing aneuploid concordance. The type of aneuploidy was 100% concordant.

Limitations, reasons for caution: The amplification rates for the blastomere/trophectoderm biopsies and the warming survival rates for blastocysts were inexplicably lower than those in clinical cases during the same time period (90% and 95% respectively).

Wider implications of the findings: Trophectoderm biopsy of blastocysts gave robust concordance data, and perhaps reflects poor reliance upon Day 3 biopsy. A successful PGT program requires robust freezing and frozen embryo transfer. Our 95% vitrification/warming survival rates, 90% amplification rates and pregnancy rates comparable to fresh embryo transfers provides for dependable PGT-A service.

Trial registration number: not applicable

P-528 Pre-conceptional maternal exposure to cyclophosphamide results in modifications of DNA methylation in F1 and F2 mouse oocytes: evidence for transgenerational effects

M. D'Aurora[1], G. Di Emidio[2], S. Franchi[1], M. Placidi[2], G. Rossi[2], L. Stuppia[1], P.G. Artini[3], C. Tatone[2], V. Gatta[1]
[1]*University of Chieti, Department of Psychological- Health and Territorial Sciences, Chieti, Italy*
[2]*University of L'Aquila, Department of Life- Health and Environmental Sciences-, L'Aquila, Italy*
[3]*University of Pisa, Department of Clinical and Experimental Medicine- Division of Obstetrics and Gynecology Oncology, Pisa, Italy*

Study question: Does pre-conceptional maternal exposure of mice (F0) to cyclophosphamide (CPM) induce modifications of DNA methylation of imprinted genes in F1 and F2 mouse oocytes?

Summary answer: CPM pre-conceptional administration causes alterations of methylation in F1 germline, which are trans-generational inherited by F2, which has not been directly exposed to CPM.

What is known already: CPM, an agent widely used in cancer therapy, alters the ovarian reserve, is mutagenic, teratogenic and embryolethal. Conceptions early after CPM exposure result in a high rate of pregnancy failure and high malformation rate. By contrast, potential effects of maternal exposure to CPM on the health of offspring conceived during the "safe" late period following CPM exposure have never been investigated. A crucial factor for oocyte competence is correct methylation of imprinted genes during gametogenesis. Methylation of maternally imprinted genes including IGF2R e PEG3 is completed in the fully-grown oocyte, whereas paternally imprinted genes including H19, remain unmethylated.

Study design, size, duration: 32 CD-1 young female mice (F0) received vehicle, Crocetin or AS101 for 15 days prior to a single dose of CPM (100 mg/kg) and 12-weeks after CPM were mated with untreated males. Mean number of pups (F1) per mouse, weight at birth, weaning and at 2 month of age were recorded. At this age F1 females were mated and the mean number of pups (F2) per mouse and weight at birth and weaning were recorded.

Participants/materials, setting, methods: Pools of at least 200 healthy germinal vesicle (GV) oocytes from 21-day old mice of each experimental group were processed for DNA extraction. DNA was bisulfite-converted and H19, Peg3 and Igf2r promoters were amplified by PCR. Pyrosequencing reaction was run on a PyroMark Q96ID (Qiagen) and CpGs methylation analysis was conducted by the PyroMark CpG software (Qiagen). The methylation for each

amplicon was calculated as the median of methylation status of each analyzed CpG.

Main results and the role of chance: Twelve-weeks after CPM, all F0 mice got pregnant after mating and gave birth to F1 pups. F1 offspring born from CPM mice presented growth retardation as demonstrated by reduced weight at weaning (Ctrl-F1 vs. CPM-F1: 10.88±0.79 g vs. 6.42±0.58 g, P<0.001) which was recovered at adult age. Pre-conceptional maternal exposure to fertoprotectors AS101 and Crocetin prior to CPM prevented this growth retardation in F1 (AS101-F1: 9.06±0.92 g, Crocetin-F1: 11.11±0.58 g, not significant to Ctrl-F1, P<0.001 to CPM-F1). GV oocytes obtained from 21-day-old CPM-F1 mice presented a reduced methylation of maternally imprinted genes Igf2r (Ctrl-F1 vs. CPM-F1: 69±3.79% vs. 8±2.03%, P<0.05) and Peg3 (Ctrl-F1 vs. CPM-F1: 78±3.61% vs. 59±2.33%, P<0.05) and increase methylation of paternally imprinted gene H19 (Ctrl-F1 vs. CPM-F1: 5±2.19% vs. 28±173%, P<0.05). Nevertheless, F1 mice from all experimental groups were fertile and gave birth to healthy F2 pups. The alterations of maternally imprinted genes observed in CPM-F1 oocytes were present also in oocytes generated by F2 mice (Peg3, Ctrl-F2 vs. CPM-F2: 86±3.61% vs. 61±4.04%, P<0.05; Igf2r, Ctrl-F2 vs. CPM-F2: 90±2.60% vs. 54±5.78%, P<0.05). Pre-conceptional maternal exposure to AS101 and Crocetin prior to CPM was not able to fully counteract alterations in oocyte imprinting of F1 and F2 offspring.

Limitations, reasons for caution: This pilot study needs further investigations of the long-lasting effects of methylation changes at DMRs on the health of next generations, implying possible risk for adult onset of metabolic or neurological pathologies.

Wider implications of the findings: Pre-conceptional CPM maternal exposure influences the health of offspring conceived during the "safe" period following treatment and affects the competence of offspring's oocytes. Our data warns on possible long-term effects on the health of next generations. Supplementation with fertoprotective agents may induce epigenetic long-lasting effects, which requires further investigation.

Trial registration number: not applicable

P-529 Chromosomal aberrations and aneuploidy features in IVF blastocysts and abortion villus

X. Zhang[1], Y. Wang[1], N. Zhao[1], P. Liu[1], J. Huang[1]

[1] *Peking University Third Hospital, Obstetrics and Gynecology, Beijing, China*

Study question: What are the chromosomal aberrations and aneuploidy features in blastocysts following IVF and first trimester pregnancy losses?

Summary answer: The chromosome aberration spectrum shows specific characteristics in blastocysts and abortive villi, indicating specific chromosomal abnormalities could affect certain developmental stage of embryos.

What is known already: Chromosomal abnormalities in human embryos is one of the main reasons that lead to developmental arrest and implantation failure. Studies have shown the types of chromosomal abnormalities are incongruous between recurrent implantation failure (RIF) and recurrent miscarriage (RM) patients, for instance, more diploid/heterozygous chimeric embryos appearing in RIF group. In natural conceptions that reach clinical recognition, 35% of human pregnancies are aneuploidy for which easily causes abortion. Miscarriage caused by trisomy abnormalities ranks top, with rare cases of miscarriage by chromosomal structural abnormality.

Study design, size, duration: This is a retrospective study, and was ethically approved by our hospital in China. We analyzed the data of 220 PGS cycles during 2017 to June 2018, after ovarian stimulation cycles. Totally, 1014 blastocysts were genetically analyzed. Meanwhile, we also analyzed 1724 abortion villus data. These data were collected and statistically analyzed.

Participants/materials, setting, methods: No average age of the females were found to be significantly different between the two groups (32.99 in PGS and 33.02 in abortion).SNP array was applied in both the blastocysts and early abortive villi tests. Comparison in chromosomal aberrations and aneuploidy were performed by Chi-square and F-test.

Main results and the role of chance: ①Normal chromosome rates were significantly different between blastocysts and abortive villi, 60.85% and 43.27% respectively(P < 0.001).②Comparatively, higher chromosomal aberration in abortive villi were found to be trisomy (27.71% vs 66.46%), sex chromosome abnormality (3.02% vs 7.98%) and polyploidy (1.00% vs 7 .57%), showing significant different. In addition, higher abnormalities in blastocysts were discovered in the types of complex aberrations (27.96% vs 11.55%), monosome (22.17% vs 0.72%), and fragment abnormality (16.88% vs 5.21%).③In view of the constituent of chromosomal abnormalities, chromosome X monosome is significantly higher in early abortive villi.④According to the International System for Human Cytogenetic Nomenclature (ISCN), group comparison of chromosome monosome between blastocysts and early abortion villi: Abnormalities in blastocysts were more common in group G (39.00% vs 28.87%; P=0.011), and that in early spontaneous abortive villi were in group E (22.72% vs 32.12%; P=0.007).

Limitations, reasons for caution: PGS samples were collected from IVF patients with ICSI fertilization methods. Abortion samples were obtained from patients with natural and IVF pregnancy. Different sources of samples may have an impact on the results. But in practice,it is impossible to detect embryonic chromosomes in natural pregnancies.

Wider implications of the findings: To compare the chromosomal abnormality spectrum in IVF blastocyst and abortive tissues, help to explore the mechanisms that could affect embryo development and implantation. Findings in the chromosomes susceptible to damage embryo development, also help clinical assessment in prenatal diagnosis, reducing abnormal fetus incidence.

Trial registration number: no

P-530 Demystifying the effect of paternal age on blastocyst ploidy status

W. Saab[1], S. Seshadri[1], X. Vinals-Gonzalez[2], R. Odia[2], D. Cansfield[2], J. Bennagi[1], P. Serhal[1], F. Steyn[3], S. Cawood[2], W. Saab[4], C. Heath[2]

[1] *Centre for Reproductive and Genetic Health, Clinicians, London, United Kingdom*
[2] *Centre for Reproductive and Genetic Health, Embryologist, London, United Kingdom*
[3] *Centre for Reproductive and Genetic Health, nursing, London, United Kingdom*
[4] *The Lebanese American University, Medical Student, Beirut, Lebanon*

Study question: Does paternal age affect euploidy rate in blastocysts analysed in PGT-A treatment cycles?

Summary answer: The effect of paternal age on blastocysts euploidy rate was not statistically significant, after controlling for maternal age.

What is known already: It is well established that embryo aneuploidy increases with advanced maternal age and this has been mainly attributed to chromosomal nondisjunction that occurs during meiosis II of oogenesis. The existence of a similar paternal age effect is still controversial and inconclusive

Study design, size, duration: Sinle centre retrospective cohort study evaluating the effect of paternal age on euploidy rate was performed. Preimplantation genetic testing was carried out on 5-10 blastomeres and analysis was done by Next Generation Sequencing (NGS) via a single genetic provider (Cooper Genomics).The study included a total of 1877 biopsied blastocysts from 436 preimplantation genetic testing for aneuploidy (PGT-A) cycles performed between January 2016 to December 2017. Study was conducted at a UK centre, CRGH London.

Participants/materials, setting, methods: Patients undergoing PGT-A treatment for the specified period were included. Euploidy rates were calculated for different paternal and maternal age groups. Paternal age was grouped as follows (<40,40-44,45-50,>50yrs). Maternal age was grouped according to the HFEA-UK (Human Fertilisation and Embryology Authority) age categories.Data was age controlled and analysed. Analysis of variance (ANOVA) was required for continuous data, continuous variables were compared using the Student's T test, and logistic regression analysis was performed.

Main results and the role of chance: Main indication for PGT-A was advanced maternal age (56.3%); clinically presenting as recurrent implantation failures and/or previous miscarriages. Mean paternal age was 41.11+/-6.6 years. Mean maternal age was 38.48+/-4.1 years. The euploidy rates for the paternal age groups (<40,40-44,45-50,>50yrs) are 33.8%, 27.5%, 14.9% and 16.5 % respectively. When controlling for maternal age, paternal age effect on euploidy rate was not statistically significant for all age categories. When maternal age is <35 yrs there was no statistical difference in eupliody rates whether the paternal age was <45 or > 45 years; OR=0.72 (0.3-1.7).

Logistic regression model analysis of all variables (regardless of age categories) revealed no correlation between paternal age and euploidy status OR 0.92 (0.7-1.2), p-value 0.63. On the other hand, advanced maternal age

was negatively related to blastocysts euploidy rates OR 0.45 (0.2-0.6), p-value 0.0001.

Limitations, reasons for caution: The study is a retrospective cohort study, further randomised clinical trials are required to confirm findings. The effect of semen parameters on ploidy status were not analysed as ICSI was the mode of insemination for all cases and controls.

Wider implications of the findings: This is the first large prospective study to analyse the effect of advanced paternal age on blastocyst ploidy status. The results are reassuring suggesting that older men can still have a positive reproductive outcome without the concern of having a higher risk of chromosomal abnormalities.

Trial registration number: Not applicable.

P-531 Follicle Diameter Predicts Oocyte Maturity and Blastocyst Formation but not Blastocyst Euploidy

D. McCulloh[1], N. Kutchukhidze[2], T. Charkviani[3], T. Zhorzholadze[2], T. Barbakadze[3], S. Munné[4], L. Chkonia[5]

[1]New York Univerisity Langone Health, NYU Fertility Center, New York- New York, U.S.A.

[2]ReproART: Georgian American Center for Reproductive Medicine, Embryology, Tbilisi, Georgia

[3]ReproART: Georgian American Center for Reproductive Medicine, Reproductive Endocrinology, Tbilisi, Georgia;

[4]Overture Life, Administration, New York, U.S.A.

[5]ReproART: Georgian American Center for Reproductive Medicine, Administration, Tbilisi, Georgia

Study question: Are the oocytes within larger follicles better candidates for pregnancy as judged by the incidence of blastocyst euploidy?

Summary answer: The ploidy of biopsiable blastocysts was not related to the diameter of the follicle from which the oocyte was retrieved.

What is known already: Although oocyte maturity and blastocyst formation are known to be associated with follicle diameter, there has been no study relating the incidence of blastocyst euploidy to follicle diameter. The purpose of this study was to examine follicle diameters, the oocytes from those follicles and the embryos that result from those oocytes to see if there is an association between follicle diameter and the quality of oocytes as judged by blastocyst formation and blastocyst ploidy.

Study design, size, duration: Twenty-two oocyte donors (ages: 24.5 + 3.5 yr) whose oocytes would be inseminated in vitro using intracytoplasmic sperm injection (ICSI) were enrolled in this study. Retrieved oocytes and embryos arising from follicles of known diameter were analyzed for associations between follicle diameter and oocyte/embryo quality.

Participants/materials, setting, methods: Follicles, measured ultrasonographically, were aspirated one-at-a-time. Oocytes were cultured individually in sequential media (Quinn's Advantage, SAGE) associating follicle diameter with each oocyte. Trophectoderm biopsies of blastocysts on days 5/6 were tested for ploidy using next generation sequencing (NGS, CooperGenomics, NJ). Maturity, fertilization, blastocyst formation and ploidy were analyzed according to the oocyte's follicle diameter. Comparisons were made using cumulative histograms, rolling averages and receiver operator characteristic (ROC) curves and areas under the curves (AUC).

Main results and the role of chance: Of 330 retrieved oocytes, 315 (96.1%) had an associated follicle diameter. Of the oocytes with follicle diameters, 255 (80.4%) had a polar body (MII), and 60 (18.9%) were immature: 31 (9.8%) with a visible germinal vesicle (GV stage) and 29 (9.1%) with neither a polar body nor a visible germinal vesicle (MI). The incidence of MII oocytes was significantly associated with larger follicle diameters (ROC AUC = 0.87; $P < 0.0001$). The incidence of GV oocytes was significantly associated with smaller follicle diameters (ROC AUC = 0.96; $P < 0.0001$). Among MII oocytes there was no association with follicle diameter for the appearance of 228 oocytes with 2 pronuclei (2 PN). Among 2 PN's the development of 94 biopsiable blastocysts (TE Bx) exhibited a small but significant association with larger follicles (ROC AUC = .59; P = 0.01). From the 94 biopsiable blastocysts, 51 were determined to be euploid by NGS. The incidence of euploidy among biopsied blastocysts was not significantly associated with follicle diameter (ROC AUC = 0.51).

Limitations, reasons for caution: Follicle diameter is an excellent predictor of oocyte maturity and is a significant albeit weak predictor of the ability of fertilized oocytes to become biopsiable blastocysts. The incidence of euploidy is indistinguishable for biopsiable blastocysts arising from small, medium or large follicles and is unrelated to follicle diameter.

Wider implications of the findings: The relationship between follicle diameter and maturity may help to predict the number of mature oocytes for egg banking. There is no reason to preferentially retrieve follicles of a particular size when attempting to maximize the incidence of euploid blastocysts other than by improving maturity and/or blastocyst formation.

Trial registration number: not applicable

P-532 Karyotype analysis of blastocyst chromosomes derived from three pronuclear fertilized embryos using preimplantation genetic testing-aneuploidy (PGT-A)

Y. KANEKO[1], Y. Matsui[1], S. Tsuchiya[1], A. Iizumi[1], A. Wada[1], K. Itakura[1], K. Nishimura[1], T. Ozaki[1], Y. Tamura[2], M. Santo[2], Y. Araki[2,3], M. Nishimura[1]

[1]Nishimura Women's Clinic, Private Clinic, Hamamatsu, Japan

[2]Nippon Reprogenetics Inc, ART laboratory, Maebashi, Japan

[3]Gunma Paz College, School of Medical Technology, Takasaki, Japan

Study question: The rate of blastocyst formation from three pronuclear (3PN) zygotes is generally low. Do blastocysts derived from 3PN zygotes exhibit triploid or normal chromosomes?

Summary answer: Several chromosome patterns were observed, including triploidy, diploidy, euploidy and aneuploidy. Triploidy appeared at a higher rate than expected.

What is known already: Zygotes possessing 3PN have been reported to occur at a low rate in both c-IVF (conventional in vitro fertilization) and ICSI (intracytoplasmic sperm injection). Several hypotheses exist to explain such aneuploidies, but the underlying causes in human assisted reproductive technology (ART)-derived zygotes remain unknown. Furthermore, whether the chromosomal karyotype is normal or not, is also unclear. Here, we used next generation sequencer (NGS) to analyze the chromosome karyotype of blastocysts derived from 3PN.To the best of our knowledge, there is only very small report usage of NGS for analysis of chromosome karyotype.

Study design, size, duration:

Study 1:

This study compared the incidence of 3PN under c-IVF and ICSI treatment cycles. Between January 2014 and December 2017, we observed a development and formation morphology of blastocysts through 7005 oocytes in vitro culture.

Study 2:

All 1013 blastocysts were vitrified and required embryos were thawed, and in final study, 14 blastocysts which derived original 3PN from ICSI were analyzed the chromosome patterns by using NGS.

Participants/materials, setting, methods: The experimental 3PN zygotes were derived from embryos for which informed consent was obtained for disposal. These zygotes were cultured until the blastocyst stage and observed using time lapse imaging. Laser biopsy was used to separate cells from trophectoderm.

Whole genome amplification was carried out using the SurePlex DNA Amplification System (Illumina Inc., San Diego, USA), and further chromosome profiles were analyzed by the VeriSeq-PGS kit (Illumina).

Main results and the role of chance:

Study 1:

The overall incidence of 3PN zygotes was 380/7005 (5.4%), of which 296/4499 (6.6%) occurred under c-IVF and 84/2506 (3.4%) under ICSI. Therefore, the rate of 3PN was higher under c-IVF than ICSI treatment. Blastulation was successful in 39/296 (13.2%) 3PN zygotes obtained from IVF and in 20/84 (23.8%) 3PN zygotes from ICSI.

Study 2:

We biopsied 3PN blastocysts obtained only from ICSI, at a success rate of 14/14 (100%). The ICSI 3PN blastocysts yielded 6/14 (42.9%) normal (euploidy) embryos, 6/14 (42.9%) confirmed or suspected triploid embryos, and 2/14 (14.3%) suspected diploid embryos. Only one euploid embryo was identified as XY. As second polar bodies were observed 43% after ICSI by time lapse cinematography, it is suggested that release of the second polar body may be involved. However, the cause of 3PN zygote formation is unclear.

Limitations, reasons for caution: Further studies are required to conclusively identify the mechanisms responsible for 3PN zygote formation and the high rate of triploid embryo formation**.** Likewise, whether or not euploid embryos can form normal blastocysts is unknown. We were unable to identify normal diploid and triploid chromosome profiles by NGS.
Wider implications of the findings: Here, we report for the application of NGS for identification of euploid/aneuploid/triploid blastocysts derived from 3PN zygotes. It is a clue to elucidate the mechanism of occurrence of triploids.
Trial registration number: Not applicable.

P-533 Does the oocyte vitrification affect the aneuploidy and mosaicism rate in the blastocysts?

R. Morales Sabater[1], B. Lledo[1], J.A. Ortiz[1], F. Lozano[1], J. Guerrero[2], L. Herrero[3], L. Cascales[3], J. Llacer[4], R. Bernabeu[4]
[1]*Instituto Bernabeu, Biotech, Alicante, Spain*
[2]*Instituto Bernabeu, Embriología, Alicante, Spain*
[3]*Instituto Bernabeu, Embriología, Madrid, Spain*
[4]*Instituto Bernabeu, Medicina Reproductiva, Alicante, Spain*

Study question: The main objective of our study was to evaluate if the blastocysts from vitrified/warmed oocytes have more aneuploidies or mosaicism than those from fresh oocytes.
Summary answer: There were no differences in the aneuploidy and mosaicism rates among the blastocysts from vitrified/warmed oocytes and the blastocysts from fresh oocytes.
What is known already: Oocyte vitrification is a common practice in IVF treatments both in cycles with autologous oocytes and in cycles with donated oocytes. This procedure allows to increase the number of blastocysts to analyze in a PGT-A cycle by accumulating vitrified oocytes from different ovarian stimulations in poor responder patients. Moreover, in oocyte donation programs, it can make easier the coordination with the recipient patient. In a robust cryopreservation oocyte program, vitrified oocytes can lead to a pregnancy rate similar to fresh. Nevertheless, there are a paucity of data about aneuploidy and mosaicism rates in blastocysts from vitrified oocytes.
Study design, size, duration: Preimplantation genetic testing for aneuploidy (PGT-A) was performed in 225 oocyte donation cycles in couples who demanded chromosome analysis of the embryos from January 2017 until December 2018. A total of 797 blastocysts were analyzed (644 obtained from fresh oocytes and 153 from vitrified/warmed oocytes). The trophoectoderm biopsies of day 5 and 6 blastocysts were analyzed by NGS. Cycles from males with an abnormal aneuploidy rate in the sperm were not included.
Participants/materials, setting, methods: Embryo analysis were performed using Veriseq NGS (Illumina), with previous whole genome amplification (Sureplex, Illumina). The analysis was performed using the BlueFuse Multi software (Illumina). The main measures were the aneuploidy rate (whole and segmental aneuploidy) and the mosaicism rate (whole and segmental mosaicism) evaluated in the two sources of oocytes. Other measures evaluated were implantation and pregnancy rate of euploid blastocyst. The differences between groups were evaluated by logistic regression and chi-square (SPSSv20.0).
Main results and the role of chance: A total of 797 blastocysts from donate oocytes (153 from vitrified oocytes and 644 from fresh) were analyzed to identify euploid embryos. The aneuploidy and mosaicism rates obtained were comparable in embryos coming from vitrified/warmed oocytes and from fresh oocytes (30.1% vs. 29.8%, p=0.881 and 20.3% vs. 25.3%, p=0.250, respectively). Also, no differences were observed when we separated segmental errors and entire chromosome errors. The incidence of segmental aneuploidies was 7.2% in blastocysts from vitrified oocytes vs. 5.4% in blastocysts from fresh oocytes (p=0.339), while the incidence of segmental mosaicism was 6.5% in vitrified oocytes and 7.6% in fresh oocytes (p=0.580). To evaluate the clinical outcomes, a total of 159 cycles were analysed (94.3% of which were single embryo transfer). The average age of the donors was 25.7 years. There were no significant differences between euploid blastocysts from vitrified oocytes and fresh oocytes regarding to the implantation rate (OR 0.521, 95% CI 0.245-1.107), pregnancy rate (OR 0.562, 95% CI 0.264-1.194), biochemical miscarriage rate (OR 1.194, 95% CI 0.307-4.650) and clinical pregnancy rate (OR 0.514, 95% CI 0.240-1.102).
Limitations, reasons for caution: This study was limited by the small sample size. Larger study is needed to ensure that the percentage of aneuploidies and mosaicism detected in blastocysts are similar independently to the source of oocytes.
Wider implications of the findings: There are few data about aneuploidies in embryos from vitrified/warned oocytes, so this study broad the published data showing that the oocyte vitrification does not increase the aneuploidy or mosaicism rate in embryos. Moreover, this study confirms that the oocyte vitrification is a safe practice in terms of clinical outcomes.
Trial registration number: Not applicable

P-534 A fast and non-invasive workflow for the detection of clinical outcomes on mass spectral data from urine: Application to aneuploidies in high-risk pregnancy.

R. Pais[1], K. Nicolaides[2], S. Butler[1], R. Zmuidinaite[1], S. Keshavarz[1], R. Iles[1]
[1]*MAP Sciences Ltd, Research & Development, Bedford, United Kingdom*
[2]*Harris Birthright Centre, Fetal medicine, London, United Kingdom*

Study question: Is it possible to develop a fully automated computational tool for the detection of aneuploidies from mass spectral data of high-risk pregnancy from the UK?
Summary answer: First-trimester pregnancy urine subjected to computer-based MALDI-TOF mass spectral pattern analysis identifies trisomy 21 and 18 in a single rapid cost-effective screening test.
What is known already: MALDI-ToF generated urine mass spectra is a non-invasive approach shown to have the potential for mass market diagnostic or screening tests, with relevance to obstetrics and reproductive medicine. However, urine mass spectra of large data sets are too complex and time-consuming to be tackled with conventional statistical methods. Thus, automated computational-based workflows are needed. The previous study on a small data set of urine mass spectra from high-risk pregnant in the UK has shown promising results forscreening of aneuploidies. This was based on identified mass spectra differences between pregnancies that resulted in non-aneuploid and aneuploid children with trisomy 21.
Study design, size, duration: A computational workflow was developed during a period of 6 months to perform automated mass spectra quality assessment, comparative analysis, and generation of predictive models. Workflow robustness for pre-processing and quality control was tested against 10000 mass spectra. The workflow was further applied to 438 mass spectra of high-risk pregnant urine, previously collected from King's College Hospital (UK). Down syndrome and trisomy 18 pregnancy-outcomes were the tested groups, whereas non-aneuploid the control group.
Participants/materials, setting, methods: Urine was collected prospectively from patients attending a high-risk antenatal clinic at Kings College London, identification blinded and analysed at MAPDiagnostics Laboratory using a Shimadzu instrument. The computational workflow was developed in python by the bioinformatics team of MAP Sciences. Predictive models based on identification of mass spectral patterns were systematically generated using a subset of the data (training set). Models were tested retrospectively by accessing sensitivities and false positive rates on the remaining data.
Main results and the role of chance: The computational workflow was able to process 10000 urine samples in a total of 4 hours. The computational workflow was accurate in quality control decisions on urine spectra, in agreement with independently made manual inspection of 3000 samples. On a small subset of the data with known clinical outcomes, the computational tool identified multiple characteristic patterns for Downs and trisomy 18, when compared with non-aneuploids and considered to be high-risk pregnancies. Based on these patterns, and using the tool, 200 predictive models were systematically generated for the identification of Downs syndrome and trisomy 18. Several models showed good performance with sensitivities up to 100% and false positive rates < 12%. Several specific spectral changes correlated with gestational age and, in general, the performance of the models was improved when designed for the 13th week of gestation. In addition, the performance of the models also depended on the m/z window tolerance for comparisons.
Limitations, reasons for caution: Limiting factor in this study was the total number of known outcomes from pregnancies analysed in the UK population (n < 250). In addition, gestational age is a critical spectral pattern

determinant and thus dating samples to the nearest week of gestation is needed.

Wider implications of the findings: Fast and fully automated tool for extracting diagnostic potential from urine without relying on traditional biomarkers. This tool saves time, money and human resources which enables fast and cheaper screening tests for larger populations worldwide regardless of economic status.

Trial registration number: not applicable

P-535 Reproductive outcomes after PGT cycles in Turner's Syndrome

J. Liao[1], K. Luo[2], G. Lin[3], F. Gong[1]

[1]*Central South University, Institute of Reproductive & Stem Cell Engineering, changsha, China*

[2]*Reproductive & Genetic Hospital of CITIC-XIANGYA, reproductive centre, changsha, China*

[3]*Central South Universit, Institute of Reproductive & Stem Cell Engineering, changsha, China*

Study question: What are embryo chromosomal abnormality rates and reproductive outcomes in women with Turner's Syndrome using their own oocytes after assisted reproduction ?

Summary answer: Embryo chromosomal abnormality rates were 34%,sex chromosomal abnormality rates were 6.9%.Livebirth rates,clinical pregnancy rates and miscarriage rates of thawed cycles after PGT were 42.86%,57.81%,13.5%.

What is known already: Most patients of Turner's Syndrome suffer from gonadal dysgenesis and result in pubertal delay or failure,infertility and premature ovarian failure.Chances of spontaneous pregnancy in Turner's Syndrome are rare,pregnancy outcomes are poor due to increasing risk of miscarriage.Mosaic cases present milder phenotypic abnormality.

Study design, size, duration: This is a retrospective study including 76 Turner's Syndrome women went ART in china from 2013 to 2018.Data from 100 PGT cycles ,followed 65 thrawed cycles and 203 embryos were analysed.

Participants/materials, setting, methods: Patients were devided into three groups according to mosaic cell line ratio,G1≤10%,10%<G2<50%, G3≧50%.Ovary reserve markers and embryo chromosome abnormality rate,sex chromosome abnormality rate,clinical pregnancy rate,miscarriage rate,live birth rate after thawed cycles were evaluated between groups.Chromosome abnormality between Turner's Syndrome patients and women in normal genotype went PGT cycles were compared.

Main results and the role of chance: Live birth rates,clinical pregnancy rates and miscarriage rates of thawed cycles after PGT in Turner's Syndrome patients were 42.86%,57.81%,13.5%.There was no statistical difference between embryo total chromosome abnormality rates in Turner syndrome patients and those of patients went PGS treatments due to repeated abortion or poor pregnancy history(34%vs33.05%).Sexual chromosomal abnormalities include monosomic, trisomy, and fragment abnormalities were more common in embryos of Turner's syndrome(6.9%vs1.07%).45,X mosaic cell ratio of Turner's Syndrome women has no effect on embryo chromosome abnormality probability, sex chromosome abnormality probability, and clinical pregnancy rates,live birth rates,miscarriage rates of PGT followed-frozen embryo transplantation.

Limitations, reasons for caution: Limitations include the retrospective study design and the heterogeneity of the included patients. Additionally, genotype of lymphocytes in blood may be different from ovary.

Wider implications of the findings: PGT is essential for women in Turner's Syndrome using their own oocytes in ART due to high risk of sex chromosome abnormality.The reproductive outcomes of thawed cycles after PGT treatment in patients with Tuner's Syndrome are acceptable.

Trial registration number: na

P-536 Identification of a novel gene responsible of the Oligoasthenoteratospermia (OATs) phenotype in a Tunisian consanguineous family

M. Ben Rhouma[1,2], H. Ghédir[3], A. Braham[3], O. Okutman[1,4], S. Ibala-Romdhane[3], A. Saad[3], J. Muller[4,5], M. Sakly[2], O. Tebourbi[2], S. Viville[1,4]

[1]*Institut de Parasitologie et Pathologie Tropicale-, EA 7292- Fédération de Médecine Translationelle-, Strasbourg, France*

[2]*Laboratoire de Physiologie Intégrée, UR11S33-Faculté des Sciences de Bizerte, Bizerte, Tunisia*

[3]*Laboratoire de Cytogénétique- Génétique Moléculaire et Biologie de la Reproduction Humaines, CHU Farhat Hached, Sousse, Tunisia*

[4]*Laboratoire de Diagnostic Génétique- Hôpitaux Universitaires de Strasbourg, UF3472-génétique de l'infertilité, Strasbourg, France*

[5]*Laboratoire de Génétique Médicale, Université de Strasbourg, Strasbourg, France*

Study question: Is it possible to identify the causative genetic mutation responsible of an OATs phenotype in a Tunisian consanguineous family via whole exome sequencing?

Summary answer: A homozygous variation in a conserved promoter region of an autosomal gene was identified by using whole exome sequencing in the two affected brothers.

What is known already: Infertility is a global health problem affecting 48.5 million couples worldwide**.** A male factor is found in approximatively 20 to 30% of infertile couples. Due to the complexity of the reproduction process, 40 to 50% of cases remain idiopathic with 15% having a genetic etiology. OATs is a known cause of infertility in men. Patients show a combination of sperm abnormalities characterized by a reduced motility, number and an altered morphology. Until now, only one gene NANOS1 have already been related to this phenotype.

Study design, size, duration: This study was carried out on a consanguineous Tunisian family comprising seven siblings including five brothers and two sisters. The parents are first degree cousins; the father passed away and the mother is alive. Two brothers showed the OATs phenotype, the two others are fertile and one with unknown fertility status. One sister is fertile and the other one is handicapped with unknown fertility status.

Participants/materials, setting, methods: We obtained blood samples from the two affected brothers, two fertile brothers, the mother and the fertile sister. Genomic DNA was extracted using the FlexiGene DNA Kit (Qiagen, France) according to the manufacturer's instructions. Whole exome sequencing was performed for the two infertile brothers by IGBMC Sequencing Platform (GenomEast) via Illumina technology. Sequencing results were analyzed with *Varank* software developed by our collaborator.

Main results and the role of chance: Whole exome sequencing results revealed a homozygous variation in the promoter region of a gene on chromosome 6. The variation (c.-61 G>A,p?) is in a conserved region through evolution (Human to Elephant) suspected to be a transcription factors (POL II) binding sequence [CGCGGAAGC (WT)/CGCAGAAGC (MT)]. The wild-type protein is part of the complex regulating N6-methyladenosine (m^6A) formation known to play a role in human fertility. Knock out mice for two other subunits of the m^6A complex show an infertility phenotype with an altered spermatogenesis; one knock out results in the OATs phenotype in the mice. Functional studies are being performed to analyze the effect of the variation on the gene transcription. Preliminary results using reporter gene technique based on Luciferase activity showed a decrease in transcription between the Wild Type and the mutated gene.

Limitations, reasons for caution: Our study is limited to one family only and we still have to screen a cohort of patients presenting the same phenotype. The segregation of the variation is being controlled for the family members with Sanger Sequencing.

Wider implications of the findings: Our findings identified a novel gene responsible of the OATs phenotype. This study provides a better understanding of the physiology of male spermatogenesis as well as an advance in the field of diagnosis of infertility.

Trial registration number: Not applicable

P-537 GSTM1 and GSTT1 deletion is a risk factor for infertility in women

M.M. Casteleiro-Alves[1,2], M. Almeida[2], S.M. Rocha[2], A.H. Oliani[1], L. Breitenfeld[2], A. Ramalhinho[1,2]

[1]*Academic Hospital Center of Cova da Beira, Assisted Reproduction Unit, Covilhã, Portugal*

[2]*University of Beira Interior, CICS-UBI-Health Sciences Research Centre, Covilhã, Portugal*

Study question: Is GSTM1 and GSTT1 deletion associated with the development of female infertility?
Summary answer: Yes, GSTM1 and GSTT1 null genotypes, alone or in association, are associated with an increased susceptibility to infertility development in women.
What is known already: Infertility is characterized by the failure to establish a clinical pregnancy after 12 months of regular, unprotected sex or due to an impairment of a person's capacity to reproduce either as an individual or with his/her partner. GSTM1 and GSTT1 belong to the Glutathione S-transferases family, that catalyze the conjugation of oxidative stress products, environmental toxins, carcinogens and reactive electrophiles. Individuals with a homozygous deletion at the locus of these genes do not exhibit any functional enzymatic activity, which may lead to increased oxidative stress and consequently an increased likelihood of developing infertility, or pathologies that are known infertility causes.
Study design, size, duration: A case-control study was designed to investigate the association of GSTM1 and GSTT1 gene polymorphisms with female infertility. Case subjects, 143 women with infertility established as women under 39 years of age, were enrolled between October 2015 and July 2018. 95 fertile female controls, with no previous history of infertility, no previous history of gynecological pathologies compatible with infertility, and no previous history of IVF treatments, were selected in Obstetrics Consultation.
Participants/materials, setting, methods: Blood was collected by venous puncture in ethylenediamine tetraacetic acid (EDTA)-containing tubes, as part of the routine analyzes. Genomic DNA was extracted using a DNA extraction kit and stored at 4°C. Genotyping for GSTM1 and GSTT1 was performed using polymerase chain reaction (PCR)-based methods. The presence of the wild-type and/or the null alleles was analyzed by multiplex PCR together with co-amplification of a fragment of beta-globulin gene as a positive control.
Main results and the role of chance: We found an increased risk of developing endometriosis associated with GSTM1 null genotype (OR 0.149; 95% CI 0.064-0.348; p<0.001) as well as GSTT1 null genotype (OR 0.392; 95% CI 0.178-0.863; p=0.017). We also observed an increased prevalence of polycystic ovary syndrome (PCOS) associated with deletion of GSTM1 (OR 0.304; 95% CI 0.139-0.663; p=0.002). We found an increased risk of premature ovarian failure associated with GSTM1 null genotype (OR 0.371; 95% CI 0.166-0.831; p=0.013) as well as GSTT1 null genotype (OR 0.397; 95% CI 0.175-0.900; p=0.023). We verified an increased prevalence of tubal pathology associated with deletion of GSTM1 (OR 0.182; 95% CI 0.077-0.431; p<0.001) and GSTT1 (OR 0.424; 95% CI 0.185-0.970; p=0.034). A strong association of GSTM1 null genotype with female infertility, regardless of the cause was found (OR 0.277; 95% CI 0.159-0.482; p<0.001) as well as the GSTT1 null genotype (OR 0.430; 95% CI 0.243-0.761; p=0.003). The two-way combination of GSTM1 and GSTT1 null genotypes resulted in an increased susceptibility to infertility development (OR 0.113; 95% CI 0.046-0.282; p<0.001).
Limitations, reasons for caution: The genotyping method does not identify homozygous wild-type and heterozygous individuals but classifies as "present" individuals with one or two copies of the relevant gene, and individuals with homozygous deletions as "null". The sample size may eventually be considered small, despite the strong significance found.
Wider implications of the findings: There are not many studies in this area and the few existing exhibit very disparate results. The association of GSTM1 and GSTT1 null genotypes with endometriosis was observed in other studies, but others disagree. The association of GSTM1 null genotype with PCOS, is not corroborated by another study.
Trial registration number: Not applicable.

P-538 Is there a difference in the efficacy of recombinant and urinary purified FSH hormones in patients with different FSHR genotype? A study on 3268 cycles

G. Filippini[1], M. Zoia[1], E. Crugnola[1], L. Risch[2], M. Jemec[3], M. Bellavia[3]
[1]*ProcreaLab SA, Molecular genetic laboratory, Lugano, Switzerland*
[2]*Laboratorien Dr. Risch, Genetic department, Bern, Switzerland*
[3]*Procrea SA, Swiss fertility center, Lugano, Switzerland*

Study question: Is the FSHR genotype Ser680Asn correlated with the effectiveness of recombinant (rFSH) or urinary highly purified FSH (HP-FSH) in terms of oocytes retrieved and pregnancy rate?
Summary answer: No difference was observed in number of retrieved oocytes, pregnancy rate and take-home babies in relation to the FSHR genotype and the FSH source
What is known already: In 2015 a study on 382 cycles and 191 egg donors (Lledo et al), demonstrated that there was a difference in terms of retrieved oocytes according to the *FSHR* genotype. It is already known that this polymorphism can modify the response to FSH during ovarian stimulation. HP-FSH was more effective than rFSH in patients with the *FSHR* genotype 680 Ser/Ser; rFSH was more effective in patients with the genotype Ser/Asn and no difference was seen in the group with the genotype Asn/Asn. A large study showing a difference in pregnancy and delivery rate by FSH type is still missing
Study design, size, duration: Our study includes 3268 cycles (fresh and thawing) performed in our center in the last 10 years. All female patients were tested for *FSHR* genotype. Cycles were divided according to FSH type: 694 with Merional (HP-FSH), 606 with Menopur (HP-FSH), 1240 with Gonal F (rFSH) and 728 with Puregon (rFSH). We compared the efficacy of the different FSH in the 3 genotype groups. Outcomes were oocyte yield, metaphase II oocytes, pregnancy rate and delivery rate
Participants/materials, setting, methods: 3268 cycles, fresh and frozen, coming from 2094 *FSHR*-genotyped patients were enrolled in this retrospective study. There were no exclusion criteria. Genotyping of the *FSHR* Ser680Asn polymorphism was performed by Taqman analysis. Stimulation was achieved by conventional long or short protocols. The results were evaluated for the three genotypes in two groups: female patients < 38 years and ≥38 years. Statistics were performed using a chi-squared test
Main results and the role of chance: 30% of patients were *FSHR* Asn/Asn (n = 624), 47% were Ser/Asn (n= 988) and 23% were Ser/Ser (n = 482). No difference was observed for oocyte retrieval, pregnancy or delivery rate comparing the different FSH sources in the different genotype groups.

No difference was observed for oocytes retrieval in patients < 38 years and ≥38 years (mean value 10.5 for <38 years and 9.2 for ≥38; p>0.05). The pregnancy rate (biochemical + evolutive + delivery) in women <38 years was higher with rFSH (43% with rFSH versus 39% with HP-FSH, p = 0.043). No significant difference between rFSH and HP-FSH was observed in this group by considering only the delivery rate. In women ≥38 years the delivery rate was slightly increased using the HP-FSH: 16% with HP-FSH versus 12% with rFSH, but this difference was not statistically significant (p=0.24)
Limitations, reasons for caution: Despite the high number of patients and cycles, it is a retrospective study where different stimulation protocols have been used. Prospective and randomized studies should be performed
Wider implications of the findings: No major differences in efficacy of hormonal ovary stimulation was observed between HP-FSH and rFSH in a large, 10 year retrospective study
Trial registration number: not applicable

P-539 Ep300-mediated crotonylation of EGFR in cumulus cells is essential for the human oocyte maturation in vitro

C. Zhou[1], H. Zeng[1], X. Liang[1]
[1]*Sixth Affiliated Hospital of Sun Yat-Sen University, Reproductive Medicine Center, Guangzhou, China*

Study question: Is crotonylation modifications in cumulus cells essential for the human oocyte maturation in vitro?
Summary answer: Crotonylation of EGFR in cumulus cells is essential for the oocyte maturation in an Ep300-dependent manner.
What is known already: IVM (oocyte maturation in vitro) is an attractive approach forinfertile women, especially the ones with PCOS(polycystic ovarian syndrome) and cancers, due to minimal even no FSH and hCG use. Protein post-translational modifications are crucial epigenetic mechanisms regulating a variety of biological events. Lysine crotonylation is a newly identified posttranslational modification on a series of histone and non-histone proteins.
Study design, size, duration: By analyzing online data (GEO profiles) and detecting clinical samples from the IVM, we detected the level of crotonylation during the oocyte maturation in vitro and confirmed the key modulator of crotonylation in the process. Cell experiments and mechanism exploration were performed to evaluate the role of crotonylation in cumulus cells expansion by

increasing crotonylation level by exogenous sodium crotonate or modulator of crotonylation alteration by siRNAs and specific activator.

Participants/materials, setting, methods: Cumulus cells from human IVM cycles were used to detected the crotonylation level during human IVM by PCR and protein dot blot. Cumulus cells and normal 293T cells were used to evaluated the effects of increasing crotonylation level on cell proliferation and apoptosis by CCK-8 assays and apoptosis markers detection. Mice IVM model was used to measure the effect of crotonylation increase on oocyte maturation in vitro.

Main results and the role of chance: Here we report that crotonyltransferase Ep300 is increased in cumulus cells during human IVM, and associated with cumulus cells expansions. Increased expression of Ep300 mediates enhanced total crotonylation level in cumulus cells. Cell experiments show that increased crotonylation level by exogenous sodium crotonate regulates the cumulus cell proliferation, apoptosis and oocyte maturation in vitro, as well as Ep300 alteration caused by siRNAs and specific activator. We further confirm that EGFR is crotonylated by interacting with Ep300 and crotonylated EGFR mediates the cell functions of increasing total crotonylation. Moreover, crotonylated lysine residue hinders the EGFR degradation and enhances the ATP binding with EGFR, thus activates EGFR pathway.

Limitations, reasons for caution: The effects of crotonylation on oocyte maturation were only evaluated on mice model but not human oocytes.

Wider implications of the findings: Our results reveal that crotonylation of EGFR in cumulus cells is essential for the oocyte maturation, and Ep300 is a candidate target for improving the culture of human oocyte in vitro.

Trial registration number: not applicable

P-540 Mosaicism in human blastocysts and technical factors of laser trophectoderm biopsy

C. Scarica[1], V. Montalvo[2], S. Novo[2], C. Castelló[2], M. López-Teijón[2]

[1]*Casa di Cura Villa Salaria in partnership with Institut Marques, Reproductive Medicine, Rome, Italy*

[2]*Instituto Marques, Center for Reproductive Medicine, Barcelona, Spain*

Study question: Is there any correlation between technical aspects of laser trophectoderm (TE) biopsy and the incidence of mosaicism?

Summary answer: There is no correlation between technical aspects such as mechanical type of biopsy, operator, lengths or number of laser pulses, and the incidence of mosaicism

What is known already: Currently, TE biopsy has become as a gold standard for preimplantation genetic testing (PGT). However, the use of new diagnostic techniques, such as Next Generation Sequencing (NGS), which better discriminate and quantify the genetic material amount, increases the possibility of identifying embryonic mosaicism. Estimating the incidence of mosaicism in human blastocysts is a difficult challenge, due to technical and biological limitations. Different laboratories reported a wide range of mosaicism rate and the involvement of technical factors is still debated. The purpose of this study is to determine whether mosaicism rate is affected by any technical aspects of TE biopsy

Study design, size, duration: A multicentric (two laboratories) prospective observational cohort study involving 53 patients (age= 33.6±7.2) and 192 TE biopsies, was performed between September and December 2018 (3.8±0.4 biopsied embryos/patient). Blastocyst's morphological characteristics and technical factors were recorded. The primary outcome was mosaicism rate correlated with blastocyst's features and technical factors. Chi-square tests were used to assess the association of the selected parameters with the observed mosaicism. Logistic regression analysis was performed to correct the confounding factors

Participants/materials, setting, methods: Laser assisted hatching was performed on Day 3 and culture prolonged up to Day 5/6. Blastocysts were individually vitrified after biopsy. Blastocyst's biopsies were performed by five experienced embryologists who set the procedure according to TE characteristics. TE samples were sent for PGT of aneuploidies (PGT-A) using NGS. The day of TE biopsy, blastocysts quality and expansion (Gardner score), laser pulses number and length, and TE biopsy mechanical technique (flicking or pulling) were recorded

Main results and the role of chance: PGT-A data reported 57 euploid blastocysts (29.7%), 44 mosaic (22.9%), 84 aneuploid (43.8%), 3 inconclusive (1.6%) and 4 not amplified (2.1%). Although some studies consider the impact of technical variation as one possible cause contributing to overestimate the incidence of mosaicism in embryos, it has not yet been demonstrated. In this way, our results show that none of the biopsy technical factors analyzed correlate with the incidence of mosaicism: biopsy technique (flicking= 26.6%; pulling= 26.6%), laser pulse lengths (400ms= 26.2%; 500ms= 20.7%; 600ms= 27.3%), number of laser pulses (<3= 22.1%; 4 to 6= 22.5%; >7= 37.5%). On the contrary, some authors have previously correlated this latter feature with an increase of the aneuploidy diagnosis probability in biopsies performed with more than 10 laser pulses.

About the inherent characteristics of biopsied blastocysts, no significance variation of the mosaicism rate was correlated with blastocyst's quality (excellent= 22.6%; good= 20.6%; regular= 24.2%; poor= 25.9), blastocyst's expansion (≤4= 20.5%; 5= 29.6%; 6= 18.8%) or the day of TE biopsy (5= 22.6%; 6= 23.2%)

Limitations, reasons for caution: These are preliminary results. For the moment, the low number of the collected samples is an important limitation. Moreover, PGT-A mosaicism data refer only to blastocysts resulted as euploid/aneuploid mosaics. For a robust association between mosaicism and technical aspects of TE biopsy, aneuploid/aneuploid mosaics should be included

Wider implications of the findings: In our setting, we have not found any implication of technical parameters of the biopsy and the incidence of mosaicism. Considering our observations, the incidence of mosaicism seems to be only influenced by biological factors, or other technical limitations

Trial registration number: none

P-541 STR and SNP markers for PGT-M: bioinformatic identification, availability and informativity

K. Osetek[1], T. Harasim[1], A. Wagner[1], I. Rost[1], H.G. Klein[1]

[1]*MVZ Martinsried GmbH, Reproduction Genetics, Martinsried, Germany*

Study question: The aim was to compare a PCR-based STR approach versus SNP array regarding the number and informativity of genetic markers for PGT-M.

Summary answer: The coverage of SNP and STR markers is gene locus-dependent. Therefore, the number of genetic markers should be carefully assessed before selecting the analytical method.

What is known already: Preimplantation genetic testing (PGT-M) gives couples at risk of transmitting a monogenetic disorder a possibility to have healthy offspring. The embryo's genotype can be determined by PCR-based direct mutation testing combined with linkage analysis by using short tandem repeats (STRs). Recently, single nucleotide polymorphism (SNP) microarrays and next generation sequencing were introduced for PGT-M. These high-throughput whole genome methods do not require any family- or disease-specific design. However, allelic drop-out can affect up to 80 % of SNPs spotted on a SNP array. Additionally, pretesting of parents and one close relative is necessary to evaluate the number of informative SNPs.

Study design, size, duration: 1) The numbers of potentially informative STRs and SNPs at the corresponding gene locus and 2 Mb flanking regions were compared in six monogenic disorders. The distribution of SNPs on the karyomapping platform (Natesan et al. 2014) was used as a reference. 2) Additionally, for two families, one affected with cystic fibrosis and another with a familial adrenoleukodystrophy, the informativity of STR and SNP markers as well as allelic drop-out rates were examined.

Participants/materials, setting, methods: 1) To identify the number and location of potential and known STR repeats, a python script was developed. Five UCSC Genome Browser tracks were filtered and STRs present in at least two categories were counted. 2) Genomic DNA of selected family members was amplified with either a multiplex PCR assay followed by capillary electrophoresis (ABI 3730XL) or multiple displacement amplification and the karyomapping protocol (Illumina Inc.). The statistical analysis was carried out by paired t-test.

Main results and the role of chance: The use of bioinformatics drastically reduced the likelihood of missing some genetic markers and significantly shortened the time of their identification. The overall number of available SNP markers was significantly higher. However, for two out of six analysed disorders (cystic fibrosis and spinal muscular dystrophy) the difference in STR and SNP marker coverage was marginal. Secondly, although only one-fifth of all

available STRs were selected for genotyping, the number of informative STR and SNP markers inside and around the *CFTR* gene was comparable. In case of adrenoleukodystrophy, no informative genetic markers were detected within the *ABCD1* gene. Furthermore, the distribution of SNPs on the karyomapping array was non-uniform, encompassing only 16 informative maternal SNPs in the 3' flanking region. Finally, the analysis of at least 50 single buccal cells demonstrated that the mean amplification efficiency per cell over all analysed STR markers equalled 93.8 % for cystic fibrosis and 98.7 % for adrenoleukodystrophy. Moreover, the allelic drop-out rate for both disorders was low (2.5 %). These results indicate that for some monogenic disorders, the PCR-based approach is favourable.

Limitations, reasons for caution: So far, the informativity of STR markers was analysed for two monogenic disorders and 20 % of available STRs were assessed.

Wider implications of the findings: Implementation of bioinformatics significantly reduces the time required for the identification of STRs. For loci with a low number of available SNP markers or higher recombination rates, conducting traditional STR linkage analyses may still be advantageous. Therefore it is useful, to compare *a priori* the number of available genetic markers.

Trial registration number: not applicable

P-542 Preimplantation genetic screening for abnormal number of chromosomes (aneuploidies) in in vitro fertilization or intracytoplasmic sperm injection

S. Cornelisse[1], M. Zagers[2], E. Kostova[2], K. Fleischer[1], M. Van Wely[2], S. Mastenbroek[2]

[1]Radboud University Medical Center, Gynaecology- Reproductive Medicine, Nijmegen, The Netherlands

[2]Amsterdam UMC- University of Amsterdam, Center for Reproductive Medicine-Amsterdam Reproduction & Development research institute, Amsterdam, The Netherlands

Study question: What is the effectiveness and safety of preimplantation genetic screening (PGS) in women undergoing IVF or ICSI treatment?

Summary answer: This updated Cochrane systematic review shows there is no increase in (cumulative) live birth rate by performing PGS in an IVF/ICSI treatment.

What is known already: PGS is being offered to patients to select embryos for transfer in an IVF/ICSI treatment to improve treatment effectiveness in terms of live birth rate. It was demonstrated that the first generation of PGS, using cleavage-stage biopsy and fluorescence in situ hybridization (FISH) for the analysis, was ineffective in improving live birth rates. Newer forms of PGS were developed that perform the procedure at other stages of embryo development and use a different method of genetic analysis. These new forms of PGS have been introduced into routine clinical practice, however effectiveness of this practice still needs to be established.

Study design, size, duration: We performed a systematic review and meta-analysis of relevant randomized controlled trials (RTCs). We searched the Cochrane Gynaecology and Fertility Group Specialised Register of controlled trials, the Cochrane Central Register of Controlled Trials (CENTRAL) , MEDLINE, Embase, CINAHL, PsycINFO, WHO clinical trials register, and clinicaltrials.gov from inception to November 2018. RCTs comparing IVF/ICSI with PGS versus IVF/ICSI without PGS were eligible for inclusion. Two review authors independently selected trials and extracted data.

Participants/materials, setting, methods: The primary outcome was cumulative live birth rate (CLBR). Secondary outcomes included live birth rate (LBR) after a maximum of one transfer, per women randomized and miscarriage rate, per women randomized. Studies that only reported results on women reaching an embryo transfer and studies where multiple ovum pickups were allowed to collect multiple oocytes, were excluded due to bias by design in favor of PGS.

Main results and the role of chance: For this update,1281 titles and abstracts were screened, eleven studies (2076 women) with sample sizes ranging from 47 to 408 were included. Ten studies performed cleavage- or blastocyst stage biopsies followed by FISH- analysis. Based on one study (408 women), results showed that PGS reduced CLBR compared to no PGS in IVF/ICSI treatment (odds ratio(OR) 0.58, 95% confidence interval (CI) 0.35-0.98; moderate-quality evidence). LBR was decreased in the PGS group (OR 0.67, 95% CI 0.54-0.84, 10 studies; 1668 women; high-quality evidence). There was no difference in miscarriage rate between PGS and no PGS (OR 1.03, 95%, CI 0.75-1.41; 10 studies; 1668 women; moderate-quality evidence). One study (396 women) performed PGS on polar bodies using array comparative genomic hybridization (aCGH) and showed no difference in CLBR (OR 1.05, 95% CI 0.66-1.66; moderate-quality evidence) and LBR (1.10, 95% OR 0.68-1.79; moderate-quality evidence), however the miscarriage rate was lower in the PGS group (OR 0.45, 95% CI 0.23- 0.88; moderate-quality evidence). There were no studies on PGS as currently performed in routine clinical practice, i.e. using blastocyst stage biopsy and one of the new methods for the genetic-analysis, that could be included in the review.

Limitations, reasons for caution: The number of RCTs is limited, and those available are heterogeneous in study population, methods of genetic analysis and timing of biopsy.

Wider implications of the findings: This Cochrane systematic review confirmed earlier findings of harm by using early PGS methods. There was no improvement of live birth rate by PGS using polar body biopsy and aCGH for the analysis. PGS should only be considered in studies designed to demonstrate its effectiveness.

Trial registration number: Not a trial

P-543 Can asking hypothetical questions about being the product of sex selection, provide information regarding the impact on parent's use of pre-conception sex-selection?

C. Pascale, Ph.D.[1], S. Chen[1], R. Miller[2]

[1]IRMS at Saint Barnabas, Reproducitve Medicine, Livingston, U.S.A.

[2]Saint Barnabas Medical Center, Department of Obstetrics and Gynecology, Livingston, U.S.A.

Study question: Do attitudes regarding pre-conception sex selection change when one imagines being the product of such technology?

Summary answer: Personalizing questions change perspective. The impact of social sex selection has not been researched. Effects of sex-selection may be necessary to consider in implications counseling.

What is known already: Today the majority of fertility clinics in the US offer pre-implantation genetic technologies that allow for pre-conception sex selection to avoid a medical condition, facilitate family balancing, and cater to social preferences. Previous surveys have inquired about sex selection attitudes in general and mostly within the infertility population. Arguments of reproductive autonomy vs bio-ethical practices have been discussed but no survey to date, has asked about if the *individual* were the product of sex selection. Despite being the result of conjecture, asking this question is important. To date, the social consequences of such practices have not been emphasized or researched.

Study design, size, duration: Participants (n=352) responded to an IRB approved, self-administered, web-based, non-validated survey designed by the author and collected through Survey Monkey®. Solicitation for subjects were conducted for 4 $^{1}/_{2}$ months in 2014 between April through August. Statistical analysis was performed using a series of t-tests with selected groups for comparison.

Participants/materials, setting, methods: Participants were predominantly females (n=269) between the ages of 18-32. Questions were asked about sexual preference (89.5% identified heterosexual), professional degrees held (25%), religious upbringing (61% Christian), and any former pregnancies (19%). Not all questions were answered. Survey questions related to reproductive history, attitudes regarding sex-selection technology, preferences for use, and individual's hypothetical perspective of being the product of such technology. Surveys were distributed via Facebook, email, and college campus posts. Responses were de-identified.

Main results and the role of chance: Most questions required a Positive, Negative or Unsure/Neutral response. Responses were collapsed to create binary data with a 2-part question: Unsure/Neutral and Definite. The second part to the question required a Positive or Negative response. Overall, 68% favored sex-selection for medical reasons; 9% were against this and 23% were unsure. Overall, 29% favored sex selection for social reasons; 47% were against this and 24% were unsure. Women (50.9%) were significantly more likely to be against social sex selection.

When asked, hypothetically, how they might feel if they discovered their sex was chosen, 58% reported they would have neutral feelings. Of the other 42%, 8% of the men and 25% of the women indicated they would feel positively; 13% of the men and 52% of the definitive women imagined they would feel negatively. When asked if they would want to know about their sex being chosen, 30% were unsure. 45% n=104 indicated they would want to know; and 55% n=126 said they would not want to know. Women were significantly more likely than men ($p<.05$) to feel negatively about knowing they were the product of sex selection.

Limitations, reasons for caution: This was a web-based survey potentially creating selection bias. Participants responded if they were interested and those not interested, it is assumed, did not respond. Questions posed on the effects of sex selection were hypothetical. As such, true feelings of actual children of sex selection are unknown

Wider implications of the findings: The advancement and progressive options of novelreproductive technologies brings new decisions for patients. Patients need to consider the use of the technology and the possible impacts for their offspring. This research is designed to facilitate conversations in implications counseling with patients to aid their decision making and parental preparation

Trial registration number: NA

P-544 Tunable copy number algorithm parameters improve the detection and accuracy of small CNV event calling in PGT-A

C.J. Davidson[1], J. Wei[2], C. Zhang[2], X. Qin[2], Z. Rosenwaks[1], K. Xu[2], A. Harris[3]

[1]Thermo Fisher Scientific, Reproductive Health, South San Francisco, U.S.A.
[2]Weill Cornell Medical College, Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine-, New York-, U.S.A.
[3]Thermo Fisher Scientific, Reproductive Health, Carlsbad, U.S.A.

Study question: What are the copy number algorithm parameters that influence the detection and accuracy of small copy number variation (CNV) event calling in PGT-A?

Summary answer: Reduced tile size baselines and custom sensitivity settings enable improved detection of small CNV events in the range of 1.81 Mb to 3.36 Mb.

What is known already: PGT-A can be required to detect the unbalanced products of reciprocal translocations in embryo biopsies without a priori information since carriers of a balanced reciprocal translocation with derivative chromosomes may be undiagnosed prior to engaging in IVF. The resultant embryos from balanced reciprocal translocation carriers may have segmental unbalanced chromosomal aberrations that have the potential to be of various sizes and locations across all chromosomes. As a result, it is important to determine the analysis parameters and resolution limitations of PGT-A workflows to detect putative segmental unbalanced products from translocations and other segmental aneuploidies in preimplantation embryos.

Study design, size, duration: Analysis parameters for a NGS-based PGT-A assay were optimized for sensitivity and specificity using samples sequenced between September to December 2018. The dataset consisted of a range of event sizes including four whole chromosome events (45,XX,-21; 47,XY,+18; 48,XXX,+21), 12 segmental CNV events (del(5p) 32Mb, dup(9p) 11Mb; dup(16p) 3.66Mb; dup(22q) 14.8Mb; del(4p) 26.9Mb; del(5q) 2.31Mb, dup(6p) 20.97Mb; dup(3q) 99.1Mb, del(9p) 1.81Mb; del(5p) 30.1Mb, dup(6p) 2.19Mb, del(14q) 1.19Mb), and two euploid cell lines (46,XY; 46,XX).

Participants/materials, setting, methods: Using 4-5 cell inputs picked under a microscope, three replicates per cell line were processed using the protocol for the Ion ReproSeq™ PGS Kits for the Ion GeneStudio S5™ System (Thermo Fisher Scientific) covering: whole genome amplification, library preparation, template preparation, and sequencing. Ploidy calling and size accuracy for segmental CNV events were assessed using aneuploidy analysis workflows in Ion Reporter software v5.10 with transition penalty and baseline tile size parameter adjustments.

Main results and the role of chance: Different aneuploidy analysis parameters were compared for sensitivity, positive predictive value (PPV) and size calling accuracy. Algorithms assessed included decimal ploidy value copy number calling (mosaic) and integer ploidy value copy number calling (non-mosaic) with parameter adjustments (transition penalty (TP) and baseline tile size). The sensitivity for the detection of all events ranged from 68.8%-93.8%. The greatest sensitivity was observed for a non-mosaic workflow with TP= -3 and baseline tile size of 0.2Mb; all events were called except for del(14q) 1.19Mb. In contrast, the least sensitive workflow had a PPV of 100% using a non-mosaic workflow with TP=-3 and baseline tile size of 2Mb; however, only events >3.36Mb were called.

Assessing the size accuracy of calls for events ≥11Mb, a non-mosaic workflow with TP= -2 and baseline tile size of 0.5Mb called events with the best concordance to the expected sizes with a maximum size discrepancy of 10%. Investigating breakpoint accuracy, this workflow called events that overlapped with annotated CNVs with an average of 6% of the called event size that did not correspond to the annotated region for the eight events with positional information (del(9p) 1.81Mb Del(9), dup(6p) 2.19Mb, del(5p) 2.53Mb, dup(6p) 20.97Mb, del(4p) 25Mb, del(5p) 30Mb, dup(3q) 99.1Mb).

Limitations, reasons for caution: The range of CNV events assessed was small with a size distribution that had gaps and effects of sequencing depth were not studied. For a better understanding of the resolution that can be achieved, more cell lines with a greater range of CNV sizes on different chromosomes should be studied.

Wider implications of the findings: Sensitivity, PPV, and accuracy of small CNV event calling in PGT-A can be greatly influenced by the adjustment of copy number algorithm parameters. This study provides guidance on the workflow parameter settings needed to achieve calling of CNV events at a particular size threshold.

Trial registration number: None

P-545 Relationship between Plakophilin-3 (PKP3 rs10902158 SNP) genotype and IVF outcome (Pilot study).

M. AlHalabi[1]

[1]Faculty of Medicine of Damascus University, Embryology- Reproductive Medicine and Genetics, Damascus, Syria

Study question: Is there an association between PKP3 rs10902158 (G>A) polymorphisms and the risk of implantation failure after ICSI treatment?

Summary answer: The presence of the allele A of the PKP3 SNP rs10902158 is associated with a reduced clinical pregnancy outcome in the patients undergoing ICSI.

What is known already: Plakophilin-3 (PKP3) belongs to the Plakophilin family. It is described as beta- catenin and *armadillo* protein of the desmosomal plaque, which is synthesized in simple and stratified epithelia, present in cytoplasm, membrane and nucleus. The importance of cell-cell junction proteins in placentation and implantation biology is known. Although many studies indicate that alterations of intercellular adhesion may be associated with implantation failure, no study has investigated if the dysregulation or genetic polymorphisms of Plakophilins are associated with Implantation Failure.

Study design, size, duration: A total of 97 women, who underwent ICSI treatment for male factor infertility, were prospectively recruited in this cross-sectional study from 1 October 2017 to 1 April 2018, at Assisted Reproduction Unit at Orient Hospital, Syria.

Participants/materials, setting, methods: Genomic DNA was prepared from peripheral blood samples in order to analyze the polymorphism (rs10902158) at the PKP3 gene by PCR-RFLP. The Results were presented as a genotype (GG, GA, and AA), and their relationship to IVF outcome was analyzed.

Main results and the role of chance: The patients were divided into two groups according to clinical pregnancy: the pregnant group included 51 patients (53%) and the non-pregnant group included 46 patients (47%). The clinical pregnancy outcome was significantly different between genotypes, which was 0%, 45.8% and 58.8% in the patients having the genotype AA, GA and GG respectively (p-value = 0.03).

Limitations, reasons for caution: We could not do the genetic analysis for participants' parents. More studies are needed for both parents to demonstrate this hypothesis and to elucidate the precise molecular mechanism of PKP3 in folliculogenesis and embryo development.

Wider implications of the findings: The present study is the first pilot study, which indicates that the presence of the allele A of the *PKP3* SNP rs10902158 is

associated with a reduced clinical pregnancy outcome in the patients undergoing ICSI treatment. This variant may also constitute a novel predictor biomarker for implantation failure.
Trial registration number: none

P-546 Efficacy of whole genome amplification (WGA) and nested PCR methods for single cell analysis in preimplantation genetic diagnosis (PGD) for monogenic diseases

M.J. Kim[1], S.O. Park[1], M. Kim[1], Y.S. Hong[1], Y.S. Kim[1], E.B. Joe[2], Y.J. Cho[2], E.A. Park[2], J.H. Lee[3], R. Kim[4], Y. Lee[4], T.K. Yoon[4], I.S. Kang[4]
[1]CHA Fertility Center- Seoul Station- CHA University, Lab. of Medical Genetics, Seoul, Korea- South
[2]CHA Fertility Center- Seoul Station- CHA University, Lab. of Fertility, Seoul, Korea-South
[3]CHA University, Biomedical Science, Pocheon, Korea- South
[4]CHA Fertility Center Seoul station-CHA University, Department of Obstetrics and Gynecology, Seoul, Korea- South

Study question: Is whole WGA more efficient and reliable than nested PCR for single cell analysis in PGD for monogenic diseases?
Summary answer: The nested PCR technique may be more sensitive and specific method compared to WGA in single cell analysis.
What is known already: Both WGA and nested PCR technique are frequently used methods for genetic analysis in PGD. However, the data regarding the efficacy of different PGD molecular techniques for detecting gene mutations are still lacking. Allele dropout (ADO) remains the one of the most significant problem in PCR-based PGD since it can lead to misdiagnosis.
Study design, size, duration: A total of 222 lymphocytes from 7 couples with monogenic disease were allocated to WGA and nested PCR method. The efficacy of amplification rate and ADO rate for causative genes and short tandem repeat (STR) markers was compared.
Participants/materials, setting, methods: Single lymphocytes obtained from seven individuals who had heterozygous mutations of the causative genes (neurofibromatosis, gangliosidosis, familial adenomatous polyposis coli) and informative STR markers (Charcot-Marie-Tooth disease, Duchenne muscular dystrophy) were used. Using WGA method and nested PCR, the amplification rate and ADO rate were evaluated. The number of lymphocytes used in the WGA method was one to five lymphocytes, while only single lymphocyte was used in the nested PCR method.
Main results and the role of chance: For all experimental groups using mutant loci and markers, overall mean amplification rate in WGA and nested PCR were 94.3% and 99.3% and ADO rates were 22.7% and 4.6%, respectively. For six mutated loci, amplification rate were 97.9% of WGA and 98.7% of nested PCR, and ADO rates for these loci were 23.4% and 2.7%, respectively. In the analysis of informative STR markers in two genetic disorders, the ADO rate of WGA method was higher than direct nested PCR method (21.1% vs. 6.6%). Although WGA method is recommended in various genetic disorders, especially for simultaneous detection of two or more loci, it showed high ADO rate in this study. It is assumed that DNA fragmentation of the genome by restriction enzyme during WGA may cause the degradation of binding site of primers, resulting in higher ADO rate and non-specific products.
Limitations, reasons for caution: We need further study regarding techniques.
Wider implications of the findings: Our results suggest that nested PCR method, a less expensive without using commercial kits is more reliable method in the single cell analysis for PGD as compared to WGA method.
Trial registration number: None

P-547 Metaphase II (MII) oocytes obtained at different time points in the same patient undergoing Assisted Reproduction – Aneuploidy rate of resulting embryos

G. Emerson[1], E. Budak[1], M. Fakih[1]
[1]Fakih IVF Medical Center, IVF dept., AbuDhabi, United Arab Emirates

Study question: Is there a difference in aneuploidy rates in embryos resulting from fresh versus frozen/thawed oocytes for the same patient?
Summary answer: In fresh and frozen/thawed oocytes sets, analysis of the day of biopsy and age showed no significance in aneuploidy rate between the same patient.
What is known already: Oocyte cryopreservation is now an established technology with a wide range of indications. Increasing evidence on the efficiency of IVF using vitrified oocytes has suggested that it could achieve similar outcomes to IVF using fresh eggs with survival rates of over 84%. Moreover, aneuploidy rates in embryos from frozen/thawed oocytes used in egg donor programs has shown no significant increase in chromosomal error types when compared to fresh oocyte donation. As the number of oocyte cryopreservation cycles increases there is a real need to monitor outcomes of this technique with regard to the health of live-offspring.
Study design, size, duration: We performed a retrospective data analysis to determine aneuploidy rates in 679 embryos as a result of fresh and frozen thawed oocytes in patients undergoing assisted reproduction (ART) between, 2016–2018. Patients who had previous oocytes vitrified due to either a high response to gonadotropins, or no sperm at time of oocyte pick up (OPU), returned for a fresh OPU where they also consented to the thawing of their stored oocytes.
Participants/materials, setting, methods: Embryo aneuploidy was detected using NGS HR. Aneuploidy rates were compared between both sets of fresh and frozen/thawed oocytes, for day 3, day 5 biopsy and age, ($\leq$ 36 years and $\geq$ 37 years) at the time of fresh OPU. Chromosomal error types, monosomy, trisomy and complex abnormals (more than 2 error types) were also determined within both fresh and frozen oocytes. Significant difference was determined when P= $<$0.05.
Main results and the role of chance: The average age of patients studied was 37 years old (23 to 45 years). Time between vitrification and the thaw of cryopreserved oocytes averaged 5 months (1 - 48 months). Between fresh and frozen oocytes embryo aneuploidy rates from biopsies on day 3 was 68% versus 70% respectively. On day 5 biopsy, 43% of fresh oocytes versus 61% of vitrified oocytes were aneuploid. In patients $\leq$ 36 years old, the rate of aneuploidy was 50% versus 56%. In $\geq$ 37 years, 78% of fresh versus 75% for frozen/thawed oocytes were aneuploid. No significance was found for all sets of data p= $>$0.05. Aneuploidy rate was raised for fresh (50% v 78%) and frozen/thawed oocytes (56% v 75%) between both age groups. Monosomy, trisomy and complex abnormal showed no significance for both biopsy day and age groups, p=$>$0.05. However, it was observed that there was a decrease in complex abnormalities between day 3 and day 5 biopsy due to a possible correction factor in extended embryo development.
Limitations, reasons for caution: The frozen/thawed oocytes were not recruited from the same fresh cycle, therefore the impact of different stimulation protocols on oocyte quality should be viewed with caution. Sample size is small for day 5 biopsied embryos compared to day 3 biopsy due to a restriction on embryo cryopreservation in the UAE.
Wider implications of the findings: This study aids health professionals in counseling patients when no sperm has been collected on the day of OPU, oocyte banking and oncology patients showing no increase in aneuploid embryos . It adds to the existing published data on the prevalence of aneuploidy in embryos from fresh and frozen/thawed oocytes.
Trial registration number: not applicable

P-548 Detection of embryonic monogenetic defects and chromosomal aneuploidies by whole genome sequencing

Y. Xuyang[1], C. Songchang[2], L. Ping[1], X. Jun[1], C. Fang[1], X. Chenming[2]
[1]MGI-Shenzhen, R&D center, Shenzhen, China
[2]The International Peace Maternity & Child Health Hospital of China welfare institute IPMCH, IVF center, Shanghai, China

Study question: To evaluate the performance of whole genome sequencing (WGS) combining linkage information in pedigree for the detection of embryonic monogenetic defects and chromosomal aneuploidies.
Summary answer: WGS with pedigree member of 15X depth and embryo of 4X depth can accurately detect embryonic monogenetic defects and aneuploidies.
What is known already: Comprehensive chromosomal screening (CCS) based on WGS has been used for the detection of embryonic chromosomal copy number variants with the widely clinical application of preimplantation

genetic testing for aneuploidy (PGT-A). Preimplantation genetic testing for monogenic defects (PGT-M) using target sequencing has been applied clinically as well.

Study design, size, duration: We performed WGS to detect embryonic monogenic defects and aneuploidies simultaneously in 7 families that had undergone *in vitro*fertilization (IVF) with totally 36 embryos. Seven families who had undergone IVF with risk of monogenetic defects in the genes of *COL1A1*, *IDUA*, *DMD*, *EXT1*, *IL2RG*, *ITGB4*and *FLG*respectively participated in this study. Each participant was recruited with informed written consent. The WGS results were validated by SNP-array karyomapping.

Participants/materials, setting, methods: There were 7, 6, 7, 5, 1, 4 and 6 embryos obtained for each family respectively. Blood from each pedigree member were used for averagely 15X depth WGS with MGISEQ-2000, and 3-10 cells were biopsied from each blastocyst and multiple displacement amplified (MDA) and used for averagely 10.5X WGS. We constructed the haplotype for the target gene, and confirmed genetic status of pathogenic mutation according to the haplotype in the target gene of each embryo.

Main results and the role of chance: For monogenetic defects, totally 16 embryos were confirmed to be heterozygous mutation, 3 embryos to be homozygous mutation, and 17 embryos to be normal; all the results were validated by karyomapping and were 100% concordant. For aneuploidies, totally 17 embryos were detected to be with aneuploidies or chromosomal copy number variants, 19 embryos were to be normal, all the results were 100% concordant with karyomapping. Combining the results of monogenetic defects and aneuploidies, there were 1, 1, 4, 1, 1, 0 and 0 embryos for each family respectively with both normal chromosomal karyomap and normal genetic status of target gene. We performed data volume gradient test and find that embryonic data as low as 4X depth WGS can accurately detect monogenetic defects and aneuploidies. The allele drop-out (ADO) rate was averagely 19.39% for embryo 10.5X WGS, and averagely 36.3% for embryo 4X WGS.

Limitations, reasons for caution: Limitation may be due to the size of the sample. More families with monogenetic defects who had undergone IVF need to be recruited and more embryos need to be sequenced. Performance of our method such as specificity and sensitivity can be evaluated in a large-sample study.

Wider implications of the findings: Our results demonstrated the reliability of WGS for the detection of embryonic monogenetic defects and chromosomal aneuploidies. Moreover, WGS provide the extendibility of our testing to detect embryonic complex mutations, de novo mutations, translocations, mitochondrial DNA variations etc.

Trial registration number: None

P-549 Preventing the recurrence risk by NGS-based PGT-M for monogenic disease resulting from mosaic germline mutation

X. Hu[1], W.B. He[1,2], J. Dai[1], Y. Zhang[1], W. Li[1,2], G.X. Lu[1,2], G. Lin[1,2], Y.Q. Tan[1,2], J. Du[1,2]

[1]*Reproductive&Genetic Hospital Of CITIC-Xiangya, Genetic center, Chang Sha, China*

[2]*Central South University, The institute of Reproduce and Stem Cell Engineering, Chang Sha, China*

Study question: How to prevent the recurrent risk of monogenic disease resulting from mosaic germline mutation by NGS-based PGT-M technology?

Summary answer: The recurrence risk of monogenic disease with germline mosaicism could be prevented by mutation detection combined with haplotype analysis by NGS-based PGT-M.

What is known already: Mosaicism is due to post-zygotic de novo mutation, resulting in two or more cell populations with or without presenting distinct clinical phenotypes in a single individual. The identification of mosaic mutation could not only explain the phenotype heterogeneity and the cause of de novo dominant genetic disorder in some families, but also provide a basis for genetic counseling when mosaic mutation was found in a parent. Individuals are increasing to be discovered to carry mosaic harmful mutations by NGS-based deep sequencing. However, it is a still challenge how to prevent the recurrent risk when a parent carries a mosaic mutation.

Study design, size, duration: This is a retrospective study for four couples seeking for PGT between August 2017 and December 2018. Three couples were healthy. Couple 1 and Couple 2 delivered babies with adrenoleukodystrophy and Fanconi anemia, respectively. Couple 3 had two consecutive pregnancies with fetus skeletal malformations. In Couple 4 the female partner was affected neurofibroma. PGT-M was carried out after the causing genes were determined, including *ABCD1*, *FANCB*, *COL1A2*, and *NF1*, respectively.

Participants/materials, setting, methods: The four recruited couples underwent PGT-M in our hospital. Mosaic mutations were indicated by pedigree analysis or contradictory PGT results and were finally confirmed by deep sequencing (from 1142X to 5129X). After informative STR and/or SNP haplotypes were constructed, ICSI-PGT treatment was provided. Mutation detection combining linkage analysis was performed on biopsied blastocyst trophectoderm cells and polar bodies. The embryos without affected the related disease were considered to transfer to the uterus.

Main results and the role of chance: PGT-M successfully underwent for 4 families in which wild haplotype, mutant haplotype and mutant haplotype with no mutation were all distinguished. The results were analyzed according to the same evaluation standard as Couple 1. In Couple 1, 9 biopsied blastocysts were detected. Five inheriting wild maternal chromosome were considered for preferential transfer. Two male embryos inheriting risk chromosome but no mutation were also considered for transfer. Two female embryos carrying risk chromosome but no mutation were not considered for transfer for ADO could not be precluded. A wild-type embryo was transferred, resulting in a normal pregnancy by prenatal diagnosis, and delivering a healthy boy.

Other 3 couples have been finished PGT-M and were awaiting embryo transfer. 8, 5, and 3 blastocysts were biopsied in Couple 2-4 respectively, and the blastocysts considering for preferential transfer were 3, 2 and 1 respectively. For Couple 4, polar bodies were detected to construct haplotype analysis.

An interesting finding is that mutation detection and haplotype analysis could indicate germline mosaicism. The haplotypes of 2 embryos in Couple 2 and polar bodies in Couple 4 were contradictory to the mutation detection, which indicated maternal mosaicisms for both couples and was confirmed by deeping sequencing.

Limitations, reasons for caution: Male germline mosaicism was not included in this study. Only one couple had clinical outcome and other couples are awaiting transplantation.

Wider implications of the findings: Polar body analysis could be used to confirm mosaicism during PGT-M. The possibility of germline mosaicism should be considered when the proband carried de-novo mutation or asymptomatic couple delivered an affected offspring. During PGT-M, comprehensive analysis including mutation detection and haplotype analysis is necessary.

Trial registration number: Not applicable

P-550 Utilization of Magnetic-activated Cell Sorting after the failure of a first Pre-implantation Genetic Testing cycle improves the outcome of assisted reproduction treatments.

F. Scarselli[1], E. Cursio[1], M.G. Minasi[1], A. Ruberti[1], V. Zazzaro[1], S. Gatti[1], A. Pristerà[1], M.T. Varricchio[1], A. Caragia[1], M.C. Greco[1], P.F. Greco[1], A. Biricik[2], F. Spinella[2], F. Fiorentino[2], E. Greco[1]

[1]*European Hospital, Reproductive Medicine, Rome, Italy*

[2]*Genoma Group, Genetics, Rome, Italy*

Study question: Can MACS (Magnetic-activated Cell Sorting) reduce aneuploid and increase euploid rate in Pre-implantation Genetic Testing cycles for AMA (Advanced Maternal Age) after a failed attempt?

Summary answer: Our study highlighted a decrease in aneuploid blastocysts rate using MACS in infertile patients undergoing a Pre-implantation Genetic Testing cycle after a failed attempt.

What is known already: Many authors have demonstrated a strict correlation between the presence of apoptotic markers on spermatozoa and the failure of assisted reproduction treatments. An early indicator of apoptosis is the externalization of phosphatidylserine (PS) residues, a phospholipid-binding protein, on the sperm cytoplasmic membrane. The MACS system consists in a column selection method: apoptotic speramatozoa bind to magnetically-labeled Annexin-V at the PS residues and are retained in the column whereas non apoptotic sperm can flow through it. It has been showed that the use of MACS allows improving sperm quality, fertilization and cleavage rates, pregnancy and reducing miscarriage rates.

Study design, size, duration: From January 2015 to November 2018, 13 couples were enrolled in the study. All couples had a previous PGT (Pre-implantation Genetic Testing) cycle in which no euploid blastocysts were obtained; in some cases mosaic diploid-euploid blastocysts were obtained, which gave no pregnancy after a frozen embryo-transfer. All the couples underwent a second PGT cycle attempt in which sperms were treated with MACS in order to select non-apoptotic spermatozoa.

Participants/materials, setting, methods: Patients with severe oligoasthenoteratozoospermia were excluded. The MACS protocol was performed as follows: the semen sample was analyzed (WHO 2010), washed with buffered medium; the pellet was removed and a swim-up performed. The retrieved spermatozoa were washed with a binder buffer (Miltenyi Biotec), centrifuged and the supernatant discarded. The pellet was covered with Annexin-V and re-suspended. After a 15' incubation at room temperature, the sample was eluted through the column and collected to perform ICSI.

Main results and the role of chance: Female and male mean age±SD were 40.5±3.7 and 43.1±4.5, respectively, on the first PGT cycle (No-MACS Group=NMG). Female and male mean age±SD were 40.9±3.7 and 43.5±4.7, respectively, on the second cycle (MACS Group=MG). Respectively in NMG and MG, the injected oocytes were 114 and 118; fertilized oocytes were 79 (69.3%) and 71 (60.2%) (NS); blastocysts formation rates were 53.2% (42/79) and 53.5% (38/71) (NS). In NMG, 22 (52.3%) blastocysts formed on day-5, 17 (40.6%) on day-6 and 3 (7.1%) on day-7. In MG, 19 (50.0%) blastocysts formed on day-5, 15 (39.5%) on day-6 and 4 (10.5%) on day-7 (NS). In the NMG and MG respectively, no euploid blastocysts and 4 (10.5%) euploid blastocysts were obtained. In NMG, 3 mosaic diploid-euploid blastocysts were formed (7.1%) whereas in the MG, there were 4 (10.5%) (NS). Aneuploid blastocysts were 37 (88.2%) in NMG and 27 (71.1%) in MG ($p<0.05$). In NMG, 3 frozen embryo transfer of 3 mosaic blastocysts were performed, giving 2 biochemical pregnancies (66.7%). In MG, 8 frozen embryo transfer of 8 blastocysts (4 euploid and 4 diploid-euploid mosaics) were performed obtaining 2 clinical pregnancies (25.0%) with 2 babies born and 2 biochemical pregnancies (25.0%) (NS).

Limitations, reasons for caution: The sample size is small and the project is still ongoing to enlarge the number of couples enrolled. Study of aneuploidies with a possible male origin (chromosomes 9,13,15,16,17,18,21,22,X,Y) and analysis of clinical results needs a larger number of patients and biopsied blastocysts in order to perform a robust statistic analysis.

Wider implications of the findings: MACS is useful to select non apoptotic sperms; although fertilization, cleavage and blastocyst rates are not improved, aneuploid blastocyst rate statistically decreases with the use of MACS. By selecting spermatozoa free from PS residues, MACS probably selects spermatozoa with a better DNA packaging, thus affecting the embryo ploidy.

Trial registration number: not applicable

P-552 Contributions of new genomic analyzes (array-CGH and next generation sequencing (NGS)) in the identification of rare causes of human ovarian infertility.

F. Scheffler Gharieni[1], N. Celton[1], G. Gedraszak[2], N. Belhadri-Mansouri[1], M. Gallet[1], R. Cabry[1], H. Copin[1], M. Benkhalifa[1]

[1]CHU Amiens Picardie SUD, Service de médecine et biologie de la reproduction-cytogénétique et CECOS de Picardie, Amiens, France

[2]CHU Amiens Picardie SUD, Laboratoire de génétique moléculaire médicale, Amiens, France

Study question: Identify rare genetic causes of human ovarian infertility using new genomic exploration technologies.

Summary answer: A genetic origin was identified for 40% of the cohort: 6 patients and variants of interest requiring further studies in 4 patients.

What is known already: Between 30 and 40% of the etiologies of infertilities are ovarian origin. Among them, 1% of women under 40 have premature ovarian failure (POF), many causes as been indentified including genetic, autoimmune, infectious, or iatrogenic. But the majority remains to be elucidated. Genetic causes of POF account for approximately 20–25% of patients and can be isolated (nonsyndromic), or as one component of a pleiotropic genetic syndrome. Chromosomal abnormalities could explain 10–15% of POF cases. Array-CGH and a recent approach using next generation sequencing (NGS) have led to new causatives being identified and candidates' genes being proposed.

Study design, size, duration: We carried out a cohort study in the departments of reproductive medicine and biology, cytogenetics and molecular genetics of the University Hospital of Amiens from January 2016 to December 2018.

We include 25 patients under 36 years of age with ovarian infertility (premature ovarian failure, or folliculogenesis blockage) without identified etiology after standard genetic assessment (karyotype and search for premature X fragile).

Participants/materials, setting, methods: For each patient:

-Search for small chromosomal variants (deletion/duplication) by array-CGH of 180K oligonucleotide type (Agilent technology) giving an average resolution of 60 kb.

-In the absence of chromosome variant, search for gene variants by NGS (high throughput sequencing) type "clinical exome" (panel of about 5000 genes involved in human pathology).

-Confirmation of identified variants and familial investigation by karyotype and FISH, semi-quantitative PCR or Sanger sequencing according to the nature of the variant identified.

Main results and the role of chance: The array-CGH identified a CNV of interest for infertility for 6 patients. One of the 5 CNVs identified is a recurrent abnormality described known to be responsible for infertility (deletion 15q25.2). Another CNV has already been described once as implicated in female infertility (5q13.2 duplication). Chromosomal reworking of X undetected karyotype was also found in another patient. Finally, three other CNVs of interest corresponding to undescribed microremanyments include potentially candidate genes in female infertility.

The analysis of 4 patients, including two sisters, in clinical exome allowed to identify variants of interest in each case. A truncating mutation in the homozygous state was identified in the FIGLA gene, a gene previously implicated in premature ovarian failure, in two sisters. Two heterozygous missense variants in the MLH3 gene were identified in another patient with meiotic blockade after ovarian stimulation. Finally, a pathogenic mutation in the homozygous state has been identified in the gene ZP1, a gene previously implicated in the syndrome of empty cumulo-oocyte complexes, in a patient with this rare pathology.

Limitations, reasons for caution: The main limitation of our study is the small number of patient.

Wider implications of the findings: There are many causes of infertility and infertility is often multifactorial. Genetic etiologies is estimated that about 50% of infertilities, isolated genetic component or associated with other factors. Combining a chromosome approach and a gene approach could identify the molecular substratum of unexplained female infertility.

Trial registration number: not applicable

P-553 FMR1-CGG-repeat length can induce AKT/mTOR signaling in human granulosa cells from IVF patients

J. Rehnitz[1,2], B. Messmer[1], J.E. Dietrich[2], S. Roesner[2], A. Freis[2], T. Strowitzki[2], K. Hinderhofer[3], P.H. Vogt[1]

[1]Universitäts-Frauenklinik, Gynecological Endocrinology and Fertily Disorders- Division of Reproductive Genetics, Heidelberg, Germany

[2]Universitäts-Frauenklinik, Gynecological Endocrinology and Fertily Disorders, Heidelberg, Germany

[3]University Hospital Heidelberg, Institute of Human Genetics - Molecular Genetics Diagnostic Laboratory, Heidelberg, Germany

Study question: Does variable *FMR1*-gene-expression due to different CGG-Repeat-Lengths (RL) affect gene(s)-expression of mTOR-signaling-pathway functioning in human granulosa cells (GC) and interfere with the ovarian stimulation process applied for women undergoing IVF/ICSI?

Summary answer: Women with homozygous-low-CGG-RL (<26) display increased *AKT*, *mTOR* and *TSC2*-expression although *S6K*-expression remains stable suggesting involvement of *FMR1* in modulating mTOR-signal-pathway-activation during folliculogenesis in GC.

What is known already: *FMR1*-gene is a major-regulator in folliculogenesis; it contains a highly variable CGG triplet-block in its promoter-region and RL between 54-200 are associated in ~20% with premature-ovarian-insufficiency/failure. The protein FMRP is highly expressed in women´s GC

and known to control translation of a number of cellular transcripts involved in RISC-(RNA-induced-silencing-complex)-function.

The AKT/mTOR-signaling-pathway is a major-regulator for cellular-proliferation and differentiation involved in primordial-follicle-activation for follicular-pool-maintenance. Ovarian-reserve and -response to hormone stimulation impacts substantially women´s success during IVF/ICSI-treatment. Elevated *FMR1*-gene-expression in GCs of women with poor-response suggests the variable CGG RL as causative agent for this impairment probably due to mTOR-signal-pathway interference.

Study design, size, duration: 269 women undergoing controlled ovarian hyperstimulation for IVF/ICSI-treatment were prospectively enrolled. This study was approved by the local ethical committee and conducted according to the principles of the Declaration of Helsinki.

212 of the patients could be divided according to their ovarian response into either normal (n:150) or poor (n:62) responders. Poor response was defined according to Bologna-criteria.

Participants/materials, setting, methods: DNA was extracted from peripheral blood.*FMR1*-CGG-RL was determined using ABI 3100/3130x1-sequencer. A RL of 26-34 was considered as "normal", <26 as "low" and >34 as "high". Patientswere than subdivided into six genotypes (high/high; high/low; low/low; low/norm; high/norm, norm/norm) according to their CGG-repeat length on both alleles.

mRNA was extracted from GCs after follicular aspiration; quantitative gene-expression of *mTOR, AK* and*S6K*was determined using specific TaqMan-Assays. Statistical analyses with SPSS; significance set $p \leq 0.05$.

Main results and the role of chance: Expression levels of *AKT, mTOR* and *TSC2* were clearly variable between the six *FMR1*-genotypes; statistically most significant for *AKT* (p=0.045) and *mTOR* (p=0.08). Post-hoc analysis demonstrated that this difference was mainly due to samples carrying a homozygous low/low CGG genotype displaying significantly elevated gene-expression levels compared to the other CGG genotypes.

After subdivision the collective for ovarian response this effect of the CGG low/low-genotypes was even more prominent in patients with a poor response to ovarian stimulation (e.g. *AKT* p=0.035).

Most interestingly, *S6K*-expression levels between the different CGG genotypes were rather stable. Our data therefore suggest interference of *FMR1*/FMRP expression with AKT/mTOR signal pathway but not downstream because *S6K*-expression looks stable (internal control).

A clear correlation of *FMR1*-genotypes with mTOR-signaling can be assumed from these results. Homozygous low CGG triplet alleles putatively lead to lower FMR-protein levels causing lower RNA binding capacities in the RISC reducing cellular translation efficiency resulting in poor ovarian response.

Limitations, reasons for caution: Future experiments evaluating the RNA-protein interactions between FMRP and transcripts of mTOR-pathway are needed to understand how such RNP guided RISC interactions operate at the molecular level. Further *FMR1/mTOR*genes expression analyses on larger sample sizes are required to substantiate given data.

Wider implications of the findings: Our data can help to understand how *FMR1*/FMRP expression and expression of genes in the mTOR-signal-pathway functionally interact in the granulosa cells of the female germline and offer novel diagnostic points for optimization of infertility treatment for women with impaired folliculogenesis and/or poor ovarian reserve.

Trial registration number: not needed

P-554 Novel mutations in PLCζ: Expanding mutational and phenotypic spectrum associated with male Infertility

Abstract withdrawn by the authors

P-555 Can gene expression profiling help characterize human spermatogenesis in infertile men?

B. Barker[1], S. Cheung[1], A. Parrella[1], Z. Rosenwaks[1], G.D. Palermo[1]

[1]Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, NEW YORK, U.S.A.

Study question: Can gene products isolated from infertile men shed light on seminiferous tubule function and gamete competence?

Summary answer: Loss of DNA repair and apoptotic gene expression provides insight into the likelihood of assisted reproductive technology (ART) success.

What is known already: Evaluating human semen characteristics, even when using the most stringent criteria, has limited predictive value in terms of spermatozoa performance, even when used for ART. Moreover, standard semen analysis is inadequate for predicting reproductive outcome in men with unexplained infertility. As a result, attempts have been made to detect ploidy, DNA integrity, and the maturational status of the spermatozoon, as well as to conduct highly detailed morphologic assessments. Epigenetic assessment by profiling RNA transcripts in the sperm cell has been proposed as an alternative method to screen the male partner for infertility and predict pregnancy outcome.

Study design, size, duration: During the past year, we have analyzed the expression of genes involved in meiotic spermatogenesis in relation to reproductive outcome. RNA sequencing was carried out on the specimens of 13 consenting men.

By sequencing the genome, we compared the gene expression of ejaculated specimens from 5 infertile couples who were able to conceive with those of 8 fertile couples acting as controls.

Participants/materials, setting, methods: Ejaculated spermatozoa were used to isolate total RNA using a commercially available spin column kit. The RNA samples were then made into paired-end libraries. Pilot paired-end 76bp RNA-Seq using an Illumina platform (NextSeq 500) was performed and expanded to 60M reads. Expression values were calculated in fragments per kilobase of transcript per million fragments mapped reads (FPKM) and normalized read counts.

Main results and the role of chance: The infertile group (N=5) had a mean age of 37.6±3. The average semen parameters were: a concentration of 45.3±15 x10^6/mL, with 45.2±14% motility and 2.7±2% morphology. These men underwent 5 ICSI cycles with their female partners, resulting in a fertilization rate of 71.4% (30/42), with no pregnancies.

The control couples (n=8) had a mean age of 32.8±4 with an average sperm concentration of 42.4±13 x10^6/mL, with 44.2±11% motility and 2.9±2% morphology. These men underwent 8 ICSI cycles with their female partners, resulting in a fertilization rate of 79.3% (23/29) and all delivered.

A total of 86 genes were differentially expressed ($P<0.001$) between the infertile and control cohorts. Of them, 24 genes were overexpressed and 62 were under-expressed. Specifically, DNA repair genes (*APLF*, *CYB5R4*, *ERCC4*, and *TNRFSF21*) and apoptotic modulating genes (*MORC1*, *PIWIL1*, and *ZFAND6*) were remarkably under-expressed ($P<0.001$) in the study cohort. *MORC1* and *PIWIL1* were also significantly under-expressed in NOA men ($P<0.0001$).

Limitations, reasons for caution: This study profiles men with various stages of spermatogenesis and must be confirmed in a larger cohort. While the contribution of the female partner cannot be excluded, gene expression profiling of infertile men may serve as an assay to measure seminiferous tubule function and reproductive potential of the male gamete.

Wider implications of the findings: Deep sequencing of sperm RNA is a reliable and reproducible technique that may aid in the diagnosis and screening of infertile men. Epigenetic analysis demonstrated that DNA repair and apoptosis genes are linked to seminiferous tubule function, indicating that their involvement in meiosis and apoptosis is typical of germ cells.

Trial registration number: N/A

P-556 Assessing male gamete production and the impact of spermatozoa from azoospermic men on embryonic development by genome profiling

A. Melnick[1], S. Cheung[1], Z. Rosenwaks[1], G.D. Palermo[1]

[1]Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.

Study question: Can NGS of DNA isolated from surgically retrieved specimens identify the genes involved in gamete production and the impact of spermatozoa on embryonic development?

Summary answer: Men with secretory azoospermia have a mutated set of genes responsible for producing spermatozoa that compromises meiotic function and impairs embryonic development.

What is known already: Azoospermia accounts for about 15% of male factor infertility cases. Although azoospermia is rarely caused by pre-testicular factors, the most common forms are testicular and post-testicular. The

post-testicular type is due to obstruction, congenital or acquired, but the more complicated type is secretory azoospermia, where scattered functional germinal epithelium strive to support the germline meiotic process in the generation of spermatozoa.

Study design, size, duration: Specimens were provided by consenting men who were being treated at our center for infertility. NGS assessment was carried out on the surgically retrieved spermatozoa from 15 azoospermic men, who were characterized as obstructive (OA) post-vasectomy or non-obstructive (NOA) according to their spermatogenetic profile. Since specific gene mutations may affect ICSI clinical outcome, they were assessed and compared between the two etiologies.

Participants/materials, setting, methods: DNA was extracted and amplified from at least 500 spermatozoa (DNA concentration, 395±217 ng/ul; quality, 1.7±0.1 nm). NGS was performed, and gene mutations, duplications, and deletions were detected using CLC Genomics Server 9.0. Genes were considered duplicated or deleted when the read depth was >1.5 or <0.5 times the median read depth in the control. Gene mutation profiles of the OA and NOA men, in relation to their ability to generate a pregnancy, were assessed.

Main results and the role of chance: Of the 15 couples (paternal age, 41.2±6yrs; maternal age, 39.5±4yrs), 9 OA men underwent surgical sperm retrieval with a concentration of $2.0\pm3\times10^6$/ml and 0.5±1% motility. Six NOA men yielded spermatozoa with a concentration of $0.03\pm0.1\times10^6$/ml and 0.3±1% motility. NGS assessment showed no significant differences in sperm aneuploidy between the groups.

OA patients underwent 9 ICSI cycles, resulting in a pregnancy and delivery rate of 66.7% (6/9). OA men shared mutations of the SPINK14 and NXF2B genes, involved in serine protease inhibition and mRNA export from the nucleus to the cytoplasm, respectively. Interestingly, in all OA patients unable to generate a pregnancy, only the PRB1 gene was found to be duplicated.

NOA patients treated in 6 ICSI cycles, with a pregnancy and delivery rate of 50% (3/6), had shared mutations in 129 genes ($P<0.0001$). Clustering of these genes demonstrated that they were most involved in mRNA transcription (n=27), spermatogenesis (n=16), DNA repair (n=15), centrosomal function (n=14), and apoptosis (n=12).

When this assessment was performed in the NOA group, the fertile cohort had 1 gene duplicated (MPIG6B), related to organ development, while the infertile cohort had 2 deleted (MBD5 and RBFOX2) and 3 duplicated (CSRNP3, ARL4C, FRMPD1) that support early embryonic development.

Limitations, reasons for caution: This study contains a limited number of observations, which should be compared to azoospermic men with complete spermatogenic arrest or germ cell aplasia. Gene clustering and its function require further investigated in order to define the etiology of male infertility and predict reproductive outcome.

Wider implications of the findings: Screening men for gene mutations can potentially help characterize the spermatogenic function of their germinal epithelium. This study may help to identify patients who would benefit from testicular sampling. Moreover, assessment of the genome and epigenome will shed light on the etiology of this severe form of infertility.

Trial registration number: N/A

P-557 Interpreting the spermatogenic profile of NOA men through transcriptome analysis

A. Parrella[1], B. Barker[1], Z. Rosenwaks[1], G.D. Palermo[1]
[1]*Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.*

Study question: Can transcriptome analysis be used to characterize the spermatogenic function of NOA men?

Summary answer: Transcriptome analysis can be used to characterize the spermatogenic function of NOA men by predicting whether spermatozoa can be retrieved via testicular biopsy.

What is known already: In men with non-obstructive azoospermia (NOA) who undergo micro-testicular sperm extraction (TESE), about 40-60% of procedures fail to yield spermatozoa. The histological variations reported range from hypospermatogenesis, to spermatogenic arrest, to Sertoli-cell-only syndrome.

During spermatogenesis, precursor diploid stem cells are needed to form haploid sperm cells. Within this developmental process, various molecular mechanisms are involved, including signal transduction, DNA repair, DNA packaging, and chromosome condensation and silencing. These are required for steroidogenesis, spermatogenesis, and spermiogenesis, respectively. In the event that any of these mechanisms is compromised, spermatogenic arrest could occur, leading to the failure of spermatozoa retrieval after testicular biopsy.

Study design, size, duration: During the past year, we have assessed the expression of genes in relation to spermatogenesis and reproductive outcome. RNA sequencing (RNA-Seq) was performed on the specimens of 6 consenting men. Four non-obstructive azoospermic men where no sperm was found (NOA-) and one non-obstructive azoospermic man with recovered spermatozoa (NOA+) were compared to one obstructive azoospermia (OA) control.

Participants/materials, setting, methods: RNA was isolated from testicular biopsy tissues from 5 NOA and 1 OA men using a spin column commercial kit. No Y microdeletions were detected for any patients. Several embryologists extensively searched (71 ± 10 minutes) samples not demonstrating spermatozoa to confirm a failed TESE attempt. RNA isolates were sequenced by Illumina HiSeq at 2x150bp configuration per lane with ~64M reads per sample. Genes with $P<0.001$ and an absolute log2fold change >1 were considered significant.

Main results and the role of chance: This study included 6 consenting men: 1 NOA+, 4 NOA-, and 1 OA control. The NOA+ man (female age, 38 yr; male age, 45 yr) had a sperm concentration of 1.2×10^6/mL with 0.05% motility. The fertilization rate was 66.7% (8/12), and a clinical pregnancy was achieved. No spermatozoa were found in the 4 NOA- groups (male age, 42.5±6 yrs). The OA control (female age, 38 yr; male age, 39 yr) had a concentration of 21×10^6/mL with 48% motility. This couple also had a clinical pregnancy. A total of 8 genes were significantly under-expressed in all NOA men, regardless of whether spermatozoa were present (*FAM57B*, *GGN*, *OPLAH*, *OXCT2*, *MEX3D*, *WFDC3*, *TSKS*, *FAR2P1*), and are mainly involved in spermatogenesis and DNA double-strand repair.

A total of 20 genes were significantly under-expressed exclusively in the NOA- groups, which failed to yield spermatozoa compared to the OA control.

Among those genes, 6 were related to steroidogenesis (*AKAP4*, *DKKL1*, *PGK2*, *SLC26A8*, *ELFN2*, *POM121L12*), 4 were associated with spermatogenesis (*ACSBG2*, *CATSPERD*, *CATSPERG*, *ODF1*, *BOD1L2*), 7 were linked to spermiogenesis (*PRMI*, *PRM2*, *TNP1*, *H1FNT*, *DYDC1*, *HIST3H3*, *HIST1H2AA*), 1 involved cell-cell adhesion (*CRISP2*), and 1 was associated with negative regulation fat cell differentiation (*FAM95B1*).

Limitations, reasons for caution: Gene expression profiles of men failing to yield spermatozoa must be confirmed by a larger cohort. While the contribution of the female partner cannot be excluded, gene expression profiling of infertile men may serve as an assay to assess seminiferous tubule function and the reproductive competence of the male gamete.

Wider implications of the findings: Deep sequencing of sperm RNA is a reliable and reproducible technique that may aid in the diagnosis and screening of infertile men. Epigenetic analysis showed that DNA repair and spermatogenic genes are linked to seminiferous tubule function, suggesting their involvement in meiosis and apoptosis, typical of germ cells.

Trial registration number: N/A

P-558 A therapeutic approach for couples with compromised sperm DNA integrity and a history of aneuploid embryos

A. Petrini[1], A. Parrella[1], P. Xie[1], Z. Rosenwaks[1], G.D. Palermo[1]
[1]*Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.*

Study question: Does selecting the highest progressively motile spermatozoa with optimal genomic integrity enhance the likelihood of generating euploid embryos?

Summary answer: Microfluidic sperm selection (MFSS) identified spermatozoa with the highest chromatin integrity, capable of generating euploid embryos in couples with a history of persistent implantation failure.

What is known already: Genomic impairment of the male gamete can hinder embryo cleavage and implantation. Dysfunction of the male genital tract increases both single-strand (ss) and double-strand (ds) DNA nicks and breaks that can inhibit the developmental competence of embryos.

In particular, ds DNA breaks present in the spermatozoa of fertile donors, at a concentration as high as 40%, may contribute to embryo aneuploidy with consequent implantation impairment.

Study design, size, duration: From October 2016 through January 2019, nine consenting couples with a history of embryo aneuploidy and/or recurring implantation failure and a male partner with high sperm chromatin fragmentation (SCF) in their ejaculate underwent a new ICSI cycle in which semen specimens were processed by density gradient centrifugation (DGC) and MFSS.

Participants/materials, setting, methods: SCF was measured by TUNEL on raw semen specimens as well as after DGC and MFSS. ICSI with pre-implantation genetic testing for aneuploidy (PGT-A) was carried out with spermatozoa selected by the two different methods. Fertilization and clinical pregnancy outcomes were assessed and compared between the two sperm selection methods. Embryo implantation and pregnancies were recorded after replacement of thawed euploid blastocysts.

Main results and the role of chance: A total of 9 men of average age 43±12 years had a mean sperm concentration of 55.1±47 x 10^6/mL, 30±14.7 motility, and 2.4±1% morphology. After DGC and MFSS, the sperm concentration was 36.2±48 and 11±17 x 10^6/mL, with 59±41% and 97±4% motility, respectively ($P<0.0001$).

The raw sample sperm morphology improved from 2.4±1% to 4.0±1% after MFSS, while after DGC it was 3±1%. The average SCF decreased from 31% in raw samples to 21% following DGC, and became 1.4% after MFSS processing ($P<0.0001$).

These couples (female partners, 37±5 years) underwent 12 cycles with DGC-selected spermatozoa and achieved a fertilization rate of 78% (75/96), which generated 30% (12/40) morphologically good-quality embryos. PGT-A did not show any euploid embryos for transfer. Subsequently, the couples underwent ICSI cycles with MFSS, showing a fertilization rate of 73% (76/104), with 41% (14/34) good-quality embryos.

In this group, 24% (8/33) of euploid embryos were identified and cryopreserved.

Four couples received a thawed single euploid blastocyst and all 4 became pregnant ($P<0.0001$), resulting in a clinical pregnancy rate per cycle of 44% (4/9) and 100% per transfer.

Limitations, reasons for caution: This study represents a preliminary experiment on a small number of subjects.

While the oocyte contribution to aneuploidy cannot be discounted, MFSS was able to yield the highest progressive motile spermatozoa with optimal genomic integrity capable of enhancing the chances of generating euploid embryos.

Wider implications of the findings: The occasional presence of ds DNA in the male gamete has been considered responsible for contributing to embryo aneuploidy. MFSS of highly motile and genetically competent male gametes may enhance the chances of obtaining a euploid conceptus for transfer.

[3]*University of Western Australia & Women and Infants Research Foundation, Division of Obstetrics and Gynaecology, Perth, Australia*

[4]*University of Copenhagen, Department of Growth and Reproduction & EDMaRC, Copenhagen, Denmark*

[5]*University of Melbourne, Department of Obstetrics and Gynaecology, Melbourne, Australia*

Study question: Does *in-utero* exposure to circulating maternal phthalate metabolites influence the timing of menarche?

Summary answer: Metabolites in the middle tertiles of high molecular weight (MW) phthalate MCMHP and low MW phthalate MEP were associated with later and earlier menarche respectively.

What is known already: Phthalates are ubiquitous environmental chemicals suspected to be endocrine disruptors, potentially impacting reproductive development. Animal studies, and limited human data, suggest that antenatal exposure influences pubertal timing. Understanding the influence of antenatal phthalate exposures on reproductive development is important as they are ubiquitous and present within cosmetics. Menarchal age is a sentinel event for reproductive function and long-term health. Preliminary data from a large, population based pregnancy cohort suggested that antenatal phthalate exposures influenced menarchal age. We aimed to measure the association between maternal phthalate metabolites (as a marker of exposure) and timing of menarche across the entire birth cohort.

Study design, size, duration: The Western Australian Pregnancy Cohort (Raine) Study is a longitudinal study of children born in 1989-1991 (1413 female infants born). Maternal serum was collected at 18 and 34 weeks of gestation, pooled and assayed to determine concentrations of 32 phthalate metabolites of 15 phthalate diesters. Phthalate metabolite concentrations were available for up to 516 mothers, BMI was measured at 8 years (n=324). Prospective recording of menarchal timing was available (n= 231).

Participants/materials, setting, methods: Maternal serum was stored at -80^{0}C. Aliquots from both samples were combined as an estimate of antenatal exposure.

Phthalate metabolites were measured by isotope diluted LC-MS/MS. Metabolites of five phthalate di-esters were detected above the limit of detection, and were included in the analysis: mono-ethyl phthalate (MEP), mono-iso-butyl phthalate (MiBP), mono-n-butyl phthalate (MnBP), mono-(2-ethylhexyl) phthalate (MEHP), mono-(2-ethyl-5-carboxypentyl) phthalate (MECPP), Mono-(2-carboxymethyl-hexyl) phthalate (MCMHP), mono-iso-nonyl phthalate (MiNP), mono-(carboxy-iso-octyl) phthalate (MCiOP).

Timing of menarche was prospectively recorded.

Main results and the role of chance: Demographic characteristics of adolescents with maternal phthalate metabolite exposure and menarchal age data available, were similar to cohort members with missing data, apart from having a higher family income. Prospective data on age at menarche was available for n=231 girls (median age 12.9 years [IQR 12.0-13.6].

All models were adjusted for maternal education, smoking during pregnancy; expected birthweight ratio (observed birth weight over median birth weight appropriate for maternal height), sex, nulliparity and gestational age; and body mass index (BMI) at the 8 year follow up.

Maternal concentration of middle tertile MCMHP was associated with later menarche (adjusted hazard ratio [aHR] 0.690, 95% confidence intervals [CI] 0.499-0.953, p=0.025), (concentrations 1.04 - 1.73 ng/ml), when compared with lowest tertile MCMHP. There was no association between the highest tertile MCMHP and age at menarche, (aHR 0.759, 95% CI 0.548-1.052, p=0.098). Middle tertile MEP, (concentration 1.19 - 4.65 ng/ml), was associated with earlier menarche (aHR 1.45, 95% CI 1.033-2.037, p=0.032) compared with lowest tertile MEP, although there were no association of the highest tertile MEP with menarchal age. (aHR 1.019, 95% CI 0.740-1.403, p=0.907).

There were no associations of menarchal age with maternal phthalate metabolite concentrations when the metabolites were categorised as 'detectable' or 'non-detectable'.

Limitations, reasons for caution:

This study is limited by the sample size, prolonged storage of maternal serum samples, and multiple comparisons. The associations do not prove causation and we cannot account for postnatal environmental exposures that may influence age at menarche, and no dose response relationships between phthalates exposure and menarchal age were noted.

Wider implications of the findings: Irrespective of proven causation, the study findings are important, as the potential association of MEP exposure with an earlier menarche is consistent with the literature. Further it is important to

note that it is believed that some phthalates influence body fat distribution which is well known to modulate menarchal age.
Trial registration number: not applicable

P-560 Ovarian reserve and oocyte maturation rates are not correlated with the expression of aging markers in human cumulus cells

M. Barragan[1], D. Cornet[1], S. Balcells[2], A. Rodriguez[1], D. Grinberg[2], R. Vassena[1]
[1]*Clinica Eugin, Assisted reproduction, Barcelona, Spain*
[2]*Universidad de Barcelona, Department of Genetics- Microbiology and Statistic-CIBERER- IBUB- IRSJD, Barcelona, Spain*

Study question: Does the expression of somatic aging markers in human cumulus cells correlate with age, ovarian reserve and oocyte maturation rates?
Summary answer: While *TXNIP* and *CLU* were positively correlated with age, none of the aging markers tested were correlated with ovarian reserve or oocyte maturation rates.
What is known already: A distinct gene expression signature has been associated with ageing in several somatic tissues, including brain, muscle, liver and kidney. Reproductive aging in women is associated with a decrease in both ovarian reserve and oocyte developmental competence. The acquisition of developmental competence relies on interactions of the oocytes with the surrounding somatic cumulus cells (CC). We therefore hypothesize that CC from follicles of aged women might also show the characteristic somatic aging gene expression signature, affecting the process of oocyte maturation and possibly altering acquisition of oocyte developmental competence.
Study design, size, duration: This basic research study involved 82 CC samples from patients undergoing IVF recruited from March to October 2018. The mean woman age was 32 years old (SD=8.0, range 18-45), the mean ovarian reserve measured by antral follicle count (AFC) was 18.6 (SD=10.63, range 2-47) and the mean maturation, defined as the number of MII divided by the number of cumulus oocyte complexes at OPU, was 72.2% (range 20%-100%).
Participants/materials, setting, methods: For each participant, CC samples were pooled after oocyte denudation. Total RNA was extracted using a phenol-free method, reverse transcribed to cDNA using random hexamers and expression of 11 markers of aging was performed by qPCR (in triplicate) and normalized against *TBP*. Expression levels of aging markers were then plotted against woman age, ovarian reserve and oocyte maturation rates. Non-parametric Spearman's correlation were used to determine the relationship between variables.
Main results and the role of chance: As expected, our results showed lower ovarian reserve and oocyte maturation rates with increasing woman age (r_s=-0.42, p=0.00008) and (r_s=-0.3, p=0.0078), respectively. Six of the 11 genes analyzed (*LYZ, TXNIP, CLU, FABP3, TGFBR3 and ANXA5*) were expressed in human CCs. Woman age showed a moderate positive correlation with *CLU* (r_s=0.23, p=0.0362), a secreted chaperone involved in cell death and tumor progression and *TXNIP* (r_s=0.36, p=0.0007), a tumor suppressor gene involved in redox regulation and recently described as a non-invasive biomarker of oocyte quality in the corona cells of human oocytes. The remaining aging markers did not correlate with age, ovarian reserve or oocyte maturation rates (r_s<0.1 and p>0.05).
Limitations, reasons for caution: CC analyzed in this study are obtained after controlled ovarian stimulation. Thus, the CC transcriptome obtained might differ from CC obtained from non-stimulated follicles.
Wider implications of the findings: The general lack of correlation between the signature observed in CCs from women of different ages and that previously found in aged human tissues suggests that these ovaries were not prematurely aged, but rather at the end of their reproductive life.
Trial registration number: not applicable

P-561 impact of melatonin and resveratrol on embryo quality in poor prognosis IVF patients

M. Takahashi, B.Sc.[1], N. Aono[1,2], Y. Nakajo[1], H. Hattori[1], Y. Nakamura[1], N. Okuyama[2], M. Kataoka[1], T. Tai[1,2], M. Toya[1], T. Hashimoto[2], H. Igarashi[1], K. Kyono[1,2]
[1]*Kyono ART Clinic, Department of Obstetrics and Gynecology, Sendai- Miyagi, Japan*
[2]*Kyono ART Clinic Takanawa, Department of Obstetrics and Gynecology, Tokyo, Japan*

Study question: Can melatonin, resveratrol, or a combination of the two improve embryo quality in poor prognosis IVF patients? How long is the appropriate administration period?
Summary answer: More than two weeks administration of melatonin, resveratrol, or a combination of the two significantly improved embryo quality in poor prognosis IVF patients.
What is known already: Oxidative stress is well known as a factor of aging-related deterioration of oocyte quality. Recently, limited evidence has suggested that antioxidants improve fertility in animal models and ART cycles. In assisted reproductive technology (ART), melatonin has been reported to improve embryo quality. Meanwhile, resveratrol acts not only as an antioxidant but also as an activator of mammalian sirtuin-1 (SIRT1). SIRT1 behaves as a protector from many aging-related diseases. However, there have been no clinical studies that evaluated the benefit of resveratrol for embryo quality. Furthermore, the appropriate period of administration has not yet been determined.
Study design, size, duration: This retrospective study was conducted at a private clinic from October 2010 to September 2018. A total of 257 patients who had failed to conceive in an ART cycle were included and divided into three groups: melatonin administration (MLT group), resveratrol administration (RSV group), and melatonin and resveratrol co-administration (MLT/RSV group). These were divided by administration period as follows: less than two weeks (2w), two to three weeks (3w), and 4 weeks or more (4w).
Participants/materials, setting, methods: ycle numbers were 161 in the MLT group (aged 39.8±3.6 years), 35 in the RSV group (aged 40.0±3.5 years), and 136 in the MLT/RSV group (aged 40.6±3.2 years). We designated the previous ART cycle of each patient as control. Development of each embryo was compared with that of its control. Patients took 2 mg/day melatonin and/or 250 mg/day resveratrol before and/or during controlled ovarian stimulation in an IVF cycle.
Main results and the role of chance: In the MLT, RSV, and MLT/RSV groups, AMH levels were 1.5±1.6ng/ml, 1.2±2.4ng/ml, and 1.3±1.4ng/ml, respectively. The number of collected oocytes in these groups were 5.2±4.7, 4.1±3.7, and 4.6±3.3, respectively. In the MLT group, 2w administration significantly improved fertilization rate [69.5% (383/551) vs. 57.1% (343/551), p<0.01] and day3 good-embryo rate [30.3% (109/360) vs. 16.1% (51/316), p<0.01] compared with control. Furthermore, 2w, 3w, and 4w administration significantly improved good-blastocyst rate [12.3% (65/528), 7.1% (3/42), 8.5% (6/71) vs. 0.2% (1/557), respectively, p<0.01]. In the RSV group, 2w administration significantly improved fertilization rate [72.0% (18/25) vs. 45.1% (46/102), p<0.05] and 2w and 4w administration significantly improved good-blastocyst rate [18.2% (4/22), 15.6% (7/45) vs. 1.3% (1/80), respectively, p<0.01]. In the MLT/RST group, 2w, 3w, and 4w administration significantly improved good-blastocyst rate [15.3% (24/157), 22.7% (20/88), 14.5% (25/172) vs. 0.7% (3/402), respectively, p<0.01] compared with control. In the MLT and MLT/RSV groups, clinical pregnancy rate was significantly higher than control. In the RSV group, clinical pregnancy rate tended to be higher, although the difference was not statistically significant. There were no notable side effects during or after MLT and/or RSV administration.
Limitations, reasons for caution: An age bias may exist among the administration period. Advanced age patients tended to be included in 4 weeks or more. A larger scale, more extensive clinical study, such as a well-designed double blind randomized placebo-controlled study, is needed to recommend the use of melatonin and/or resveratrol in clinical practice.
Wider implications of the findings: This study is the first clinical trial to demonstrate the efficacy of resveratrol in poor prognosis IVF patients. Although administration of melatonin or resveratrol alone gave improved embryo quality, the combination of melatonin and resveratrol having synergistic effects on embryo quality, might be more favorable for poor prognosis IVF patients.
Trial registration number: N/A

P-562 Optimal metabolic and hormonal modulation induced by the combination of acetyl-L-carnitine, L-carnitine, L-arginine and N-acetyl cysteine in overweight/obese PCOS patients – A pilot study

M.A. Virmani[1], A.D. Genazzani[2], A. Napolitano[2], A. Prati[2], M. Blazej[3]

[1]Alfasigma HealthScience BV, Innovation- Research and Development, Utrecht, The Netherlands
[2]University di Modena and Reggio Emilia, Department of Obstetrics and Gynecology, Modena, Italy
[3]Posnan University of Medical Sciiences, Department of Gynecological Endocrinology, Poznan, Poland

Study question: Can the metabolic and endocrine impairments seen in overweight/obese polycystic ovary syndrome (PCOS) patients be ameliorated by supplementation with specific metabolic and nutrient compounds.
Summary answer: The test combination was greatly effective in overweight/obese PCOS patients with particular efficiency in those with hyperinsulinemia as tested with the oral glucose tolerance test.
What is known already: PCOS is a frequent disease characterized by several endocrine impairments and frequent metabolic abnormality, that is a compensatory hyperinsulinemia. The role of obesity and exercise has been suggested in this disorder. We have examined the role of supplementation with compounds that may modulate the metabolism and thereby also the endocrine parameters in this disorder.
Study design, size, duration: A total of 30 overweight/obese patients were evaluated. Patients were administered the combination of the compounds per os for at least 12 weeks. The test combination included acetyl-L-carnitine (ALC) 250 mg, L-carnitine (500 mg), L-arginine (500 mg) and N-acetylcysteine (NAC) (50 mg).
Participants/materials, setting, methods: All patients were evaluated before and after a 12-week treatment interval for LH, FSH, estradiol (E2), progesterone (P), androstenedione (AS), insulin, plasma levels, lipid profile, oral glucose tolerance test (OGTT) for glucose, insulin and c-peptide response.
Main results and the role of chance: The integrative treatment decreased AS and insulin as well as LDL and HOMA index in all the group of PCOS. Also, insulin and c-peptide response to OGTT were significantly reduced. Considering patients according to the insulin response to OGTT the combination of integrators was more effective in PCOS subjects with hyperinsulinemia (77% of the patients) on both metabolic and hormonal profiles. In addition, the insulin response to OGTT was greatly reduced.
Limitations, reasons for caution: This is a small pilot study and more data are needed from a larger study.
Wider implications of the findings: This study suggests that in overweight/obese PCOS patients there is possibility to ameliorate metabolic and endocrine parameters with supplementation of specific metabolism modulating compounds.
Trial registration number: PXW-001B

P-563 Poor ovarian response in ART as a predictor for pregnancy complications

S. Farladansky-Gershnabel[1], M. Sharon Weiner[1], Y. Furman[1], I. Heusler[1], G. Cohen[1], A. Hershko-Klement[1], A. Wiser[1], A. Berkovitz[1], A. Shulman[1]
[1]Meir medical center, Obstetrics and Gynecology, Kfar Saba, Israel

Study question: Is there a possible association between poor ovarian response in artificial reproductive technology (ART) and pregnancy complications?
Summary answer: Ovarian poor response in ART is an independent risk factor for gestational diabetes mellitus (GDM) and intrauterine growth restriction (IUGR).
What is known already: The term "poor responder" refers to patients with diminished ovarian reserve. Approximately 10% of women seeking fertility treatment fit this definition; very often, older patients presenting with low ovarian reserve.

It is generally accepted that obstetric and perinatal complications (GDM, preeclampsia, IUGR) are more common in older women. Whether this is due to the general aging process or due to the aging of the ovary and the ovum, is not known. The results of studies that investigated this issue were inconclusive.
Study design, size, duration: Retrospective, case-control study, conducted at a tertiary, university-affiliated IVF center, between 2011 and 2017. Patients who conceived and delivered after ART treatment were analyzed. 75 Poor responders (3 or fewer oocytes retrieved) after stimulation with gonadotropins (study group) were matched by the same day as the ovum pick-up (OPU) to 75 normo-responders (4 or more oocytes retrieved).
Participants/materials, setting, methods: A total of 150 patients were included: 75 poor responders were compared to 75 normo-responders. Main outcome measures were the incidence of preeclampsia (PET), gestational diabetes mellitus (GDM) and neonatal birth weight.
Main results and the role of chance: There were no significant differences in maternal age, gravity, parity, maternal BMI, gestational age at delivery, mode of delivery and Apgar score between groups. The use of intracytoplasmic sperm injection (ICSI) was similar between groups (P=0.08). Poor responders had higher incidence of gestational diabetes mellitus (GDM) (27% compared to 6.8%, P=0.001) and higher incidence of intrauterine growth restriction (IUGR) (13.5% compared to 4.1%, P=0.04) than did normo responders. Although poor responder patients experienced a higher incidence of preeclampsia (8.1% compared to 5.4%), this did not achieve statistical significance (P=0.74). Poor responders with GDM were of similar age (34.6+5.6 vs. 34.4+5.1, P=0.8) and BMI (27.8+6 vs. 24.8+5.4, P=0.06) as poor responders without GDM. However, normo-responders who had GDM were older (34.6+3.7 vs. 32.4+5.8, P=0.01) and had higher BMI (29.5+0.6 vs. 22.9+4.7, P=0.008) than normo-responders without GDM.
Limitations, reasons for caution: This study is retrospective and the presence of residual unknown bias cannot be excluded.
Wider implications of the findings: Poor responders had higher incidence of GDM and IUGR compared to women with normal ovarian response. These findings were not due to older maternal age or higher maternal BMI. This may have a wider implication on the mother and the fetus, and appropriate counseling should be considered.
Trial registration number: Not applicable.

P-564 Dual trigger of final oocyte maturation in overweight women improves oocyte maturity rates during GnRH antagonist cycles in women of advanced age.

K.E. Park[1], H.R. Park[1], S. Park[1], J.H. Lee[1], H.G. Park[1], K. Chang[1]
[1]Dion fertility center, Department of Obstetrics and Gynecology, Hwaseong, Korea- South

Study question: Does dual trigger with GnRH agonist and human chorionic gonadotropin improve IVF outcomes according to body-mass index (BMI) of women compared with hCG-only trigger?
Summary answer: Dual trigger in women ≥35 years old improves oocyte maturity rate of overweight Korean women (BMI ≥ 23 kg/m^2).
What is known already: Dual trigger is a feasible alternative to hCG in GnRH antagonist cycles.
Study design, size, duration: This is a retrospective cohort study including 235 infertile couples with 262 completed IVF/ICSI-ET cycles between January 2017 and September 2018 in single Korean IVF unit.
Participants/materials, setting, methods: Patients were categorized in four groups: young (<35 years), normal weighted women (BMI < 23 kg/m^2) (G1 = 77 cycles), young, overweighted women (BMI ≥ 23 kg/m^2) (G2 = 52 cycles), old (≥35 years), normal weighted women (G3 = 88 cycles), old, overweighted women (G4 = 45 cycles). In each group, IVF outcome measures were compared between dual triggering and hCG-only triggering. The primary outcome measure was the oocyte maturation rate.
Main results and the role of chance: Oocyte maturation rate in dual triggering was significantly higher than that in hCG-only triggering, only in old, overweighted women group (81.9%, 70.1%, respectively, P =0.03). Clinical pregnancy rate in dual triggering also had a higher tendency than that in hCG-only triggering, only in same group (52.9%, 28.6%, respectively, P =0.05). There were no significant differences in other groups, even in overall.
Limitations, reasons for caution: Because of a limitation of retrospective study, our present data should be confirmed by a prospective study. Although many investigators have revealed dual triggering would be helpful whether normal or poor responders, our data did not confirm the effect of dual trigger in overall.
Wider implications of the findings: This is the first report studying the effect of dual trigger according to the BMI. Our study provides the preference dual trigger for final oocyte maturation to hCG-only trigger when women is old and overweighted.

Trial registration number: N/A

P-565 HCG-induced AREG stimulates aromatase expression in human granulosa-lutein cells: a mechanism for E2 production in the luteal phase

L. Fang[1], Y. Yu[1], L. Yiran[1], W. Sijia[1], R. Zhang[1], Y. Guo[1], S. Ying-pu[1]

[1]The First Affiliated Hospital of Zhengzhou University, Center for Reproductive Medicine, Zhengzhou, China

Study question: Does amphiregulin (AREG), the most abundant and important epidermal growth factor receptor (EGFR) ligand in the follicular fluid, regulate aromatase expression in human granulosa-lutein (hGL) cells?
Summary answer: AREG mediates the hCG-induced up-regulation of aromatase expression and estradiol (E2) production in hGL cells.
What is known already: AREG expression is rapidly induced by human chorionic gonadotropin (hCG) in hGL cells and mediates physiological functions of luteinizing hormone (LH)/hCG in the ovary. EGFR protein is expressed not only in preovulatory follicles but also throughout the luteal phase of menstrual cycle. After LH surge, human corpus luteum secretes high levels of E2 which regulates various luteal cell functions. Aromatase is an enzyme responsible for a key step in the biosynthesis of E2. However, whether AREG regulates aromatase expression and E2 production in hGL cells remains unexplored.
Study design, size, duration: This is an experimental study which was performed over a 1-year period. *In vitro* investigations were directed towards examining the role of AREG in regulation of aromatase expression and E2 production in primary hGL cells.
Participants/materials, setting, methods: Primary hGL cells were obtained from women undergoing *in vitro* fertilization (IVF) treatment in an academic research center. Aromatase mRNA and protein levels were examined after exposure of hGL cells to recombinant human AREG or hCG. The EGFR tyrosine kinase inhibitor AG1478, PI3K inhibitor LY294002 and small interfering RNAs (siRNAs) targeting EGFR and AREG were used to verify the specificity of the effects and to investigate the underlying molecular mechanism.
Main results and the role of chance: Treatment of hGL cells with AREG stimulated aromatase expression and E2 production. Using pharmacological inhibitor and specific siRNA, we revealed that AREG stimulated aromatase expression and E2 production via EGFR-mediated activation of the AKT signaling pathway. In addition, inhibition of EGFR activity and AREG knockdown attenuated hCG-induced up-regulation of aromatase expression and E2 production. Follicular fluid and serum were collected from 65 infertile women during IVF treatment.Importantly, the protein levels of AREG in the follicular fluid were positively correlated with the serum E2 levels after 2 days of oocyte pick-up in the IVF patients.
Limitations, reasons for caution: The *in vitro* setting of the study is a limitation which may not reflect the real intra-ovarian microenvironment. Clinical data were obtained from a small sample size.
Wider implications of the findings: Our results provide the first evidence that hCG-induced AREG contributes to the aromatase expression and E2 production in the luteal phase of menstrual cycle. Better understanding of the hormonal regulation of female reproductive function may help for developing new strategies for the treatment of clinical infertility.
Trial registration number: Not applicable.

P-566 Luteal after follicular-phase-stimulation in the same ovarian cycle is a promising strategy to increase the chance of delivery in poor responder women fulfilling Bologna Criteria

A. Vaiarelli[1], D. Cimadomo[1], M. Giuliani[1], S. Colamaria[1], C. Argento[1], S. Ferrero[1], L. Buffo[2], F. Fiorini[3], R. Venturella[4], E. Trabucco[5], A. Conforti[6], C. Alviggi[6], L. Rienzi[1], F.M. Ubaldi[1]

[1]Clinica Valle Giulia, Genera- Centers for Reproductive Medicine, roma, Italy
[2]Genera Veneto, Genera- Centers for Reproductive Medicine, Marostica, Italy
[3]Genera Umbria, Genera- Centers for Reproductive Medicine, Umbertide, Italy
[4]Magna Graecia' University, Department of Obstetrics and Gynecology-', Catanzaro, Italy
[5]Clinica Ruesch, Genera- Centers for Reproductive Medicine, Napoli, Italy
[6]University of Naples Federico II University., Departement of Neuroscience- Reproductive Science and Odontostomatology, Napoli, Italy

Study question: Is Luteal Phase-Stimulation (LPS) after Follicular-Phase-Stimulation (FPS) in the same ovarian cycle (Duostim) an efficient strategy for poor responder women fulfilling the Bologna Criteria?
Summary answer: LPS performed after FPS in women fulfilling the Bologna criteria increased the overall live-birth-rate (LBR) per intention-to-treat (ITT) from 7% (FPS-only) to 15% (DuoStim)
What is known already: Three theories of follicle recruitment were postulated to picture the dynamism of folliculogenesis: 'continuous recruitment', 'single recruitment' and 'wave' theories. The advances in IVF such as blastocyst culture, aneuploidy-testing and vitrification encouraged clinicians to maximize the exploitation of the ovarian reserve via tailored stimulation protocols especially in poor-responder women. In this regard, larger cohorts of oocytes might be collected from LPS during DuoStim protocols. These oocytes showed similar developmental, chromosomal and reproductive competence as paired FPS-derived ones. Therefore, DuoStim protocol might be an intriguing option to obtain more competent blastocysts in a single ovarian cycle also in poor-responder women
Study design, size, duration: This paired observational study was performed in a private IVF clinic between January 2015 and January 2018. One hundred consecutive poor-responder women fulfilling the Bologna Criteria underwent DuoStim combined with preimplantation-genetic-testing-of-aneuploidies (PGT-A). All patients included satisfied $\geq$ 2 of the following characteristics: maternal age $\geq$ 40yr and/or $\leq$ 3 oocytes previously retrieved after conventional stimulation and/or reduced ovarian reserve (assessed as astral-follicle-count <5–7 follicles or AMH <0.5–1.1ng/ml). Couples with severe male factors were excluded.
Participants/materials, setting, methods: FPS and LPS were performed with recombinant-gonadotrophins in an antagonist protocol with the same daily dose. Final oocyte maturation was induced by agonist trigger to reduce the time of luteolysis. LPS was started 5 days after the first retrieval. All oocytes underwent ICSI, blastocyst culture, trophectoderm biopsy and vitrification. The primary outcome was LBR per ITT. Only single euploid blastocyst transfers were performed in an artificial cycle. All embryological outcomes per stimulation were also monitored.
Main results and the role of chance: One hundred patients started FPS. Mean maternal age was 42.1±1.4yr; they already went through 0.7±0.9 IVF cycles with $\leq$3 oocytes collected; their AFC was 3.8±1.2 and their AMH was 0.56±0.3 ng/ml. Ninety-one patients completed DuoStim, since 5 did not respond to FPS and 4 to LPS, respectively. Nevertheless, all the patients were included in the analysis. The total number of oocytes after FPS and LPS were 237 (mean per stimulation: 2.4±1.5) and 309 (3.1±2.2; $p<0.01$), respectively. The total number of blastocysts after FPS and LPS were 70 (0.7±0.8) and 107 (1.1±1.1; $p<0.01$), respectively. The mean blastulation rate per inseminated oocyte was 30.7%±32.8% per FPS and 36.2%±33.5% per LPS (p=NS). The number of euploid blastocysts after FPS and LPS were 14 (0.1±0.4) and 21 (0.2±0.5; p=NS), respectively. The mean euploid blastocyst rate per MII was 4.8%±12.7% per FPS and 6.6%±16.2% per LPS (p=NS). The rate of patients obtaining $\geq$1 blastocyst increased from 53% after FPS to 82% with the contribution of LPS. Similarly, the rate of patients obtaining $\geq$1 euploid blastocyst increased from 14% after FPS to 31% with the contribution of LPS. Lastly, the LBR per ITT increased from 7% after FPS to 15% after Duostim.
Limitations, reasons for caution: Single center retrospective study. No cost-effective and time to pregnancy analyses were performed. Lastly, more data are required to confirm the safety of LPS in terms of obstetrical and peri-/post-natal outcomes.
Wider implications of the findings: These data highlight that LPS in a DuoStim protocol is promising for the treatment of a thorny population of patients like poor responder women fulfilling the Bologna-Criteria.No ideal protocol has been outlined yet to manage these women.Therefore,these data encourage future trials to assess the consistency and reproduciblity of this strategy
Trial registration number: none

P-567 To explore the mechanisms of Insulin Resistance in Polycystic Ovarian Syndrome by analysis of their Body Composition before and after the lifestyle intervention

J. Lin[1], C. Su[1]

[1]Obstetrics and Gynecology Hospital of Fudan university, Gynecology, Shanghai, China

Study question: By comparing the changes of body composition in PCOS patients before and after lifestyle intervention,we wanted to know the the mechanism of IR in PCOS patients .
Summary answer: We found that lifestyle intervention improved insulin resistance by reducing body fat in obese PCOS patients or increasing skeletal muscles in non-obese PCOS patients
What is known already: Studies have shown that insulin resistance is key in the pathogenesis of PCOS.Improving the IR of PCOS patients is an important part of PCOS treatment.Lifestyle intervention can significantly reduce visceral fat content, improve insulin sensitivity, reduce androgen levels, and restore spontaneous ovulation; therefore, lifestyle intervention is the first-line treatment for PCOS patients.
Study design, size, duration: We used a prospective self-control study.89 PCOS patients were divided into two groups according to BMI: overweight and obesity group (n=46,BMI $\geqq$ 24) and non-obesity group (n=43,BMI < 24). Individualized diet and exercise intervention programs were formulated based on the results of body composition measurement(according to the results of their body fat rate, standard proportion of skeletal muscle weight) and group management. Lifestyle Intervention was for 12 Weeks.
Participants/materials, setting, methods: Before and after lifestyle intervention,all patients were tested for body composition by Inbody270 body composition analyzer.Serum follicle stimulating hormone (FSH), luteinizing hormone (LH) and total testosterone (TT) were measured by immunofluorescence chemiluminescence assay. Oral glucose tolerance test (OGTT) and insulin release test of 75 g glucose load were performed by glucose oxidase method. Blood glucose and insulin levels were measured at 0.5, 1, 2 and 3 hours after fasting and glucose administration.
Main results and the role of chance: After 12 weeks of treatment: 1.Body fat percentage of both groups significantly decreased ($p<0.01$), while only skeletal muscle mass percentage increased in the non-obese group ($p<0.01$); 2. HOMA-IR and insulin area under curve (AUC) in both groups significantly decreased ($p<0.01$). Intervention improved glucose tolerance in four diabetic patients (2 cases of obese group, 2 cases of non-obese group) . 3. The decrease of HOMA-IR in obese group was positively correlated with the decrease of body fat percentage in the obese group (r=0.368,p=0.021); while, positively correlated with the increase of skeletal muscle mass percentage in the non-obese group (r=-0.512,p=0.001). 4. The recoveries of spontaneous ovulation in obese group and non-obese group were (28/46) 60.9% and (31/43) 72.1%, respectively. The recovery of ovulation was positively correlated with the decrease of body fat percentage in the obese group (r=0.343,p=0.003); while, positively correlated with the increase of skeletal muscle mass percent in the non-obese group (r=0.506,p=0.001).
Limitations, reasons for caution: Our study was designed to be self-controlled, lacking randomized grouping and control groups. We will further expand the sample size and use randomized controlled trials to further validate the above conclusions.
Wider implications of the findings: We found that the mechanism of insulin resistance in PCOS is related to its body composition, that is, the insulin resistance in obese PCOS patients is related to the increase of body fat, and the insulin resistance in non-obese PCOS patients is related to the decrease of skeletal muscle
Trial registration number: ChiCTR-OOC17011175

P-568 Vitamin D3 regulates mitochondrial biogenesis and function in granulosa cells through mitogen activated protein kinase-extracellular signa- regulated kinase pathway in polycystic ovary syndrome mouse model

Z. Safaei[1], R. Shirazi[2], S. Bakhshalizadeh[3], A. Akbari Sene[4], M.H. Nasr-Esfahani[5]

[1]Iran University of Medical Sciences- Tehran- Iran, Anatomical Sciences and Reproductive Biology, Tehran, Iran
[2]Iran University of Medical Sciences- Tehran- Iran, Anatomical Sciences, Tehran, Iran
[3]-Zanjan university of Medical Sciences- Zanjan- Iran, Department of Anatomical Sciences- School of Medicine, Zanjan, Iran
[4]Iran University of Medical Sciences- Tehran- Iran, Department of Obstetrics and Gynecology- Shahid Akbarabadi Hospital IVF Center-, Tehran, Iran
[5]Cell Science Research Center- Royan Institute for Biotechnology- ACECR- Isfahan-Iran, Department of Cellular Biotechnology, Isfahan, Iran

Study question: Could vitamin D3 regulates mitochondrial biogenesis and function in granulosa cells through mitogen activated protein kinase-extracellular signal-regulated kinase (MAPK-ERK1/2) pathway in a mouse model of polycystic ovary syndrome?
Summary answer: Vitamin D3 could improve mitochondrial biogenesis and function through MAPK pathway in granulosa cells of PCOS mice that may improve follicular development and oocyte quality
What is known already: Since oocyte quality, as one of the most crucial determinant in fertility output, requires undisturbed mitochondrial biogenesis and is easily affected by low mitochondrial membrane potential, increased oxidative stress and apoptosis, application of a suitable treatment preventing these problems may increase fertility and pregnancy rate. Various treatments, mainly vitamin D3, have been administered to lessen features of PCOS. Vitamin D can affect the function of MAPK-ERK pathway through phosphorylation of tyrosin kinase receptors to regulate mitochondrial biogenesis
Study design, size, duration:
Granulosa cells isolated from PCOS were cultured in six groups: (1) granulosa cells treated with vitamin D3 (100 nM for 24 hours)
(2) granulosa cells treated with MAPK activator (10 μM for 4 hours)
(3) granulosa cells treated with MAPK inhibitor (10 μM for 4 hours)
(4) granulosa cells treated with vitamin D3 and MAPK inhibitor
(5) granulosa cells treated with MAPK inhibitor and MAPK activator
(6) non-treated granulosa cells
Participants/materials, setting, methods: PCOS model was triggered by dehydroepiandrosterone to prepubertal female BALB/C mice for 20 days (N=20). To approve the effect of hormone, Seasame oil was injected to mice. Sex hormones by ELISA and ovaries by H&E staining were assessed. Granulosa cells were identified using FSHR and CD45 and cultured. Genes expression was compared using RT-PCR. MAPK-ERK1/2 expression was investigated by western blotting. ROS levels were determined using 2', 7'-dichlorofluorescin diacetate. mtMP was determined by JC1 staining
Main results and the role of chance: We observed Corpus luteum in control group indicating ovulation. Numbers of pre-antral and antral follicles, atretic follicles, and degenerated granulosa cells were high in the PCOS group, and there was no corpus luteum due to the ovulation disturbance. High amounts of estradiol, progesterone, LH, and FSH serum levels were observed in the PCOS group in comparison to control and vehicle groups. We detected a significantly increased ratio of LH/FSH in the PCOS group. Mitochondrial biogenesis, function and anti-apoptotic genes including PGC1-a, NRF1, SOD1, GPX, UCP1, catalase and BCL-2 were downregulated in granulosa cells of PCOS mice when compared to normal mice, but treatment with vitamin D3 and MAPK activator increased mRNA expression levels of these genes. Vitamin D3 and MAPK activator also decreased ROS levels.The mtMP was lowered in PCOS cells, while treatment of PCOS granulosa cells with vitamin D3 promoted an increased mtMP. Like vitamin D3, MAPK activator could enhance the mtMP. Western blot analysis revealed that treatment of granulosa cells with vitamin D3 (100 nM) intensified phosphorylation of MAPK-ERK1/2 after 24 hours. MAPK activator also increased phosphorylation of MAPK but MAPK pathway was not activate in the other groups
Limitations, reasons for caution: In this study, all experiments were performed on animal. So, we encountered with some difficulties in keeping animals in an appropriate condition
Wider implications of the findings: Considering that the quality of oocyte determines the success of fertility and mitochondria is major determinant of oocyte quality, vitamin D3 can be prescribed to improve the mitochondrial function and biogenesis of granulosic cells and find a way to improve fertility in PCOS patients
Trial registration number: non-clinical trials

P-569 Live birth rate is higher in primary subfertile women undergoing ICSI with high normal compared to low normal range TSH levels

C. Delprat[1], E. Van Dam[2], P. Van de Ven[3], K. Aissa[1], M. Ter Haar[1], Y. Feenstra[1], A. De Roos[1], G. Beelen[1], R. Schats[1], C. Lambalk[1]

[1]Amsterdam UMC- Vrije Universiteit Amsterdam, Department of Obstetrics- Gynaecology and Reproductive Medicine- Division of Reproductive Medicine, Amsterdam, The Netherlands

[2]Amsterdam UMC- Vrije Universiteit Amsterdam-, Department of Internal Medicine-Division of Endocrinology, Amsterdam, The Netherlands
[3]Amsterdam UMC- Vrije Universiteit Amsterdam, Department of Epidemiology and Biostatistics, Amsterdam, The Netherlands

Study question: Are TSH levels within the normal range in women not using thyroid hormone substitution associated with live birth rate in IVF/ ICSI?
Summary answer: Live birth rate is higher in primary subfertile women with high compared to low normal TSH levels undergoing ICSI.
What is known already: If and how TSH levels are associated with live birth rate in subfertile women undergoing IVF/ ICSI is a matter of debate. Studies show contradictory results concerning live birth rate, pregnancy rate, pregnancy loss and embryo quality, comparing women with high normal TSH levels (2.5-4.5 mIU/L) to women with low normal TSH levels (0.3-2.49 mIU/L). Subclinical hypothyroidism and/ or thyroid autoimmunity are hypothesized as a pathologic mechanism. Because of the conflicting results, the relevance of TSH levels and thyroid function might count for subgroups, possibly meeting benefit from special attention or treatment.
Study design, size, duration: For that reason we analyzed a large database on TSH levels and pregnancy outcomes in a retrospective cohort study in women starting IVF (n=949) or ICSI (n=752) between the first of January 2008 and the first of March 2012 with follow up till 2014. Pregnancy outcomes of 4451 cycles were compared, till first ongoing pregnancy, with patient as unit of analysis. Primary and secondary subfertility were used to define subgroups.
Participants/materials, setting, methods: Women aged 22-45 years with TSH 0.3-4.5 mIU/L not using thyroid hormone substitution were included in a single center in an Iodine-sufficient area. Logistic regression was used with (the natural logarithm of) TSH as continuous predictor, a quadratic term was added in a second model to account for a non-linear relationship. Chi-square tests and logistic regression were used to compare two groups of patients based on TSH levels on aforementioned outcomes while adjusting for confounders.
Main results and the role of chance: In primary subfertile women undergoing ICSI (n=455) the odds ratio for live birth rate is higher for high TSH, with the natural logarithm of TSH used as a continuous variable (OR 1.66, p=0.02) or TSH as a continuous variable (OR 1.37, p=0.01). An added quadratic term to TSH to look for possible u-shaped/ non-linear associations shows no difference (OR 1.00, p=0.99). Comparison of two groups based on TSH level (0.3-2.49 mIU/l vs 2.50-4.5 mIU/L) corrected for age, BMI, smoking, use of alcohol and diminished ovarian reserve shows also a significantly higher odds ratio for live birth rate in primary subfertile women undergoing ICSI with high normal TSH values (n=111) compared to women with low normal TSH values (n=344; OR 2.38, p=0.001). For clinical pregnancy and ongoing pregnancy rates odds ratios were also significantly higher, where no difference was seen in rate of pregnancy loss. The higher odds for live birth rate with high normal TSH is not seen in primary subfertile women undergoing IVF, (OR 1.02, p=0.94) nor in secondary subfertile women undergoing IVF (OR 1.14, p=0.63) or ICSI (OR 0.72, p=0.30). The role of chance is little because of consistency in linear and categorical outcomes and small p-values.
Limitations, reasons for caution: The retrospective character of the study with unknown levels of free thyroxine and of thyroid peroxidase or thyroglobulin antibodies limit the understanding of the results.
Wider implications of the findings: Our findings suggest that TSH levels count in primary subfertile women undergoing ICSI. Using (higher) TSH as a marker for thyroid autoimmunity might disclose ICSI as a treatment for a female factor hindering natural fertilization. In future studies measurement of TPO- and TG-antibodies are warranted to further explore these observations.

P-570 Derivation of reference intervals (RIs) for Anti-Müllerian hormone (AMH), specific for Russian population, using automated Access AMH assay

I. Guzov[1], E. Pecherina[2], A. Ruzhanskaia[3], V. Kozlov[2], O. Laskina[2], N. Sintyrina[2], E. Sedyshkina[4], E. Gvozdik[4], S. Tye[5], A. Zenkina[5], A. Kurgannikov[5]
[1]CIR Laboratories, Director, Moscow, Russia C.I.S.
[2]CIR Laboratories, Analytical department, Moscow, Russia C.I.S.
[3]Beckman Coulter LLC, Scientific marketing department, Moscow, Russia C.I.S.
[4]Beckman Coulter LLC, Immunochemistry department, Moscow, Russia C.I.S.
[5]Immunology and Reproduction Center, Ultrasound department, Moscow, Russia C.I.S.

Study question: Each laboratory is expected to establish its own RIs, but most laboratories use RIs provided by assay manufacturers which may not match to the Russian
Summary answer: Age-specific Russian RIs for AMH in women and men were derived and compared to the published literature for other populations and by the assay manufacturer.
What is known already: The age-specific RIs were established by the assay manufacturer for an American population. Another investigation for derivation of age-specific RIs for AMH for women and men was performed by Woloszynek R. et al. for a Brazilian population.
Study design, size, duration: Following CLSI EP 28AC, 436 women and 24 men were recruited; women were further grouped by age. Pregnant women, women with polycystic ovary syndrome and women undergoing ovarian surgery were excluded. Antral follicle counts (AFCs) were defined as sum of follicles 2–10 mm in diameter in both ovaries. The women were divided into groups with non-detectable, low (<10) and normal (11-20) AFCs by transvaginal ultrasound (TVUS). The duration of the study was 1 year.
Participants/materials, setting, methods: 460 volunteers aged 18-60 years were recruited, AMH was measured on the Access 2 analyzer (Beckman Coulter, Inc.) at CIR Laboratories on peripheral blood collected without regard to menstrual cycle day. AFCs were assessed in women on days 1–4 of their menstrual cycles using TVUS (Medison Ultrasound Systems). A non-parametric analysis of RIs was carried out using Stata 11 statistical analysis software.
Main results and the role of chance: In the Russian population, women aged 26-30 and 31-35 years had median and upper limit (UL) values for AMH that were significantly higher than those provided by the manufacturer (median 3.38 vs. 2.27, 2.85 vs. 1.88; UL 11.03 vs. 7.37, 11.61 vs. 7.35, respectively). In comparison to a Brazilian study (Woloszynek, 2015), the median and UL in the Russian population were lower for women aged 18-30 years group (median 3.35 vs. 3.7, respectively). In women aged 41-45, >46 and men, RIs were consistent with those provided by the manufacturer. Significant negative correlation between AMH and age was shown in women over 35 (rp=-0.46). Correlation between AMH concentration and AFC in both ovaries was demonstrated (rp=0.64; 0.69), with significant differences noted between AMH levels in groups of the same age but with different AFCs (low vs. normal AFC, 1.15 vs. 2.6, respectively).
Limitations, reasons for caution: No limitations found.
Wider implications of the findings: This study establishes Russian population-specific RIs for AMH using Beckman Coulter's Access AMH assay. These results reinforce the importance of obtaining population-specific reference intervals. Correlation among age, AMH concentration and antral follicle count (AFC) was estimated.
Trial registration number: N/A

P-571 Real world evidence : long term live birth rate in a French fertility care unit, a retrospective cohort study of the patient's journey

M. Pasquier[1], N. Salaun-Penquer[2], C. Piétin-Vialle[1], C. Villette[1], L. Vienet-Legué[1], B. Haddad[3], M. Ortala[2], H. Bry[1], N. Massin[1]
[1]Intercommunal Hospital- University Paris XII, Department of Reproductive Medicine, Creteil, France
[2]SAS, Kaduceo, Toulouse, France
[3]Intercommunal Hospital- University Paris XII, Department of Gynecology and Obstetrics, Creteil, France

Study question: Can we easily evaluate the cumulative live birth chances for a couple beginning medically assisted reproduction in our fertility care unit? What about the patients who drop out?
Summary answer: Administrative and medical data show that half of the couples who reach our unit leaves it with a baby after medically assisted reproduction (MAR).
What is known already: The pregnancy rate by attempt is no longer an appropriate method to estimate a couple's real chances of having a baby. Indeed,

improvement in reproductive technology and the promotion of single embryo transfers lead to increase the number of frozen-thawed embryo transfers. The cumulative live birth rate (CLBR) is a better indicator. Unfortunately this crucial information is difficult to obtain and time consuming. Only few studies try to evaluate it with different approaches. Every fertility centre should have the tools to make is own evaluation and give to their patients precise and true information about the overall medical journey.

Study design, size, duration: It is a retrospective cohort study. All the couples who had their first attempt of IVF, ICSI or IUI between January 2012 and December 2015 were selected. They were followed at least 2 years until delivery or drop out.

Participants/materials, setting, methods: We analysed data extracted from the billing department software completed with medical data extracted from a medical software specialized in MAR management. 1475 patient's journeys were studied, divided into three groups: "IUI alone" (group 1), "first attempt embryo transfer" (group 2)" and "mixed attempts" (group 3), corresponding to patients who began with IUI and then needed ART after IUI failure. Then we analyzed the journey of the patients with delivery success and without delivery.

Main results and the role of chance: The women were 33.8 years old in average. 56% began their journey with IVF, 44% with IUI but 46.7% of them needed to continue with IVF after IUI failure.

In total 50.3% had a baby after MAR. These patients are 33.2 years old in average. The live-birth rate (LBR) is respectively 56.3%, 49% and 46.8% in the three groups. The LBR is better for the younger women : 60% after 4 trials for women before 38 and less than 45% for women older than 38. For all groups there is a plateau after four attempts.

The pregnancy leading to the delivery is fast and detected in the first two attempts for the groups 1 and 2. It is interesting to see that the impact of age is minor in terms of number of attempts when we focus on the group of patients with delivery success.

The patients for which ART failed are 34.4 years old in average with a statistically significant difference with the success group . We notice that they drop out soon : only 10% pursue the 4 oocyte retrievals possibly reimbursed by the healthcare system. After one year of treatment failure 56% of the couples have stopped MAR.

Limitations, reasons for caution: The estimation of the CLBR doesn't take into account spontaneous pregnancies nor success after moving to another centre.

The study period is limited and some patients could deliver after this period.

The reasons why the patient stopped the treatments are not known (medical or personal decision?).

Wider implications of the findings: This study is a real word evidence of the patient's course in our unit and gives a valid estimation of MAR cumulative success rate. The characteristics of the different groups of patients could be further analyzed and provide us huge information to improve our decision-making and our patients counselling.

Trial registration number: not applicable

P-572 Convenience and efficacy of treatments for endometrial preparation prior to frozen embryo transfer (FET): a randomised-controlled trial comparing stimulated cycle (SC) versus natural cycle (NC)

J. Labrosse[1], A. Lobersztajn[2], C. Pietin-Vialle[1], C. Villette[1], A.L. Dessapt[3], C. Jung[4], M. Brussieux[4], H. Bry-Gauillard[1], M. Pasquier[1], N. Massin[1]

[2]Hopital Pierre Rouques- les Bluets, Dpt of Gynecology- Obstetrics and Reproductive Medicine, Paris, France

[3]IVI, Reproductive Medicine, Barcelona, Spain

[4]Intercommunal Hospital- University Paris Est Creteil, Clinical Research Center, Creteil, France

Study question: Is ovarian stimulation with recombinant FSH (rec-FSH) more convenient than natural cycle for endometrial preparation prior to FET in terms of number of visits reduced?

Summary answer: Endometrial preparation with recombinant FSH significantly reduces the number of visits needed to schedule frozen embryo transfer compared to natural cycle.

What is known already: Frozen embryo transfer has to be carried out at a time when the endometrium is receptive, defined as "implantation window". Hormone replacement therapy, stimulated cycle (SC), or close monitoring of a natural cycle (NC) can be performed to prepare the endometrium before FET. So far, neither option has shown superiority in terms of live birth rates. Although natural cycle may appear more physiological, it might also be more burdensome for patients and centers by requiring more monitoring and reducing flexibility. To date, no study has compared the convenience of stimulated cycle versus natural cycle for frozen embryo transfer.

Study design, size, duration: Our prospective open-labeled randomised controlled study was lead in a public IVF center from May 2015 to October 2017. We calculated that 48 patients per group were required to demonstrate a decrease of 1 visit using stimulated cycle compared to natural cycle (two-sided alpha-error of 0.05 and 90% power). Sample size was increased by 30% to consider transfer cancellations and patients lost to follow-up, representing a total of 124 patients (62 patients per group).

Participants/materials, setting, methods: Women aged 20 to 38yo undergoing their first or second FET (day 2/3 embryos) were randomised to either NC (monitoring by ultrasound and hormonal measurements from day 12), or to SC (75 IU/day rec-FSH from day 6 to 11 and HCG triggering when leading follicle > 17 mm). Number of visits (ultrasounds and blood tests), quality of life (FertiQol score), HCG positive rates, ongoing pregnancy rates, spontaneous miscarriage rates, and live birth rates were compared.

Main results and the role of chance: 124 women were selected, of which 5 were excluded. Our final population study was composed of 119 patients (NC group= 59; SC group=60). Mean age was of 32.9(+3.7) years old. Baseline characteristics were comparable between the two groups. The number of visits (primary outcome) was significantly lower in the SC group compared to the NC group (3.7+0.9 *vs.* 4.5+1.0, respectively, $p<0.0001$). Furthermore, the SC group was significantly associated to a lower number of blood tests (2.7+0.8 *vs.* 3.5+1.0, respectively, $p<0.0001$), and to a lower number of ultrasounds performed (1.2+0.4 *vs.* 1.5+0.6, respectively, $p<0.05$). Both the number of FET during "non-opening" hours (22.6% *vs.* 27.5%, respectively, $p=0.32$) and cancellation rates (8.6% *vs.* 12.3%, respectively, $p=0.52$) were lower for patients in the SC group compared to NC, without reaching significant difference. Concerning pregnancies, HCG-positive rates were higher but not significantly different in SC compared to NC patients (29.1% *vs.* 23.1%, respectively, $p=0.47$). No difference concerning life birth rates was observed between the two groups (20.0% for SC *vs.* 23.1% for NC, respectively, $p=0.69$). Quality of life as defined by the FertiQol score was not different between the two groups ($p>0.05$ for every item).

Limitations, reasons for caution: Potential biases are limited by the strict monitoring of cycles. The advantage of SC versus NC on pregnancy and cancellation rates has to be confirmed on larger effectives. Comparing the costs of rec-FSH to the cost and constraints of more visits engendered by the natural cycle protocol is also required.

Wider implications of the findings: Treatment burden is a major issue for infertile patients. Natural cycle appears as a good option for women reluctant to have injections, but patients have to be informed of the increased monitoring. FSH stimulation enables to reduce the number of visits, and offers more flexibility for patients and IVF centers.

ClinicalTrials.gov ID: NCT02834117

P-573 Fertility treatment in women with primary ovarian insufficiency who reject foreign oocytes

Y. Xu[1], X. Zhen[1], R. Li[1], J. Qiao[1], P. Liu[1], R. Yang[1], J. Huang[1]

[1]Peking University Third Hospital, Reproductive Center, Beijing, China

Study question: The aim of the study was to explore the resumption of ovarian activity and the proper fertility treatment in women with POI who reject foreign oocytes.

Summary answer: Timed intercourse or IVF/IVM combined HRT may be the proper alternative to those women with POI who reject foreign oocyte.

What is known already: POI is a disorder associated with women infertility, It affects 1-2% of women younger than 40 years of age and 0.1% of women younger than 30 years of age. the mechanism is not clear. POI women especially those in late stage with FSH>40IU/ml represents a major challenge in reproductive medicine and brings a great dilemma to patients and their caregivers.
Study design, size, duration: retrospective study, 255 women with POI between July 2013 to December 2017 received HRT (Climen, Schering, Berlin, Germany) every month. If the resumption of ovarian activity was observed, timed intercourse or IVF/IVM was performed.
Participants/materials, setting, methods: 255 women with POI between July 2013 to December 2017 received HRT (Climen, Schering, Berlin, Germany) every month. If the resumption of ovarian activity was observed, timed intercourse or IVF/IVM was performed.
Main results and the role of chance: A total of 206 POI women with consistent HRT were followed up, 46 patients presented with resumption of ovarian activities, Among them 1/46 women got pregnant spontaneously, 4/25 women became pregnant with timed intercourse, 6/20 women became pregnant with IVF/IVM treatment
Limitations, reasons for caution:
small sample in IVF/IVM, And the retrospective study nature that these POI women without strict enrollment and standard intervention, Everyone's lifestyle and habits vary greatly.
Wider implications of the findings: The resumption of ovarian function is temporary and intermittent, it should be always taken into consideration, catching the intermittent chance and taking appropriate intervention measures such as timed intercourse and IVF/IVM could improve the pregnancy rate to those who reject foreign oocytes
Trial registration number: ChiCTR-IPR-17010945

P-574 mitochondrial dysfunction induced by high estradiol concentrations in endometrial epithelial cells

J.H. Yang[1], Y.A. Tu[2], Y.S. Yang[3]
[1]*National Taiwan University Hospital, Department of Obstetrics and Gynecology, Taipei, Taiwan R.O.C.*
[2]*National Taiwan University Hospital, Obstetrics and Gynecology, Taipei, Taiwan R.O.C.*
[3]*Fu Jen Catholic University Hospital, Obstetrics and Gynecology, Taipei, Taiwan R.O.C.*

Study question: Are there changes of mitochondrial function in high estradiol (E_2)-stimulated endometrial epithelial cells (EECs)?
Summary answer: High E_2 concentrations increase reactive oxygen species (ROS) production in EECs that subsequently induce mitochondrial dysfunction.
What is known already: A supraphysiological E_2 concentration after ovarian stimulation is known to result in lower embryo implantation rates in *in vitro* fertilization (IVF). EECs apoptosis occurs after the stimulation with high E_2 concentrations, and mitochondria play important roles in cell apoptosis.
Study design, size, duration: *In vivo* and *in vitro* experiments were done to examine mitochondrial functions in EECs stimulated with different E_2 concentrations.
Participants/materials, setting, methods: Isolated human EECs (hEECs) were purified from 6 women in the follicular phase, and were *in vitro* cultured with different E_2 concentrations (10^{-10}, 10^{-9}, 10^{-8}, 10^{-7} M), in which 10^{-7} M is supraphysiologically high. Eight-week-old female ICR mouse endometrium was obtained 5.5 days after the injection of 1.25 IU or 20 IU equine chorionic gonadotropin (eCG).
Main results and the role of chance: *In vivo* and *in vitro* experiments showed decreased mitochondrial DNA contents and ATP formation after EECs were stimulated with supraphysiologically high E_2 concentrations than those stimulated with a physiologic E_2 concentration. Less prominent immunofluorescence mitochondrial staining, fewer mitochondria number under electron microscopy, lower JC-1 aggregate/monomer ratio, and more ROS production were found after EECs were stimulated with supraphysiologically high E_2 concentrations. The high E_2-induced ROS production was reduced when EECs were pretreated with N-acetyl-cysteine (NAC), but remained unchanged after the pretreatment with coenzyme Q10 (mitoQ).
Limitations, reasons for caution: Since mitochondria contribute to many processes central to cellular function and dysfunction, it is difficult to investigate all the mitochondrial functions in this study.
Wider implications of the findings: The high E_2-induced mitochondrial dysfunction in EECs is probably a temporary rather than a permanent effect. The mitochondrial function might return to a normal level when the high E_2 effect is gone.
Trial registration number: N/A

P-575 Association of BRCA mutations with serum anti-Müllerian hormone level in young breast cancer patients

D.Y. Lee[1], K.A. Son[1], D. Choi[1]
[1]*Samsung Medical Center, Obstetrics & Gynecology, Seoul, Korea- South*

Study question: What is the relationship between *BRCA* mutation and serum anti-Müllerian hormone (AMH) level in young breast cancer patients?
Summary answer: Young breast cancer patients with *BRCA* mutation have significantly lower AMH value, which is indicative of decreased ovarian reserve, compared to BRCA-negative patients.
What is known already: Several studies have demonstrated significantly decreased serum AMH level in *BRCA* mutation carriers. Moreover, in breast cancer patients who underwent ovarian stimulation for fertility-preservation, there was a higher rate of poor ovarian response in *BRCA*-mutation carriers compared to non-carriers. However, some studies have found no difference in serum AMH level according to *BRCA* mutation status, and therefore, the association between *BRCA* mutation status and decreased ovarian reserve is not conclusive. In addition, only a few studies have shown a significant association between *BRCA* mutation and decreased ovarian reserve in young breast cancer patients.
Study design, size, duration: A cross-sectional study. Between December 2011 and May 2018, 316 young breast cancer patients were included in this study, and 264 were *BRCA*-negative and 52 were *BRCA*-positive (27 *BRCA1*-positive and 25 *BRCA2*-positive).
Participants/materials, setting, methods: This study included pre-menopausal patients $\leq$ 40 years of age who were diagnosed with breast cancer and had a known baseline status regarding *BRCA* mutation and serum AMH level. The serum level of AMH was compared according to presence of a *BRCA* mutation, and linear and logistic regression analyses were performed to evaluate the association between *BRCA* mutation and serum AMH level.
Main results and the role of chance: The median age was 34 years. No differences were found in the clinical characteristics between the *BRCA*-positive and *BRCA*-negative groups. Patients with any *BRCA* mutation had a significantly lower median AMH than those without a mutation (2.60 vs. 3.85 ng/mL, P=0.004). Both serum AMH levels of the *BRCA1* (2.56 ng/mL, P=0.001) and *BRCA2* groups (2.64 ng/mL, P=0.036) were significantly lower than that of BRCA-negative group, but no difference was found between the *BRCA1* and *BRCA2* groups. In linear regression analysis, serum AMH level was still significantly lower in the *BRCA*-positive group than in the BRCA-negative group (P=0.039) after adjusting for age and body mass index. When evaluating the association between risk of poor ovarian response and *BRCA* mutation status by the logistic regression model, 35 (13.3%) and 9 (17.3%) patients had AMH level less than 1.2 ng/mL in the *BRCA*-negative and *BRCA*-positive groups, respectively, presenting no statistical difference. After adjusting for age and body mass index, there was no increased likelihood of poor ovarian response in the *BRCA*-positive group. In addition, no differences were found between the *BRCA1*- and *BRCA2*-positive groups in either the linear or logistic regression analysis.
Limitations, reasons for caution: This was a cross-sectional study in one center. In addition, not all the potential confounders affecting serum AMH level were considered for analysis. Moreover, although we measured AMH and estimated poor ovarian response, long-term fertility outcomes were not assessed in the present study.
Wider implications of the findings: Considering that it is currently recommended for *BRCA*-mutation carriers to undergo a risk-reducing salpingo-oophorectomy after childbearing and that various anti-cancer therapies are necessary in young breast cancer patients, our finding can support that fertility preservation should be considered more aggressively in young breast cancer patients with *BRCA* mutation.

Trial registration number: Not appicable

P-576 The combination of daily vaginal progesterone administration and intramuscular progesterone every-third day secures ongoing pregnancy rates in artificial frozen-embryo transfer cycles

M. Polat[1], G. Bozdag[2], I. Yarali Ozbek[1], S. Mumusoglu[2], P. Humaidan[3], H. Yarali[1]

[1]*Anatolia IVF and Women's Health Center, Obstetrics and Gynecology, Ankara, Turkey*

[2]*Hacettepe University- School of Medicine, Obstetrics and Gynecology, Ankara, Turkey*

[3]*Skive Regional Hospital, Fertility Clinic, Skive, Denmark*

Study question: Does intramuscular progesterone every third day (imP4-suppl) secure serum progesterone levels and enhance ongoing pregnancy rates (OPR) compared to vaginal progesterone-only (VP4-only) in artificial frozen embryo transfer (FET) cycles?

Summary answer: Although imP4-suppl and VP4-only arms have comparable OPRs, 10% of patients in the VP4-only arm have lower progesterone levels and significantly lower OPRs.

What is known already: Despite the worldwide common use of the hormone replacement therapy (HRT) cycle for FET, the optimal route and dosing of progesterone is uncertain. A recent randomized controlled trial reported lower OPRs with VP4-only when compared to daily imP4 or imP4-suppl (Devine at al-2018). Although significant inter- and intra-personal variation exists, there is paucity of data as regards serum progesterone levels and monitoring in HRT cycles. Moreover, a threshold and ceiling level of serum progesterone has not been clearly defined.

Study design, size, duration: Observational cohort study from October 2017-November 2018, having OPR as primary outcome measure. A total of 302 patients undergoing Day 5/6 vitrified FET in an HRT cycle, were included. From October-February 2018 VP4-only was used for luteal support (n=111). From March 2018 and onwards imP4-suppl every third day was added to the vaginal support (n=191). In all cycles, a blood sample was drawn and cryo-preserved immediately before transfer on the 6th day of progesterone administration.

Participants/materials, setting, methods: In the VP4-only arm vaginal progesterone gel (Crinone 8%, Merck) bid was administered. In the imP4-suppl arm, starting from the first day of vaginal progesterone administration, 50 mg im progesterone (Progynex, Farmako) was administered every third day. The blood sample was drawn 3-4 hours after the morning administration of vaginal gel. The impact of serum progesterone percentiles on the OPR, was retrospectively assessed. Logistic regression analysis was performed to delineate the covariates affecting OPR.

Main results and the role of chance: Female age, body-mass index and the number of previous attempts were comparable between the two arms. Although the mean number of embryos transferred was significantly higher in the imP4-suppl arm (1.36±0.48 vs 1.23±0.43, p=0.018), the OPRs in the imP4-suppl and VP4-only arms were comparable (51.3% and 48.7%, respectively, p=0.372). The pregnancy loss rates were also comparable between the two arms. The impact of serum progesterone on OPR was assessed by percentiles (<10%, 10-49%, 50-75%, >75%), taking the 50-75% as reference subgroup, in both the imP4-suppl and VP4-only arms. In the VP4-only arm (n=111), 11 patients were in the <10% percentile (<7.95 ng/ml), having significantly lower OPR (18.2% vs 64.3%; OR=0.12 (95%CI 0.02-0.69), p=0.01). There was a trend for a ceiling effect with lower OPR in the >75% subgroup (>16.10 ng/ml; 48.1% vs 64.3%; OR=0.52 (95%CI, 0.18-1.52), p=0.228). In the imP4-suppl group, no differences were seen as regards OPRs in percentiles. Similar to the VP4-only arm, there was a trend for a ceiling effect with lower OPR in the >75% percentile (>28.60 ng/ml; 48.9% vs 66.7%; OR=0.48 (95%CI, 0.21-1.10), p=0.080). Logistic regression analysis showed that only female age and BMI, whereas mode of supplementation and serum progesterone did not predict OPR.

Limitations, reasons for caution: Although baseline demographic features were comparable between the two arms, the retrospective study design is a limitation. More embryos were transferred in the imP4-suppl arm.

Wider implications of the findings: Overall, imP4-suppl and VP4-only groups had comparable OPRs. However, 10% of patients in the VP4-only group had low progesterone levels and significantly lower OPRs. In contrast, imP4-suppl secured the OPRs in all progesterone percentiles, suggesting the addition of imP4-suppl every third day to vaginal support in HRT cycles.

Trial registration number: Not available.

P-577 The ovarian sensitivity index (OSI) is in infertile patients predictive of live birth chances after IVF

D. Barad[1], A. Weghofer[2], S. Darmon, K[3], V. Kushnir, A[3], D. Albertini, F[3], N. Gleicher[3]

[1]*The Center for Human Reproduction, n/a, New York- NY, U.S.A.*

[2]*Medical University Vienna, n/a, Vienna, Austria*

[3]*Center for Human Reproduction, n/a, New York, U.S.A.*

Study question: Does the ovarian sensitivity index (OSI) predict embryo quality, pregnancy and live birth in patients undergoing FSH/hMG stimulation for in vitro fertilization (IVF)?

Summary answer: The ovarian sensitivity index is predictive of pregnancy and live birth in women undergoing FSH/hMG stimulation for IVF.

What is known already: The OSI was previously reported to reflect gonadotropin requirements among high, normal and poor responders and to predict pregnancy potential in younger patients undergoing ovarian stimulation with FSH.

Study design, size, duration: Retrospective cohort study that included 1934 fresh IVF cycles in 1282 women undergoing IVF with FSH/ hMG stimulation between January 2010 and December 2016. OSI [n oocytes x1000/total gonadotropin dosage], based on ROC curve analyses of randomly selected development sample comprising a third of cycles, was grouped into two classes.

Participants/materials, setting, methods: Remaining cycles comprised a validation group. ROC curves were also used to compare predictive values of OSI to baseline FSH and AMH. Logistic regression models evaluated effect of high (>0.83) and low OSI (≤ 0.83) on pregnancies and live births in validation group. Models were adjusted for female age, baseline FSH, AMH, oocyte yield and gonadotropin dose.

Main results and the role of chance: Women were 39.3±5.3 years old and had AMH levels of 0.6 (95% CI 0.56 to 0.65) ng/mL. They received 5,375 ± 2,412 IU of gonadotropins and produced 5.2 (95% CI 5.0 to 5.4) oocytes. Pregnancy and live birth rates for all were 18.7% and 14.0 %, respectively. Cycles with higher OSI (less gonadotropin requirement per oocyte retrieved) produced significantly more high-quality embryos than cycles with low OSI (3.6 ± 3.7 vs. 1.1 ± 1.1, P=0.001) and demonstrated higher pregnancy (24.2 % vs. 9.7 %) and live birth rates (18.2 % vs. 6.2%) than their counterparts (P=0.001 and P=0.001, respectively). After adjustments for age, baseline AMH and FSH, total gonadotropin dosage and oocyte yield, OSI > 0.83 was associated with greater odds of pregnancy (OSI: OR 2.12, 95% CI 1.30-3.45, 0.003) and live birth: OSI: OR 1.91, 95% CI 1.07 to 3.41, p=0.028.

Limitations, reasons for caution: Here presented results may not be applicable to women with other ovarian stimulations.

Wider implications of the findings: OSI's predictive capacity for determining embryo quality, pregnancy and live births, may add in counseling patients about their pregnancy potential and live birth chances to other currently available means.

Trial registration number: n/a

P-578 Good clinical results of natural cycle IVF: A 10 year record in our clinic

S. Watanabe[1], R. Matsunaga[1], M. Miura[1], Y. Kobayashi[1], M. Kamihata[1], H. Yoshizawa[1], H. Miyamura[1], T. Maeda[1], H. Makino[1], M. Ochi[1], T. Horiuchi[2]

[1]*Ochi Yume Clinic Nagoya, ART Lab., Nagoya, Japan*

[2]*Prefectural University of Hiroshima, Faculty of Life and Environmental Sciences, Shobara, Japan*

Study question: We examined the clinical outcome of natural cycle IVF where the burden on patients is extremely low.

Summary answer: A high pregnancy and production rate was obtained from natural cycle IVF.

What is known already: Although multiple oocytes can be collected after stimulation cycle IVF, there is a risk of OHSS, which can cause health risks to the patient and also impose a large financial burden. In Japan, some patients require natural cycle IVF with its attendant lower physical risk and financial burden. However, there are very few reports on the clinical outcome of long-term natural cycle IVF.
Study design, size, duration: We examined the clinical outcome of long-term natural cycle IVF in a retrospective study of 1768 cycles in which natural cycle IVF was performed during the period 2008–2017. The patients included in the study were under 37 years of age.
Participants/materials, setting, methods: GnRHa was administered nasally when the dominant follicle was 17 mm or more in diameter in a natural cycle; 34 hours later, the oocyte was collected. The retrieved oocyte was used for IVF or ICSI. Following successful fertilization of the oocyte, the resultant embryo was cultured for 2 or 5 days; at the end of the culture period, single fresh embryo transfer (early embryo or blastocyst) was performed.
Main results and the role of chance: One or more mature oocytes were obtained in 1412/1768 cycles (79.9%). In 172 cycles, immature or degenerate oocytes were obtained; oocytes could not be obtained in 184 cycles. A fertilization rate of 85.8% (1693/1974) was achieved: IVF, 85.3% (1012/1186); ICSI, 86.4% (681/788). The pregnancy rate after single fresh embryo transfer was 44.3% (467/1054), and the production rate was 83.1% (388/467).
Limitations, reasons for caution: The data in this study includes cases in which multiple mature oocytes were obtained when oocytes were taken from small follicles and not only from the dominant follicle (327 cases). When multiple embryos were obtained, one of the best-grade embryos was transferred.
Wider implications of the findings: Natural cycle IVF has been shown to provide a high pregnancy rate and a high production rate while minimizing the OHSS risk and reducing the financial burden on patients.
Trial registration number: None.

P-579 The relationship between the factual ovarian volume and serum hormone levels including the levels of the AMH, LH/FSH ratio, and total testosterone

Y. Wakimoto[1], J. Cadenas[2], S.E. Pors[2], C.Y. Andersen[2]
[1]Hyogo College of Medicine, Obstetrics and Gynecology, Nishinomiya- Hyogo, Japan [2]University Hospital of Copenhagen- Rigshospitalet, Laboratory of Reproductive Biology- The Juliane Marie Centre for Women- Children and Reproduction, Copenhagen, Denmark

Study question: Is there a relationship between ovarian volume equivalent to the weight and serum hormone levels including the AMH level, LH/FSH hormone ratio or total testosterone?
Summary answer: Serum AMH, LH/FSH ratio, and testosterone were significantly positively associated with ovarian volume.
What is known already: Ovarian volume is used to distinguish between normal women and women with polycystic ovary syndrome (PCOS) with a cutoff of around 10 ml. Some studies have reported that the AMH and the LH/FSH ratio are significantly related to the ovarian volume estimated with transvaginal ultrasound. The standard technique for measuring the ovarian volume in women is transvaginal ultrasonography and ovarian volumes are calculated using prolate ellipsoid formula (width×depth×length×0.52) . However, it has been reported that ovarian volume measured by ultrasound was at least 27% smaller as compared to the volume obtained by weight.
Study design, size, duration: This study is a retrospective cohort study. The study population included female patients older than 15years (range: 15.0-43.1 years) with diagnosis requiring fertility preservation and was referred for ovarian tissue cryopreservation (OTC) at the Laboratory of Reproductive Biology in Copenhagen, Denmark from August 1999 to December 2018. This research targeted 264 patients who have had a checkup serum hormone levels including the AMH, LH, FSH, or testosterone before OTC.
Participants/materials, setting, methods: 264 patients were enrolled in this retrospective study. The ovarian volume of one ovary excised from each patient for OTC was recorded by weighing the tissue. Ovarian weights were measured using a precision analytical weight – we have previously shown that 1 g of ovarian tissue corresponds to 1ml of tissue. We retrospectively collected these data from the patients' medical records. We evaluated the relation with ovarian volumes and AMH values, LH/FSH level, and testosterone.
Main results and the role of chance: All data are presented as the mean ± SD. The patients' average age was 28.2±6.1 years. In our study, the average AMH level was 19.1±17.2 pmol/L, LH level was 7.41±7.48 IU/L, FSH level was 6.5±11.5 IU/L, LH/FSH ratio was 1.47±1.23, total testosterone level was 0.78±0.56 nmol/L, and the ovarian volume by weight was 7.17±3.73 ml (range: 2.1-20.8 ml) . The ovarian volume was statistically significant positive associated to AMH levels ($p<0.001$) . Also ovarian volume was statistically significant positively associated with increasing the LH/FSH ratio and total testosterone (both $p<0.001$) .
Limitations, reasons for caution: In our study, ovarian volume was measured at a random day during the menstrual cycle due to prioritizing immediate initiation of cancer therapy. Ovarian volume has been shown to be associated to the day of the menstrual cycle and possess the biggest volume on cycle day 19.
Wider implications of the findings: Serum AMH, LH/FSH ratio, and testosterone show a continuous positive association to ovarian volume and does not suggest that marked differences occur when the volume increase beyond 10 ml, which has been suggested as a point to distinguish between women with normal and PCOS.
Trial registration number: not applicable

P-580 Transfer of frozen-thawed embryos in or out of window of implantation yields similar live birth rates

T.A. Boza[1], M. Ceyhan[1], G.E. Aksakal[1], A. Seyhan Ata[1], O. Bulduk[1], A. Isıklar[1], B. Balaban[1], C.B. Urman[1]
[1]Amerikan Hastanesi - American Hospital, Womens' Health Centre- Assisted Reproduction Unit, Istanbul, Turkey

Study question: Does transfer of frozen-thawed embryos in relation to the proposed window of implantation (WOI) affect live birth rates (LBR)?
Summary answer: Frozen-thawed single blastocyst transfer performed in and out-of-WOI yields similar LBR.
What is known already: The WOI, the time when the endometrium is most able to support trophoblast-endometrial interactions, is proposed to remain open between cycle days (CD) 19-23 of an ideal 28-day natural cycle. It is not clear whether it is important that frozen-thawed embryo transfer (FTET) in an artificially prepared cycle coincides with this relatively short period of time.
Study design, size, duration: A retrospective cohort study was conducted in the American Hospital (Koc University affiliated private hospital) between October 2015 and October 2017. All FTET cycles with a single blastocyst transfer using artificial endometrial preparation w/o GnRH agonist pretreatment were included. Only grade 1 and grade 2 blastocysts had been cryopreserved. Women >43 years of age, treatment cycles with incomplete data and women who were lost to follow-up were excluded.
Participants/materials, setting, methods: All women received oral E treatment starting on day 2 of a spontaneous menstrual bleeding. The duration of E administration varied from 8 to 19 days due to concerns regarding ET scheduling. A total of 498 FTET cycles was analyzed according to the timing of ET that was performed in (CD-19-23, n=256) or out (CD<19 or >23, n=242) of WOI. The primary outcome measure was LBR.
Main results and the role of chance: The timing of ET varied from CD-15 to CD-26 according to the changing duration of E administration. Among a total of 498 frozen thawed single blastocyst transfers, 51.5% (in-WOI) and 48.5% (out-of-WOI), LBR was not significantly affected (OR=0.85, 95%CI [0.6-1.2, p=0.36]). On logistic regression analysis, GnRH pretreatment, E duration, total dose of E used were not associated with the analyzed outcomes.
Limitations, reasons for caution: Retrospective design of the study may have inevitably resulted in bias that may affect the conclusions.
Wider implications of the findings: According to the results of this retrospective study FTET in or out of the proposed natural WOI leads to similar LBR questioning the need for a rigid pretransfer hormone administration period.
Trial registration number: Not applicable

P-581 Comparison of the outcome between conventional mild stimulation and progestin-primed ovarian stimulation in women of advanced age: a retrospective study

Q. Peng[1], X. Cao[1], J. Zhu[2], X. Dong[1]

[1]Zhongshan hospital-Fudan University, Reproductive medicine centre, Shanghai, China
[2]Shanghai Obstetrics and Gynecology Hospital-Fudan University, Department of Obstetrics and Gynecology, Shanghai, China

Study question: Does progestin-primed ovarian stimulation (PPOS) result in a better embryonic and clinical outcome compared to mild stimulation in women aged ≥ 40 years old?
Summary answer: Higher percentage of top-quality embryos on Day 3 and comparable clinical pregnancy rate was obtained in PPOS protocol than in mild stimulation protocol.
What is known already: Women with advanced age, especially above 40 years old, is a rapidly growing population in IVF patients since universal two-child policy took effect in 2015 in China. Along with the increase of maternal age, oocyte quantities and qualities decline. PPOS protocol has become a feasible and efficient way to obtain good embryos and better clinical outcomes in normal and poor ovarian responders when compared with GnRH agonist/antagonist protocol and natural cycle. No significant differences are found in neonatal outcomes and congenital malformations risks between PPOS and conventional GnRH agonist short protocol.
Study design, size, duration: This was a retrospective study that included 169 women aged ≥40 years and underwent IVF/ICSI and subsequent frozen embryo transfer (FET) cycle between April 2016 and January 2019 in the reproductive medicine centre of Zhongshan hospital in Shanghai.
Participants/materials, setting, methods: Patients who were above 40 years old at the time point of ovarian stimulation were included. In mild stimulation protocol, daily clomiphene citrate (100 mg/d) and HMG (150-225 IU/d) were used. In PPOS protocol, patients received dydrogesterone (DYG, 20 mg/d) with HMG or recombinant FSH (150-225 IU/d) daily. Freeze-all strategy was employed, and FET cycle was followed. The primary outcome was top-quality embryo rate on day 3, and the second outcome was clinical pregnancy rate.
Main results and the role of chance: Baseline characteristics of patients was similar in mild stimulation group (122 cycles) and PPOS group (47 cycles). The mean values (mean±SD) of age (43.32±2.49 vs 43.15±2.56), body mass index (22.63±2.68 vs 21.95±2.63 kg/m^2), AFC (8.23±3.17 vs 7.09±3.29), basal FSH (8.70±2.51 vs 7.91±2.21 mIU/ml) and LH (4.58±1.60 vs 4.68±1.98 mIU/ml) level and duration of infertility (5.78±4.49 vs 6.33±5.95) were comparable. No significant differences were found in the number of retrieved oocytes (3.57±2.77 vs 3.72±2.76) and mature oocytes (3.08±2.39 vs 2.87±2.20). Meanwhile, the fertilization rate (79.05% vs 77.36%) and cleavage rate (87.25% vs 90.06%) was similar too. Of interest, the rate of top-quality embryos was significantly higher (33.29% vs 50.08%, p=0.015) in PPOS group, with an increasing trend of viable embryo rate (61.16% vs 73.55%) as well. Although the duration of stimulation was comparable, a greater amount of gonadotropin was used in PPOS protocol (1518.14±547.25 IU vs 2061.17±1254.63 IU, p<0.05). During the following FET cycle, 77 cycles was completed, in which 59 cycles was from mild stimulation group and 18 cycles was from PPOS group. The data showed no significant difference in the clinical pregnancy rate (mild stimulation group 16.9% vs PPOS group 16.7%, p= 1.000).
Limitations, reasons for caution: This is a retrospective study and the sample size is small, which is a drawback for the interpretation of the current results. Besides, the data is lack of blastocyst formation rate due to the fact that a proportion of top-quality embryos is vitrified on Day 3.
Wider implications of the findings: This study provides evidence of the efficiency of PPOS in women above 40 years old. Although clinical pregnancy rate hasn't been improved yet, PPOS can be used when these patients are trying to accumulate transferrable embryos in a short period, but randomized clinical trials are required to confirm these findings.
Trial registration number: Not clinical trial.

P-582 Cumulin and FSH cooperate to regulate inhibin B and activin B production by human granulosa-lutein cells in vitro

D. Richani[1], K. Constance[1], S. Lien[1], D. Agapiou[1], W. Stocker[2], M. Hedger[3], W. Ledger[1], J. Thompson[4], D. Robertson[1], D. Mottershead[5], K. Walton[2], C. Harrison[2], R. Gilchrist[1]
[1]University of New South Wales Sydney, Fertility and Research Centre- School of Women's and Children's Health, Sydney, Australia
[2]Monash University, Department of Physiology- Monash Biomedicine Discovery Institute, Clayton, Australia
[3]Hudson Institute of Medical Research, Centre for Reproductive Health, Clayton, Australia
[4]The University of Adelaide, Robinson Research Institute- Adelaide Medical School, Adelaide, Australia
[5]Keele University, Institute for Science and Technology in Medicine- School of Pharmacy, Newcastle-under-Lyme, United Kingdom

Study question: Does the GDF9:BMP15 heterodimer termed cumulin regulate granulosa cell inhibin and activin production and does this require cooperation with FSH?
Summary answer: Cumulin, but not the homodimers GDF9 or BMP15, exerts paracrine control of FSH-induced regulation of inhibin B and activin B.
What is known already: There is genetic evidence that the oocyte-secreted factors bone morphogenetic protein 15 (BMP15) and growth differentiation factor 9 (GDF9) constitute key regulators of folliculogenesis, ovulation rate and fecundity in mammals. BMP15 and GDF9 interact functionally and it is hypothesised that this interaction may be mediated by formation of a GDF9:BMP15 heterodimer, termed cumulin. BMP15 and GDF9 regulate folliculogenesis by acting as paracrine growth factors in the follicle and are known to regulate inhibin expression, although the participation of cumulin in control of the inhibin-activin system is unknown.
Study design, size, duration: To assess the effects of cumulin versus GDF9 and BMP15, we bioengineered and purified wild-type non-covalent cumulin, as well as various covalent dimers of cumulin, GDF9 and BMP15, containing an introduced inter-subunit disulphide bridge. To assess the effect of the pro-domain, we engineered mature cumulin (without the pro-domain).
Participants/materials, setting, methods: Human granulosa-lutein (hGL) cells from IVF patients were cultured for 5 days, then treated for 24h ± FSH with various forms of recombinant cumulin (native and cysteine mutants, and with-/without the pro-domains), and the disulphide-subunit bridged forms of GDF9 or BMP15. Messenger RNA expression of the subunits of inhibins/activins (*INHA*, *INHBA*, *INHBB*), and secretion of inhibin A, inhibin B, and activin B protein by immunoassay into media were measured (n=3-7 biological replicates per experiment).
Main results and the role of chance: Mature and pro-forms of cumulin dose-dependently stimulated (P<0.05) *INHBB* mRNA expression (encoding the inhibin βB subunit of inhibin B or activin B), but did not alter *INHBA* (encoding the βA subunit of inhibin A). Correspondingly, cumulin stimulated ≥5-fold secretion of inhibin B and activin B (P<0.05), but did not alter inhibin A. In contrast to cumulin, GDF9 or BMP15 exhibited no significant effect on inhibin B or activin B expression (P≥0.05). Furthermore, cumulin, but not GDF9 or BMP15, interacted synergistically (two-way ANOVA interaction, P<0.05) with FSH to increase *INHBB* mRNA and inhibin B expression. FSH markedly stimulated (≥16-fold) *INHA* expression, which encodes the α subunit of inhibin A/B, and suppressed activin B (P<0.05). Mature and pro-forms of cumulin ± FSH stimulated comparable effects on *INHBB, INHBA*, inhibin B, activin B and inhibin A (P≥0.05), suggesting that the pro-domains of cumulin has a minimal role in its actions on granulosa cells.
Limitations, reasons for caution: In vitro study using granulosa-lutein cells from women undergoing stimulation for IVF.
Wider implications of the findings: Together these data demonstrate that the GDF9:BMP15 heterodimer cumulin exerts control of FSH-induced regulation of inhibin B and activin B, which may contribute to oocyte-secreted factor regulation of folliculogenesis and fecundity in women.
Trial registration number: not applicable

P-583 Relationship between diminished ovarian reserve and matrix metalloproteinase-9 (MMP9) p.Gln279Arg polymorphism

B. Petersen[1,2], A. Renzi[2], L.D. Vagnini[2], C.G. Petersen[1,2], A.L. Mauri[1,2], M. Mattila[1], J. Ricci[1], F. Dieamant[1,2], J.B.A. Oliveira[1,2], R.L.R. Baruffi[1,2], J.G. Franco Jr[1,2]
[1]Centre for Human Reproduction Prof. Franco Jr, Research, Ribeirão Preto, Brazil
[2]Paulista Center for Diagnosis Research and Training, Research, Ribeirao Preto, Brazil

Study question: Are there any MMP9 gene polymorphisms associated with diminished ovarian reserve (DOR)?

Summary answer: MMP9p.Glutamine(Gln)279Arginine(Arg)(rs17576) polymorphism is associated with diminished ovarian reserve. The presence of the Gln amino acid in homozygosis increases the chance of women presenting with DOR.

What is known already: Ovarian reserve refers to the woman's reproductive potential based on number and quality of eggs. DOR is the loss of normal reproductive potential in the ovaries due to a lower count of the remaining eggs. Normal aging causes most cases of DOR but environmental, medical treatments (as radiotherapy) and genetic factors can influence DOR as well. MMP9 has been suggested to be involved in different stages in female reproduction, such as menstrual cycle, ovulation, implantation, parturition and involution of the mammary glands after lactation but little is known about its influence on ovary functions.

Study design, size, duration: All of the recruited women (n=144) met the following inclusion criteria: age ≤37years, normal karyotype, ultrasonographic evidence of the two ovaries and no surgery on ovaries, endometriosis, hydrosalpinx, infections or endocrine problems. The women were divided into two groups according to Anti-Müllerian hormone/AMH (ng/ml) levels and antral follicle count/AFC (2-9 mm), evaluated during the early follicular phase:

Diminished ovarian reserve (DOR/n=85): AMH<1+AFC<9

Normal ovarian reserve (NOR/=59): AMH≥2+AFC≥15

Participants/materials, setting, methods: DNA was extracted from peripheral blood samples taken from DOR and NOR groups. DNA was sequenced on MiSeq(Illumina) to search for single nucleotide polymorphisms (SNPs) in the MMP9 gene. SNPs were identified using TruSeq Custom Amplicon (TSCA) Panel (DesignStudio Illumina). This design was performed in order to sequencing the exons, 3' and 5' untranslated regions (UTRs) and some intronic regions. SNPs found by Next-Generation Sequencing (NGS) were analysed to find a possible association with DOR.

Main results and the role of chance: The MMP9 p.Gln279Arg polymorphism was identified. The genotyping results showed an association between MMP9 Gln/Gln and women presenting with DOR (table1).

Logistic regression (table 2) showed that patients with MMP9 Gln/Gln genotype had 3.0-fold increase in the chance of being included in the DOR group.

Table 1 Distribution of genotype/allele frequency in diminished and normal ovarian reserve groups.

MMP9 p.Gln279Arg	Diminished ovarian reserve	Normal ovarian reserve	*P*
Genotypes			
Gln/Gln	70.6%	44.1%	0.005
Gln/Arg	21.2%	44.1%	
Arg/Arg	8.2%	11.8%	
Alleles			
Gln	81.2%	66.1%	0.006
Arg	18.8%	33.9%	

Limitations, reasons for caution: Additional validation of the SNP analysed would be important to provide more information about the relationship of this polymorphism and ovarian reserve, once sample size was limited despite recruiting all eligible participants during the study period. Differences in the genetic backgrounds of various ethnic populations should also be considered.

Wider implications of the findings: The SNP identified could provide an additional tool to test ovarian reserve, helping in the individualization of ovarian stimulation protocols. To the best of our knowledge this is the first study relating this SNP and ovarian reserve.

Trial registration number: Not applicable. The local ethics committee authorized the study. This study was supported by Merck Grant for Fertility Innovation (GFI-2014-16).

Table 2 Logistic regression. Genotype X chance of diminished ovarian reserve.

MMP9 Genotypes	Odds Ratio	95% Confidence Interval	*P*
Gln/Gln	3.02	1.44 – 6.47	0.002
Gln/Arg	0.32	0.15 – 0.71	0.004
Arg/Arg	0.77	0.26 – 2.26	0.64

P-584 Cumulus cell telomere length is associated with vitamin D3's main catabolite 24,25-dihydroxyvitamin D3 concentration in serum and follicular fluid: An ovarian ageing explanation.

Study question: Is Vitamin D status associated with telomere length (TL) in cumulus cells (CC) and therefore implicated in ovarian ageing?

Summary answer: 24,25-dihydroxyvitamin D_3 ($24,25(OH)_2D_3$) concentrations in serum (S) and follicular fluid (FF) positively correlates with TL in CC of mature follicles in women of reproductive age.

What is known already: The vitamin D hypothesis of ageing has been recently proposed and involves the process of telomere shortening. Progressive shortening of telomeres has been associated with reproductive ageing and genomic instability during early development. $24,25(OH)_2D$, the main catabolite of 25-hydroxyvitamin D (25(OH)D), has been suggested as a systemic indicator of vitamin D status. We previously reported a high correlation between this metabolite and $25(OH)D_3$ concentrations in S and FF. Furthermore, after analyzing each metabolite separately, the strongest correlation between S and FF concentrations was observed for $24,25(OH)_2D_3$, suggesting $24,25(OH)_2D_3$ is an accurate indicator of ovarian vitamin D status.

Study design, size, duration: 35 egg donors were included during four months in this prospective, non-interventional cohort study. Following controlled ovarian stimulation using an antagonist protocol and standard doses of subcutaneous FSH, oocytes retrieval was performed 36 hours after a bolus of GnRH agonist. S samples and pooled FF from mature follicles were collected during the pick-up for $24,25(OH)_2D_3$ measurement via liquid chromatography-tandem mass spectrometry (LC-MS/MS). CC for cumulus cells telomere length (CCTL) measurement were obtained after oocyte stripping.

Participants/materials, setting, methods: Genomic DNA of CC from the 35 subjects was isolated. For relative CCTL, average delta cycle threshold (dCt) was obtained using a SYBR green quantitative real-time PCR protocol. A Taqman assay for the multicopy gene Alu was used for normalization of measurements. $24,25(OH)_2D_3$ concentrations were measured via LC-MS/MS using a UPLC-TQ-S Xevo Waters system with a Waters Acquity BEH C18 (1,7µm 2,1 x100mm) column. Pearson correlation analysis between $24,25(OH)_2D_3$ concentrations and relative CCTL was used.

Main results and the role of chance: Mean donor's age was 25.43±4.56 years. All the cases were included and studied during autumn and winter months.

None of them had taken vitamin D oral supplements during the last six months before sampling.

Mean value for $24,25(OH)_2D_3$ concentrations in S was 15.616±10.997 nmol/l. A previous report in a large British healthy population identified a serum concentration of $24,25(OH)_2D$>4.2 nmol/L as a diagnostic cut-off for 25(OH)D replete status. According to this, there was no vitamin D deficiency in our studied population of 35 healthy egg donors.

Mean value for $24,25(OH)_2D_3$ concentrations in FF was 11.263±6.0859 nmol/l, showing a high correlation with S values (R2=0.768, P-value=1.121e-7). Wilcoxon paired test showed significantly lower concentrations in pooled FF (P-value=0.004).

CCTL (Average dCt) mean value was 7.184 ± 0.477. Average dCt for CCTL was significantly correlated with $24,25(OH)_2D_3$ concentrations in S and FF (R2=-0.349, P-value=0.043 and R2=-0.365, P value=0.031, respectively). Since Ct values are inversely proportional to the amount of nucleic acids amplified, a higher dCt value indicates a shorter TL. Therefore, the obtained significant inverse correlation means that, the higher the vitamin D concentrations in S and FF, the longer the telomeres in the cumulus cells.

Limitations, reasons for caution: Our real-time PCR protocol measures relative telomere length, which allows for comparisons between samples, but does not provide an absolute length of the telomeres. It might not be sensitive enough to detect slight differences. Further, although a correlation exists, there are no known mechanisms by which vitamin D alters TL.

Wider implications of the findings: This is the first reported association between CCTL and the concentrations in S and FF of the first catabolite of vitamin D_3, $24,25(OH)_2D_3$. These results suggest that ovarian ageing could be associated with this accurate indicator of vitamin D status at systemic and reproductive level.

Trial registration number: Not applicable

P-585 Inhibition of GnRH-mediated intracellular signaling in vitro differs according to type of antagonist

L. Casarini[1], S. Sperduti[1], S. Limoncella[1], C. Lazzaretti[1], E. Paradiso[1], L. Riccetti[1], J. Bertacchini[1], C. Palumbo[1], R. Millar, P[2], S. Longobardi[3], F. Wieser[3], T. D'Hooghe[3], M. Simoni[1], C. Newton, L[2]

[1]*University of Modena and Reggio Emilia, Department of Biomedical- Metabolic and Neural Sciences, Modena, Italy*

[2]*University of Pretoria, Centre for Neuroendocrinology and Department, Petoria, South Africa*

[3]*Merck KGaA, Global Medical Affairs Fertility, Darmstadt, Germany*

Study question: Do Cetrorelix, Ganirelix and Teverelix have similar potency to antagonize GnRH?

Summary answer: 10 nM Cetrorelix is more potent than Ganirelix and Teverelix in inhibiting GnRH-mediated cAMP and intracellular Ca^{2+} increase *in vitro*.

What is known already: Cetrorelix, Ganirelix and Teverelix are GnRH antagonists that have decapeptidic structures that differ by only one and two amino acids. Cetrorelix and Ganirelix are used during ovarian stimulation as part of treatment with assisted reproduction technologies for preventing premature luteinizing hormone (LH) surges and inhibit LH production within about 3–12 hours. Although some reports have suggested that GnRH antagonists have different potencies at the cellular level, potentially leading to differences in outcomes, these differences are not well understood.

Study design, size, duration: This was an *in-vitro* model study of different doses of Cetrorelix, Ganirelix and Teverelix (ranging from pm to µM) for evaluating the inhibition of GnRH-induced short-term (0–30 minutes) and long-term (0–24 h) responses. Between three and six treated samples were compared, and GnRH antagonist-untreated samples served as controls.

Participants/materials, setting, methods: GnRH receptor I (GnRHR)-transfected HEK293 cells were used. Transfected and untransfected human neuroblastoma SH-SY5Y and the LβT2 mouse pituitary cell lines were also studied. Inhibition of GnRH-induced intracellular cAMP and Ca^{2+} increase, and pCREB, pERK1/2 and β-catenin activation were evaluated by bioluminescence resonance energy transfer (BRET), western blotting and immunostaining. Inhibition of 12-h *Lhb* gene expression was evaluated by real-time PCR.

Main results and the role of chance: In GnRHR-transfected HEK293 cells, 10 nM Cetrorelix inhibited GnRH-induced intracellular Ca^{2+} increase, whereas similar inhibition was seen with Ganirelix and Teverelix at a ten-fold higher concentration (100 nM [Mann-Whitney's U-test; $p<0.05$; n=6]). These findings were confirmed in GnRHR-transfected SH-SY5Y cells, where the 3 x 50% effective concentrations of GnRH antagonists were 10-fold higher than in HEK293 cells, probably due to differences in receptor expression at the cell surface between the two transfected cell lines. Untransfected HEK293 and SH-SY5Y cells did not reveal any detectable response to GnRH. Cetrorelix had higher efficacy than Ganirelix or Teverelix, resulting in an inhibitory concentration (IC_{50}) of 1.56±2.49 nM, which was lower than the inhibitory concentrations of Ganirelix (IC_{50}=16.60±3.76) or Teverelix (IC_{50}=62.80±3.77) (Mann-Whitney's U-test; $p<0.05$; n=5). In spite of the aforementioned differences between drugs in inhibiting short-term GnRH-mediated cell response, the antagonists depleted pCREB, pERK1/2 and β-catenin activation at similar concentrations (range 100 nM–1.0 µM; one-way ANOVA; $p\geq0.05$; n=3). All the antagonists tested inhibited GnRH-induced *Lhb* expression in LβT2 cells, suggesting that they may efficiently target luteinizing hormone production.

Limitations, reasons for caution: This was an *in-vitro* study and the differences in potency/efficacy seen for the three antagonists might not translate to *in-vivo* effects, as the metabolic clearance and pharmacokinetics may differ between the antagonists, especially due to different formulations and solubility.

Wider implications of the findings: The GnRH antagonists Cetrorelix, Ganirelix and Teverelix were different with respect to *in-vitro* activity for inducing intracellular Ca^{2+} increase. This may lead to different short-term regulation in the target cells, which could modulate the *in-vivo* outcomes.

Trial registration number: not applicable

P-586 Growth differential factor 9 suppresses expression of STAR, CYP17A1 and LHCGR in cultured human theca cells

X. Guo[1], M.H. Chen[1], L. Huang[1], Y.P. Zhong[1], C.Q. Zhou[1]

[1]*The First Affiliated Hospital of Sun Yat-sen University, Reproductive Medicine Center, Guangzhou, China*

Study question: What's the effect of growth differential factor 9 (GDF9) on production of androgen in human theca cells?

Summary answer: GDF9 can suppress expression of *STAR*, *CYP17A1*, *LHCGR* in cultured human theca cells; ALK5 and Smad4 may mediate suppression of *CYP17A1* by GDF9.

What is known already: GDF9, one of the oocyte-derived factors, has a critical impact on folliculogenesis. It has been shown that GDF9 can inhibit *CYP17A1* expression and production of androgen in cultured bovine theca cells and mouse theca-interstitial cells.

Study design, size, duration: This is a control versus treatment study. Each experiment was triplicated.

Participants/materials, setting, methods: Human theca cells were collected from discarded ovarian tissue after surgery and pathological examination and cultured in vitro. After the first 48 hours of culture, cells were treated with GDF9, GDF9 with SB525334 (an ALK5 inhibitor) or Kartogenin (an agonist of Smad4) at various doses. The medium was then collected to determine the concentration of androstenedione by chemiluminescent immunoassay. Cellular RNA was collected and extracted for quantification by real-time quantitative fluorescence PCR (RT-PCR).

Main results and the role of chance: GDF9 suppressed expression of *CYP17A1* and inhibited androstenedione production in human theca cells at a dose-dependent manner. At the dosage of 800ng/ml, GDF9 significantly suppressed *STAR* mRNA by 61% (p=0.014), *CYP17A1* mRNA by 54% (p=0.016)and *LHCGR* mRNA by 80% (p=0.02) and did not affect expression of *HSD3B* and *CYP11A1* in human theca cells. SB525334 antagonized the suppression of *CYP17A1* ($p<0.001$) by GDF9 while its antagonistic effect on suppression of *STAR* and *LHCGR* by GDF9 did not show statistically significance. Kartogenin significantly suppressed expression of *STAR* mRNA by 46% (p=0.010)and *CYP17A1* mRNA by 54% (p=0.042)and did not affect expression of *LHCGR, HSD3B* and *CYP11A1* in human theca cells.

Limitations, reasons for caution: This is an in vitro experimental study mainly focused on the association of GDF9 and GDF9 signaling pathway. In vivo

study and other possible signaling pathway should be taken into consideration for further research.

Wider implications of the findings: According to our results, dysregulation of GDF9 will result in an increased expression of *STAR*, *CYP17A1* and *LHCGR* genes in human theca cells, subsequently increasing the sensitivity to LH and androgen production in theca cells and finally forming hyperandrogenism phenotype in PCOS.

Trial registration number: N/A

P-587 Prevalence of psychological distress in polycystic ovarian syndrome (PCOS) infertile patients and non PCOS infertile controls and their relationship with clinical-biochemical parameters of the syndrome.

P. Nayar[1], K.D. Nayar[1], S. Gupta[1], M. Singh[1], M. Gupta[1], R. Gahlot[1], G. Kant[1], K. Nayar[1]

[1]Akanksha IVF Centre- Mata Chanan Devi Hospital, Reproductive Medicine, New Delhi, India

Study question: Are there increased levels of psychological distress in PCOS infertile patients in comparison to infertile controls and its association with clinical-biochemical features of the syndrome.

Summary answer: PCOS is associated with increased levels of psychological distress when compared to non PCOS infertile controls. Screening and management should be considered during routine assessment.

What is known already: Polycystic ovarian syndrome is the commonest endocrine disease affecting young women. Forty percent of infertile women are diagnosed with PCOS as a cause of infertility. Apart from infertility, PCOS has huge long term metabolic consequences that affects patient's quality of life (QOL). Coexisting mental health disorders have also been shown to impair patient's QOL. However it is difficult to say if they are particularly attributable to some clinical - biochemical features of PCOS per se. The emotional and financial strain of infertility treatment might also contribute to increased psychological distress in such patients.

Study design, size, duration: A single centre cross sectional study was carried out at a tertiary care infertility centre in India from 1st January 2018 through 31st December 2018. Two hundred and thirty eight infertile patients consented to participate in the study. One hundred and twenty PCOS infertile patients were matched to one hundred and eighteen non PCOS infertile controls.

Participants/materials, setting, methods: For assessing levels of anxiety and depression, Hamilton's Rating Scales (HAM-A, and HAM-D) were used. Schoff Questionnaire for eating disorders was used. Fertility and Quality of Life Questionnaire (FertiQoL) was used to index the quality of life. Hirsutism score and body mass index (BMI) were determined. Primary outcomes were the incidence of psychological disorders and their association with BMI and hyperandrogenism.

Main results and the role of chance: The baseline prevalence of depression in PCOS patients was 37.5% and in non PCOS infertile controls was 25.42% (p=0.04), baseline prevalence of anxiety in PCOS patients was 41.67% and in non PCOS infertile controls was 29.66% (p=0.05); both were statistically significant. The prevalence of eating disorders in POCS patients was 0.02% and in non PCOS infertile controls was 0.01%; the difference was not statistically significant (p=0.57). The HAM-A scores in PCOS and non- PCOS infertile controls (14.45±8.24 vs. 11.75±8.39; p= 0.012) and HAM-D scores (14.25±8.06 vs. 11.45±7.05; p=0.004) in PCOS and non-PCOS infertile controls; the difference was statistically significant. There was no difference in scores of Core FertiQoL for both the groups. Both groups showed comparable reduced quality of life. BMI and hirsutism score was positively correlated with HAM-A and HAM-D scores.

Limitations, reasons for caution: Although it is a prospective study, it has limitation of small sample size.

Wider implications of the findings: PCOS is a complex disorder associated with alarming levels of psychological distress which is much greater when compared to non PCOS infertile controls. Counsellor should routinely evaluate all infertile patients, especially PCOS from a mental health perspective. Counselling in addition to pharmacotherapy would help improve their quality of life.

Trial registration number: MCDH/2018/80

P-588 What is the optimal duration of progesterone supplementation prior to frozen-warmed blastocyst transfer in a hormone replacement therapy cycle?

C. Roelens[1], S. Santos-Ribeiro[2], L. Becu[3], S. Mackens[1,3], L. Van Landuyt[1], A. Racca[1], A. Van de Vijver[1,4], H. Tournaye[1], C. Blockeel[1,5]

[3]Vrije Universiteit Brussel, Faculty of Medicine and Pharmacy, Jette, Belgium

[4]AZ Sint-Jan, Fertiliteitskliniek - Campus Sint-Jan, Brugge, Belgium

[5]University of Zagreb, Department of Obstetrics and Gynecology- School of Medicine, Zagreb, Croatia

Study question: Is there a difference in live birth rate (LBR) between 6 and 7 days of progesterone (P) administration, prior to frozen-warmed embryo transfer (FET)?

Summary answer: LBRs are not significantly different when 6 or 7 days of P are administered. Six days of P yields higher clinical pregnancy and miscarriage rates.

What is known already: Thanks to recent developments, embryo cryopreservation has become a first-line procedure. Concerning the optimal duration of P administration prior to FET no consensus is yet defined. Current evidence showed no significant difference in clinical pregnancy rates between 5 and 7 days of P administration preceding blastocyst transfer. Although some studies presumed that endometrial receptivity could be achieved after very short P exposure, other studies showed a higher risk of pregnancy loss if the endometrium was insufficiently decidualized. These findings could be explained by an embryo-endometrium asynchrony potentially caused by transferring an embryo in a not yet sufficiently P primed endometrium.

Study design, size, duration: We performed a retrospective cohort study in a tertiary university-based referral hospital from December 2015 until December 2017. A total of 984 patients, undergoing a FET in a hormone replacement therapy cycle (HRT) were included. Day 5 and day 6 vitrified blastocysts were warmed and transferred the same day. Patients were included only once with the first FET.

Participants/materials, setting, methods: The primary outcome was live birth defined as a live born delivery after 24 weeks. LBRs were compared between 6 and 7 days of P supplementation. Multivariable regression analysis was used to account for confounding variables, specifically: age at vitrification, BMI, indication for treatment, parity, smoking habits, outcome of the fresh IVF/ICSI cycle, applied type of in vitro technique, embryo quality, endometrial thickness, duration of estradiol supplementation preceding FET and single or double embryo transfer.

Main results and the role of chance: The median age at vitrification was 31 years (6 days) and 32 years (7 days), respectively (p=0.31). Preimplantation genetic testing was performed significantly more in the day 6 group (5.5% versus 1.6% for respectively 6 and 7 days; p=0.001). Ovulation disorders and polycystic ovarian syndrome were also more common in the day 6 group (23.2% for 6 days and 17.0% for 7 days, p=0.018). Double embryo transfer was performed more frequently in the day 7 group (9.0% versus 13.2%, p=0.036).

Pregnancy outcomes after univariable analysis showed significantly higher positive hCG rates and clinical pregnancy rates after 6 days of P supplementation compared to 7 days (60.1% versus 53.6%, p=0.041 and 55.7% versus 48.4%, p=0.023).

LBRs showed similar results in both treatment arms (36.9% for 6 days and 37.2% for 7 days, respectively, p=0.91), even after adjusting for confounding factors (aOR 1.05, 95% CI 0.78-1.40, p=0.75). Biochemical pregnancy rates were comparable between both groups (4.4% for 6 days and 5.2% for 7 days, p=0.55), but miscarriage rates were significantly higher in the 6 days group compared to the 7 days group (27.2% versus 19.5%, respectively, p=0.034).

Limitations, reasons for caution: Although this study adjusts for multiple potential confounding factors and includes patients only once with the first FET, the results remains limited by the retrospective nature of the study and its potentially associated bias and should be interpreted with caution. Confirmation of the findings in a prospective setting is necessary.

Wider implications of the findings: Six or 7 days of P administration does not significantly affect LBRs. However, we argue that 6 days could be insufficient to induce adequate endometrial secretory changes, showing significantly higher clinical pregnancy and miscarriage rates in this group. Further research is needed to reach consensus regarding the ideal P duration.

[3]The Fertility Clinic, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark
[4]Department of Occupational- and Environmental Medicine, Bispebjerg and Frederiksberg University Hospital, Copenhagen, Denmark
[5]Department of Gynaecology, Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark

Study question: Can ovarian biopsying per se and/or autotransplantation of cortical tissue fragments activate and increase the number of recruitable follicles for IVF/ICSI in women with DOR?
Summary answer: Neither ovarian biopsying nor autotransplantation of the cortical tissue fragments increased the number of recruitable follicles after ovarian stimulation for IVF/ICSI after 10 weeks follow-up.
What is known already: Infertile women with DOR constitute a group of patients with poor reproductive outcome mainly due to the low number of mature oocytes available after ovarian stimulation for IVF/ICSI. Recent studies have shown, that *in vitro activation* of residual follicles by both chemical drug treatment and ovarian tissue fragmentation followed by autotransplantation resulted in return of menstrual cycles and pregnancies in a fraction of women with premature ovarian insufficiency.
Study design, size, duration: A prospective clinical cohort study including 20 women with DOR treated at the Fertility clinic at Rigshospitalet, Denmark during April 2016 - December 2017. Follow-up of non-pregnant women ended in September 2018 and were on average 280 days (range 118-408). Women who conceived are followed until delivery.
Participants/materials, setting, methods: Infertile, menstruating women aged 30-39 years with IVF/ICSI indication and repeated AMH measurements < 5 pmol/L (0.7 ng/ml) were included. By laparoscopy four biopsies were taken from one ovary randomized between the left or right ovary. The other ovary served as control. Cortical tissue was fragmented and autotransplanted to peritoneum. Recordings of hormones, antral follicle count (AFC) and assessment of ectopic follicle growth were done weekly. After 10 weeks ovarian stimulation for IVF/ICSI was initiated.
Main results and the role of chance: In term of our primary out-come, no difference was observed in the number of mature follicles in the biopsied ovary versus the control ovary after ovarian stimulation (1.0 versus 0.7 follicles, p=0.35). In only three women, growth of four follicles were detected at the graft site 24-268 days after the procedure. One ectopic oocyte was retrieved and fertilized, but embryonic development failed. Overall AMH levels did not change significantly (p=0.2). Mean AFC increased by 0.14 (95%CI: 0.06;0.21) per week (p<0.005) and the biopsied ovary had on average 0.6 (95%CI: 0.36;0.88) follicles less than the control ovary (p = 0.01). Serum levels of androstenedione and testosterone increased significantly by 0.63 nmol/L (95%CI: 0.21;1.04) and 0.11 nmol/L (95%CI: 0.01;0.21) one week after the procedure, respectively. Testosterone increased continuously by 0.0095 nmol/L (95%CI: 0.0002;0.0188) per week (p=0.045). In 7 of the 20 women mean AMH increased from 2.08 pmol/L (range 1.74-2.34) to 3.94 pmol/L (range 3.66-4.29) from week 1-4 to week 5-8. Clinical pregnancies were obtained in 12 of the 20 (60%) women, either naturally (n=3) or after a total of 55 IVF/ICSI/insemination treatments (n=9). We expect a cumulated live birth rate per started IVF/ICSI cycle of 18.4% (including two ongoing pregnancies).
Limitations, reasons for caution: Limitations of the study were the low number of included women and the lack of a control group. Moreover, 45% of the women had no male partner at inclusion. However, these women had an average of 6.5 (range 4-9) unsuccessful medically assisted reproduction treatments with donor sperm prior to inclusion.
Wider implications of the findings: These findings suggest that biopsying and autotransplanting of ovarian fragments do not augment the number of recruitable follicles for IVF/ICSI after 10 weeks. However, a high pregnancy rate and that some women had an AMH increase after 5-8 weeks warrant a larger study on the possible effects of biopsying alone.
Trial registration number: NCT02792569

P-590 Effect of serum vitamin D level on the cumulative live birth rate of the first in vitro fertilization cycle

J. Ko[1], J. Shi[1,2], R.H.W. Li[1], W.S.B. Yeung[1], E.H.Y. Ng[1]

[1]The University of Hong Kong- Queen Mary Hospital, Department of Obstetrics and Gynaecology, Hong Kong, Hong Kong
[2]Peking Union Medical College Hospital- Peking Union Medical College and Chinese Academy of Medical Sciences, Department of Obstetrics and Gynaecology, Beijing, China

Study question: Is serum vitamin D level associated with the cumulative live birth rate (CLBR) of the first in vitro fertilization (IVF) cycle?
Summary answer: Serum vitamin D level is not associated with the CLBR in women undergoing the first IVF cycle.
What is known already: Vitamin D receptors are present in various tissue in the female reproductive tract. Studies on the association between serum vitamin D level and clinical outcome after IVF showed conflicting results. Data from meta-analyses showed a lower live birth rate for women with vitamin D deficiency, the possible mechanism being mediated through the endometrium. The existing reports mainly focused on a single fresh or frozen embryo transfer cycle. There is no data on the effect of vitamin D on the CLBR in one IVF cycle.
Study design, size, duration: This is a retrospective cohort study including 1220 infertile women aged less than 43 years who underwent the first IVF cycle in a university reproductive medicine centre from January 2013 to December 2016 inclusive. Women using donor oocytes, modified natural cycles, in vitro maturation, pre-implantation genetic testing or those whose archived serum sample cannot be retrieved were excluded.
Participants/materials, setting, methods: All women underwent their first IVF cycle in the unit. Archived serum samples taken on the second day of menses before gonadotrophin stimulation and stored at -20°C until measurement were analyzed for 25(OH)D levels. The main outcome measure was the CLBR following the fresh embryo transfer and replacement of frozen embryos derived from the index stimulation cycle. Vitamin D deficiency/insufficiency was defined as serum 25(OH)D < 30ng/ml based on the Endocrine Society Clinical Practice guidelines.
Main results and the role of chance: Among the 1220 women, 5 had ongoing pregnancy, 78 women still had embryos in storage and 3 were lost to follow up. The median age was 36 (25^{th}-75^{th}percentile 34-38) years and the median serum 25(OH)D level was 18.2 (25^{th}-75^{th}percentile 14.7-22.0)ng/ml. 61.7% had deficient vitamin D levels (< 20ng/ml) and 95.7% had vitamin D in the deficient/ insufficient range (<30ng/ml). There was no significant difference in the median vitamin D levels in those who achieved a live birth and those who did not [18.1 (14.9-21.8)ng/ml vs 18.1(14.5-21.9)ng/ml, p=0.997]. When analyzing the result based on the Endocrine Society Clinical Practice guideline threshold of 30ng/ml, there was no significant difference in the CLBR in the vitamin D deficient/ insufficient group compared to the replete group (515/1088, 47.3% vs 21/46, 45.7% respectively, p=0.823). There was no difference in the clinical pregnancy rates in the fresh cycle in both groups (423/1168, 36.2% vs. 16/52, 30.7%, p=0.423) but a lower live birth rate per fresh transfer in the vitamin D replete group (327/891, 36.7% vs 11/34, 32.4%, p<0.001). Vitamin D did not independently affect the live birth rate per fresh transfer after controlling for age and antral follicle count.
Limitations, reasons for caution: Our study was retrospective in nature and the majority of the women in the study were vitamin D deficient/ insufficient. The recommended serum vitamin D levels were based on evidence

on bone health and there is no consensus on the appropriate cut-off for non-skeletal effects.

Wider implications of the findings: 95.7% of infertile women undergoing IVF in our study were vitamin D deficient/ insufficient. Future interventional studies on the effect of vitamin D on the live birth rate in infertile women undergoing IVF are needed to answer the question on whether preconceptual vitamin D supplement should be provided.

Trial registration number: HKUCTR-2361

P-591 Late-follicular phase progesterone rise does not affect embryo euploidy and cumulative live birth rates. An analysis of 1500 embryos following PGT-A

N.P. Polyzos[1], S. Garcia-Martinez[1], I. Rodriguez[1], P. Montoya-Botero[1], F. Martinez[1], P. Barri[1], B. Coroleu[1]

[1]Dexeus University Hospital, Reproductive Medicine Department, Barcelona, Spain

Study question: Is late-follicular phase progesterone rise associated with a deleterious on embryo quality or embryo euploidy rates and cumulative live birth rates (CLBRs)?

Summary answer: Late-follicular progesterone rise does not have a deleterius effect on embryo quality and embryo euploidy rates nor on cumulative LBRs.

What is known already: Previous studies have shown that late follicular phase progesterone elevation may adversely affect pregnancy outcomes in IVF/ICSI cycles. Although the vast majority of the studies supported a potential detrimental effect of progesterone elevation on implantation rates, recent reports support a potential detrimental effect of progesterone elevation on embryo quality

Study design, size, duration: A retrospective analysis of all GnRH antagonist down-regulated ICSI cycles followed by (PGT-A) and deferred Frozen embryo transfer between 2016 and 2017 was performed. The sample was stratified according to the following P levels on the day of triggering: <1.50 and ≥1.50 ng/ml. The primary outcomes were embryo euploidy rates, embryo utilization rates and cumulative LBR

Participants/materials, setting, methods: Overall 1525 embryos were from 345 ICSI PGT-A cycles were treated in a university-affiliated hospital. Results were compared between patients with normal or elevated progesterone levels on the day of triggering, using multivariable regression analysis in order to account for potential confounding factors. Furthermore, mixed regression models were created using progesterone on the day of triggering as a continuous variable to evaluate its effect on embryo euploidy rates, embryo utilization rates, and cumulative LBRs.

Main results and the role of chance: Late follicular phase progesterone was associated with a higher number of oocytes retrieved, higher BMI, higher gonadotropin starting dose and late follicular estradiol levels.

Embryo euploidy rates were comparable between patients with normal (<1.50ng/ml) vs. high (≥1.50 ng/ml) late follicular phase serum progesterone levels 39.5% [36.4%-42.5%] vs. 38.7% [29.4%-48.0%].

Similarly, no differences were observed in embryo utilization rate 59.5% [56.9%-62.1%] vs. 58.0% [50.6%-65.4%] and clinical pregnancy 63.4% vs 68.3%, p=0.543.

Live birth rate in the first FET cycle 49.2% vs. 46.3%, p=0.733 and CLBR 40.4% vs. 50%, p=0.257. Cycles with elevated progesterone were cycles with higher number of embryos, normal (<1.50ng/ml) vs. high (≥1.50 ng/ml) 4.19±2.7 vs. 6.21±2.99 p<0.001 and borderline non-significant higher number of euploid embryos 1.66±1.69 vs. 2.34±2.27, p=0.082.

Multinomial regression analysis adjusted by age, number of oocytes retrieved and progesterone elevation (<1.50ng/ml vs. ≥1.50 ng/ml) demonstrated that progesterone rise (>1.50) does nor affect euploidy rates (OR 0.942 95% CI [0.671-1.321]). Similarly, a regression analysis failed to demonstrate any effect of progesterone levels on the number of euploid embryos following adjustments for age and number of oocytes retrieved whereas CLBRs were also not associated with progesterone elevation OR 0.91 (0.398-1.649).

Limitations, reasons for caution: This is a retrospective study and despite the use of regression models, residual confounding bias cannot be excluded. In addition, our study focused mainly on embryo quality and euploidy rates and was restricted only in PGT-A cycles followed by FET preventing us from evaluating progesterone elevation effect on fresh ET.

Wider implications of the findings: Our findings seriously question results from previous studies claiming a detrimental effect of progesterone elevation on embryo quality and progesterone elevation appears to have no effect on embryo euploidy and embryo utilization rates.

Trial registration number: NA

P-592 hCG improves steroidogenic activity and luteal function through the activation of JNK signaling pathway in human luteal granulosa cells

G. Bildik[1], N. Akin[1], K. Yakin[2,3], T. Onder[4], Y. Esmaeilian[1], B. Balaban[3], B. Urman[2,3], O. Oktem[2,3]

[1]Koc University School of Medicine and Graduate School of Health Sciences, Reproductive Medicine, Istanbul, Turkey

[2]Koc University School of Medicine, Department of Obstetrics and Gynecology, Istanbul, Turkey

[3]American Hospital Women's Health Center, Assisted Reproduction Unit, Istanbul, Turkey

[4]Koc University School of Medicine, Department of Molecular Biology and Genetics, Istanbul, Turkey

Study question: What is the molecular mechanism of improvement of luteal function after hCG treatment in luteal granulosa cells?

Summary answer: hCG-induced up-regulation of steroidogenic enzymes and increased progesterone (P_4) production involves activation of JNK pathway in human luteal granulosa cells (HLGCs).

What is known already: hCG improves luteal function (luteal phase support) and increases P_4 production by binding to LH receptors expressed on the luteal granulosa cells in human. But the molecular mechanisms underlying these actions of hCG are not well-characterized.

Study design, size, duration: An in vitro translational research study conducted on human luteal granulosa cells obtained from IVF patients stimulated with GnRH antagonist (n=15) and agonist protocols triggered with recombinant hCG (15) or with a GnRH agonist (n=15).

Participants/materials, setting, methods: Human luteal granulosa cells were isolated from follicular aspirates during oocyte retrieval procedure. The expression of steroidogenic enzymes and LH receptor were validated by qRT-PCR and western blotting. E_2/P_4 productions were measured by ECLIA method. Endogenous JNK activity was measured using a commercially available kit. siRNA technology was used to interfere with JNK and LH receptor. Pharmacological JNK inhibitors were also used to interrupt the pathway.

Main results and the role of chance: hCG significantly increased the expression and activity of JNK along with up-regulated expression of steroidogenic enzymes (stAR, SCC, 3B-HSD, 17B-HSD, aromatase), LH receptor and VEGF in a dose-dependent manner in the HLGCs in all three types of stimulation protocols. As a result, in vitro E_2/P_4 production of the cells were increased in a dose-dependent manner. These effects were abolished when the cells were treated with hCG after down-regulation of LH receptor via siRNA. The inhibition of basal and hCG induced JNK activation via pharmacological inhibitors (AS601245/SP600125) or siRNA down-regulated the expression of steroidogenic enzymes and decreased in vitro hormone production. Promoter assay revealed that c-Jun binds to activator protein-1 (AP-1) motif in the promoter region of stAR and increases both stAR transcription and P_4 synthesis in the luteal granulosa cells and hCG enhanced this effect. Activin-A opposes hCG and reverses luteinization. Activin-A treatment significantly up-regulated the expression of FSH and suppressed LH receptors, steroidogenic enzymes and P_4 and E_2 production in a dose-dependent manner along with down-regulated expression and activity of JNK in the cells. These suppressive effects of activin-A on steroidogenesis and JNK pathway were reversed when its receptor was antagonized with a specific blocker.

Limitations, reasons for caution: Corpus luteum is composed of many different cell types and has as early, mid and late phases. Mural luteal graulosa cells is only one of those cell types and represent early stage of the phase.

Wider implications of the findings: Our findings could be important from the perspective of corpus luteum biology in human because we have for the

first time identified a role for JNK pathway in the regulation of steroid synthesis in human luteal granulosa cells.
Trial registration number: None

P-593 Can post-hoc progesterone supplementation rescue the clinical outcomes in the patients with low serum progesterone on the day of embryo transfer?

Y.P. Chang[1], T.H. Chuang[1], S.C. Huang[1], Y.H. Hsu[1], M.J. Lee[1], H.L. Wang [1], H.H. Lai [1]
[1]Stork Fertility Center- Stork Ladies Clinic, Stork Fertility Center, Hsinchu City, Taiwan R.O.C.

Study question: Can the low serum progesterone (P) on the day of embryo transfer (ET) be rescued by post-hoc supplementation in patients with frozen embryo transfer?
Summary answer: With additional P supplements, 15.8% of patients with low P on ET day displayed low P on pregnancy test (PT) day and diminished clinical outcomes.
What is known already: Progesterone plays an important role in the embryo implantation. In a natural cycle, P is secreted by corpus luteum mediating endometrial receptivity and stability. Previous reports indicated that embryo implantation and ongoing pregnancy required exogenous P influence on the endometrium, leading to lower miscarriage rate and higher implantation rate in IVF patients.
Study design, size, duration: A retrospective cohort study went from January to November in 2018 (11 months). A total of 1057 cycles from 911 patients were involved in the cohort, consisting of 469 cycles from 420 auto-IVF patients and 588 cycles from 491 oocyte recipients.
Participants/materials, setting, methods: All the patients received hormonal replacement therapy (HRT), with mean endometrium thickness of 9.79 mm, mean age at 38.58 years (24-56), and mean body mass index (BMI) of 21.95 kg/m^2. The administration of exogenous P included intramuscular injection (25 mg/vial), oral (100 mg/tablet), or vaginal supplements (90 mg). Serum P was monitored on the two endpoints during transfer cycle: P on the day of ET, and P on the day of PT.
Main results and the role of chance: Thirty-eight patients (4.2%, 38/911) had serum P $\leq$ 10 ng/ml on the day of ET, and thus their post-hoc dose of exogenous P supplements was significantly higher than that in the patients with P $>$ 10 ng/ml (805.44 $\pm$ 35.3 mg/day versus 734.82 $\pm$ 5.21 mg/day, p=0.01). Then, no difference was observed in the serum P levels on the day of PT between the above two groups (34.42 $\pm$ 5.96 ng/ml versus 41.97 $\pm$ 1.51 ng/ml; p=0.34), and the following b-HCG(+) rate, clinical pregnancy rate (CPR), implantation rate (IR), and ongoing pregnancy rate (OPR) showed comparable performances. Thirty-two patients (84.2%, 32/38) with originally low P on the day of ET had acceptable P on the day of PT (39.55 $\pm$ 6.71 ng/ml), while 6 patients remained low P on the day of PT (15.8%, 6/38); OR (95% CI): 2.74 (1.10-6.81). When analyzed by the serum P on the day of PT, 62 patients had P $\leq$ 10 ng/ml (6.8%, 62/911), and their clinical outcomes were significantly compromised than that in the group with P $>$ 10 ng/ml.
Limitations, reasons for caution: Women with abnormal uterine state, thin endometrium thickness ($<$ 6 mm), or displaced window of implantation were not analyzed in the study.
Wider implications of the findings: Administration of additional dose of post-hoc P supplements according to the minimum threshold of serum P level on the day of ET may recover the clinical outcomes.
Trial registration number: Not applicable.

P-594 Prospective randomized trial comparing corifollitropin-alfa late start (day 4) vs. corifollitropin-alfa standard start (day 2) in expected poor, normal and high-responders undergoing IVF/ICSI

A. Revelli[1], M. Sestero[1], S. Canosa[1], C. Filippini[2], G. Pittatore[1], F. Salvagno[1], G. Gennarelli[1], C. Benedetto[1]
[1]Physiopathology of Reproduction and IVF Unit- Sant'Anna Hospital, Surgical Sciences- University of Torino, Torino, Italy
[2]Statistics- Molinette Hospital, Department of Surgical Sciences- University of Torino, Torino, Italy

Study question: Can CF-alfa late start administration obtain similar oocyte yield (primary outcome) and clinical pregnancy rate/ embryo transfer (cPR/ET) than CF-alfa standard day 2 administration?
Summary answer: In high or normal responders to controlled ovarian stimulation (COS), CF-alfa may be administered either on day 4 or day 2 obtaining comparable IVF outcome.
What is known already: It is known that acceptable IVF results may be obtained when FSH is started on day 4-5 of GnRH-antagonist cycle, with the advantage of reducing the number of injections. The quick rise of circulating FSH levels after CF-alfa administration makes it very fit for use in late start COS regimens. A previously published retrospective analysis showed that late-start CF-alfa is as effective as late-start daily recombinant FSH in obtaining oocytes. Moreover, a pilot prospective study comparing CF-alpha day 2 vs. day 4 start in a small cohort of IVF patients reported a similar outcome with the two regimens.
Study design, size, duration: RCT included 113 women undergoing IVF/ICSI for tubal or male infertility, aged 18-43, without polycystic ovary or history of severe ovarian hyperstimulation syndrome. According to biomarkers (anti-Mullerian hormone and antral follicle count), patients were subgrouped as follows: 43 patients with expected high responsiveness to COS (AFC$>$15, AMH$>$3.5 ng/ml), 31 patients with expected poor responsiveness (Bologna criteria for poor response, AMH$<$1.1 ng/ml, AFC$<$7), 39 patients with expected normal responsiveness (AFC 7-15, AMH 1.1-3.5 ng/ml).
Participants/materials, setting, methods: In all subgroups, patients were randomized (computer-driven randomization) into 2 treatment arms: a) CF-alfa 100-150 mcg on day 4 + GnRH-antagonist 0.25/d s.c from day 8 + (eventually) recFSH 150-300 IU/d from day 11; b) CF-alfa 100-150 mcg on day 2 + GnRH-antagonist 0.25/d s.c from day 6 + (eventually) recFSH 150-300 IU/d from day 9. IVF or ICSI were performed according to standard protocols of our IVF Unit.
Main results and the role of chance: Considering all patients, CF-alfa late start regimen obtained comparable oocyte yield and cPR/ET than standard day 2 administration (8.9$\pm$5.6 vs. 8.8$\pm$6.2 and 24.1% vs. 30.5% respectively, p=n.s.). The same was observed in both high and normal responders, in which oocyte yield and cPR/ET were comparable (12.8$\pm$5.1 vs. 12.8$\pm$6.1 and 44% vs. 34.5%, respectively, in high responders, p= n.s.; 6.7$\pm$4 vs. 7.3$\pm$5.2 and 16.7% vs. 26.3%, respectively, in normal responders, p=n.s.). Differently, in poor responders oocyte yield was similar (4.2$\pm$2.9 vs. 4.3$\pm$3.3), but cPR/ET was significantly lower with late start CF-alfa administration than with standard administration (zero vs. 27.2%; p=0.03), with 40% cancellation rate due to monofollicular response in the late start arm. The analysis of ROC curves showed that the threshold AMH level implying a high probability of cycle cancellation (specificity 90%) was $\leq$0.6 ng/ml for late start regimen, $\leq$0.2 ng/ml for standard regimen.
Limitations, reasons for caution: The power analysis was performed according to the primary outcome (number of retrieved oocytes), and therefore all differences between treatment arms for the secondary outcomes should be considered as purely indicative, and verified in further adequately powered trials.
Wider implications of the findings: CF-alfa allows flexibility in COS as it may be administered either on day 2 or 4 to patients with expected high or normal response to FSH. Late start administration seems to be unadvisable for expected poor responders with AMH $\leq$0.6 ng/ml due to the high risk of cycle cancellation.
Trial registration number: NCT03816670

P-595 Controlled ovarian stimulation (COS) for breast cancer patients: the effect of starting day of letrozole

M. Jeong[1], J.Y. Han[1], H. Kim[1,2], S.Y. Ku[1,2], C.S. Suh[1,2], S.H. Kim[1,2], Y.M. Choi[1,2]
[1]Department of Obstetrics and Gynecology, Seoul National University Hospital, Seoul, Korea- South
[2]Department of Obstetrics and Gynecology, Seoul National University College of Medicine, Seoul, Korea- South

Study question: Is there any difference in the results of controlled ovarian stimulation (COS) for breast cancer patients depending on the starting day of letrozole?

Summary answer: When letrozole was started prior to gonadotropin, the duration of gonadotropin stimulation was shorter than when letrozole and gonadotropin were started on the same day.

What is known already: For breast cancer patients, COS with letrozole has been performed to prevent the elevation of serum estradiol levels. Initially a COS protocol was suggested in which letrozole was started at the early follicular phase and follicle-stimulating hormone (FSH) was added 2 days later. Since the random-start COS protocol for fertility preservation was introduced, letrozole and gonadotropin have usually been started on the same day of the menstrual cycle. There is no consensus on when to initiate letrozole and the effect of starting day of letrozole on COS outcome is not well known.

Study design, size, duration: In this retrospective study, data from 74 breast cancer patients who underwent total of 78 COS cycles at a single tertiary center were examined. Cycles for fertility preservation (n=65) and general in vitro fertilization (IVF) cycles (n=13) were all included. Cases for fertility preservation comprised of cycles for oocyte cryopreservation (n=43) and those for embryo cryopreservation (n=35).

Participants/materials, setting, methods: Subjects were classified into two groups, 'pre-start' group (n=21) in which letrozole was initiated one or two days before gonadotropin and 'co-start' group (n=57) where letrozole and gonadotropin were started from the same day. Clinical characteristics and outcome variables of COS were compared between two groups. Subgroup analysis was carried out for the cycles started at the follicular phase.

Main results and the role of chance: Baseline characteristics were not significantly different between two groups. In the 'pre-start' group, the duration of ovarian stimulation (days) was shorter and total dosage of gonadotropin (IU) was less than the 'co-start' group (7.0 ± 1.8 vs. 8.8 ± 1.9, $p<0.001$, 1826.8 ± 1053.3 vs. 2500.7 ± 1208, $p=0.013$, respectively). The number of total oocyte retrieved and mature oocyte, oocyte maturity rate were similar between two groups. For cases with embryo cryopreservation, total number of embryo and fertilization rate were also examined and showed no significant difference between 'pre-start' cases and 'co-start' ones. Among random-start cycles which were initiated at the luteal phase, letrozole and gonadotropin were started from the same day in all cases. Accordingly, subgroup analysis was performed only for the cycles initiated at the follicular phase. In subgroup analysis, the duration of stimulation (days) was still significantly shorter in the 'pre-start' cycles (n=21) than the 'co-start' ones (n=25) (7.0 ± 1.8 vs. 8.0 ± 1.6, $p=0.009$). Total dosage of gonadotropin (IU) was less and peak estradiol (E2) level was lower in the 'pre-start' subgroup than the 'co-start' subgroup, though not statistically significant.

Limitations, reasons for caution: Limitations of this study included the retrospective design and the small sample size. Another limitation is the heterogeneity of subjects, including both fertility preservation and conventional IVF cases, which makes it difficult to analyze the results and compare the pregnancy outcome. Further prospective studies with larger, homogenous cohorts are needed.

Wider implications of the findings: When performing COS in patients with breast cancer, administering letrozole earlier than gonadotropin may result in comparable outcomes with less dosage of gonadotropin and shorter injection period, which can be regarded as a cost-effective and more patient-friendly method.

Trial registration number: No external funding was used for this study. None of the authors has any potential

P-596 PPARG splicing variant inhibits cell proliferation,migration and apoptosis in granulosa cells of PCOS patients

C. Shi[1], J. Xu[1], Y. Wu[1], H. Huang[1]

[1]International Peace Maternal and Child Health Hospital- School of Medicine-Shanghai Jiao Tong University-, Department of reproductive centre, Shanghai, China

Study question: What's the effects of PPARG splicing variant on granulosa cells of PCOS patients?

Summary answer: PPARG splicing variant inhibits cell proliferation, migration and apoptosis in granulosa cells.

What is known already: Polycystic ovarian syndrome (PCOS) is the most common endocrine disorder in women of reproductive age, with hyperandrogenism, rare ovulation or anovulation, and ovarian polycystic changes. In recent years, the role of epigenetic modification abnormalities in PCOS has gradually become a hot spot in reproductive research. Peroxisome proliferator activated receptor gamma(PPARG) belongs to the nuclear hormone receptor superfamily and is implicated in a wide range of physiological processes. PPARG plays an irreplaceable physiological function in reproduction and metabolism. Quantities of studies have suggested that epigenetic modifications of PPARG regulate ovarian hormone synthesis/secretion, follicular development, insulin resistance, and lipid metabolism etc.

Study design, size, duration: 153 women with PCOS and 153 normal women who underwent in vitro fertilization-embryo transfer therapy due to tubal factors or male factors were recruited. The expression of PPARG and its splicing variant in granulosa cells in both groups were detected by PCR and analyzed with clinical data. The overexpressed KGN cell model stably transfected with PPARG and its splicing variant were established using lentivirus. Then we detected cell proliferation, migration and apoptosis through multiple experiments.

Participants/materials, setting, methods: Expression of normal PPARG and PPARG splicing variant(SV) in human granulosa cells was determined by RT-PCR. Then the over-expression of PPARG and PPARG SV were constructed in KGN cell. Cell proliferation, migration and apoptosis were measured by western blot, immunofluorescence, and wound healing assay, respectively. Western blot analysis was used to measure the protein expression of apoptosis-related proteins.

Main results and the role of chance: The expression of PPARG splicing variant was detected in both PCOS and control groups. The sequencing results showed that exon5 was deleted. The expression of PPARG was decreased in PCOS group and the expression of its splicing variant was increased compared to the control group . Clinical data showed that there were obvious menstrual disorders, higher androgen and estrogen level in PCOS group .Besides, the clinical phenotype of PCOS patients with PPARG splicing variant was more obvious. Upregulation of PPARG splicing variant inhibits cell proliferation, migration and cell apoptosis. While granulosa cells contribute a lot to the development of follicles, our results suggest that PPARG SV may dysregulate cell proliferation and apoptosis in granulosa cells, which could partially explain mechanisms of ovulation dysfunction in PCOS.

Limitations, reasons for caution: The oocytes present in the follicles are encapsulated in granulosa cells. This study found that PPARG SV in granulosa cells inhibited cell proliferation, migration and apoptosis. However, we still don't known the direct effects of PPARG SV on the oocytes.

Wider implications of the findings: The results suggest the epigenetic role of PPARG splicing variant in the pathogenesis and throw new light on the treatment of PCOS. Our findings will allow us to take the next step in the new field of PCOS pathogenesis.

P-597 Pharmacological Treatment vs. Combination of Electroacupuncture and Medication in Improving Menstrual Cycle, Ovarian Volume, and Antral Follicle Count in PCOS Patients: Double-Blind Randomized Clinical Trial

R. Muharam[1], A. Baziad[2], R. Rajuddin[3], W. Kurniawan[4]

[1]University of Indonesia, Departement of Obstetrics and Gynecology- Faculty of Medicine, Jakarta, Indonesia

[2]University of Malikussaleh, Faculty of Medicine, Lhokseumawe, Indonesia

[3]Syiah Kuala University, Departement of Obstetrics and Gynecology- Faculty of Medicine, Aceh, Indonesia

[4]University of Indonesia, Departement of Medical Acupunture, Jakarta, Indonesia

Study question: Does combination of electroacupuncture and pharmacological treatment improve menstrual cycle, ovarian volume, and antral follicle count in PCOS patients?

Summary answer: Combination of electroacupuncture with medical therapy has better efficacy in decreasing menstrual cycle length, ovarian volume, and antral follicle counts in PCOS patients

What is known already: Ovulatory dysfunction is one of the pivotal properties of PCOS. Acupuncture has been shown to improve ovulatory function in PCOS patients through several mechanisms, such as the reduction of free androgen, which in turn helps normalize the menstrual cycle. Acupuncture

exerts its effect on ovulatory function through the modulation of somatic and autonomic nervous systems, which modulate endocrine and metabolic functions.

Study design, size, duration: This double blind randomized clinical trial was performed on 44 subjects from 2017-2018. Subjects're randomly assigned to treatment (true electroacupuncture+medication) and control group (sham electroacupuncture+medication) in 1:1 ratio, using web-based computer random-number generator. Based on a power of 80%, a of 0.05(two sided) and the assumption of 10% drop out,22 subjects per group was needed to observe a 1.58 difference in menstrual cycle length. Randomization was carried out by a project manager that not involved.

Participants/materials, setting, methods: PCOS patients between 18-40 years old at Yasmin clinic were recruited in a consecutive manner. Each subject underwent medical interview to assess the menstrual cycle length and ultrasound examination to measure number of antral follicles and ovarian volume. Both procedures were performed for 12 session, 3 times a week. Points of Needles inserted were ZhongjiCV3, GuanyuanCV4, QihaiCV6, TianshuST25, ST28Shuidao, ST36Zusanli, SanyinjiaoSP6, and ChengsanBL57. Needles in treatment groups got stimulated electrically at 2 Hz frequency.

Main results and the role of chance: The study showed there' significant menstrual incidence during the treatment with combination of electroacupunture, absolute risk reduction 50% (95% CI, p=0.001). The mean cycle lenght in treatment group also shorter than before (ARR 0.5, 95% CI, p = 0.003) meanwhile in control group not. The initial mean ovarian volume in the treatment group was 11.52 ± 4.316 and control group was 12.03 ± 3.075. After 12 session, mean ovarian volume in treatment group decreased, 9.61 ± 3.939 otherwise its increase in control group 13.21±3.414. This difference was statistically significant. (ARR 0.68, 95% CI, p=0.002).There's no difference mean of antral follicle count before treatment, mean of treatment group was 14.50±2.365 and the control group was 14.86±1.833. After treatment, number of antral follicles in the control group was 14.18 ± 2.239 while the treatment group was decrease 11.50 ± 3.569. Combination of electroacupunture also decrease number of antral follicles (ARR 0.68; 95% CI, p=0.005). As the result, there are significant mean differences between ovarian volume in two groups before and after treatment (p=0,002); antral follicle count (p=0,005); menstrual incidence during the treatment (p=0,001); and shortened menstrual cycle (p=0,003). Electroacupuncture combined with medical treatment could improve PCOS patients' complaint and ovarian image.

Limitations, reasons for caution: There are some confounding factors that might affect number of antral follicles, ovarian volume,and menstrual cycle length which weren't assessed,such as AMH, inhibin B, FSH, LH, androgen, free testosterone,and lipid profiles.Longer follow-up times is needed to determine persistence of shortening menstrual cycle and antral follicles for 3 forward menstrual cycles.

Wider implications of the findings: The findings of this study implicate that electroacupuncture combination therapy might serve better treatment outcomes in respect to menstrual cycle length, ovarian volume, and number of antral follicles in PCOS patients.

Trial registration number: not applicable

P-598 Does oocyte accumulation optimize clinical outcomes in poor ovarian responders? A real-life non-randomized prospective study.

C. Herbemont[1], S. Sarandi[1], M. Comtet[1], C. Vinolas[1], B. Dagher-Hayeck[1], J. Calvo[1], F. Krief[1], I. Cedrin-Durnerin[1], M. Grynberg[1], C. Sifer[1]

[1]Jean Verdier Hospital, ART Unit, Bondy, France

Study question: Does oocyte accumulation offer reasonable chances of pregnancy in infertile poor ovarian responders (PORs)?

Summary answer: Oocyte accumulation in PORs appears as a successful strategy for both treating infertility as well as preserving female fertility potential through embryo cryopreservation.

What is known already: In Assisted Reproductive Technology (ART), chances of live birth are highly correlated to the number of retrieved oocytes. PORs are particularly affected by this issue, since recent studies have set a threshold of 3 oocytes as a predictive factor of live birth. Moreover, repeating ART cycles in such patients represents a high risk of repeated failure, associated to an elevated drop-out rate. Hence, the management of PORs remains quite challenging, and the strategy of oocyte accumulation might constitute an interesting option to optimize clinical outcomes in these patients. However, data on this topic are still scarce.

Study design, size, duration: This single-center, prospective study has been in progress since January 2014. To date, a total of 100 infertile couples have been enrolled in an oocyte accumulation program when female partner was diagnosed as POR according to Bologna criteria (2 out of the 3 following criteria: <4 oocytes in a previous cycle, abnormal markers of ovarian reserve, age >40 years) associated to any other infertility cause (male, female or both).

Participants/materials, setting, methods: Enrollment in the program required patients' written informed consent. Metaphase-2 (M2) oocytes were accumulated by vitrification during one or more controlled ovarian hyperstimulation cycle(s). Then, all vitrified oocytes were warmed and inseminated using ICSI simultaneously with fresh M2-oocytes retrieved during a last cycle of ovarian stimulation. Thirty-nine (n=39) couples underwent the whole procedure (n=101 oocyte-vitrification cycles, followed by oocyte warming +/- simultaneous fresh ICSI cycles). Biological and clinical outcomes of these cycles were analyzed.

Main results and the role of chance: Briefly, median patients' age was 36.0 years (28-42). Their median serum AMH and FSH levels as well as antral follicle count were 0.9 ng/mL (0.2-2.8), 8.9 IU/L (3.2-15), and 8 follicles (3-14), respectively. Each couple underwent an average of 2.3 previous IVF/ICSI attempts before entering our program of oocyte accumulation. During the oocyte accumulation period, a mean of 2.3 cycles/couple (in total, 101 cycles) were performed, leading to the vitrification of 6.4 M2-oocytes/couple. A total of 244 M2 oocytes were warmed (survival rate=87.7%), and 214 M2-oocytes were micro-injected simultaneously with 127 fresh M2-oocytes (9.0 M2-oocytes injected/couple). Number of oocytes retrieved, maturation, fertilization rates and embryo quality were comparable between oocyte accumulation and fresh cycles. So far, oocyte accumulation strategy resulted in 38 embryo transfers (ET) (mean number of transferred embryos=2.5): 15 ET arose only from warmed oocytes (39.5%), 10 only from fresh oocytes (26.3%) and 13 from both warmed and fresh oocytes (34.2%). Finally, clinical pregnancy rate (CPR) of 41.0%/cycle (16/39), and cumulative CPR of 43.6/cycle (17/39) were achieved. Furthermore, supernumerary embryos have been cryopreserved for 20 couples (51.3%).

Limitations, reasons for caution: This preliminary study lacks statistical power, and further investigations are required to confirm the efficiency of oocyte accumulation in the management of infertile PORs. Then, cost-effectiveness issues will have to be considered.

Wider implications of the findings: This study highlighted acceptable CPR for poor-prognosis patients. Thus, enrollment of infertile PORs in oocyte accumulation programs might optimize their success rates. Moreover, this strategy could offer an opportunity of fertility preservation for women whose ovarian reserve is inexorably decreasing and enhance their chances of achieving a subsequent pregnancy.

P-599 Alpha-lactalbumin enhances the intestinal absorption of myo-inositol but not glucose in healthy volunteers

A. Bevilacqua[1], G. Monastra[2], M. Bizzarri[3]

[1]Sapienza University of Rome, Dynamic and Clinical Psychology, ROMA RM, Italy
[2]Sapienza University of Rome, Systems Biology Group Lab, Rome, Italy
[3]Sapienza University of Rome, Department of Experimental Medicine and Systems Biology Group Lab, Rome, Italy

Study question: Is alpha-lactalbumin specific in increasing the intestinal absorption of myo-inositol and/or glucose?

Summary answer: Alpha-lactalbumin enhances intestinal myo-inositol uptake but does not affect glucose absorption.

What is known already: Myo-inositol is a well-known insulin-sensitizing agent, successfully used in the therapy for Polycystic Ovary Syndrome (PCOS) and other disorders. It is known that alpha-lactalbumin can improve myo-inositol absorption in the gut, while no data are as of now available for sugars. In this preliminary study, we evaluated the specificity of alpha-lactalbumin

effect in increasing the intestinal absorption of myo-inositol in the presence of glucose, which shares structural similarities with myo-inositol and, under certain conditions, can compete with it for the same membrane transporter.

Study design, size, duration: The kinetics of intestinal absorption of myo-inositol and glucose in the absence or the presence of alpha-lactalbumin were analysed in male and female young healthy volunteers by measuring their plasma levels at increasing times, 0', 30', 60', 120', 180', 240, 300', after their oral administration. Observations were performed on the same subjects at a time interval of one week: the first one in the absence of alpha lactalbumin, the second one in its presence.

Participants/materials, setting, methods: Thirteen men and 17 women (18-35 years, normal BMI), divided in two groups, received orally 6 g myo-inositol (6 men, 9 women) or 75 g glucose (7 men, 8 women) in water. After 7 days, they received the same solutions with 150 mg alpha-lactalbumin. Myo-inositol and glucose plasma levels were respectively detected chromatographically and electrochemically, at increasing times after administration. Maximum plasma concentration, time to reach it and time-course curve were calculated.

Main results and the role of chance: All the healthy volunteers completed the trial without adverse events. Analysis of myo-inositol and glucose plasma concentrations after being administered alone or with alpha-lactalbumin, allowed to obtain the respective pharmacokinetic profiles. The overall shape of the pharmacokinetic curves for both compounds did not change when administered with alpha-lactalbumin. However, when alpha-lactalbumin was administered, myo-inositol maximum plasma concentration and time-course curve significantly increased ($p< 0.0001$), whereas no changes were observed for glucose. This finding suggests that alpha-lactalbumin enhances myo-inositol but not glucose uptake.

In conclusion, alpha-lactalbumin seems to have a specificity of action on the pharmacokinetic profile of myo-inositol after oral administration and this may have significant, positive implications in the management of PCOS patients that are resistant to intestinal absorption of the insulin-sensitizing agent.

Limitations, reasons for caution: This is a preliminary study with several limitations, since we tested only glucose and only one dose of alpha-lactalbumin. We are thus properly extending our observations.

Wider implications of the findings: We believe that this field of research may represent an advancement in the clinical approach of PCOS and thus deserves to be investigated in-depth.

Trial registration number: Not applicable

P-600 Assisted reproductive outcomes in chronic viral illness-infected women: HIV, HBV, HCV

A. Garnier[1], M. Bourdon[1], C. Maignien[1], K. Pocate[2], A. Chargui[2], C. Patrat[2], C. Chapron[1], P. Santulli[1]

[1]Cochin - Port Royal, Service de Gynécologie et médecine de la reproduction, Paris Cedex 14, France

[2]Cochin - Port Royal, Service de biologie et médecine de la reproduction, Paris Cedex 14, France

Study question: What outcomes can be expected in women undergoing IVF/ICSI depending on the type of chronic infection (HIV, HBV, HCV)?

Summary answer: HIV infected women have poorer cumulative delivery rate and a higher risk of perinatal complications compared to women with hepatitis B.

What is known already: Although fertility remains a priority for many individuals living with chronic viral illness, this topic is often unaddressed. Concerning HIV, there has been concern that the virus, and/or its treatment, may negatively impact female fertility and IVF/ICSI outcomes but studies are conflicting and of small size. In the same manner, to date, only few studies have focused on fertility outcomes after IVF/ICSI cycles in women infected by chronic hepatitis B or C. Thus, more data about IVF/ICSI outcomes in patients with chronic viral illness are required to provide accurate reproductive counseling to patients.

Study design, size, duration: This cohort study was conducted in a tertiary care university hospital between 01/2012 and 10/2018. All women with a chronic viral illness – HIV or HBV or HCV undergoing IVF/ICSI cycles were included. Women were followed until four ART cycles were completed until delivery or until discontinuation of treatment before completion of four cycles. Co-infected women were excluded.

Participants/materials, setting, methods: A total 235 women with a chronic viral illness were allocated to three groups according to the type of infection: 101 HIV - infected women, 114 HBV - infected women and 20 HCV - infected women. The main outcome measured was the cumulative delivery rate. Main secondary outcomes were the cancellation rate, obstetrical and neonatal outcomes. Statistical analysis was conducted using univariate and multivariate logistic regression models.

Main results and the role of chance: At baseline, HIV- and HBV- infected women did not have the same characteristics: Women infected with HIV had significantly more often a previous history of pregnancy, a tubal cause of infertility and the ovarian reserve parameters were significantly lower (AMH and AFC). There were no significant differences concerning the women age, the smoking habits and the duration of infertility. The mean number of IVF/ICSI cycles was significantly higher in HIV- compared to HBV/HCV- infected women (2.01 ± 1.05 versus 1.67 ± 0.9 and 1.5 ± 0.8 respectively; $p=0.012$). The cumulative delivery rate was significantly lower in HIV- compared to HBV- infected women (23/101 (22.8%) versus 44/114(38.6%) respectively; p:0.036). The mean number of cancelled cycles were not significantly different among groups ($p=0.323$). Concerning obstetrical outcomes, the mean birth weight was lower in HIV- compared to HBV - infected women (2799 ± 588 versus 3200 ± 562; $p=0,038$). After multivariate analysis, the type of chronic viral illness did not have a significant effect on delivery chances but women age, the AMH level and the number of IVF/ICSI cycles performed were significantly associated with delivery chances.

Limitations, reasons for caution: No solid conclusion could be made for HCV given the small number of women included in this group.

Wider implications of the findings: This study confirms that HIV- infected women have poorer ART outcomes probably due to poorer ovarian reserve parameters. Those results seem essential to better inform infectiologists and chronic viral illness-infected women of their fertility and to not postpone fertility assessment.

Trial registration number: NA

P-601 Impact of elevated progesterone on cumulative live birth rates: an analysis of 956 freeze-only cycles

A. Racca[1], V.S. Vanni[2], E. Somigliana[3], P. Viganò[4], S. Santos-Ribeiro[5], J. De Coppel[6], G. Campo[2], H. Tournaye[7], P. Enrico[8], C. Blockeel[7]

[5]IVI - Lisboa, IVI .LIsboa, Lisbon, Portugal

[6]Vrije Universiteit Brussel, Vrije Universiteit Brussel, Bruxelles, Belgium

[7]UZ Brussel, Centre for Reproductive Medicine, Bruxelles, Belgium

[8]IRCCS San Raffaele Scientific Institute, Obstetrics and Gynecology Unit-, Milan, Italy

Study question: Is late follicular elevated progesterone (LFEP) in the fresh cycle hindering cumulative live birth (CLBR) rates when a freeze only strategy is applied?

Summary answer: LFEP in the fresh cycle does not affect embryo utilization rate, nor CLBR of the frozen transfers in a freeze only approach.

What is known already: Ovarian stimulation promotes the production of progesterone (P) which has been demonstrated to have a deleterious effect on IVF outcomes. While there is robust evidence that this elevation produces impaired endometrial receptivity, the impact on EQ remains still a matter of debate. Previous studies have shown that LFEP is associated with hindered CLBR, nonetheless, clinical insight on the effect of progesterone on embryo quality in terms of cumulative live birth rates should be derived from freeze-all cycles where no fresh embryo transfer is performed in the presence of progesterone elevation, and the entire cohort of embryos is cryopreserved.

Study design, size, duration: This was a matched case-control, multicentre (three centres), retrospective analysis including all GnRH antagonist ICSI cycles where a freeze-only policy of embryos on day 3/5/6 of development was applied between 2012-2018. A total of 956 patients (478 cases with elevated

P and 478 matched controls with normal P values) were included in the analysis. Each patient was included only once.
Participants/materials, setting, methods: The sample was stratified according to the following P levels on the day of ovulation triggering: ≤1.5 ng/mL and >1.50 ng/mL. The matching of the controls was performed according per age ±1 year and number of oocytes retrieved ±10%. The main outcome was CLBR defined as a live-born delivery after 24 weeks
Main results and the role of chance: The baseline characteristics of the two groups were not significantly different. The estradiol levels on the day of trigger were significantly higher in the elevated P group. There was no significant difference in terms of number of fertilization rate between the two groups. The elevated P group had significantly more cleavage stage embryos frozen compared to the normal P group; while the total number of cryopreserved blastocyst stage embryos was the same. The CLBR did not differ between the two study groups, (29.1% and 28.0%, p=0.720, respectively), also when following confounder adjustment using multivariable logistic regression analysis (accounting for age at pick up, number of fertilized oocytes, progesterone levels, total number of cryopreserved embryos and top-quality embryos).
Limitations, reasons for caution: This is a multicentre observational study based on a retrospective data analysis. Better extrapolation of the results could be validated by performing a prospective analysis.
Wider implications of the findings: This is the first study demonstrating that LFEP in the fresh cycle does not hinder CLBR of the subsequent frozen cycles in a freeze only approach.
Trial registration number: N/A

P-602 Cumulus cell-bound bone morphogenetic protein-15 varies with maternal age and PCO/S in ICSI patients

A. Krysta[1,2], A.H. Riepsamen[1], S. Kilani[1,2], C.A. Harrison[3], K.A. Mallitt[1,4], W.L. Ledger[1,2], D.M. Robertson[1], R.B. Gilchrist[1]
[1]Fertility and Research Centre- School of Women's and Children's Health, University of New South Wales Sydney, Kensington- NSW, Australia
[2]IVF Australia, Virtus Health, Alexandria- NSW, Australia
[3]Monash Biomedicine Discovery Institute, Monash University, Clayton- NSW, Australia
[4]Centre for Big Data Research in Health, University of New South Wales Sydney, Kensington- NSW, Australia

Study question: Is the oocyte-secreted factor bone morphogenetic protein-15 (BMP15) on cumulus cells (CCs) associated with infertile pathologies, age or embryology outcomes in women undergoing ICSI?
Summary answer: BMP15/CC DNA positively correlated with the number of oocytes retrieved and negatively correlated with maternal age in patients without polycystic ovaries or polycystic ovary syndrome.
What is known already: BMP15 is an oocyte-specific factor and is a central regulator of folliculogenesis, differentiation and function of CCs, and mammalian fecundity. BMP15 is captured by cumulus cells which are discarded prior to ICSI during infertility treatment. Measuring BMP15 protein levels from CCs could provide a novel, non-invasive diagnostic tool for assessing oocyte and embryo quality and for investigating reproductive pathologies of infertile patients. Thus far reliable quantification of BMP15 protein has not been reported.
Study design, size, duration: A novel BMP15 immunoassay was developed in-house, validated and applied to protein extracts from pooled CCs of individual patients. A total of 120 patients aged 29-47 years who underwent controlled ovarian stimulation between September 2017 and April 2018 were included in the study. PCO patients (antral follicle count ≥12 in unstimulated cycle) and PCOS patients were grouped into a PCO/S group. Maternal age, endometriosis (diagnosed laparoscopically), embryology outcomes and ovarian stimulation protocols were recorded.
Participants/materials, setting, methods: Pooled CCs from individual patients were collected post oocyte denudation, hyaluronidase was removed, and cell pellets stored at -80°C. Recombinant-BMP15 showed non-parallelism with native BMP15 on CCs hence an extract of granulosa cells was used as reference preparation for BMP15 quantification and assigned an arbitrary unitage. Total BMP15 was normalised to total CC DNA (BMP15/CC DNA) in the same CC extract (measure of cell count). Interactions between parameters were examined by multivariate linear regression analyses.
Main results and the role of chance: The BMP15 immunoassay was validated for specificity and reproducibility. Total BMP15 from pooled CCs of individual patients showed a tight correlation with total CC DNA (r=0.95, p<0.0001, n=120) compared to a moderate correlation with the number of oocytes retrieved (r=0.53, p<0.0001, n=120), necessitating normalisation of BMP15 to DNA (BMP15/CC DNA). BMP15 levels on CCs varied considerably between individual patients from undetectable to 19-fold above the baseline, suggesting that factors such as underlying clinical pathologies influence oocyte production of BMP15. In patients without PCO/S, BMP15/CC DNA positively correlated with the number of oocytes retrieved (r=0.26, p<0.05, n=84) and negatively correlated with maternal age (r=-0.30, p<0.01, n=84), suggesting that BMP15 may correlate with reproductive potential in non-PCO/S patients. By contrast, BMP15/CC DNA did not correlate with age (p>0.05) or the number of oocytes retrieved (p>0.05) in the PCO/S group, suggesting aberrant production of BMP15 in those patients. BMP15/CC DNA was not significantly different between patients with and without known history of endometriosis and was not affected by the type of ovarian stimulation protocol or trigger type. BMP15/CC DNA did not correlate with embryo developmental trajectory (%MII, %2PN, % day 3 embryos, % day 5 blastocysts, % euploid embryos).
Limitations, reasons for caution: BMP15/CC DNA was measured from pooled cumulus cells from all oocytes retrieved from individual patients. Investigation of BMP15 from individual oocytes is required to assess the relationship between BMP15 and oocyte quality in patients with differing infertility conditions. Further investigation of native forms of the ligand measured is necessary.
Wider implications of the findings: This is the first study reporting the development of an assay for quantification of oocyte-secreted BMP15 protein. This study opens the opportunity to measure BMP15 in ICSI patients, as a novel non-invasive diagnostic test of oocyte quality and for providing insight into the role of oocyte-secreted factors in infertility pathologies.
Trial registration number: N/A

P-603 BMI is not associated with oocyte recovery rate or maturation rate in high-risk for severe OHSS patients triggered with GnRH-agonist for final oocyte maturation

I. Sfontouris[1], G. Lainas[1], T. Lainas[1], J. Bosdou[2], A. Chatzimeletiou[2], G. Grimbizis[2], E. Kolibianakis[2]
[1]Eugonia, Assisted Reproduction Unit, Athens, Greece
[2]Aristotle University of Thessaloniki, Unit of Human reproduction- 1st Department of Ob/Gyn- Medical school, Thessaloniki, Greece

Study question: Is body mass index associated with oocyte recovery rate or maturation rate in high-risk for severe OHSS patients triggered with GnRH-agonist for final oocyte maturation?
Summary answer: BMI is not associated with oocyte recovery rate or maturation rate in high-risk for severe OHSS patients triggered with GnRH-agonist for final oocyte maturation.
What is known already: Previous studies using human chorionic gonadotrophin (hCG) for triggering of final oocyte maturation have shown a negative effect of high body-mass index (BMI) on IVF outcomes. Overweight women face a lower likelihood of pregnancy and an increased risk of miscarriage after IVF. They also have reduced number of oocytes retrieved despite requiring higher gonadotrophin doses. No data, however, are currently available regarding the association between body mass index (BMI) oocyte recovery rate or maturation rate following triggering of final oocyte maturation with GnRH-agonist in women at high risk for severe OHSS.
Study design, size, duration: Prospective observational cohort study of 94 patients undergoing ovarian stimulation for intracytoplasmic sperm injection (ICSI) between January 2017 until July 2018, who received 0.2mg of triptorelin to trigger final oocyte maturation. All patients were at high risk for developing severe OHSS, defined by the presence of at least 18 follicles≥11mm in diameter.
Participants/materials, setting, methods: Ovarian stimulation was performed with recombinant follicle stimulating hormone (rec-FSH) and gonadotrophin releasing hormone (GnRH) antagonists. Final oocyte maturation was triggered using 0.2 mg of the GnRH agonist triptorelin. All resulting blastocysts were cryopreserved. Hormonal evaluation included assessment of FSH, LH, oestradiol and progesterone on the day of triggering, 8 hrs, 36 hrs

as well as on days 3, 5, 7, 10 following triptorelin administration. Statistical analysis was performed using generalized linear models.

Main results and the role of chance: A negative association was present between BMI and the number of oocytes retrieved(OR: 0.66, 95% CI 0.45 - 0.98). The association between BMI and the number of mature oocytes was not significant (OR: 0.74, 95% CI 0.53 – 1.04). In addition, no association was present between BMI and oocyte recovery rate in either bivariate analysis (OR:= 0.99, 95% CI 0.98 to 1.01, p=0.991) or multivariable analysis controlling for maternal age and AMH (OR: = 1, 95% CI 0.99 to 1.01, p=0.868). Moreover, no association was present between BMI and oocyte maturation rate in bivariate analysis (OR: = 0.99, 95% CI 0.99 to 1.01, p=0.993) or multivariable analysis controlling for maternal age and AMH (OR: = 0.99, 95% CI 0.99 to 1.01, p=0.868).

Limitations, reasons for caution: The results of the present study refer to the use of a standard dose of 0.2 mg triptorelin in a limited number of patients. Whether these results are also valid for different doses of triptorelin used for triggering final oocyte maturation cannot be deducted from this study.

Wider implications of the findings: The absence of an association between BMI and oocyte recovery rate or maturation rate suggests that BMI might not exert an effect on these variables in high-risk for severe OHSS patients triggered with GnRH-agonist for final oocyte maturation.

Trial registration number: Not applicable.

P-604 Intrauterine insemination (IUI) with or without letrozole for unexplained or mild male factor infertility: a randomized pilot study

S. Huang[1], R. Wang[2,3], R. Li[1], H. Yan[1], N. Li[1], H. Wang[1], L. Luo[1], R.J. Norman[2], B.W.J. Mol[3], J. Qiao[1]

[1]*Centre of Reproductive Medicine, Department of Obstetrics and Gynecology-Peking University Third Hospital, Beijing, China*

[2]*Robinson Research Institute, University of Adelaide, Adelaide, Australia*

[3]*Department of Obstetrics and Gynaecology, Monash Medical Centre- Monash Health and Monash University, Melbourne, Australia*

Study question: Is a randomized controlled trial (RCT) comparing intrauterine insemination (IUI) with and without letrozole in couples with unexplained or mild male factor infertility feasible?

Summary answer: We showed that an RCT comparing IUI with letrozole versus unstimulated IUI in couples with unexplained or mild male factor infertility is feasible.

What is known already: IUI is the treatment of first choice for couples with unexplained or mild male factor infertility, but it is unclear whether ovarian stimulation improves fertility outcomes. In our recent retrospective cohort study, we found that in couples undergoing IUI ovarian stimulation with letrozole increased live birth rate as compared to unstimulated IUI without increasing multiple pregnancy rates. There are no RCTs comparing IUI with letrozole versus unstimulated IUI and therefore we plan a large RCT to test the hypothesis. Here, we present the results of our pilot study to evaluate the feasibility of a subsequent RCT.

Study design, size, duration: We performed a randomized pilot study in the Reproductive Medicine Centre of Peking University Third Hospital in China. This pilot study included 100 couples with unexplained or mild male infertility. There was no masking. The study was registered under trial number NCT03455426.

Participants/materials, setting, methods: Couples with unexplained or mild male factor infertility scheduled for IUI were randomized to IUI with or without ovarian stimulation (letrozole) for up to 3 IUI cycles within a time horizon of 4 months. Women in the letrozole group received letrozole 5 mg oral tablets daily starting from cycle day 3-5 for 5 days. Women in the unstimulated IUI group did not receive ovarian stimulation before IUI. The primary outcome was ongoing pregnancy.

Main results and the role of chance: Between March 2018 and January 2019, 158 couples were eligible to participate after initial screening, and 100 (63.3%) couples agreed to participate in this study. Of the 100 recruited couples, 50 were randomly allocated to IUI with letrozole and 50 to unstimulated IUI. The women's mean age was 31.8 years (SD3.3) and 30.3 years (SD3.3) in the letrozole group and unstimulated group, respectively. At the moment, we have follow up data of 81% of the recruited couples (41 in letrozole group and 40 in unstimulated group). Ongoing pregnancy occurred in 29.2% in the letrozole group and 20.0% in the unstimulated group (RR 1.46 (95% CI 0.67 to 3.20)). Clinical pregnancy rates were 34.1% and 22.5% (RR 1.41 (95% CI 0.68 to2.92)). There were no multiple pregnancies. There was one ectopic pregnancy and one miscarriage in the group with letrozole versus one miscarriage in the unstimulated group.

Limitations, reasons for caution: This is a pilot study with a limited sample size. Full follow up data will be available before July 2019. Based on these data, we plan a large randomised clinical trial in our centre.

Wider implications of the findings: This pilot study confirmed the feasibility of a well powered clinical trial. In couples with unexplained or mild male infertility scheduled for IUI, we hypothesise letrozole results in higher ongoing pregnancy rate without substantially increasing multiple pregnancy rate.

Trial registration number: NCT03455426

P-605 Patients < 38 years old and diminished ovarian reserve: Qualitative reduction in IVF success?

J. Belaisch Allart[1], O. Kulski[1], L. Prevotat[1], Y. Belaid[1], J.M. Mayenga[1], I. Grefenstette[1], N. Kalhorpour[1]

[1]*Gynecologie Obstétrique et Médecine de la Reproduction, Haut de Seine, Saint Cloud, France*

Study question: Do infertile women aged <38 years old with quantitative evidence of diminished ovarian reserve have also diminished live birth rates or no?

Summary answer: There is no significantly difference in live birth rates between young women with AMH< 1ng/ml compared with young women controls with AMH> 1ng/ml.

What is known already: Previous studies are conflicted as to whether young women with evidence of diminished ovarian reserve are also at increased risk of poor oocyte quality.

Study design, size, duration: This was a retrospective cohort study at a single center between 2012 and 2017. We included 4150 women ongoing IVF cycle in the center in this period. For each group of women < 38 years old and ≥ 38 years old, we compared live birth rates regarding AMH level as AMH<1ng/ml versus AMH≥1ng/ml.

Participants/materials, setting, methods: We included 4211 women. The primary outcome was live birth rate. To analyze ovarian reserve, we included women with AMH level available. We defined diminished ovarian reserve as AMH< 1ng/ml. For the group < 38 years old, there were 2496 women with AMH level ≥ 1ng/ml and 250 women with AMH < 1ng/ml. For the group ≥ 38 years old, there were1263 women with AMH level ≥ 1ng/ml and 202 women with AMH < 1ng/ml.

Main results and the role of chance: Live birth rate was not significatively different in young women from a cycle with ovarian reserve parameters AMH < 1 ng/ml compared with women with good AMH values(18% versus 23.7%, p=0.1) whereas in older women ≥ 38, AMH≥ 1ng/ml is positively correlated with live birth rates (14.17% versus 5.4%, p=0.001).

Limitations, reasons for caution: Some biases are likely to be present because of the retrospective nature of the study. We also defined diminished ovarian reserve as AMH level < 1ng/ml as defined in many other studies but this definition is not consensual.

Wider implications of the findings: Our study suggests that low ovarian reserve do not impact live birth rates in young women: an oocyte retrieved from young women with diminished ovarian reserve performs similarly to that with age matched controls with normal ovarian reserve. Our observation represents valuable information for treatment counseling and cycle planning.

Trial registration number: not applicable

P-606 Is oocyte maturation rate associated with the dose of triptorelin used for triggering final oocyte maturation in high-risk for severe OHSS patients, undergoing ovarian stimulation.

T.G. Lainas[1], G. Lainas[1], I. Sfontouris[1], C. Venetis[2], J. Bosdou[3], A. Chatzimeletiou[3], B. Tarlatzis[3], G. Grimbizis[3], E. Kolibianakis[3]

[1]*Eugonia, Unit of Assisted Reproduction, Athens, Greece*

[2]University of New South Wales, School of Women's and Children's Health UNSW Medicine, Sydney, Australia
[3]Aristotle University of Thessaloniki Medical School, Unit for Human Reproduction - 1st Dept of Obstetrics and Gynecology, Thessaloniki, Greece

Study question: Is oocyte maturation rate associated with the dose of triptorelin used for triggering final oocyte maturation in high-risk for severe OHSS patients, undergoing ovarian stimulation?

Summary answer: Triptorelin doses of 0.1, 0.2 and 0.4mg, used for triggering final oocyte maturation, result in similar maturation rates, in high-risk for OHSS patients undergoing ICSI.

What is known already: Gonadotrophin releasing hormone (GnRH) agonist triptorelin is widely used instead of human chorionic gonadotrophin (hCG), for triggering final oocyte maturation, to eliminate the risk of severe OHSS in patients undergoing ovarian stimulation for IVF/ICSI. Several different types and doses of GnRH agonists have been used to trigger final oocyte maturation, including subcutaneous administration of triptorelin (0.2mg) buserelin (0.2-0.5-1mg), leuprolide acetate (0.5-1-1.5mg) , nafarelin 400μg and intranasal administration of buserelin 0.2mg. Although the most commonly used GnRH agonist for triggering is triptorelin, limited data are currently available regarding the optimal dose used for this purpose in high risk for OHSS patients.

Study design, size, duration: Retrospective study, performed between 2015 and 2017, in 131 infertile patients at high risk for severe OHSS (defined as the presence ≥19 follicles ≥11mm) undergoing ovarian stimulation for ICSI. The primary outcome measure was oocyte maturation rate, defined as the number of mature (metaphase II) oocytes divided by the number of cumulous oocyte complexes (COCs) retrieved. Patients received 0.1 (n=42) or 0.2 (n=46) or 0.4 mg (n=43) of triptorelin for triggering final oocyte maturation.

Participants/materials, setting, methods: Ovarian stimulation was performed with recombinant follicle stimulating hormone (FSH) and GnRH antagonists. Hormonal evaluation of FSH, luteinizing hormone (LH), estradiol (E2) and progesterone (PRG) was carried out on the day of triggering, 8 and 36 hours later as well as on days 3, 5, 7, and 10 post-triggering. During this period, all patients were assessed for symptoms and signs indicative of severe OHSS development. Results are expressed as median (interquartile range).

Main results and the role of chance: No significant differences in patient baseline characteristics were observed among the 0.1mg, the 0.2mg and the 0.4mg groups. Regarding the primary outcome measure, no differences were observed in oocyte maturation rate among the three groups compared [82.6 (17.8)% vs. 83.3 (18.8)% vs. 85.1 (17.2)%, respectively, p=0.686].

In addition, no significant differences were present among the 0.1 mg, 0.2 mg and 0.4mg groups, regarding the number of mature (metaphase-II) oocytes [21 (13) vs. 20 (6) vs. 20 (11), p=0.582], the number of oocytes retrieved [25.5 (13) vs. 24.5 (11) vs. 23 (12), p=0.452], oocyte retrieval rate [81.0 (17.7)% vs. 76.5 (23.5)% vs. 75.0 (22.5)%, p=0.088), the number of fertilized (2PN) oocytes [12.5 (9) vs. 14.5 (7) vs. 14.0 (8), p=0.985], fertilization rate [71.7 (22)% vs. 77.1 (19.1)% vs. 76.6 (23.3)%, p=0.525] and duration of luteal phase [7 (1) vs. 8 (2) vs. 7 (1) days, p=0.632] respectively.

No significant differences were present among the different triptorelin doses compared regarding serum levels of LH, FSH, E2, PRG, at any of the time points assessed following triggering of final oocyte maturation.

No patient was diagnosed with severe early OHSS in any of the three groups of triptorelin compared.

Limitations, reasons for caution: This is a retrospective study and although there were no differences in the baseline characteristics of the three groups compared, the presence of bias cannot be excluded.

Wider implications of the findings: It appears that triggering final oocyte maturation with a lower (0.1 mg) or a higher dose (0.4mg) of triptorelin, as compared to the most commonly used dose of 0.2mg, does not confer any benefit considering oocyte maturation rate in high risk for severe OHSS patients.

Trial registration number: Not required

P-607 The Effect of Controlled Ovarian Stimulation on Polycystic Ovary Syndrome-Related Chronic low-grade Inflammation

V.S. Vanni[1], E. Alleva[1], L. Privitera[1], S. Faulisi[1], M. Molgora[1], L. Pagliardini[2], E. Papaleo[1]

[1]IRCCS San Raffaele Scientific Institute, Obstetrics and Gynecology Unit, Milano, Italy
[2]IRCCS San Raffaele Scientific Institute, Reproductive Sciences Lab- Division of Genetics and Cell Biology, Milano, Italy

Study question: Are polycystic ovary syndrome (PCOS) patients at increased risk for Controlled Ovarian Stimulation (COS)-related inflammation during ART cycle?

Summary answer: PCOS patients show a greater leukemoid reaction to COS, unravelling one potential co-factor in the pathogenesis of their increased risk for ovarian hyperstimulation syndrome (OHSS)

What is known already: Increasing evidence suggests that PCOS may be characterized by a chronic low-grade inflammation, independently from other comorbidities such as insulin resistance and obesity. COS is also known to induce an inflammatory response which, in severe cases, may contribute lead to the development of OHSS, a dreaded complication of IVF treatments. As PCOS is a common indication for IVF and a risk factor for the development of OHSS, we sought to investigate whether the inflammatory drive of COS is increased in PCOS patients.

Study design, size, duration: Retrospective cohort study analyzing n=2800 first-attempt IVF cycles performed on n=250 PCOS patients and n=2550 non-PCOS controls at the San Raffaele Hospital between January 2010 and February 2018.

Participants/materials, setting, methods: Venous blood samples from 2800 patients undergoing first-cycle IVF were taken twice, within 3 months before COS (baseline) and on the day of oocyte pick up, and analyzed for total blood cell count including total and differential white blood cell counts. Blood parameters were compared using Student's T test. Multivariate linear regression analyses controlling for BMI, age, and number of oocytes retrieved was also performed.

Main results and the role of chance: Baseline absolute lymphocytes (LYM) and basophil counts – but not total white blood cell (WBC) and absolute neutrophil (NEU) counts - were significantly higher in PCOS patients compared to controls ($p<0,01$). In both groups, WBC, NEU counts and neutrophil-to-lymphocyte ratio increased significantly on the day of pick up with respect to baseline values - but the increase was greater in PCOS patients ($p<0,01$).On the day of pick up, absolute counts of WBC, NEU and LYM counts - but not BAS counts - were all significantly higher in the PCOS group compared to non-PCOS patients ($p<0,01$).

Thus, even though COS lead to a leukemoid reaction both in PCOS patients and controls, both the increase and the absolute values of white blood cells on the day of pick up were greater in the study group. These resulta suggest that PCOS-patients are more susceptible to the inflammatory drive of COS than non-PCOS patients.

Limitations, reasons for caution: The retrospective nature of the study and heterogeneity of the population limits our study. Moreover, information on ovulation trigger used was available only for a small proportion of the population - preventing us from performing a stratified analysis.

Wider implications of the findings: This finding is especially interesting in face of the increased risk for OHSS seen in PCOS, which may be partly due to the enhanced inflammatory response caused by COS in these patients.

Trial registration number: n/a

P-608 Serum metabolites as molecular predictive markers of ovarian response to controlled stimulation

D. MONTANI[1], D. Braga, Paes de Almeida[2], A. Setti[2], A. Iaconelli Jr.[2], E. Borges Jr.[2], D. Oliveira-Silva[1]

[1]Sao Paulo Federal University, Chemistry, Sao Paulo, Brazil
[2]Fertility Medical Group and Instituto Sapientiae, Centro de Estudos e Pesquisa em Reprodução Assistida, Sao Paulo, Brazil

Study question: Whether the serum metabolite composition may predict the ovarian response to controlled ovarian stimulation (COS)?

Summary answer: The serum levels of Glycerophospholipid and Phenylsulfate species are associated with high and poor responses to COS, respectively.

What is known already: COS is an essential step of IVF. However, the balance between the retrieval of too few or too many oocytes is difficult to strike, and is decisive to reduce the success rate or increase the risk of negative outcomes. It is nearly impossible to accurately predict ovarian response based on parameters such as maternal age, antral follicle count, antimüllerian

hormone or FSH levels, or a previous poor or excessive response to COS. The development of noninvasive techniques, capable of predicting the ovarian response would allow individualized treatment and significantly increase treatment success, and decrease patients' physical, emotional and economic burden.
Study design, size, duration: For this case-control study, serum samples from 30 patients, undergoing COS, from January to August 2017, in a university-affiliated assisted reproduction centre were analysed. Samples were split into groups depending on the response to COS: Poor-Response-Group: < 4 retrieved oocytes (PR group, n=10), Normo-Response-Group: ≥ 8 and ≤ 12 retrieved oocytes (NR group, n=10), and Hyper-Response-Group: > 25 retrieved oocytes (HR, n=10). The metabolic profiles of the serum samples were compared between the groups.
Participants/materials, setting, methods: Samples were collected before the beginning of COS. After extraction, metabolites were injected into a TOF-QII mass spectrometer, equipped with an Apollo-I-electrospray ion source and coupled to a UFLC-liquid chromatograph. Spectra were acquired in the positive mode and data for NR group were compared with the other groups. A ROC curve was built considering the ions with higher predictive power, and a cross-validation test was conducted. Metabolites were tentatively identified in online Human Metabolite databases
Main results and the role of chance: Considering the components 1 and 2, the principal component analysis (PCA) was able to clearly distinguish the PR, NR and HR groups. The ROC curve considering PR and NR groups presented an area under the curve (AUC) of 99.6% (CI 95%: 88.9 – 100%, p<0,001). As for the identified metabolites, phenylsulfate was hiperrepresented in the PR group (AUC: 100%, CI 95%: 89.4 – 100%, p=0.01) and glycerophospholipid was increased in the HR group (AUC: 86.7%, CI 95%: 60.8 – 100%, p=0.05). Glycerophospholipid was also increased in the NR group. Altogether, our evidence suggests a higher membrane stability, cell proliferation potential and cellular growth capacity among patients in the NR and HR groups when compared with those in the PR group.
Limitations, reasons for caution: Although these results may favour the implementation of individualized COS protocols and despite its high sensitivity, the model did not allow the exact identification of all metabolites due to the limited available human metabolite databases.
Wider implications of the findings: The identification of metabolites correlated with ovarian reserve and ovarian response to COS may allow migration towards the era of personalized treatment in the field of reproductive medicine. This will offer a valuable opportunity for achieving the treatment success with reduced discomfort, emotional and financial costs for the patients.
Trial registration number: None

P-609 the prevalence of cervical insufficiency in Chinese women with polycystic ovarian syndrome after ART treatment: a retrospective analysis

W. Yaoqiu[1], C. Meihong[2], L. Xiaoyan[1], Y. Xing[1]
[1]*Sixth Affiliated Hospital of Sun Yat-sen University- Guangzhou- China, Reproductive Medicine Center, Guangzhou, China*
[2]*Guangzhou First People's Hospital- School of Medicine- South China University of Technology- Guangzhou- Guangdong- China, Reproductive Medicine Centre-, Guangzhou, China*

Study question: the relationship between cervical insufficiency(CI)and polycystic ovarian syndrome(PCOS) in Chinese women with the second trimester miscarriage after ART.
Summary answer: A high prevalence of CI in PCOS women may originate from insufficient uterine development and may be related to higher serum T levels.
What is known already: Polycystic ovarian syndrome (PCOS) is a common endocrine disorder affecting 6–10% of women of reproductive age. PCOS is associated with menstrual irregularities, hyperandrogenism, insulin resistance and subfertility. Adverse pregnancy outcomes, including early pregnancy loss and preterm birth, are also related to PCOS.Cervical insufficiency (CI) is a major cause of miscarriage and premature birth that affects 0.1%–1.0% of all pregnancies and accounts for approximately 8%-25% of recurrent spontaneous abortions during the second trimester.Few studies have investigated the risk of CI among PCOS women, just one study reported that CI occurred with a higher frequency in PCOS women.
Study design, size, duration: The present retrospective study included all the women who underwent ART treatment who experienced second trimester miscarriage at the Reproductive Medicine Center at The Six Affiliated Hospital of Sun Yat-sen University between May 1st, 2010, and December 31st, 2017.Patient characteristics including age, body mass index, basal hormone level, infertility duration, parity, uterine diameter and any history of spontaneous abortion were obtained by detailed review of the pre-pregnancy, antenatal and delivery records.
Participants/materials, setting, methods: PCOS was defined by Rotterdam criteria. Women were diagnosed as CI based on cervical dilation and/or cervical shortening in the absence of other clear causes without contractions or labor. The prevalence of CI and the clinical characteristics of these women were analyzed. Chi-square, Fisher's exact test, Student's t-test, point biserial correlation analysis and multivariable logistic regression were used for data analysis. A P<0.05 indicated significant result.
Main results and the role of chance: A total of 490 women with a second trimester miscarriage were included, among which 67 women were diagnosed with CI (13.67%). 26 PCOS women were diagnosed with CI (30.23%) compared with 41 of non-PCOS women (10.15%), P<0.001. PCOS women had a significantly smaller uterus and higher serum T level compared with non-PCOS women. Point biserial correlation analysis showed that negative correlation existed between CI pregnancy and the average uterine length(r=-0.242, P <0.001).The ROC curve analyses of the average uterine length showed the area under curve was 0.710, P <0.001,in which the optimal cut-off point was 4cm. The CI frequency of women with a mean uterine length shorter than 4.0 cm was 25% (17/68),while the rate of women with a mean uterine length longer than 4.0 cm was 11%(48/422),P=0.02.After adjusting for maternal age, body mass index (BMI), infertility duration, number of fetuses and basal hormone levels, PCOS status (OR: 3.93, 95%CI 1.54-10.02), uterine size(OR: 4.323, 95%CI 1.699-10.002) and serum testosterone levels (OR: 1.02, 95%CI 1.01-1.03) were associated with an increased risk of CI.
Limitations, reasons for caution: The cohort was limited to Chinese women who underwent ART treatment due to infertility, and miscarriage is defined as fetal delivery earlier than 28 weeks of gestational age in China which is different from other western countries. The relatively number of PCOS women included in the miscarriage group is limited.
Wider implications of the findings: Therapeutic measures should be taken to reduce the influence of hyperandrogenism in PCOS patients. Pre-pregnancy physical examinations and regular prenatal examinations are recommended for PCOS women. Regularly monitoring cervical length during pregnancy may benefit PCOS patients and lead to the early diagnosis and treatment of CI to prevent fetal loss.
Trial registration number: 2018ZSLYEC-043

P-610 Short term effects of metformin, myo-inositol or combination on metabolic and endocrine profile of infertile women with polycystic ovarian syndrome (PCOS)

N. Malhotra[1], R. Mahey[2], A. Agarwal[2], K. Rajasekaran[2], M. Gupta[3]
[1]*AIIMS All India Institute of Medical Science, Department of Obstetrics and Gynecology, New Delhi, India*
[2]*All India Institute of Medical sciences, Obstetrics and Gynecology, New Delhi, India*
[3]*All India Institute of Medical sciences, Obstetrics and Gynaecology, New Delhi, India*

Study question: What is the effect of of different insulin sanitizers (metformin, myo-inositol or combination) on metabolic and endocrine profile in infertile women with PCOS?
Summary answer: Metformin, **m**yo-inositol and combination of both improve the endocrine and metabolic profile in infertile PCOS. Myo-inositol is significantly better in lowering high AMH levels.
What is known already: Use of insulin sensitisers including metformin and myo-inositol lead to an improvement in insulin sensitivity, restoration of ovulation, improvement in oocyte quality and a reduction in hyperandrogenism through the reduction of insulin plasma levels, which may help to ameliorate clinical symptoms and increase their fertility. Both improve outcome when used alone. There is little knowledge on their metabolic and endocrine benefits when used in combinations.

Study design, size, duration: Data from two randomised trials were analysed to compare the effects of metformin in combination with myo-inositol or each drug alone on some of the metabolic [BMI, insulin levels, HOMA-IR (Homeostatic Mode Assessment of Insulin Resistance) and lipid profile] and endocrine (LH, FSH, testosterone, SHBG and AMH) profile in infertile PCOS women undergoing IUI (combinations versus metformin) or IVF (myo-inositol versus metformin) cycle. Both trial were conducted over 2 years (December 2016-December 2018)

Participants/materials, setting, methods: One hundred and seventy infertile PCOS women (Rotterdam's criteria) were randomised to Group 1 (n=60) who received combination of metformin (1500mg) + myo-inositol (1800mg); Group 2 (n=60) received metformin (1500mg) and group 3 (n=50) received myo-inositol 4g/day. Insulin sensitisers were given for 3 months and groups were compared in terms of improvement in metabolic and endocrine profiles with respect to baseline within and between different groups.

Main results and the role of chance: The baseline parameters including BMI, FG score, global acne score, antral follicle count, ovarian volume were comparable among the three groups. The number of women with abnormal BMI (> 25 kg/m2) decreased to 73% from 93% (p=0.001), 78% from 87% (p=0.05) and 58% from 88% (p=0.002) in group 1, 2 and 3 respectively. The percentage of women having HOMA-IR >2.4 at 3 months was significantly higher in group 3 (28%) compared to group 2 (11.7%) and group 1 (8.3%) with p=0.017.The change in total, LDL and HDL cholesterol at 3 months from baseline was not statistically significant among the three groups. The percentage change in LH was significantly higher in group 1 (31.1%) than group 2 (27.2%) and group 3 (11.2%) with p< 0.001. Serum AMH levels were significantly reduced after 3 months of therapy in all the groups but the reduction was significantly higher in group 3. The percentage change was significantly higher in group 3 (44%) versus group 1 (33.4%) with p=0.033 whereas group 1 (33.4%) versus group 2 (32.8%), showed no significant difference (p=0.0779).

Limitations, reasons for caution: The participants were taken from two RCT with similar characteristics and primary outcomes but different interventions. This study analysed the metabolic and endocrine improvements with insulin sensitisers in PCOS. Further the doses of myo-inositol varied between two groups (Group I and III).

Wider implications of the findings: Both insulin sensitisers (metformin and myo-inositol) are effective in improving the metabolic profile in PCOS women. Myo-inositol has better potential in reducing AMH level, perhaps due to its local action at ovary and may be more beneficial in infertile PCOS with high AMH levels.

CTRI/2017/07/009021

P-611 Assessment of ovarian reserve using the SonoAVC antral tool

A. Rodriguez-Fuentes[1], J. Hernandez[1], J.P. Rouleau[1], A. Palumbo[1]
[1]Centro de Asistencia a la Reproducción Humana de Canarias, Reproductive Endocrinology and Infertility, La Laguna, Spain

Study question: To assess the reliability and potential advantages of automatic antral follicle count (AFC) using the SonoAVC*antral* tool compared to manual count.

Summary answer: Automatic AFC using the new SonoAVC*antral* tool is reliable and reproducible compared to manual count.

What is known already: AFC is a rutine parameter for ovarian reserve assessment. Three-dimensional(3D) US has added precision to follicular monitoring with the introduction of the SonoAVC follicle software (GE Healthcare, Austria). This software allows quick and precise measurement of follicular volumes and these correlate with oocyte maturity. More recently a new software has been designed that is specific for evaluation of small antral follicles. Studies are nessesary to assess the reliability of this method in clinical practice. FORT (follicular output rate) is the ratio of preovulatory follicle count on the day of trigger×100/baseline AFC and is an indicator of follicular response to gonadotropin.

Study design, size, duration: Prospective study of 43 women undergoing assessment of ovarian reserve prior to an IVF cycle (36 egg donors and 7 infertility patients with good ovarian reserve). 35 women underwent ovarian stimulation during the study period and an antagonist protocol was used in all cases. Data were collected from May to October 2018 in a single private infertility clinic. All exams were performed by one of 4 operators and then analyzed by a single operator (AR).

Participants/materials, setting, methods: A Voluson S10 ultrasound device (GE Healthcare, Austria) with a RIC 5-9 vaginal probe and the SonoAVC*antral* tool was used for all assessments. Manual(2D) and automatic(3D) ovarian volume and AFC and the time needed to perform each measurement were recorded. On the day of trigger the number of follicles 16-22 mm was recorded to assess FORT. FORT was also calculated using number of follicles >0,7cc x100/automatic AFC. The interobserver variability of automated measurements was calculated.

Main results and the role of chance: Manual and automatic AFC were 38,11 and 34,74 respectively (P>0,05). Ovarian volume measured using two-dimensional(2D) and 3D US was: Right Ovary 5,28 vs 4,77 (P>0.05); Left Ovary 5,53 vs 4,65 (P=0,036). The time needed for manual(2D) AFC and ovarian volume assessment was 4,02 minutes. The total time needed for measurement of ovarian volume and AFC using 3D US and the sonoAVC*antral* tool was 9,91 minutes (P=0,00). This includes the time spent by the operator to perform the exam (volume adquisition) (1,91 minutes) and the time necessary for automatic volume calculation and post-processing (8 minutes). Improvements in the software and increasing experience of the operators will reduce the time needed for post-processing. The interobserver variability for automatic assessment was not statistically significant. The number of follicles between 16 and 22 mm on the day of trigger was 8,77 manual and 10,43 automatic (P=0,025). The calculated FORT was not significantly different using manual diameters and AFC (27,34) or automatic diameters by SonoAVC*follicle* and AFC by SonoAVC*antral* tool (29,4). When FORT was calculated using number of follicles >0,7cc x100/baseline automatic AFC (59,02) the result was statistically significantly greater that "conventional" FORT.

Limitations, reasons for caution: These results are limited by the small number of subjects included and we are collecting more data to confirm these findings. Patients with poor quality of image limit the application of automatic measurements. Improvements of the automatic softwares are needed to increase accuracy of automatic measurements.

Wider implications of the findings: AFC is widely used in fertility clinics to assess ovarian reserve and the availability of an automatic tool is promising. The SonoAVC*antral* tool may be useful to achieve the final goal of determining what is the ideal follicular size to be included in the AFC.

Trial registration number: Not applicable.

P-612 No evidence of different miRNomic profiles in the follicular fluids retrieved after stimulation conducted in follicular and luteal phase of the same ovarian cycle.

R. Carmelo[1], D. Cimadomo[2], E.I. Parrotta[3], S. Scalise[3], G. Santamaria[3], E. Alviggi[1], M.T. De Angelis[3], G. Sarro[3], R. Vallefuoco[1], A. Vaiarelli[2], R. Venturella[3], F. Zullo[3], L. Rienzi[2], F.M. Ubaldi[2], G. Cuda[3]
[1]Clinica Ruesch, G.en.e.r.a. centers for reproductive medicine, Napoli, Italy
[2]Clinica Valle Giulia, G.en.e.r.a. centers for reproductive medicine, Rome, Italy
[3]Università degli Studi "Magna Graecia" di Catanzaro, Department of experimental and clinical medicine, Catanzaro, Italy

Study question: Is there any difference in the miRNomic profile of follicular fluids retrieved after follicular-phase-stimulation (FPS-FFs) and luteal-phase-stimulation (LPS-FFs) conducted in the same ovarian cycle?

Summary answer: Pooled FPS-FFs and paired-LPS-FFs from 15 poor-prognosis women resulted in similar miRNomic profiles.

What is known already: Multiple waves of follicular growth can arise during an ovarian cycle, an evidence that questioned the classic "single recruitment" theory of folliculogenesis. The "wave theory" paved the way for the implementation in IVF of stimulation protocols conducted in the luteal-phase of the ovarian cycle, theoretically anovulatory. Nevertheless, LPS-derived cohorts of oocytes were reported larger and competent as paired FPS-derived ones. DuoStim (FPS+LPS in the same ovarian cycle) was therefore suggested to treat poor-prognosis women. Still, more data are needed to investigate putative

differences in the follicular environment. MiRNomic signatures of FFs after FPS+paired-LPS represent a promising tool to this end.

Study design, size, duration: Exploratory study. Fifteen poor-prognosis women (AMH≤1.5ng/mL and/or AFC≤6 and/or ≤5 oocytes retrieved from a previous cycle and/or ≥35yr) completed FPS and paired-LPS with recombinant-gonadotrophins in an antagonist protocol between September-2016 and April-2017. Three pools of FPS-FFs (N=15) and three pools from paired-LPS-FFs (N=15) were collected. Mean maternal age and number of follicles were balanced between the pools. The miRNomic profiles of FPS-FFs and paired-LPS-FFs were compared to define putative differences.

Participants/materials, setting, methods: RNA-isolation was performed with the Plasma/Serum RNA Purification Kit (Norgen-Biotek). MicroRNAs were analysed with the Bioanalyzer2100 using the Agilent Small RNA Chip. 50ng of total-RNA were pooled and processed with the TrueSeq Small-RNA Library Prep Kit (Illumina) for library indexing. The Illumina HiSeq2500 was used for cluster generation and sequencing in a 1x36 single-end format. After quality-control, differential expression was reported as Fold-Change with adjusted *p*-values. Gene-ontology analysis was performed with IPA software.

Main results and the role of chance: Intra- and inter-variability among and between FPS-FFs pools and paired-LPS-FFs were limited in terms of maternal age and number of cumulus-oocyte-complexes collected (pool-A: 39.2±3.0yr, FPS 5.4±3.6 COCs and LPS 5.8±3.2; pool-B: 39.6±2.5yr, FPS 5.2±2.1 COCs, LPS 5.8±4.3 COCs; pool-C: 39.6±2.3yr, FPS 5.0±2.3, LPS 6.0±5.1). The transcripts identified clustered in the following classes: Small-Nucleolar RNAs, RNA5S ribosomal pseudogenes, mitochondrial genes and miRNAs. A comparative analysis revealed no statistically-significant difference between FPS-FFs and paired-LPS-FFs (paired t-tests conducted). When focusing on miRNAs, 57 were identified in both FPS-FFs and LPS-FFs (filtering parameters: detected in ≥2/3 FPS-FFs and LPS-FFs pools with ≥10 reads). No miRNA was found either only in FPS-FFs or only in LPS-FFs. The Pearson's correlation among and between FPS-FFs and paired-LPS-FFs was always ≥0.9, thereby testifying the consistency in the design of the pools and in the miRNomic profiles. Some of the 57 miRNAs identified contribute to molecular pathways involved in cell proliferation, regulation of progesterone concentration, follicular and post-fertilization development. Also key-miRNAs previously outlined as biomarkers of conditions such as polycystic-ovarian-syndrome (e.g. miR-182,-30a,-193b,-222,-483) or IVF outcomes (e.g. miR-10b,-16-1,-320a) did not show differences.

Limitations, reasons for caution: More studies are required to confirm the safety of LPS. This study suggests a similar miRNomic profile in FFs after FPS and paired-LPS. Although molecular investigations, possibly proteomic, should be performed on a wider population to draw clear conclusions.

Wider implications of the findings: LPS in a DuoStim-approach is promising for poor-prognosis or oncological patients, as it allows to collect large cohorts of competent oocytes in a short timeframe. Comprehensive assessments of DuoStim safety, like the one adopted in this study, are crucial among the requirements for a widespread implementation of this strategy.

Trial registration number: None.

P-613 BMI MIGHT BE A RISK FACTOR FOR LOW PROGNOSIS IN PATIENTS WITH PCOS UNDERGOING ART

Y. Guo[1], F. Yuan[2], T. Li[2]

[1] *Peking University International Hospital, Reproduction Center, Beijing, China*
[2] *Peking University People's Hospital, Reproduction Center, Beijing, China*

Study question: To find the risk factor for low prognosis in patients with PCOS undergoing ART.

Summary answer: BMI might be the possible risk factor for POR in patients with PCOS.

What is known already: Polycystic ovary syndrome (PCOS) affects 5–10% of women in reproductive age and is characterized by chronic anovulation and hyperandrogenism. IVF-ET is the main treatment for ovulation induction therapy failure of PCOS patient, but there is still a few part of patients present as a poor ovarian response (POR), which always leads to a "low prognosis". What is the risk factor of these patients for the POR remains unclear. This retrospective study is going to find the possible risk factors for POR of women with PCOS.

Study design, size, duration: 334 patients with PCOS who underwent assisted reproductive technology (ART) in Peking University People's Hospital Reproductive Center from Jan 1st , 2016 to Dec 31st , 2017 were enrolled into this study.

Participants/materials, setting, methods: The number of oocytes were calculated, and the pregnancy rate and live birth rate related to the oocytes number were also estimated. Patients with POR were grouped according to the POSEIDON stratification. Multivariate logistic regression analysis were used to value the risk factors for the POR of patients with PCOS.

Main results and the role of chance: The mean number of oocytes in the enrolled 334 patients was 16.28. Forty-two patients were diagnose as POR with the mean oocytes number of 2.8. The pregnancy rate in patients with POR was similar with other patients (56.5% vs. 41.3%, P=0.194), but the live birth rate was significantly decreased (13.0% vs. 21.3%, P=0.047). The duration of infertility (P=0.022), BMI (P=0.010) and duration of GnRH use (P=0.027) was significantly higher in patients with POR than that in other patients. After the multivariate logistic regression analysis, BMI remained to be the risk factor for the POR of patients with PCOS (RR=1.101, 95%CI: 1.002-1.209, P=0.045).

Limitations, reasons for caution: The scale of the study is still small, and more larger, multicenter researches are needed to confirms this conclusion.

Wider implications of the findings: The results of this study show that obesity (BMI>24) is indeed the main risk factor for POR in patients with PCOS, which is consistent with the results reported in foreign literature.This study firstly revealed a direct link between MIB and POR or low prognostic factors in patients with PCOS.

Trial registration number: Not applicable.

P-614 Can GnRH agonist-trigger reduce multiple pregnancy risk without affecting live birth in clomiphene and letrozole resistant PCOS women undergoing letrozole-gonadotropin stimulation?

S. Sharma[1], S. Roy chowdhury[2], I. Saha[3], S. Kalapahar[3], S. Ghosh[3], B. Chakraborty[3]

[1] *Institute of Reproductive Medicine, ART, Kolkata, India*
[2] *Institute Of Reproductive medicine kolkata- India, Assisted reproduction, Kolkata, India*
[3] *Institute Of Reproductive Medicine- Kolkata- India, Assisted reproduction, Kolkata, India*

Study question: Can GnRH agonist (GnRHa) trigger reduce multiple pregnancy risk and associated complications in clomiphene citrate (CC) and letrozole resistant PCOS women undergoing letrozole-gonadotropin stimulation?

Summary answer: GnRHa trigger lowers multiple pregnancy rate and associated complications without affecting live birth in CC/Letrozole resistant PCOS women when compared with hCG trigger

What is known already: When CC resistant women are treated with letrozole, many turn out to be resistant to letrozole also. The next option for these cases remains gonadotropins which are expensive, associated with increased risk of ovarian hyperstimulation (OHSS) and multiple pregnancies. Letrozole-gonadotropin co-treatment was reported to be more cost-effective in CC resistant PCOS women than CC-gonadotropin or gonadotropin alone. GnRHa trigger has been successfully used for follicular maturation in both IUI and IVF cycles

Study design, size, duration: This non-randamised prospective study was conducted at the Institute of Reproductive Medicine, Kolkata, India between March 2016 and September 2018. The study was approved by the Institute Ethics Committee. 591 PCOS women (1374 cycles) resistant to CC (150mg) and letrozole (7.5mg) were recruited for the study. On the day of trigger, 273 women (673 cycles) were given GnRHa trigger, whereas 318 women (701 cycles) were given hCG trigger following ovulation induction .

Participants/materials, setting, methods: Ovulation was induced with 5mg letrozole (day 3-7) and uFSH (75-150 IU) stimulation (day 7 onward) until follicular size reached ≥14mm. Ovulation was triggered when leading follicle reached ≥18mm and endometrial thickness >7mm. Following confirmed ovulation, patients were advised for timed intercourse. All the patients received luteal support. Number of follicles, endometrial thickness, terminal E_2, clinical pregnancy rate, multiple pregnancy, miscarriage rate, obstetric complications and live birth were compared between GnRHa and hCG trigger groups.

Main results and the role of chance: 152 cycles were cancelled due to poor ovarian respone (4.12%), hyper response (when >4 follicles reached ≥14

mm, 2.68%), premature LH surge (0.52%) and poor endometrial thickness on day of trigger (2.03%). Mean age, BMI, duration of infertility, baseline E2, AMH and AFC were comparable in both the GnRHa and hCG groups. Dose of gonadotropin, days of ovulation trigger, endometrial thickness on the day of trigger, number of follicles ≥ 14mm and less than <14mm were also observed to be comparable between the two groups. A non-significant, but higher clinical pregnancy rate was observed in hCG trigger group (19.83%) when compared with GnRHa trigger group (17.26%), whereas significantly higher miscarriage rate ($p<0.05$) was observed in hCG group (19.83%) compared to that of GnRHa (10.63%). Multiple pregnancy were significantly low ($p<0.05$) in GnRHa group (one triplet and four twins, 5.88 %) than in hCG group (One quadruplet, three triplet and 11 twins ,15.46 %). Live birth was found to be comparable between the GnRHa (12.33%) and hCG group (12.69%). One patient in GnRHa group and three in hCG group had mild OHSS. Fewer obstetric complications were also observed in women of GnRHa trigger group when compared to hCG trigger group.

Limitations, reasons for caution: A limitation of this study is non-randomized design. Due to dearth of any similar reported study, the present observations were important to precede any multicentric, randomized studies with larger sample to check feasibility of using letrozole-gonadotropin co-treatment with GnRHa trigger to reduce multiple pregnancy risk without compromising live birth rate.

Wider implications of the findings: To reduce multiple pregnancies and its complications associated with gonadotropin stimulated cycle, expensive option like IVF with elective single embryo transfer is offered. GnRH agonist trigger instead of hCG in letrozole-gonadotropin cycle can reduce multiple pregnancy and provides cost effective and safe treatment to these CC/letrozole resistant PCOS patients

Trial registration number: Not applicable

P-615 Pilot observational study evaluating the effect of L-Leucine pretreatment on ovarian response and embryo quality in Poor Ovarian Response (POR) patients undergoing controlled ovarian stimulation

A. Vohra[1], M. Dwarkanath[1], D. Krishna[1], J. Esanakula[1], G. Pranesh[1], K. Rao[1]

[1]Milann Fertility Centre, Reproductive Medicine, Bangalore, India

Study question: Is there any change in the ovarian response and embryo quality after L-Leucine (800 mg MTorr capsule) therapy in POR patients undergoing Controlled Ovarian Stimulation for IVF/ICSI ?

Summary answer: 90 days L-Leucine therapy showed an improvement in mean AMH, AFC, more retrieved oocytes, higher peak estradiol levels and more high-quality embryos in poor responders.

What is known already: Leucine is an essential amino acid and a nutrient signal that activates complex 1 of the mammalian target of rapamycin (mTORC1). mTOR signalling integrates extracellular and intracellular signals to regulate protein translation, cell metabolism, growth, proliferation, and survival. Thus, mTOR is activated during cellular processes that use energy and it also regulates primordial follicle activation.

The association of the mTOR pathway in folliculogenesis and the involvement of leucine in the regulation of mTOR pathway has been studied in animal models. However, no human study has investigated whether pre-treatment with L-leucine could improve the ovarian response and embryo quality in poor responders.

Study design, size, duration: Pilot Observational longitudinal cohort study of 30 POR patients pretreated with L-leucine for 90 days before undergoing Controlled Ovarian Stimulation(COS) for IVF/ICSI in a tertiary care Reproductive Medicine Institute. The total study duration was 120 days. 30 POR patients with one previous failed IVF cycle were supplemented with Mtorr 800 capsules containing 800mg of L-leucine once a day after meals for 90 days before undergoing COS. Treatment non-compliant patients were excluded from the study.

Participants/materials, setting, methods: Pilot Observational cohort study of 30 POR patients after 1 failed ART(Assisted Reproductive Technology) cycle undergoing COS for IVF/ICSI in a tertiary care Fertility Centre and Reproductive Medicine Institute. These patients were supplemented with Mtorr 800 capsules containing 800mg of L-leucine once a day after meals for 90 days before undergoing the second cycle of COS. The baseline characteristics, changes in AFC,AMH,Peak E2 levels,Oocyte and Embryo details were collected and analysed using MS EXCEL and SPSS software.

Main results and the role of chance: The mean AFC(antral follicle count) before treatment was 6.9 and the mean AFC after 90 days of treatment with Mtorr 800 capsules was 8.2 (p value 0.01).

The mean AMH(anti Mullerian hormone) before treatment was 1.3ng/ml and mean AMH after treatment was 1.8ng/ml which showed a rising trend.

The Peak Estradiol(E2) levels on the day of trigger before treatment were 1308pg/ml and Peak Estradiol levels after treatment were 1473.4pg/ml. An increasing trend in mean peak E2 levels was observed after 90 days of treatment with L-leucine.

The average oocyte number before treatment was 4.53 and after treatment was 5.53(p value 0.06).Total Metaphase 2(M2) oocytes retrieved were observed to increase by an average of 1 oocyte after 90 days of treatment with L-leucine, which could reduce cycle cancellation.

The average number of day3 cleavage Grade A Embryos before treatment were 1.4 and Grade A Embryos after treatment were 2.23 (p value 0.01).Increase in total grade A embryos improves likelihood of an embryo transfer in a poor responder.

An increasing trend in the mean AMH,AFC,Peak Estradiol levels, oocytes retrieved and number of Grade A embryos was observed.For a poor responder, one extra oocyte or embryo could increase the chance of pregnancy and possibly avoid donor egg program.

Limitations, reasons for caution: The limitation of our study was the small sample size as it was an observational pilot study. A randomised controlled trial would better assess the effect of L-leucine on ovarian response and live birth rate.

Wider implications of the findings: Mtorr 800 capsules containing 800mg of L-leucine could offer hope to POR patients where improvement in ovarian response and embryo quality could offer better chances of pregnancy.After 90 days of therapy, an improvement in mean AMH,AFC, more retrieved oocytes and high-quality embryos in poor responders could avoid donor egg program.

Trial registration number: Institutional Ethics Committee Project Number 042/P/19/01

P-616 A randomised controlled trial assessing the effect of micronised progesterone versus medroxyprogesterone acetate on the coagulation cascade of women with premature ovarian insufficiency

M. Mittal[1], P. Chitongo[2], P.R. Supramaniam[3], R. Arya[4], H. Hamoda[5]

[1]Imperial College Hospital NHS Trust, Women's and Children's, London, United Kingdom

[2]King's College Hospital NHS Trust, Pathology, London, United Kingdom

[3]Oxford University Hospitals NHS Foundation Trust, Women's and Children's, Oxford, United Kingdom

[4]King's College Hospital NHS Trust, Haematology, London, United Kingdom

[5]King's College Hospital NHS Trust, Women's and Children's, London, United Kingdom

Study question: Do progestogen preparations impact the thrombotic profile of women with premature ovarian insufficiency (POI) through markers of haemostatic activation when controlled for route of administration?

Summary answer: Fluctuations in traditional haemostatic biomarkers is not reproduced by thrombin generation changes, a marker of global coagulation, demonstrating no increased thrombotic risk with either progestogen.

What is known already: Natural menopause is associated with a pro-thrombotic state secondary to coagulation pathway changes. Limited evidence exists on venous thromboembolic (VTE) disease risk in POI. Hormone replacement therapy (HRT) has been implicated in the development of VTE disease, with oestrogen route of administration and progestogen preparation being independent causative factors.

The thrombin generation curve measures four main parameters, lag time (LT), time to peak (ttP), peak height and endogenous thrombin potential (ETP), differing from classical clotting assays in its ability to globally reflect all three phases of coagulation in contrast to the initiation phase only, better characterising the underlying prothrombotic states.

Study design, size, duration: Prospective open-label randomised trial conducted over 2 years. Subjects were randomised to one of two treatment arms.

Venous blood was collected for thrombin generation and coagulation profile. Samples were taken at baseline and 3-months.

Seventy-one subjects were consented. 44 (21 randomised to Utrogestan; 23 to MPA) underwent sampling at baseline and 3-months for thrombin generation. 61 underwent a baseline coagulation screen and 43 (20 allocated to Utrogestan; 23 to MPA) had sampling repeated at 3-months.

Participants/materials, setting, methods: POI subjects were recruited from two tertiary Reproductive Clinics. Both groups received 50mcg/day transdermal oestradiol (Evorel® Patches) in conjunction with either cyclical oral Utrogestan® (200mg for 12 days) or medroxyprogesterone acetate (MPA) (10mg for 11 days).

Independent sample t-test was used to assess the percentage difference between the groups. Paired t-test was used for continuous variables. ANOVA and MANOVA were performed to determine the impact of dependent and independent variables (age/BMI): $p<0.05$ considered statistically significant.

Main results and the role of chance: The baseline characteristics of the two study populations were not statistically different. The data has been presented as mean±standard deviation (SD).

The coagulation profile included an assessment of the following parameters: Protein C, Protein S, Antithrombin III, Lupus anticoagulants (DRVVT), Clauss fibrinogen, D-dimer, APC Resistance, Factor VIII, international normalised ratio (INR) and Activated Partial Thromboplasti Time Ratio (APTR).

Utrogestan was noted to result in a reduction in Protein S (-9.24±15.53%; 95% confidence interval [CI] -17.22 to -1.25; p=0.03) and Antithrombin III (-8.78±11.25%; 95% CI -14.37 to -3.18; $p<0.001$) levels at 3-months from baseline. Changes in Protein C levels were not found to be significant.

MPA use was associated with a reduction in Protein C levels at 3-months from baseline: -11.64±20.47%; 95% CI -20.71 to -2.56; p=0.01. Non-significant changes occurred in Protein S and Antithrombin III levels.

Thrombin generation analysis demonstrated no statistical change in the measured parameters, 3-months from baseline for both groups.

Limitations, reasons for caution: The study did not achieve statistical power with wide confidence intervals for the demonstrated differences, therefore, clinical relevance of these small differences requires further evaluation in larger studies.

Wider implications of the findings: The absence of statistically significant changes in the global coagulation assay confers no additional adverse effect with either progestogen preparation when combined with transdermal oestrogen in the management of women with POI. This finding helps create an evidence-based choice for women without increasing their overall thrombotic risk.

Trial registration number: Ethical approval and patient consent were obtained.

REC Number: 12/LO/1957.

EudraCT Number: 2012-004511-30.

P-617 Comparative results of IUI performed 24 hours and 40 hours after HCG-Trigger

M. Singh[1], R. Singh[2]

[1]*Bhopal Test Tube Baby Centre, Gynaecology and Obstetrics, Bhopal, India*

[2]*Bhopal Test - Tube - Baby Centre - Bhopal, Infertility, Bhopal, India*

Study question: Is an IUI at 24 hours post HCG Trigger as effective as an IUI after 40 hours ?

Summary answer: Results of 24 hours IUI post HCG Trigger are comparable to 40 hours IUI without compromising efficacy and convenience.

What is known already: When natural intercourse occurs, before ovulation, it yields a good probability of pregnancy in fertile couples.

Therefore an IUI performed in Pre-Ovulatory period is as effective as post ovulatory IUI.

Study design, size, duration: 326 infertile women, 25-40 years of age (2016-2018) , were randomized equally to a single IUI, either 24 hours or 40 hours after receiving hCG trigger .

All patients had evidence of tubal patency .

Participants/materials, setting, methods: 326 infertile women, 25-40 years of age, were randomized equally to a single IUI, either 24 hours or 40 hours after receiving hCG trigger. Study duration: 2016-2018.

All patients had evidence of tubal patency, with a Day- 2 FSH < 12 mIU /ml.

1 to 4 IUI cycles were performed per couple.

Primary outcome measured was the clinical pregnancy rate.

Main results and the role of chance: The 24 hour group pregnancy rates were similar to the 40 hours group.

The clinical pregnancy rate was 11% in the 24 hour IUI group (n-163) and 13% in 40 hours IUI group (n-163)

Limitations, reasons for caution: Timing of IUI is most frequently performed with human chorionic gonadotropin (hCG) injection. Limitations of timing by ultrasound and hCG administration are frequent hospital visits and the occurrence of premature LH surges or the possibility of triggering ovulation in the presence of an immature follicle.

Wider implications of the findings: IUI performed 24 hours after administration of hCG yields similar pregnancy rates compared to an IUI performed 40 hours after hCG.

The comparative clinical pregnancy rates seen in both timings of IUI suggests that efficacy and similar results can be obtained along with convenience to patient and treating physician .

Trial registration number: not applicable

P-618 Machine Learning approaches to Predicting Personalized Response to Controlled Ovarian Hyperstimulation (COH) During In Vitro Fertilization (IVF).

S. Thukral[1], D. Sakkas[2], D.A. Vaughan[3], T.L. Toth[4], A.S. Penzias[5], S. Bhasin[6], R. Jasuja[1]

[6]*Brigham and Women's Hospital/Harvard Medical School, Research Program in Men's Health: Aging and Metabolism, Boston MA, U.S.A.*

Study question: Statistical methods in machine learning (ML) provide exciting tools for developing patient specific prediction systems. Can a supervised learning framework predict ovarian response to Controlled Ovarian Hyperstimulation (COH)?

Summary answer: Our study demonstrates that an ensemble framework for ML models provides an efficient framework for predicting follicular development in women undergoing COH during IVF.

What is known already: IVF is a widely utilized method in the treatment of sub-fertile couples. Central to the IVF cycle is COH of the female, thereby stimulating the development of numerous follicles, yielding multiple oocytes at the time of retrieval. The stimulation process involves a concerted program of interleaving hormone and drug administration. While these protocols have been developed over many decades, unexplained divergent responses are frequently observed in women undergoing identical stimulation regimes.

Study design, size, duration: The ovarian response to controlled hyperstimulation in patients seeking IVF treatment was analyzed retrospectively for 36 months (02/2015-02/2018). A total of 6072 patient data were initially examined. The cohort was reduced to 2746 records after eliminating any incomplete sets. 80% of data records were randomly used to train the network and 20% were used for the validation set.

Participants/materials, setting, methods: An extensive medical record library from one large IVF clinic was used to create a training (80%) and prediction (20%) database. The training database contained baseline data from all IVF patients including age, FSH, estradiol, progesterone and other anthropometric data.

Main results and the role of chance: The ML approaches have been successfully applied for several biological signaling models in the recent years. However, a successful IVF cycle presents a complex challenge which involves a multitude of latent modifiers including genetic, anthropometric and age-related components. Accordingly, we set up several ML schemas to examine the predictive accuracy for the ovarian stimulation. In order to limit predictability to

a female factor, we chose endometrial lining thickness, mature follicle number and oocyte number as the outcomes. The mean age of the cohort was 36.3 years (range 22-46), had an average BMI of 26.8 and 2.2% were self-reported smokers. The patient characteristics (E2, P4, LH) had a minimum root-mean-square error (RMSE) of 0.4, 0.3 and 0.4, respectively) and were found to be log normal except for the endometrial lining, which was normally distributed. Of the several machine learning algorithms (random forest, SVM, Neural Networks), the ensemble approaches were found to be most accurate in predicting ovarian response outcomes. The ensemble model used to generate correlations plots displayed excellent concordance with predicted trajectories of E2, LH, P4, and Follicular size >14mm (log normal RMSE of 0.4, 0.7, 0.4 and 0.4 respectively).

Limitations, reasons for caution: Machine learning approaches, while extremely powerful in modeling latent modifiers, suffer from an intrinsic bias towards the quality of training set and its correspondence with the test set. ML based applications must be validated for sensitivity analysis of input parameters for the treatment seeking population at large.

Wider implications of the findings: The model presented here uses the laboratory tests routinely performed in IVF clinics. For a wider adoption of this ML framework, it is imperative that clinicians use harmonized laboratory values as input parameters prior to expanding it to other centers.

Trial registration number: The de-identified data from patients' charts was analyzed under the IRB protocol number 2018P000062.

P-619 the novel potential molecule involved in polycystic ovary: overexpression of phosphodiesterase 4D (Pde4d) disturbs antral follicle development

L. Jin[1], M. Guo[1], B. Chen[1], H. Xu[1], Z. Ke[1], H. Pan[2], Y. Cheng[2], Q. Yang[3], C. Zhou[1], Y. Liu[3], J. Sheng[2], H. Huang[1]

Study question: what's the possible molecular mechanism underlying the arrested antral follicle development in Polycystic ovary syndrome (PCOS) women?

Summary answer: Novel candidate pathogenic genes of polycystic ovary were identified, among which the overexpression of Pde4d was investigated to impair the antral follicle development.

What is known already: Most PCOS women have polycystic ovary, with excessive arrested small antral follicles. However, when stimulated with gonadotropins, these stunted follicles could continue to mature. Many key molecules, participating in primordial to preantral follicles growth as well as ovulation, have been well reviewed. Although cAMP/PKA/pCREB, activated by gonadotropins on G-protein-coupled receptors (GPCR), is widely admitted that it's vital in gonadotropin-dependent follicle growth, it is few studied on the potential molecular mechanism of the arrested antral follicle development.

Study design, size, duration: RNA-Seq was performed on granulosa cells (each group n=4) from three kinds of rat polycystic ovary (PCO) models (each group n=20). The overlapped differentially expressed genes (DEGs) were matched in three groups and further screened for candidate PCO pathogenic gene (Pde4d). The RNA-Seq result was then verified. Moreover, the pathophysiology of upregulated Pde4d and its role in arrested antral follicle development were investigated.

Participants/materials, setting, methods: 21-day-old SD rats were induced respectively by estradiol valerate (EV), testosterone propionate (TP), constant light (CL) for 8 weeks. The vaginal opening time, estrous cycle, and ovary morphology were observed. RNA-Seq was performed with Illumina Hiseq 2500 and the DEGs were screened by cuffdif2 test. The Pde4d expression was verified by PCR and Western Blot. Pde4d hydrolysis function was detected by cAMP level, folliculogenesis-related genes by PCR, and signal pathway by Western Blot.

Main results and the role of chance: The EV/TP/CL induced PCO rats had advanced vaginal opening time, disturbed estrous cycle, and polycystic ovary (arrested antral follicle development), compared to their own control rats. In EV group, there were 367 DEGs (189 up-regulated, 178 down-regulated). In TP group, there were 447 DEGs (226 up-regulated, 221 downregulated). In CL group, there were 886 DEGs (399 up-regulated, 487 down-regulated). 86 DEGs were overlapped within all three PCO groups, of which only 16 DEGs had the same tendency of upregulation or downregulation in all three groups. As Areg, Ereg, Lyve1, Ptger2, and Tnfaip6 have been investigated to be involved in follicular physiology, candidate genes were reduced to 10. As to Pde4d, its protein level was verified increased in PCO rats. When stimulated with FSH, the cAMP level was comparable between PCO and control rats after 30m, while markedly decreased in PCO rats after 60m. Consequently, the intensity of pCREB, usually phosphorylated by cAMP-activated PKA, was obviously weakened in PCO rats. Moreover, genes involved in early immature follicle growth were upregulated, while genes associated with follicular maturation was downregulated.

Limitations, reasons for caution: Rats are multi-ovulatory, inconsistent with mono-ovulatory female, implying difference in follicle selection process. So, our results need to be further verified in human samples before applied to women.

Wider implications of the findings: The newly found molecules are strong candidates for investigations of their roles in dysfunctional folliculogenesis in PCOS, which could be diagnostic markers or therapeutic targets in clinic. Pde4d, one of them, was initially investigated to shed light on the possible pathophysiological mechanism participating in arrested antral follicle growth in PCOS.

Trial registration number: not applicable

P-620 Correlation between serum and follicular fluid levels of oxidative stress markers in women who undergo in vitro fertilization/intracycoplasmatic sperm injection

V. Castañón[1], C. Barneo[2], S. Rodriguez[3], I. Vega[3], L. Sanchez[1], P. Antuña[1], M. Méndez[1], C. González[1], E. Fernández[1], P. Llaneza[1]

[1] *University Central Hospital of Asturias, Assisted Reproduction Department, Oviedo, Spain*
[2] *University Central Hospital of Asturias, Biochemistry laboratory, Oviedo, Spain*
[3] *University of Medicine, Cell Biology Department, Oviedo, Spain*

Study question: Is the serum level of oxidative stress markers representative of ovarian levels in assisted reproduction techniques patients at different times?

Summary answer: Lipoperoxidation level is similar both in serum and follicular fluid (FF) and there was a strong correlation in antioxidant defense measured in serum and FF.

What is known already: The role of oxidative status in women´s reproductive physiology has not yet been clearly elucidated. Although we know a correct oxidative status is necessary for normal endocrine function, there are few studies in human reproduction about this topic.

The pathological effects of reactive oxygen species result basically from damage to lipids.

Finding out a correlation between serum and FF would involve the power to predict the ovarian situation with a simple blood extraction.

Study design, size, duration: This study is a prospective pilot study, a total of 20 patients were recruited twice in the period between april 2017 and february 2018.

Patients undergoing IVF/ICSI and embryo transfer were stimulated with recombinant FSH and monitored by regular ultrasound and serum estradiol assays.

The follicular fluid (FF) was collected the recovery day and the serum sample was collected 48 hours before. Both samples were centrifugated and frozen at -80º until analysis.

Participants/materials, setting, methods: Patients underwent treatment twice and the anaysis was carried out in both cycles to increase consistency of the results.

Lipid peroxidation (LP), total antioxidant activity (TAA) and ratio LP/TAA were measured by spectrophotometry, using N-metil-2-phenilindol as chromogen which reacts with derivative lipids, and the acid ABTS to form a radical with a characteristic spectrum at 414 and 730 nm. The t-Student test and Pearson or Spearman correlation coefficients were calculated depending on the normality condition.

Main results and the role of chance: Means (+SD) were: for age of women 35.56 (+2.83) years, for BMI 23.92 (+5.04) Kg/m^2 and for time between

treatments 7.28 (+1.5) months. The sterility causes were: 33.33% male factor, 27.78% mixed factor, 22.22% unknown factor and 16.67% female factor.

Serum vs FF results showed as (mean + DS) followed by p:

1st cycle: LP (62.12±25.21) vs (50.57±24.06), p=0.109, TAA (3.89±2.70) vs (6.21±4.25), p<0.001, ratio LP/TAA: 17.84(12.31-28.96) vs 9.46(6.33-15.15), p<0.001.

2nd cycle: LP (75.54±36.01) vs (49.58±20.58), p=0.033, TAA (4.75±2.05) vs (6.45±2.92), p=0.002, ratio LP/TAA: 17.56(8.59-21.66) vs 8.21(4.37-12.13), p=0.001.

TAA (mg Tx/g prot) is the only one parameter greater in FF in both cycles. The antioxidant activity is expressed as Trolox equivalents which produce the same antioxidant effect tan the studied sample. LP is expressed as µmol MDA + 4HNE/g of protein or µM of MDA + 4 HNE.

To predict ovarian values based on serum, lineal regression models were put up when lineal relationship were statistically significant. The achieved coefficients were: 1st cycle: TAA (1.38, p<0.001). 2nd cycle: TAA (1.034, p<0.001).

Limitations, reasons for caution: These results, should be confirmed in a larger study population.

Funding by hospital/clinic(s). The study was partially supported by a grant from Jose Luis Castaño Foundation and Spanish Society of Clinical Biochemistry, FJLC-SEQC. The authors declare no conflicto of interest.

Wider implications of the findings: We find strong correlation between serum and FF in TAA, on contrary ratio LP/TAA does not show a statistically significant lineal correlation between serum and FF although it shows significant lower levels in FF. Finding correlations as this one is important to predict ovarian situation using blood samples.

Trial registration number: None

P-621 High basal estrogen levels (≥40 pg/ml) affect the clinical pregnancy rate of a cryo-thawed single blastocyst transfer during Hormone Replacement following Oocyte Retrieval

S. Ohgi[1], S. Hatakeyama[1], Y. Taga[1], R. Taniguchi[1], A. Yanaihara[1]

[1]*Yanaihara Women's Clinic, Division of Reproductive Medicine, Kanagawa, Japan*

Study question: Could cryo-thawed blastocyst transfer (thawed BT) be performed following oocyte retrieval (OR)?

Summary answer: Cryo-thawed blastocyst transfer in a hormone replacement cycle (HRC) can follow the OR cycle when the basal estradiol (E2) level is lower than 40 pg/ml.

What is known already: Currently, the practice of freezing all cases has increased in order to avoid OHSS. Moreover, in Japan the use of fresh BT has resulted in lower pregnancy rates compared with using thawed BT. Therefore, both clinicians and patients tend to prefer a freeze-all policy. But, there obviously is no standard as to whether thawed BT can be used following the oocyte retrieval cycle. Additionally, few studies have focused on the influence of remaining follicular cysts and basal E2 levels on day 3 following the OR cycle.

Study design, size, duration: This is a prospective case-control study. From January 2018 until December 2018, patients who accounted for 173 thawed BT cycles were recruited at Yanaihara Women's Clinic. All patients followed our "freeze-all policy" and none received fresh blastocyst transfers. Thawed BTs were used for the first cycle of treatment and were performed immediately after either the OR or the spontaneous cycle. This study was approved by the Local Ethics Committee of our clinic.

Participants/materials, setting, methods: Endometrial preparations for thawed BT were accomplished via estrogen supplementation, which was begun on day 3. The morphologically good blastocysts of either Gardner A or B grade were transferred. On day 3, all patients had their serum E2 levels checked for the presence of remaining follicular cysts via transvaginal ultrasound. Despite the results, all patients started HRC, and the clinical pregnancy rates were evaluated accordingly.

Main results and the role of chance: Out of 173 cycles, 96 achieved pregnancy for a clinical pregnancy rate of 55.5%. Among them, 119 cycles were performed using thawed BT just after OR cycles (after group), and the others (n=54) were performed after one cycle interval following OR (interval group). The clinical pregnancy rate in the after group was 57.9% (69/119) and that in the interval group was 50.0% (27/54), and there were no significant differences.

Follicular cysts remained in 37 cycles (cyst group) and did not exist in the other groups (non-cyst group; n=136), the clinical pregnancy rates in the cyst and non-cyst groups were 48.6 (18/37) and 57.4% (78/136), respectively, with no significant differences (p=0.3449).

On day 3, there were 74 cycles (high E2 group) that showed an elevated E2 level (≥40 pg/ml); the others (n=99) showed normal E2 levels (<40 pg/ml) on day 3 (normal E2 group). The clinical pregnancy rate for the high E2 group was 41.9% (31/74), which was significantly lower than that for the normal E2 group (65.7% [65/99], p=0.0019).

Limitations, reasons for caution: Although the follicle growth was checked on the day of progesterone in all cycles, the progesterone level was not measured on that day. This study was an observational study, and all transferred blastocysts were evaluated by morphological analysis rather than by a chromosome of analysis such as PGT-A.

Wider implications of the findings: The high E2 group showed a lower pregnancy rate because this condition might shorten the period before progesterone elevation compared with the normal E2 group in HRC. The thawed BT could be performed following OR via HRC, when patients showed a normal E2 on Day 3 with or without cyst.

Trial registration number: This study has no RCT status, and, therefore, it did not receive a trial registration number.

P-622 The endocrine milieu in naturally matured follicles is different in women with high serum AMH concentrations

M. Von Wolff[1], A. Kohl Schwartz[1], P. Stute[1], M. Eisenhut[1], N. Bersinger[1]

[1]*University of Bern - Inselspital, Department of Endocrinology & Reproductive Medicine, Bern, Switzerland*

Study question: Is the endocrine milieu in follicular fluid (FF) different in women with high serum Anti-Mullerian hormone (AMH) concentrations, and what regulates follicular endocrine parameters?

Summary answer: FF AMH and A2 concentrations are higher in women with high serum AMH levels. FF AMH does not seem to be regulated by FF hormones.

What is known already: Polycystic ovarian syndrome is associated with high serum androgen and AMH concentrations, which is assumed to be due only to a high number of antral follicles. LH stimulates FF androgens which are converted into E2. FF androgens and E2 have been suggested to regulate FF AMH secretion. The intrafollicular concentration of AMH has been shown in Natural Cycle IVF (NC-IVF) to be positively correlated with oocyte fertilisation and implantation rates. It is unknown what regulates AMH synthesis.

Study design, size, duration: Cross-sectional study involving 4 groups with each 21 NC-IVF treatment cycles with the aspiration of one oocyte, performed in 2013 – 2016. Groups were defined by serum AMH concentration. In group A AMH was not detectable, in group B AMH concentrations were detectable but <7.14 pml/L (<1ng/ml), in group C AMH was 7.14-35.7pmol/L (1-5ng/ml) and in group D AMH concentrations were >35.7 pmol/L (>5ng/ml).

Participants/materials, setting, methods: Mean age was 37.6 ± 4.2 (SD, range 27–42) years in all participants and age did not differ between the four groups. FF was collected from the leading follicles. AMH, Androstendione (A2), total Testosterone (T), Estradiol (E2), Luteinizing hormone (LH) and Follicle stimulation hormone (FSH) were determined by immunoassays. Hormone concentrations were compared between groups and associations were analysed by correlation and regression analysis.

Main results and the role of chance: FF AMH and A2 concentrations were highest in group D (p<0.0001 and 0.0025 by one-way ANOVA, respectively). Median FF AMH concentrations were 9.54, 13.2, 37.7, and 36.2 pM in groups A to D, respectively and median A2 concentrations were 9.8, 9.4, 18.8, and 63.2nM, respectively. Regression analysis confirmed the association of serum AMH with FF AMH concentrations (p<0.0001, r^2=0.2933).

FF LH concentrations were positively correlated with T (p=0.05 over all groups), and with A2 (p=0.032 in group D only) concentrations. T and A2 were correlated with increasing E2 concentrations (p<0.001 and 0.010, respectively, over all groups). Neither LH, T, nor E2 were correlated with FF AMH concentrations. None of the hormone parameters were significantly correlated with follicle diameter, oocyte maturity, embryo quality and pregnancy rate.

Limitations, reasons for caution: As NC-IVF follicles were stimulated by HCG the endocrine milieu in these patients does not exactly correspond to the physiological situation. The study was not powered to analyse the pregnancy rate in relation to AMH concentration.
Wider implications of the findings: The endocrine follicular milieu is significantly different in women with high (>5ng/ml) serum AMH concentrations. High serum AMH concentrations do not only seem to reflect a high number of antral follicles but are apparently also due to overproduction of follicular AMH. Women with high serum AMH have a follicular dyfunction.
Trial registration number: Not applicable

P-623 Lack of predictive value of ovarian reserve tests for pregnancy likelihood. The huge difference between quantity and quality

G. Barrenetxea Ziarrusta[1,2], E. Martínez[1], M. De Las Heras[1], O. Gómez[1], J.I. Arambarri[1], M. Axpe[3], E. Rodríguez[1], A. Da Silva[1], J. Barrenetxea[4]
[1] *Reproducción Bilbao, Gynecolgy & Assisted Reproduction, Bilbao, Spain*
[2] *Universidad del País Vasco/Euskal Herriko Unibertsitatea, Gynecology and Obstetrics, Bilbao, Spain*
[3] *Laboratorio Axpe, Clinical Analysis, Bilbao, Spain*
[4] *Complejo Hospitalario de Navarra, Gynecology and Obstetrics, Pamplona, Spain*

Study question: Are ovarian reserve tests predictive of pregnancy and, thus, should they be used as criteria for assisted reproduction exclusion?
Summary answer: Ovarian reserve tests are important to predict ovarian response to COS, but reproductive potential is more related to factors associated to oocyte quality.
What is known already: As a consequence of delayed childbearing, poorer results can be expected in terms of pregnancy rates due to two different factors related to age: declining of follicular pool (quantity) and oocyte quality. Whereas number of oocytes may be predicted by using ovarian reserve tests, chance of pregnancy resulting in a healthy newborn depends on factors not directly related to number of oocytes.

A myriad of markers of ovarian reserve have become part of routine diagnostic testing performed prior to IVF. Moreover, such tests have been used "predictors of successful full term pregnancies" or even as "fertility tests" in many centers.
Study design, size, duration: Cohort study carried out by analyzing prospectively data of 718 consecutive patients who underwent their first IVF treatment during 2017-18 period at a university associated private AR center.

First, we tried to identify factors capable of predicting the quantitative ovarian response (number of MII oocytes). Second, we assessed whether the same parameters were useful for identifying chances of successful ongoing pregnancy.

The study was conducted according to the principles expressed in the Declaration of Helsinki.
Participants/materials, setting, methods: First: Multiple stepwise linear regression analysis. Number of MII oocytes as dependent variable. Age, BMI, AFC, AMH, basal FSH, LH and Estradiol on day 3 to 5 and administered rFSH during stimulation as dependent variables. (P=0.05 significant (Hosmer and Lemeshow).

Second: multivariable logistic (binomial) analysis. Ongoing pregnancy as dependent variable. Number of MII oocytes included as independent variable. The AUC (ROC curves) was used to assess the discriminative power of the logistic regression models.
Main results and the role of chance: The only factor with no influence on the number of retrieved of mature oocytes by applying a simple linear regression analysis was BMI (R2=0,001;p=0,989).

The other variables were evaluated by a multiple stepwise linear regression. Over 78% of the variance of the dependent variable (MII oocytes) is explained by AFC (R2=0,786;t=32,514;p=0,000). By adding the value of AMH to the predictive model, the prediction in the number of oocytes to be obtained improves less than 0,1% (Increase of R2 from 0,786 to 0,787;t= 1,511;p=0,132). Furthermore, the inclusion of all the assessed variables in the multiple lineal regression analysis after AFC does not increase significantly the ability to predict the number of oocytes (From R2=0,786 to 0,794 (t=0,099;p= 0,921).

In 299 cycles(41,64%) an ongoing pregnancy was achieved. Age represented the most important factor influencing ongoing pregnancies (38,8% of the variance;R2: 0,388). AFC and AMH values (the most important variables predicting number of oocytes) increase the predictability by only a 0,6% and 0,7% respectively (R2 increase of 0,006 and 0,007;p=0,170 and p=0,160.

By using ROC curves, the only variable that showed a good accuracy in predicting ongoing pregnancy was age (AUC=0,817). Other variables showed poorer accuracy even though a statistical significance is present.
Limitations, reasons for caution: The descriptive nature of the study may be a limitation for the results of the present study.

A downfall of AFC as predictor of ovarian reserve may be lack of standardization in ultrasound equipment, technique, and inter-observer variability, which results in challenges with cross-comparing results from studies and different centers.
Wider implications of the findings: AMH measurement adds little value to AFC determination in predicting the number of retrieved oocytes. It is worthless to determine basal FSH,E2 or LH levels.

However, ovarian reserve tests should not be offered as "fertility tests" since they are not independently related to pregnancy chance,neither after sexual intercourse nor ART.
Trial registration number: Not applicable

P-624 Evaluation of the Second Follicular Wave Phenomenon in Natural Cycle Assisted Reproduction: A Key Option for Poor Responders Through Luteal Phase Oocyte Retrieval

K. Sfakianoudis[1], M. Simopoulou[2], E. Maziotis[2], P. Giannelou[1], P. Tsioulou[2], A. Rapani[2], A. Pantou[1], K. Petroutsou[1], I. Angeli[1], E. Deligeoroglou[3], M. Koutsilieris[2], K. Pantos[1]
[1] *Athens Genesis Clinic, Reproductive Medicine Unit, Athens, Greece*
[2] *National and Kapodistrian University of Athens, Department of Physiology, Athens, Greece*
[3] *National and Kapodistrian University of Athens, Department of Obstetrics and Gynaecology, Athens, Greece*

Study question: What is the role of Luteal Phase Oocyte Retrieval (LuPOR) in the management of poor responders undergoing natural cycles?
Summary answer: Emergence of LuPOR may revolutionize the practice regarding the time-sensitive nature of poor responders ascertaining a higher number of good quality oocytes faster.
What is known already: Observation of a second follicular wave (SFW) in the luteal phase of a menstrual cycle has altered the traditional theory on folliculogenesis. This led the In Vitro Fertilization (IVF) specialists to the implementation of LuPOR, with favorable results regarding the management of poor responders in stimulated cycles.
Study design, size, duration: The present study represents a retrospective observational clinical study including 136 patients during the time period of 2015 to 2018.
Participants/materials, setting, methods: Collection and statistical analysis was performed based on data from 136 poor responders who underwent follicular oocyte retrieval (FoPOR) and subsequent LuPOR in natural cycles, during IVF treatment. All 136 participants were diagnosed with poor ovarian reserve (POR) according to Bologna criteria. The 272 cycles were categorized as follows: 136 natural cycles with only FoPORs (Control Group) and 136 natural cycles including both FoPORs and LuPORs.
Main results and the role of chance: Our primary results indicate no statistically significant differences with regards to the mean number of oocytes, the maturation status, and fertilization rate between FoPOR and LuPOR in natural cycles. Secondarily, we demonstrate a statistically significant higher yield of oocytes (2.50±0.78 vs 1.25±0.53), better oocyte maturity status (1.93±0.69 vs 0.95±0.59) and higher fertilization rate (1.31±0.87 vs 0.61±0.60) in natural cycles including both FoPOR and LuPOR, when compared to cycles including only FoPOR.
Limitations, reasons for caution: Our study constitutes a retrospective single center analysis.
Wider implications of the findings:

Our study may contribute towards the establishment of an efficient poor responders' management through the natural cycle approach. This novel clinical practice may ascertain the opportunity to employ oocytes and embryos

originating from a luteal phase follicular wave for this time sensitive cohort of patients.

Trial registration number: Not applicable.

P-625 Female obesity does not impact live birth rate after frozen thawed blastocyst transfer

E. Prost[1], T. Freour[1,2,3], A. Reignier[1,3], P. Barriere[1,3], T. Lefebvre[1,3]

[1]*Hospital University of Nantes- 38 bd Jean Monnet 44093 Nantes- France., Department of Reproductive Medicine-, Nantes, France*

[2]*3 Inserm UMR 1064, University of Nantes, Nantes, France*

[3]*Faculty of Medicine, University of Nantes, Nantes, France*

Study question: Does female obesity affect live birth rate after frozen-thawed blastocyst transfer?

Summary answer: Live birth rate was not statistically different between obese and normal weight patients after frozen thawed blastocyst transfer (FBT)

What is known already: Obesity is a major and increasing health problem, especially in women of reproductive age. It impacts spontaneous fertility and increases delay to conception. Although some studies yielded discordant results, most authors found that female obesity impacted negatively all assisted reproductive technology outcomes. Among them, pregnancy rate after fresh embryo transfer in IVF were generally found to be lower than in normal weight women, probably because of reduced uterine receptivity. Surprisingly, only one study evaluated the effects of female body mass index (BMI) on implantation rate after FBT. The authors did not find any association between female BMI and FBT outcome.

Study design, size, duration: This retrospective case control study was conducted in all consecutive frozen thawed autologous blastocyt transfer (FBT) cycles conducted between 2012 and 2017 in our center. FBT cycles in obese women (BMI>30 kg/m^2) were considered as cases (n=252), while FBT cycles conducted in normal weight women (BMI=18.5-24.9 kg/m^2) were considered as controls (n=1415).

Participants/materials, setting, methods: This study was conducted in a single University-based hospital. A total of 252 FBT cycles performed in obese women and 1415 FBT cycles performed in normal weight women were included in the analysis. Endometrial preparation was based on hormonal replacement therapy. Vaginal progesterone was started when endometrial thickness was >7mm. One or 2 blastocyst were transferred after 7 days of progesterone administration. Descriptive analysis of both groups, followed by univariate and multivariate analysis was performed.

Main results and the role of chance: Both female and male age and smoking status, and type of infertility were comparable in both groups (obese and normal weight). Anti mullerian hormone level was statistically higher in obese women than in normal weight women (5,9±5,2µg/L vs 4,8±4,1µg/L, p<0,0002). Concerning FBT cycles, the duration of hormonal treatment, the stage and number of embryos used for transfer were comparable between both groups. Mean endometrium thickness was significantly higher in obese than in normal weight group (8,7±1,8mm vs 8,1±1,6mm, p <0,0001). Concerning FBT cycle outcome, live birth rate was comparable in obese and in normal weight groups (19,05% vs 20,35% respectively, p=NS). The implantation rate (14% vs 19% respectively) and pregnancy rate (21,83 vs 22,05%) were also comparable between two groups

Limitations, reasons for caution: Patient's weight data may have been declarative in some cases. The anthropometric parameters such as hips waist ratio were not used. Polycystic ovarian syndrome status was not systematically available and was not included in the analysis. Neither FBT cycles after ovarian stimulation nor natural cycle were included.

Wider implications of the findings: Our study showed that live birth rate after frozen thawed blastocyst transfer was not statistically different in obese and in normal weight women. Although this needs confirmation, this suggests that the impairment of uterine receptivity observed in obese women might be associated with ovarian stimulation and its hormonal perturbations.

Trial registration number: not applicable

P-626 Progesterone dose adjustment and transfer postponement in patients with low progesterone levels following hormonal replacement therapy for frozen thawed embryo transfer.

I. Cedrin - Durnerin[1], L. Laup[1], C. Vinolas[1], M. Comtet[1], B. Dagher Hayeck[1], C. Herbemont[2], C. Sifer[2], M. Grynberg[1]

[1]*Hôpital Jean Verdier, service medecine de la reproduction et preservation fertilité, Bondy, France*

[2]*Hôpital Jean Verdier, service biologie de la reproduction et preservation fertilité, Bondy, France*

Study question: Is progesterone (P) dose adjustment and postponement of frozen thawed embryo transfer (FET) effective to improve outcome in patients with low P levels following hormonal replacement therapy?

Summary answer: Dose adjustment to obtain serum P levels >10 ng/ml and 1 day transfer postponement gave similar outcome to those of normal P "in phase" transfers.

What is known already: Several studies dealing with HRT FET cycles have demonstrated that low serum P levels on the day of FET or on the day of pregnancy test were associated with decreased pregnancy and live birth rates. However, in our hands, P dose adjustment after ET to obtain P levels >10 ng/ml was ineffective to correct impaired outcome. Therefore, we decided to measure serum P levels and adjust P dose to obtain a serum P level >10 ng/ml prior to ET and to postpone ET by one or two days accordingly.

Study design, size, duration: This is a retrospective analysis of 481 prospectively collected HRT FET cycles from March 2017 to October 2018. Endometrial preparation was achieved by sequential administration of vaginal estradiol until endometrial thickness >7 mm, followed by transdermal estradiol combined with 600 mg/day vaginal micronized P (200 mg three times a day).

Participants/materials, setting, methods: This study was conducted in a university hospital. Serum P was measured on D2 following exogenous P introduction in the evening (referred as D0). When P levels were >10 ng/ml, ET was performed on D2, D3 or D5 depending on embryo stage at cryopreservation. When P levels were <10 ng/ml, P dose was increased to 1200 mg/day. Serum P level was checked one day later and the next day if necessary. ET was postponed accordingly.

Main results and the role of chance: Mean serum P level on D2 was 12.4 + 4.29 ng/ml and serum P <10 ng/ml were observed in 28% of cycles. Cycles were cancelled in 39 patients because of inability to obtain P >10 ng/ml despite increased P dose to 1200 mg/day (n=36) or failure in performing P measurement timely (n=3). Therefore, 442 FET were performed with P >10 ng/ml prior to ET: 346 FET were in phase according to embryo stage, 80 FET were postponed by 1 day and 16 FET by 2 days (P >10 ng/ml on the first or second day following increased P dose to 1200 mg/day respectively). Characteristics of patients in the 3 groups were similar except for mean E2 levels prior to P onset and mean P levels of the last measurement before transfer that were significantly lower in postponed transfer groups. This strategy led to similar positive pregnancy test (38.7 % vs 47.5 %, NS), heartbeat activity at 8 weeks (29.7 % vs 31.2 %, NS) and ongoing pregnancy rates at 12 weeks (29.5 % vs 28.7 %, NS) between "in phase" and "postponed by 1 day" ET while results in "postponed by 2 days" were poor (12.5 %, 6.2 %, 6.2%).

Limitations, reasons for caution: The number of cycles with FET postponed by 1 day following P dose adjustment has to be extended to confirm these preliminary data. In contrast, when serum P levels are not corrected 1 day after P dose adjustment, waiting 1 more day does not seem a suitable option.

Wider implications of the findings: These results suggest that serum P measurement prior to ET and further adjustment of exogenous P dose and postponement of transfer might optimise the outcome of FET cycles performed using HRT and avoid cancellation of a large number of cycles with low serum P levels.

Trial registration number: Not applicable.

P-627 Female obesity significantly impairs live birth rate following IVF: a systematic review and meta-analysis

N. Sermondade[1], S. Huberlant[2], V. Bourhis-Lefebvre[3], E. Arbo[4], V. Gallot[5], M. Colombani[3], T. Fréour[6]

[6]CHU de Nantes, Service de biologie et médecine de la reproduction, Nantes, France

Study question: Does female obesity, defined as Body Mass Index (BMI) ≥ 30 kg/m^2, impact live birth rate following in vitro fertilization (IVF)?
Summary answer: Female obesity negatively and significantly impacts live birth rates following IVF.
What is known already: Female obesity has been clearly associated with impaired spontaneous fertility and evidence from the literature shows that it seems also to impact clinical outcomes following In Vitro Fertilisation (IVF) procedures. However, as published studies are heterogenous in terms of populations, groups definition and outcomes no formal conclusion can be established. A previous meta-analysis published in 2011 (Rittenberg et al., 2011) concluded to a marginal but significant negative effect of female Body Mass Index (BMI) on IVF results. Since several studies, including large cohort from national registries, have been published later, an updated review and meta-analysis was performed.
Study design, size, duration: A systematic review was performed out using the following key words: ('obesity', 'body mass index', 'live birth', 'IVF', 'ICSI'). Searches were conducted on MEDLINE, EMBASE, Cochrane Library, Eudract and clinicaltrial.gov from January 01, 2007 to November 30, 2017.
Participants/materials, setting, methods: Study selection was based on title and abstract, and then by utilizing the quality assessed using the Newcastle-Ottawa Quality Assessment Scales. Two independent reviewers carried out study selection and data extraction according to Cochrane methods. Random-effect meta-analysis was performed using Review Manager software on all data (overall analysis). Sub-groups analysis according to ovulatory status, oocytes origin, fresh or frozen embryo transfer and cycle rank were also performed.
Main results and the role of chance: After review of 407 abstracts, 54 full-text articles were assessed for eligibility. A total of 21 studies were included in the meta-analysis, corresponding to 682,532 IVF cycles. Compared to normal weight women (BMI between 18.5 and 24.9kg/m^2), the risk ratio (RR) for live birth rate after IVF was 0.85 (95%CI=0.82;0.87) in obese women. Sub-groups analyses demonstrated that prognosis was poorer when obesity was associated to Polycystic Ovary Syndrome (RR=0.78; 95%CI=0.74-0.82). The oocytes' origin did not modify the overall interpretation: when only studies including only donated oocytes were analysed, the RR was 0.80 (95%CI=0.68-0.94). Only one study included frozen-thawed only transfers, then conclusions cannot be drawn.
Limitations, reasons for caution: The numerous confounding factors that potentially influence the chance of live birth after IVF procedures were not evaluated in this meta-analysis. Heterogeneity among studies included in the meta-analysis was moderate.
Wider implications of the findings: Our meta-analysis demonstrates that female obesity impairs live birth rate irrespective of PCOS status and oocytes origin raising the hypothesis of endometrial role. The impact of weight loss through lifestyle modifications or bariatric surgery for reversing this effect should be further evaluated.

P-628 Mifepristone influences natural killer cells function mediated by macrophages

L. Cao[1]
[1]Women's Hospital- Zhejiang University School of Medicine, Family Planning Department, Hangzhou, China

Study question: The mechanism of mifepristone influencing the development of maternal-fetal interface is still unknown.
Summary answer: The migration ability and cytotoxicity of NK cells can be increased by macrophages treated with mifepristone.
What is known already: Mifepristone, a modulator of progesterone receptor has been the primary choice for first trimester abortion in some parts of the world. Additional studies have also observed its role in achieving contraception.
Study design, size, duration: we collected decidua tissues from 40 women who had undergone surgical termination of unwanted pregnancy. 20 patients were treated with 150mg mifepristone 24 hours before the surgery. And another 20 patients who not using mifepristone before the surgery were control group.
Participants/materials, setting, methods: The decidual tissues from all study participants were collected to analyze the effect of mifepristone on NK cells and macrophages. In addition, in a separate in vitro assay, NK cells were co-cultured with macrophages pre-treated with different concentrations of mifepristone, to test their migration ability using transwell system, and cytotoxicity by MTT assay. SiRNA was used to determine whether CD48 and TGF-β were involved in the mifepristone influencing the functions of NK cells.
Main results and the role of chance: Our study revealed that the distribution and proximity of NK cells and macrophages changed after mifepristone treatment. Moreover, the migration ability and cytotoxicity of NK cells were significantly increased by macrophages treated with mifepristone in a dose-dependent manner. Furthermore, the numbers of CD56+NK cells and CD206+ macrophages significantly decreased in women who received mifepristone compared to those in the control group. After interfering with CD48 expression, mifepristone has a reduced effect on macrophage migration and cytotoxicity. After interfering with TGF-β expression, mifepristone has a increased effect on macrophage migration and cytotoxicity.
Limitations, reasons for caution: further in vivo studies would be required to decipher the exact mechanism of mifepristone action in inducing abortion.
Wider implications of the findings: These results indicated that mifepristone may mediate the function of NK cells via macrophages.
Trial registration number: not applicable

P-629 Identification of microRNAs associated with an impaired metabolic profile in women with polycystic ovary syndrome

P.B. Udesen[1], **A.E. Sørensen**[2], **R. Svendsen**[2], **N.L.S. Nielsen**[2], **M.L.M. Wissing**[1], **L.T. Dalgaard**[2], **A.L.M. Englund**[1]
[1]Fertility Clinic Koege, Dept. of Gynecology and Obstetrics, Koege, Denmark
[2]Roskilde University Center, Department of Science and Environment, Roskilde, Denmark

Study question: Can we identify microRNAs associated with an altered metabolic profile in women with Polycystic Ovary Syndrome (PCOS), which can serve as biomarkers for early diabetes?
Summary answer: Circulating miR-122-5p is a possible marker of prediabetes in women with PCOS and is associated with the severity of metabolic disease.
What is known already: It is well established that women with PCOS are at greater risk of developing metabolic syndrome and type 2 diabetes. Recent discoveries indicate that miRNAs play an important role in development of diabetes in general and reflect the clinical status of patients. However, to date there are no existing studies of circulating miRNAs as biomarkers for a challenged metabolism and a prediabetic phenotype in women with PCOS.
Study design, size, duration: A prospective follow-up-study with a cohort of 46 women with PCOS diagnosed according to Rotterdam 2003 criteria and nine healthy controls, aged 18 to 39 years. The women were examined twice 6 years apart. Circulating miRNA levels were analyzed at both visits and compared with clinical data. A cross sectional cohort of 162 PCOS patients (133 PCOS and 29 controls) were investigated for biological validation of findings.
Participants/materials, setting, methods: Relevant clinical data of PCOS status and measurements of metabolic disease were obtained at both visits. Peripheral fasting serum samples collected at both time points were used for microRNA analysis. Total RNA was extracted using TriReagent. MiRNA levels were measured using custom Taqman® Array cards of 96 selected miRNAs. MiRNA relative levels were quantified by the $2^{-\Delta\Delta Ct}$ method. MiR-122-5p were analyzed with individual qRT-PCR in the validation cohort.
Main results and the role of chance: During the 6-year follow-up, more participants became prediabetic (defined by Impaired Glucose Tolerance (IGT) or Impaired Fasting Glucose (IFG)) (Six (10.9%) participants at baseline vs 10 (18.2%) participants at follow-up). Analysis of miRNA did not reveal significant differences in circulating levels of any of the tested miRNAs comparing PCOS

with controls neither at baseline nor at follow-up. However, comparing the non-prediabetic with prediabetic, we found that miR-122-5p was significantly upregulated in the prediabetic group both at follow-up (p=0.03) and at baseline, as predictor of prediabetic status at follow-up (p=0.03, OR=7.7 (95%CI: 1.2-51.3) adjusted for BMI, smoking and age). Next, the participants were evaluated for degree of metabolic disease by numbers of metabolic factors present (0-5: hypertension, dyslipidemia, triglyceridemia, increased waist circumference and IGT or IFG). Applying linear regression on the levels of miR-122-5p vs the degree of metabolic disease, the models were statistically significant both at baseline (R^2=0.10, B=0.51, p=0.05) and follow-up (R^2=0.17 B=0.9, p<0.01). In the validation of findings in the cohort of 162 participants, we found significantly elevated levels of miR-122-5p in participants with IFG both in PCOS patients alone (p<0.05) and in the cohort as a whole (p<0.01) after adjustment for BMI and age.

Limitations, reasons for caution: Few participants with prediabetes in the follow-up study causes weak modelling.

Wider implications of the findings: Our results are in line with earlier studies of miR-122-5p, which have demonstrated strong correlation with both metabolic and hepatic disease. Further, validation in the larger cohort strengthen the findings, but suggests that miR-122-5p is probably more a general marker of metabolic disease, than a PCOS-specific marker of metabolic disease.

Trial registration number: ClinicalTrials.gov. Identifier: NCT03142633

P-630 A comparison of IVF outcomes transferring a fresh single ideal blastocyst in women with polycystic ovary syndrome and normal controls with normal ovarian reserve

N. Steiner[1], S. Ates[1], T. Shaulov[1], G. Shrem[1], A. Volodarsky-perel[1], S. Tannus[1], S. Weon Young[1], M.H. Dahan[1]

[1]MUHC Reproductive Center- McGill University- Montreal- QC- Canada, Department of Obstetrics and Gynecology- Division of Reproductive Endocrinology and Infertility- McGill University- Montreal- QC- Canada, Montreal, Canada

Study question: To assess the effects PCOS on live birth rates when transferring a single fresh ideal blastocyst.

Summary answer: After controlling for confounders, when transferring a fresh single ideal blastocyst, live birth rates were lower among the women with PCOS than normal ovulatory controls.

What is known already: PCOS is the most common cause of anovulatory infertility. Although PCOS patient have higher number of obtained oocytes, the quality and maturity of these oocytes might be compromised, leading to reduce fertilization, cleavage, implantation, pregnancy and live birth rates, compared to controls. Stimulated PCOS may have endometrial sub-competence, since ovulatory controls demonstrated similar pregnancy and live birth rates in frozen cycles while PCOS, FET resulted in a higher rate of live birth than do fresh embryo transfer, in prospective randomized studies.

Study design, size, duration: This is a retrospective cohort study performed between August 2010 and March 2014 at the McGill University Health Centre Reproductive Centre. Women with PCOS who underwent their first fresh embryo transfer were included in the study. A control group of women who underwent fresh IVF cycles in the same study period was included in 1:3 ratio.

Participants/materials, setting, methods: 71 PCOS and 272 normal ovulatory controls were included in the study. Statistical analysis was performed with independent-T or chi-squared tests where appropriate. Stepwise multivariate logistic regression was used to calculate pregnancy outcomes while controlling confounders. Data is presented as mean±SD, percentages and confidence ratios (CI). Two-sided p values $\leq$ 0.05 were accepted as significant.

Main results and the role of chance: PCOS patient were younger (31.0± 3.7 vs. 33.1± 3.2, p=0.0001), with higher antral follicle counts (40.0± 9.3 vs. 13.3± 4.6, p=0.0001), required lower dose of gonadotropins to stimulate (1198±786 vs. 1891± 1224, p=0.0001), and had higher serum total testosterone levels (2.3± 0.7 vs. 1.1± 0.3, p=0.0001).

No significant different was fount between the two groups regarding the number of previous pregnancies, the number of previous full-term pregnancies, the level of basal serum FSH and the BMI. Garder's grade of transferred embryo did not differ. When compared by chi-squared testing pregnancy rates, clinical pregnancy rates and live birth rates did not differ. However, when controlling (with multivariate stepwise logistic regression) for female age, total gonadotropin dose used, previous number of pregnancies and previous number of live births, live birth rates was lower among the women with PCOS (p=0.035, CI:0.18-0.92)

Limitations, reasons for caution: It was a retrospective cohort and as such undetected biases may be present.

Wider implications of the findings: This finding suggests that in PCOS patients, the pre-existing hyperandrogenic milieu may have a negative impact on the oocytes or the endometrium which may translate into lower embryo potential at fresh cycles.

Trial registration number: not applicable

P-631 A novel and simple method to schedule GnRH antagonist cycles with a short course of oral estradiol in the early follicular phase

E. Turkgeldi[1], S. Yildiz[1], B. Angun[2], B. Ata[3]

[1]Koc University Hospital, Obstetrics and Gynecology, Istanbul, Turkey
[2]Dunya, IVF Clinic, Kyrenia, Cyprus
[3]Koc University Faculty of Medicine, Obstetrics and Gynecology, Istanbul, Turkey

Study question: Does scheduling GnRH antagonist cycles with a short course of estradiol in the early follicular phase affect oocyte yield?

Summary answer: Early follicular phase estradiol scheduling(FES) enables collection of similar numbers of oocytes without a clinically significant increase in gonadotropin consumption as compared with unscheduled cycles.

What is known already: Widely used GnRH antagonist protocol has limited flexibility regarding to timing of oocyte retrieval, sometimes unable to accommodate the needs of the patient and the medical staff. While various methods have been put to use, they either gain only one or two days, increase gonadotropin/GnRH antagonist injections, require advance planning/monitoring, or risk impairing implantation rates.

Study design, size, duration: A retrospective analysis of 118 cycles from 59 oocyte donors between 2015 and 2018. Each donor underwent two GnRH antagonist stimulation cycles within 6 months, one with and one without FES, and served as her own control to ensure similar baseline and biological characteristics, as in a randomized controlled trial.

Participants/materials, setting, methods: Women aged between 20-30 years who had no medical contraindication to oocyte donation that underwent karyotype analysis/routine screening for infectious diseases were recruited as oocyte donors. FES was achieved by giving 6 mg/day estradiol valerate orally from the 2nd or 3rd day of menstrual cycle until the desired day of gonadotropin start. Gonadotropin was started on the 2nd or 3rd day of menstrual bleeding in unscheduled cycles. Daily gonadotropin dosage was 225-300 IU recombinant FSH.

Main results and the role of chance: A total of 118 cycles, 59 FES and 59 unscheduled GnRH antagonist, were included in the study. Median duration of estradiol administration was 3 days (25th – 75th percentile, 2-4) in FES cycles. The longest duration of estradiol use was 7 days. Median gonadotropin starting dosage was similar at 225 IU/day in FES and unscheduled cycles. In the FES group, stimulation lasted significantly longer by one day (11 vs. 10 days, p=0.03) and total gonadotropin consumption (2497 vs. 2404 IU, p=0.03) was statistically significantly higher, albeit minimal absolute difference, which is probably short of clinical significance. Number of GnRH antagonist injections were similar between FES and unscheduled cycles (5 vs 5). Numbers of COC (21 vs 20) and metaphase two oocytes (17 vs 17) were similar between the two groups.

Limitations, reasons for caution: Although this is a non-randomized retrospective study, each woman serving as her own control assures similar characteristics. Participants or clinicians were not blinded, however, performance bias is unlikely. Pregnancy outcomes are not available, yet prior studies of estradiol scheduling does not suggest a harmful effect on implantation or pregnancy rates.

Wider implications of the findings: Our results suggest similar oocyte yield following FES. FES does not require advance planning, involves shorter use of estradiol/oral contraceptive tablets and can be advantageous to scheduling with luteal estradiol/oral contraceptive administration. If further studies provide reassurance for pregnancy rates, FES can be the method of choice for cycle scheduling.

Trial registration number: None.

P-632 Comparison between prepubertal and postpubertal patients with Obstructed hemivagina and ipsilateral renal anomaly (OHVIRA) syndrome

Y.N. Kim[1], I. Lee[1], J.H. Han[2], Y.S. Lee[2], S.W. Han[2], B.H. Yun[1]

[1]Yonsei University College of Medicine, Department of Obstetrics and Gynecology-Institute of Women's Life Medical Science, Korea, Korea- South

[2]Yonsei University College of Medicine, Department of Urology and Urological Science Institute, Korea, Korea- South

Study question: How does prepubertal and postpubertal patients with OHVIRA syndrome differ in terms of clinical presentation, management, and long-term outcome?

Summary answer: Contrast to postpubertal, prepubertal patients showed ectopic ureter with multicystic dysplastic kidney and were conservatively managed through serial evaluation of hemivaginal obstruction and renal function.

What is known already: OHVIRA syndrome is one of the most common causes of obstructive Mullerian anomaly in menstruating female, with a hallmark presentation of progressively worsening, severe dysmenorrhea at 2 months to 2 years after menarche. Most commonly suspected mechanism is an arrest in development of Mullerian structure and in reciprocal formation of renal structure, leading to a triad of renal agenesis, uterine didelphys, and hemivaginal obstruction. However, with an increased use of prenatal and neonatal sonography, prepubertal cases of OHVIRA syndrome have been reported.

Study design, size, duration: We retrospectively reviewed all patients with the diagnosis of OHVIRA syndrome at Severance Hospital from January 2004 to September 2018. A total of 68 patients were included for final analysis: postpubertal (n=24) and prepubertal (n=44).

Participants/materials, setting, methods: First, subgroup analysis was performed in postpubertal and prepubertal cohorts separately. In postpubertal group, prognosis was compared according to the degree of suspicion for complete (n=12) versus incomplete (n=12) hemivaginal obstruction based on chief complaint. In prepubertal group, patients with ectopic ureter and multicystic dysplastic kidney (n=30) were compared to those without (n=14). Then, as a whole postpubertal and prepubertal OHVIRA patients were compared in terms of clinical presentation, radiological finding, management, and long-term outcome.

Main results and the role of chance: Median age at diagnosis was 20 years old (range: 11-26) for postpubertal (n=24) and 8 days old (range: 0-817) for prepubertal (n=44). All postpubertal patients were symptomatic, and those with abdominal pain or palpable mass (n=12) were more likely show a large amount of obstruction (p=0.046) and up to a higher anatomical level (p=0.029). A majority of prepubertal patients were incidentally diagnosed by ultrasound (81.8%). Among prepubertal patients, those with ectopic ureter were more likely to develop urinary incontinence (33.3% vs. 0.0%, p=0.022) and recurrent urinary tract infection (50.0% vs. 7.1%, p=0.006). Compared to postpubertal who presented with ipsilateral renal agenesis, prepubertal patients presented with ectopic ureter (68.2% vs. 20.8%, p<0.001) and multicystic dysplastic kidney (61.4% vs. 16.7%, p<0.001) and developed contralateral kidney hypertrophy (54.5% vs. 20.8%, p=0.002). Most postpubertal patients underwent primary operation (91.7%), whereas only 8 prepubertal patients (18.2%) underwent operation: nephrectomy in 6 patients and aspiration of hemivaginal obstruction in 4 patients. Serial sonographic evaluation of the amount of hemivaginal obstruction in prepubertal patients showed no change at minimal amount in 44.4% and at least a sign of improvement in 27.8%, reaching a complete resolution in another 25.0%.

Limitations, reasons for caution: Limitations include retrospective design and a relatively small sample size. Sample size could have been larger had we decide to include the anatomical variants of OHVIRA syndrome in a multicenter setting. A future prospective study on prepubertal patients would help provide an effective guideline for follow up and consultation.

Wider implications of the findings: With the recent inclusion of prepubertal patients, clinical spectrum of OHVIRA syndrome has drastically widened in terms of presentation, anatomical features, management, and prognosis. Contrast to postpubertal patients who require timely surgery, prepubertal patients benefit from an individualized approach in the context of maturing gynecologic and urologic organs in children.

Trial registration number: Not applicable

P-633 A slower age-related decline in treatment outcomes associated with in vitro fertilization in women with polycystic ovary syndrome

J. Li[1], Y. Guo[1]

[1]Reproductive Medicine Center- The First Affiliated Hospital of Zhengzhou University- Henan Key Laboratory for Reproduction and Genetics- Zhengzhou- China, Reproductive Medicine Center- The First Affiliated Hospital of Zhengzhou University- Henan Key La,

Study question: what is the exact impact of age on pregnancy outcomes of women with PCOS?

Summary answer: The decline in treatment outcomes with age is slower in PCOS women .Older PCOS patients (≥35 years) show better pregnancy outcomes than age-matched controls.

What is known already: The age-related improvement of endocrine disturbance and relatively good ovarian reserve does not indicate that PCOS women will definitely acquire reproductive superiority over normal women, as other factors that affect female fertility cannot be ignored. For example, obesity, insulin resistance, and metabolic disorders may persist or even worsen in PCOS women with advancing age. Some extra- and/or intra-ovarian factors may also negatively affect oocyte quality and embryonic development potential and thus result in unsuccessful pregnancy outcomes in patients with PCOS.

Study design, size, duration: To study the effect of age on pregnancy outcomes of in vitro fertilization and embryo transfer (IVF-ET) in patients with polycystic ovary syndrome (PCOS). A retrospective cohort study involving 3502 patients with PCOS and 18596 age-matched patients with tubal factor infertility who had undergone their first attempted IVF-ET between January 2010 and July 2015.

Participants/materials, setting, methods: Among the 22098 patients, 3502 were diagnosed with PCOS, and the remaining 18596 were diagnosed with infertility due to tubal factors. The diagnosis of PCOS was based on the Rotterdam criteria. Women in the non-PCOS group exhibited normal menstrual cycles and ovulation and had no evidence of polycystic morphology. SPSS 17.0 (IBM) was used for statistical analyses.

Main results and the role of chance: In both the PCOS and non-PCOS groups, the clinical pregnancy rate and live-birth rate were consistently more favorable in younger than in older women. In the control group, both the clinical pregnancy rate and live-birth rate showed a sharp decline with age (20 to 50 years), while in the PCOS group, the decline in the clinical pregnancy rate and live-birth rate with age (20 to 50 years) was relatively slow. For women over 35 years old, the PCOS group showed a higher implantation rate, clinical pregnancy rate, and live-birth rate than the age-matched control group.

Limitations, reasons for caution: Only a relatively small number of patients at an advanced age were included, especially in the group of older PCOS women. We cannot exclude that the different treatment outcomes between the younger and older patients are the result of this limited sample size.

Wider implications of the findings: PCOS patients manifest a significant but slow decline in fecundity associated with IVF. An advantage in fecundity can be expected in PCOS women of an older age, while early pregnancy loss still cannot be ignored in this period.

Trial registration number: not applicable

P-634 Randomised controlled trial of connected ovulation test system demonstrates double the chances of pregnancy in first cycle and reveal other factors affecting pregnancy likelihood.

S. Johnson[1], G. Warren[2], S. Bond[1], S. Bench-capon[1]

[1]SPD Development Company Ltd, Clinical Affairs, Bedford, United Kingdom

[2]SPD Development Company Ltd, Statistics and Datamanagement, Bedford, United Kingdom

Study question: Does using an ovulation predictor test connected to an App increase chances of pregnancy, and what other factors are related to likelihood of natural conception?

Summary answer: The test arm (connected ovulation test system) had double the odds of conception compared to the control arm (no ovulation test) in first cycle.

What is known already: Natural conception requires intercourse during the fertile period of the cycle, and this period can be conveniently identified using ovulation tests. Most ovulation tests measure only luteinising hormone, so detect the day before and day of ovulation. However, intercourse the day before the LH surge is associated with highest likelihood of pregnancy. Monitoring of estrogen enables identification of the wider fertile phase; indeed the only randomised controlled study on ovulation tests considered a fertility monitor, which found an 89% increased chance of pregnancy. Apps are now very popular, but calendar based Apps provide inaccurate information on fertile phase prediction.

Study design, size, duration: Randomised, controlled study of 844 volunteers seeking to conceive. Volunteers were randomized 1:1 into the test or control arm. Randomization was stratified by the age of the volunteers, with two cohorts (<35 and ≥35 years of age). Volunteers participated for two full cycles if pregnancy was not achieved. Volunteers conducted digital pregnancy tests (Clearblue), collected urine samples (hCG measurement, AutoDELFIA, Perking Elmer), and a diary of menses to determine pregnancy status.

Participants/materials, setting, methods: Home based study of women between the age of 18–40 years. Test group used the Clearblue Connected Ovulation Test System, which measures lutenising hormone and estrogen to detect the wider fertile window, and results are synced to an App. The control group were instructed not to use ovulation tests. Both groups were able to use other methods to time intercourse. Admission questionnaires collected demographics, and post study questionnaires examined behaviour during the study.

Main results and the role of chance: More women became pregnant after one cycle using the test system (25.4%) compared to the control group (14.7%; $P<0.001$), with an odds ratio of 2.0. After two cycles pregnancy rate was still higher in the test group (36.2% vs 28.6%; $P=0.026$), with an odds ratio of 1.4. The test group reported less frequent intercourse per cycle compared to controls (9 vs 10; $P=0.027$), however, the test group did report greater targeting of intercourse (88.5% vs 57.8%; $P<0.001$). The control group indicated they had used methods, most commonly Apps (40.0%) and cervical mucus (35.2%). Neither, use of a non-study App or cervical mucus monitoring was associated with a higher pregnancy rate.

Other factors related to likelihood of pregnancy were folic acid use (p=0.004), average cycle length (p=0.021) and intercourse/month (p=<0.0001). The odds ratio for pregnancy was 2.0 for folic acid users vs non-users. This is likely to be a non-causative observation, linked to overall healthy lifestyle and higher fertility knowledge. Shorter (≤25 days) cycles had lower conception probability. Interestingly, the higher number of intercourse acts, the lower the likelihood of conception; odds ratio for pregnancy 5.9 for ≤5 acts, 4.0 for 6-10, 2.6 for 11-15 and 1.0 for 16-20 vs >20 acts.

Limitations, reasons for caution: An exclusion criteria was trying to conceive for >6months, because a considerably higher sample size would have been required due to low conception rates in this group. Therefore, findings may not extrapolate to those who have been trying for a long period of time.

Wider implications of the findings: With women delaying pregnancy and desiring control over their future, tools demonstrated to help conception, such as the Clearblue Connected Ovulation Test System, are of great relevance today. High levels of intercourse without conception probably indicates infertility, so could be used to guide couples for infertility investigation.

Trial registration number: NCT03424590

P-635 No increased risk of adverse perinatal outcomes in singleton pregnancy of polycystic ovary syndrome(PCOS): a propensity score matching study

S. Xu[1], G. Yihong[1]

[1]The First Affiliated Hospital of Zhengzhou University, Reproductive Medicine Center, Zhengzhou, China

Study question: To evaluate the effect of the PCOS on the pregnancy complications compared with control cases of women undergoing IVF or ICSI.

Summary answer: Women with PCOS have a higher incidence of pregnancy complications in twin pregnancies and a lower incidence of pregnancy complications in singleton pregnancies than non-PCOS.

What is known already: PCOS is an endocrine disorder and accounts for 18-25% of infertility cases. Many women with PCOS pregnancies through IVF or ICSI, which may increase the risk for multiple pregnancies.To evaluate the effect of the PCOS on the pregnancy and perinatal complications of singleton and twin births compared with control cases of women undergoing IVF or ICSI.

Study design, size, duration: We did a retrospective cohort study of the data using propensity score-matching, which included of data of 8066 deliveries in women conceived after their first fresh IVF/ICSI from January 1, 2009 to December 31, 2016.

Participants/materials, setting, methods: The 8066 women were divided into four groups in accordance with the number of fetuses delivered and the diagnosis: group A (277 PCOS women with twin pregnancy), group B (2038 non-PCOS women with twin pregnancy), group C (687 PCOS women with singleton pregnancy), and group D (5064 non-PCOS women with singleton pregnancy).

Main results and the role of chance: After propensity score matching, the risks of gestational diabetes mellitus, preterm birth, and small for gestational age were comparable between the PCOS and control groups for both singleton and twin births. Nevertheless, in the twin pregnancy group, women with PCOS had higher risks for hypertensive disorders of pregnancy (odds ratio [OR] 3.17, 95% confidence interval [CI]: 1.33-7.60, P=0.010) and preterm premature rupture of membranes (OR 4.70, 95% CI: 1.90-11.62, P=0.001) than the control subjects. In the singleton pregnancy group, women with PCOS had lower risks for cesarean section (OR 0.58, 95% CI: 0.43-0.77, P<0.001) and iatrogenic preterm birth (OR 0.39, 95% CI: 0.19-0.80, P=0.010) than the control subjects.

Limitations, reasons for caution: Because of the design of our study, we cannot explain the mechanism behind these phenomena. Due to individual differences between PCOS cases, we did not analyze them according to PCOS phenotypes, although we did enroll cases with various phenotypes.

Wider implications of the findings: Additional monitoring and attention to singleton births from women with PCOS after ART is unnecessary; however, twin births in women with PCOS need to be more closely watched and monitored than those in women without PCOS. Therefore, singleton pregnancies should be recommended to women with PCOS undergoing IVF/ICSI.

Trial registration number: Not applicable

P-636 Follitropin delta for controlled ovarian stimulation: a one-year analysis

N. Holtmann[1], P. Edimiris[1], J. Hirchenhain[1], J.S. Kruessel[1], A.P. Bielfeld[1]

[1]Medical Center University of Duesseldorf, Department of OB/GYN and REI UniKiD, Duesseldorf, Germany

Study question: How is the ovarian response and the clinical pregnancy rate (CPR) of an individualized controlled ovarian stimulation (COS) with follitropin delta in the daily clinical routine?

Summary answer: The mean number of oocytes retrieved was 11. In fresh embryo transfer (ET) cycles the CPR was 35.7 % with 1.18 embryos being transferred.

What is known already: Follitropin delta, a new human recombinant follicle-stimulating hormone (rFSH), was introduced for controlled ovarian stimulation (COS) in 2015 and shown to be non-inferior to a COS with conventional rFSH by the randomized, multicentre ESTHER-1 trial. The unique glycosylation pattern of follitropin delta leads to a higher level of sialylation with more acidic isoforms, displaying a higher exposure and pharmacodynamic response. According to the patient's body weight and antimüllerian hormone (AMH) level, an individualized dosing regimen is calculated to aim for an optimal ovarian response (8-14 oocytes) with a minimized risk for an ovarian hyperstimulation syndrome (OHSS).

Study design, size, duration: Single centre cohort study with 98 patients who underwent COS with follitropin delta for in-vitro fertilization (IVF)/intracytoplasmic sperm injection (ICSI) cycles at the reproductive unit UniKiD of the women's university hospital in Duesseldorf. The study period comprises 1st of August 2017 to 31st of August 2018.

Participants/materials, setting, methods: Patients undergoing COS with follitropin delta at the women's university hospital in Duesseldorf. The primary endpoint was clinical pregnancy rate (CPR). Cycle characteristics, mean number of oocytes retrieved and cases of OHSS were also analysed.

Main results and the role of chance: 89 patients were included in the analysis (mean age: 34.3 years, mean weight: 65.3 kg). The mean duration of stimulation was 10.4 days (range: 6-22 days) with a mean dose of follitropin delta of 81.8 µg (range: 45-181.2 µg) injected. The mean number of retrieved oocytes, metaphase II oocytes and two pronuclear zygotes was 11, 8 and 6, respectively. The time interval between the measurement of AMH and the start of COS did not show any impact on ovarian response. 64% of patients received a fresh ET with a single embryo transfer (SET) in 82.5%. Elective frozen embryo transfer (eFET) was performed in 27% of the cases to prevent an OHSS. Of the 24 cases receiving OHSS preventive measures, 2 presented an OHSS grade II and 2 an OHSS grade III. CPR was 35.7% in fresh ET cycles with a mean number of 1.18 embryos per transfer. In comparison the age-adjusted CPR in Germany for 2017 is 31.5% with 1.80 embryos per transfer.
Limitations, reasons for caution: Single centre descriptive study with an unselected patient group. Small sample size.
Wider implications of the findings: The present study confirms that individualized follitropin delta dosing is efficient and safe in the daily clinical routine. Furthermore, a comparable CPR is possible with a lower number of embryos transferred compared to the age-adjusted data of the German national registry.
Trial registration number: N/A

P-637 Modified natural cycle IVF versus conventional stimulation in advanced-age Bologna poor responders

J. Errazuriz[1,2], A. Romito[1,3], S. Santos-Ribeiro[1,4], B. Popovic-Todorovic[1], A. Racca[1], H. Tournaye[1], M. De Vos[5], C. Blockeel[5,6]

[3]*Sapienza University, Department of Ginecological-Obstetrical and Urological Sciences, Rome, Italy*
[4]*IVI-RMA Lisboa, center for Reproductive Medicine, lisboa, Portugal*
[5]*Avenue du Laerbeek 101- 1090 Jette, center for Reproductive Medicine- Universitair Ziekenhuis Brussel- Brussels- Belgium, Brussels, Belgium*
[6]*University of Zagreb-School of Medicine, Department of Obstetrics and Gynecology, Zagreb, Croatia*

Study question: Do reproductive outcomes differ between modified natural cycle (MNC) and conventional high-dose ovarian stimulation (HDOS) in advanced-age poor responders?
Summary answer: In advanced-age poor ovarian responders as defined by the Bologna criteria, MNC and HDOS appear to be equally effective.
What is known already: Poor ovarian response (POR) remains one of the main therapeutic challenges in women undergoing ovarian stimulation for in vitro-fertilization, associated with low live birth rates and high cancellation rates. Traditionally, the stimulation protocol in POR includes high doses of gonadotropins. MNCs with minimal stimulation have been proposed as an alternative for conventional ovarian stimulation and have become increasingly popular in this challenging population with POR. However, although MNCs have been shown to result in acceptable cumulative pregnancy rates in normal responders, evidence is sparse in POR and, more specifically, in women of advanced age.
Study design, size, duration: This is a retrospective cohort study including patients with POR attending a tertiary referral University Hospital from 1st January 2011 until 1st March 2017.
Participants/materials, setting, methods: All women who fulfilled the Bologna criteria for POR and aged ≥ 40 years who underwent their first intracytoplasmic sperm injection (ICSI) cycle in our center were included.
Main results and the role of chance: In total, 476 advanced-age Bologna poor responder patients were included in the study: 189 in the MNC group and 287 in the HDOS group. MNC resulted in significantly fewer oocytes (0.8 vs. 4.1; P <0.001), lower embryo transfer rates (45% vs. 75%; P <0.001) and lower top embryo quality rates (83% vs. 94%; P = 0.002) compared with HDOS. Biochemical (5.0% vs. 19.0%; P <0.001), clinical (4.8% vs. 17.4%; P <0.001) and ongoing pregnancy rates (OPR) (2.6% vs. 10.0%; P = 0.002) were significantly lower in the MNC group as compared with the HDOS group. Live birth was achieved in 3/189 (1.6%) MNC and in 23/287 (8.0%) HDOS cycles. However, multivariate logistic regression analysis for relevant confounders showed that the type of treatment strategy (HDOS or MNC) was not significantly associated with OPR (OR 0.6, 95% CI 0.2-2.07).
Limitations, reasons for caution: In spite of its large sample size, the main limitation is the retrospective design of our study, with an inherent risk of bias. OPR was selected as primary endpoint due to the low number of live births encountered in this population, which precluded the application of a valid statistical approach.
Wider implications of the findings: In advanced-age poor ovarian responders as defined by the Bologna criteria, MNC and HDOS appear to be equally effective. Since MNC is a more patient-friendly approach, this strategy emerges as a reasonable alternative in these poor prognosis patients, when they reject the option of oocyte donation.
Trial registration number: not applicable

P-638 A shorter duration of estrogen administration yields equivalent live birth rates in non-downregulated hormone replacement frozen thawed embryo transfer cycles

T.A. Boza[1], G.E. Aksakal[1], M. Ceyhan[1], S. Ertas[1], O. Bulduk[1], A. Isiklar[1], B. Balaban[1], B. Urman[1]
[1]*American Hospital, Womens' Health Centre- Assisted Reproduction Unit, Istanbul, Turkey*

Study question: Does a shorter duration of estradiol (E) exposure prior to progesterone (P) administration decrease live pregnancy rate (LBR) in frozen thawed embryo transfer (FTET) cycles?
Summary answer: Shorter E exposure does not significantly affect LBR in FTET cycles.
What is known already: There is a little consensus regarding the necessary minimal duration of E supplementation in FTET cycles. The usual practice is to administer E for 12-14 days prior to initiation of P.
Study design, size, duration: A retrospective cohort study was conducted in the American Hospital (Koc University affiliated private hospital) between October 2015 and October 2017. All FTET cycles with a single blastocyst transfer using artificial endometrial preparation without GnRH agonist pretreatment were included. Only G1 and G2 blastocysts had been cryopreserved. Women >43 years of age, treatment cycles with incomplete data and women who were lost to follow-up were excluded.
Participants/materials, setting, methods: All women received oral E treatment starting on day 2 of menstrual bleeding in a fixed dose of 6mg/day. The duration of E administration varied from 8 to 14 days due to concerns regarding embryo transfer scheduling. A total of 241 frozen thawed single blastocyst transfer cycles were analyzed according to the duration of E administration (Group 1: <12 days, n=105; Group 2: >12 days, n=136). The main measure outcome was LBR per transfer.
Main results and the role of chance: Among a total of 241 frozen thawed blastocyst transfers, E exposure prior to P supplementation was as follows: 8 days (3%), 9 days (8%), 10 days (16%), 11 days (16.5%), 12 days (22.5%), 13 days (20.5%), 14 days (13.5%). LBR was not significantly affected when the E treatment was administered for less than 12 days (OR=1.25; 95%CI [0.75-2.1], p=0.38). Mean endometrial thickness was similar among the groups (9.5mm). When Group 1 was sub-divided according to the duration of E treatment, early loss and clinical loss rates were likewise similar.
Limitations, reasons for caution: Retrospective design of the study may have inevitably resulted in bias that may affect the conclusions.
Wider implications of the findings: Shorter than the normally accepted duration of E administration yields similar live birth rates in FTET cycles, thus questioning the need to adhere strictly to an untested protocol.
Trial registration number: Not applicable

P-639 Live baby rate per oocyte with no stimulation

K. Kato[1], T. Abe[2], A. Yabuuchi[3], K. Ezoe[3], H. Skaletsky[4], J. Fukuda[1], S. Ueno[5], T. Kobayashi[1], S. Silber[6]
[1]*Kato Ladies Clinic, Department of Gynecology, Tokyo, Japan*
[2]*Shinjuku ART Clinic, Department of Gynecology, Tokyo, Japan*
[3]*Kato Ladies Clinic, R & D division, Tokyo, Japan*
[4]*Howard Hughes Medical Institute- Whitehead Institute, David C. Page Laboratory, Cambridge, U.S.A.*

[5]Kato Ladies Clinic, IVF Laboratory, Tokyo, Japan
[6]St. Luke's Hospital, Infertility Center of St. Louis, St. Louis, U.S.A.

Study question: What is the age adjusted intrinsic fertility rate of human oocytes with no stimulation or with only clomiphene citrate stimulation?
Summary answer: Live baby rate per oocyte with no stimulation is similar to that with minimal stimulation, is age dependent, and 4-5 times greater than with hyperstimulation.
What is known already: Ovarian hyperstimulation has been found to yield a live baby rate per oocyte of only about 4-6%. Thus on average more than 20 to 25 oocytes would be required to produce a single live baby. But this is in stimulated cycles. The live baby rate per oocyte in a natural cycle or a minimal stimulation cycle with single embryo transfer IVF would estimate better the intrinsic fertility of the human oocyte.
Study design, size, duration: 13,949 oocyte retrievals were performed in a natural cycle program with single embryo transfer in women from age 29 to 47 years, and 839 women (mean age: 38.4±0.1 y; 2,488 cycles) underwent clomiphene citrate only minimal stimulation cycle IVF (mini-IVF). Live birth rate per oocyte retrieved were retrospectively analyzed. The total live birth rate per oocyte was calculated and compared to what has been previously reported for controlled ovarian hyperstimulation (COH).
Participants/materials, setting, methods: In a private Japanese IVF center, infertile women underwent natural cycle with a single embryo transfer or clomiphene citrate only mini-IVF. The primary data of live baby rate per oocyte was approximated with a logistic curve r +1 (a+exp[b(t-c)]) where r is live baby rate per oocyte and t is age in years. The coefficients were evaluated using gradient method as implemented in statistical package R (version 3.2.5).
Main results and the role of chance: The fertility per oocyte was similar for both natural cycle and clomiphene citrate stimulation, and 4-5 times greater than reported for hyperstimulation. For women ≤42 years, the overall live baby rate per oocyte was 18%, which translated into only 5.5 oocytes needed to produce one baby. For women 42 years of age, every oocyte would have a 4% chance of becoming a baby, which means for a 42 year old woman it would require 22.7 rather than 5.5 eggs to produce a baby. The drop in intrinsic fertility per oocyte is summarized remarkably robustly in a logistic curve. There is at first a steady (almost horizontal) maintenance of fertility per oocyte (26%), followed after age 34 with a sharp linear decline until age 42 (4%), with a 10% loss of fertility every year. This decline slows down after age 43, with only 3% of original fertility remaining at age 45.
Limitations, reasons for caution: This is a retrospective study, and the hyperstimulation cohort is just from the reported literature. Also there is the inevitable likelihood of variation in treatment techniques by different physicians.
Wider implications of the findings: Overstimulating IVF patients may create extra expense and complications without improvement in success rate. Furthermore IVF of itself without any other factors, even in the absence of ovarian stimulation, can help infertile couples become successfully pregnant, possibly correcting problems of ovum pickup, sperm transport, tubal dysfunction, and even timing.
Trial registration number: None

P-640 Lipid Profiling of Endometrium at the Window of Implantation in Patients with Premature Progesterone Rise on the day of human chorionic gonadotrophin administration

J. Li[1], P. Chen[2], X. Liang[1]
[1]the Sixth Affiliated Hospital- Sun Yat-sen University, Reproductive Medicine Research Centre, Guangzhou, China
[2]the First Affiliated Hospital- Sun Yat-sen University, Department of Pharmacy, Guangzhou, China

Study question: Do patients with premature progesterone rise at the end of the follicular phase affect endometrial lipids metabolism at the window of implantation?
Summary answer: We found the lipid profiling alteration at the window of implantation in patients with high progesterone level (P ≥1.5) on the day of HCG administration.
What is known already: Premature progesterone rise in stimulated in vitro fertilization (IVF) / intracytoplasmic sperm injection (ICSI) cycles negatively affects the outcome of assisted reproductive techniques due to worsen endometrial-embryo asynchrony. But, there is still no study to investigate the effect of abnormally elevated progesterone level on endometrial lipid metabolism during the window of implantation.
Study design, size, duration: This was a retrospective cohort study with 43 patients undergoing IVF/ICSI by the reason of tubal factor or male factor in Center of Reproductive Medicine, the Sixth Affiliated Hospital, Sun Yat-sen University from 2014 to 2016.
Participants/materials, setting, methods: The endometrium tissues were obtained by pipelle biopsy 7 days after human chorionic gonadotropin (hCG) administration from the patients underwent GnRH-agonist long protocol or GnRH antagonist protocol and cancelled embryo transfer due to high estradiol level or lack of embryo. We evaluated lipidomics variation of endometrium by ultra high performance liquid chromatography coupled with electrospray ionization high-resolution mass spectrometry (UHPLC-ESI-HRMS).
Main results and the role of chance: The patients were divided into high progesterone group (15 patients) and control group (28 patients) on the day of hCG administration. There were no significant differences in age, BMI, basal FSH, LH and E2 level between the two groups. A total of 1026 ions were identified and 25 lipids were showed significantly up-regulated. The endometrium lipid profile of endometrium at the window of implantation was characterized by significant increase in concentration of phosphatidylcholine (PC), phosphatidylethanolamine (PE), lysophosphatidylcholine (LPC), diacylglycerol (DG), ceramide (Cer), phosphatidylinositol (PI), phosphatidylserine (PS) in patients with premature progesterone rise at the end of the follicular phase. The correlation analysis between P level with the lipids showed stronger negative correlation between PE(18:0p/18:1)+H with P level(r= -0.5235, P= 0.0003), PE(18:1p/18:1)-H with P level (r= -0.6060, P= 0.0006), PE(18:0p/18:1)-H with P level (r=-0.5003, P= 0.0006) and PS(16:0/19:0)-H with P level (r= -0.6340, P= 0.0063). In order to rule out the effects of confounding factors, we distinguished estrogen levels. We found the stronger negative correlation only between PS (16:0/19:0)-H with P level (r=-0.6527, P= 0.0083) and PE (18:1p/18:1)-H with P level (r= -0.5697, P= 0.0045).
Limitations, reasons for caution: Limitations include the retrospective design and small sample size in low estrogen patients on HCG day to exclude the effect of high level estrogen on lipids metabolism.
Wider implications of the findings: We investigated the lipid profiling alteration at the window of implantation in patients with premature progesterone rise for the first time. The alterations of lipids at the window of implantation suggest an adverse effect of elevated progesterone on endometrial receptivity. Our findings also provide potential targets for endometrial receptivity.
Trial registration number: N/A

P-641 improvement of ovarian function and oocyte quality by water-extracted perilla frutescens in aged female mice

K.S. Lee[1], S. Lee[2], J. Bang[2], J. Son[2], J. Choi[2], B. Joo[3]
[1]Pusan National University Hospital, Obstetrics and Gynecology, Busan, Korea- South
[2]Centumeroom Woman's Clinic, Obstetrics & Gynecology, Busan, Korea- South
[3]Pohang Women's Hospital, Obstetrics & Gynecology, Pohang, Korea- South

Study question: To investigate whether administration of water-extracted Perilla frutescens (PF) rescues ovarian function and oocyte quality in aged female mice
Summary answer: The beneficial effects of PF on ovarian function and oocyte quality may be attributed to the activation of ovarian angiogenesis and follicular development.
What is known already: Women of advanced reproductive age have a high risk of infertility. A recent study showed that water-extracted Perilla frutescens (PF) increases endometrial receptivity though leukemia inhibitory factor-dependent expression of integrins. In addition, PF has been well known to contain various chemical compounds, such as phenolic compound, flavonoid, and anthocyanin, which exhibited antioxidant properties. However, there are no reports on the effects of PF on ovarian function, oocyte quality, and oocyte development competency, especially for reproductive aged female.
Study design, size, duration: Study design is controlled experimental study.
Participants/materials, setting, methods: Female mice were treated orally with PF of 26.5mg/kg (n=7) and 53mg/kg (n=7) for 4 weeks. The control group (n=7) was treated with normal saline. Ovaries and serum were collected for the H&E stain and the evaluation of ROS levels. After another 21 female mice were

administered with PF, followed by mated with male. Zygotes were retrieved and cultured for 4 days. Ovaries were provided for examination of expressions of target genes.

Main results and the role of chance: PF significantly increased numbers of surviving follicles (primary, secondary, and antral), numbers of zygotes retrieved, embryo development rate, and ovarian expression of VEGF, visfatin, cKit, BMP-15, and GDF-9 at both doses. However, ovarian expression of Sirt1 and Sirt2 was increased at PF of 53mg/kg. Serum ROS levels were not affected by PF.

Limitations, reasons for caution: This study experimented on 8-monthold mice. This age may be around 40 years of age in humans considering the sexual maturity. Therefore, it is necessary to investigate whether PF improves ovarian function, oocyte quality and further fertility in older mice aged corresponding to around 50s of women.

Wider implications of the findings: The beneficial effects of PF may be attributed to the activation of ovarian angiogenesis and early follicular development, but may not associated with the reduction of agerelated increase in oxidative stress and anti-aging events. This study can be implicated to aging related infertility.

Trial registration number: not applicable

P-642 Accumulation of advanced glycation end products in follicles is associated with poor oocyte quality: inducing inflammation in granulosa cells via activation of unfolded protein response

M. Harada[1], N. Takahashi[1], J. Azhary[1], C. Kunitomi[1], E. Nose[1], H. Terao[1], O. Wada-Hiraike[1], Y. Hirota[1], T. Fujii[1], Y. Osuga[1]

[1]Faculty of Medicine- University of Tokyo, Dept. of Obstetrics and Gynecology, Tokyo, Japan

Study question: Does advanced glycation end products (AGE) accumulated in follicles induce inflammation via unfolded protein response activation in granulosa cells (GCs) and thus affect oocyte quality?

Summary answer: Follicles containing poor-quality oocyte showed higher free AGE levels, and AGE stimulated interleukin-6 and 8 production in GCs via activation of activating transcription factor 4.

What is known already: The levels of soluble receptor for AGE (sRAGE), that antagonizes the deleterious effects of AGE, in serum and follicular fluid serve as positive predictive markers of the number of oocytes retrieved in IVF. The accumulation of AGE is reported in GCs of women in their late reproductive age and of PCOS patients. The close relationship between AGE, proinflammatory cytokine production, and induction of endoplasmic reticulum (ER) stress is observed in various pathologies, including atherosclerosis and osteoarthritis. ER stress activates a group of signal transduction cascades termed unfolded protein response (UPR), which includes activating transcription factor 4 (ATF4).

Study design, size, duration: AGE and sRAGE concentrations in follicular fluid were examined in 42 follicles of 21 patients (37.1 ± 5.1 years old, average ± S.D.) who underwent ICSI treatment for male factor infertility. AGE and sRAGE concentrations in each follicle were analyzed according to the quality of enclosed oocyte, namely, whether the oocyte yielded poor or good-quality embryo. For *in vitro* experiments, human granulosa-lutein cells (GLCs) were obtained from pooled follicular fluids from patients undergoing oocyte retrieval.

Participants/materials, setting, methods: The concentrations of AGE and sRAGE were examined by ELISA and quality of embryos was retrospectively reviewed in medical charts. Human GLCs were incubated with AGE for 24 or 48 hours, while GLCs were transfected with siRNA prior to the treatment with AGE to examine the intermediary role of ATF4. Interleukin (IL)-6, IL-8, and ATF4 mRNA expression was examined by quantitative RT-PCR. Protein secretion of IL-6 and IL-8 in the supernatant was examined by ELISA.

Main results and the role of chance: The levels of AGE in follicular fluid were increased with a marginal significance in follicles with poor-quality oocytes, compared with those with good-quality oocytes (9.32 ± 1.47 μg/mL vs 5.97 ± 1.81 μg/mL, average ± SEM; p=0.0852), while there was no significant difference in the levels of sRAGE, a decoy receptor for AGE, between the two groups (3.65 ± 0.34 μg/mL vs 4.21 ± 0.38 μg/mL; p=0.1573). The resultant AGE/sRAGE ratios, which indicate the intrafollicular level of free AGE that can bind to membranous receptor for AGE (RAGE) and activate intracellular signaling cascades, were significantly higher in follicles with poor-quality oocytes, compared with those with good-quality oocytes (2.65 ± 0.39 vs 1.36 ± 0.36; p=0.0166). Treatment of cultured human GLCs with AGE increased ATF4, IL-6 and IL-8 mRNA expression in a dose-dependent manner. Knockdown of ATF4 abrogated the stimulatory effects of AGE on mRNA expression and protein secretion of IL-6 and IL-8. AGE stimulated the production of inflammatory cytokines including IL-6 and IL-8 in cultured human GLCs via activation of ER stress, especially the UPR branch of ATF4.

Limitations, reasons for caution: Small sample size for the evaluation of AGE and sRAGE concentrations in follicular fluids is a limitation of this study. The direct effect of increased production of IL-6 and IL-8 by granulosa cells, stimulated by AGE, on oocyte quality was not examined in the present study.

Wider implications of the findings: AGE in follicles affects oocyte quality by inducing inflammation in follicular microenvironment via activation of ER stress in granulosa cells. Administration of RAGE antagonists and/or ER stress inhibitors could improve embryo quality in patients with high ovarian AGE, including those in their late reproductive age and PCOS patients.

Trial registration number: not applicable

P-643 rescue of age-related decline in fertilty of female mice aged 18 months by visfatin

J.I. Bang[1], S.J. Lee[1], J.B. Son[1], J.R. Choi[1], B.K. Park[2], J.K. Joo[3], K.S. Lee[3]

[1]Centum Eroom Women's Clinic, obstetrics and gynecology, Buasn, Korea- South
[2]Hyosung Hospital, obstetrics and gynecology, Daegu, Korea- South
[3]Pusan national university hospital, obstetrics and gynecology, Busan, Korea- South

Study question: This study investigated whether visfatin stimulates the mTOR/PI3K and Hippo signaling pathways associated with the activation of primordial follicles and OGSCs and rescues age-related decline in fertility in mice.

Summary answer: The present study shows that administration of visfatin improves ovarian function and fertility potential at different doses in female mice aged 12 and 18 months.

What is known already: Visfatin activates migration, invasion, and tube formation in human umbilical vein endothelial cells (HUVECs). Moreover, visfatin evokes activation of the extracellular signal-regulated kinase 1/2 (ERK1/2) in endothelial cells, which is closely linked to angiogenesis. Inhibition of ERK activation markedly decreases visfatin-induced tube formation of HUVECs and visfatin-stimulated endothelial cell sprouting from rat aortic rings.

Study design, size, duration: age-course (C57BL/6 female mice aged 12 and 18 months),

control versus treatment (intraperitoneally injected with 0.1 ml of 500 ng/ml or 1,000 ng/ml of rmVisfatin for three times at intervals of two days),

Participants/materials, setting, methods: C57BL/6 female mice aged 12 and 18 months were intraperitoneally injected with 0.1 ml of 500 ng/ml or 1,000 ng/ml of rmVisfatin for three times at intervals of two days. The mice were superovulated with 5 IU PMSG and 5 IU hCG injection 48 hours later. Zygotes were cultured for 4 days after mated with male. Then, we analyzed the expression of 4EBP1, S6K1, RPS6, MST!, OCT4, VEGF, visfatin and SDF1a in ovaries by RT-PCR.

Main results and the role of chance: In both ages, visfatin treatment significantly increased the number of zygotes retrieved and embryo development rate to blastocyst and finally improved fertility potential compared to the control at different doses depending on age ($P < 0.05$). Visfatin increased ovarian expression of S6K1, RPS6, MST1, VEGF, visfatin, and SDF-1α just in mice aged 18 months, but not in mice aged 12 months. There was no difference in ovarian expression of Oct4 in both age groups.

Limitations, reasons for caution: The limitation of this study is the 12 and 18 months aged C57BL6 mice in vitro.

Wider implications of the findings: The present study shows that visfatin increases ovarian expression of molecules associated with angiogenesis as well as the mTOR/PI3K and the Hippo signaling pathways at the same dose that enhanced ovarian function and fertility in mice aged 18 months, but not in mice aged 12 months.

Trial registration number: Not applicable

P-644 Self-detection of the endogenous LH surge using urine testing as a simple and efficient confirmation of successful GnRH agonist trigger in IVF.

J.A. Garcia-Velasco[1], S. Matey[1], A. Alvarez[1], M. Toribio[1], V. Lopez[1], M. Perona[1], E. Henzenn[1], M. Piro[1], P. Humaidan[2]
[1]IVI RMA Madrid, Reproductive Endocrinology and Infertility, Madrid, Spain
[2]Aarhus University, Fertility Clinic, Skive, Denmark

Study question: How can we ascertain that an endogenous LH surge was efficiently induced by a GnRH agonist (GnRHa) trigger in order to avoid oocyte retrieval failure?
Summary answer: Urine LH testing performed at home by the patient is a simple, cheap, and efficient way to confirm the efficacy of a GnRHa trigger.
What is known already: Since GnRHa trigger was introduced in daily practice, questions have arisen about how to detect involuntary errors in the administration of the medication or patient compliance, particularly in oocyte donors. When hCG is used as a trigger, a urine pregnancy test can easily detect if hCG was administered or not. As for GnRHa trigger no recommendations exist, however, some clinics advocate LH testing in blood the morning after the trigger. From a practical point of view this is inconvenient for the patient/donor as she needs to visit the center again.
Study design, size, duration: Prospective cohort study including a total of 371 oocyte donors from May 2017 till November 2018, and approved by our IRB (1701-MAD-006-JG). Urine LH testing was performed at home, using the same test (Ruedafarma, Spain, sensibility 25 mIU/mL) and urines from the first micturition in the morning after the GnRHa trigger. Donors had to send a picture of the LH test outcome to the nurse by WhatsApp as soon as the test was performed.
Participants/materials, setting, methods: A total of 371 oocyte donors were included in the study. A single dose of 0.2 mg GnRHa (Decapeptyl 0.1 daily, Ipsen Pharma, Spain) was administered to trigger final oocyte maturation when at least three follicles reached a mean diameter of 17 mm. The nurse instructed the donor to self-administer the GnRHa at night according to the time of retrieval, and to perform the urine LH test next morning with first micturition.
Main results and the role of chance: Of a total of 371 donors included in the study, 12 forgot to perform it, leaving a total of 359 oocyte donors and oocyte retrievals for analysis. A total of 355 donors had (98.88%) positive LH testing and an uneventful oocyte retrieval with good retrieval rates. One test was positive, however, no oocytes were retrieved (false positive rate 0.28%). A total of three tests were negative (false negative rate 0.85%). In one of these cases, LH was tested in serum and values confirmed an LH rise consistent with a GnRHa trigger. In two cases, the pickup was rescheduled after hCG trigger and a good number of mature oocytes were retrieved.
Limitations, reasons for caution: Failure to respond to a GnRHa trigger in terms of an adequate LH rise is a relatively rare phenomenon, and a future larger sample size is needed to confirm the findings of this study.
Wider implications of the findings: This new approach of LH surge self-testing in urine and communication via a picture provides a simple and cheap method to confirm that LH rise was induced by a GnRHa trigger. It may help to detect errors in the administration, improving patient compliance and minimizing failure to retrieve oocytes.
Trial registration number: not applicable

P-645 Endometrial fluid aspiration with diosmin intake in ART cycles: A randomized controlled trial

A.S. Saad[1], K. Mohammed[2], S. Eissa[3], W. Abdelhaleem[1]
[1]benha university- hawaa fertility center, Obstetrics & Gynecology department, Benha, Egypt
[2]Banha University, obstetrics & gynecology, banha, Egypt
[3]benha university- hawaa fertility center, IVF lab, Benha, Egypt

Study question: To evaluate the effect of aspiration & diosmin intake where endometrial fluid is present at ovum pick up in ART cycles.
Summary answer: Endometrial fluid was decreased in cases where aspiration & diosmin was given with increased chance of fresh embryo transfer and without affecting the pregnancy rate.
What is known already: Endometrial fluid accumulation in controlled ovarian stimulation occurred in 2.9% - 8.2% of ART cycles. When present without hydrosalpinx, the mechanism is not well understood. Theories include: over response of the endometrium to gonadotropin therapy, subclinical endometrial infection & obstruction of the cervical canal with the hCG administration.
Diosmin was widely used for the treatment of varicose veins & pelvic congestion syndrome. It causes a reduction in plasma levels of endothelial adhesion molecules, neutrophil activation, inflammatory mediators, such as prostaglandin E2 (PGE2) and thromboxane A2 (TxA2). Thus, providing protection against microcirculatory damage.
Study design, size, duration: This was a prospective randomized single blinded controlled trial in 100 cases presented with endometrial fluid at the day of ovum pickup in their ART cycles from 2014-2018.
Participants/materials, setting, methods: The study was conducted at a private fertility center. Cases were divided into 2 groups. Group 1 (50 cases): conservative management with follow up by ultrasound at day 5. Group 2 (50 cases): aspiration of the fluid was done by an intrauterine insemination catheter then the cases were given diosmin 500 mg thrice daily till day 5. In both groups, fresh embryo transfer was conducted if fluid resolution occurred or freeze-all policy if still present.
Main results and the role of chance: Our main outcome was the presence of endometrial fluid at Day 5 embryo transfer. It persisted in 31 case in group1 (conservative management) versus 2 cases in group 2 (aspiration+diosmin) with a highly significant difference (P value < 0.0001). All the cases where endometrial fluid persisted at Day 5, underwent freeze-all policy. If no endometrial fluid was detected at Day 5, fresh embryo transfer was done. That included 19 cases in group1 versus 48 cases in group 2. Clinical pregnancy was detected in 10 cases in group 1 versus 23 cases in group 2 (52.63% vs 47.92%). The difference was not statistically significant between both group s (p value= 0.73).
Limitations, reasons for caution: 1- Single blind, not double blind study.
2- The number of cases is small.
Wider implications of the findings: Aspiration of endometrial fluid & diosmin have a role in decreasing the presence of endometrial fluid. However, this was a pilot study on a small number of cases due to the low incidence of the condition. A wider application on a bigger sample size is warranted.
Trial registration number: NCT02158000

P-646 The pretreatment with collagenase before vitrification improves the ovarian reserve due to the maintenance of the cell-cell attachments with oocyte and granulosa cells

T. Kawai[1], M. Shimada[1]
[1]Hiroshima university, Graduate School of Biosphere Science, higashi-hiroshima, Japan

Study question: Why is the ovarian reserve decreased in the frozen-thawed ovary? How are ovarian functions kept after vitrification?
Summary answer: The cell-cell adhesion in ovary was broken by the high-osmotic solution. The pretreatment with collagenase kept the communications in the vitrificated ovary.
What is known already: The auto-transplantation of cryopreserved ovary is used for fertility preservation of women before anti-cancer chemotherapy. The slow-freezing method is commonly used for ovarian cryopreservation and the vitrification is also adapted. More than 100 live births were achieved after transplantation of cryopreserved human ovarian tissue. However, most of the developed follicles induced atresia when the frozen-thawed ovary was cultured or transplanted. The ovarian reserve judged by the circular AMH level was much lower when frozen-thawed ovary was transplanted as compared with the transplanted fresh ovary. Thus, the method of ovarian cryopreservation has been insufficient to become the general medical.
Study design, size, duration: To examine the influence of vitrification treatment on the ovarian morphology, the mouse ovaries were exposed to hyper-osmotic vitrification solution and were made for paraffin sections. To loosen the tight connections between ovarian stroma and follicles, ovaries were treated with the different dose of collagenase before vitrification procedure. After ovarian replacement-transplantation were done to adult female mouse,

the estrus cycle, the reproductive performance and the circular level of AMH were analyzed up to 6 months.

Participants/materials, setting, methods: The vitrification of mouse ovaries was performed using Ova Cryo Kit. The morphology was observed by HE staining and the localization of cadherin was detected by immunofluorescence staining. After transplantation of frozen-thawed ovaries, the estrus cycle was observed by vaginal smear test. To evaluate the reproductive performance, the female mice in which ovarian transplantation was done were mated with male mice. The circular level of AMH was analyzed by mouse AMH ELISA kit.

Main results and the role of chance: The space between oocyte and granulosa cells was observed in secondary follicle and antral follicles of ovaries exposed to hyperosmotic vitrification solution. The space was disappeared in frozen-thawed ovaries under the isotonic condition. However, the positive signals of anti-pan cadherin antibody were not detected between them, suggesting that the cell-cell adhesions were broken during the vitrification process. To relax the follicles from ovarian stroma, especially collagen-rich membrane, ovaries were treated with different doses of collagenase. When ovaries were treated with 10 μg/ml of collagenase for 5 min, the collagen-rich membranes were disappeared in stroma. The treated ovaries were exposed to hyperosmotic vitrification solution and then moved to liquid nitrogen. The frozen-thawed ovaries were transplanted to the receipient adult female mouse. The estrus cycles were recovered at 8 days after transplantation of frozen-thawed ovaries that were pretreated with collagenase, and the period was 4 days earlier than the frozen-thawed ovaries without the collagenase pretreatment. Furthermore, the circular levels of AMH at 6 months after transplantation of frozen-thawed collagenase pretreated ovaries were similar to those in same age mice without the ovarian transplantation. The average numbers of pups for 6 months were significantly increased by the collagenase treatment.

Limitations, reasons for caution: Because the characteristics of ovarian stroma were different among species, it is necessary to find the optimal condition of collagenase pretreatment in each animal species.

Wider implications of the findings: The cell-cell adhesions between oocyte and granulosa cells were disrupted by the vitrification procedure in ovary. The different shrink speeds between oocyte and follicular somatic cells would be induced by the connection with ovarian stroma, which might be a possible reason for the disruption.

Trial registration number: not applicable

P-647 Interleukin-34(IL-34) and macrophage colony-stimulating factor(M-CSF) regulates macrophage colony-stimulating factor receptor(M-CSFR) and natriuretic peptide receptor2(NPR2) in human Granulosa Cells : potentially serving a role in ovulation

C.H. Won Yun[1], E. JinHee[1], K. SoYoung[1], K. SoJung[1], B. SoYoung[1], K. MinJung[1], L. JinIl[1], C. EunMi[1], L. WooSik[1]

[1]CHA Hospital- Infertility Medical Centre, Infertility Medical Center, Seoul, Korea-South

Study question: Do IL-34 and M-CSF form a novel heteromeric cytokine and regulate the M-CSFR and NPR2 signaling in human granulose cells?

Summary answer: IL-34 and M-CSF regulate signal transduction associated with M-CSFR and NFR2 in human GC, which can affect the ovulation process.

What is known already: M-CSF, a hemopoietic growth factor with classic function of controlling the proliferation and differentiation of macrophages, has recently been shown to involve oocyte maturation and ovulation. It has been clear that action of M-CSF is exerted via a high-affinity transmembrane tyrosine kinase receptor(M-CSFR). M-CSF can modulate generation of natriuretic peptide precursor type C(NPPC). NPPC and its receptor(NPR2) have been assumed to be involved in female reproduction and have recently been shown to play an essential role in maintaining meiotic arrest of oocytes. IL-34, recently recognized as another ligand for M-CSFR, is a cytokine identified as protein present in human tissues.

Study design, size, duration: In a previous study, we found that the M-CSFR gene expressed in the GC of IVF patients was associated with a clinical outcome. It was also confirmed that M-CSF is involved in the expression of MCSFR and NPR2 genes. In this study, we tried to confirm whether IL-34 could play the same role as M-CSF. Compared to M-CSF, IL-34 facilitates phosphorylation of M-CSFR.

Participants/materials, setting, methods: We investigated expression levels of M-CSFR genes in luteinized GCs(210 IVF patients). M-CSFR expression patterns were divided into two groups and their results were compared with clinical outcome. To determine the effect of M-CSF and IL-34 on GC during folliculogenesis, GC was cultured in the culture medium containing rhM-CSF and rhIL-34(GC from 30 IVF patients). Cell proliferation was assessed by MTT assay and the expression of M-CSFR and NPR2 mRNA were analyzed by RT-PCR.

Main results and the role of chance: Expression of M-CSFR gene in GC obtained from 210 IVF patients was confirmed by RT-PCR. We compared the clinical outcome with two groups according to the presence or absence of M-CSFR gene expression. The pregnancy rate of the group in which M-CSFR was expressed was significantly higher than the group in which the M-CSFR was not expressed(72.7% ***vs.*** 17.12%). These groups were comparable with respect to patients' characteristics such as age of patients, infertility duration. GC culture was performed to confirm the effect of M-CSF and IL-34 on GC. In GC culture, 10 g/ml of rhM-CSF, rhIL34 and both were added to the culture medium. We determined the changes in expression of M-CSFR and NPR2 and proliferation of cell. The growth rate of GC cells grown in the medium supplemented with rhM-CSF, rhIL-34 and both was increased and M-CSFR gene expression was increased, while NPR2 gene expression was decreased($p<0.01$, respectively). We also examined the changes in GC according to Estrogen level; less than low-response, appropriate response and high-response group. Comparing three groups, we confirmed that the same change was not shown by the hormone response.

Limitations, reasons for caution: This experiment was carried out in human GC cultured in vitro. Unlike animal experiments, the use of human oocytes is limited. So we have not identified the outcome of oocyte maturation and did not know whether the same results would be obtained in vivo.

Wider implications of the findings: We confirmed that the expression of M-CSFR has positively correlation with IVF-ET pregnancy outcome. In rhM-CSF and rhIL-34, GC proliferation rate and M-CSFR expression were increased and NPR2 expression was decreased. Our study suggests that M-CSF and IL-34 influence folliculogenesis through direct action on GCs, also may regulate follicular development.

Trial registration number: Not applicable.

P-648 Do reproductive ageing and parity modulate the expression of VEGF/VEGFR2 and cell cycle control proteins?

G. Di Luigi[1], V. Di Nisio[2], G. Rossi[2], S. Antonouli[2], M.C. Budani[3], G.M. Tiboni[3], G. Macchiarelli[2], S. Cecconi[2]

[1]Hospital dell'Annunziata. Sulmona AQ PhD University of L'Aquila., Department of Obstetrics & Gynecology, Montorio al Vomano-Teramo, Italy

[2]University of L'Aquila, Department of Life- Health and Environmental Sciences, L'Aquila, Italy

[3]University "G. D'Annunzio", Department of Medicine and Aging Science, Chieti, Italy

Study question: Can age- and parity-dependent comparative analysis of VEGF/VEGFR2 and of cell cycle control proteins help to identify alterations predisposing to ovarian cancer onset?

Summary answer: Nulliparity and parity can differentially modulate expression levels of VEGF/VEGFR2 and of cyclin D1, cyclin E, Cdk4, Cdk2, cdc25A in an age-dependent manner.

What is known already: Ovarian cancer (OC) is the third most common gynecological cancer, characterized by tardive diagnosis and high mortality. Women's advanced age plays a role in OC onset, and older patients show higher risk of peritoneal metastasis in comparison to younger patients. Important risk factors are considered also infertility *per se* and nulliparity. In fact, this is supported by the observation that OC is more frequent in infertile or nulliparous women than in those with at least one child, a correlation confirmed by the extreme example of catholic nuns.

Study design, size, duration: To point out how parity can exert a protective effect against OC onset, expression levels of VEGF/VEGFR2 and of proteins controlling cell cycle progression (cyclin D1, cyclin E, Cdk4, Cdk2, cdc25A) were determined in both nulliparous (Virgins, V; n=40) and parous (Mothers,

M; n=40) mice aged up to reach late (L)- or post (P)-reproductive age. Each group, i.e. LM, LV, PM, PV, consisted of 20 mice.
Participants/materials, setting, methods: CD1 female mice 8 weeks-old were either kept unmated (V) or mated (M). After the 1 full-term pregnancy, M were kept alone. Animals were housed up to 40-42 weeks or 66-70 weeks, corresponding to late-reproductive or post-reproductive age, respectively. Ovaries were collected from 4 different groups: LM, LV, PM, PV mice. Expression levels of VEGF-A, VEGFR-2, Cyclin E1, cyclin D1, Cdk4, Cdk2, cdc25A were detected by Western blot. Experiments were repeated at least 4 times.
Main results and the role of chance: VEGF expression was similar in L ovaries (M vs V, P>0.05), but in older M mice it decreased to low/undetectable levels (PM vs PV, P<0.05). Although total VEGFR2 content was unchanged, phospho-receptor content decreased significantly only in PM mice (P<0.05). Cyclin D1 content decreased significantly in post-reproductive ovaries, especially in M ovaries (PV, PM vs LM, LV, P<0.05). Cdk4 level was always higher in V than M mice (LM, PM vs LV, PV, P<0.05). A 3-fold increase in cyclin E1 content was recorded in PV but not in PM ovaries, where it was undetectable (PV vs LM, LV, PM, P<0.05). Also Cdk2 expression decreased drastically in PM (LM, LV, PV vs PM, P<0.05). Cdc25a expression was not altered in all L ovaries (P>0.05), but in older ovaries a 1.5-fold increase was recorded in PV (L vs PV, P<0.05). The above results evidence that ovarian levels of VEGF/VEGFR2 and cell cycle control proteins are modulated in a parity-dependent manner, and that older parous M mice show the lowest contents of VEGF/VEGFR2, cyclins and Cdks. Therefore, parity should exert a protective role by down-regulating expression levels of proteins that are commonly altered in OC.
Limitations, reasons for caution: The study was performed in a mouse model, and the correlation with human should be considered. Results on protein expression levels should be confirmed with human ovaries, before being utilized as useful markers of alterations predisposing to OC onset.
Wider implications of the findings: This report suggest that parity can exert a protective effect not only on mammary gland but also on ovary. The differences here recorded could be part of a more complex mechanism that, at least in mice ovaries, is activated after the first pregnancy and maintained throughout whole life.
Trial registration number: None

P-649 A multicenter, randomized study comparing the efficacy of follitropin alpha biosimilar and the original follitropin alpha

M. Polzikov[1], Z. Barakhoeva[2], S. Yakovenko[2,3], M. Ovchinnikova[4], L. Vovk[5], Y. Fetisova[5]

[3]Lomonosov Moscow State University, Biophysics department, Moscow, Russia C.I.S.
[4]Hospital Lapino- Group of companies "Mother and Child", IVF department, Moscow region, Russia C.I.S.
[5]Perinatal Medical Centre PMC- Group of companies "Mother and Child", IVF department, Moscow, Russia C.I.S.

Study question: To investigate the therapeutic equivalence between a novel follitropin alpha biosimilar and the reference medication in women undergoing IVF.
Summary answer: This study demonstrated similar therapeutic equivalence and safety profiles between two follitropin solutions in women who underwent controlled ovarian hyperstimulation (COH) in GnRH-antagonist cycles.
What is known already: Biosimilars are not exact copies of the reference molecule due to the differences in genetic modifications of host cell lines and the manufacturing process. The manufacturer of biosimilars is required to conduct randomized pharmacokinetic/pharmacodynamic studies aiming to demonstrate that two medicines are equal at clinical level. The results of randomized, crossover, comparative study on the bioequivalence of follitropin alpha biosimilar indicated that a 300 IU single dose of biosimilar exhibits pharmacokinetic and safety profiles comparable to those of original follitropin in healthy young women.
Study design, size, duration: A multicenter, randomized (1:1), embryologist-blinded, parallel-group, therapeutic equivalence study of two solutions of follitropin alpha. All of the subjects underwent COH using a GnRH-antagonist protocol. Over the 5-day fixed-dose regimen, the women received 150 IU/day of follitropin, followed by dose adaptation. A study power of 80% at a significance level of α=0.05, clinical equivalence margin of ±3.4 oocytes, the required sample size was 55 subjects per group and 110 subjects in total (intention-to-treat [ITT] population).
Participants/materials, setting, methods: The inclusion criteria were: women aged 20-35 years old, established causes of infertility: tubal and/or male factors, first or second attempt at IVF/ICSI; 18 ≤ BMI ≤ 30 kg/m^2; FSH 10< IU/l and oestradiol level <50 pg/ml; AMH≥1.0 ng/ml. The exclusion criteria were: women with established contraindications to the use of ART methods; PCOS; endometriosis. Of 118 women screened, 110 were randomized into the trial. Demographic and clinical characteristics were comparable between the treatment groups.
Main results and the role of chance: The number of oocytes retrieved is the recommended primary endpoint as stated by European Medicinal Agency for the development of biosimilars containing follitropin. Similar numbers of oocytes were retrieved in both treated groups: 12.16±7.28 in the follitropin alpha biosimilar group and 11.62±6.29 in the reference group, with mean difference of 0.546±1.297 oocytes (95% confidence interval [CI]: -2.026, 3.116), p-value for equivalence of p=0.002 (ITT population). Additionally, no statistically significant differences were found for secondary endpoints: (1) in the number of follicles (≥16 mm) on the day of trigger injection 12.09±6.159 and 11.38±4.965 [95% CI: -1.405, 2.824], p=0.709; (2) in the number of MII oocytes 9.64±6.27 and 9.86±5.55 [95% CI: -2.455, 2.019], p=0.617; (3) and 2PN zygotes 8.13±6.61 and 8.76±5.85 [95% CI: -2.995, 1.723], p=0.445 (ITT population). The mean total follitropin doses (IU) per treatment cycle were 1532.7±267.2 and 1517.9± 255.2 [95% CI: -83.9, 113.6] (p=0.488), duration of treatment (days) 9.75±1.08 and 9.73±1.03 [95% CI: -0.379, 0.416] (p=0.629) were similar in both groups. Ovarian hyperstimulation syndrome was observed in subjects with a positive pregnancy test in 0% and 3.64% of cases and after triggering ovulation in 7.27% and 3.64% for the biosimilar and reference medication groups, respectively.
Limitations, reasons for caution: Normogonadotrophic patients enrolled in this study were representative, showing the ability of exogenous FSH to the stimulate development of multiple follicles in women without endocrine and ovarian disturbances during COH. Additional comparative studies are needed to confirm efficacy of follitropin alpha biosimilar in patients with other causes of infertility.
Wider implications of the findings: In this study, we demonstrated the therapeutic equivalence in terms of oocytes retrieved in women undergoing COH with a GnRH-antagonist cycle. Further post-authorization studies will be conducted to evaluate the efficacy of biosimilar in patients undergoing ART in GnRH-agonist cycles and with other causes of infertility: endometriosis, PCOS, poor response.
Trial registration number: ClinicalTrials.gov: NCT03088137. Date of registration: 2 March, 2017, retrospectively registered; conducted between 08.02.2017 and 17.08.2018.

P-650 Comparison between adjuvant 1500I.U. hCG + GnRH agonist on trigger day or 1500 I.U. hCG 35-36h later, in OHSS high-risk patient with peak E2 level<4000pg/mL

E. Petanovska Kostova[1]
[1]ReMedika-16ta Makedonska Brigada 18- 1000 Skopje- Macedonia, Gynecology and obstetric, Skopje, Macedonia

Study question: Study question is to compare the ongoing pregnancy and live birth rates between 1500IU.of hCG at the time of GnRH agonist triger day or 35-36h later on the OPU day.
Summary answer: Results suggest that adjuvant1500IU of hCG at the time of GnRH agonist trigger day significantly improve clinical pregnancy and live birth rates in high-risk patient.
What is known already: Ovarian hyperstimulation syndrome is serious complication of controlled ovarian hyperstimulation.The use of GnRH- a for final oocyte maturation in GnRH antagonist cycle significantly decrease the incidence of OHSS, but there have been studies showing lower pregnancy rates in patients triggered with GnRHa compared with hCG in autologous cycles.

The lower pregnancy rates after GnRH-a trigger have been attributed to a defective luteal phase. By providing intensive luteal-phase support satisfactory pregnancy rates can be sustained,but the probability of conception after GnRH-a trigger was significantly lower in patients with estradiol peak<4,000pg/mL despite intensive luteal phase support.

Study design, size, duration: This single center prospective study encompassed the period from March2016 to March 2018 year. The initial inclusion criteria were:women age ≥18 years and ≤35 years, with FSH <10mIU/mL, AMH≥4 ng/ml and have PCOSy/PCOM.All patients have ≥14 follicles and peak estradiol level <4000pg/ml, on trigger day. Patients with peak estradiol ≥4000pg/ml on trigger day, patients with significant risk for OHSS, where freeze all of oocytes or embryos were performed or OPU with no ET, were excluded.

Participants/materials, setting, methods: Total of 217patients were entered for final analysis, underwent antagonist protocol, ICSI and ET on 3th or 5th day.Patients were randomized in one of two groups:Group A- Dual trigger group -1500IU. of hCG at the time of GnRH agonist trigger day and Group B-1500IU. of HCG 35-36 h later, on the OPU day. For comparison of the groups we used nonparametric and parametric statistical tests .Significant differences were considered all values of $p < 0.05$

Main results and the role of chance: Both groups are homogenous regarding several variables: age, BMI, type of sterility, smoking status of man and women, previous IVF attempts, AMH, PCOSy / PCOM, normospermia, oligospermia and duration of COS. Peak estradiol level were significantly higher in group B(2851.3 vs 2262.9 pg/ml, p < 0,05), peak LH level were non significantly higher in group B(2,55 vs 2,17) on the trigger day. There is approximately to or no significant difference between the two(A vs B) groups according to average number of retrieved oocytes(13.08 vs 14.41 p < 0,08), M II oocytes(10.5 vs 10.95 p<0.47),GV(1.24 vs 1.52 p<0.09),fertility rate(68.46 % vs 64.04 % p<0,07).The dual trigger group(A) had a higher live birth rate(62,29 % vs 40,68%), and ongoing pregnancy rate(64,29% vs 45,76%) compared with GnRH-a trigger group(B). When the LH level on the day of trigger is≤1,0 IU/L the dual trigger group(A) had a significantly more MII oocytes(11,61 vs 9,95), higher fertility rate(66,75% vs 59,72%) ,significantly higher percentage of blastocyst transfer (74,49 % vs 54,24%) , higher live birth rate (60,00% vs 29,41%), and higher ongoing pregnancy rate(60,00% vs 35,29%) compared with GnRH-a trigger group(B). There were no cases of moderate or severe OHSS in both groups.

Limitations, reasons for caution: Our study should be further investigated.Prior to the dual trigger's routine implementation, further large prospective studies are needed.Dual trigger in GnRH antagonist protocols should be advocated as a safe approach but in undetected high risk patients reasons for caution is developing clinically significant OHSS.

Wider implications of the findings: Adjuvant low dose of hCG(1,500 IU) at the time of GnRH agonist trigger day improve clinical pregnancy and live birth rates in high responders with peak E2<4,000pg/mL without increasing the risk of clinically significant OHSS.Protocol of dual trigger and freezing all oocytes or embryos is promising technique in everyday practice.

Trial registration number: N/A

P-651 Quality Approaches in Adipose Tissue; Differences in Fatty Acid Profiles of Subcutaneous Adipose Tissue among Pregnant Women with PCOS and Non-PCOS

Study question: Are there differences between fatty acid (FA) profiles and desaturase indices in subcutaneous adipose tissue (AT) of PCOS and non-PCOS pregnant women?

Summary answer: Eicosapentaenoic acid (*EPA*; C20:5 n-3) were 10-times lower in AT of PCOS than non-PCOS. In contrast, monounsaturated FAs and desaturase indices were elevated in PCOS.

What is known already: Whereas the crucial roles of AT quantity were understood, little information exists on the quality of AT in PCOS. FA profiles of AT are established long-term biomarker for FA status, but AT samples are not easily available. Limited studies illustrated the association between FA profiles and gene expression in AT of non-PCOS women which warrants further studies for FA profiles in AT of PCOS. Moreover, the mother must meet her own needs as well as meeting the requirements of the developing infant by her AT supports and FA profiles imbalance in AT of PCOS mother may deal with infant's health.

Study design, size, duration: Following permission from the Royan Institute ethics committee and after written consent was obtained from all subjects, demographic data and abdominal subcutaneous AT samples were collected. The subjects were twenty-four age-matched and BMI-matched Iranian pregnant women underwent cesarean section (12 PCOS and 12 non–PCOS; age 31.8 ±1.1 and BMI at delivery day 30.5±1.5 kg/m^2). Intake of any medication affecting lipid metabolism and diabetic, alcoholic, smoking defined as exclusion criteria.

Participants/materials, setting, methods: At the time of cesarean section, three grams of AT were collected, washed, segmented, floated in liquid nitrogen and storage. Gas chromatography with a 100 meters capillary column was utilized to determine the concentration of FA. Data were initially tested for normal distribution using Kolmogorov-Smirnov test. Data with normal distribution were analyzed using *t* test. Data that did not have normal distribution were analyzed using Mann–Whitney U test. All analyses were conducted in SAS.

Main results and the role of chance: No significant differences were found with respect to age and BMI at delivery day. Total monounsaturated FA (MUFA), EPA, C18:1/C18:0 and C16:1/C16:0 index in subcutaneous AT were significantly different among experimental groups. Total MUFA and desaturase indices were significantly lower in non-PCOS than PCOS (P<0.05). In contrast, total n-3 FA in non-PCOS group was significantly higher than PCOS (1.11 *vs.* 0.97%; P<0.05). Interestingly, EPA (C20:5n3) percentage of non-PCOS was also much higher (10-fold) than observed in PCOS (0.10% *vs.* 0.01%, P<0.001). Saturated FA, unsaturated FA, odd chain FA, total n-6 FA, total poly unsaturated FA (PUFA), n-6/n-3 ratio and saturated: unsaturated ratio were similar in PCOS and non-PCOS groups. Palmitic acid (C16:0) was the most prevalent with 23 % and 21.7% for non-PCOS and PCOS, respectively that were similar among PCOS and non-PCOS. Unsaturated FA accounted for more half (68.6% of total fatty acids), the major being oleic acid (18:1 n-9 *cis*). Saturated: unsaturated ratio were 0.43 for non-PCOS and 0.40 for PCOS which they were unaltered in PCOS and non-PCOS groups. The mean composition of total PUFA also were present no significant differences between two groups (22.5 % and 20 % for non-PCOS and PCOS, respectively).

Limitations, reasons for caution: Although we collected 24 samples during one year, the small sample size is a limitation. Nevertheless, the strength of the observed differences in aged-matched and BMI-matched subjects suggests that power was not an important issue and that a larger study would be able to detect same findings.

Wider implications of the findings: Our study opens the road for exploration regarding FA and AT metabolism for PCOS. This is the first report for Iranian mother's FA profiles in AT and this attitude may improve the aspects of maternal nutrition in Iran.

Trial registration number: -

P-652 A novel nomogram for individualized gonadotropin starting dose in GnRH antagonist protocol: a prospective cohort study

Y. LI[1], Y. Duan[1], Y. Xu[1]

[1]*The First Hospital of Sun Yet-sen University, The Reprodutive Center, Guangzhou, China*

Study question: To develop a predictive nomogram for individualized gonadotropin starting dose in gonadotropin releasing hormone (GnRH) antagonist protocol.
Summary answer: We developed a clinically practical nomogram for prediction of appropriate gonadotropin starting dose.
What is known already: AMH, AFC and BMI are the most importent fact affect the outcome of the control ovarian stimulation. Starting dose is one of the most imprtant aspect in GnRH antaonist protocol.
Study design, size, duration: This is a single-center prospective cohort study between April 2018 and July 2018.A total of 198 women aged 20-45 years underwent in vitro fertilization/ intracytoplasmic sperm injection-embryo transfer (IVF/ICSI-ET) cycles.
Participants/materials, setting, methods: The women undergoing COS with a GnRH antagonist protocol at the Reproductivecenter of the First Affiliated Hospital of Sun Yat-sen University.

All patients received ovarian stimulation using GnRH antagonist protocol. Univariate and multivariate analysis were performed to identify predictive factors of ovarian sensitivity (OS). A nomogram for gonadotropin starting dose was developed based on the multivariate regression model. Validation was performed using concordance statistics and bootstrap resampling
Main results and the role of chance: A multivariate regression model based on serum anti-Müllerian hormone (AMH) level, antral follicle count (AFC), and body mass index (BMI) was developed and accounted for 59% of the variability of OS. An easy-to-use predictive nomogram for gonadotropin starting dose was established with excellent accuracy. The concordance index (C-index) of the nomogram was 0.833 (95%CI, 0.829-0.837). Internal validation using bootstrap resampling further showed the good performance of the nomogram.
Limitations, reasons for caution: If the patient's BMI is too higher such as more than 30, and the patient has FSH recepor mutation gene, the predictive nomogram may be not **accuracy. Because the** predictive nomogram was developed from normal BMI women(BMI less than 30).
Wider implications of the findings: In the antagonist protocol, it is estimated that using the predictive nomogram to determining the Gn starting dose could help to obtain a satisfactory number of eggs.

P-653 Natural estradiol in combined oral contraceptive has a favorable inflammation and lipid profile compared with preparation containing ethinyl estradiol– a randomized controlled trial

Abstract withdrawn by the authors

P-654 Impact of supraphysiologic estradiol serum levels on birth weight in singletons born after fresh embryo transfer

M. Ouazana[1], M. Bourdon[1], C. Maignien[1], K. Pocate[1], C. Patrat[1], C. Chapron[1], P. Santulli[1]
[1]Centre Hospitalier Universitaire CHU Cochin-Bâtiment Port Royal, Department of Gynaecology Obstetrics and Reproductive Medicine Paris, Paris, France

Study question: Does estradiol level at trigger-day impact low-birth weight incidence in singleton born after fresh transfer in a center practicing 'freeze-all' strategy to prevent ovarian-hyperstimulation syndrome?
Summary answer: In controlled ovarian stimulation followed by a fresh embryo transfer, estradiol (E2) level at trigger-day is not associated with low-birth weight (LBW) in singleton babies.
What is known already: Assisted reproductive technology is known to increase the risk of LBW. Factors involved are not yet clearly identified but high level of E2 on the day of hCG trigger could be implicated. Since the expansion of "freeze all" policy to prevent the ovarian hyperstimulation syndrome, embryos are mostly cryopreserved in case of high E2 level.
Study design, size, duration: An observational retrospective cohort study was conducted in a tertiary care university hospital between November 2012 and January 2017. All women having a live singleton birth after fresh embryo transfer were included. In case of high risk of ovarian hyperstimulation syndrome women did not have a fresh transfer but benefited from a "freeze all" strategy.
Participants/materials, setting, methods: The main inclusion criteria was having a live singleton birth (≥24 Weeks of gestation (WG)) after a fresh embryo transfer. Four groups were defined according to E2 level on the day of hCG trigger, into quartiles of the whole population. The main measured outcome was the LBW rate. Statistical analysis was conducted using univariate and multivariate logistic regression models.$p < 0.05$ was considered significant.
Main results and the role of chance: During the study period, a total of 1538 embryo transfers had led to a live birth (LB). Among them, 497 LB were obtained after a fresh embryo transfer. The mean E2 level on the day of hCG trigger was 1608,4 ± 945,5 pg/ml. Repartition between groups according to the E2 level, dividing into quartile was as followed: 124 LB in the Group E2<25 percentile (p) (1106.5 pg/ml), 124 LB in the Group E2 [25p-50p](1106.5 -1440 pg/ml),124 LB in the Group E2 [50p-75p] (1440 -1915 pg/ml) and125 LB in the Group E2 > 75p (> 1915 pg/ml). There was no significant difference for LBW rate according to the E2 level (GroupE2 <25p, n= 8/124, (6.5%), Group E2 [25p-50p], n= 15/124, (12.1%), Group E2 [50p-75p], n=13/124, (10.4%) and Group E2>75p, n= 10/125, (8.1%); (p= 0.43)). Others neonatal outcomes were not significantly different among groups. After multivariate analysis, E2 level on the day of hCG trigger did not have a significant effect on LBW in this study. Mother's age over 35 years old and the presence of a gestational pathology were found as significantly associated with LBW.
Limitations, reasons for caution: The main limitation of our study is its retrospective and monocentric nature. Further, practice of freeze all cycles is carried out in our center since November 2012, we do not dispose of data corresponding to the previous period when only fresh transfers were performed for comparison.
Wider implications of the findings: The fresh transfer strategy, in case of moderate E2 levels on the day of trigger, remains one possible approach considering the absence of increased risk of low birth weight.
Trial registration number: NA

P-655 Dual Triggering versus hCG final maduration in patients over 38 years old, our experience in IVI Santiago

E. SANCHEZ ESTEVES[1], D. Machuca[2], N. Carvajal Abumohor, Andrés[3], R. Carvajal Gavilán[3], M. Calonge Varela, Loreto[2], M. Chivite Jimenez, Ekaitz[2], E. Andres Martin[2], R.M. Meier Furst[3], C. Troncoso Reyes, Alberto[3]
[1]Gynecology, Reproduction, Santiago, Chile
[2]Instituto Valenciano de Infertilidad, Embryology, santiago, Chile
[3]Instituto Valenciano de Infertilidad, Gynecology, Santiago, Chile

Study question: The addition of gonadotropin-releasing hormone agonist (GnRH-a) to the hCG final triggering in low responder patients enhance the percentage of mature oocytes (MII) ?
Summary answer: In patients with advanced maternal age and low ovarian reserve, the use of dual triggering do not increase the percentage of mature oocytes
What is known already: In the recent years, the use of the dual triggering in ovarian stimulation has been increased in patients with high rates of immature oocytes in previous cycles in order to obtain higher number of MII and fecundation rate. Also, it has been described higher number of good quality embryos with this technic for oocyte´s maturation induction. These Hypothesis are still controversial
Study design, size, duration: This is a retrospective study in patients older than 38 years old with low ovarian reserve measured as AMH < 1 ng/ml, ICSI cycles and normal semen or moderate oligoastenoteratozoosperm (OAT). It was divided in 2 groups. The first group has 40 cycles in which the induction was made with hCG and the other group has 58 cycles inducted with dual triggering. Data where obtained between January 2014 and March 2018.
Participants/materials, setting, methods: This clinical study was performed in IVI Santiago, a private reproduction Clinic with authorization of Ethics Committee of Santiago de Chile. Our patients had no previous ovary pathology like surgery or endometriosis or ovarian cysts. There was no hormonal stimulation in previous cycles. Couples had normal sperm or OAT moderate. We divide them in two groups:

Group A: Triggering with hCG 6500 UI
Group B: Triggering with dual triggering: hCG 6500 UI and a-GnRH 20 UI

Main results and the role of chance: There was no statistical difference between both groups in the selection criteria like Age, days of stimulation, or AMH value. We couldn´t determinate a statistical difference in number

of aspirated oocytes triggered with DT vs hCG 4.45+2.26 (3.85; 5.04) vs 5.1+3.36 (4.03; 6.17), in the number of mature oocytes retrieved with dual trigger: 3.2+1.66 (2.74-3.67) vs hCG alone 3.9+2.01 (3.11-4.69). There was also no statistical difference on fecundation rate in DT 2,36+1.76 (1.93- 2.80) vs hCG 2.83+2.47 (2.18- 3.47), or good blastocysts formation DT 0.91+0.96 (0.66-1.17) vs hCG alone 1.02+1.35 (0.59-1.46). With these results we can conclude that there is no benefit in adding a-GnRH to hCG to final induction for oocyte maturation in patients with advance maternal age and low ovarian reserve.

Limitations, reasons for caution: A limitation of this study was the low statistical power, because we had only 98 cycles studied in this period. Whether dual triggering favors embryo implantation or not is still controversial. In this study the implantation rate was not an objective because we included cycles with and without PGT-A

Wider implications of the findings: Our results agree with the study of Ding et al, who did not find significant difference in number of oocytes, MII or fecundation rate. High-quality RCTs are warranted to define more-eligible evidence of the efficacy of dual triggering in the GnRH antagonist cycle for IVF in low responders.

Trial registration number: 1806-SCL-051-ES

P-656 EFFICACY OF DOUBLE STIMULATION IN FOLLICULAR AND LUTEAL PHASE (DUOSTIM PROTOCOL) IN PATIENTS WITH LOW OVARIAN RESPONSE: SYSTEMATIC REVIEW AND META-ANALYSIS

J.L. Gomez-Palomares[1], M. Carrera[2], M. Morales[1], M.A. Manzanares[1], E. Hernandez[1], E. Ricciarelli[1]

[1]*FivMadrid, Gynecology, Madrid, Spain*

[2]*FivMadrid, Biology, Madrid, Spain*

Study question: Can follicular and luteal phase ovarian stimulation (double stimulation) be effective in patients with low ovarian reserve?

Summary answer: Double stimulation may be effective in patients with low response

What is known already: Since the work by Baerwald who found the existence of two to three waves of follicular development during the ovarian menstrual cycle, it has been studied the possibility to take advantage of these waves for dual stimulation (in follicular and luteal phase) in the same cycle, the DuoStim protocol

Study design, size, duration: Systematic review and meta-analysis

Participants/materials, setting, methods: A systematic literature search was conducted in: Pubmed/MEDLINE, EMBASE, Web of Science and clinicalTrials.gov from 2014 until today. We identified a total of 14 papers related to , 4 met the inclusion criteria and were included in the meta-analysis. The statistical analysis was done with RevMan 5.3.

Main results and the role of chance: The duration of the ovarian stimulation was longer in the luteal phase though didn't reach statistical significance (standardized mean differences (SMD)=0.43, 95% CI= -0.44 to 1.31; RE Model) The total of eggs retrieved was significantly higher in luteal phase (SMD=0.46, 95% CI= 0.31 to 0.61; FE Model), as well as the number of MII oocytes (SMD=0.45, 95% CI= 0,3051 to 0,6078; FE Model) The number of embryos obtained was also higher in luteal phase (SMD=0,42, CI 95%=0,21 to 0,62; FE Model), as well as the number of good quality embryos (SMD=0.24, 95% CI=0.03 to 0.44; FE Model).

Limitations, reasons for caution: This meta-analysisi only contains 4 studies.

Wider implications of the findings: Although more prospective randomized studies are needed, it seems that this stimulation could be more effective than stimulation in two different cycles, since in luteal phase are obtained significantly more eggs and more embryos than in follicular phase.

Trial registration number: Not applicable

P-657 Oral dydrogesterone versus micronized vaginal progesterone for artificial frozen-thawed embryo transfer cycles

A. Alahmad[1], K. Neumann[1], M. Depenbusch[1], A. Schultze-Mosgau[1], T. Osterholz-Zaleski[1], J. Hajek[1], B. Schöpper[1], G. Griesinger[1]

[1]*University Hospital of Schleswig-Holstein, Department of Gynecological Endocrinology and Reproductive Medicine, Lübeck-, Germany*

Study question: What are clinical outcomes of artificial frozen-thawed embryo transfer (FET) cycles utilizing oral dydrogesterone (DYD) versus (vs.) micronized vaginal progesterone (MVP) for luteal phase support?

Summary answer: Oral dydrogesterone 30mg was associated with similar pregnancy rates, as well as a similar incidence of early pregnancy bleeding and D&C, as compared to MVP.

What is known already: The "luteal phase" of an artificial FET-cycle is vulnerable, as ovulation is suppressed, a corpus luteum therefore absent, and the establishment of endometrial receptivity and the early pregnancy support completely relying upon the orchestrated exogenous administration of sex steroids. DYD is a convenient oral progestogen that has recently been shown to be effective and safe in fresh IVF-cycles (Tournaye et al., 2017; Griesinger et al., 2018). So far only two small-sized RCTs have compared daily 20 mg (Zarei et al., 2016) or daily 40mg oral DYD (Rashidi et al., 2016) with daily 800mg MVP for FETs, however with conflicting results.

Study design, size, duration: Retrospective analysis, 4/2016-4/2018, all patients initiating a FET cycle with constant daily oral 6mg E2 and daily oral 30mg DYD or MVP (600mg capsules or 90mg gel). Each patient contributed one, the first, IVF/ICSI cycle of stimulation and fresh transfer with cryopreservation of surplus 2PN or freeze-all, and all subsequent FETs from that first treatment cycle. All FETs had to be on the same endometrial preparation protocol. Sex steroid administration continued until gestational week 10.

Participants/materials, setting, methods: In 5/2017, the FET routine at the department was gradually switched from MVP to oral DYD. Accordingly, approx. one year of oral DYD usage is compared with the previous year of MVP usage. Primary outcomes were pregnancy and birth rate (the latter still incomplete at the time of writing), secondary outcomes were early pregnancy bleeding and dilatation and curettage incidence.

Main results and the role of chance: 314 patients underwent a first IVF/ICSI cycle with cryopreservation (surplus or freeze-all) and later FET.

Age, BMI, parity, IVF:ICSI ratio, gonadotropin type, trigger type(hCG or GnRH-agonist), peak E2 and peak progesterone were similar in patients later on DYD or MVP for their FETs as was the mean cumulus-oocyte-complex number(DYD: 13.9±7.6; MVP: 14.3±7.4 [p=0.65]). The proportion of patients undergoing freeze-all and the pregnancy rate (PR) in patients with fresh transfer was similar in the two groups as well

109 (DYD) and 204 (MVP) patients underwent 160 and 295 FET cycles, respectively (mean FET cycles per patient: 1.47 versus (vs.) 1.45). The cumulative clinical PR was 40/109 (36.7%, 95%CI: 27.9-46.5) with DYD vs. 72/204 (35.3%, 95%CI: 28.8 – 42.3) with MVP(difference: 1.4%, 95% CI: -9.4 – 12.6, p= 0.80). The PR of the first FET cycle was 27/109 (24.8%, 95%CI: 17.6-33.6) with DYD and 57/204 (27.9%, 95%CI: 22.2 – 34.5) with MVP (difference: -3.2%, 95%CI: -12.8 – 7.4, p= 0.54)Vaginal bleeding after establishment of a clinical pregnancy occured in 26/40 (65%, 95%CI: 49.5-77.9%) vs. 42/72 (58%, 95%CI: 46.8-69.0) pregnancies in DYD and MVP patients (difference: 6.7%, 95%CI: -12.2 – 23.9, p=0.49). Incidence dilatation & curettage: 13/40 (32.5%) DYD vs. 20/72 (27.7%) MVP (p=0.60)

Limitations, reasons for caution: A retrospective study has inherent risks of bias. Sampling error is potentially high, illustrated by the wide CI for the primary outcome. Selection bias, however, is unlikely as the FET protocol was changed to DYD for all patients starting a cycle after 5/2017.

Wider implications of the findings: Because of ease of administration, oral DYD may be preferable to vaginally administered or injectable progestogens, especially in artificial FET cycles with prolonged administration up to the completed luteo-placental shift. DYD 30mg is a dose to be tested further for artificial FET in randomized controlled

Trial registration number: not applicable

P-658 Antichlamydial antibodies and poor response to ovarian stimulation in women with tubal factor infertility undergoing in vitro fertilization

V. Muller[1], A. Savicheva[2], I. Kogan[1], A. Gzgzyan[1]

[1]*D.O.Ott Research Institute of Obstetrics- Gynecology and Reproductology, IVF Departement, Saint-Petersburg, Russia C.I.S.*

[2]D.O.Ott Research Institute of Obstetrics- Gynecology and Reproductology, Microbiology, Saint-Petersburg, Russia C.I.S.

Study question: Does past or persistent chlamydial infection affect the response to controlled ovarian stimulation in women with tubal factor infertility undergoing *in vitro* fertilization (IVF)?

Summary answer: IgG-antibody positivity to *C.trachomatis*, as serological marker of past infection, is associated with both 'expected' and actual poor ovarian response (POR) to exogenous gonadotropin stimulation

What is known already: The absence of universal definition and standardized efficient treatment encourage further debate on the topic of POR in modern reproductive medicine. In some studies, pelvic inflammatory disease and its sequelae in the upper reproductive tract were suggested as factors, unequivocally associated with POR. Strong correlation between tubal factor infertility (TFI) and seropositivity for antichlamydial antibodies in women undergoing IVF was repeatedly established. However, knowledge about the prognostic value of chlamydia antibody testing for the definition of POR in this substantial subset of patients remains limited.

Study design, size, duration: A prospective comparative cohort study of 246 women with laparoscopically confirmed TFI was conducted at the IVF department of a state institution between February 2015 – December 2017. Patients with endometriosis or previous ovarian cystectomy were excluded.

Participants/materials, setting, methods: Blood serum (obtained at the start of stimulation) and follicular fluid (aspirated at oocyte retrieval) were analyzed using enzyme-linked immunosorbent assay for IgG, IgA to major chlamydial antigens and for IgG to chlamydial heat shock protein 60 kDa (cHSP60). According to the results of serum anti-*C.trachomatis* IgG test, 124 seropositive (main group) and 122 seronegative subjects (comparison) were defined. The number of pre-ovulatory follicles on the day of ovulation triggering was measured as primary outcome.

Main results and the role of chance: Maternal age, antral follicle count and serum anti-Müllerian hormone (AMH) levels did not differ between the studied groups. Nevertheless, the proportion of 'expected' poor responders (POSEIDON criteria, 2016; group 3 and 4) due to reduced ovarian reserve (AMH<1.1 ng/ml) was higher in women, positive for IgG to *C.trachomatis* in sera and follicular fluid (46.40% vs. 36.26%, p=0.023). Detection of this antibodies was also related to severity of peritoneal adhesions (R=0.46, p<0.001), repeated pelvic surgeries (OR: 1.93, 95%CI 1.12-3.29) and previously diagnosed fallopian tube pathology (OR: 4.51, 95%CI 2.60-7.84). The proportion of younger 'expected' hypo-responders (<35 years, POSEIDON group 3) was almost two times higher in the main group. Albeit the pre-ovulatory follicle count and the number of retrieved oocytes were comparable, anti-*C.trachomatis* IgG detection in sera was associated with actual POR (<4 retrieved oocytes; OR: 2.63, 95%CI 1.35-5.11) and oocyte maturity (R=-0.22, p=0.019). Follicular output, fertilization and blastulation rates did not vary between the groups. Seropositive and seronegative women demonstrated similar clinical pregnancy (20.49% vs. 25.00%, p=0.142) and life birth rates (13.1% vs. 20.0%, p=0.149). No significant correlations between ovarian response parameters and anti-cHSP60 IgG or anti-*C.trachomatis* IgA positivity of sera or follicular fluid were observed.

Limitations, reasons for caution: The proportion of patients with antibodies to cHSP60 (markers of persistent infection) was rather small. Exclusively women with endoscopically confirmed TFI were recruited for the study. Neither genetic polymorphisms, known to be linked to POR, nor cumulative pregnancy rates could be assessed. All this limits generalizability of the obtained results.

Wider implications of the findings: For the subpopulation of women with TFI undergoing IVF, chlamydia antibody testing should be employed in prediction, counseling and planning of management of 'low prognosis patients'. Further randomized trials may investigate advisability of empiric antimicrobial therapy prior an IVF cycle for women, diagnosed with TFI and/or positive for antichlamydial antibodies.

Trial registration number: Not available

P-659 A first description of a novel 20mg letrozole stimulated IVF cycle as compared to gonadotropins in GnRH-antagonist cycles, in extremely poor ovarian reserve

M. Khojah[1], S.Y. Dahan[1], S. Khayat[1], M.D. Dahan[1]

[1]McGill University, Obstetrics and Gynecology, montreal, Canada

Study question: To evaluate the outcome of IVF stimulated with 20mg letrozole as compared to high-dose gonadotropins in ultra poor responders

Summary answer: 20mg letrozole in women who previously stimulated 0-2 follicles and may yield lower cancellation rates, better pregnancy rates and at lower costs than high-dose gonadotropins

What is known already: Poor ovarian response presents a significant challenge in IVF. There is no consensus in the literature on the ideal controlled ovarian hyperstimulation protocol for these patients and pregnancy rates remain low. Many strategies have been studied in such patients, including increasing the gonadotropin dosage and administration of adjuvant therapies, such as clomiphene but have failed to improve pregnancy outcomes. Clomiphene while cheaper than gonadotropins may lead to stimulation without increases in pregnancies. Clomiphene is not available in our country; as such high dose letrozole was investigated, with expected rapid recovery of the endometrium, possibly prior to transfer unlike clomiphene.

Study design, size, duration: A retrospective cohort study conducted at a university hospital with data from January 01, 2015 to June 01, 2018. The analysis included women who were up to 42 years of age. All subjects had performed 1-2 previous IVF cycles in the year prior with at most 0 to 2 follicles stimulated with 300-450IU gonadotropins daily. Sample size calculations required a total population of >190 to detect an increase of 0.5 follicles/oocytes with SD=1.2 follicles.

Participants/materials, setting, methods: All were GnRH-antagonist cycles. Controls (N=247) were treated with 300-450 IU/daily of HMG. The study group (N=62) received 20mg/daily of letrozole orally, with the GnRH-antagonist and HMG(150IU) commencing when the lead follicle was 14mm. Statistics were analyzed with T or chi-squared tests. Logistic regression was used to control for confounding effects of any statistically different baseline parameters. Cycles were canceled if no follicles grew by 20-days stimulation or linings <6mm on day of the transfer

Main results and the role of chance: The two groups were comparable in terms of age, infertility duration, #failed transfers, AFC and basal-FSH. The letrozole group received less total gonadotropin with lower medication costs (645±175IU, $555±150) compared to controls (5360±1028IU, $4616±885) (p=0.0001 twice). The number of metaphase-II oocytes per cycle start (1.9±1.0 vs. 1.0±0.8) and per collection (2.1±1.0 vs. 1.6±0.8) were higher for letrozole than controls (p=0.0001 twice). Cancelation rates were lower with letrozole 7/62 vs. 95/247, p=0.0001. Max ET at triggering was thinner with letrozole 6.4±1.o vs. 7.4±1.7mm (p=0.0001). No subjects had transfer canceled for linings <6.0mm on transfer day. Ongoing pregnancy rate per cycle start (14.5 vs. 4.5 %, p=0.004) and per transfer (16 vs. 7%, p=0.05) were higher with letrozole

Limitations, reasons for caution: A moderate number and non-randomization of the study participants may result in undetected bias. The main outcome which is live birth is still to be determined, an ongoing pregnancy in the third trimester was used as a surrogate outcome

Wider implications of the findings: 20mg letrozole can be used in poor ovarian responders with a history of stimulating 0-2 follicles and may yield lower cancellation rates, better pregnancy rates and at lower costs than high-dose gonadotropins. A prospective randomized study should be performed to evaluate this protocol described for the first time here

Trial registration number: none

P-660 Consecutive minimal controlled ovarian stimulation (COMCOS) to increase the number of oocytes in patients with poor ovarian response or poor ovarian reserve.

S. Geber[1], M. Sampaio[2]

[1]ORIGEN, Assisted Reproduction, Belo Horizonte, Brazil

[2]Origen - center for reproductive medicine, assisted reproduction, Belo Horizonte, Brazil

Study question: Investigate the impact of consecutive minimal controlled ovarian stimulation associated to oocyte vitrification on the reproductive outcome of women with poor ovarian response or reserve.

Summary answer: Consecutive minimal controlled ovarian stimulation associated to oocyte vitrification is a suitable alternative for patients with poor ovarian response or reserve

What is known already: Although different controlled ovarian stimulation protocols have been proposed for women with poor ovarian response or reserve there are still women who respond poorly to gonadotropins, thus resulting in few oocytes at retrieval, reduced number of embryos for transfer, and unsatisfactory pregnancy rates. An interesting alternative is to refer those patients for oocyte donation program. However, many patients still do not agree with this alternative. Also, no consensus has been reached for the best alternative to increase the number of oocytes and embryos available for transfer in this group of patients.

Study design, size, duration: We report an observational study of 84 patients submitted to assisted reproductive technologytreatment from April 2015 to November 2018.

Participants/materials, setting, methods: We evaluated 434 cycles of that were referred to receive donated oocytes and did not agree. Treatment started with Clomiphene Citrate and Letrozol. When follicles reached 13mm, patients received GnRH antagonist and rFSH/LH. GnRH agonists was administered for oocyte maturation when follicles reached 17mm. Oocyte retrieval was performed 36h later and oocytes were vitrified 2h later. A new stimulation was started on the following day, until reached 6 oocytes or a maximum of 6 retrievals.

Main results and the role of chance: The patients mean age was 38.3 ± 3.2 years (range 32-45). The number of oocyte retrievals ranged from 3 to 6 with a mean number of 5,1. A total of 444 Metaphase II oocytes were recovered (mean = 5.3 ± 2.4) ranging from 1 to 8. A total of 426 oocytes survived after warming (96%), 354 showed normal fertilization after ICSI (83%) and 278 reached cleavage stage (78% - mean=3.3). The number of transferred embryos ranged from 1 to 3. Overall clinical pregnancy rate was 27.3% (n=23) and miscarriage rate was 26% (n=6).

Limitations, reasons for caution: Additional controlled studies are necessary to confirm our results as this was an observational study and, to our knowledge, this is the first study to perform such analysis.

Wider implications of the findings: Consecutive minimal controlled ovarian stimulation might be an alternative to increase the number of oocytes and embryos and improve pregnancy rates, in patients with poor ovarian response or poor ovarian reserve. This alternative might be a suitable option for patient who do not agree to receive donated oocytes.

Trial registration number: not applicable

P-661 Anti-Müllerian Hormone (AMH) is an independent marker for oocyte survival post vitrification.

L. Melado Vidales[1], A. Arnanz[2], A. Bayram[2], A. Nkuhlu[2], E. Ibrahim[2], A.T. Navarro[3], B. Lawrenz[4], H.M. Fatemi[4]

[1]IVI Middle East Fertility Clinic, Medical department, Abu Dhabi, United Arab Emirates

[2]IVI Middle East, IVF Lab, Abu Dhabi, United Arab Emirates

[3]IVI Valencia, Fundación IVI - UAGI, Valencia, Spain

[4]IVI Middle East, Medical department, Abu Dhabi, United Arab Emirates

Study question: Is Anti-Müllerian hormone related with oocyte survival and blastocyst formation after oocyte vitrification?

Summary answer: AMH shows a positive significant correlation with oocyte survival. Although blastocyst formation is lower after oocyte vitrification, no correlation was found with AMH.

What is known already: Oocyte cryopreservation is increasingly being used for medical and social reasons. Vitrification techniques led to improved survival rates for oocytes. Recent meta-analysis demonstrated that vitrified oocytes have a good survival, fertilization and cleavage rates. However, subgroup analysis indicated better results with donor oocytes, possibly explained by the likelihood of better-quality oocytes obtained from younger women.

Nonetheless, not only age, likewise ovarian reserve seems to be correlated with oocyte competence. AMH is one of the best quantitative predictors for ovarian reserve; however, it may also play an important role on prediction of survival rate after oocyte vitrification and embryo development.

Study design, size, duration: Retrospective observational analysis including 487 cycles for ICSI with devitrified oocytes and/or fresh plus devitrified oocytes, performed between August 2015 and August 2018.

Participants/materials, setting, methods: Patients with primary or secondary infertility undergoing ICSI treatment with previous stimulations for oocyte vitrification were included. Serum AMH was measured using a fully automated assay Elecsys® (Roche). Vitrification and warming were performed with the Cryotop method (Kitazato, Biopharma). Only cycles using ejaculatory sperm were considered for the secondary objectives.

Main results and the role of chance: We included 487 cycles with a total of 4530 devitrified oocytes. Patient median age was 36,2±6,08 years (CI.95 24,3-48,1), AMH 2,58±3,38 ng/mL and body mass index (BMI) of 26,5±4,59 Kg/m^2. Oocyte survival rate after vitrification was 85,9±20,4% (CI.95: 84,1-87,7%).

AMH showed a significant positive correlation (Tau´s Kendall=0,091, p=0,0055) with oocyte survival rate independently of the oocyte yield, using univariate correlation analysis. The correlation between AMH and oocyte survival was also significant (OR=1,017, p=0,0475) when a multivariant model was performed including AMH, age and BMI. A ROC curve was performed andAMH cut-off value to obtain at least 70% survival rate was 1.09 ng/mL with an AUC=0.669.

Regarding embryo development in cycles including fresh and thawed oocytes for the same patient, fertilization and cleavage rate were similar between embryos from fresh and thawed oocytes (OR=0,97, p=0,496; OR=0,99, p=0,997 respectively). However, blastocyst formation was better for embryos from fresh than thawed oocytes (OR=1,34, p<0,001). No significant correlation was seen between fertilization, cleavage or blastocyst rate with AMH, age or BMI.

Limitations, reasons for caution: The strength of the study is the number of included thawed oocytes (4,530) with AMH data for all cycles. Limitation is the retrospective design.

Wider implications of the findings: As AMH shows strong positive correlation with oocyte survival, clinicians should reconsider oocyte vitrification carefully for patients with AMH below 1,09 ng/mL, especially as blastocyst formation after oocyte vitrification also seems lower. Therefore, embryo accumulation should be recommended above oocyte accumulation. Further prospective studies should confirm these findings.

Trial registration number: NO

P-662 Two new compound heterozygous truncating mutations in NOBOX gene identified by Whole Exome sequencing (WES) in 2 sisters with premature ovarian insufficiency (POI).

A. Sassi[1], J. Désir[2], S. Duerinckx[3], J. Soblet[2], S. Van Dooren[4], M. Bonduelle[5], A. Delbaere[1]

[3]IRIBHM- Université Libre de Bruxelles, Department of Neurology, Brussels, Belgium

[4]Brussels Interuniversity Genomics High Throughput core Bright Core, Department of Human Genetics, Brussels, Belgium

[5]UZ Brussel- Vrije Universiteit Brussel, Centre for Medical Genetics- Reproduction and Genetics and Regenerative Medicine, Brussels, Belgium

Study question: Can WES uncover genetic etiology of POI in 2 sisters presenting primary amenorrhea (PA) and delayed puberty?

Summary answer: WES identified two new compound heterozygous NOBOX truncating mutations. The familial segregation of the mutations strongly supported their implications in the development of POI.

What is known already: *NOBOX* is a homeobox gene playing a critical role in early folliculogenesis. Two chromosomal deletions involving NOBOX and fourteen *NOBOX* mutations have been reported so far in patients affected by POI. While the only 2 reported homozygous mutations were associated to PA, heterozygous mutations were mostly reported in patients with secondary amenorrhea although in some cases they were also identified in patients with PA with absent or incomplete pubertal development. Functional studies of the reported mutations gave more evidence of haploinsufficiency of *NOBOX* gene in human in contrary to data obtained from knockout *NOBOX* mice.

Study design, size, duration: WES was performed in trio in a POI Belgian patient and her two healthy non consanguineous parents on HiSeq 2000 Illumina sequencer at the BRIGHTcore platform. Identified mutations were confirmed by Sanger sequencing in the proband's POI sister. The proband and her family

members gave their informed consent to undergo genetic testing to uncover the etiology of POI in the affected sisters.
Participants/materials, setting, methods: The proband presented at our Fertility Clinic for oocyte donation. She had been diagnosed with idiopathic POI at 17 years old as she showed no pubertal development and PA. Laparoscopic investigation performed at adolescence showed a small uterus and hypoplastic ovaries. FSH and estradiol levels were respectively of 106 IU/L and <12ng/l. Her puberty was induced with hormonal treatment. Karyotype and array CGH were normal. Her sister presented the same POI phenotype.
Main results and the role of chance: WES identified 2 new compound heterozygous NOBOX truncating mutations in the patient: c.1421delG (p.Gly474fs) inherited from the mother (menopaused at 50 years) in exon 8 which induced a frame shift and c.826C>T (p.Arg276*) inherited from the father in exon 4 which induced a premature stop codon leading to a truncated protein devoid of its homeodomain. These 2 variants were not reported in different NGS databases including EXAC, 1000Genomes, ESP6500 and genomAD databases. The sister carried the same mutations. Both variants presented strong evidence of pathogenicity and are very likely responsible of the severe POI phenotype in our 2 sisters. Previously reported functional studies on NOBOX gene truncated at the level of the DNA binding homeodomain showed a defective transcriptional activity, an impairment of nuclear localization of the truncated protein, its intracellular aggregation suggestive of protein instability and subsequent cell toxicity as well as a potential partial sequestration of wild type protein.
Limitations, reasons for caution: The contribution of c.1421delG (Exon 8) mutation to the severity of the 2 sisters POI phenotype can't be assessed as functional study has not been performed.
Wider implications of the findings: NGS is a promising genetic tool that should be used for genetic diagnosis approach in idiopathic POI cases. We suggest using a specific panel of causal POI gene in the diagnosis management of all idiopathic POI cases, and restrict WES to families with a least two affected women.
Trial registration number: P2016/196/CCB B406201628264

P-663 Time of oocyte recruitment can affect their ploidy status

J. Liss[1,2], A. Knight[1], K. Lukaszuk[1,3,4]
[1]*Invicta, Fertility and Reproductive Centre, Gdansk, Poland*
[2]*University of Gdansk, Department of Biology and Medical Genetics, Gdansk, Poland*
[3]*Medical University of Warsaw, Department of Gynecological Endocrinology, Warsaw, Poland*
[4]*Medical University of Gdansk, Department of Obstetrics and Gynecological Nursing- Faculty of Health Sciences, Gdansk, Poland*

Study question: To evaluate the efficacy of double stimulation in terms of embryo developmental potential and their genetic status.
Summary answer: The shorter time of oocyte recruitment can help increase the number of blastocysts and euploid blastocysts.
What is known already: Recent evidence indicates that folliculogenesis occurs in a wave-like fashion indicating that there are multiple follicular recruitment waves in the same menstrual cycle. This relatively new scientific concept provides new opportunities for the utilization of ovarian stimulation especially in women with diminished ovarian reserve, poor ovarian response or for patients who need to collect the highest number of oocytes in the shortest possible time. It is important to know if embryos resulting from this type of stimulation have similar developmental potential and euploidy rate when compared to embryos obtained by more traditional ovarian stimulation.
Study design, size, duration: This was a retrospective case-control study and consisted of 68 women (median age 38 years, range 28-43) with the diagnosis of infertility who were undergoing IVF treatment with PGT with double ovarian stimulation in the follicular (FPS) and luteal phase (LPS) between September 2017 and Juni 2018 at INVICTA Fertility Centre, Poland.
Participants/materials, setting, methods: A total of 932 MII were derived (428 FPS and 504 LPS) and 208 blastocyst (130 blastocysts FPS and 190 LPS) were evaluated with the NGS protocol. Ion Torrent Suite Software and Invicta Bioinformatics Team Script were used for chromosome copy number variation analysis.
Main results and the role of chance: No significant differences were observed in the mean number of metaphase II oocytes (6.5 ± 3.6; median 6; range 1-21 vs. 7.4 ± 3.7; median 6,5; range 2-17) and fertilized oocytes (4.5 ± 2.1, median 4; range 1-9 vs. 4.8 ± 2.6, median 4; range 0-11) between FPS and LPS. Blastulation rates were significantly higher ($p<0.01$) in LPS compared to FPS. The mean number of blastocyst in LPS was 2.8 ± 1.7, median 2; range 1-7 vs. 1.9 ± 1.1, median 2; range 1-5 in FPS. There was also a higher number of euploid embryos obtained after LPS ($p<0.01$). The mean fertilization rate calculated per number of MII oocytes collected from FPS and LPS was similar but the mean blastocyst and euploid blastocysts rate per MII were higher and were 35.7% vs. 41.1% and 17.6% vs. 25.2 respectively.
Limitations, reasons for caution: More data are required to confirm that better quality of oocytes is a result of shorter recruitment time of antral follicles.
Wider implications of the findings: The evidence of multiple follicular waves during a single menstrual cycle in women has important implications for the treatment of infertility. This strategy can maximize the number of oocytes obtained per menstrual cycle, in turn increasing the chance to obtain reproductively competent, euploid embryos in the shortest possible time.
Trial registration number: not applicable

P-664 Assessment of the feasibility and safety of a novel transvaginal ovarian drilling method in a bovine model: ovarian rebalancing.

A. Bongrani[1], D. Mickael[1], C. Rame[1], S. Amer[2], E. Briant[1], J. Dupont[1]
[1]*inra, physiology of reproduction, Nouzilly, France*
[2]*University hospitals of Derby, Room 4120 Derby Medical School, Derby, United Kingdom*

Study question: The objective was to evaluate the technical feasibility and safety of a new transvaginal ovarian drilling procedure using a dedicated device in a bovine model.
Summary answer: The procedure was successfully and safely completed in all animals with no incidents of inadvertent damage to other organs and without disruption of ovarian folliculogenesis.
What is known already: Polycystic Ovary Syndrome (PCOS), the most common endocrinopathy affecting women of reproductive age, is defined by at least two of the following features: ovulatory dysfunction, hyperandrogenism and polycystic ovarian morphology. In PCOS women with anovulatory infertility, the accepted first-line treatment is clomiphene citrate (CC). For patients resistant to CC, laparoscopic ovarian drilling (LOD) is recommended as a second-line therapy. Whilst very effective, LOD is an invasive technique requiring general anaesthesia and is associated with a significant risk of postoperative adhesions. To overcome these drawbacks, other techniques such as transvaginal ovarian drilling are being developed and tested in animal models.
Study design, size, duration: The study was conducted on thirteen female cattle aged 3-8 years, selected to have ovarian morphology and size similar to human PCOS ovaries. Most animals were in the follicular phase of the oestrus cycle. On days 0, 7, 36 or 69-72 (n=3, 4, 3, 3 respectively) following the procedure, the animals were slaughtered or subjected to ovariectomy to harvest the reproductive tract and ovaries and perform a macroscopic and histological analysis of the tissues.
Participants/materials, setting, methods: The procedure was performed under light epidural anaesthesia by an animal technician experienced in egg retrieval. A dedicated kit (*AblaCare*) was used comprising a device (ablation catheter deployed through a needle) and a radiofrequency energy generator. The device was mounted on a vaginal ultrasound probe, then introduced transvaginally and brought in close proximity to each ovary. The needle was inserted into the ovary and the catheter released to deliver 4-6 ablations/ovary (settings: 85° for 60s).
Main results and the role of chance: The procedure was successfully performed via transvaginal access and under ultrasound guidance in all animals. The animals did not manifest signs of pain or significant discomfort. The needle and catheter were clearly visualised on ultrasound and therefore easily located within the ovary ahead of performing the ablations. No adverse events or significant technical difficulties occurred during or after procedure, demonstrating good technical feasibility. From a safety standpoint, the macroscopic analysis of

harvested ovaries showed no damage to ovarian surface aside from the needle puncture. Thermal lesions, quantified using the ImageJ software, were confined to the ablation zones, were visible at days 0 and 7 - lesion volume amounting to 5.74% and 5.20% of the total ovary volume respectively, in line with what is known in terms of target volume reduction to achieve efficacy of ovarian drilling - and were no longer visible at days 36 and 69-72 ($p<0.001$). The ovarian structure was conserved, and no lesion secondary to ablation or puncture was found in surrounding organs, especially the tractus. All animals followed up for 7 days or longer presented no adhesions on ovarian surface and maintained a normal cycle with no disruption of folliculogenesis/corpus luteum development as monitored by ultrasound.

Limitations, reasons for caution: All animals followed up for 7 days or longer maintained a normal cycle with no disruption of folliculogenesis/corpus luteum development as monitored by ultrasound. However, the efficacy of the procedure in terms of ovulation induction was not evaluated in this protocol, as the chosen model was not a pathological model.

Wider implications of the findings: The technical feasibility and safety of this new procedure, ovarian rebalancing, using a dedicated device were successfully assessed in the bovine model. These preclinical results need to be validated by a clinical trial on anovulatory PCOS women, resistant to first-line treatment.

Trial registration number: NCT03760926

P-665 Recombinant LH (rLH) supplementation during GnRh-antagonist delayed-start OPCs-synchronized IVF cycles in an unselected population of infertile women

A. Nazzaro[1], A. Salerno[1], M. De Martino[1], L. Di Iorio[1]

[1]Futuraivf - Reoproductive medicine Center, Human Reproduction Unit, Benevento, Italy

Study question: May endocrine dynamics evaluation be used as a predictor of ovarian response and IVF outcome in an unselected population in GnRh-antagonist down-regulated cycles?

Summary answer: Endocrine dynamics may identify patients needing rLH supplementation,the threshold under which supplementation is mandatory and at what point of follicular stimulation rLH must be added.

What is known already: Oocyte quality is programmed well before ovulation and may be influenced with exogenous gonadotrophins earlier than oocyte collection,being amenable to endocrine/paracrine manipulation.Thus stimulation protocols may impact on oocytes quality other than quantity,and an inappropriate use of exogenous gonadotrophins might be deleterious.To date not clear picture emerges regarding the usefulness of rLH supplementation as a routinary part of an assisted reproductive technique:previous results do not support the hypothesis that rLH addiction increases pregnancy rate in unselected patients even if there may be a potential benefit when rLH is supplemented during ovarian stimulation in poor responders or women of an advanced age.

Study design, size, duration: 300 unselected women were enrolled.A delayed-start protocol with rhFSH, following daily 0,25 µg GnRh-antagonist administration was used.LH, E2, and Pg determinations were performed on day 3-4 of spontaneous menstruation (basal), at t0 (day of OCP stop),t1 (day of first GnRh-antagonist administration), t2 (first us scan),t3 (second us scan) to evaluate the need of rLH adding.An arbitrary cut off of 2,4 mIU/ml of circulating LH at t1 was considered as the threshold for rLH tailored supplementation

Participants/materials, setting, methods: 103 patients out of 300 (group I) received only tailored rFSH,whilst197 patients (group II) received tailored rFSH plus rLH starting from day six of rFSH administration.Primary outcomes were total number and MII retrieved oocytes,number of 2PN,top embryo quality rate.Secondary outcomes included total number of transferred embryos,BhcG/started cycle and BhcG/ET,implantation rate,clinical pregnancy rate/started cycle,clinical pregnancy rate/ET.Data were analyzed by using the SPSS version 20.0: Mann–Whitney U-test and Z-test were used.Significancewas set at $P<.05$.

Main results and the role of chance: Serum E2 and P level at t2 and t3 did not show any statistical significant difference between the two groups.LH values at basal time (t0)were similar in both groups(5,57 +2,80 vs 5,55 +2,65 mIU/ml),whereas LH serological values at t2(3,05+3,64 vs 1,85+1,69 mIU/ml)and at t3 (2,60 +2,10 vs 1,93+1,66 mIU/ml)were markedly reduced when COS was driven with rFSH alone respect to the stimulation supplemented with rLH,reaching a statistically significant difference between the two groups (*p*value <.05 and <.002 respectively)at any time.Notably Metaphase II oocytes (6,48+3,42 vs 4,70+2,63),fertilization rate (4,08+2,26 vs 2,91+1,46;) and top scoring embryos (3,07+1,84 vs 2,10+1,05) showed a statistical significance difference in favour of women receiving and add back of rLH (*p*values <.00001;<.00001 and <.00001 respectively).Total dosage of rFSH administration, total number of retrieved oocytes, total number of embryo transferred at day 2/3 were similar in the two groups.BhcG for started cycle and for embryo transfer,implantation rate and ongoing pregnancy rate for started cycle and for embryo transfer,whilst not reaching a statistically significant difference,showed a clear trend towards a better outcome in favour of the added rLH group (47,72% vs 37,86%; 50,81% vs 40,21%; 20,29% vs 16,1%; 38,50 vs 28,16%; 38,92 vs 29,9% respectively).

Limitations, reasons for caution: We are far from a clear comprehension of paracrine/endocrine signals regarding bidirectional cumulus-oocyte dialogue and more robust studies are needed to clarify who really needs of LH supplementation,which is the threshold under which supplementation with rLH is mandatory and at what point of follicular stimulation we need to add rLH.

Wider implications of the findings: As IVF main outcomes are all in favour of rLH-supplemented cycles,it may be argued that is not so much important the absolute value of a single LH snap-shot determination,rather the endocrine milieu throughout the entire length of follicular phase.It is possible that other iatrogenic interference may further impair the outcome.

Trial registration number: none

P-666 Effects of testosterone administration in patients poor ovarian responder undergoing IVF: a meta-analysis of randomized controlled trials

M. Noventa[1], A. Andrisani[1], G. Ambrosini[1], S. Mosele[1], B. Bellamio[1], S. Borgato[1], A. Politi[1], L. Marin[1], F. Esposito[1], V. Amerigo[1]

[1]University of Padua, Department of Women and Children's health, padova, Italy

Study question: To evaluate whether testosterone administration before or during controlled ovarian stimulation (COS) in patients defined poor ovarian responder can modify IVF outcomes

Summary answer: Compared to controls, women receiving testosterone showed significant higher live birth rate (LBR), clinical pregnancy rate (CPR), total M2 oocytes and total embryos.

What is known already: In-vitro and in-vivo studies demonstrated that testosterone is implied in the transition of follicles from the quiescent to the growing pool, it could increase the number of pre-antral and antral follicles and augment the expression of FSH receptors in granulosa cells potentially enhancing the ovarian responsiveness to gonadotropins. Over the last years, different observational studies and RCTs have evaluated the role of testosterone supplementation before or during controlled ovarian stimulation (COS) in POR, with variable results. Thus the debate on its effectiveness is still open.

Study design, size, duration: This is a systematic review and meta-analysis including 7 RCTs with 573 participants. In all except one trial (using oral route), testosterone was administered trans-dermally. Timing of administration was before starting COS for two-three weeks in four trials, for at least 40 days in one trial, for only five days preceding COS in one trial and until ovulation induction in one trial. The daily dose of testosterone varied among studies

Participants/materials, setting, methods: This is a systematic review and meta-analysis of RCTs evaluating the effectiveness of pre-treatment with testosterone on IVF outcomes in POR. Primary outcome: live birth rate(LBR); secondary outcome: clinical pregnancy rate(CPR), miscarriage rate(MR), total oocytes, MII oocytes, total embryos. All analyses were performed with the random effects model with an intention-to-treat approach. Variables were compared using the risk ratio(RR) or mean differences(MD), with a 95 % confidence interval (95%CI). A $p<0.05$ was considered statistically significant.

Main results and the role of chance: Those women who received testosterone treatment showed higher LBR than controls (RR=2.29;p=0.004); an advantage from intervention was also in terms of CPR (RR=2.32;P=0.0003), total number of oocytes,M2 oocytes and total embryos. No difference was found for MR.

We didn't found significant differences from the subgroup analysis according way of administration in terms of both LBR (transdermal RR=2.11; p=0.78,

oral RR=3.09; p=0.06) and CPR (transdermal RR=2.15; p=0.74, oral RR=3.15; p=0.03). Moreover. subgroup analysis according the days (≥21 days versus < 21 days) and the timing of testosterone administration (before the beginning of COS versus during COS), showed no statistical difference among the subgroups (p= ns).

No adverse effects were recorded.

Limitations, reasons for caution: Some limitations must be considered; firstly, different outcomes were calculated by pooling the results of a small number of studies, patients and events. Additionally, certain heterogeneity across studies was present in terms of POR definition and testosterone therapy.

Wider implications of the findings: Pre-treatment with testosterone seems promising. Our data support a positive impact of testosterone on different COS parameters. Further RCTs on larger populations, with rigorous inclusion criteria are still mandatory to finally confirm testosterone clinical effectiveness and to establish the best timing, dose and duration of its administration before IVF

Trial registration number: PROSPERO CRD42017067270

P-667 FSH requirements for follicle growth during controlled ovarian stimulation

T. Hunjan[1], A. Abbara[1], A. Patel[1], S. Clarke[1], G. Chia[1], P. Eng[1], M. Phylactou[1], A. Comninos[1], S. Lavery[2], G. Trew[2], R. Salim[2], R. Rai[2], T. Kelsey[3], W. Dhillo[1]

[1]*Imperial College London, Department of Endocrinology and Investigative Medicine, London, United Kingdom*

[2]*Hammersmith Hospital- Imperial College Healthcare NHS Trust, IVF Unit, London, United Kingdom*

[3]*University of St Andrews, School of Computer Science, St Andrews, United Kingdom*

Study question: What is the relationship between recombinant FSH (rFSH) dose and follicular growth during controlled ovarian stimulation?

Summary answer: A sufficient weight-adjusted starting dose of rFSH reduces variability in follicle size by time of trigger and maximises the number of mature oocytes retrieved.

What is known already: A key factor determining success of IVF treatment is the induction of sufficient ovarian follicular growth in response to exogenous FSH administration. This must be balanced against the risk of excessive stimulation that could lead to an uncontrolled response, increasing the risk of the life-threatening complication 'ovarian hyperstimulation syndrome' (OHSS). Choosing an appropriate starting dose of rFSH can be challenged by inter-individual variability in response. A number of algorithms / nomograms have been developed to predict oocyte number to assist clinicians in choosing an appropriate starting dose, but limited data exists to directly relate rFSH dose to follicle growth.

Study design, size, duration: We performed a single centre retrospective cohort study of 1,034 GnRH antagonist co-treated and 103 GnRH agonist co-treated IVF treatment cycles (n=1,137) conducted between January 2012 and January 2016, who had ovarian stimulation by rFSH (Gonal F) alone.

Participants/materials, setting, methods: Women treated with rFSH alone for controlled ovarian stimulation during IVF treatment at Hammersmith Hospital, London, UK. Size of each individual follicle at every monitoring ultrasound scan and rFSH doses were analysed. The main outcome measure was median follicle size after five days of rFSH and the proportion of antral follicles recruited by the end of stimulation.

Main results and the role of chance: Serum FSH level correlated with rFSH dose adjusted for weight (r^2=0.352, p<0.0001). Starting rFSH dose (iU/kg) was associated with both median follicle size after five days, and the proportion of antral follicles recruited. Day 5 median follicle size predicted median follicle size on subsequent ultrasound scans (r^2=0.58-0.62; p<0.0001), and hence time to oocyte maturation trigger (r^2=0.22, P<0.0001). The dose-response relationship was lost in predicted poorer responders (age ≥35 years and antral follicle count ≤15) who were treated with doses greater than 2.25iU/kg. The proportion of follicles 12-19mm in diameter (which are most likely to yield mature oocytes) at the end of stimulation significantly increased with starting dose of rFSH and was associated with an increased number of mature oocytes retrieved. Insufficient starting dose of rFSH that required >5% dose-increase was associated with increased variability in follicle size on the day of oocyte maturation trigger, and negatively impacted the number of mature oocytes retrieved. Median follicle size after 5 days of rFSH was reduced in the 103 GnRH agonist co-treated cycles when compared to an equivalent subset of GnRH antagonist cycles (age 18-34 years, AFC 15-25).

Limitations, reasons for caution: This study was limited by its retrospective nature and variation in the day of monitoring ultrasound scans. Prospective studies to evaluate weight-adjusted doses of rFSH are required to investigate this relationship further.

Wider implications of the findings: These data inform the selection of rFSH dose to tailor follicular recruitment according to individual patient-need, for example to manage the risk of OHSS. Adjusting rFSH dose during the stimulation phase increases variability in follicle size by the end of stimulation and negatively impacts the number of mature oocytes.

Trial registration number: The trials were registered on the National Institutes of Health Clinical Trials database (NCT01667406).

P-668 Effects of follicular fluid and serum vitamin D levels on IVF outcome

A. Mitra[1], M. Bhattacharya[1], S. Kundu[2], J. Bhattacharya[2]

[1]*A.H IVF & Infertility Research Centre, Embryology, Kolkata, India*

[2]*A.H IVF & Infertility Research Centre, Gynecology, Kolkata, India*

Study question: Is there any association between vitamin D levels in serum and follicular fluid (FF) with IVF outcomes in infertile women of Asian population?

Summary answer: Different concentrations of vitamin D in serum and FF have a significant correlation with the number of mature oocytes, fertilization rate and clinical pregnancy rate.

What is known already: According to current studies vitamin D in complex with its receptor, by regulating gene expression, endometrial immune response and stimulation of endometrium decidualization can be involved in implantation. The recent evidence indicates that the amount of vitamin D in follicular fluid may have the potential effects on ovarian function, endometrial receptivity, embryo maturation and embryo quality. The results regarding the effect of vitamin D on clinical pregnancy outcomes in assisted reproductive technologies are still now conflicting.

Study design, size, duration: A prospective cohort study was conducted in a private infertility center, Kolkata, India. In this study 76 infertile women were included who were all aged below 40 years and underwent In Vitro Fertilization (IVF) treatment after taking their written consent between November 2017 to November 2018.

Participants/materials, setting, methods: Stimulation protocol was same for all of them, long protocol of induction ovulation. Serum sample was collected for baseline endocrine profiling and vitamin D estimation. Serum Vitamin D was also checked on the day of HCG (human chorionic gonadotropin) triggering. FF was extracted from follicles over 14 mm. FF and blood samples were centrifuged and then level of 25-OH-vit D was measured by immunoassay method. Number of oocytes, fertilization rate and pregnancy outcome were noted.

Main results and the role of chance: A significant correlation was found between the levels of vitamin D in follicular fluid and serum (p = 0.001). The data regarding to baseline characteristics including age, endocrine profile, type and cause of infertility, endometrial thickness, and number of transferred embryos were similar between women with different serum and follicular fluid 25OH-D levels. Study population has been divided into three groups according to serum vitamin D status: 60% had vitamin D deficiency (group A), 20% had vitamin D insufficiency (group B) and 20% had replete vitamin D status (group C). The overall rates of clinical and ongoing pregnancy were 23.2% (n=19), 29.3% (n= 24) and 35.5% respectively. No significant difference was found in pregnancy rates and 25OH-D level in FF (p = 0.949, 0.985 and 0.614, respectively). The fertilization rate decreased significantly and the implantation rate increased (not significantly) with increasing 25OH-D level in FF. The fertilization rates associated with these three levels of vitamin D were 43.17%, 53.37%, and 58.77 %, respectively, (P = 0.055). No significant correlation was seen between the pregnancy rate and FF vitamin D level (P = 0.170), but the serum vitamin D levels showed a significant correlation (P = 0.000) with increasing pregnancy rate.

Limitations, reasons for caution: This study evaluated vitamin D levels from the follicles above 14mm only, but we haven't study the Vitamin D level in individual follicle of the same patients. We also did not measure vitamin D binding globulin level (VDBP) and oocyte quality. Also our study is based on Asian population only.
Wider implications of the findings: Vitamin D has an impact on IVF outcomes. As serum and FF vitamin D has a significant correlation, it is highly recommended to measure the vitamin D level before undergoing IVF procedure and if required vitamin D supplementation should be considered prior to the treatment to increase the success rate.
Trial registration number: Not applicable

P-669 Predicting accumulated pregnancy rates before IVF according to woman´s age and AMH.

E. Santiago Romero[1], P. Blanca[1], M. Esther[1], G.D.M. Laura[1]
[1]clinician, Gynecology, Madrid, Spain

Study question: To determine whether the use of AMH and the age of the woman can predict the accumulative pregnancy probability before starting an IVF treatment.
Summary answer: IVF accumulative pregnancy outcomes are affected in a statistically significant way by the association between woman´s age and AMH.
What is known already: IVF outcomes will strongly depend on ovarian reserve, as the more eggs we obtain, the greater the chances will be. In the same way, accumulative pregnancy rates will increase depending on the number of good quality embryos obtained. Furthermore, chances of success will depend on woman´s age, as egg quality decreases with time.

Ovarian reserve will decrease with women´s age, but there is a great variability between each case, so it is very important to estimate ovarian reserve with a vaginal ultrasound to see the number of antral follicles and compare this with AMH blood value.
Study design, size, duration: Retrospective study of 80 patients who did an AMH and follicle count before IVF at our center during 2017-2018. The main aim was to study the association between AMH with age and the probability of accumulative pregnancy. Secondary outcome variables were antral follicle count, number of follicles equal or greater than 16mm measured before trigger, number of eggs obtained after retrieval, number of mature eggs microinjected, and number of good quality blastocysts obtained.
Participants/materials, setting, methods: IVF cycles included were performed with ICSI and blastocyst culture. 97% were single embryo transfers. Exclusion criteria were donor´s sperm, testicle biopsy, severe masculine factor, severe endometriosis and PGS cycles.

Logistic regression was performed to assess the association between AMH and age with probability of accumulated pregnancy. Lineal regression was performed to study the association between AMH and age with secondary outcome variables.

P below 0.005 was considered statistically significant and no significant above 0.05.
Main results and the role of chance: In our study group, the total accumulative pregnancy rate was 40.2%.

Global significance test shows that the association between AMH and age can predict the probability of pregnancy in a significant way. When we asses both parameters by themselves, we found out that each ng/ml more of AMH will multiply the probability of pregnancy by 1.36 in a significant way ($p<0.03$), however the older the women, the probability will decrease by multiplying it by 0.98 but in a non-significant way ($p=0.77$).

The association between AMH and age compared to secondary outcomes showed that either the antral follicle count, the number of follicles greater than 16mm before trigger, the number of eggs obtained after retrieval, the number of mature eggs microinjected, and the number of good quality blastocysts obtained increased in a significant way with higher AMH values ($p<0.001$). Nevertheless, this association was not significant when compared to woman´s age.
Limitations, reasons for caution: Many variables can influence pregnancy outcomes, therefore the prediction based in AMH and age has 30.3% sensibility but an 85.71% specificity.

Due to the statistical design and sample size, more studies are needed to obtain an accurate model to predict accumulative pregnancy rates before IVF.
Wider implications of the findings: Although age does not influence in a significant way regarding all the stimulation and laboratory parameters mentioned, the older the woman is, the lower the embryo quality will be. This means that despite an older woman has a good ovarian reserve, pregnancy outcomes will be worse than younger women.
Trial registration number: not applicable

P-670 Can cytochrome P450 2D6's polymorphism explain the variability in clinical response to clomiphene citrate in infertile women with ovulation disorders ?

C. Robin[1], B. Hennart[2], F. Broly[2], D. Dewailly[3], S. Jonard[1]

[2]Centre de Biologie Pathologie - Chru Lille, Nord, LIlle, France
[3]Université Henri Warembourg, Nord, Lille, France

Study question: Is it a link between the cytochrome genotype and the response to clomiphene citrate?
Summary answer: The genetic polymorphism of cytochromes P450 2D6 does not appear to influence the clinical response to clomiphene citrate used in the induction of ovulation.
What is known already: Cytochrome P450 2D6 participates in the metabolism of many drugs. It has a genetic polymorphism responsible for four different metabolic phenotypes. The genotype of this protein is used to predict the efficacy and / or adjust the dosages of certain drugs, including tamoxifen, which is similar in structure to clomiphene citrate, used in the induction of ovulation. The response to this treatment, which is very often proposed in the management of dysovulation of polycystic ovarian syndrome (PCOS), is variable and no predictive factor has been identified at this time.
Study design, size, duration: This is a retrospective, observational, unicentric study performed in our institution, from July 2005 to January 2018, concerning 77 patients aged 20 to 39 years. All patients signed informed consent for genetic study and data analysis.
Participants/materials, setting, methods: Seventy-seven patients with ovulation disorders treated with clomiphene citrate benefited from the cytochrome P450 2D6, 3A4 and 3A5 genotype study. Response predictions have been established based on these genetic examinations. The ovarian response was assessed by ultrasound at the tenth day of the cycle and by the dosage of progesteronemia 9 days after the expected date of ovulation. The response predictions according to the genetic status of cytochromes were compared with the observed clinical responses.
Main results and the role of chance: Regarding their genotype, 4 patients with limited metabolizers were detected, including 1 patient with a homozygous deletion of the CYP2D6 gene. In contrast, 5 ultra-rapid, 41 normal and 27 intermediate metabolizers were included. For response predictions according to the combination of the three cytochromes, the concordance between the response predictions and the actual responses was 36.71%, with a negative Kappa coefficient ($K = -0.0240$), which corresponds to a big disagreement. Similarly, for predictions based on the genetic status of cytochrome P450 2D6 alone, only 39.24% of predictions were verified (coefficient $K = -0.0609$). Several mechanisms may explain our results. The metabolism of clomiphene citrate may be different than the one supposed. There are probably unknown mutations of the cytochroms, thus modifying the predicted phenotypes.
Limitations, reasons for caution: The strength of our population is the presence of "extreme" phenotypes. Nevertheless, the number of these phenotypes remains low and it follows a lack of power of our study. It is therefore a first study, the results of which need to be confirmed by other broader studies with higher numbers.
Wider implications of the findings: This study shows that the CYP2D6 phenotype is not correlate with the clinical response to clomiphene citrate in female dysovulatory infertile women. Broader studies are necessary to define the predictors of response to this treatment commonly used in gynecology. Our study brings elements on the metabolism of clomiphene citrate.
Trial registration number: not applicable

Table I The distribution of different genotypes association in low and normal ovarian reserve groups.

Variable	TP53/TT+TP73/GG	Other genotypes association	*P*	OR	95% CI
n	26	113			
Age (y)	33.9±3.5	33.5±2.8	0.56		
AMH (ng/mL)	0.95±1.3	2.62±3.6	0.0001		
AFC (2-9mm)	8.3±5.5	15.4±11.4	<0.0001		
Groups					
Low ovarian reserve (AMH<1+AFC≤9)	22 (84.6%)	58 (51.3%)	0.004	5.2	1.6-16.1
Normal ovarian reserve (AMH≥2+AFC≥15)	4 (15.4%)	55 (48.7%)			

P-671 Association between TP53 (rs1625895) and TP73 (rs3765730) polymorphisms can help in the prediction of low ovarian reserve.

J.B.A. Oliveira[1,2], L.D. Vagnini[2], A. Renzi[2], B. Petersen[1,2], C.G. Petersen[1,2], A.L. Mauri[1,2], M. Mattila[1], A. Nicoletti[1], F. Dieamant[1,2], R. Baruffi[1,2], J.G. Franco Jr[1,2]

[1] *Centre for Human Reproduction Prof Franco Jr, Research, Ribeirao Preto, Brazil*

[2] *Paulista Center for Diagnosis Research and Training, Research, Ribeirao Preto, Brazil*

Study question: Is low ovarian reserve associated with TP53 and TP73 polymorphisms?

Summary answer: The association between TP53/TT (rs1625895) and TP73/GG (rs3765730) genotypes can help in the prediction of low ovarian reserve

What is known already: The ovarian reserve is a complex clinical phenomenon influenced not only by age but also by external pathogenic factors and genetic abnormalities. Research on new ovarian biomarkers is being developed to ensure optimal patient care and true personalization of ovarian stimulation. The p53 family members are powerful transcription factors and small variations in their DNA structure can modify gene expression patterns. The TP53 gene is involved in genomic stability and regulation of blastocyst implantation and TP73 gene controls the meiotic spindle, but the influence of these genes on the ovarian reserve is still unclear.

Study design, size, duration: All of the recruited women (n:139) met the following inclusion criteria: age ≤37years, normal karyotype, ultrasound evidence of the two ovaries and no ovarian surgery, endometriosis, hydrosalpinx, infections or endocrine problems. The women were divided into two groups according to their Anti-Müllerian hormone/AMH (ng/ml) levels and antral follicle count/AFC (2-9mm), evaluated during the early follicular phase:

-Low ovarian reserve (LOR/n=80): AMH<1+AFC≤9
-Normal ovarian reserve (NOR/=59): AMH≥2+AFC≥15

Participants/materials, setting, methods: DNA was extracted from peripheral blood samples taken from LOR and NOR groups. DNA was sequenced on MiSeq/Illumina to search for single nucleotide polymorphisms (SNPs) in the TP53 and TP73 genes. SNPs found by Next-Generation Sequencing (NGS) were analysed to find a possible association with LOR. Statistical analyses were performed to evaluate the power of the association between TP53 and TP73 polymorphisms and LOR. All statistical tests were considered significant at a level of $P<0.05$.

Main results and the role of chance: The TP53 T>C (rs1625895) and TP73 G>A (rs3765730) SNPs were identified by NGS associated to low ovarian reserve. The association of TP53/TT and TP73/GG genotypes was more frequent in the LOR group, leading to a 5.2-fold increase in the chance of women being included in this group when compared with women in the normal ovarian reserve group. Table I shows the results.

Limitations, reasons for caution: Additional validation of the SNPs analysed would be important to provide more information about the relationship of theses polymorphisms and ovarian reserve, once sample size was limited despite recruiting all eligible participants during the study period. Differences in the genetic backgrounds of various ethnic populations should also be considered.

Wider implications of the findings: The SNPs identified could provide an additional tool to test ovarian reserve, helping in the individualization of ovarian stimulation protocols. To the best of our knowledge this is the first study relating the association between TP53/TT (rs1625895) and TP73/GG (rs3765730) genotypes and low ovarian reserve.

Trial registration number: Not applicable. The local ethics committee authorised the study. Merck Grant for Fertility Innovation (GFI-2014-16) supported this study.

P-672 Baseline hyperandrogenemia and oocyte maturation in women undergoing in vitro fertilization

L. Sekhon[1], D. Cassis, Marie[2], C. Hernandez-Nieto[2], D. Gounko[2], J. Lee[2], T. Mukherjee[1], B. Sandler[1], A. Copperman, B.[1]

[1] *Icahn School of Medicine at Mount Sinai, Obstetrics- Gynecology and Reproductive Science, New York, U.S.A.*

[2] *Reproductive Medicine Associates of New York, Research, New York, U.S.A.*

Study question: Do women with baseline hyperandrogenemia have differential ovarian response, oocyte maturation, and/or embryo quality as compared to normoandrogenemic women?

Summary answer: Despite greater ovarian reserve, hyperandrogenemic patients had similar oocyte yield, blastulation, and aneuploidy compared to normoandrogenemic women. Hyperandrogenemia was associated with reduced oocyte maturity.

What is known already: While serum androgen levels have been proposed to have an important impact on early follicular development and granulosa cell proliferation, the relationship with ovarian stimulation outcome and on oocyte/embryo development remains unclear. In women with diminished ovarian reserve, treatment with exogenous androgens has been used to increase oocyte quantity and quality. Conversely, hyperandrogenemia has been proposed as a cause for reduced oocyte maturity and quality in patients with polycystic ovarian syndrome (PCOS). To clarify the relationship between endogenous androgens and oocyte/embryo maturity and quality, we examined the relationship between baseline hyperandrogenemia and the outcome of ovarian stimulation for IVF.

Study design, size, duration: This is a retrospective cohort study, including 97 hyperandrogenemic patients (69.4% PCOS; 4.7% congenital adrenal hyperplasia (CAH)) and 635 normoandrogenemic patients (72.9% PCOS; 5.0% CAH) who underwent 162 and 996 IVF cycles, respectively. Patients underwent testing of serum androgen levels as part of routine fertility work up prior to undergoing IVF. Approximately half of the cycles in both the subject and control group involved the utilization of preimplantation genetic screening (51.9% vs 51.4%, respectively).

Participants/materials, setting, methods: Patients, from 2010 to 2017, who underwent serum free testosterone and DHEAS testing and were categorized as hyperandrogenemic or normoandrogenemic. PCOS was diagnosed according to Rotterdam criteria. Baseline demographics, ovarian reserve, response to stimulation, oocyte yield, IVF laboratory outcomes, and embryo quality were compared using student's t-test and chi-square test. Multivariate linear and logistic regression analyses (controlling for age and ovarian

reserve) assessed whether baseline hyperandrogenemia associated with ovarian response, embryo development, and embryo ploidy.

Main results and the role of chance: Hyperandrogenemic patients with elevated serum free testosterone (95.8 ± 155.4 vs. 24.4 ± 17.7, p<0.0001) and DHEAS (523.4 ± 1066.9 vs. 171.3 ± 82.9, p<0.0001) were similar in age (34.3 ± 4.8 vs. 34.8 ± 5.0, p=0.3), compared with controls. Study patients had increased anti-mullerian hormone (AMH) levels (8.5 ± 13.1 vs. 5.0 ± 5.7, p=0.008) and basal antral follicle count (BAFC) (17.6 ± 11.3 vs. 15.4 ± 9.8, p=0.04). Groups significantly differed by stimulation protocol, with a higher proportion of GnRH antagonist protocol use in hyperandrogenemic patients (75.3% vs. 67.1%, p=0.04) and GnRH agonist downregulation in controls (18.1% vs. 9.9%, p=0.003). The cumulative gonadotropin dosage was similar (3249.3 ± 1854.1 vs. 3057.9 ± 1417.2, p=0.2) among groups. Controlling for age and ovarian reserve, study patients received more days of ovarian stimulation as compared to controls (β=0.5, p=0.0007). Hyperandrogenemia was not associated with the odds of cycle cancellation due to lack of response (OR 1.35 (95% CI 0.68-2.69), p=0.4), the number of eggs retrieved (β= -0.8, p=0.3), the degree of blastulation (β=0.0004, p=0.9), blastocysts amenable to trophectoderm biopsy (β=0.03, p=0.4), and the degree of embryonic aneuploidy (β= -0.009, p=0.8). Patients with baseline hyperandrogenemia had reduced oocyte maturity (β=-0.04, p=0.04).

Limitations, reasons for caution: This analysis is retrospective, and therefore vulnerable to confounding bias. While the multivariate model aimed to account for possible confounders, our findings should be supported by future studies that prospectively analyze the effect of hyperandrogenemia on ovarian stimulation in all patients, accounting for their ovulatory status and underlying diagnosis.

Wider implications of the findings: Baseline hyperandrogenemia was not correlated with egg/embryo yield or quality. However, there was an association with reduced oocyte maturity. Further studies should assess whether hyperandrogenemic patients with poor oocyte maturity in prior cycles could benefit from androgen suppression treatment prior to stimulation, and/or increased stimulation duration.

Trial registration number: This study was approved by the Western Institutional Review Board (Study Number: 1167398).

P-673 Follitropin delta in real-life clinical practice: short term AMH variation and treatment outcomes

K. Neumann[1], M. Depenbusch[1], A. Schultze - Mosgau[1], T. Osterholz-Zaleski[1], G. Griesinger[1]

[1]University of Schleswig-Holstein- Campus Luebeck, Section of Reproductive Medicine, Lübeck, Germany

Study question: How often and to what extent does short term AMH variation affect follitropin-delta (FD) dosing and what is the treatment outcome in high AMH patients?

Summary answer: Short term serum AMH level variation affects dosing of FD in approximately 50% of patients by a magnitude of 1.6±1.3 µg/d dose change.

What is known already: Dosing of FD is based on a distinct algorithm utilizing one serum AMH value (measured within 12 months before treatment in one distinct ELISA) and body weight. Short-term intra-individual AMH and body weight variation could cause dosing inconsistencies.

The phase-III trial ESTHER-1 (Nyboe-Andersen et al., 2017) reported less patients with excessive ovarian response and OHSS/preventive interventions for patients receiving an individualized FD dose in a cohort of patients with a mean AMH level of only 2.28 ng/ml and a mean body weight of 64.7 kg. In the ESTHER-1 trial patients with cycle irregularities and BMI >32.0 kg/m^2 were excluded.

Study design, size, duration: Analysis of all patients receiving FD for ovarian stimulation for IVF/ICSI. At treatment planning, patients' most recent AMH and body weight were used for prescribing FD, and weight and AMH were determined again on treatment cycle-day 2/3 (and the dosage changed, if necessary). The target ovarian response was defined as 8-14 cumulus-oocyte-complexes (COCs) alike to the ESTHER-1 study. Weight and AMH are expressed as ±standard deviation (SD). The study is ongoing.

Participants/materials, setting, methods: AMH levels measured within 12 months and ad-hoc body weight was used for initial dosing. On the first day of follitropin delta injection, AMH and body weight were re-assessed and FD dose was adjusted accordingly. COC numbers in FD and previous and/or following controlled ovarian stimulation (COS) cycles using conventional FSH were analysed for intra-individual response comparison. AMH assessment was conducted using the Roche Elecsys ELISA AMH assay.

Main results and the role of chance: 74 patients (mean age 33.2±4.1 years) with 79 FD COS cycles and 61 cycles with complete bodyweight and AMH data were included in this analysis. 13 patients were diagnosed with cycle irregularities (oligomenorrhea). The mean body weight was 69.5±16.4 kg on first and 70.6±14.4 kg on second assessment. Mean AMH was 4.8±3.6 ng/ml on first and 3.9±2.5 ng/ml on second assessment, respectively. Accordingly, there was a dose change of, on average, 1.6±1.3 µg/d FD in 31 out of 61 cycles (50%, 95%CI: 37 - 62%).

A target response in COC numbers was achieved in 35 patient cycles (44%, 95% CI: 35-53%). Interestingly, 14 out of 67 (20.9%) patients with AMH levels >2 ng/ml showed a hyporesponse with less than eight COCs including three patients who had cancelation of the COS cycle. No predictor for hypo-response (age, body weight, size, daily or total FD dose, duration of stimulation, AMH levels or cycle irregularities) could be identified in this subgroup. A hyper-response with >14 COCs was observed in 25 patient cycles (31.6%, 95% CI: 21 - 41%). In 16 out of 50 (32% 95% CI: 18 - 45%) cycles having a fresh a fresh embryo transfer, a pregnancy was achieved.

Limitations, reasons for caution: The cohort is small and the study uncontrolled. Patients at risk of hyperresponse as well as patients with irregular cycles were included.

Wider implications of the findings: AMH and body weight changes which cause FD dose change occur frequently. A risk of underexposure to FSH and thereby hyporesponse for some patients with normal to high AMH needs to be explored by further investigations.

Trial registration number: not applicable

P-674 Initiation of ovarian stimulation independent of the menstrual cycle (random-start) in an egg donor program: a one-year single center experience.

J.C. Castillo[1], J. Guerrero[1], R. Delgado[2], B. Moliner[1], L. Luque[1], J. Ten[1], A. Fuentes[1], A. Herencia[1], D. Bodri[1], P. Cirillo[1], A. Bernabeu[1], J. Llácer[1], R. Bernabeu[1]

[1]Instituto Bernabeu, Assisted Reproduction Unit, Alicante, Spain
[2]ACCUNA, Assisted Reproductive Unit, Alicante, Spain

Study question: Are the cycle and reproductive outcomes after randomly initiating ovarian stimulation during the mid to late-follicular/luteal phase versus conventional protocols in egg-donors similar?

Summary answer: The oocyte yield and competence from random-start ovarian stimulation appears comparable to conventional protocols in egg-donors. Luteal-phase stimulation requires longer stimulation and higher FSH consumption.

What is known already: Recently, random-start ovarian stimulation protocols have emerged as an alternative to conventional ovarian stimulation allowing treatment to begin independently of the day of the cycle. Random-start protocols have been well studied in oncologic patients for fertility preservation and in women who desire "elective" cryopreservation of oocytes, resulting in optimal outcomes. A recent pilot study has also explored this protocol in oocyte donors (NCT02821819). In the context of an egg donation program, if ovarian stimulation can be initiated irrespective of the phase of the menstrual cycle without adversely impacting oocyte yield or quality, the approach may facilitate schedules.

Study design, size, duration: Retrospective analysis of egg-donation cycles (n=805) performed between January and November 2018. Egg-donor cycles starting stimulation on day 1-3 of the cycle were compared to egg-donor cycles initiating the ovarian stimulation independently of the menstrual cycle (day 4 onwards). The cycle, laboratory and clinical outcomes per embryo transfer in matched recipients (n=455) receiving a fresh embryo-transfer were also assessed.

Participants/materials, setting, methods: Egg-donors were stimulated following a conventional antagonist protocol and started stimulation with 150-300 IU/day uFSH (according to AFC/BMI) on day 1-3 of the menstrual cycle

(n=203) or alternatively in mid to late (Day 4-14) follicular phase (n=375) or luteal (Day 15-29) phase (n=227). A GnRH agonist was used for final triggering. Donors in the random-start group were not using OC pills the month before starting ovarian stimulation. Cycles were performed in a private IVF center.

Main results and the role of chance: Overall, baseline and cycle characteristics were similar between conventional vs random-start stimulation cycles with regards to: age, AFC, BMI, total dose of gonadotropins, duration of stimulation and days of GnRH-antagonist use. Additionally, the number of collected eggs were also similar: 17.49 ±8.9 vs 17.46 ±8.4, p=0.9, respectively.

A sub-group analysis showed an increased number of days of stimulation (10.4 ± 1.7 vs 9.8 ± 1.7 vs 10.2 ± 1.7, p=0.001) and gonadotrophin consumption (IU) (2171 ± 684 vs 2003 ± 647 vs 2037 ± 647, p=0.01) in the luteal phase group vs the mid/late follicular and conventional groups; respectively. Importantly, in matched recipients receiving a fresh embryo-transfer, the pregnancy rates (%) (62,7 vs 63,7 vs 63,4) and clinical pregnancy rates (%) (52.1 vs 55.7 vs 53.5) per embryo-transfer were similar between these sub-groups. Additionally, the mean number of transferred embryos 1.1 ± 0.3 vs 1.2 ± 0.4 vs 1.1 ± 0.3 and the number of surplus blastocyst stage embryos for freezing (3.1 ± 1.9 vs 3.1 ± 1.9 vs 2.7 ± 1.8) were also similar between sub-groups.

Limitations, reasons for caution: The inherent limitations of a retrospective design. Additionally, studies need to be conducted in the future including preimplantation genetic testing for aneuploidies (PGT-A) in embryos coming from the cohorts of oocytes obtained after random-start protocols and especially in terms of peri/post-natal outcomes to confirm the safety of random-start protocols.

Wider implications of the findings: These data, from a retrospective study design, shows that ovarian stimulation can be initiated regardless of the day of the menstrual cycle in egg donors without adversely impacting oocyte yield or competence; the approach may facilitate schedules in egg donation programs.

Trial registration number: Not applicable

P-675 TGF-β1 promotes hyaluronan synthesis by upregulating hyaluronan synthase 2 expression in human granulosa-lutein cells

F. Wang[1], H.M. Chang[2], H. Li[1], P.C.K. Leung[2]

[1]*The Affiliated Suzhou Hospital of Nanjing Medical university- Suzhou Municipal Hosipital, Reproductive and Genetic center, Suzhou, China*

[2]*The university of British Columbia, Department of Obestetrics and Gynaecology, Vancouver, Canada*

Study question: The aim of this study was to explore the effects and the underlying molecular mechanism of Transforming growth factor-β(TGF-β)1 on hyaluronan(HA)production in primary and immortalized human granulosa-lutein cells.

Summary answer: We demonstrated that TGF-β1 significantly increased the production of HA through up-regulation of HA synthase 2(HAS2) in human granulosa lutein cells.

What is known already: HA is the major component of extracellular matrix(ECM)of the cumulus oocyte complex (COC). HA-mediated ECM remodeling plays a pivotal role in antral formation and ovulation. TGF-β1 is an important cytokine in regulating follicular development including the ovulation processes. TGF-β1 participates in the process of extracellular matrix deposition in patients with chocolate cyst or PCOS. Moreover, also belonging to the TGF-β superfamily, our previous data showed that BMP4, BMP6, BMP7 are involved in the regulation of HA production. Taken together, we hypothesized that TGF-β1 may involve in the ECM synthesis in COC expansion via targeting HA synthesis in human granulosa cells.

Study design, size, duration: This is an experimental study which was performed over a 1 year period.

Participants/materials, setting, methods: Primary human granulosa-lutein cells obtained from women undergoing IVF and immortalized human granulosa cells were used as study models. HAS2 mRNA and protein expression were studied after treating with TGF-β1. An TGF-β1 type I receptor inhibitor SB505124,and small interfering RNAs of SMAD2, SMAD3,SMAD4,SNAIL,ALK4 and ALK5 were transfected to the cell models to explore the effects of TGF-β1 on HAS2 regulation. ELISA was used to evaluate the expression level of hyalurona.

Main results and the role of chance: For the first time, we demonstrated that TGF-β1 significantly increased the production of HA through up-regulation of HA synthase 2(HAS2), not through HA synthase 1 or 3, or HA degradases in human granulosa lutein cells. We confirmed TGF-β1 type II and type I receptors were associated with the TGF-β1-induced HA production by using the inhibitors of the receptors. Using small interfering RNA knockdown technique, we further demonstrated that the up-regulation of TGF-β1-induced expression of HAS2 and HA production was mediated by SMAD2, SAMD3 and SNAIL.

Limitations, reasons for caution: The results were conducted in the in vitro system and may not reflect the intra-ovarian microenviroment in vivo

Wider implications of the findings: Our study for the first time demonstrated that TGF-β1 induced HAS2 expression and enhanced HA synthesis. Both SMAD2 and SMAD3 independently contributed to TGF-β1-induced production of HAS2. Knocking down of SNAIL expression impaired HA generation. These results provides us new insights on HA production in human granulosa cells.

Trial registration number: NA

P-676 Poor ovarian response according to the Bologna criteria is associated with an increased aneuploidy rates in women undergoing preimplantation genetic testing for aneuploidy (PGT-A)

B. Demir[1], N. Fındıklı[2], M. Gultomruk[3], K. Boynukalin[4], M. Bahceci[4]

[1]*Bahceci Health Group- Ankara IVF Center, Obstetrics and Gynecology, Ankara, Turkey*

[2]*Bahceci Health Group, Embryology Laboratory, Istanbul, Turkey*

[3]*Bahceci Health Group- Fulya IVF Center, Genetics, Istanbul, Turkey*

[4]*Bahceci Health Group- Fulya IVF Center, Obstetrics and Gynecology, Istanbul, Turkey*

Study question: Does poor ovarian response (POR) defined by Bologna criteria have an impact on the aneuploidy rate in cycles undergoing preimplantation genetic testing for aneuploidy (PGT-A)?

Summary answer: Embryos of patients with poor ovarian response defined by Bologna criteria are found to associated with an increased aneuploidy rate when compared to normo-responders.

What is known already: It is well known that advancing maternal age negatively affects both oocyte quality and quantity. However, the impact of ovarian reserve on the oocyte aneuploidy, independently from the female age is still controversial. Moreover, defining "poor ovarian response" itself is still one of the unresolved issues of contemporary infertility management and treatment. Bologna criteria has recently been proposed and so far increasingly used internationally to define POR. Its main goal is to minimize these definition-related discrepancies and maximize the comparability of the published literature.

Study design, size, duration: This is a retrospective cohort study performed between January 2013 and September 2018. Patient records were analyzed and grouped according to normal or poor ovarian response defined by the Bologna criteria. 2123 ICSI cycles undergoing PGT-A for the indications of unexplained repeated pregnancy loss, unexplained repeated implantation failure and advanced maternal age were included. After evaluation, 318 of these cycles were found to be belonged to women with POR and 1805 were from normo-responders.

Participants/materials, setting, methods: A total of 5117 embryos were biopsied and trophectoderm biopsy materials were tested by either aCGH (between 2013 – 2016) or NGS (2016-2018) or aCGH for PGT-A. Demographic features, controlled ovarian stimulation characteristics, and embryology laboratory results were compared. The aneuploidy rates were also subjected to a subgroup analysis based on women's age.

Main results and the role of chance: Poor ovarian response group (POR) was significantly higher aneuploidy rate compared with normo-responders (NR) (74% vs. 63%, p=0.0001). Subgroup analysis according to the woman age also showed higher aneuploidy rates except in the most young age group [(POR vs. NR, p): <30 years: 27.5 % vs. 42.5, p>0.05; 30-34 years: 69.4% vs. 49.8, p=0.003; 35-37 years: 54.5 vs. 56%, p>0.05; 38-39 years: 71.7% vs.

67.7%, p>0.05; 40-41 years: 84% vs. 78.9%, p=0.022; 42 years: 93.2% vs. 89.8, p>0.05].

Limitations, reasons for caution: Its retrospective nature is the main limitation of the study.

Wider implications of the findings: The findings of this study indicate that higher embryonic aneuploidy exists in cases with poor ovarian response based on Bologna criteria. An additional contribution of diminished ovarian reserve on the age-related aneuploidy rate should be taken in consideration a potential negative effect on the reproductive outcome.

Trial registration number: N/A

P-677 Higher risk of gestational diabetes mellitus (GDM) after assisted reproductive technologies (ART) compared with spontaneous conception in singleton pregnancies: a systematic review and meta-analysis

J. Bosdou[1], P. Anagnostis[1], D. Goulis[1], G. Lainas[1], B. Tarlatzis[1], G. Grimbizis[1], E. Kolibianakis[1]

[1]Aristotle University of Thessaloniki- Medical School, Unit for Human Reproduction-1st Dept. of Obstetrics and Gynecology, Thessaloniki, Greece

Study question: Are singleton pregnancies after ART associated with a higher risk of GDM compared with singleton pregnancies after spontaneous conception?

Summary answer: Singleton pregnancies after ART are associated with a higher risk of GDM compared with singleton pregnancies after spontaneous conception.

What is known already: Pregnancies resulting from ART have been associated with increased risks for obstetric and perinatal complications, such as preeclampsia, placental anomalies, preterm birth and increased caesarean sections, compared with spontaneous conception. However, it is not clear whether ART is associated with an increased risk of GDM. Several, recent, retrospective studies have evaluated the risk of GDM in singletons pregnancies resulting from ART compared with spontaneous conceptions. Thus it is feasible, by synthesizing the available evidence, to reach more solid conclusions.

Study design, size, duration: A systematic review and meta-analysis was performed aiming to identify studies comparing the risk of GDM in singleton pregnancies after ART and after spontaneous conception. For this purpose, a literature search was carried out until 20/01/2019.

Participants/materials, setting, methods: Matched and unmatched studies that compared the risk of GDM in singleton pregnancies following ART and spontaneous conception were included in the systematic review and meta-analysis. Studies were excluded if pregnancies were achieved after ovulation induction or intrauterine insemination. Meta-analysis of weighted data was performed using random effects model. Results were reported as risk ratio (RR) with 95% confidence interval (CI).

Main results and the role of chance: Thirty-two eligible studies (15 matched and 17 unmatched), published between 1995 and 2017, were eligible for the meta-analysis evaluating a total of 1,145,114 women. Diagnosis of GDM was made in 2,962 out of 36,367 women who underwent ART and in 61,267 out of 1,108,747 women who became pregnant spontaneously. In studies evaluating GDM after ART, *in vitro* fertilization (IVF) / intracytoplasmic sperm injection (ICSI) was performed in 16 studies, IVF in 13 studies and ICSI in three studies. Maternal age and parity were the most commonly used variables for matching pregnant women after ART with their counterparts after spontaneous conception. Additional matching variables included height, weight, ethnic origin and smoking.

Singleton pregnancies after ART were associated with higher risk of GDM compared with spontaneously conceived pregnancies (RR: 1.63, 95% CI: 1.43 to 1.85; heterogeneity: I^2=79%; random effects model; n=32 studies). A sensitivity analysis was performed using only the matched studies, without materially changing the direction or the magnitude of the effect (RR: 1.67, 95% CI: 1.33 to 2.01; heterogeneity: I^2=49.8%; random effects model; n=15 studies).

Limitations, reasons for caution: This systematic review and meta-analysis is based on observational studies and thus the presence of bias cannot be excluded. Moreover, the definition of GDM was not reported in the majority of studies. These limitations should be taken into account when interpreting the results obtained.

Wider implications of the findings: Women achieving pregnancy after ART should be monitored for GDM since the risk is increased compared with naturally conceived pregnancies. Whether this risk is attributed to the underlying infertility status of the couples undergoing ART as compared with those who conceived spontaneously, needs to be further explored.

Trial registration number: not applicable

P-678 A novel flexible progestin primed ovarian stimulation protocol for ART and its effect on oocyte yield compared to the flexible GnRH antagonist protocol

S. Yildiz[1], E. Turkgeldi[1], B. Angun[2], B. Ata[3]

[1]Koc University Hospital, Assisted Reproduction Unit, Istanbul, Turkey

[2]Dunya IVF Clinic, Assisted Reproduction Unit, Kyrenia, Cyprus

[3]Koc University Faculty of Medicine, Assisted Reproduction Unit, Istanbul, Turkey

Study question: Is pituitary suppression with medroxyprogesterone acetate (MPA) started on stimulation day seven or when the leading follicle is 14mm effective for ovarian stimulation for ART?

Summary answer: Flexible progestin primed ovarian stimulation(PPOS) with MPA effectively prevents premature ovulation and yields more oocytes than a flexible GnRH antagonist protocol with similar gonadotropin consumption.

What is known already: Currently, GnRH antagonists are the most commonly used agents for pituitary suppression in ovarian stimulation for ART. Progestins can also be used for preventing endogenous LH surge, when a fresh embryo transfer is not intended, e.g. freeze-all, oocyte cryopreservation, oocyte donation cycles. While various progestins have been used to this end, they have all been started at the beginning of stimulation simultaneously with gonadotropin. However, an LH surge is not imminent that early and whether progestins can effectively prevent a premature LH surge when started later in the cycle, like in a flexible GnRH antagonist protocol, is unknown.

Study design, size, duration: This is a retrospective analysis of 174 ovarian stimulation cycles of 87 oocyte donors between 2017 and 2018. Two stimulation cycles of the same donors, one with flexible GnRH antagonist and one with the new flexible PPOS, within a period of 6 months, were matched and compared. Thus, each woman acted as her own control, providing identical demographic and biological baseline characteristics, as would be in a randomized trial.

Participants/materials, setting, methods: Women were aged <35 years, had antral follicle count(AFC) of ≥20 and no contraindication to oocyte donation. 225IU/day rFSH was started on cycle day 2-3, 0.25mg/day GnRH antagonist or 10mg/day MPA was started on stimulation day 7 or when the leading follicle reached 14mm, whichever came first. 20IU leuprolide acetate was given when there were ≥3 follicles >17 mm. Data are defined with median (25^{th}– 75^{th}percentile). Wilcoxon signed rank test was used for comparisons.

Main results and the role of chance: There was a total of 87 donors who underwent both the flexible PPOS and GnRH antagonist cycles within six months during the study period. Mean age, body mass index and AFC were 25.46 years, 21.23 kg/$m^2$and 44, respectively. The duration of stimulation was 11 (10-11) days in both groups (p=0.13). Total gonadotropin consumption was similar with 2475 (2250 – 2475) IU in the flexible PPOS group and 2400 (2250 – 2475) IU in the GnRH antagonist group (p=0.35). Pituitary suppression was started similarly on day 7 (7-8), (p=0.37), and lasted similarly for 5 (5-6) days (p=0.37). There were no premature ovulations in flexible PPOS or GnRH antagonist cycles. The flexible PPOS cycles yielded a significantly higher number of cumulus oocyte complexes (COC) than GnRH antagonist cycles [33 (21-39) vs 26 (18-36), respectively; p=0.02]. Likewise, the flexible PPOS cycles generated significantly more metaphase-two oocytes than GnRH antagonist cycles [24 (17-34) vs 21 (15-28), respectively; p<0.01].

Limitations, reasons for caution: Retrospective design has limitations, however, participants acting as own controls ensures similar baseline characteristics between study groups. Although higher oocyte yield is associated with higher cumulative pregnancy rates and previous studies of progestin priming suggest comparable implantation, pregnancy and live birth rates, the unavailability of this information is a limitation.

Wider implications of the findings: The flexible PPOS can provide significantly more oocytes and an opportunity to choose pituitary suppression protocol later in the cycle depending on ovarian response and other factors,

e.g. switching to flexible PPOS from an intended flexible GnRH antagonist in case of unexpected excessive ovarian response requiring a freeze all policy.
Trial registration number: None

P-679 Effectiveness of Bariatric Surgery on Infertility in Morbidly Obese PCOS and non-PCOS Women

R. Nayak [1], D. Gunasheela [1], W.-Y. Son [2], V.K. Kariyappa [1]
[1] *Gunasheela Surgical and Maternity Hospital, General and Gastrointestinal Surgery, Bangalore, India*
[2] *Mc Gill University, Dept. of Embryology, Montreal, Canada*

Study question: What are the effects of bariatric surgery-induced weight loss on various endocrine parameters and pregnancy in infertile women with and without PCOS ?
Summary answer: Bariatric surgery showed favorable effects on certain parameters as well as in managing other metabolic co-morbidities like impaired OGTT, serum insulin levels, and successful pregnancy.
What is known already: Obesity has negative effects on fertility and IVF outcomes, and possibly also on AMH levels and other metabolic parameters.
Study design, size, duration: A retrospective cohort study of 28 women followed pre-bariatric surgery and followed postoperatively for 1 additional year between August 2007 and December 2015.
Participants/materials, setting, methods: This was a retrospective cohort study, comprising of 28 women (mean age=29.6±4.2 years). The study groups comprised of morbidly obese women (BMI > 37.5kg/ m^2)with (n=17) and without PCOS (n=11), with a prior history of infertility (average duration: 6.9±4.9 years), who underwent bariatric surgery. Retrospective analysis was performed for pregnancy rate, weight loss (in terms of body mass index), Anti-mullerian hormone (AMH) levels, OGTT value and serum insulin levels pre-surgeryand 1 year postoperatively.
Main results and the role of chance: At 1-year follow-up, the mean BMI among all the study participants decreased from 49.1 pre-surgery to 29.3 post-surgery. Similarly, there was substantial reduction in prevalence of impaired OGTT from 42.9% to 3.6% in the study groups. Prior to surgery, the mean AMH level was more than normal (3.5 ng/ml) in the PCOS group while it was 1.3 ng/ml in the non-PCOS group. After surgery, the AMH level for PCOS patients reduced to 3.1±0.6 and increased to 3.9±5.9 for non-PCOS patients. The total pregnancy rate was 64.3% (spontaneous pregnancy: n=14, IVF pregnancy: n=4).
Limitations, reasons for caution: This study is a retrospective analysis. Although the study period is long, sample size is still low and it should be enlarged.
Wider implications of the findings: Bariatric surgery may be a viable option for obese young women with infertility. More research is needed to evaluate the clinical effect of bariatric surgery prior to IVF treatment.
Trial registration number: NA

P-680 A model using a Comprehensive Algorithm of Reproductive Efficiency (CARE) system to predict outcome of IVF cycles

X. Viñals Gonzalez[1], R. Odia[1], S. Deepa[2], W. Saab[3], P. Serhal[3], S. Seshadri[3]
[1] *The Centre for Reproductive and Genetic Health, Embryology, London, United Kingdom*
[2] *Institute to confirm, Department of Statistics, Chennai, India*
[3] *The Centre for Reproductive and Genetic Health, Clinical, London, United Kingdom*

Study question: Can male and female pre-treatment characteristics predict the laboratory performance of their gametes and embryos?
Summary answer: CARE system can predict number of cumulus-oocyte complexes retrieved and blastulation rates in patients undergoing IVF treatment
What is known already: Application of artificial intelligence (AI) in IVF has become a useful tool to boost treatment outcomes and improve patient counselling. McLernon et al. (2016) provided a predictive model for live birth for couples having up to six cycles but it was not adjusted for potential important predictors. Siristaidis et al. (2011) evaluated the potential use of artificial neural networks to predict clinical outcomes proposing several features for future algorithms. Recently, Correa et al. (2018) established an AI-based algorithm able to predict number of mature oocytes for first IVF cycles (unpublished).
Study design, size, duration: A total of 750 IVF cycles were included in this single centre retrospective cohort study from January 2018 to December 2018. Male and female pre-treatment characteristics included were: age, BMI, smoking/drinking habit, time of infertility, attempt, ovarian reserve test parameters (such as AMH, FSH, estradiol and antral follicle count) and sperm characteristics (ie. volume, concentration, motility and normal forms). Laboratory parameters included: oocytes collected, maturation, insemination protocol (IVF/ICSI), fertilisation rates and number of blastocysts developed.
Participants/materials, setting, methods: Sample was split into different sets for training the model (60%), cross-validate to tune hyperparameters (20%) and to test for accuracy (20%). A two-step strategy was designed and algorithms based on regression analysis were used for prediction analysis. CARE system was trained to predict number of cumulus-oocyte complexes (COCs) retrieved after stimulation and blastocyst formation after insemination.
Main results and the role of chance: A total of 7950 oocytes were collected, 4991 zygotes formed from which a total of 2682 developed blastocyst (mean 3.45 ± 3.2). Female and male age were on average 37.1 ± 4.1 years old (range 24-47) and 38.9 ± 5.8 (range 24-66), respectively. Ovarian response was categorised according to the number of COCs in sub-optimal (0-9), normal (10-14), and hyper response (>15). Moreover, blastocyst number was predicted with female and male pre-treatment variables in the following categories 0-1, 2-5 and >=6. In this first approach, CARE system algorithm could predict with a 63% accuracy the number of COCs obtained by a female patient only considering pre-treatment characteristics. Blastocyst formation was predicted with an accuracy of up to 61% for patients undergoing IVF treatment. The system could predict with more precision categories including 0 to 1 blastocysts precision=0.61, fscore=0.56) although accuracy decreased when blastocyst number was >6.
Limitations, reasons for caution: Larger sample studies are needed to increase accuracy and consolidate prospective application. Moreover, the inclusion of new variables will help to increase the discrimination power of the model.
Wider implications of the findings: Future models ought to provide not only predictive information on ovarian response but also information regarding blastulation and clinical outcomes. Such models would help clinicians to tailor treatment strategies for couples based only on their specific characteristics prior to ovarian stimulation.
Trial registration number: Not applicable

P-681 Increased primordial follicle retention by progesterone is counteracted by the concomitant application of Estradiol

I. Kosmas[1], M. Pargianas[2], K. Papageorgiou[3], A. Dalkalitsis[4], A. Papoudou-Bai[5], A. Batistatou[5], S. Fiorentzis[6], E. Kolibianakis[7], B. Tarlatzis[7], T. Michaelidis[8], I. Georgiou[4]

[8] *Foundation for Research and Technology-Hellas- Institute of Molecular Biology & Biotechnology, Department of Biomedical Research-Department of Biological Applications and Technologies, Ioannina, Greece*

Study question: The aim of this study is to examine the effect of progesterone and estradiol alone or in combination on primordial follicles retention.
Summary answer: Progesterone significantly increases the number of primordial follicles. Estradiol alone decreased the number of primordial follicles and the combination counterbalanced the effects of progesterone.

What is known already: Progesterone suppresses the mTOR pathway (Lee et al, 2012) and preserves the primordial follicles (Zheng et al, 2018, Tsuyoshi et al, 2015). Estradiol stimulates the formation and development of primordial follicles in neonatal ovaries (Chen et al.2009, Kezele et al, 2003) although it is not clear the combined effect of the two hormones on the developed ovary.
Study design, size, duration: In a randomized preclinical study, 40 female immature Wistar rats were divided into four groups. All animals received the planned intervention from the 9 week and for 20 days in total. The combination of progesterone + estradiol was also used, to examine the effect on primordial follicles. Eight animals in each group were examined for the intervention effect and two animals from each group were allowed to mate.
Participants/materials, setting, methods: The control group received injections of corn-oil, subcutaneously. The other groups received progesterone (5mg/daily), estradiol (2mg/kg/daily) and progesterone together with estradiol (5mg + 2mg/kg/daily). Primary and secondary outcomes were measured at the left ovary after a treatment period of 20 days with histology. Serum AMH, estradiol and progesterone levels were assessed at the end of the intervention. Protein and RNA were extracted from the right ovary for further analysis.
Main results and the role of chance: Significantly more primordial follicles were observed in the Progesterone group (27. 75±12.8) whereas in the estradiol group they were less (13.12±6.4) (*P*=0.0114). The simultaneous administration of progesterone and estradiol reduced the primordial follicles (15±8.5).No difference was observed in the Atretic follicles between the groups (*P*=0.2107),or in the primary, secondary, pre-antral and Graafian follicles. All intervention groups displayed significantly less antral follicles (*P*=0.0024) than the Control group. The progesterone plus estradiol (11.37±4.65) and the Estradiol alone group (13.62±3.92) presented with significantly lower numbers of Corpora Lutea (*P*=0.0001) than the progesterone alone (35.75±4.39)and the control Group (34.37±8.97).

Gene expression analysis revealed that progesterone increased the mRNA levels of *SOHLH2* (a marker of the quiescent state of the follicles),whereas it decreased *GDF9* (present in the growing oocytes). Estradiol decreased the *FSHR* mRNA, possibly indicating a compensatory mechanism used by granulosa cells to reduce the FSH–driven production of estradiol. Both hormones decreased expression of *CYP17A1*, a gene important for steroid hormone biosynthesis. When progesterone and estradiol were administered together, the effect on *SOHLH2* and *GDF9* was similar to the Estradiol group, whereas the progesterone-mediated increases in *FSHR* and *CYP17A1* were smaller, suggesting that estradiol exerts a dominant effect on progesterone in the ovaries.
Limitations, reasons for caution: The time for hormonal intervention of 20 days, may be a limitation to fully understand the effect of progesterone on primordial follicle retention.
Wider implications of the findings: These findings may be used in with endometriotic cysts patients before undergoing surgery that may compromise ovarian reserve. The data might stimulate further research in the combined effect of progesterone and estradiol as well as on the mechanism by which estradiol overcomes the progesterone effect on primordial follicles retention.

P-682 The cardiometabolic risk profile of middle-aged women with polycystic ovary syndrome (PCOS)

C. Meun[1], M. Gunning[2], Y. Louwers[1], H. Peters[3], J. Roos - Hesselink[4], J. Roeters van Lennep[5], O. Ochoa Rueda, Leonel[6], A. Ikram[6], Y. Appelman[6], N. Lambalk[3], E. Boersma[4], M. Kavousi[6], B. Fauser[2], J. Laven[1]
[1]*Erasmus University Medical Center, Obstectrics and Gynaecology, Rotterdam, The Netherlands*
[2]*University Medical Center Utrecht, Obstetrics and Gynaecology, Utrecht, The Netherlands*
[3]*Amsterdam UMC – location VUmc, Obstetrics and Gynaecology, Amsterdam, The Netherlands*
[4]*Erasmus University Medical Center, Cardiology, Rotterdam, The Netherlands*
[5]*Erasmus University Medical Center, Internal Medicine, Rotterdam, The Netherlands*
[6]*Erasmus University Medical Center, Epidemiology, Rotterdam, The Netherlands*

Study question: To assess the cardiometabolic risk profile and prevalence of cardiovascular disease (CVD) in women with PCOS around the age of 50
Summary answer: Compared to age-matched controls from the general population, middle-aged women with PCOS exhibited metabolic disturbances, but no signs of premature atherosclerosis or increased CVD risk
What is known already: An increased prevalence and clustering of risk factors for CVD, such as metabolic syndrome, type II diabetes and hypertension, has been observed in women with PCOS. Contradicting results have been reported for the association of PCOS with surrogate markers for CVD and CVD end-points
Study design, size, duration: A cross-sectional study of 200 women diagnosed with PCOS during their reproductive years, and 200 age-matched control women from the general population
Participants/materials, setting, methods: We selected age-matched controls via propensity score matching (Greedy approach). We compared anthropomorphics, lipid levels and the prevalence of insulin resistance, type II diabetes, metabolic syndrome (NCEP definition) and cardiovascular events between both groups. We further compared carotid intima media thickness (IMT), 10-year CVD risk and cardiovascular health score between PCOS women and age-matched controls from the general population
Main results and the role of chance: The mean age was 50.5 (SD 5.5 years) in PCOS and 51.0 (SD 5.2 years) in controls. Increased waist circumference (93.0 versus 85.9cm), body mass index (28.4 versus 26.3) and prevalent hypertension (48.2% versus 26.5%) were more often found in PCOS women (P<0.001). The prevalence of type II diabetes (11.1% versus 6.5%) or metabolic syndrome (25.0% versus 17.0%) was not significantly increased and lipid levels were not different from controls. IMT was lower in women with PCOS (P<0.001). The estimated 10-year CVD risk (calculated according to the Framingham risk score) and cardiovascular health score (based on cholesterol and glucose levels, blood pressure, smoking status and BMI) in women with PCOS were similar to the controls
Limitations, reasons for caution: The results contradict with some previous reports and seem contra-intuitive but are nevertheless robust. Whether this relates to a more healthy population and environment needs confirmation in studies with similar demographic conditions
Wider implications of the findings: Although some unfavorable metabolic features were present in middle-aged women with PCOS, we found no evidence for premature atherosclerosis or an increased prevalence of metabolic syndrome, diabetes or CVD. Long term follow-up is necessary to provide a definitive answer on the long-term CVD risk in women with PCOS
Trial registration number: NCT02616510

P-683 Exploring outcomes with the use exogenous progesterone to replace the use of an antagonist in egg-donation cycles

J. Guerrero Villena[1], J.C. Castillo[2], R. Delgado[3], B. Moliner[4], L. Luque[2], J. Ten[1], A. Fuentes[2], A. Herencia[2], P. Cirillo[2], D. Bodri[2], A. Bernabeu[2], J. Llácer[2], R. Bernabeu[2]
[1]*Instituto Bernabeu Alicante, Embryology Unit, Alicante, Spain*
[2]*Instituto Bernabeu Alicante, Reproductive Medicine, Alicante, Spain*
[3]*Accuna, Reproductive Medicine, Alicante, Spain*
[4]*Instituto Bernabeu Alicante, Reprductive Medicine, Alicante, Spain*

Study question: Is exogenous progesterone sufficient to block the LH surge and produce a similar oocyte yield in egg-donation cycles?
Summary answer: Exogenous progesterone seems sufficient to block the LH surge but a lower oocyte yield was detected in egg-donation cycles.
What is known already: Studies in own eggs IVF cycles shows that exogenous progesterone is capable to block the LH surge without compromising oocyte competence. The strategy may be also suitable for egg-donors (cost effective, patient-friendly, oral administration). However, very limited evidence is available with regards to the use of this strategy in the context of ovarian stimulation in egg-donors.
Study design, size, duration: Pilot, observational, prospective, (same-patient) comparative, cohort study in a private fertility center during year 2018. The pilot study planned to include 10 egg-donors in this exploratory phase.
Participants/materials, setting, methods: The study group started ovarian stimulation on day 2/3 of the cycle. Participants received urinary FSH 150-225 IU/d s.c. concomitantly with 100 mg micronized progesterone *per os*-.

Triptorelin 0.2mg induced the final follicular maturation. Controls: a previous cycle within 6 months performed by the same egg donor using the same type/dose of gonadotrophins and trigger agent but receiving cetrorelix 0.25 mg/d beginning with a leading follicle >14 mm. Egg-collection was performed 36 hours after triggering.

Main results and the role of chance: This exploratory trial was stopped prematurely after the inclusion of six egg-donation cycles in view of the suboptimal results in the study group. As expected, age was similar (23.6 ± 4.3 vs 24.6 ± 6.0 p=0.7) between control and study groups. The results were also similar with regards to: number of days of stimulation (9.2 ± 1.3 vs 10 ± 1.5 p=0.2) and gonadotrophin (IU) consumption (1641 ± 518 vs 1800 ± 653 p=0.7); however, a statistically significant difference was found in the number of collected eggs (23.6 ± 11.2 vs 8.4 ± 3.2 p=0.02) between control and study groups respectively. The average levels of LH (IU/L) and Progesterone (ng/ml) were: 3.7 ± 1.7 and 0.77 ± 0.2 on the trigger day in the study group. No premature LH peak (> 10 IU/L) was detected.

Limitations, reasons for caution: Although a statistical analysis is provided, the main limitation is the small number of cycles included which preclude strong conclusions. The LH/progesterone levels do not support a premature LH peak/luteinization as explanation for the significant difference in the number of collected eggs. Laboratory outcomes beyond fertilization were not analyzed.

Wider implications of the findings: Although the use of exogenous progesterone seems sufficient to block the LH surge, some concerns in relation with a potential suboptimal oocyte yield in egg-donor cycles warrants further investigations.

Trial registration number: No trial registration number

P-684 Aiding the decision-making process of subfertile couples by using a diagnostic test (ReceptIVFity) for recognition of embryo implantation failure in practice

R. Koedooder[1], S. Schoenmakers[1], A. Budding[2], J. Laven[1]

[1]*Erasmus University Medical Centre, Obstetrics and Gynaecology, Rotterdam, The Netherlands*

[2]*Amsterdam UMC – location VUmc, Medical Microbiology and Infection Control, Amsterdam, The Netherlands*

Study question: Does the ReceptIVFity-test influence a couples decision to postpone IVF or IVF-ICSI treatment?

Summary answer: Subfertile couples with a low chance to conceive, based on their individual profile of the ReceptIVFity-test, decide in >50% to postpone IVF or IVF-ICSI treatment.

What is known already: Research has shown that the bacterial composition within the vaginal microbiome can be used to predict the chance to conceive with an *in-vitro* fertilization without (IVF) or with intracytoplasmic sperm injection (IVF-ICSI). The ReceptIVFity test stratifies the vaginal microbiome into a low, medium or high microbiome profile, which correspond with the chance to conceive with IVF or IVF-ICSI treatment within two months, respectively low (6%), medium (24%) and high profile (53%). The predictive accuracy of the ReceptIVFity test with a low microbiome profile is 94% (with a sensitivity 26%, specificity 97%), indicating a chance of 94% to not conceive.

Study design, size, duration: In a randomised follow up trial, we intend to include 303 women prior to their first, second or third IVF/IVF-ICSI attempt. The women who are randomized in the 'intervention group' will receive a profile by the ReceptIVFity test and the women in the 'control group' will not. Inclusions started in September 2017 and is still ongoing.

Participants/materials, setting, methods: Women eligible for IVF/IVF-ICSI treatment and willing to perform a test prior to treatment are included. The ReceptIVFity test includes collecting a vaginal swab, which is subsequently analysed by the IS-pro technique. IS-pro is an eubacterial technique based on detection and categorisation of 16S-23S rRNA gene interspace regions with lengths specific for different microbial species. The resulting ReceptIVFity profile will be discussed with the couple by their physician using shared decision making before starting treatment.

Main results and the role of chance: So far, 168 women have been included of whom 161 are randomized in the intervention group, the other 7 women were randomized in the control group. In the intervention group, 26.1% (42/161) women had a low microbiome profile; subdivided in the first cycle 25.8% (32/124), second cycle 25.0% (8/32) and third cycle 21.4% (3/14). 54.8% (23/42) of the couples decided to temporarily refrain from initiating further treatment in case of a low profile. Moreover, couples who have a previous failed attempt seem more inclined to postpone treatment: first cycle 40.6% (13/32), second cycle 87.5% (7/8), third cycle 100% (3/3). None of the couples with a medium or high profile has discontinued treatment based on the result of the ReceptIVFity test.

Limitations, reasons for caution: Therapeutic interventions to improve a low vaginal microbiome profile are not yet available. Repeated empirical measurements of the effects of an intervention on local microbial communities are necessary to find a solution for patients with a low profile. Nevertheless, the vaginal microbiome is dynamic and can change spontaneously over time.

Wider implications of the findings: The ReceptIVFity acts as a timing tool and gives insight in the patients current (two months after sampling) success rate after IVF or IVF-ICSI treatment. Benefits include reducing unnecessary treatment burden, stress and disappointment, while increasing efficiency of treatment. ReceptIVFity might also benefit the development and monitoring of therapeutic solutions.

Trial registration number: Trial NL6442 (NTR6620)

P-685 Benefits of progesterone pituitary suppression stimulation protocol in comparison with a standard long protocol

K. Łukaszuk[1,2,3], A. Knight[1], M. Kunicki[2,4], G. Jakiel[4,5]

[1]*INVICTA Fertility and Reproductive Center, Fertility Clinic, Gdansk, Poland*

[2]*Medical University of Warsaw, Department of Gynecological Endocrinology, Warsaw, Poland*

[3]*Medical University of Gdansk, Department of Obstetrics and Gynecological Nursing- Faculty of Health Sciences, Gdansk, Poland*

[4]*INVICTA Fertility and Reproductive Center, Fertility Clinic, Warsaw, Poland*

[5]*Centre of Postgraduate Medical Education, Department of Obstetrics and Gynecology, Warsaw, Poland*

Study question: To compare stimulation protocol with progesterone given from first and 5th day of stimulation to standard long protocol.

Summary answer: The progesterone stimulation protocol could be good alternative for patients who do not plan a fresh embryo transfer.

What is known already: External supplementation of progesterone can act as a strong LH suppressor. This type of ovarian stimulation can be applicable for patients with any indication when fresh embryo transfer is not planned. Previously, this type of stimulation has been shown to significantly lengthen duration of stimulation and increase dosage of gonadotropins.

The use of progesterone to prevent premature LH surge has numerous advantages such as increased patient comfort level thanks to lower number of total injection during treatment, allows the use of GnRH agonist ovulation trigger instead of hCG and thus lowering the risk of OHSS.

Study design, size, duration: This was a multicentre prospective study at Invicta Fertility Clinics. The inclusion criteria were: age – 18-48 years, 1-2 previous IVF cycles. Statistical comparisons were performed using paired Wilcoxon test.

116 patients were included in the analysis. Median patient ages was 36 years old (IQR: 32 – 40). Two cycles were analyzed for each patient: first long protocol stimulation (long), then stimulation with progesterone (progesterone).

Participants/materials, setting, methods: First stimulation with long protocol had oral contraceptive (OC) priming, GnRH agonist (14 days after OC) and gonadotropin dosage based on patient's AMH level. HCG was used as ovulation trigger at 34-6 hours before retrieval.

Next stimulation also had OC priming. 7 days after the last pill stimulation started with daily gonadotropins. Progesterone was added starting from day 5 of stimulation – 100mg 3x daily vaginally. Trigger was 0.2 mg triptorelin 34-6 hours before retrieval.

Main results and the role of chance: Main outcome measures were duration of treatment, number of cumulus oocyte complexes and mature oocytes retrieved, number of top quality embryos on day 3 and final day of culture.

Duration of stimulation between long and progesterone stimulation was not significantly different. The difference in number of cumulus oocyte complexes (COC) retrieved was significant - more COC were obtained in the progesterone cycles (median: 10 (25th-75th: 6–14) than in the long protocol cycles (median: 8 (25th-75th: 4–14, p = 0.023). However, the number of matured oocytes was not significantly higher.

Embryo culture results showed statistically significant differences:

- number of correctly fertilized oocytes - progesterone: median:4 (25th-75th:2-6), long: median: 3 (25th-75th: 1-5), p = 0.006

- number of top quality embryos on day 3 - progesterone: median:2 (25th-75th:1-3), long: median:1 (25th-75th:0-2), p = 0.006

- number of top quality embryos on the final day of culture - progesterone: median:1 (25th-75th:0-2), long: median:1 (25th-75th:0-1), p = 0.008.

Limitations, reasons for caution: We found that short progesterone administration is sufficient to prevent premature LH surge. We did not find negative influence of progesterone on stimulation duration. No negative impact on embryo culture was found with higher numbers of TQ embryos obtained.

Wider implications of the findings: The progesterone stimulation protocol could be good alternative for patients who do not plan a fresh embryo transfer.

Trial registration number: not applicable

P-686 HMG does not improve the clinical pregnancy rate in poor responder patients undergoing IVF/ICSI: a meta-analysis.

A.A. Marino[1], S. Gullo[2], A. Volpes[1], F. Sammartano[1], A. Allegra[1]

[2]*ANDROS Day Surgery Clinic, Medical Statistics Unit, Palermo, Italy*

Study question: Is there a clinical advantage by using HMG for the ovarian stimulation in patients with poor ovarian response (POR) undergoing IVF/ICSI?

Summary answer: The stimulation treatment with HMG, compared with rFSH, does not improve the clinical pregnancy rate and it is associated with a longer duration of stimulation.

What is known already: Poor ovarian response to gonadotropins in IVF/ICSI cycles still today represents a challenge for reproductive physicians and a significant psychological burden for the patients. Different treatment regimens and gonadotropin combinations have been proposed during the years for improving the clinical pregnancy rates in these patients. Several studies suggest a positive effect of rLH in addition to rFSH in poor responders. HMG represents another source of LH activity and it is widely used for the ovarian stimulation in poor responders. Surprisingly, no systematic review or meta-analysis comparing HMG with rFSH, in poor responders, has been yet performed.

Study design, size, duration: A meta-analysis, based on PubMed, ISI-Web, Cochrane CENTRAL, EMBASE, was conducted to verify the effectiveness of the stimulation with HMG in poor responders. According to *PICO* format, inclusion criteria were: *Population*, poor responders; *Intervention*, treatment with HMG alone or in addition to rFSH or Corifollitropin alfa; *Control*, treatment with rFSH alone; *Outcome*, clinical pregnancy in patients undergoing IVF/ICSI. Secondary outcomes: duration of stimulation, total gonadotropins dose, cancelled cycles, retrieved oocytes, mature oocytes, fertilization rate.

Participants/materials, setting, methods: Electronic and hand search strategy, conducted from 1998 to 2018, yielded 211 studies. Two researches (A.M., S.G.) reviewed independently the studies, excluding 196 studies after the first screening (title and abstract) and 10 studies after the second screening. The Mantel-Haenszel method was used to calculate odds ratios (OR) and heterogeneity among studies (I^2). The results were expressed as OR with 95% confidence intervals (CI). Standardized mean differences (SMD) between groups were used for continuous outcomes.

Main results and the role of chance: Five studies with 1,076 participants were included. Two were RCTs; the other three were retrospective/prospective cohort studies.

In two studies (Eskandar et al., 2004; Youssef et al., 2017), HMG and rFSH treatments were directly compared; in the remaining three studies (Loutradis et al, 2004; Chung et al., 2005; Drakopoulos et al., 2017), HMG as treatment in addition to rFSH or Corifollitropin alfa was compared with rFSH treatment. The female age was similar among the studies.

Clinical pregnancy rate was not significantly different in women receiving HMG treatment (alone or combined) [93/550] compared with rFSH treatment [89/526] (OR 0.99, 95% CI 0.72 to 1.37, I^2=0%). No differences in number of retrieved oocytes (t= -1.46, p=0.15, SMD -0.93, 95%CI -2.17 to 0.32, I^2=86%), number of mature oocytes (t= 1.65, p=0.10, SMD 0.27, 95%CI -0.05 to 0.59, I^2=67%) and number of cancelled cycles [91/591 vs 106/580] (OR= 0.81, 95%CI 0.59 to 1.11, I^2=44%) were found between the two groups of treatment. The patients treated with HMG showed longer duration of stimulation (t=4.84, p=0.01, SMD 0.42, 95%CI 0.25 to 0.59, I^2=0%). The selected studies did not report sufficient data to analyze total dose of gonadotropins and fertilization rate.

Limitations, reasons for caution: In the selected studies, the definition of POR was not exactly the same but very similar. The couples' basal characteristics were not indicated in all the studies. Although the treatment with HMG was comparable among the studies, the dosages were different.

Wider implications of the findings: This meta-analysis indicates no improvement in IVF/ICSI success when the stimulation is performed with HMG alone or added to rFSH or Corifollitropin alfa, compared with rFSH.

The choice concerning the stimulation drug in poor responders should be mainly based on the costs of each treatment.

Well-designed cost-effectiveness studies are needed.

Trial registration number: Not applicable for non-clinical trials

P-687 Does Acupuncture Treatment Really Change the Outcome of IVF-ET in Poor Ovarian Response Population? –A Systematic Review and Meta-Analysis

J.L. Guo[1]

[1]*West China Second University Hospital- Key Laboratory of Birth Defects and Related Diseases of Women and Children- Ministry of Education- Sichuan University, Center for Reproductive Medicine- Department of Gynecology and Obstetrics, Chengdu City, China*

Study question: Does Acupuncture Treatment Really Change the Outcome of IVF-ET in Poor Ovarian Response Population?

Summary answer: Acupuncture treatment could improve the average number of retrieved oocytes and clinical pregnancy rate in POR patients. The deep mechanism still needs further consideration.

What is known already: Poor ovarian response (POR) remains a strict challenge for IVF-ET treatment. Due to a low number of retrieved oocytes, POR patients usually have significantly fewer transferable embryos. However, there is no consensus on the treatment of POR. Acupuncture was applied to females with infertility thousands of years ago in ancient China. According to the Traditional Chinese Medicine (TCM) theory, the insertion of microscopic needles at a specific point on human body will balance the inner Yin and Yang to lead a healthier situation. Multiple clinical approaches have been attempted to evaluate the effectiveness of Acupuncture in POR population.

Study design, size, duration: This article tried to summarise evidences from 7 RCT studies in recent 20years (1998-2018)by systematic review and meta-analysis to guide clinical decision.

Participants/materials, setting, methods: We started an RCT meta-analysis under Cochrane Systematic Review Guideline. After database searching and quality assessment, we enrolled 7 RCT studies (including 524 patients) focusing on acupuncture treatment in POR patients undergoing IVF-ET procedure. The intervention should be acupuncture and related techniques, with placebo or no treatment as control group. We set the outcomes as main endpoint characters in IVF-ET treatment.

Main results and the role of chance: After statistical analysis, our study found that, in POR population, although acupuncture improved average number of retrieved oocytes ($P<0.00001$). Other IVF-ET characters, like fertilization rate, cleavage rate and high-quality embryo rate did not show any difference($P>0.05$). Interestingly, the overall clinical pregnancy rate was markedly higher in the acupuncture group($P<0.0001$). This result might suggest that the more oocytes retrieved, the more transferable embryos could be gotten in POR patients.

Limitations, reasons for caution: The limitation of our study lies on the lack of original RCT studies, which would reduce the robustness of our result. We hope to make progress in this field.

Wider implications of the findings: Deep mechism of acupunture may still need further exploration.

Trial registration number: not applicable

P-688 Examining the effect of nicotine on a mouse model of the ovarian reserve

S. Idrees[1], M. Fenwick[1], A. Pacey[1]
[1]*University of Sheffield, Academic Unit of Reproductive and Developmental Medicine- Department of Oncology and Metabolism, sheffield, United Kingdom*

Study question: Does nicotine have an effect on small follicles in the mouse ovary?
Summary answer: Neonatal ovaries express specific acetylcholine receptor sub-types and exposure to nicotine in vitro slightly inhibited growth of small, developing oocytes in comparison to controls.
What is known already: The substantial shift towards vaporiser and e-cigarette usage has led to the general assumption that these are safer alternatives to cigarettes. Although the negative effects of cigarette toxins and by products on the reproductive system are well established, very little is known about nicotine on its own; specifically, whether it has any impact on the ovarian reserve.
Study design, size, duration: Ovaries from 4-day old mice (n=6), 8-day old mice (n=5) and 16-day old mice (n=6) were initially used for gene expression analysis. To analyse effects of nicotine on small follicles, ovaries from 4-day old mice were maintained in culture for seven days exposed to high (45ng/ml; n=19), medium (15ng/ml; n=19), low (5ng/ml; n=19), or no nicotine (control; n=19) as determined by published plasma levels from e-cigarette users.
Participants/materials, setting, methods: RT-PCR was used to determine presence/absence of nicotinic acetylcholine receptor sub-types (alpha and beta nAChRs) in ovaries derived from C57Bl6 mice aged 4, 8 and 16 days. Expressed candidates were quantified between the same age groups using qPCR and proteins localised by immunofluorescence. Cultured ovaries were sectioned and stained for morphological assessment of follicle development, or qPCR to evaluate expression of genes associated with growth and viability.
Main results and the role of chance: Three specific alpha (*Chrna4*, *Chrna5* and *Chrna7*) and three beta (*Chrnb1*, *Chrnb2, Chrnb4*) nAChR subunits were detectable by RT-PCR in ovaries from immature mice. Expression of these subunits were relatively higher in ovaries from 4-day old mice (densely populated with primordial follicles) relative to older ages as determined by qPCR ($P<0.05$). Furthermore, CHRNA4, CHRNA5 and CHRNA7 proteins localised to granulosa cells and oocytes of small follicles, suggesting nicotine signalling in small follicles is plausible; therefore, day 4 ovaries were cultured in different concentrations of nicotine to evaluate the effects on gene expression and follicle development. After seven days, there were no differences in expression of *Amh, Gdf9, p63*or *Bcl2*between ovaries exposed to 0 (control), 5 (low), 15 (medium) or 45 (high) ng/ml nicotine ($P>0.05$). Interestingly, a slight decrease in the pro-apoptotic *Bax*gene transcript was detected in the high nicotine group relative to the low group ($P<0.05$). When morphological parameters were analysed, no differences were detectable between the proportion of primordial, transitional or early growing follicles between groups ($P>0.05$). However, the mean oocyte size was slightly reduced in transitional and early growing follicles of ovaries exposed to the high dose of nicotine relative to control ($P<0.05$).
Limitations, reasons for caution: This is a preliminary study using the immature mouse ovary as a developmental paradigm of the ovarian reserve. nAChR subunit expression may differ in humans and therefore the response to nicotine may not be extrapolatable. A single endpoint was evaluated after short-term culture and therefore longer-term effects are unknown.
Wider implications of the findings: This study raises the possibility that nicotine alone, when used at physiologically relevant levels, can cause subtle effects on the supply of small oocytes; however, the long-term consequence on ovarian function and fertility are yet to be determined.
Trial registration number: Not applicable.

P-689 Response to ovarian stimulation in IVF/ICSI cycles and its relationship with clinical pregnancy and live birth rates

A. Astorga[1], J.C. Barros Delgadillo[1]
[1]*Instituto Nacional de Perinatología, Infertility and Assisted Reproduction, Mexico City, Mexico*

Study question: Which is the association between the number of oocytes retrieved and live birth rates in patients undergoing IVF/ICSI cycles?
Summary answer: The number of eggs in IVF/ICSI cycles is a predictor for clinical success. The number of oocytes to maximize live birth rate is 10-15.
What is known already: Several studies have shown that the number of retrieved oocytes in IVF/ICSI cycles is a possible predictor for live birth rate. It has been suggested that 6 to 15 oocytes is the optimal amount in order to increase the live birth rate in fresh embryo transfer IVF cycles.

The rate of newborns decrease if the number of oocytes obtained is lower to 6 or higher than 15.

Sunkara et al (2011) suggest that the number of eggs retrieved to maximize the live birth rate is 15.
Study design, size, duration: It was a retrospective cohort study including 1020 fresh IVF/ICSI cycles in the period from January 2012 to March 2017.

A binary logistic regression model was used to select the prognostic factors of clinical pregnancy and live newborn. In all hypothesis contrast a $p < 0.05$ was chosen as an alpha error.
Participants/materials, setting, methods: The data from all the fresh IVF/ICSI cycles of an Assisted Reproduction Unit of a public tertiary hospital were analyzed. 1186 cycles of controlled ovarian hyperstimulation of which 1020 reached the embryo transfer were included. The clinical pregnancy and live birth rate were estimated according to the ovarian response (poor response <4 oocytes, suboptimal response 4 to 9 oocytes, optimal response 10 to 15 oocytes and hyper response >15).
Main results and the role of chance: The probability of achieving a clinical pregnancy and the birth of a live newborn is greater when the number of retrieved oocytes increases reaching a maximum when 10 to 16 oocytes were obtained (optimal response) OR 1.79 IC 95% 1.33 - 2.49 and 1.62 IC 95% 1.17 – 2.24 respectively, decreasing the probability when more than 16 oocytes are captured OR 0.78 IC 95% 0.50 – 1.21

A significant difference was found in the rate of clinical pregnancy and of live newborns being lower in women in whom less than 4 oocytes were captured (poor response) since the probability of achieving a clinical pregnancy decreases up to 73% (OR 0.364 IC 95% 0.247- 0.536) and for a live newborn it decreases by 54.3% (OR 0.467 95% CI 0.306 – 0.712)
Limitations, reasons for caution: The cycles with frozen embryo transfer were not analyzed, its inclusion could increase the accumulated live birth rate.

The decrease in live birth rates in the hyper response group could be explained because the majority of fresh embryo transfer was avoided in order to reduce the risk of hyperstimulation ovarian syndrome.
Wider implications of the findings: The number of retrieved oocytes is a prognostic indicator of clinical success. The results showed a relationship between the number of eggs and the live birth rate in IVF cycles in agreement with some authors.
Trial registration number: Not Applicable

P-690 Myo-inositol may improve oocyte quality and fertilization rate in women with polycystic ovary syndrome undergoing assisted reproductive technology cycles

A. Akbari sene[1], F. Amjadi[2], A. Tabatabaie[3], M. Ashrafi[3], A. Alizadeh[4], K. Sheibani[5]
[1]*Iran University of Medical Sciences, Shahid Akbar-abadi Hospital IVF Center, Tehran, Iran*
[2]*Iran University of Medical Sciences, Shahid Akbarabadi Clinical Research Development Unit ShACRDU, Teharn, Iran*
[3]*Iran University of Medical Sciences, Shahid Akbarabadi Clinical Research Development Unit ShACRDU, Tehran, Iran*
[4]*Royan Institute for Reproductive Biomedicine, Department of Epidemiology and Reproductive Health, Tehran, Iran*
[5]*Basir Eye Health Research Center, Research Center, Tehran, Iran*

Study question: Whether, if myo-inositol could improve the oocytes quality, fertilization rate and embryo quality in PCOS patients undergoing ART cycles based on molecular mechanisms?
Summary answer: Myo-inositol improved the percentage of MII oocytes, fertilization rate and ratio of good quality embryos by altering the expression of genes related to oocyte quality.

What is known already: Although some studies have shown the positive effects of Myo-Inositol supplementation among PCOS patients on the quality of oocytes and embryos but there are controversial opinions in this regard and the mechanism of Myo-Inositol effect on the quality of embryo and oocyte has not yet been fully elucidated.
Study design, size, duration: This placebo-controlled double-blind randomized clinical trial was conducted in Shahid Akbar Abadi hospital IVF center, Iran University of Medical Sciences, Tehran, Iran, Feb 2017- May 2018. Fifty infertile PCOS patients were randomly designated in two groups.
Participants/materials, setting, methods: Subjects received daily dose of 4g Myo-Inositol combined with 400mg folic acid from one month before starting the antagonist cycle until day of OPU. Oocytes and embryos quality were assessed according to ESHRE guidelines. The gene expression of PGK1, RGS2 and CDC42, as a factor of oocyte quality in granulosa cells, was analyzed using real-time RT-PCR. Levels of Total Antioxidant Capacity (TAC) and Reactive Oxygen Species (ROS) in follicular fluid were evaluated using chemiluminescence assay.
Main results and the role of chance: The number of retrieved oocytes and follicle count were not statistically different between the two groups, but the percentage of metaphase II oocyte, fertilization rate and embryo quality was significantly higher in the study group ($P < 0.05$). Furthermore, the gene expression of PGK1, RGS2 and CDC42 were significantly higher in the study group ($P < 0.05$), but no differences were found between two groups in terms of TAC and ROS levels. The cumulative pregnancy rate was not significantly improved in the case group either.
Limitations, reasons for caution: Our study provides some new molecular evidence about the possible mechanism of Myo-Inositol effect on the quality of oocyte and embryo based on improved granulose cell gene expression,but we did not observe an improved cumulative pregnancy rate which might be related to the limited number of subjects in this trial.
Wider implications of the findings: We observed that Myo-Inositol alters the gene expression in granulosa cells and improves oocyte and embryo quality. If the clinical efficacy of our findings on pregnancy rate is approved by further RCTs , the use of Myo-inositol as an adjuvant in ART cycle can be suggested for PCOS patients.
Trial registration number: IRCT20171208037790N1

P-691 Metformin versus the combined oral contraceptive pill for hirsutism, acne, and menstrual pattern in polycystic ovary syndrome

E. Fraison[1], L. Moran[2], S. Bilal[3], C. Ee[4], C. Venetis[5], M. Costello[6]
[1]*Hôpital Femme Mère Enfant, Reproductive Medicine, Lyon, France*
[2]*Monash University, Monash Centre for Health Research Implementation, Clayton, Australia*
[3]*Royal Hospital for Women, Division of Obstetrics & Gynaecology, Sydney, Australia*
[4]*Western Sydney University, National Institute of Complementary Medicine, Penrith, Australia*
[5]*UNSW Medicine, Centre for Big Data Research in Health & School of Women's & Children's Health, Sydney, Australia*
[6]*Royal Hospital for Women and IVF Australia, Division of Obstetrics & Gynaecology-School of Women's & Children's Health, Sydney, Australia*

Study question: To assess the effectiveness and safety of Metformin versus the Oral Contraceptive Pill (OCP) in improving clinical features of Polycystic Ovary Syndrome (PCOS) in adult women.
Summary answer: This updated systematic review shows an improvement in menstrual pattern and hirsutism with the OCP whilst Metformin shows an improvement in BMI.
What is known already: Hyperinsulinemia is one of the PCOS features and participates in hyperandrogenemia through the stimulation of both ovarian and adrenal androgen secretion and the suppression of liver sex hormone-binding globulin (SHBG). This excess of androgens is also responsible for irregular menses. It was thus advocated that Metformin could be a treatment for PCOS as effective as the OCP for improving hyperandrogenemia and menstrual cyclicity. In the previous systematic review, the OCP resulted in an improvement of menstrual patterns. However, there was insufficient evidence in favour of either Metformin or the OCP in treating hirsutism, acne (pimples) or BMI.
Study design, size, duration: For the update of this Cochrane systematic review we conducted a search according to the Cochrane Gynaecology and Fertility search strategy for randomized controlled trials (RCTs) in which Metformin was used versus OCP or OCP versus Metformin combined with OCP or Metformin versus Metformin combined with OCP from inception to October 2018. Eighty-three articles were identified (12 abstracts, 71 full texts). Thirty-three new RCTs met inclusion criteria added to the six original ones.
Participants/materials, setting, methods: Only randomized controlled trials (RCTs) comparing Metformin versus OCP, OCP versus Metformin combined with OCP, Metformin versus Metformin combined with OCP were considered for inclusion. Crossover trials were not included unless pre-crossover data were available, in which case only these data were used for the purpose of the review. The inclusion criteria were the presence of PCOS based on clinical (ovulatory dysfunction, hirsutism, acne, androgen dependent alopecia), biochemical (hyperandrogenemia), or ultrasound (polycystic ovaries) evidence.
Main results and the role of chance: The OCP resulted in an improvement in hirsutism (Ferriman and Gallwey score) compared to Metformin (Mean difference (MD) 1.08, 95% CI 0.57 to 1.59, 10 RCTs, n = 473, I^2= 50%). Metformin combined with the OCP resulted in an improvement in hirsutism (Ferriman and Gallwey score) compared to the OCP alone (MD 0.54, 95% CI 0.2 to 0.89, 6 RCTs, n = 389, I^2= 1%) and also compared to Metformin alone (MD 1.36, 95% CI 0.62 to 2.11, 3 RCTs, n = 135, I^2= 9%). The OCP resulted in an improvement of menstrual cyclicity compared to Metformin (MD 6.05, 95% CI 2.37 to 9.74, 2 RCTs, n = 153, I^2= 0%). The OCP alone resulted in an improvement in acne (clinical acne score) compared to Metformin combined with the OCP (MD -0.09, 95% CI -0.10 to -0.08, 1 RCT, n = 82). Metformin resulted in an improvement in BMI compared to the OCP (MD -0.63, 95% CI -0.97 to -0.29, 19 RCTs, n = 887, I^2 = 95%). Metformin resulted in an improvement in BMI compared to Metformin combined with the OCP (MD -1.47, 95% CI -2.27 to -0.66, 5 RCTs, n = 199, I^2= 25%).
Limitations, reasons for caution: There was heterogeneity between the trials and some results were made only on one trial. Therefore, the results must be interpreted with caution.
Wider implications of the findings: The OCP remains superior to Metformin in improving menstrual pattern. The OCP alone or combined with Metformin seems to improve hirsutism. Metformin is superior to the OCP regarding BMI. Concerning acne, further RCTs are required for any conclusions to be drawn.
Trial registration number: Not applicable

P-692 Vascular endothelial growth factor antagonist reduces the early onset and the severity of ovarian hyperstimulation syndrome

S. Jellad[1], N. Soyah[1], M. Basly[1], M. Chibani[1], R. Rachdi[1]
[1]*Medical assisted procreation center, Military Hospital of Tunis, Tunis, Tunisia*

Study question: This study aims' at evaluating the efficiency of prophylactic and therapeutic use of cabergoline in women with higher risk of developing ovarian hyperstimulation syndrome (OHSS).
Summary answer: Cabergoline use reduce the rate of early OHSS and its severity and does not affect ART outcomes in terms of pregnancy, implantation and miscarriage rates.
What is known already: OHSS is s the most serious complication of controlled ovarian stimulation(COH) during assisted reproductive technology protocols. This syndrome is a result of ovarian expression of vascular endothelial growth factor (VEGF), which increases vascular permeability. The rationale behind using cabergoline,a dopamine agonist is that it might counteract the increased production of VEGF by the follicles. It has been demonstrated in an animal model that cabergoline, partially inhibits the ovarian VEGF receptor-2 through dereasing its phosphorylation levels. in addition, several human studies reported that cabergoline might provide a new specific and non toxicapproch to the treatment of OHSS without altering angiogenesis
Study design, size, duration: A prospective randomized study including 146 couples undergoing ICSI cycles with agonist protocols and having higher risk of OHSS diagnosed during the hCG day injection .Two groups were identified

according to the administration or not of dopamine agonist (Dostinex©). A first group (n=78) women who received 0.5mg per day of cabergoline orally for 7 days starting from hCG administration day. The second group (n=68)who received no medication treatment.

Participants/materials, setting, methods: A total of 25 patients in each group developed OHSS and were admitted in our hospital. Subgroup 1, 25 cases of OHSS obtained in group 1received cabergoline and subgroup 2 where 25 cases of OHSS obtained in group 2 received no medication. Diagnosis of OHSS was made according to Golan criteria. According to Carriz et al, early OHSS was identified when the onset of OHSS was initiated during the first 9 days after hCG administration.

Main results and the role of chance: There was no evidence of a statistically significant reduction in the incidence of OHSS in cabergoline group (32.05%vs36.76%;p>0.05).Late OHSS was observed in 60.6% of cases in cabergoline group while 39.4% of cases in the other group(p=0.036).Early OHSS decreased significantly in the cabergoline group(p<0.05). Severe OHSS cases were more common within subgroup 2 than subgroup1 (32% vs 8%, P=0.000). There was no difference in clinical pregnancy rates and miscarriages rates between the two subgroups.

Limitations, reasons for caution: An important clinical question can still be raised concerning the best time for using Cabergoline to prevent and treat OHSS. Further studies can be carried out to evaluate the most effective time and dose of Cabergoline administration.

Wider implications of the findings: A low oral dose administration of dopamine agonist(Cabergoine) for patients with high risk of OHSS can reduce the rate of early OHSS and its severity in GnRH agonist IVF cycles, but can not prevent the incidence of OHSS.

Trial registration number: not applicable

P-693 Enhancing of human oocyte maturation by Kisspeptin-54

S.S. Umarghanies[1]

[1]*University of Oxford, Nuffield Department of Women and Reproductive Health, Oxfordshire, United Kingdom*

Study question: Can Kisspeptin-54 be used to induce oocyte maturation in women undergoing in vitro fertilisation (IVF)?

Summary answer: Kisspeptin-54 is able to trigger oocyte maturation in women undergoing IVF

What is known already: Human chorionic gonadotropin (hCG) is currently used as the gold standard to trigger final oocyte maturation, despite its risk of developing ovarian hyperstimulation syndrome (OHSS). Animal studies showed that administration of Kisspeptin-54 could trigger LH surge and oocyte maturation through a GnRH-dependent mechanism.

Study design, size, duration: A systematic review was performed to related clinical trials published in Pubmed, Cochrane, and Medline

Participants/materials, setting, methods: Three clinical trials were analysed in this study with a total of 175 patients included

Main results and the role of chance: in normal women, oocyte maturation was observed in 75-85% of patients and increased with higher doses of kisspeptin-54. The fertilisation and embryo transfer rate were both 92%, the biochemical pregnancy was 40%, and the clinical pregnancy rate was 23%. In women at high risk of OHSS, oocyte maturation occurred in 95% of patients with 62-85% of pregnancy rates, 25-58% of implantation rates, and 25-62% of live birth rate. No patients developed moderate, severe, and critical OHSS whilst only 5% were having mild early OHSS and 2% were having mild late OHSS that needed no medical intervention. If Kisppeptin-54 was given twice, the proportions of ≥60% oocyte yield was greater (71%) than the single dose (45%) without significant difference in the occurrence of OHSS. Compared to single dose, the implantation rates and live birth rate were higher in patients received two doses of Kisspeptin (37.1% vs 23.3% and 39% vs 19.4%, respectively)

Limitations, reasons for caution: All trials were conducted by the same research group with limited samples. Some patients have had previous oocyte maturation trigger during previous cycle that might alter the results. Thus, further study with larger sample and comparison between current standard treatment (hCG and GnRH agonist) are recommended

Wider implications of the findings: This review revealed the efficacy of Kisspeptin-54 to trigger final oocyte maturation with less risk of developing OHSS, which was very important to develop a suitable IVF protocol for patient at risk of OHSS

Trial registration number: Not applicable

P-694 The correlation between serum progesterone level and clinical outcomes in hormone replacement prepared thawed embryo transfer cycle

X. Xiao[1]

[1]*the sixth affiliated hospital, Sun Yat-Sen university, guangzhou, China*

Study question:

- Is there any correlation between serum progesterone level and clinical outcomes in hormone replacement prepared thawed embryo transfer cycle?

Summary answer:

- No correlation was found between serum progesterone level on the day before embryo transfer and the clinical pregnancy rate in hormone replacement-thawed embryo transfer cycle.

What is known already:

- Artificial hormone replacement was widely used in thawed embryo transfer cycle to prepare endometrium, especially when exogenous vaginal administrated-progesterone was introduced. However, there was no consistent conclusion if there was an optimal serum progesterone level after exogenous progesterone administrated. A recent prospective study claimed that a minimum threshold of serum P values (>9.2 ng/ml) on the day of ET should be reached in artificial endometrial preparation cycles to optimize outcome.

Study design, size, duration:

- This is a retrospective cohort study. From January 2011 to January 2017, 395 patients who underwent their first HRT-TET cycle with one good blastocyst(>3BB) transferred were recruited.

Participants/materials, setting, methods: Patients who underwent their first HRT-TET cycle with single one good blastocyst(>3BB) transferred were recruited. To prepare endometrium, 4-6mg estradiol valerate was administrated for at least 10 days, when endometrial thickness reached 8 mm, vaginal micronized progesterone (200mg tid) and dydrogesterone (10mg tid) were administrated, and five days later, thawed blastocyst was transferred. Patients with severe adenomyosis, abnormal uterine cavity (intrauterine adhesions) or hydrosalpinx were excluded from this study.

Main results and the role of chance: No significant difference was observed in basic characteristics and serum estrogen and progesterone level on the day of progesterone supplementation (All P >0.05) . The cycle characteristics were listed in following table.

Logistic regression analysis was also performed and the result showed that only patients' age was negatively associated with clinical pregnancy rate, while progesterone level has no correlation with clinical pregnancy rate

Limitations, reasons for caution: Retrospective nature of this study might introduce some bias. After strictly screening, only patients with adequate endomentrial growth and good quality blastocyst were recruited to exclude interference from confounding factors, besides, the multivariate logistic regression analysis was also performed in this study to guarantee the reliability of our results.

Wider implications of the findings: Based on our results, serum progesterone level on the day before embryo transfer has no correlation with clinical pregnancy rate in HRT-TET cycles, therefore there was limited value to routinely check serum progesterone level before thawed embryo transfer . At last, large-scale multi-center RCT is needed to verify our results.

	Group1(n=)	Group2(n=)	Group3(n=)	Group4(n=)	P
Age	30.38±4.20	31.84±4.78	30.44±4.44	31.46±4.54	0.257

P-695 characterization of circular RNA profiles in plasma from healthy women and women with primary ovarian insufficiency

Y. FENG[1], **Y. Ning**[2], **J. Li**[3], **S. Chen**[1], **Z. Xu**[1], **S. Luo**[1], **Y. Zhao**[1]
[1]*Guangzhou University of Chinese Medicine, Department of Gynecology, Guangzhou, China*
[2]*Shenzhen Maternity & Child Healthcare Hospital, Department of Chinese Medicine, Shenzhen, China*
[3]*Guangzhou University of Chinese Medicine, Key Laboratory for Gynecology, Guangzhou, China*

Study question: Are there expression differences in plasma circular RNA (circRNA) between healthy women and women with primary ovarian insufficiency (POI)?
Summary answer: Our study demonstrated that circRNA profiles in plasma from healthy women and POI patients differed significantly.
What is known already: The mechanisms of POI remain largely unknown, approximately 50% accordingly. More effective therapeutic measures might be taken in time if clinical diagnostic biomarkers are discovered. Circular RNAs (circRNAs) have recently been implicated in ovarian aging, but their potential as biomarkers was never investigated in POI. It is reasonable to sequence circRNAs in plasma from POI patients, which might predict their biological functions in the development of POI. Herein, this study aimed to identify the role of circRNAs as a potential biomarker in POI patients.
Study design, size, duration: A total of 25 POI patients and 25 age- and sex-matched controls were included in this study. Recruitment took place from July to November 2018.
Participants/materials, setting, methods: CircRNA expression screening was performed in plasma RNA from five pairs of POI patients and age- and sex-matched controls using circRNA microarray. In the validation phase, 18 circRNA candidates were validated by quantitative reverse transcription polymerase chain reaction (qRT-PCR) in a cohort of 15 patients diagnosed with POI and 15 age- and sample storage time-matched controls. For further verification, We performed qRT-PCR on samples from 10 POI patients and 10 controls.
Main results and the role of chance: A total of 6644 differentially expressed circRNAs, 12 significantly up-regulated and 23 significantly down-regulated circRNAs were identified in the POI patients compared with the control group, which showed as red points in the volcano plot analysis($p<0.05$, fold change>1.5). Based on the evaluation of the initial expression quantity and fold change values, 18 circRNAs candidates were selected for the validation phase. Hsa_circ_0000376 was significantly downregulated in POI patients compared with the control group in qRT-PCR ($P<0.05$). The area under the ROC curve (AUC) of hsa_circ_0000376 was 0.698(95% CI 0.499-0.897). The sensitivity and specificity at the cutoff value of 0.685 were 73.3% and 60%, respectively.
Limitations, reasons for caution: Primary ovarian insufficiency (POI) is a reproductive disorder occurs to women before 40 years old, which affects approximately 1%-3% of women of reproductive age. Due to the limitation of time, larger sample size is expected in our futher study.
Wider implications of the findings: Taken together, our study indicates that hsa_circ_0000376 may play potential roles in predicting POI.
Trial registration number: ChiCTR1800017312

P-696 The relationship between endogenous androgens levels and ovarian response to controlled ovarian stimulation for in vitro fertilization

A. Albu[1], **D. Albu**[2]
[1]*Carol Davila University of Medicine and Pharmacy, 2nd Clinical Department, Voluntari, Romania*
[2]*Carol Davila University of Medicine and Pharmacy, Gynecology Department, Voluntari, Romania*

Study question: Are endogenous androgens serum levels related to ovarian response to controlled ovarian stimulation (COS) performed for in vitro fertilization (IVF)?
Summary answer: The serum level of the androgens seems to be related to the oocytes and zygotes number obtained after COS performed for IVF.
What is known already: The endogenous androgens have a central role in folliculogenesis and both low and high androgens levels were related with inadequate response to controlled ovarian stimulation in in vitro fertilization in particular conditions as poor ovarian responders or polycystic ovary syndrome. However, limited data are available about a possible relationship between endogenous androgens levels and ovarian response to stimulation in a population of infertile patients without a specific pathology affecting androgens production.
Study design, size, duration: We performed a retrospective study in the Department of Reproductive Medicine of a private hospital. The medical records of all consecutive patients who underwent IVF between January 2017 and January 2018 with all causes of infertility were reviewed. Two hundred eighty patients were included in the study. Patients with conditions known to be associated with abnormal androgen production like polycystic ovary syndrome or advanced reproductive age (over 40 years old) were excluded from the study.
Participants/materials, setting, methods: The following were measured in serum at the first evaluation for infertility before IVF: total testosterone, dehydroepiandrosterone sulphate (DHEAS), sex hormone binding globulin (SHBG) and free androgen index (FAI) was calculated. The number of the oocytes obtained after COS, zygotes number and fertilization rate were also retrieved from the medical files of the patients.
Main results and the role of chance: We found a positive correlation between total testosterone and oocytes (beta=0.176, p=0.001) and zygotes number (beta=0.230, $p<0.0001$) which was maintained after adjustment for age. Patients in the lowest quartile of DHEAS serum level had a significantly lower number of oocytes as compared with patients in the highest three quartiles (6.92±5.6 versus 8.49±5.43, p=0.045). A value of FAI above median value was associated with higher oocytes (9.36±5.98 versus 6.96±4.88, p=0.001) and zygotes (6±4 versus 4.59±3.2, p=0.003) number in comparison with

patients with lower FAI level. No relationship between androgens level and fertilization rate was identified.

Limitations, reasons for caution: The main limitation of the study is the relatively small number of patients included in the study. Another limitation is the fact that the serum androgen level was measured before IVF was performed and were probably influenced by the COS protocol.

Wider implications of the findings: Since the oocytes and zygotes number was reported to be an important predictor of live birth, the association between higher androgen levels and these parameters in patients without obvious abnormalities of androgen production offers an interesting perspective of possible ways to influence therapeutic success.

Trial registration number: NA

P-697 Investigation and management of fertility problems: A systematic review of guidelines

A. Kolokythas[1], P. Kolokytha[2], L. Abel[3], J. Duffy[3]

[1]*University of Oxford, Department of Continuing Education, Oxford, United Kingdom*

[2]*National and Kapodistrian University of Athens, Obstetrics & Gynecology, Athens, Greece*

[3]*University of Oxford, Department for Continuing Education, Oxford, United Kingdom*

Study question: What is the variation in recommendations and the methodological quality of the different national and international guidelines on the investigation and management of infertility?

Summary answer: There is substantial variability on the scope as well as on the methodological quality of the guidelines.

What is known already: Infertility is a complex term including a plethora of etiologies and possible therapies. The infertile patients are also a unique category of patients, with high hopes for procreation that makes them potential easy targets for exploitation. For those reasons, the existence of good quality clinical guidelines on infertility could help towards universal, evidence-based, high-quality standards of care.

Study design, size, duration: Systematic review.

Participants/materials, setting, methods: A database search in EMBASE, MEDLINE, Pubmed and the International Guideline Library as well as an additional purposive search from leading national and international authorities and Google took place on 07.07.2018 in order to identify relevant guidelines on investigation and/or management of infertility. Their recommendations were mapped, a presence and a disagreement rate was calculated and their methodological quality was assessed using the AGREE-II instrument.

Main results and the role of chance: A total of 24 guidelines were included in the study. Only 2 of them addressed infertility as an entity, whereas the rest addressed only a specific etiology. Overall, substantial variability on the scope of the guidelines was observed, but individual recommendations appeared to be coherent. Methodologically there was substantial variability on the quality not only across guidelines but also in different methodological aspects within the same guideline.

The development of universal guidelines for complex medical entities is challenging. However, for infertility, the majority of the recommendations agreed among different guidelines. Methodologically, all the guideline had their pros and cons but the domains needing the biggest improvement are public involvement, financial transparency and suggestions for better applicability

Limitations, reasons for caution: Due to the language restrictions, 7 guidelines written in Spanish, Russian and Polish were excluded and the possibility that valuable information on variability, especially for the 4 Spanish-speaking countries of Central and Latin America that have clear ethnological, cultural and geographical differences from any other included guideline cannot be excluded.

Wider implications of the findings: The discrepancies of the present guidelines can potentially create confusion among patients with infertility but also health providers in that field. A consensus on the most important steps in the investigation and management of infertility would be advantageous for all parties.

Trial registration number: PROSPERO ID CRD42018111255

P-698 Follicular fluid composition impact on folliculogenesis - age and BMI as major factors contributing to oxidative/inflammatory biomarkers levels

L. Costa[1,2], P. Oliveira[3], B.M. Fonseca[1], I. Rebelo[1]

[1]*University of Porto, UCIBIO- REQUIMTE- Biochemistry laboratory- Faculty of Pharmacy, Porto, Portugal*

[2]*Hospitalar Center of Vila Nova de Gaia/Espinho, Human Assisted Reproduction Unit Dra. Ingeborg Chaves, Vila Nova de Gaia, Portugal*

[3]*University of Porto, EPIUnit- Department of Population Studies- Institute of Biomedical Sciences Abel Salazar, Porto, Portugal*

Study question: How does oxidative and inflammatory biomarkers levels correlate with patients' intrinsic factors?

Summary answer: Age and BMI appear the be major factors correlated with CRP, AOPPs and TAS levels on FF

What is known already: Follicular fluid (FF) composition results from the contribution of blood plasma constituents that cross the blood follicular barrier and granulosa cells (GC) secretory activity. Since it provides the microenvironment for oocytes development, it represents an optimal source of non-invasive biochemical predictors of reproductive potential. Any dysregulation in FF composition can alter ovarian follicular dynamics and, thus, impair oocyte quality and fertility. Although the research in this area has progressed towards a more complex type of molecular analysis, no reliable biochemical predictors of oocyte quality in FF has been determined so far, nor the main factors affecting FF composition.

Study design, size, duration: This study was conducted in 238 women undergoing IVF at Hospitalar Center of Vila Nova de Gaia/ Espinho, Portugal, from March to December 2018. This study was approved by the Ethical Committee of the Hospital and by the National Data Protection Commission (authorization number 526/2017). All patients provided written consent before entering the study. Cluster Analysis was carried so that groups with similar subjects, with respect to the study variables, could be defined.

Participants/materials, setting, methods: At oocyte pick-up, FF was collected, centrifuged and supernatants were stored at -80°C for further analysis. The quantification of C-reactive protein (CRP), Total Antioxidant Status (TAS), Superoxide Dismutase (SOD) and Glutathione were performed automatically using commercial kits; Advanced Oxidation Protein products (AOPPs) and Total Hydroperoxides (TH) were measured using in-house spectrophotometry methods. The different clusters were compared by an Analysis of Variance (ANOVA). Significance was assessed for $p<0.05$.

Main results and the role of chance: Four clusters were identified based on age and BMI (low BMI/older; low BMI/younger; high BMI/older; high BMI/younger). Significant differences (ANOVA $F=3.537$, $p=0.016$) in AOPPs levels between higher BMI/young and higher BMI/older; in TAS levels (ANOVA $F=4.023$, $p=0.009$) between low BMI/young and low BMI/older; and in CRP levels (ANOVA $F=10.089$, $p<0.001$) between low and high BMI patients. No significant differences were found for the other factors. Thus, age and BMI were the patients' intrinsic factors that mostly contribute for the clusters formation.

Limitations, reasons for caution: Since this study was performed using the pool of FF, our results indicate the global implications of FF composition for follicular development.

Wider implications of the findings: The use of FF as a source for fertility biomarkers is of great interest since it is non-invasive and easily available. In this study we suggest that age and BMI strongly affect FF composition and may contribute to an imbalance in the oxidative or inflammatory status, ultimately affecting reproductive potential.

Trial registration number: not applicable

P-699 free luteal phase support in mild ovarian stimulation with clomiphene citrate in IVF patients: a randomized prospective controlled trial

A.R. Oumeziane[1], S. Barbara[1], N. Boucekkine[2], N. Tazairt[1], A. Lacheheb[1], S. Chemoul[1], N. Chabane[1], S. Mouhoub[1], R. Bourihane[1], K. Djerroudib[2], F. Nanouche[1], P. Devroey[3]

[1]*TIZIRI IVF center, Reproductive medicine, Algiers, Algeria*

[2]*TIZIRI IVF center, Embryology, Algiers, Algeria*

[3]None, None, none, Belgium

Study question: Is there a need for a luteal phase support in mild ovarian stimulation with clomiphene citrate (CC) in IVF patients?
Summary answer: There is no need for luteal phase support with clomiphene citrate in IVF.
What is known already: The benefit of mild ovarian stimulation with clomiphene citrate with or without human menopausal gonadtropins (hMG) has been well established in previous studies (Benadiva 1995, Fauser 1999, Nargund 2007,Cohen 2012, Ferrareti 2015).

The endocrine profile of the luteal phase in ovarian stimulation with clomiphene citrate and hMG was analyzed and it has been demonstrated that LH concentrations were normal (Smitz 1988).

In a pilot study it has been demonstrated that there is no need for luteal phase support in IVF cycles after mild stimulation with clomifene citrate and hMG (Ferrareti 2016).
Study design, size, duration: It is a randomized prospective controlled trial including 61 patients.

Patients are divided in two groups: 31 patients are allocated in group 1 with luteal phase support. 30 patients are allocated in group 2 without luteal phase support.

Endocrine profile in the luteal phase was analyzed: progesterone, LH and estradiol were measured

The study was conducted from September 2017 to December 2018.

Chi^2 T-test , multivariate linear regression and curve Roc analysis were performed.
Participants/materials, setting, methods: 61 normo-responders patients <37 years old, BMI <29Kg/m^2, 1st or 2 nd attempt.

Patients were stimulated in antagonist protocol with 100mg of CC and 150IU of hMG. One blastocyst was replaced. Group 1 received 600mg of vaginal progesterone from the evening of egg retrieval, and in group 2 the luteal phase was not supported. Supernumerary blastocysts were vitrified, after thawing, one blastocyst was replaced in a natural cycle.

The study was performed in Tiziri IVF center.
Main results and the role of chance: The baseline characteristics were similar in the two groups. The total dose of gonadotrophins was 609.7±159.4 IU in group 1 and 655±234.6 IU in group 2 (P=.0.379)

The mean of metaphase-II oocytes was 3±1.8 in group1 and 3.2±2 in group 2 (P=0.739)

The 2PN rate was 90.3% in group 1 and 84.4% in group 2 (P=0.825)

The mean number of blastocyst obtained was 1.7±0.8 in group 1 and 1.8±0.9 in group 2 P=0.688)

The blastulation rate was 61.9% in group 1 and 62.2% in group 2. (P=0.880)

Clinical pregnancy rate was 35.4% in group 1 and 33.3% in group 2. (P= 0.850)

The Ongoing pregnancy rate per fresh transfer was .22.6% for group1 and 20% for group 2. (P=0.806)

In the first transfers of frozen blastocysts, 5 pregnancies were obtained out of 14 replacements (35.7%). 21 blastocysts are still vitrified.

In a multivariable analysis progesterone, LH and estradiol level at day 5 and day 7 ajusted to arm intervention with or without luteal phase support, only progesterone level at day 5 was a predictor of the ongoing pregnancy. Roc curve analysis identifed progesterone level ≥ 37.4 as the best threshold to ipredict of the ongoing pregnancy (AUC 0.795) OR 11.32 (95CI%, 1.33-96,13) P=0.026.
Limitations, reasons for caution: This protocol has been tested in patients with normal ovarian function i.e. with normal AMH , normal AFC and normal ovulatory cycle. It has not been tested in poor prognosis patients and high responders
Wider implications of the findings: The mild ovarian stimulation with clomiphene citrate without luteal phase support in IVF normal responders patients is a promising and realiable approach ,minimizing the burden and the cost .
Trial registration number: None

P-700 Gestational sympathetic stress decreases noradrenaline placental transporter an program the offspring fertility, a third generation study

H. Lara[1], B. Piquer[1]

[1]Universidad de Chile, Biochemistry and Molecular Biology, Santiago, Chile

Study question: Could exposure to sympathetic stress during gestation changes placental NE transport to modify female offspring in their reproductive function when adults?
Summary answer: The exposure to gestational sympathetic stress program their postnatal development and decreased fertility capacity for three generations.
What is known already: . During pregnancy, the placenta plays an essential role in keeping low levels of monoamines in the uteroplacental circulation, the NE transporter (NET) generates an influx of NE both from the maternal and the fetal blood circulation to the placenta, which allows to maintain low concentrations of NE in the fetal circulation. If this system fails, NE clearance may be reduced, which could lead to increased fetal exposure to NE.
Study design, size, duration: The aim of this work was to determine the changes caused by gestational sympathetic stress (exposure to 4°C/3h/day during all gestation), in the functional capacity of the NE transport by placental NET and the reproductive capacity of the female offspring as adults. We studied if the next generation were also affected by these stress exposure of the first generation of pups. Morphological analysis of the ovaries was performed.
Participants/materials, setting, methods: Sprague Dawley rats were used. We determined: a.- at gestating mother level, the NE plasma concentration by high performance liquid chromatography (HPLC), placental NET functionality by the capacity to incorporate 3H-NA and protein by western blot analysis. To study the programming of reproductive capacity, we studied second and third generation female offspring (percentage of pregnancy, number and weight of female offspring) and preliminary the fourth-generation of rats.
Main results and the role of chance: : Gestational stress increases plasma NE concentrations in pregnant rats throughout gestation, which correlates with a decrease in the ability of the placenta to perform NE clearance from the fetus to the mother. This would indicate that the exposure of fetuses to high NE could program their postnatal development. In the first generation, we found a small number of secondary and antral follicles in the ovary of the female rats; delayed puberty and disrupted estrous cycling activity that conduct to a decreased fertility. A small number of pups per litter and a decrease of about 20% characterize the second generation in their fertility capacity. The third generation decreased even more their estrous cycling activity and have a 50% decrease in their fertility capacity.
Limitations, reasons for caution: The fourth generation is being studied but it seems to recover their estrous cycling activity and preliminary evidence shows that there is also a recovery of their reproductive capacity, thus it is important to study the possible epigenetic effect involved in these changes.
Wider implications of the findings: The results strongly suggest that changes in the environment in which the gestating mother maintain gestation, affect in a permanently form some reproductive capacities of the offspring
Trial registration number: This study was authorized the Bioethics committee of Universidad de Chile number CBE2012-18

P-701 Antimullerian Hormone predicts supernumerary blastocysts for cryopreservation in first IVF cycles

C. Canon, M.D.[1], R. Setton[2], L. Zimmerman[2], Z. Rosenwaks[2], S. Spandorfer[2]

[1]NYP- Weill Cornell, Obstetrics and Gynecology, New York, U.S.A.
[2]Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.

Study question: Can antimullerian hormone (AMH) levels, independent of age, be used to predict the availability and number of supernumerary blastocysts for cryopreservation in the first IVF cycle?
Summary answer: AMH levels of <1 are associated with a lower likelihood of obtaining supernumerary blastocysts for cryopreservation across all age groups.
What is known already: Antimullerian hormone (AMH) has been established as a marker of ovarian reserve and as a predictor of response to controlled ovarian hyperstimulation. The ability of AMH to predict the availability and number of supernumerary blastocysts after a single in-vitro fertilization (IVF) cycle across age groups has not been well-delineated.

Study design, size, duration: This is a retrospective cohort study. A total of 2,561 patients who initiated an IVF cycle with the intention of fresh transfer and cryopreservation of excess blastocysts between January 2010 and December 2016 were analyzed.

Participants/materials, setting, methods: Patients who underwent their first IVF cycle with the intention of fresh transfer and cryopreservation of supernumerary blastocysts were included. Patients were divided into three age groups (Group A: age <35, Group B: age 35-39, and Group C: age ≥40), and then analysis was performed based on AMH levels of <1 or ≥1 ng/mL. Statistical analysis included student's t-test and chi-square test. $P<0.05$ was deemed statistically significant.

Main results and the role of chance: Patients were divided into three groups: Group A consisted of 860 patients (AMH<1 = 163, AMH≥1 = 697), Group B had 919 patients (AMH<1 = 424, AMH ≥1 = 495), and Group C included 782 patients (AMH<1 = 510, AMH ≥1 = 272). A total of 430 patients did not undergo embryo transfer due to cycle cancellation, no oocytes retrieved, no normal fertilization, no normal embryo development, or the decision to cryopreserve to avoid OHSS. The groups were similar for gravity, parity, BMI, and fertilization rates per oocyte retrieved. Peak estradiol levels, the number of oocytes harvested, and the number of mature oocytes decreased with older age and lower AMH. AMH levels of ≥1 were associated with an increased likelihood of having day-5 or day-6 blastocysts available for cryopreservation across all age groups (Group A: 34% vs. 64%, Group B: 19% vs. 52%, and Group C: 26.5% vs. 4%, for AMH<1 vs. ≥1, respectively; all $P<0.001$). For each age group, there was a significantly greater number of supernumerary blastocysts cryopreserved per cycle start in patients with an AMH of ≥1 compared to an AMH of <1.

Limitations, reasons for caution: This is a retrospective study. A multicenter study may help to prove the generalizability of our single-center data.

Wider implications of the findings: The use of AMH to predict the availability and number of supernumerary blastocysts for cryopreservation in the first IVF cycle regardless of age could help in counseling these patients regarding outcomes in the first IVF cycle.

Trial registration number: Not applicable

P-702 Use of oral micronized natural progesterone to prevent LH surge during controlled ovarian stimulation in oocyte donors with a previous donation cycle with antagonists.

A.M. Gutierrez[1], D. Zepeda Escamilla[1], H.J. Juarez Santacruz[1], A.M. Gutierrez Gamiño[1], P. Cancino Villarreal[2], P. Zuñiga Sanchez[3], C. Lanuza Lopez[1], L. Ruvalcaba Ortega[1], C. Gonzalez Ortega[4]

[1]*Instituto VIDA, Infertility, Leon, Mexico*
[2]*Instituto VIDA, InVItro laboratory, leon, Mexico*
[3]*Instituto VIDA, Investigation, leon, Mexico*
[4]*Institito VIDA, InVitro laboratory, leon, Mexico*

Study question: Can oral progesterone be as good as antagonist protocol when used to prevent LH surge in donors of our oocyte donation program?

Summary answer: The number of mature oocytes obtained, stimulation days, gonadotrophin consumption, as well as gestation, implantation and abortion rates were similar between both protocols**.**

What is known already: In order to reduce costs and avoid discomfort to patients, hyperstimulation protocols have recently been designed using progesterone primed ovarian stimulation (PPOS), instead of GnRH analogues, achieving good cycle control in patients undergoing In vitro fertilization. In these patients "freeze all" strategy is applied because progesterone during follicular phase produces non-receptive endometrium, with the need to transfer the embryos later in a substituted cycle with good results.

There is not much information about the use of PPOS in oocyte donors.

Study design, size, duration: Prospective case control study performed with 30 oocyte donors and 60 controlled ovarian stimulation (COS) cycles from July 2017 to September 2018. All donors had a previous cycle of COS with menotropins and GnRH antagonists. The donors served as their own control for the next cycle using PPOS. Oocytes retrieved could be used for one or more recipients. Results obtained in the recipients were also analyzed in order to verify embryo competence.

Participants/materials, setting, methods: 30 donors with an age between 18 and 30 years and normal ovarian reserve who had a previous COS cycle of oocyte donation with menotropins (Merapur 225 IU/day, Ferring) and GnRH antagonists (Cetrotide 0.25 mg/day, Merck) starting on day 7. PPOS started on day 3 with 225 IU of HMG (Merapur, Ferring) and with 100 mg of oral micronized natural progesterone (Utrogestan, CORNE) daily until the day of the triptorelin application for oocyte maturation.

Main results and the role of chance: There was no significant difference in the number of oocytes retrieved (20.3±12.1 for antagonists and 21.5±7.5 for PPOS, p=0.27) and MII oocytes obtained 17.3±5.2 and 18.1±6.1, respectively, p=0.48), with similar number of days required for stimulation (9.0±1.1 and 9.2±1.5, p=0.24) and HMG required. There was no premature elevation of LH in either of the two protocols and the mean value of LH on the day of the trigger was similar also (3.7±1.7 and 3.4±1.5, respectively). There was a profound suppression of LH values (<2mUI/ml) in three patients of the PPOS protocol (10%), while none was found in the antagonist protocol ($p\leq0.05$).

Pregnancy between both protocols was similar: (OR: 0.84, 95% CL 0.38-1.87, p=0.68): 64.5% for antagonists (33/51) and 68.3% for PPOS (41/60), as well as the implantation rate (OR: 1.07, 95% CL 0.62-1.83, p=0.80): 44.4% for antagonists and 42.7% for PPOS. No difference was found in abortion rates (OR: 1.29, 95% CL 0.37-4.47, p=0.68): 18.18% for antagonists and 14.6% for PPOS. The majority of pregnancies continue until the moment in course, without finding any congenital malformations in ultrasound or newborns. 28 of 30 (93.3%) donors expressed preference for the PPOS cycle due to a lower number of injections applied.

Limitations, reasons for caution: This is an initial study of our group and little has been written about this use of progesterone in PPOS in egg donation. It is a limited sample in size and more studies should be carried out to corroborate these findings.

Wider implications of the findings: PPOS is a very interesting option for COS not only in oocyte donation, but also in patients requiring IVF for any reason using the "freeze all" strategy and deferred embryo transfer.

Trial registration number: Not applicable

P-703 Letrozole versus Clomiphene Citrate for induction of ovulation in PCOS Infertile patients for IUI : a comparative study

P.C. Jindal[1], R. Singh[2], M. Singh[2]

[1]*Bhopal Test Tube Baby Centre, Infertility, Bhopal, India*
[2]*B T T B C - Bhopal, iNFERTILITY, Bhopal, India*

Study question: To compare the effects of letrozole and clomiphene citrate (CC) for ovulation induction in women with polycystic ovary syndrome (PCOS) IN IUI CYCLES ?

Summary answer: Letrozole has better ovulation induction than clomiphene citrate (CC) for in women with polycystic ovary syndrome (PCOS) IN IUI CYCLES .

What is known already: Clomiphene citrate (CC) is still the standard drug for inducing or augmenting ovulation. It is not, however, equally successful in all situations. Clomiphene resistance, which refers to the persistence of anovulation after standard CC therapy, occurs in 15–20% of the patients. In addition, CC may have a negative effect on the cervical mucus and endometrium. Treatment with CC is associated with a discrepancy between ovulation and conception rates, and the incidence of miscarriage has been claimed to be higher than in the general population.

Letrozole is an aromatase inhibitor used for ovulation induction and represent a real alternative to CC?

Study design, size, duration: This prospective clinical trial was conducted on 236 infertile Patients (2016-2018) who were diagnosed as having anovulation due to PCOS.

Participants/materials, setting, methods: This prospective clinical trial was conducted on 236 infertile Patients (2016-2018) who were diagnosed as having anovulation due to PCOS.

All patients were randomised by computer in two groups -Letrazole group (2.5-5mg) and CC group(50-100mg) given for 05 days.

All patients have documented at least one patent fallopian tube by either hysterosalpingogram or laparoscopy, and history of pelvic surgery with tubal blockage was excluded from the study. The male partners had a normal seminal analysis.

Main results and the role of chance: Ovulation occurred in 34% in the letrozole group and 18% in the CC group,

with a statistically significant difference between the two groups .

Limitations, reasons for caution: Our study found advantages to using letrozole rather than CC as a first-linetreatment for inducing ovulation in women with PCOS.

The strength of our study is that we have been able to preliminarily explore the effects of letrozole and CC for ovulation induction in PCOS in IUI.

Wider implications of the findings: Compared with CC, the use of letrozole led to a statistically significant increase in the number of developing and mature follicles .

The endometrium was, astoundingly, statistically significantly thicker in the letrozole group.

Trial registration number: not required

P-704 The Impact of The Couple's Age on Fresh IVF/ICSI Outcomes

F. Bai[1], D. Wang[1], Y. Fan[1]

[1]National Center for Women and Children's Health, Assisted Reproductive Technology Management, Beijing, China

Study question: Could the husband's age and the couple's age gap be correlated with IVF/ICSI clinical outcomes?

Summary answer: Both the husband's age and the couple's age gap might be important factors for predicting the outcomes of IVF/ICSI procedures.

What is known already: It is well-known that the female's age is closely related with the outcomes of assisted reproductive technology. While the influence of the couple's age gap or the husband's age remains unknown or less certain. The couple's age gap is an important impact factor in many social and health researches such as family violence, depression, cancer and so on. Age-related fertility decline and infertility treatment outcomes were discussed and reported mostly from single gender perspective.

Study design, size, duration: A retrospective cohort study of 4340 couples (non-donor gametes) in eighteen ART clinics representing the three regions of east, west, and east of China, including 3041 IVF and 969 ICSI fresh transfer cycles between January 2013 and December 2017.

Participants/materials, setting, methods: Participants enrolled criteria included heterosexual spouse, who undertook fresh IVF/ICSI embryos transfers with non-donor gametes. Clinical procedures were completed. The age gap between the couples were divided by five intervals (>=-5,-4~-1,0,1-4,>=5). Besides, the couple age combinations were analyzed by husband <40 or >=40 and wife<35 or >=35. Treatment outcomes were analyzed by 2PN embryos, clinical pregnancy rate, abnormal pregnancy rate (ectopic pregnancy and spontaneous abortion), live birth delivery rate.

Main results and the role of chance: Age gaps among 4340 couples range from: -16 to 26 in IVF cycles,-12 to 25 in ICSI cycles. The ratio of five gap intervals were 2.2%, 17.9%, 13.7%, 47.0%, 19.3% respectively. Wives who were >=5 years older than the husbands demonstrated significantly lower normal clinical pregnancy rate and live birth delivery rate.($P<0.05$), especially in ICSI cycles, even no clinical pregnancy happened. Wives who were 1-4 years younger than the husbands showed the highest normal clinical pregnancy rate(35.4%) and lowest abnormal pregnancy rate (3.1%), whereas no statistically difference were found in other age gaps groups.

The proportion of age combination groups (H<40+W<35; H<40+W>=35; H>=40+W<35; H>=40+W>=35) were 71.5%, 13.7%, 3.0% and 13.2%. The normal pregnancy and live birth demonstrated no doubtfully lower in husband ≧40+ wife≧35 group. Besides, data showed difference by wife's age, wife's age less than 35, no matter husband's age over 40 or not, normal pregnancy and live birth rates were nearly the same. While if the wife's age was over 35, different outcomes could be seen along with the husband's age, younger husband could lead to better clinical pregnancy rate and live birth rate. For IVF, husband age >=40, clinical pregnancy rate was 15.0%, while husband age<40, 24.6%.

Limitations, reasons for caution: The study was limited by its retrospective nature, population representative have drawback due to only fresh- IVF/ICSI were analyzed. Age gap and combination are social and biological interactive factors, and the findings need further study.

Wider implications of the findings: Big age gap couples had poorer IVF and ICSI outcomes, no matter these wives are young or not. These outcomes seems far more than biological reasons.

Age combination analysis, even though a woman missed the optimal reproductive age, with younger husband (less than 40), she might also have better chances.

Trial registration number: not applicable

P-705 Analysis of menstrual cycle data from a fertility awareness based mobile application

J. Bull[1], S. Rowland[1], E. Berglund Scherwitzl[2], R. Scherwitzl[2], K. Gemzell Danielsson[3], J. Harper [4]

[1]Natural Cycles Nordic AB, Medical Affairs, Stockholm, Sweden

[2]Natural Cycles Nordic AB, Founder, New York, U.S.A.

[3]Karolinska Institutet, Department of Women's and Children's Health, Stockholm, Sweden

[4]University College London, Department of Reproductive Health, London, United Kingdom

Study question: Does analysis of menstrual cycles using a fertility app give us a new way to look at the menstrual cycle?

Summary answer: Cycle and phase lengths differed significantly from the conventional 14+14 day cycle model. Age, but not BMI, had a significant effect on cycle characteristics.

What is known already: Normal menstrual cycles are widely thought to be an average of 28 days with ovulation around day 14 and a 14 day luteal phase. The length is known to reduce with age but estimates vary as to how much. Most studies include a small number of women or restrict cycle length too much to be able to describe the general population with great accuracy.

Study design, size, duration: Prospective analysis of anonymised data collected from 155,345 users of the Natural Cycles app between August 2014 and December 2018. Users were aged 18 to 45, had BMI ranging from 15 to 40, had not recently used hormonal contraception and were not pregnant. Users had to have logged at least 30 entries in the app. Cycles between 10 and 90 days with a detected ovulation were included.

Participants/materials, setting, methods: Menstruation, basal body temperature (BBT) and luteinising hormone (LH) tests were recorded anonymously by users of the Natural Cycles app. Ovulation day was calculated by a proprietary algorithm using BBT measurements and optionally LH tests. Mean cycle and bleed lengths were calculated in cohorts of ovulatory cycles by cycle length, age and BMI. Mean follicular phase luteal phase lengths were calculated in a subsample of ovulatory cycles with LH tests meeting strict data quality criteria.

Main results and the role of chance: Data was analysed from 669,338 menstrual cycles with ovulation detected by the algorithm. The mean cycle length with 95% CI was 29.4 ± 5.7 days and the mean number of days menstruating was 4.2 ± 1.3 days per cycle. In 56,237 of the cycles ovulation was detected using BBT plus LH measurements. They had a mean follicular phase length of 16.2 ± 3.7 days and mean luteal phase length of 12.9 ± 2.0 days. Age had a statistically significant effect on mean follicular phase length, which decreased linearly by 2.4 ± 0.2 days from the age of 25 to 45, and mean cycle length, which decreased by 3.1 ± 0.1 days from the age of 25 to 45. BMI had no significant effect on the observed cycle characteristics.

The very large sample size reduces the likelihood that the results are observed by chance. All but one of the cohorts contained at least thousands of cycles. The possibility of finding false associations was eliminated by calculating confidence intervals instead of P values.

Limitations, reasons for caution: The sample was drawn from the Natural Cycles user base which is not fully representative of the general population. Medical diagnoses were self-reported. Ovulation detection by the algorithm is known to have a small bias relative to ultrasound detection. Only ovulatory cycles were included.
Wider implications of the findings: This is the largest study of menstrual cycle characteristics to date. Cycle, follicular phase and luteal phase lengths varied more than expected. The linear effect of age may have an impact on fertility research. Large scale real-world data collection from mobile applications is an invaluable tool in women's health research.
Trial registration number: not applicable

P-706 Economic analysis of preimplantation genetic testing for aneuploidy (PGT-A) by polar body biopsy in advanced maternal age

K. Neumann[1], K. Sermon[2], P. Bossuyt[3], V. Goossens[4], J. Geraedt[5], J. Traeger-Synodinos[6], M. Parriego[7], A. Schmutzler[8], K. Van der Ven[9], G. Griesinger[1]

[8]*Christian-Albrechts-University, Women's Hospital, Kiel, Germany*
[9]*MVZ für Frauenheilkunde und IvF-Medizin, Zentrum für Gynäkologische Endokrinologie und Reproduktionsmedizin Bonn, Bonn, Germany*

Study question: What is the cost per live birth and the ICER for prevention of a miscarriage by PGT-A by polar body biopsy in advanced maternal age?
Summary answer: The cost per live birth is higher with PGT-A in all cost scenarios and the ICER for preventing one miscarriage is at least 44,047.95 $.
What is known already: A recently published randomized clinical trial (ESTEEM study) reported a lower number of embryo transfers with PGT-A necessary to achieve a similar cumulative live birth rate in patients of advanced maternal age as compared to IVF/ICSI without PGT-A and fewer miscarriages after PGT-A. Furthermore, the number of patients who had at least one embryo transfer was reduced, as was the total number of embryo transfers after oocyte selection by PGT-A.
Study design, size, duration: A decision tree model was constructed using the software TreeAge Pro Suite 2018 (TreeAge Software, Inc., Williamstown, MA) based on the interventions and outcomes of the ESTEEM trial (Verpoest et al. 2018). The ESTEEM trial is the largest RCT on the utility of PGT-A using polar body biopsy and array-based comprehensive genome hybridization (aCGH) and included women in advanced maternal age (AMA) (36 - 40 years).
Participants/materials, setting, methods: Costs and effects were analysed with this model for four different IVF/ICSI treatment cost scenarios: high cost, higher medium cost, lower medium cost and low cost. The cost of PGT-A was set as 5,000 USD ($) and was kept stable across different treatment cost scenarios. A base case, sensitivity and threshold analysis were used to examine the cost-effectiveness implications of PGT-A. Additionally, the cost necessary to prevent one miscarriage was estimated for all cost scenarios.
Main results and the role of chance: The cost per live birth was increased by approximately 11% in the high-cost scenario to approximately 61% in the low-cost scenario for patients undergoing IVF/ICSI with PGT-A. The cost per patient increased likewise, by approximately 14% to 62% in the high to low cost setting, respectively. Threshold analysis revealed that PGT-A would need to be associated with an increase in live birth rate of 28% to 32% or, alternatively, would need to be 2600 $ (high-cost scenario) to 4570 $ (low-cost scenario) less expensive. The ICER to prevent one miscarriage by PGT-A using the base case assumptions was calculated to be 44,047.95 $ (high-cost scenario) to 63,607.65 $ (low-cost scenario). A probabilistic sensitivity analysis showed a cost-effectiveness for PGT-A for 0.4% (high-cost scenario) to 0% (low-cost scenario) of calculated samples.
Limitations, reasons for caution: The model is based on polar body testing using array CGH; the findings may not be valid for other settings of PGT-A. Further simulations of cost and effects in different settings are still ongoing.
Wider implications of the findings: While avoiding unnecessary embryo transfers and miscarriages are important goals, patients and doctors need to be aware of the cost implications of applying PGT-A using polar bodies.
Trial registration number: not applicable

P-708 Physical activity and sedentary lifestyle associations with infertility treatment and pregnancy outcomes among couples entering assisted reproductive procedures

Study question: Do physical activity (PA) and sedentary lifestyle influence infertility treatment and pregnancy outcomes among couples entering assisted reproductive procedures?
Summary answer: Couples undergoing ART procedures were less active and more sedentary than couples not requiring ART. However, PA and sedentary time did not affect treatment/pregnancy outcomes.
What is known already: Several factors affecting ART success, such as age and individual's genetic background are non-modifiable, while there is emerging evidence that different modifiable factors including nutrition, PA, sedentary lifestyle can influence ART outcomes. PA has been associated with reproductive outcomes in men and women, however it is not clear to what extent PA could help or harm infertility treatment outcomes. Further, previous studies have focused on assessing PA using self-reported questionnaires, which have several limitations and there is a need to assess PA and sedentarism with objective tools in order to clarify the impact of PA on infertility and its treatment.
Study design, size, duration: This study was carried out among 128 individuals, 64 women and 64 men, entering for the first-time infertility clinic for ART procedures. The data were collected from the Centre for Reproduction at Uppsala University Hospital, Sweden between February 2011 and January 2014.
Participants/materials, setting, methods: Baseline PA and sedentary time (before entering any treatment) were assessed using an objective method - accelerometry for seven consecutive days and additionally by self- reported questionnaires. For every couple the infertility treatment and pregnancy outcomes were recorded. The sedentary time and PA were compared with the general Swedish population group (n=1172 individuals) data. Pearson's correlation and logistic regression models were used for data analyses.
Main results and the role of chance: In general, the couples, entering infertility treatment were more active (moderate or high intensity PA in women was 47,0 ±16,8 min/day and men 48,0 ±16,8 min/day) compared to the general Swedish population (women 36 ±3 min/day and men 41,0 ±4 min/day respectively). However, they had recorded more sedentary time (women 683,5 ±80,8 min/day and men 709,1 ± 65,0 min/day) than the general Swedish

population (women 486 ±11 min/day and men 497 ±13 min/day respectively). Among our couples undergoing infertility treatment, the mean sedentary time of women was lower than that of men, while moderate or high-intensity PA was higher in men.

When comparing the couples, these couples who underwent ART procedures (IVF, ICSI, or IUI) were physically less active (less high-intensity PA) and were more sedentary (watched more TV) than these couples who did not need ART (after revisions became spontaneously pregnant or mild ovarian stimulation was performed) (p<0,05). Nevertheless, in the present study we did not detect any significant impact of couple's PA and sedentary time on infertility treatment and pregnancy outcomes.

Limitations, reasons for caution: The findings of the current study on the limited sample size should be confirmed in a bigger study.

Wider implications of the findings: Couples undergoing ART are likely to be less physically active and more sedentary. Nevertheless, our study results do not show any effect of PA and sedentary time on infertility treatment and pregnancy outcomes indicating that there is no need to change couple's activity habits before entering ART procedures.

Trial registration number: Not applicable

P-709 Wearable sensors reveal menses-driven changes in physiology and enable prediction of the fertile window: a prospective, observational study

M. Shilaih[1], B. Goodale[1], M. Cronin[1], L. Falco[1], F. Dammeier[1], G. Hamvas[1], B. Leeners[2]

[1]Ava Women AG, Research & Development, Zurich, Switzerland

[2]University Hospital, Department of Reproductive Endocrinology, Zurich, Switzerland

Study question: Can wearable technology predict the fertile window from changes in wrist-skin temperature, heart rate, heart rate variability, respiratory rate, and perfusion across the menstrual cycle?

Summary answer: Wearable technology revealed significant changes in physiological parameters across the menstrual cycle, enabling the development of a high accuracy algorithm for detecting the fertile window.

What is known already: Prior research examining physiological changes across the menstrual cycle has often considered biological responses to shifting hormones in isolation. Clinical studies, for example, have shown women's nightly basal body temperature increases 0.28-0.56°C following post-ovulation progesterone production. Women's resting pulse rate, respiratory rate, and heart rate variability (HRV) are similarly elevated in the luteal phase as compared to earlier in the menstrual cycle. In contrast, skin perfusion decreases significantly during the latter half of the menstrual cycle. Although initially designed for recreational purposes, wearable technology could enable more ambulatory studies of multiple, concurrent physiological changes across the menstrual cycle.

Study design, size, duration: We conducted a prospective longitudinal study, recruiting 237 Swiss women who were trying to conceive between August 2016 and June 2018. As determined a priori, we excluded individuals who: were currently undergoing hormone therapy; had health-related issues or were taking medications affecting menstruation; traveled frequently across time zones; had a sleeping disorder; and/or had been trying unsuccessfully to conceive for over a year. The final sample included 708 menstrual cycles spread across 193 participants.

Participants/materials, setting, methods: Participants wore a fertility tracking device on their wrist nightly for up to one year or until they became pregnant. They also completed an electronic daily diary about their activities in the past 24 hours and took a urinary luteinizing hormone (LH) test at several points throughout each cycle. We assessed phase-based changes in physiological parameters using mixed effects models and trained a machine learning algorithm to recognize the fertile window in real-time.

Main results and the role of chance: After removing women who failed to follow instructions and/or did not have any documented LH surges during the study, the final sample included 708 cycles spread across 193 participants (M=33.02 years old, SD=3.68). On average, participants recorded 3.57 cycles (SD=2.41), with a mean cycle length of 28.21 days (SD=2.87). Analyses using multi-level modeling demonstrated that wearable technology can detect significant, concurrent phase-based shifts in wrist-skin temperature, heart rate, and respiratory rate across the menstrual cycle (all *ps*<.001). Heart rate variability and skin perfusion similarly varied across the menstrual cycle (all *ps*<.05), although these effects only trended towards significance following a Bonferroni correction to maintain a family-wise alpha-level of 0.05. Suggesting a methodological improvement over more traditional methods of Natural Family Planning, our findings were robust to daily, individual, and cycle-level covariates. Furthermore, our machine learning algorithm detected the fertile window with an accuracy of 89% across all cycles, outperforming similar smartphone apps as reported in prior literature.

Limitations, reasons for caution: The models and significant differences detected between physiological parameters in the luteal phase, fertile window, and menstrual phase were based on data from Swiss women aged 18 to 40 years old. Future studies should recruit a larger cross-national sample to ensure culture- or location-specific variables did not bias our findings.

Wider implications of the findings: Our findings align with conclusions from prior research on physiological changes across the menstrual cycle and highlight the impact of machine learning's integration into healthcare. By monitoring numerous physiological parameters simultaneously, wearable technology uniquely improves upon retrospective methods for fertility awareness and enables the first real-time predictive model of ovulation.

Trial registration number: ClinicalTrials.gov NCT03161873

P-710 Distance evaluation of oocyte donation experience by French donors

C. Cordier[1], D. Dewailly[2], B. Ducrocq[3], G. Robin[4], S. Catteau-Jonard[4]

[1]Hôpital Jeanne de Flandre, Service de Médecine de la Reproduction- hôpital Jeanne de Flandre, lille, France

[2]Université Henri Warembourg, Université, lille, France

[3]Hôpital Calmette- CECOS, Biologie de la reproduction, lille, France

[4]hôpital Jeanne de Flandre, Service de gynécologie endocrinienne et Médecine de la Reproduction, lille, France

Study question: Evaluate the percentage of oocyte donors who regretted their donation.

Summary answer: Of the oocyte donors interviewed, none regretted their donation.

What is known already: Studies on this subject have already been conducted abroad, but in many cases oocyte donors are paid, which is not the case in France. Limited researches evaluated voluntary and non-compensated oocyte donation. These studies showed that all the volunteer donors made this donation in solidarity, altruistically, and that the majority of the donors had a parent on an infertility course. The majority was against the payment of the gift. Further, the studies showed that oocyte donors were generally satisfied with their donation.

Study design, size, duration: An observational, cross-sectional and monocentric study was conducted. All the women who gave their oocytes from 01 January 2010 to 31 December 2015 in our institution were contacted by telephone from December 2018 to January 2019.

Participants/materials, setting, methods: 105 women were contacted by telephone during the study. 45 women participated in the study by answering a questionnaire by telephone. Of those who did not respond, 14 had a number that was no longer assigned, 45 did not respond to phone calls despite several trials and one woman declined to participate in the study.

Main results and the role of chance: The response rate was 42.8%. None of the women interviewed regretted having donated oocytes. The average age of the donors at the time of the phone call was 37.7 years, with a minimum age of 30 and a maximum of 44. 98% of the surveyed women gave their oocytes once. 89% of donors would agree to do an other donation. 82% of donors regularly thought back to their gift and kept a positive experience. 64% of women were supported by their relatives and 73% by their partner. Further, 90% of the interviewed women did not have any medical problems (gynecological or not) after donation. Finally, the majority of questioned donors were to keep the oocyte donation free and anonymous.

Limitations, reasons for caution: Methodological bias related to the low response rate. This low rate was probably related to the fact that the donors were contacted remotely from their donation. A significant number of women have changed their coordinates since their egg donation. Moreover, it was a monocentric study.

Wider implications of the findings: In France, current donation principles seem to be suitable for oocyte donors. The satisfaction engendered by the altruistic act seems to be sufficient.
Trial registration number: Not applicable.

P-711 Mediterranean diet and outcomes of assisted reproduction: an Italian cohort study

S.A. Noli[1], E. Ricci[2], S. Ferrari[2], M. Reschini[2], M. Castiglioni[2], I. La Vecchia[2], S. Cipriani[2], E. Somigliana[1], F. Parazzini[1]
[1]Università degli Studi di Milano- Milan- Italy, Department of Clinical Sciences and Community Health, Milan, Italy;
[2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Dipartimento Donna-Bambino_Neonato, Milan, Italy

Study question: Is there any relation between outcomes of In Vitro Fertilization (IVF) cycles and Mediterranean Diet in women of infertile couples?
Summary answer: No clear association was observed between adherence to a Mediterranean Diet and outcomes of IVF cycles.
What is known already: Infertility is a medical condition that affects up to 25 million people in Europe and it has an idiopathic origin in 10-20% of subfertile couples.

Besides non modifiable conditions (parental age), detrimental lifestyle habits have been suggested as potential risk factors for reduced fertility. In particular, over the last decade literature on the relation between diet and fertility has expanded. Focusing on IVF outcomes, folic acid and isoflavones, for example, are suggested to increase live birth rates, as well as healthy diets. The role of specific dietary pattern and food groups is conversely under debate and evidence are still accumulating.
Study design, size, duration: From September 2014 to December 2016 infertile couples, presenting for evaluation to the Infertility Unit of Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, and eligible for IVF, were invited to participate to an ongoing prospective cohort study on the role of lifestyle habits and diet on ART outcomes. The present study reported on evidence obtained from female partners. We enrolled 474 women.
Participants/materials, setting, methods: Women of couples who agreed to participate to the study were interviewed on the day of oocyte retrieval to obtain information on personal and health history, lifestyle habits and diet. Information on diet were obtained using a validated food frequency questionnaire (FFQ) while adherence to Mediterranean Diet was evaluated using an a priori score, Mediterranean Diet Score (MDS). Relative risks (RR) and 95% confidence intervals (CI) for clinical pregnancy were the main outcome measures.
Main results and the role of chance: We distinguished 3 categories of adherence to a Mediterranean Diet: low adherence group (MDS 0-3); intermediate adherence group (MDS 4-5) and high adherence group (MDS 6-9). No significant association was observed between MDS and age, BMI, education, occupational physical activity, cause of infertility and previous ART cycles. MDS was related to daily calories intake and leisure physical activity (PA). Age was the main risk factor for IVF failure: the outcomes considered were embryo transfer, clinical pregnancy and live birth. After adjusting for age, presence of previous IVF cycles was associated to higher risk of missed embryos transfer (RR 1.79, 95% CI 1.05-3.03) and exercising for $\geq$ 5 hour weekly to higher risk of not achieving clinical pregnancy (RR 1.25, 95% CI 1.05-1.49) as compared to $<$ 2 hours per week. Adjusted RRs for IVF failure at each step (embryo transfer, clinical pregnancy, live birth) were calculated including age, leisure PA, daily calories intake, and previous ART cycles. Analyses were also performed in strata of age, previous IVF cycles and cause of infertility: findings consistently showed that MDS was not significantly associated with ART outcomes, although a slightly lower risk of adverse outcome was observed in the MDS 4-5 group.
Limitations, reasons for caution: Potential limitations should be considered: findings should be referred only to patients of infertile couples; information regarding dietary habits was self-reported.
Wider implications of the findings: No clear association was observed between adherence to a Mediterranean Diet and oocyte quality or successful IVF outcomes. However, at the light of previous research and of general benefits due to a healthy diet (including those on obstetrics outcomes), women candidates to ART should be counseled about their dietary habits.
Trial registration number: Not applicable

P-712 Bisphenol A affects the number of oocyte retrieval and embryo implantation in women undergoing in vitro fertilization

J. Shen[1], J. Fan[2]
[1]Women's Reproductive Health Laboratory of Zhejiang Province- Women's Hospital- School of Medicine- Zhejiang University-, Reproductive Endocrinology- Key Laboratory of Reproductive Genetics of National Ministry of Education- Women's Reproductive Health,
[2]Women's Reproductive Health Laboratory of Zhejiang Province- Women's Hospital- School of Medicine- Zhejiang University-, Department of Reproductive Endocrinology- Key Laboratory of Reproductive Genetics of National Ministry of Education- Women's Reprod,

Study question: Are urinary BPA concentrations associated with outcomes among women undergoing *in vitro* fertilization (IVF) treatment?
Summary answer: Bisphenol A affects the number of oocyte retrieval and embryo implantation in women from a fertility center.
What is known already: Bisphenol A (BPA) is ubiquitously present in the environment and the reproductive toxicity of BPA has been well characterized in animal models.
Study design, size, duration: In this study the associations between urinary BPA concentrations and the outcomes of *in vitro* fertilization and embryo transfer (IVF-ET) both in fresh(n=351) and frozen cycles(n=125) were analyzed in the same cohort.
Participants/materials, setting, methods: Between September 2013 and October 2016, 351 women undergoing IVF treatment at the Center for Reproductive Medicine in Women's Hospital School of Medicine Zhejiang University in China were recruited into this study. One-spot urine samples were collected on the day of oocyte retrieval to detect BPA. Multivariable generalized linear mixed model was used to evaluate the association between urinary BPA concentrations and IVF outcomes.
Main results and the role of chance: After adjustment for age, body mass index (BMI), baseline follicle stimulating hormone (FSH), baseline estradiol (E_2) and antral follicle count (AFC) levels, a significant decrease of the number of oocytes retrieval and the rates of clinical pregnancy and implantation were observed in patients with high urinary BPA concentrations. Urinary BPA concentrations were not associated with endometrial wall thickness, E_2 peak levels, cleavage rate, and the proportion of high quality embryos or fertilization rates. Furthermore, there were no associations between urinary BPA concentrations and biochemical pregnancy, abortion or live birth rates per transferred cycle.
Limitations, reasons for caution: Limitations to this study include difficulties in extrapolating the findings to the general population and non-differential misclassification of exposure which remains a concern given the single-spot urine collection and the short half-life of BPA, although such non-differential misclassification of exposures will likely bias the results towards the null.
Wider implications of the findings: Data on the effects of human female exposure to BPA have been inconsistent and further research on the plausible mechanisms of BPA's reproductive endocrine-disrupting effects is warranted.
Trial registration number: not applicable

P-713 Female intimate hygiene practice correlates with the vaginal microbiota; a comparative study between in vitro fertilization (IVF) patients with normal and abnormal vaginal microbiota

K. Rosenstand Jensen[1], P. Humaidan[1], H.O. Elbæk[1], B. Alsbjerg[1], R.J. Laursen[1], A. Mikkelsen[1], J.S. Jensen[2], T. Haahr[1]
[1]Department of Clinical Medicine- Aarhus University, The Fertility Clinic- Regional Hospital Skive, Aarhus C, Denmark
[2]Statens Serum Institute- Copenhagen, Statens Serum Institute, Copenhagen, Denmark

Study question: What is the intimate hygiene practice of women undergoing IVF treatment and its possible correlations with abnormal vaginal microbiota (AVM)?
Summary answer: 36 % of IVF patients had AVM. AVM was correlated with usage of low-pH intimate soap. Surprisingly, a total of 19 % practiced vaginal douching.

What is known already: AVM is a dysbiosis dominated by anaerobic bacteria and has been linked to irritative vaginal symptoms as well as adverse reproductive outcomes, such as increased risk of early miscarriage, preterm birth, and reduced chances of successful IVF treatment. A definitive etiology of AVM is still debated; however, intimate hygiene practice has been suggested to be a possible etiological factor, as the practice of vaginal douching is linked to bacterial vaginosis. This emphasizes the importance of studies in hygiene practice. This is the first study to investigate intimate hygiene practice in IVF patients and its correlation to AVM.

Study design, size, duration: The present study was conducted as an observational cross-sectional study, including a total of 206 IVF patients from four Danish fertility centers. Patients were included during December 2017 to October 2018.

Participants/materials, setting, methods: Patients were eligible for inclusion if they met a list of criteria and received their first, second or third IVF cycle. Besides standard gynecological work-up, patients reported intimate hygiene practice (soap, douching, probiotics) in a questionnaire. Vaginal swabs were obtained for quantitative PCR, targeting DNA of dysbiotic bacteria. Significant differences between women with normal microbiota versus women with AVM were tested using STATA. All p-values were two-sided with a significance level of 0.05.

Main results and the role of chance: From the total population of 206 women, a total of 36 % (75/206) were diagnosed with AVM. Most women used intimate soap (37 %; 76/206), followed by use of water, exclusively (33 %; 67/206); the smallest group used only regular soap for intimate hygiene (27 %; 56/206). Only a few women reported the simultaneous use of regular and intimate soaps (3 %; 6/206). Interestingly, a total of 19 % (33/206) reported the practice of vaginal douching, but surprisingly, this practice was not associated with AVM. Women with AVM tended to use intimate soap more often than women with normal microbiota, 45 % (34/75) versus 36 % (47/131); (p 0.18). No associations were seen between AVM and the use of water or regular soap, respectively. AVM positive patients were significantly older, difference 1.37 years [95 % CI 0.03;2.71] (p 0.04), and they had a significantly higher prevalence of sexual intercourse during 24 hours prior to vaginal sampling, 16 % (12/75) versus 7 % (9/131); (p 0.04). Finally, a fishy vaginal odor was significantly more often reported in AVM positive patients, 13 % (10/75) in the AVM group as compared to 2 % (3/131) in the normal group; ($p < 0.01$).

Limitations, reasons for caution: To the best of our knowledge, this is the first study to investigate intimate hygiene practice in an IVF population. While these results describe the Scandinavian IVF population specifically, more studies are needed to investigate intimate hygiene practice in other populations. Furthermore, larger populations are necessary to draw firm conclusions.

Wider implications of the findings: Future exploration in the cause and effect of the association between intimate hygiene habits and AVM is needed, requiring intervention-based prospective studies. The novel finding of a high prevalence of douching in a Scandinavian population demands further investigation, as this practice is generally discouraged by health authorities worldwide.

Trial registration number: NCT03420859

P-714 Application of a clinical pregnancy prediction model in analysis of Day5 single blastocyst transfer

J. Zhang[1]

[1] *the Third Affiliated Hospital of Zhengzhou University, Reproductive Medicine Center, Zhengzhou, China*

Study question: Construction of a prediction model to enable the selection of patients for single blastocyst transfer (Day 5).

Summary answer: The established predictive model can effectively predict the outcome of single blastocyst transfer (Day 5).

What is known already: With the improvement of sequential embryo culture media and incubation system, the blastocyst culture and transfer technique has been progressively used in ART. It has been approved that the clinical pregnancy rate of blastocyst transfer is significantly higher than that of embryo transfer from cleavage stage. Though the single blastocyst transfer significantly reduces multiple pregnancy rate, not all patients are suitable for single blastocyst transfer. Presently, single blastocyst transfer is applied to the selected patients, who have a higher risk of multiple pregnancy. However, how to judge people with better prognosis outcome remains to be solved in single blastocyst transfer.

Study design, size, duration: A case-control study was used in collecting patient data .The patients with ART treatment and single fresh blastocyst (Day 5) transfer were enrolled in the reproductive medicine center from October 2015 to March 2017.A total of 387 cases of Day 5 fresh single blastocyst were collected in this study, including which from 207 pregnant patients, aged 28.78±3.95 years. There were 180 patients without pregnancy, aged 29.23±4.44 years old. The pregnancy rate was 53.49%.

Participants/materials, setting, methods: The inclusion criteria are as follow: (1) age≤37 years old (2) single embryo transfer on day 5 from fresh cycle. A case-control study was used in collecting patient data: demographic data, history of diseases, pre-treatment examinations, and embryo laboratory data etc. The clinical pregnancy was regarded as the dependent variable, and other variables were regarded as the independent variables, which were done multi-factor logistic regression analysis.

Main results and the role of chance: 1.Univariate analysis: the number of transplantable embryos, the number of high quality embryos, the number of transplantable blastocysts, the number of transplantable blastocysts of high quality embryo, the level of inner cell mass in blastocysts and the level of transplantable in blastocysts were statistically significant ($P<0.05$). 2. Multivariate logistic regression analysis: The level of inner cell mass and the number of transplantable embryo were the factors affecting the clinical pregnancy outcome. OR (level of inner cell mass) = 4.86 (95% CI: 2.56-9.91), OR (transplantable embryo) = 1.09 (95% CI: 1.01-1.18). The predictive model $P=1/1+e^{-(1.689X1+0.087X2-0.405)}$ was established (X1 represented the level of inner cells and X2 showed the number of transplanted embryos). Patients were classified into two groups: one is predicted to be pregnant (the probability P value ≥0.509) and the other is predicted to be non-pregnant ($P<0.509$) (cut off value = 0.509). The predicted AUC of the model was 0.723 (95% CI: 0.673-0.773). 3. The sensitivity of the model (cut off value = 0.509) is 66% (137/207), The specificity of the model is 71%(127/180), the positive predictive value is 72.11%(137/190), the negative predictive value was 64.47% (127/197).

Limitations, reasons for caution: Although the model can predict the clinical pregnancy rate of D5 fresh single blastocyst transfer, the predictive power is 0.723. because of small sample size. It is expected that the predictive power will be increased as the growing of sample size in following study.

Wider implications of the findings: This study analyzed the factors affecting the clinical pregnancy rate of single fresh blastocyst transfer on D5, and established a predictive model of clinical pregnancy rate. The model helps clinicians to select patients who are suitable for single fresh blastocyst transfer on D5.

Trial registration number: None

P-715 Postponing pregnancy seeking and anticipating infertility treatments: an unwise combination.

E. Somigliana[1], **A. Busnelli**[2], **P. Vigano'**[3], **W. Vegetti**[4], **A. Goisis**[5], **P. Vercellini**[6]

[3] *Ospedale San Raffaele, Obstet-Gynecol, milano, Italy*

[4] *Fondazione Ca' Granda Ospedale Maggiore Policlinico, Obstet-Gynecol, milano, Italy*

[5] *London School of Economics and Political Science, Department of Social Policy, london, United Kingdom*

[6] *Università degli Studi di Milano, Dept Clinical Sciences and Community Health, milano, Italy*

Study question: Is the current recommendation to anticipate the infertility work-up after only 6 months of pregnancy seeking in older women justified?

Summary answer: Anticipating clinical management in older women seeking pregnancy is clinically and economically questionable and can unwisely boost over-diagnosis and over-treatment.

What is known already: Postponing motherhood exposes women to the risk of childlessness. Natural fecundity decreases with age and, unfortunately, Assisted Reproductive Techniques (ARTs) do not overcome the detrimental effects of aging. For this reason, in women older than 35 years, it is recommended to initiate the infertility work-up after only 6 months of attempts rather than after the usual one year period. In fact, it is paradoxically claimed to anticipate clinical management in a population of reduced fecundity, thus in a population who would conversely need a longer rather than a shorter duration of pregnancy seeking to reach a reliable diagnosis of infertility.
Study design, size, duration: The aim of this theoretical model was to explore the effects of starting the infertility work-up after 6 months of pregnancy seeking rather than the usual 12 months' period in women older than 35 years. We aimed at determining whether the detrimental impact of a 6 months' delay on the chances of success of ARTs could justify this position. The model was based on cost-beneficial considerations. The perspective was the one of the health provider.
Participants/materials, setting, methods: The assumptions of the model were: 1) infertile women >35 years are straightly treated with IVF for up to three cycles; 2) IVF success rate at first cycle linearly declines with age from 30% at 35 years to 0% at 45 years, 3) the drop-out rate after the 1st and 2nd cycle is 18% and 25%, respectively, 4) the relative reduction of the success rate at 2nd and 3rd cycle is 16% and 26%, respectively.
Main results and the role of chance: The increase in the success of the IVF program associated to an anticipation of 6 months changed with age, increasing from 2.0% at age 35 to 3.0% at age 43. The corresponding Number of women Needed to be Treated (NNTs) decreased from 49 at age 35 to 34 at age 43. Sensitivity analyses modifying the gradient of pregnancy loss per year (decline from 40% to 0% from age 35 to age 45, corresponding to an annual loss of 4%) did not markedly change the results (the increase in success remains <4% at all ages). In order to shed light on the incremental cost-beneficial ratio of the anticipation of treatment we also calculated the incremental success rate per cycle. In the basal situation (live birth rate at 35 years of 30%), it decreased from 1.4% to 1.3% from age 35 to age 43. When setting the live birth rate at 35 years at 40%, the incremental success rate per cycle decreased from 1.9% to 1.8% from age 35 to age 43. In all the scenarios, the estimated impact is well-below the thresholds of 4-10% of success used to define IVF as cost-beneficial (ESHRE Capri Workshop Group, 2015).
Limitations, reasons for caution: The model is theoretical and based on the still debated ideas that IVF cannot overcome the detrimental effects of age and that the available tests for the diagnosis of infertility are inaccurate (duration of infertility still plays a crucial role for a definite diagnosis).
Wider implications of the findings: The position of stakeholders and major International Societies should be less trenchant. More consideration should be given to the consistent risks of overdiagnosis and overtreatment associated to an anticipation of the infertility work-up.
Trial registration number: NA

P-716 Understanding gender differences in factors influencing family-building decisions

B. Grace[1], J. Shawe[2], S. Johnson[3], J. Stephenson[1]
[1]*University College London, Institute for Women's Health, London, United Kingdom*
[2]*The University of Plymouth, The Institute of Health and Community, Plymouth, United Kingdom*
[3]*SPD GmbH, Clinical Research Department, Bedford, United Kingdom*

Study question: Are the factors that drive family-building decision-making the same for men and women?
Summary answer: Financial stability is a key driver for family-building decisions across genders; however women were more likely than men to cite age, partner and societal expectations.
What is known already: With recent demographic changes towards delayed parenthood comes involuntary childlessness and smaller family sizes than desired. Global health policies have highlighted the importance of improving knowledge and awareness of fertility and reproductive health; and as the average age of first-time parents continues to rise, attention is being called to the need to improve fertility awareness. Understanding factors influencing family-building decision-making is therefore important. Although studies have shown that men desire parenthood as much as women do, fertility awareness studies have traditionally focussed on women and few exist on men's attitudes towards family-building. Additionally, gender differences family-building decision-making are not explored.
Study design, size, duration: The study was a qualitative component of a wider mixed methods study. We carried out 35 in-depth interviews with 15 men and 20 women. Interviews were conducted over a 5 month period and were completed in February 2017. Interviewees were purposively sampled to include men and women from the reproductive age range (18-45 years) and of varying ethnic and educational backgrounds.
Participants/materials, setting, methods: Interviewees were sampled from a UK cross-sectional survey on Fertility Awareness. Survey participants were recruited nationwide via online newspaper and social media adverts and of those who agreed to a follow-up interview, 35 were included this study. Interviews lasted an hour on average. Data was transcribed and analysed via framework analysis. Favourable ethical opinion was given by University College London Research Ethics Committee.
Main results and the role of chance: Across both genders, we found recurring themes towards education, career aspirations, affordability, money and financial stability as key factors that drive family-building decision-making. However, men viewed these from the perspective of being able to provide for the family generally and "put a roof over their family's head", while women discussed these themes in more practical terms such as maternity leave, childcare, finding a home with the right proximity to schools, as well as the impact of career breaks on job security.

Own family experiences, freedom and travel, religion, the environment and the current global situation were themes that also emerged across genders.

The women in our study were more likely than men to cite age and biological clock; finding the right partner, relationships, self-doubt, having support systems, health, cultural and societal expectations as factors that drive their family building decisions.

We found that men desired family-building and wanted to be engaged and involved in reproductive decision-making, but tended to defer to the woman's primacy as fertility was seen as the woman's territory. Compared to women, men had lower awareness of age related fertility decline and other factors affecting male fertility.
Limitations, reasons for caution: One of the main methodological limitations of this study is that the interviewees were self-selected, which has implications for generalisability. The results necessarily reflect the views of those who were willing to participate. Additionally, the online recruitment method could result in potential bias towards respondents of higher socioeconomic status.
Wider implications of the findings: To improve fertility awareness, current initiatives need to further explore gender differences that exist in family building decision-making in order to have effective campaigns which can help men and women achieve their desired fertility intentions.
Trial registration number: Not applicable.

P-717 women's anti-müllerian hormone levels predict female general health status: a cross-sectional study

A. Limena[1], V.S. Vanni[1], M. Longo[1], V. Sarais[1], P. Giardina[1], M.T. Potenza[1], G. Campo[1], L. Pagliardini[2], E. Ventimiglia[3], A. Salonia[3], E. Papaleo[1]
[1]*IRCCS San Raffaele Scientific Institute, Obstetrics and Gynecology Unit, Milan, Italy*
[2]*IRCCS San Raffaele Scientific Institute, Division of Genetics and Cell Biology, Milan, Italy*
[3]*IRCCS San Raffaele Scientific Institute, Division of Oncology- Unit of Urology, Milan, Italy*

Study question: To determine whether fertility-related clinical and hormonal data might predict women's general health in terms of significant comorbidities.
Summary answer: Lower Anti-Müllerian Hormone (AMH) levels and parity are associated with decreased women's general health after adjusting for age.
What is known already: Infertility is increasingly being recognized as a predictor and a potential marker of general health, representing a unique opportunity for surveillance and potential risk reduction. In males, specific reproductive parameters such as sperm concentration, testosterone and follicle-stimulating hormone (FSH) values have indeed been found to be inversely related with

the rate of comorbidities expressed by the Charlson comorbidity index (CCI). Conversely, no study has so far explored whether female specific reproductive parameters might be associated with general health.

Study design, size, duration: We performed a cross-sectional study of 8613 consecutive women presenting at our academic center for couple's infertility between August 2005 and April 2018.

Participants/materials, setting, methods: All-comers infertile women presenting at our academic center. Comorbidities were assessed with a self-reported medical history collected by physician, classified by the International Classification of Diseases modified 9th version (ICD-9-CM) and scored with the Charlson Comorbidity Index (CCI). Infertile women's health and fertility status were assessed by clinical and hormonal data. Univariable/multivariable linear regression and logistic analyses were used to test the association between predictors and CCI.

Main results and the role of chance: We assigned CCI=0 to 8181 (95.0%) patients, CCI=1 to 277 (3.2%) patients and CCI≥2 to 155 (1.7%) patients. Of variables studied, only AMH and parity were found to be statistically significantly different among CCI groups, both showing a decrease as general health status decreased. No other parameter including age, BMI, gravidity and hormonal levels differed among CCI groups. At multivariable linear regression models age (-0.034, 0.004; *beta, p value*), parity (-0.025, p=0.027; *beta, p value*) and AMH (-0.038, p=0.001; *beta, p value*) significantly predicted continuously coded CCI. At logistic regression models, only parity (most informative cutoff value <1, p=0.038) and AMH (most informative cutoff value < 2.25 ng/ml, p=0.006) achieved independent predictor status of CCI > 0. Subgroup analyses showed that the association between AMH remained significant after exclusion of patients with cancer or previous cancer treatments.

Limitations, reasons for caution: The design of our study does not allow causal inferences. Also, we didn't include fertile women, which could be useful to assess the generalizability of our findings. Finally, comorbidities were assessed through self-reported medical history, possibly causing information bias.

Wider implications of the findings: Our results suggest the novel finding that AMH is a marker of general female health expressed by comorbidity burden – as observed for sperm concentration, FSH and testosterone levels in males. The directionality of the causal pathways between health and infertility thus deserves further study, both in females and males.

Trial registration number: n/a

P-718 International Natural Procreative Technology Evaluation and Surveillance of Treatment for Subfertility (iNEST): enrollment and methods

M. Reeder[1], T. Parnell[2], K. Panchuk[2], E. Tham[3], J. Stanford[1]

[1]*University of Utah School of Medicine, Department of Family and Preventive Medicine, Salt Lake City, U.S.A.*

[2]*University of British Columbia Faculty of Medicine, Department of Family Practice, Vancouver, Canada*

[3]*FertilityCare, Toronto, Toronto, Canada*

Study question: What are the participation and characteristics of participants in a multi-national study of fertility treatment, including demographic and reproductive characteristics and pregnancy/birth outcomes?

Summary answer: Among 834 consenting couples, nearly 60% completed follow-up questionnaires. Unadjusted, 44% percent had a pregnancy within 3 years, and 32% had a live birth.

What is known already: While much clinical research of infertility focuses on assisted reproductive technologies (ART) such as in vitro fertilization (IVF), some couples do not wish to use ART, or cannot afford it. Natural procreative technology (NPT) is an approach to treating infertility that does not involve ART, and which incorporates medical and surgical treatments with women's fertility tracking to improve reproductive function. The goal of NPT is to optimize reproductive function for conception in vivo. However, to date, evaluation of NPT outcomes in medical practice is limited to a few studies based on single medical practices.

Study design, size, duration: iNEST was a prospective longitudinal cohort study of couples presenting for possible treatment with NPT at 10 participating practices. Characteristics of participating couples were assessed at entrance by questionnaire. Treatments (including NPT or ART), pregnancies, and birth outcomes were followed for up to three years based on data from both practices and participants.

Participants/materials, setting, methods: Couples presenting for possible treatment with NPT at 10 different study sites: USA (Utah, Massachusetts, New Jersey, Louisiana, Missouri, North Carolina, Virginia); Canada (Toronto region); the United Kingdom (Leamington Spa); and Poland (Lublin) were enrolled in the study. Practices periodically entered data about clinic visits, diagnoses, surgeries, pregnancies, and pregnancy outcomes. Yearly questionnaires to the couple (separate questionnaires to women and men) assessed treatments received (NPT, ART, and other), pregnancies, and pregnancy outcomes.

Main results and the role of chance: A total of 834 couples consented to participate in the iNEST study. Of these, 58% of women and 48% of men completed an entrance questionnaire, and nearly 60% of couples (the woman or the man or both) also completed a follow-up questionnaire. Most (60%) of participants had clinic visit data and 52% had clinic diagnosis data. Female participants were on average 34 years of age (range 19-47); 94% of reporting women had 12 or more years of education (43% missing). For time trying to conceive at entrance, 29% reported 1-2 years, 24% reported 3 or more years (33% missing). About half (54%) reported a prior live birth (18% missing). About a third (36%) reported prior ovulation drug use (33% missing), and 6% prior IVF/ICSI (45% missing), and 15% prior artificial insemination (34% missing). Among the 435 with diagnostic information, the most common diagnoses included 29% endometriosis, 49% limited cervical mucus, 24% PCOS, 24% male factor. Forty-four percent achieved a pregnancy during the study (unadjusted proportion), and 32% resulted in a live birth (unadjusted proportion). In a subset of the study, there was a very high correlation for couples' reporting of pregnancy outcomes (live birth, miscarriage) as compared to medical records.

Limitations, reasons for caution: Many of the data are self-reported and some types of data have missing responses for up to 50% of the sample.

Wider implications of the findings: The iNEST study will allow for a broader assessment of NPT treatment received and fertility outcomes based on participant characteristics, clinical diagnoses, and treatments received, in a multi-national cohort.

Trial registration number: NCT01363596 (clinicaltrials.gov)

P-719 Knowledge in Reproductive Health and degree of acceptance of Assisted Reproduction Techniques in students of the University of Castilla - La Mancha

M.J. MORENO DE LA ROSA[1], G. Blázquez Abellán[2], J.A. Ortiz[3], L. Lydia[4], R. Bernabeu Pérez[5], I. Ochando[6]

[1]*UCLM, Uclm, Albacete, Spain*

[2]*UCLM, Medicina Preventiva y Salud Pública, Albacete, Spain*

[3]*Instituto Bernabeu, Genética y Medicina molecular, Alicante, Spain*

[4]*Instituto Bernabeu, Ginecología, Albacete, Spain*

[5]*Instituto Bernabeu, Ginecología, Alicante, Spain*

[6]*Instituto Bernabeu, Biología de la Reproducción, Albacete, Spain*

Study question: What is the degree of knowledge of the students of biosanitary degrees about the concept of reproductive health and the Assisted Reproduction Techniques?

Summary answer: Despite having studied related subjects, students of biosanitary degrees are unaware of fundamental concepts related to Reproductive Health and Reproductive Medicine.

What is known already: According to the Spanish Fertility Society, one out of every six couples belonging to Western countries have fertility problems, presenting this fact a clear growing evolution. One of the causes is the age of the patients and most of the population do not have knowledge of the most basic aspects of Reproductive Health.

Study design, size, duration: Cross-sectional descriptive study that determines the knowledge and attitudes related to Reproductive Health in the university population through the realization of a questionnaire of 53 questions. 915 surveys were conducted between May and July, 2017.

Participants/materials, setting, methods: The respondents had to meet the requirements of being students of the Health Degrees of the Campus of Albacete: Nursing, Pharmacy and Medicine, as well as being willing to participate voluntarily. Those who could not do the survey in person were discarded.

The questionnaire was distributed individually in classrooms of the university itself. The time needed to answer the questions ranged between 10 and 12 minutes.

Main results and the role of chance: Regarding the concept of Reproductive Health, it is noteworthy that 42.3% of respondents considered that female reproductive problems begin after 40 years. Another alarming fact is that out of the 65.4% who had not had medical check-ups, 41.46% considered that their reproductive health was good. Regarding lifestyles, 98.3% said that they condition the time of having the first child and 65% agreed that the job situation should be a priority. Despite this, 82.1% would like to have children at the average age of 30.18 years, while Spanish statistics indicate that the average age of first-time motherhood is 31.47 years. Regarding the Assisted Reproduction Techniques, 92.1% of respondents would use them in the future in case of presenting reproductive problems, 31.4% would rule them out by the alternative of adopting. The difference is more significant when using donation of gametes, since of the 76.4% that would resort to this practice, 31.4% would prefer adoption. It should be noted that 85.6% of respondents said that there is not enough information on the process of donation of gametes.

Limitations, reasons for caution: Possible occurrence of biases that indicate the refusal not to answer certain questions due to lack of knowledge, or of responses that the student can understand as "socially acceptable", without taking into account its true point of view.

Wider implications of the findings: The lack of information present in the respondents could be extrapolated to the clinics of Reproductive Medicine, where patients who decide to postpone the moment of being mothers ends with a treatment with donated gametes, which could be the most recommended option and never the most shuffled.

Trial registration number: ..

P-720 Different sexual-romantic orientations have the same reasons for desire to have children but different prevalence for the desire itself.

R. Widmer[1], M. Von Wolff[1], N. Bitterlich[2], P. Stute[1]

[1]University of Bern- Switzerland, Department of Obstetrics and Gynecology- University of Bern- Switzerland, Bern, Switzerland

[2]Medizin & Service GmbH, Statistik, Chemnitz, Germany

Study question: The main question of this study was to assess if statements about the desire for children were rated the same by different sexual-romantic orientations.

Summary answer: Overall, people with desire for children did not rate statements significantly different. The biggest impact on desire for children were emotional motives.

What is known already: Previous studies mostly focused on hetero- and homosexuals and their reasons for a desire to have children. They demonstrated a generally lower scoring of statements within homosexual individuals. Both sexual orientations had the highest score for emotional aspects of having a child and not financial or personal constraints or social recognition. So far, there have been no studies about other sexual or sexual-romantic orientation.

Study design, size, duration: The study was a monocenter cross-sectional non-interventional cohort survey. During two months people anonymously rated in an online questionnaire statements that might influence their desire for child. Recruitment was performed via use of social media, personal contacts and queer organisations in Switzerland. The study protocol was approved by the Cantonal Ethical Committee.

Participants/materials, setting, methods: The online questionnaire applied comprised general questions about the participant's background, the validated questionnaire about the desire to have children, the "Leipziger Kinderwunschfragebogen", and additional non-validated questions addressing the impact of sexual-romantic orientation and the desire for children. Only adults without children were included. The general questions distinguished the five monogamous orientations: hetero-, homo-, bi-, pan- and asexual with the corresponding romantic orientations.

Main results and the role of chance: Of 837 participants, 642 were included into the study. There were four groups of sexual-romantic orientations that consisted of more than 35 participants: bisexual-biromantic (n=38), heterosexual-heteroromantic (n=230), homosexual-homoromantic (n=159) and pansexual-panromantic (n=55). The prevalence of desire for children varied between 53.46% (homosexual-homoromantic) and 84.55% (heterosexual-heteroromantic). Non-heterosexual-heteroromantic participants rated statements that supported a desire for having children lower and statements with possible problems higher than heterosexual-heteroromantics. However, the corresponding subgroups with participants with a desire to have children showed a very similar pattern. The emotional motives seemed more important than social recognition or financial or personal constraints. Plus, there were only significant difference between individual statements and not between whole motives.

The way people hoped to fulfil the desire for children highly depended on how they biologically could have a child. However, adoption was a valid alternative for homosexuals-homoromantics and pansexuals-panromantics with around 30% of each who voted this as their first choice.

In other words: The significant difference between the orientations in rating the questionnaire is sourced in the different rates of people with desire for children.

Limitations, reasons for caution: The main limitation was the size of the subgroups and the restriction for statistics. In addition, the total number of participants was not enough to represent smaller sexual-romantic orientations. For polygamous people the whole setting would have to be different.

Wider implications of the findings: In conclusion, all sexual-romantic orientations might have a desire for children and for the same reasons. This should be a topic approached in everyday practice and should enforce the politics to take the desire seriously and adjust laws where necessary. Further research about the realisation of the desire is recommended.

Trial registration number: not applicable

P-721 Assessing spousal concordance and its impact on outcome in couples undergoing 1st cycle of ICSI in Glasgow

D. McStay[1], S.M. Nelson[1], K. Alrashid[1]

[1]University of Glasgow, Reproductive & Maternal Medicine, Glasgow, United Kingdom

Study question: To what extent are heterosexual couples undergoing ICSI concordant with respect to baseline characteristics/behaviours and does this impact upon outcome?

Summary answer: Couples are most concordant with respect to age and education status. Couples with discordant exercise habits had increased rates of biochemical pregnancy.

What is known already: Assortative mating and cohabitation concordance cause married/cohabiting couples to share similar traits, with spousal concordance known to contribute to cardiovascular disease and be associated with worse treatment outcomes in other medical specialities. Maternal and paternal characteristics/behaviours are known to affect both natural fertility and success of IVF treatment but the contribution of concordance is unknown.

Study design, size, duration: Prospective cohort study of 306 heterosexual couples recruited between August 2016 and December 2019.

Participants/materials, setting, methods: Couples with complete baseline phenotypic and outcome date were included. All patients underwent NHS Scotland funded treatment in Glasgow, using AMH stratified ovarian stimulation. Pearson's correlation assessed spousal concordance for continuous variables, whilst kappa analysis was employed for categorical variables. Investigation of association between concordance and outcome was achieved using Mann-Whitney U tests, Chi Squared Analysis, independent t tests and logistic regression.

Main results and the role of chance: 264 underwent fresh embryo transfer, of which there were 125 ongoing pregnancies. Couples were most strongly concordant for age ($r=0.59$ $p<0.000$), alcohol consumption ($k=0.661$) and educational attainment ($k=0.655$). Exercise concordance was significantly associated with outcome, with exercise discordance a predictor of biochemical pregnancy (OR: 1.86; 95% CI 1.18-2.92 $p=0.008$). Furthermore, females in discordant couples are significantly less physically active than females in concordant couples (mean difference = 0.4527 times/week $p=0.003$). Notably, the significant association with discordance did not translate to clinical ongoing pregnancy rate. However, there was also no association between exercise concordance and early pregnancy loss.

Limitations, reasons for caution: Kappa analysis is designed for assessing concordance of inter-rater agreement when multiple investigators classify participants. Thus, its use in this study could be controversial. Additionally, NHS eligibility criteria enforces a strict selection bias, most notably with age, BMI and smoking status. Furthermore, categorical variables were self-reported by patients.
Wider implications of the findings: If replicated in further studies, shared education and public health initiatives to attain spousal concordance of lifestyle factors may be beneficial in improving IVF success rates.
Trial registration number: not applicable

P-722 Cervical mucus patterns and the fertile window in women without known subfertility: A pooled analysis of 3 cohorts

S. Najmabadi[1], K.C. Schliep[1], S.E. Simonsen[2], C. Porucznik[1], M.J. Egger[1], J. Stanford[1]
[1] *University of Utah, Department of Family and Preventive Medicine, Salt Lake City, U.S.A.*
[2] *University of Utah, College of Nursing, Salt Lake City, U.S.A.*

Study question: What are cervical mucus patterns and number of days with high or low probability of fertility in women without known subfertility, by parity and age?
Summary answer: Parous and younger (<30 years) women had more days of high estrogenic quality mucus compared to nulliparous and older (≥ 30 years) women, respectively.
What is known already: The rise in estrogen prior to ovulation supports the secretion of increasing quantity and quality of cervical mucus, and the subsequent rise in progesterone causes an abrupt decrease in mucus secretion. Prior studies have demonstrated that women can identify ovulation and the fertile window via daily observations of cervical mucus quality, as compared to follicular ultrasound, or serial serum or urine hormones. Limited data, however, are available to assess the relationship between women's observed cervical mucus patterns and key factors known to influence reproductive capacity, including age and parity.
Study design, size, duration: This study is based on a secondary data analysis, combining data from three cohorts of women. We evaluated cervical mucus patterns and the fertile window in 2,359 apparently ovulatory cycles of 502 women with no known subfertility (18–40 years of age), followed for up to 1 year. Linear and generalized linear mixed models were used to assess cervical mucus patterns and characteristics of the fertile window, taking into account women's self-reported parity and age.
Participants/materials, setting, methods: Participants were US or Canadian women age 18–40 years; not pregnant, breastfeeding or taking exogenous hormones at entry; and without any known subfertility. Women used a standardized protocol for daily observation, description, and recording of cervical mucus vaginal discharge (the Creighton Model protocol). The mucus peak day was used as the estimated day of ovulation.
Main results and the role of chance: The majority of women were <30 years of age (76%), non-Hispanic white (89%) and nulliparous (72%). The mean days of peak type mucus per cycle (one indicator of the fertile window) was 6.4 ± 4.2 days (median 6; interquartile range (IQR) 4–8). The mean number of any potentially fertile days (a broader indicator of the fertile window), identified by the defined algorithms, was 12.2 ± 5.4 days (median 11; IQR 9–15). Nulliparous women age ≥30 years had fewer mean days of peak type mucus per cycle (5.4 vs. 6.3, p=.07) and potentially fertile days (10.7 vs. 12.8, p<.01) compared to parous women age < 30 years. Regardless of parity, women aged <30 compared to women ≥30 years had more potentially fertile days (12.8 days vs. 11.8 days, p=.04). Compared to non-parous women, parous women had higher mucus cycle scores (for estrogenic quality of mucus) (9.0 vs. 8.0, p<.01), more days of peak type mucus (7.3 days vs. 6.1 days, p<.01), and fewer dry days (15.9 days vs. 18.9 days, p<.01). Among parous women, there was little difference in mucus parameters by age.
Limitations, reasons for caution: We cannot exclude the possibility that some women had unknown subfertility or undiagnosed gynecologic disorders. We did not have data on some factors that may impact ovulation, hormone levels, and mucus secretion, such as physical activity and body mass index. Study participants were geographically dispersed but relatively homogeneous demographically.
Wider implications of the findings: Patterns of cervical mucus secretion observed by women are an indicator of fecundity and the fertile window. Women's reproductive health can be enhanced by the assessment of a woman's mucus secretion patterns. Future work should investigate the distribution of similar cycle parameters in women with various reproductive or gynecologic pathologies.
Trial registration number: Not applicable

P-723 Levels and sources of education about the female human reproduction and sexuality in women at their first attempt of fertility treatment

K. Ons[1], K. Ben Ahmed[2], Y. Kissi[3]
[1] *Faculty of Medicine sousse- university of sousse, Obstetrics and gynecology, Sousse, Tunisia*
[2] *Faculty of Medicine sousse- university of sousse, Urology, Sousse, Tunisia*
[3] *Tunisian Society of Sexology 1- Faculty of Medicine sousse- university of sousse 2, psychiatry, Sousse, Tunisia*

Study question: What is the level of knowledge and understanding of infertile women of the female reproductive anatomy physiology and sexuality ?
Summary answer: There is a real lack of knowledge of infertile women about their genitals' anatomy and physiology in addition to their sexual function.
What is known already: Some studies have reported a distortion in the cognition of the female genital tract in non reproductive women, especially after the menopause. Some research have been made on the level and quality of knowledge of infertile women about the functions of their reproductive system with contradictory results but very few have evaluated the education of infertile women about the female reproductive and sexual functions.
Study design, size, duration: We conducted a cross sectional study including 500 infertile women that were referred to our reproductive medicine unit for their first fertility treatment. The study took place from January 2018 to December 2018. We included two groups of patients : 250 women with feminine infertility (G1) and 250 women in couple with an infertile partner (G2).
Participants/materials, setting, methods: All the participants were nulliparus women at the time of their first attempt of fertility treatment. To evaluate the level of knowledge of the patients, we used a 5 sections questionnaire : socio-econimic characteristics and fertility history, anatomy of the female human reproductive system, physiology of the female human reproductive system, the female sexual function and the sources of information about the reproductive and sexual health.
Main results and the role of chance: The two groups were comparable in terms of age, academic level, age of the first sexual intercourse and the duration of infertility. The knowledge about the anatomy of the female human reproductive system was low and there was no significant difference between the two groups regarding the mean correct response rate for the external female genitalia and vulva pattern (5% in G1 versus 3% in G2 , p = 0.15) and for the female internal genitalia pattern (21% versus 17%). The correct answers rate about the physiology and function of the female genitals and the physiology of the menstrual cycle of was very low with no significant difference between the groups (4% in G1 versus 6% in G2). Regarding the physiology of sexual intercourse, the rates of correct answers were also very low in both groups (4%). There was a high rate of incorrect responses regarding the erogenous organs in both groups (82% in G1 versus 89% in G2, p= 0.32). The first source of information on sexuality was the Internet (65% in G1 and 58% in G2) during the last year. All patients reported some discomfort when asking information about the reproductive and sexual health from their physician.
Limitations, reasons for caution: The questionnaire used is not a standardized one. It was adapted for our local population.
Wider implications of the findings: Reproductive and sexual education have to be an important part of the fertility consultation prior to any counselling or treatment of the infertility of the couple. It may help the patients to

fully understand the procedures and treatment sequences in order to give consent.

Trial registration number: not applicable

P-724 Risk of breast cancer in women treated with ovarian stimulation drugs for infertility: a systematic review and meta-analysis

Y. Beebeejaun[1], M. Kamath[2], I. Sarris[1], Y. Khalaf[3], S. Sunkara[3]

[1]*King's College London, Assisted Conception Unit, London, United Kingdom*
[2]*Christian Medical College, Department of Reproductive Medicine, Vellore, India*
[3]*Guy's and St Thomas' Hospital, Assisted Conception Unit, London, United Kingdom*

Study question: Does ovarian stimulation increase the risk of breast cancer in women undergoing treatment for infertility?

Summary answer: Ovarian stimulation did not increase the risk of breast cancer in women undergoing treatment for infertility.

What is known already: Infertility treatment chiefly involves the use of ovary-stimulating agents such as selective oestrogen receptor modulators (e.g Clomiphene citrate, (CC)), aromatase inhibitors (e.gLetrozole) and gonadotropins. These drugs potentiate ovarian oestrogen production. While nulliparity and prolonged exposure to oestrogen are recognised risk factors for breast cancer, the association of ovarian stimulation drugs with breast cancer has not been thoroughly investigated. Past studies were inconclusive, reported inconsistent findings and differed in terms of control population (fertile and infertile women and with or without a past history of breast cancer).

Study design, size, duration: We performed a literature search using MEDLINE, COCHRANE Library, and Scopus, up to December 2018, using a predefined search algorithm. Randomised controlled trials (RCTs), non-randomised controlled studies, case-control studies and cohort studies reporting on any association between exposure to ovary-stimulating drugs and breast cancer were found to be eligible and were included.

Participants/materials, setting, methods: Study characteristics such as study design, sample size, stimulation drug, breast cancer incidence, and follow-up time from these studies were extracted and analysed through Comprehensive Meta-Analysis (CMA) Software. Subgroup analysis for each stimulating agent was performed, comparing treated infertile women versus general population and/or unexposed infertile women, to question the superimposition of subfertility and ovarian induction as an independent risk factor for breast cancer.

Main results and the role of chance: Twenty-two studies (nine case-control and thirteen cohort studies) were eligible for inclusion with a total of 1,597,233 participants.

Twelve studies compared CC treatment to unexposed infertile women (86,710 participants). Overall, the use of CC was not associated with an increased incidence of breast cancer (risk ratio (RR) = 0.69, 95% CI = 0.261; 0.96, p – value = 0.037). However, subgroup analysis found evidence of increasing risk for those who received ≥12 cycles [RR =1.65, 95%CI=1.08; 2.51, p – value = 0.02].

Four studies (66,555 participants) compared the sole use of gonadotrophins, to unexposed infertile women. Its use was also not associated with any increased risk [RR = 0.68, 95% CI = 0.24; 2.01, p – value = 0.493]. Furthermore, when compared to treatment naïve infertile women as controls, the use of Aromatase inhibitor such as Letrozole , was also not seen to be associated with increased risk of breast cancer (RR = 1.02, 95% CI: 0.88–1.18, p-value=0.06) as did the combined use of GnRHa with gonadotrophins (RR = 1.28, 95% CI = 0.75; 2.18, p – value = 0.36].

Limitations, reasons for caution: In some studies, there was limited information given about reasons for infertility in the women included which made it impossible to separate the treatment effects from hormonal imbalances that themselves may increase the risk of breast cancer. Potential confounders such as family history or genetic predisposition were also not clear.

Wider implications of the findings: Based on current review findings, clinicians should be aware of the associated risks of breast cancer with each of the type of ovarian stimulation drugs. The findings of this review will be helpful to guide patients, especially those at risk of breast cancer.

Trial registration number: Not applicable.

POSTER VIEWING
REPRODUCTIVE SURGERY

P-725 Fertility outcomes following laparoscopic reversal of tubal ligation - a retrospective single-centre experience

S. Yeo[1], K.H. Chua[1], H.H. Tan[2]

[1]*Singhealth, Department of O&G, singapore, Singapore Rep. of*
[2]*Singhealth, Department of Reproductive Medicine, Singapore, Singapore Rep. of*

Study question: What are the fertility outcomes associated with laparoscopic reversal of tubal ligation?

Summary answer: Our study found that laparoscopic reversal of tubal ligation offers good pregnancy and live birth rates, and is a feasible alternative to in-vitro fertilization (IVF).

What is known already: Tubal sterilization is a common form of contraception which can be associated with regret and requests to restore fertility. Options for such patients include surgical reversal and in vitro fertilization (IVF). The gold standard for surgical reversal has traditionally been laparotomy and microsurgery. However, recent advances in laparoscopy have offered a minimally invasive option for patients with a desire for fertility after undergoing previous tubal sterilization.

Study design, size, duration: We performed a retrospective review on all cases of laparoscopic tubal reanastomosis surgery conducted in our tertiary centre over a period of six years. Inpatient and outpatient clinical records were traced for data analysis.

Participants/materials, setting, methods: A total of 12 cases of laparoscopic tubal reanastomosis were performed in our tertiary centre between January 2011 to December 2016.

Basic fertility investigations and counselling were performed for all patients. Bilateral tubal reanastomosis was performed with microsurgical equipment following routine laparoscopic entry. Methylene blue hydrotubation confirmed tubal patency intraoperatively.

Demographic details of the participants are as follows:

	n = 12, mean value
Age	34
BMI	23.4
Parity	2.6
AMH	5.7

Main results and the role of chance:

Outcome measures

	n = 12
Pregnancy rate	75.0% (9/12)
Miscarriage rate	8.3% (1/12)
Ectopic rate	8.3% (1/12)
Live birth rate	58.3% (7/12)
Multiple pregnancy rate	0% (0/12)

Characteristics of hospitalization, surgery and interval to pregnancy

Limitations, reasons for caution: The main limitation of our study was the small sample size, although the results are reflective of other studies in this

Length of stay, days (median)	1
Duration of surgery, minutes (mean +/- SD)	156 +/- 20
Interval to conception, months (mean +/- SD)	5 +/- 6.6

field. We aim to use this pilot study to ascertain the positive fertility outcomes associated with laparoscopic tubal reanastomosis, and as a basis for larger prospective studies.
Wider implications of the findings: Based on our experience, reversal of tubal ligation has comparable subsequent intrauterine pregnancy rates to IVF treatment. In addition, laparoscopic microsurgery offers the advantage of faster recovery with less postoperative discomfort, less complications and a smaller surgical scar. More high quality studies should be encouraged in this field.
Trial registration number: Not applicable

P-726 endometrium transplantation facilitates successful fertilization and pregnancy in rats: a preliminary study of autologous orthotopic endometrium transplantation

Y. Wang[1], J. He[2], L. Chen[1], Y. Jiang[3], W. Chen[2], J. Shu[3], J. Wang[1], B. Jin[3]
[1]Zhejiang Provincial People's Hospital People's Hospital affiliated with Hangzhou Medical College, Gynecology, Hangzhou, China
[2]School of Medicine- Zhejiang University, Children's Hospital and Institute of Translational Medicine-, Hangzhou, China
[3]Zhejiang Provincial People's Hospital People's Hospital affiliated with Hangzhou Medical College, Reproductive endocriology, Hangzhou, China

Study question: To explore the feasibility of endometrium transplantation for severe endometrial loss such as refractory Asherman's syndrome.
Summary answer: Endometrium transplantation could regenerate competent endometrium and result in successful pregnancy in rats.
What is known already: Although uterine transplantation has led to live births in some cases, there are much more patients with refractory Asherman's syndrome whose real need is the specific reconstruction of endometrium rather than uterus. In these women, the regeneration of endometrium is difficult by stem cell therapy because of a severe loss of endometrial epithelium and stroma, and for them, endometrium transplantation could be an alternative.
Study design, size, duration: The endometrium of adult Sprague Dawley rats was harvested by a procedure of endometrial stripping technique on one uterine horn randomly. A totoal length of 1 cm endometrium was removed and washed in cold phosphate buffer system, and the residual myometrium was left as recipient. In the transplantation group, stripped endometrium was inserted immediately to the eutopic space of residual myometrium, while no tissue was transplanted in control group.
Participants/materials, setting, methods: At 1 week, 2 weeks and 4 weeks after operation, the uteri were collected and endometrial regeneration was assessed by gross morphology, hematoxylin-eosin staining and Masson's trichrome stain. Immunohistochemistry was taken with antibodies against cluster of differentiation 31, cytokeratin-pan, smooth muscle actin-α.The expression of cytokeratin 7 was measure by western blot. 6 weeks after operation, rats were mated and fetuses in pregnant rats were evaluated on 20th day post coitus.
Main results and the role of chance: Endometrial stripping could remove endometrium completely while preserve myometrium, resulting in trace expression of cytokeratin 7. In the control group, uterine occlusion and hydrops occurred in all the horns of endometrial stripping (15/15), while all the grafts in the transplantation group (15/15) survived without uterine cavity occlusion or hydrops. In controls, endometrium was absent at the stripped site and replaced by fibrotic tissue; However, in transplantation group, good endometrial regeneration was revealed by intact epithelium and stroma with fine revascularization. The expression of cytokeratin 7 in transplanted site was significantly higher than that in stripped site. There were 9 viable fetuses and 1 retarded fetus implanted at the transplantation site in 5 pregnant rats with a total of 29 fetuses in the transplantation horns. The average number of fetuses on the transplantation horns was 5.8 ±1.4, which was significantly higher than that on the stripped horns in the control group (0).
Limitations, reasons for caution: The feasibility of endometrium transplantation were only tested with autologous orthotopic transplant in rats. Whether this procedure could be achieved in allogeneic endometrium transplantation and ultimately applied to the patients, and the mechanism underlying endometrium transplantation and regeneration, remain to be further explored.
Wider implications of the findings: Allogeneic endometrium transplantation has potential in the regeneration of endometrium in refractory Asherman's syndrome, and autologous endometrium transplantation could be applied to repairing cesarean scar defects.
Trial registration number: not applicable

P-727 Preoperative Magnetic Resonance Imaging Predictor for Fertility Preservation of Robotic Myomectomy

K. Jeong[1], J.W. Lee[1], Y.M. Lim[1], S.I. Jung[2], J.H. Park[3], H.S. Moon[1], H.W. Chung[1]
[1]Ewha Womans University Mokdong Hospital- College of Medicine- Ewha Womans University, Obstetrics and Gynecology, Seoul, Korea- South
[2]Konkuk University Medical Center- Research Institute of Medical Science- Konkuk University School of Medicine, Department of Radiology, Seoul, Korea- South
[3]Gangnam Severance Hospital- Yonsei University College of Medicine, Obstetrics and Gynecology, Seoul, Korea- South

Study question: The goal is to identify preoperative Magnetic Resonance Imaging(MRI) predictor for fertility preservation of robotic myomectomy for optimal selection of surgical technique: single-site(SS) or multi-site(MS).
Summary answer: Preoperative MRI predictor could be useful to select SS or MS robotic myomectomy for successful fertility preservation and assume the operative process.
What is known already: Myomas are clinically apparent in about 25% of women and become symptomatic in their reproductive age. Myomectomy is the choice of treatment for women desiring uterine preservation. Although proper minimal invasive surgical technique is requested, laparoscopic myomectomy has some limitations. Adoption of the da Vinci system made it possible to overcome the weaknesses of laparoscopic myomectomy. Owing to the ability of single-port laparoscopy to reduce pain and improve patient satisfaction, robotic SS surgery was developed and introduced. MRI was superior to transvaginal ultrasonography in ascertaining both the correct uterine wall embedment and the position of myomas.
Study design, size, duration: A total of 98 patients who underwent robotic myomectomy after MRI at Robot Surgery Center of Ewha Womans University Mokdong Hospital from July 2015 to March 2018, were evaluated. All patients underwent robotic myomectomy through SS or MS. Final pathology of leiomyoma was confirmed. The correlation was analysed between preoperative MRI predictor and operative or postoperative findings for fertility preservation of robotic myomectomy.
Participants/materials, setting, methods: We assessed FIGO classification, number(>3cm of diameter), size, signal intensity(SI), enhancement of myoma, endometrial distorsion, the thickness of endometrium and junctional zone on MRI. The operation time, estimated blood loss(EBL), chopping time for myoma removal, the number and total weight of removed myoma were measured. After two months, pelvic ultrasonography was performed to define the shape of uterus, endometrial thickness and pattern. The reproductive outcome was investigated when the patient wants to be pregnant.
Main results and the role of chance: Mean age was 35.68±5.04(range 23~45) years old and 80 patients(81.6%) were nullipara. Total diameter of myoma on MRI was 106.75±54.52(range 32.43~273.24) mm and the maximum diameter of myoma was 72.51±25.77(range 32.43~151.03) mm. The operation time was 157.89±61.22(range 60~355) minute and the chopping time was 13.83±17.31(range 1~90) minute. The number of removed myoma was 4.31±4.39(range 1~27) and total weight of removed myoma was 293.11±281.13(range 30~1260) g. The myoma with high SI could be chopped faster and EBL was increased for removal of myoma with high enhancement. Compared to SS, conventional MS robotic myomectomy was performed when preoperative number and total diameter of myoma were increased or deep-seated myoma was diagnosed by Figo classification. After

robotic myomectomy, all patients resumed normal menstruation and showed normal shape of uterus(91.8%), endometrial thickness and pattern(98.0%) by pelvic ultrasonography though 70.4% of patients had the compressed or distorted endometrium. The negative correlation between maximum diameter of myoma and postoperative endometrial thickness using Pearson correlation coefficient(R=-0.139, P=0.195). There is no significant difference of postoperative outcome according to preoperative MRI predictor or robotic surgical technique(SS versus MS). Among 12 patients who wanted to be pregnant, seven women(58.3%) got pregnant naturally(Cesarean section 2, on going 5).

Limitations, reasons for caution: All surgeries underwent using the da Vinci Si system by two gynecologic surgeons who were skilled robotic surgery at one institute and the follow-up period was not enough to conclude the outcome including reproduction.

Wider implications of the findings: The SS or MS robotic myomectomy could be recommended for patient who planned future pregnancy. However, the optimal surgical technique should be selected based on preoperative MRI predictor for effective operative process and successful fertility preservation.

Trial registration number: This study was approved by the Institutional Review Board of Ewha Womans University Mokdong Hospital (No. 05-038-003).

P-728 Does endometrial injury with bipolar electrode during office hysteroscopy improve cycle outcomes in the following or subsequent frozen embryo transfer(FET) cycles?

U. GÖKTÜRK[1], S. Kahraman[1], Y. Sahin[1]

[1]*Istanbul Memorial Hospital, Assisted Reproductive Technologies and Reproductive Genetics Center, istanbul, Turkey*

Study question: Does endometrial injury with bipolar electrode during office hysteroscopy improve pregnancy and implantation rates in following or subsequent FET cycles?

Summary answer: Endometrial injury by using bipolar electrode has no effect on cycle outcomes neither in first or in subsequent FET cycles.

What is known already: Endometrial injury done by mechanical techniques such as pipelle, curettage or hysteroscopic scissor is supposed to promote the secretion of cytokines, growth factors and interleukines, and in this way, increase the chance of implantation in the following cycle. Although its use is widespread, the benefit of endometrial injury still remains controversial.

Hysterescopy by using bipolar electrode is a minimally invasive procedure that allows the treatment of uterine lesions in the outpatient setting without general anesthesia. In comparison with monopolar electrode, thermal injury and fluid overload are less likely. However, little is known about the effect of endometrial injury by bipolar electrode.

Study design, size, duration: This retrospective study was conducted at İstanbul Memorial Hospital ART Center between 2011 and 2018. A total of 673 patients who underwent single frozen thawed blastocyst transfer were analyzed. Control group without a history endometrial injury and subjects with endometrial injury by using bipolar electrode were separated into three groups; Group A(n=150): FET in following first cycle after endometrial injury, Group B(n=523): FET in second or subsequent menstrual cycles after endometrial injury, Group C(n=1413): controls.

Participants/materials, setting, methods: Patients <37 years old with good and top quality blastocysts were included and elective single blastocyst transfer (eSET) was performed. Exclusion criteria were: repeated pregnancy losses, Mullerian abnormalities, intra-uterine adhesions, endometrial thickness <7mm during FET cycle. Endometrial injury was performed with a bipolar electrode (Versapoint ®, through a 5Fr working channel from anterior to posterior uterine walls and uterine fundus on different areas at a depth of 3mm.

Main results and the role of chance: There was no significant difference in patient characteristics such as age, body-mass index, infertility duration, endometrial thickness on embryo transfer day, and Anti Mullerian Hormone levels between the three groups. Clinical pregnancy rate(CPR) was the main outcome 69.3% (n=104), 60.0% (n=314) and 65.3% (n=923), from group A to C respectively, (p=0.11). Ongoing pregnancy rate was 58.0%(n=87),50.0%(n=262) and 54.3%(n=768) from group A to C respectively,(p=0.2) . Clinical miscarriage rate(CM) was calculated as 16.3% (n=17), 16.5% (n=52) and 16.8% (n=155) from group A to C respectively, (p=0.8).

Comparing the hysteroscopic endometrial injury groups (Group A and B), CPR and OPR was higher in group A when compared to group B. Our results indicate that, endometrial injury effect with bipolar electrode was higher in the following first FET cycle compared to second and subsequent cycles, but this difference was not statistically significant.

Limitations, reasons for caution: The limitation of the study is its retrospective nature and prospective studies are needed to elucidate the exact impact of hysteroscopic bipolar electrode endometrial injury on cycle outcomes.

Wider implications of the findings: In conclusion, performing endometrial injury with bipolar electrode during office hysteroscopy in young patients does not improve clinical pregnancy rates after frozen-thawed single blastocyst transfers when compared with control patients without endometrial injury.

Trial registration number: None

P-729 Negotiating a difficult cervix during hysteroscopy using epidural catheter as guide: a novel approach

V. Mishra[1]

[1]*Hegde Fertility, Reproductive Medicine and endocrinology, Hyderabad, India*

Study question: To evaluate the role Epidural catheter as a guide to gain entry in the uterine cavity during extremely difficult hysteroscopy procedures due to a tightly stenotic/fibrosed or tortuos cervical canal.

Summary answer: Epidural catheter can facilitate hysteroscopy in difficult cases due to cervical canal fibrosis, stenosis or extreme tortuosity.

What is known already: Under experienced hands, hysteroscopy is relatively a safe procedure, technical difficulties are rare but may include inability to pass hysteroscope due to extremely tight or totuous internal os or fibrosis in the cervical canal. Uterine perforation is the most common complication (0.13% for diagnostic; 0.76% for operative). Several studies have shown that most uterine perforations occur at the start of the case during early manipulation of the uterus and cervix and commonly occur during uterine sounding, cervical dilation, or hysteroscopic entry.

Study design, size, duration: Case report of 25 cases of extremely difficult hysteroscopies due to stenosed, tortuous or fibrotic cervical canal or internal os, performed over a period of one year (October'17- November'18).

Participants/materials, setting, methods: Hysteroscopy was carried out in an operating theatre using a rigid BETTOCHI microhysteroscope with continuous-flow surgical sheath with a diameter 2.9mm and 30 degree telescope. In each of these difficult cases the scope could not be advanced through the cervical canal despite ultrasound guidance due to extreme stenosis or fibrosis. 18Gauge epidural catheter was used as guide in each of these cases.

Main results and the role of chance: 18G Epidural catheter passed through the operating channel of hysteroscope was used as a guide to delineate the track for hysteroscope. The passage of catheter inside uterine cavity was confirmed ultrasonologically. The scope was then advanced towards the cavity with axial pressure, keeping epidural catheter always under vision. Hysteroscopy could be completed in all these cases without any complications. No episode of perforation, false tract creation, laceration or bleeding was reported. Embryo transfer was subsequently done in all these cases without any difficulty. 3 out of first 5 cases have been positive for pregnancy either after IVF-ET. The result is awaited for rest of the cases.

Limitations, reasons for caution: The role of epidural catheter as a guide in difficult hysteroscopy procedures needs to be further evaluated in larger study setting.

Wider implications of the findings: Epidural catheter by virtue of being of thin caliber, easily malleable, firm but atraumatic can be passed through tight passages also and helps in delineation of correct passage for the hysteroscope. It may be an effective and safe alternative to blind dilation or Laminaria tent insertions.

Trial registration number: not applicable

P-730 Novel use of hysteroscopy in assessment of tubal patency in difficult cannulation

K. Banerjee[1], B. Singla[1]

[1]*Advanced fertility and gynaecology center, Reproductive unit, Delhi, India*

Study question: To assess the method of chromopertubation in cases of difficult cannulation to minimize the false negative cases of tubal block.

Summary answer: Introduction of hysteroscope with visualization bypasses cervical factor and reduces false negative results of tubal patency that is added use of hysteroscope.

What is known already: Hysteroscopy is the procedure in which the uterine cavity is inspected by endoscopy with access through the cervix and it also serves as a method for surgical intervention (operative hysteroscopy). It has been known that 15 – 20% infertile women have uterine factor. So, hysteroscopy plays an important role in the preparation of patient for IVF. In the hysteroscopy, various intrauterine pathologies like polyp, fibroids, uterine deformities and adhesions can be detected and treated. All these pathologies can lead to implantation failure.

Study design, size, duration: Study design - Retrospective analysis
Size – 66 infertile females
Duration – 1 year

Participants/materials, setting, methods: We had performed the laparoscopy and hysteroscopy in 66 females as infertility work up in 1 year in which cannulation through cervical canal was difficult and tubal patency test showed tubal block with Leech Wilkinson Cannula. Then through the inlet of hysteroscope, methylene blue dye was injected and patency of tubes was assessed again.

Main results and the role of chance: In 59 out of 66 females, we observed that when cannuation and dilation of cervix was difficult, then the chromopertubation with hysteroscope showed positive tubal patency test.

Limitations, reasons for caution: In this study infertile females with difficult cannulation of cervical canal are included only

Wider implications of the findings: It reduces false negative results of tubal patency that is added use of hysteroscope that has not been reported earlier.

Trial registration number: Not applicable

P-731 Intrauterine infusion of platelet-rich plasma after hysteroscopic adhesiolysis for patients with recurrent intrauterine adhesions is a new strategy and effective therapy

J. Peng[1], M. Li[2], Z. Zeng[2], H. Zeng[2], T. Li[2], X. Liang[2]

[1]*The Sixth Affiliated Hospital of Sun Yat-sen University, Reproductive Medicine Research Center, Guangzhou City, China*

[2]*Sixth Affiliated Hospital of Sun Yat-sen University, Reproductive Medicine Research Center, Guangzhou City, China*

Study question: To evaluate the effectiveness of intrauterine infusion of platelet-rich plasma (PRP) in patients with recurrent intrauterine adhesions (r-IUA).

Summary answer: Intrauterine infusion of PRP is a new and effective strategy in the treatment of r-IUA in preventing r-IUA and promoting endometrial repair.

What is known already: Prevention of r-IUA and promotion of endometrial repair have been the key objectives for IUA cases after hysteroscopic adhesiolysis. Autologous PRP can promote endometrial growth, and improve endometrial regeneration in women with infertility and thin endometrium

Study design, size, duration: This is a retrospective study, and eleven patients with intrauterine infusion of PRP (group A) and thirteen patients with intrauterine infusion of barrier gels and balloon (group B) in the first hysteroscopy were included in the study.

Participants/materials, setting, methods: Eleven patients with intrauterine infusion of PRP and thirteen patients with intrauterine infusion of barrier gels and balloon in the first hysteroscopy were included. The second-look hysteroscopy and the third-look hysteroscopy were performed one week after the first operation and in the next menstrual cycle respectively. The fourth-look hysteroscopy was performed if necessary. AFS scoring system was used in the judgement of IUA, and the thickness of endometrium covered by endometrium was evaluated.

Main results and the role of chance: Among the 13 patients with the third-look hysteroscopy in group B, 5 patients showed no improvement. Among the 9 patients with the third-look hysteroscopy in group A, 3 patients recovered from severe or moderate IUA to slight IUA, and the remaining 6 patients showed no r-IUA with satisfying endometrial repair. The mean AFS score decreased from 8.22±1.47 in the first hysteroscopy to 2.22±0.63 in the third hysteroscopy in group A, while it decreased from 8.08±1.77 to 4.54±2.90 in group B respectively. There was significantly statistical difference comparing the AFS scores between the two groups in the third-look hysteroscopy ($P<0.05$) instead of the first hysteroscopy ($P>0.05$).

Limitations, reasons for caution: This a retrospective study instead of randomized controlled trials with larger samples. This is the first time that our study reported the application of intrauterine infusion of PRP in the treatment for patients with r-IUA. Intrauterine of autologous PRP is a new strategy in the management of r-IUA.

Wider implications of the findings: Intrauterine of autologous PRP is a safe and new strategy, as well as an effective adjuvant therapy in the management in preventing the recurrence of IUA and promoting endometrial repair in patient with r-IUA.

Trial registration number: not applicable

P-732 Fertility and clinical pregnancy outcome of modified adenomyomectomy in infertile women with uterine adenomyosis

S.H. Yoon[1]

[1]*Dongguk University Ilsan Medical Center, Obstetrics and Gynecology, Goyang city-Gyeong Gi Do, Korea- South*

Study question: Does reduction surgery of adenomyosis have clinical efficacy in infertile women?

Summary answer: Modified adenomyomectomy as a uterus-sparing surgery could be an effective method for increasing pregnancy rate and conservation of fertility potential in infertile women with adenomyosis.

What is known already: The relation between uterine adenomyosis and infertility is controversial, but it appears to affect endometrial receptivity and increase abortion rate. In infertility where uterine conservation is paramount, the treatment of adenomyosis is often complicated, that is to say, medical treatment is often transient and hysterectomy for eradication could not preserve their fertility. At this stage, there is no agreement on the most appropriate therapeutic methods on fertility outcome in infertility patients with adenomyosis. Regarding surgical removal of adenomyosis, including laparoscopic reduction, uterus-sparing surgery appears to be satisfactory and reduced the need for hysterectomy, but needs well designed prospective study.

Study design, size, duration: Prospective clinical trial was conducted. The subjects consisted of 50 infertile patients with adenomyosis and were enrolled after the failure of In Vitro Fertilization (IVF) for pregnancy from December 2007 to September 2017.

Participants/materials, setting, methods: All cases were classified as having unexplained infertility, adenomyosis with severe periodic dysmenorrhea and occasional menorrhagia. This newly designed operative procedure included pediatric foley insertion into the uterine cavity, injection of diluted vasopressin along the uterine incision, T- or transverse H-incision on the adenomyotic wall, careful excision of adenomyosis tissue using argon laser under intraoperative ultrasonography. After debulking surgery, patients underwent follow up examination for symptom relief, reduction of adenomyosis by MRI and pregnancy rate.

Main results and the role of chance: The mean age and the duration of infertility were 35.60 ± 3.37 years and 55.48 ± 48.24 months, respectively. The mean volume of excised specimens of adenomyosis was 94.15 ± 56.63g. The relief of dysmenorrhea was observed clearly in all patients at 6 months after operation (NRS; 7.28 ± 2.29 vs. 1.56 ± 1.29, $p < 0.001$). The amount of menstrual blood was also significantly decreased (140.44 ± 91.68 vs. 66.33 ± 65.85, $p = 0.009$). The CA 125 level was significantly decreased at the time of 6 months after operation (187.75 ± 229.52 vs. 20.36 ± 19.19, $p = 0.026$). Post-operational complication occurred in four patients (subfascial hematoma, ureter fistula, shrinkage of uterus and premature ovarian insufficiency). Five patients were lost in the follow-up. Of 33 patients who attempted pregnancy, 18 patients conceived by natural or IVF or thawing ET after the operation (18 of 33; 54.5%). However, miscarriage occurred in five patients, ectopic pregnancy in three patients, preterm delivery in two patients and eight patients (8 of 33; 24.2%) delivered by cesarean section at term. The rest of the patients have been trying to conceive by IVF-ET or natural course.

Limitations, reasons for caution: The sample size is small, so further study with larger number of patients will be helpful to investigate the possibility of this result.

Wider implications of the findings: This reduction surgery was related to symptom relief of dysmenorrhea, menorrhagia and increasing pregnancy rate, implying that it could be considered as a successful method for infertile women with adenomyosis who need fertility preservation. This is one of few reports on the clinical pregnancy outcome of uterus-sparing surgery in adenomyosis.
Trial registration number: N/A

P-733 Ovarian reserve in women after second surgery for recurrent ovarian endometriosis.

E. Kavteladze[1], V. Strygina[2], V. Shustova[1], Y. Tsoraeva[1]
[1]reproduction and genetics center «NOVA CLINIC», reproduction department, Moscow, Russia C.I.S.
[2]Family planning and reproduction center, Department of Gynecology, Moscow, Russia C.I.S.

Study question: The aim of this study was to evaluate ovarian reserve in women with recurrent ovarian endometriomas compared with newly diagnosed follow-up in 6 months after surgery.
Summary answer: The laparoscopic stripping of recurrent ovarian endometriomas is associated with a high risk of ovarian reserve damage and ovarian failure.
What is known already: Surgery is frequently selected for the treatment of endometriosis. Although surgical excision of endometriosis both improves pain and enhances fertility, recurrence and repeated surgery can further exacerbate pain and reduce fertility, which in turn impacts quality of life. Current guidelines on the management of endometriosis do not give specific indications for treatment of the recurrence as opposed to first diagnosis, except for a more careful consideration of the decision to proceed with surgery on case of previous interventions.
Study design, size, duration: Prospective study was conducted in the reproduction and genetics center «NOVA CLINIC» during the last year.
Participants/materials, setting, methods: A total of 128 reproductive aged women, between 18 and 40 years underwent unilateral laparoscopic cystectomy by stripping method of ovarian endometriosis. I group included 88 women with recurrent ovarian endometriosis, the II enrolled 40 women with the newly diagnosed. The primary outcome of the study was to assess the changes in antimüllerian hormone (AMH) levels and in antral follicle count (AFC), and ovarian volume in each study group.
Main results and the role of chance: Patients in both groups were comparable in age - 29,94±4,96 years and 31,5±4,93 (p>0,05). Before surgery the differences in the ultrasound indicators of ovarian reserve (OR) were significant: mean ovarian volume was 5,6±2,1 cm^3 in I group, 7,4±2,1 cm^3 before primary surgery, AFC in I - 4,9±2,2; in II - 6,1±2,7. The serum concentration of AMH in I group – 2,7±1,3; II - 3,5±0,4 ng/ml. In 6 months the preoperative level of AFC decreased by 1.4 and 1.2 times, respectively (I - 3,4±1,8; II - 5,4±2,1) (p <0,05). Ovarian volume in group I (5,0±1,6 cm^3) has decreased by 1.2 times, in II (6,8±2,6 cm^3) - 1.3 times in comparison to that before surgery. AMH levels in postoperative patients in the group after second surgery, was 1.5-fold lower (1,6±0,9 ng/ml) than in the group where the primary surgery was applied (2,6±1,2 ng/ml).
Limitations, reasons for caution: Laparoscopic excision is considered the gold standard for the surgical of ovarian endometriomas. Excisional techniques are associated with lower recurrence rates. In the same time, surgery is associated with a high risk of reducing the ovarian reserve.
Wider implications of the findings: The ultrasonographic and serum data on the ovarian reserve from the present study suggest that surgery for a recurrent endometrioma may be more harmful to the healthy ovarian tissue than primary surgery. This is extremely important to consider when choosing a treatment plan for women with infertility.
Trial registration number: Not applicable.

P-734 Natural and assisted reproductive outcomes following salpingostomy for hydrosalpinx

J. Tamblyn[1,2], P. De Silva[1], Y. Afifi[3], L. Robinson[4]
[1]Birmingham Women's & Children's Foundation Hospital Trust, Academic Dept- 3rd Floor, Birmingham, United Kingdom
[2]University of Birmingham, Institute of Metabolism and Systems Research- College of Medical and Dental Sciences-, Birmingham, United Kingdom
[3]Birmingham Women's & Children's Foundation Hospital Trust, Centre for Endometriosis, Birmingham, United Kingdom
[4]Birmingham Women's & Children's Foundation Hospital Trust, Fertility Centre- 2nd Floor, Birmingham, United Kingdom

Study question: What are the reproductive outcomes of infertile women with hydrosalpinx who undergo salpingostomy at Birmingham Women's and Children's Foundation Hospital Trust?
Summary answer: Women who underwent salpingostomy had a 10.3% chance of spontaneous conception and 33.3% chance of assisted conception, with all pregnancies proceeding to live birth.
What is known already: A quarter of all female infertility is caused by tubal factor disease. Pelvic inflammatory disease accounts for the majority of this, which if left untreated can cause inflammation of the fallopian tubes leading to the development of hydrosalpinx. Historically, reproductive surgeons used salpingostomy, in an attempt to correct tubal pathology and achieve spontaneous conception. Since the advent of IVF/ICSI, this is rarely performed, as sterilising surgery which prevents hydrosalpingeal fluid from contaminating the endometrium is preferred. In the UK, there is limited government funding for IVF cycles and so salpingostomy is more commonly employed to allow for natural conception.
Study design, size, duration: A 5 year retrospective cohort study of all salpingostomy procedures was performed at Birmingham Women's & Children's Foundation Hospital Trust from 2013-2018. In total, 39 women underwent laparoscopic salpingostomy procedures.
Participants/materials, setting, methods: The 39 women in this study had a mean age of 31 years (range 23-40 years). All procedures were performed by two experienced tubal surgeons using a cuffed stitched technique. Data were collected by two independent researchers from March 2013 to September 2018 through hospital records and a targeted telephone survey using a standardised data collection proforma.
Main results and the role of chance: Overall, 28 (71.8%) unilateral and 11 (28.2%) bilateral procedures were performed. Indications for unilateral salpingostomy were previous salpingectomy/ clipping 10 (35.7%), unilateral tubal pathology (8; 28.6%), concomitant salpingectomy (6; 21.4%) and inability to access the contralateral tube (5; 17.9%). Significant pelvic pathology (endometriosis, adenomyosis, tubo-ovarian mass, adhesions) was identified in 23 (59.0%) cases.

Post procedural patency was assessed intra-operatively in 35 (89.7%) cases, with patency achieved in 33 (84.6%). Patency was reassessed by post-operative hysterosalpingogram (HSG) in 18 (46.1%) women. Of these, patency was confirmed unilaterally in 12 (66.7%) at 3-6 months, resulting in a re-blockage rate of 33.3% in those assessed.

In total, 4 women achieved spontaneous pregnancy giving a 10.3% chance of natural conception. The mean duration to natural conception was 8 months; range 4–10m). 29 women were offered IVF/ICSI, of which 12 (30.8%) proceeded to treatment and 17 declined / were ineligible for NHS-funded cycles. The successful assisted conception rate was 33.3% (n=4). In total, 4 (10%) procedural complications were identified. All conceptions resulted in a live birth, resulting in a live birth rate of 20.6%. No ectopic pregnancies were reported.
Limitations, reasons for caution: The results of this study are based on a small population size and so must be interpreted with caution. The cases included are clinically heterogeneous in terms of patient characteristics, additional pelvic pathology and duration of follow-up after salpingostomy.
Wider implications of the findings: Whilst reported natural conception rates are lower than expected, additional pelvic pathology was encountered. We suggest the importance of postoperative HSG in order to assess tubal patency to determine if assisted conception should be sought sooner in the event of tubal re-closure.
Trial registration number: N/A

P-735 Prevalance of dysmorphic uterus among parous women

A. Seyhan[1], S. Ertas[1], C. Alatas[1], B. Urman[1]
[1]American Hospital, Reproductive Endocrinology and Infertility, Istanbul, Turkey

Study question: What is the prevalance of dysmorphic uterus (DU) among parous women?
Summary answer: Parous women who conceived spontaneously have a low prevalance of DU.
What is known already: Neither the prevalance of dysmorphic uterus in parous women nor its effect on reproductive potential is known
Study design, size, duration: Prospective cohort study including 133 women who conceived spontaneously and had at least one live birth. Participants were recruited from a contraception clinic between January 2017 and December 2018.
Participants/materials, setting, methods: Participants underwent 3D TVUS in the late luteal phase of menstrual cycle. The ESHRE/ESGE classification of congenital uterine anomalies was used. The following measurements were taken In the coronal view; 1)fundal cavity width (W1) (the distance between the two internal tubal ostia),2) width of uterine cavity at corpus-isthmic level (W2), 3) the lateral angle between the corpus-isthmic cavity and the two fundal endometrial layers (A right; A left). Uterine cavity volume was measured by VOCAL^{TM} program.
Main results and the role of chance: The mean (± standard deviation) age was 35.54±5.9 years. Mean parity was 1.88 (min 1 max 7) and time to pregnancy (TTP) was between 1- 12 months. Mean antral follicle count was 12.1±9.5 and 4.5% had at least one ultrasound feauture of adenomyosis. Four patients (3%) were diagnosed with congenital uterine abnormality of which two (1.5%) had partial septate uterus, one (0.75%) hemiuterus uterus and only one (0.75%) dysmorphic uterus. Overall mean uterine volume, W1, W2, W1/W2 ratio and mean lateral angles was 4.2 ±2.1 ml, 28.2+5.5mm, 11.8±3.3mm, 2.48±0.6 and 155.9+10.5°respectively. The women with DU had uterine volume, W1/W2 ratio and mean lateral angle of 3.62 ml, 2.26, and 108.03°, respectively. Her TTP was 7 months and she had given birth to a 3450 gr child at 39 weeks.
Limitations, reasons for caution: While the presence of only one case of dysmorhpic uterus supports a possible association between DU and fertility, the low event rate of only one case can also be regarded a limitation of the study at the current stage.
Wider implications of the findings: Low prevalance of dysmorphic uterus among fertile women may indirectly indicate poor reproductive performance of dysmorphic uterus anomaly. If women with infertility are shown to have higher prevalance of DU, a causal relationship between DU and fertility can be claimed.
Trial registration number: 2017.052.IRB1.008 Koc University Committee on Human Research

P-736 Post-surgical recurrence of benign ovarian disease: a cohort study of women in reproductive age

R. Pesce[1], J. Nagy[2], J.P. Cortez[3], S. Plou[2], A. Naessens Azpiazu[3], J. Builes[3], S. Gil[2], G. Peman[4]
[1]*Hospital Italiano de Buenos Aires, Reproductive Medicine Unit- Gynaecological Department, Buenos Aires, Argentina*
[2]*Hospital Italiano de Buenos Aires, Reproductive Medicine Unit. Gynaecological Department, Buenos Aires, Argentina*
[3]*Hospital Italiano de Buenos Aires, Gynaecological Department, Buenos Aires, Argentina*
[4]*Hospital Italiano de Buenos Aires, Epidemiology and Public Health Department-Internal Medicine, Buenos Aires, Argentina*

Study question: Which factors are associated to recurrence of benign ovarian pathology after surgery in women in reproductive age?
Summary answer: Recurrence rate: cystadenomas, 4.2 per 100 patient/years; endometriomas, 3.4; rest: 0.7. Histology and size >5 cm are independently associated to recurrence of benign ovarian pathology.
What is known already: Many of the low risk cystic tumours resolve spontaneously or with medical treatment. Nevertheless, some are treated surgically because of size, symptoms, complexity or bilateral affection. A special care must be adopted for women in reproductive age, where preservation of healthy ovarian tissue must be sought.

After surgery, the exact time recommended for follow-up is difficult to define. Medical literature on recurrence of benign ovarian pathology after surgery is limited to case series and small cohorts of single histological type of benign cysts. How different factors independently influence on its overall recurrence is not well known.
Study design, size, duration: This retrospective cohort included consecutive women that had surgery of benign ovarian pathology in the period between 01/01/2012 and 31/07/2017. We analysed crude and specific recurrence rates for cystadenomas, endometriomas, and other conditions (simple cysts, dermoid, haemorrhagic and others). We considered different independent variables: age, type of surgery (laparoscopic/laparotomic), urgent/scheduled surgery, surgical technique, previous ovarian surgery, histology, size, and medical (hormonal) treatment after surgery.
Participants/materials, setting, methods: Inclusion criteria: women in reproductive age that had a surgical procedure for a benign ovarian disease and a follow-up of at least 6 months. Exclusion criteria: malignant ovarian neoplasm. Setting: university hospital.

We calculated crude incidence density for recurrence of different types of disease per 100 patient/years of follow-up. After a univariate analysis for recurrence of ovarian disease, we built a Cox-regression model to adjust for significant independent variables.
Main results and the role of chance: In the recruitment period, 472 women had surgical procedures for benign ovarian conditions. Out of these, 397 met inclusion criteria. Follow-up time range was from 187 to 2387 days. We had a total of 1294 person/years of follow-up and 28 recurrences (7.1%). Median age: 34 years (IQR 28-40). Histopathology: endometriomas, 41.1%; dermoid cysts, 24.7%; simple cysts, 12.1%; cystadenomas, 10.8%; haemorrhagic, 4.8%; others, 6.6%.

Median size: 5 cm (IQR 4-7). Bilateral location: 24.9%. Previous ovarian surgery: 13.1%. Medical treatment after surgery: 24.2%.

Overall crude rate of recurrence: 2.2 (95%CI 1.5-3.1) per 100 person/years of follow-up. Specific rates: cystadenomas, 4.2 (95%CI 1.7-10.1); endometriomas, 3.4 (95%CI 2.2-5.3); others, 0.7 (95%CI 0.2-1.7). The median days after surgery where recurrence was detected were 1455 (5th percentile, 265; 95th, 2346).

In univariate analysis for recurrence, the only variables significantly associated were: histopathology, size and posterior medical treatment. In the Cox-regression model, hazard ratios (95%CI; p value) were: histopathology (compared to basal hazard of simple, dermoid and haemorrhagic cysts): cystadenomas, 8.29 (2.08-33.01; p 0.003); endometriomas, 4.30 (1.30-14.18; p 0.017); size (compared to cysts of 5cm or lower): >5 to 7cm: 2.93 (1.14-7.58; p 0.026); >7cm: 2.69 (1.06-6.83; p 0.037); medical treatment: 2.10 (0.87-5.08; p 0.100, non-statistically significant).
Limitations, reasons for caution: It is a retrospective cohort. There might be other known or unknown variables not included in the analyses. Although the total number of included patients is significant, some analyses have wide confidence intervals. Other small studies show similar results
Wider implications of the findings: Benign recurrences can be detected as early as 260 days after surgery or as late as 6.5 years in women in reproductive age. Cystadenomas, endometriomas, and size > 5cm are associated with higher risk of recurrence. These specific rates and hazards can be used for shared decision making with patients.
Trial registration number: -

P-737 Do fibroid size and number of large fibroids removed at laparoscopic myomectomy impact on clinical outcomes?

D. Balfoussia[1], L. Kindinger[2], H.Z. Ling[3], T. Setchell[4], T. Miskry[4]
[1]*Imperial College Healthcare NHS Trust, Reproductive Medicine, London, United Kingdom*
[2]*Institute for Women's Health- University College London, Department of Obstetrics and Gynaecology, London, United Kingdom*
[3]*Northwick Park Hospital- London Northwest University Healthcare, Department of Obstetrics and Gynaecology, London, United Kingdom*
[4]*Imperial College Healthcare NHS Trust, Department of Obstetrics and Gynaecology, London, United Kingdom*

Study question: Do fibroid size and number of large fibroids removed at laparoscopic myomectomy impact on clinical outcomes?
Summary answer: Surgical outcomes and complication rates are comparable irrespective of number and size of fibroids removed.

What is known already: Laparoscopic myomectomy has multiple advantages compared to an open approach. Yet, its use in the setting of complex fibroids is contentious with the prevailing consensus being that this surgical approach should be reserved for smaller lesions. There is no clear consensus in the literature as to what size and number of fibroids can be safely removed laparoscopically nor is it clear how increasing fibroid size and number impact on clinical outcomes.

Study design, size, duration: This was a retrospective observational study conducted in a tertiary referral centre for gynaecological laparoscopic surgery. The study examined data from 305 women of reproductive age undergoing laparoscopic myomectomy between September 2004 and December 2017 for symptomatic large (≥6cm) uterine fibroids.

Participants/materials, setting, methods: Participants were identified through the unit's theatre logs and their clinical data was collected from their medical records. Comparisons were made between women with single fibroids measuring 6-8cm and those with either single fibroids >8cm or multiple fibroids ≥6cm. Main outcome measures were operative time, blood loss, blood transfusion rate, complication rates, rate of conversion to laparotomy.

Main results and the role of chance: Sixty-two women had multiple large fibroids resected, 117 had one fibroid measuring 6-8cm resected and 126 had a single myoma >8cm removed. The median fibroid size was 8cm (range, 6-20cm) with a median blood loss of 100mls (range, 20-2000mls) and operating time of 110minutes (range, 40-320). There was a significant correlation between fibroid size and operating time (Pearson's R: 0.313 p<0.001), and fibroid size and blood loss (Pearson's R: 0.195 p=0.003). There was no significant difference in overall complication rate (6.84% versus 5.85% p=0.81), blood transfusion rate (1.71% versus 3.19% p=0.72), conversion to laparotomy rate (3.42% versus 1.06% p=0.21) or hospital stay (median: 2 days; range: 1-19days vs. median: 2 days; range: 1-9 days p=0.34) when comparing women with fibroids measuring 6-8cm to those with either larger or multiple fibroids.

Limitations, reasons for caution: Our study is limited by its retrospective design. Whilst we reported only on large fibroids, 62% of women had multiple fibroids removed. This may introduce some heterogeneity in the data. Furthermore, operative times need to be interpreted with caution as over 53% of patients had a concurrent procedure.

Wider implications of the findings: Our study suggests that with appropriate operator experience, large and multiple fibroids may be safely removed laparoscopically with no adverse impact on clinical outcomes.

Trial registration number: Not applicable

P-738 Impact of Intracytoplasmic Morphologically Selected Sperm Injection (IMSI) on birth defects. A systematic review and meta-analysis

F. Dieamant[1,2], C.G. Petersen[1,2], A.L. Mauri[1,2], M. Mattila[1], L.D. Vagnini[2], A. Renzi[2], B. Petersen[1,2], C. Zamara[1], J.B.A. Oliveira[1,2], R.L. Baruffi[1,2], J.G. Franco Jr[1,2]

[1]Centre for Human Reproduction Prof Franco Jr, Research, Ribeirao Preto, Brazil
[2]Paulista Center for Diagnosis Research and Training, Research, Ribeirao Preto, Brazil

Study question: Could the use of Intracytoplasmic Morphologically Selected Sperm Injection (IMSI) decrease the incidence of birth defects (structural defects/chromosomal abnormalities) in ART cycles?

Summary answer: IMSI seems to be an effective tool in decreasing the incidence of structural-defects compared to ICSI. However, IMSI does not change the incidence of chromosomal-abnormalities.

What is known already: It is generally accepted that the incidence of birth defects in spontaneous conception ranges between 2.0% and 4.0%. However, several studies have shown that babies born with the aid of ART tend to present more congenital malformations than naturally conceived children, with as many as 6.5% of the babies conceived from ICSI presenting birth defects. Introduced in the early 2000s, high magnification sperm selection before ICSI allowed the identification of spermatozoa at low risk of sperm DNA damage. Therefore, IMSI might change the incidence of congenital malformations. Nevertheless, data on birth defects in children conceived after IMSI are still scarce

Study design, size, duration: A systematic review based on searches on electronic databases (PubMed, EMBASE, Web of Science, SCOPUS, and Cochrane Central Register of Controlled Trails) up to January 2019 was carried out to identify trails comparing the neonatal outcomes of ICSI versus IMSI. The outcome measured was birth defects rates in children born after ICSI or IMSI.

Participants/materials, setting, methods: Three trials were included as targets for data extraction and meta-analysis. Data were combined for purposes of meta-analysis with the StatsDirect statistical software package. Dichotomous data were expressed as Relative Risk (RR) with a 95% confidence interval (CI). The degree of heterogeneity was evaluated using Cochran's Q and I^2. Study data were combined using a random-effects model. *P*-values <0.05 were considered statistically significant.

Main results and the role of chance: The meta-analysis included 3907 children conceived after IMSI(1280) and ICSI(2627), and the incidence of total birth defects was 2.5%(32/1280) when IMSI was used versus 4.5%(119/2627) when ICSI was employed, showing a statistically significant difference (RR=0.60; 95%CI = 0.41-0.88; *P*<0.01)(Table 1).

Structural defects and chromosomal abnormalities were analysed separately. The results showed that IMSI significantly decreased the incidence of structural defects when compared to ICSI [2.2%(18/830) vs. 3.8%(78/2049](RR=0.58; 95%CI =0.35-0.97; *P*=0.04). No significant difference was found for chromosomal abnormalities(Trisomy 13/18/21/ and Triple X) between the children conceived after IMSI(8/830) and ICSI(19/2049)(RR=1.08; 95%CI=0.47-2.45;*P*=0.8)(Table 2).

Limitations, reasons for caution: Randomised controlled trials on IMSI effectiveness and safety of ART cycles do not include birth defects as an endpoint. Thus, studies with larger populations are needed to estimate the actual risk of birth defects associated with IMSI.

Wider implications of the findings: The present meta-analysis demonstrated that IMSI seems to decrease the incidence of structural defects in offspring compared to ICSI. It is critical that the comparative trials involving IMSI include the health statuses of the children after birth.

Trial registration number: Not applicable. The local ethics committee authorised the study.

P-739 Extreme mitochondrial DNA sequence divergence is tolerated in primate offspring produced by mitochondrial replacement therapy

H. Darby[1], C. Van Dyken[1], H. Ma[1], N. Marti-Gutierrez[1], A. Koski[1], Y. Li[1], T. Hayama[1], E. Kang[1,2], Y. Lee[1,2], D. Liang[1], R. Ahmed[1], P. Amato[1,3], S. Mitalipov[1]

[3]*Oregon Health Science University, Division of Reproductive Endocrinology- Department of Obstetrics and Gynecology, Portland, U.S.A.*

Study question: Does donor mitochondrial DNA (mtDNA) sequence divergence compromise the health and fitness of nonhuman primate offspring achieved through mitochondrial replacement therapy (MRT)?
Summary answer: Healthy rhesus macaque MRT offspring demonstrate tolerance to extreme sequence divergence of donor mtDNA.
What is known already: Proteins encoded by mtDNA must interact with proteins encoded by nuclear genome to form multisubunit complexes of mitochondrial oxidative phosphorylation (OXPHOS), therefore, sequence divergences in these genomes could result in poor subunit interaction. Indeed, nuclear and mitochondrial genome incompatibility is one of the mechanisms responsible for reproductive barrier between species. Trans-mitochondrial infants from distinct Indian and Chinese Macaca mulatta sub-populations were successfully produced by MRT between 2009 and 2012. However, total mtDNA sequence divergence was not known.
Study design, size, duration: We performed whole mtDNA sequencing (Illumina Miseq) on blood DNA libraries from rhesus females used as oocyte donors, for maternal (n=4) and donor mtDNA (n=4), to create MRT offspring. We analyzed DNA sequences to identify single nuclear polymorphisms (SNPs) between maternal and donor mtDNA. Offspring (n=5) body weight, blood chemistry at adulthood (5-7 years), and male fertility were compared to non-manipulated controls (n=10). Three MRT adults were bred and males trained to provide semen samples.
Participants/materials, setting, methods: We used NextGene software to perform whole mtDNA genome assembly and SNP searching, the MITOS webserver for annotation and Mesquite for pairwise alignments. MRT offspring bodyweight was monitored over 6 years. Blood analyses included complete blood count (CBC) and chemistry. Sperm were counted and assessed for motility, agglutination and morphology. Adult MRT offspring reproduced naturally following a time-mated breeding program.
Main results and the role of chance: Sequence divergence between maternal and donor mtDNA pairs ranged from 8 to 755 total SNPs, or 5 x 10^{-4} to 5% of the full mtDNA genome. Sequence differences in protein coding genes ranged from 4 to 542 SNPs (50% and 74% total SNPs, respectively) and translated to a range of 2 to 113 amino acid differences. Genes that code for subunits of OXPHOS complex I, the largest enzyme of the mitochondrial electron transport chain, differed at as many as 300 sites, or 61 amino acid changes. RNA-coding gene sequence divergence ranged from 0 to 93 SNPs. In the displacement loop (D loop), a noncoding region implicated in mtDNA transcription and replication, sequence divergence ranged from 4 to 93 SNPs. MRT monkeys were developmentally normal compared to non-manipulated controls in body weight and within normal range for blood chemistry. Male MRT monkeys produced morphologically normal sperm. Natural breeding of MRT offspring (two males, one female) resulted in three healthy births (two females, one male).
Limitations, reasons for caution: Study is limited to 5 MRT offspring (four males and one female). Although the results suggest safety of "unmatched" donor mtDNA within species, there is possibility of different mtDNA replicative capacity leading to reversal after MRT.
Wider implications of the findings: The staggering number of SNP differences between maternal and donor mtDNA coupled with health of MRT monkeys suggests that mtDNA haplotypes within species are compatible. Historically, mtDNA haplotype matching has been recommended to circumvent issues relating to mtDNA donor mismatch. Evidence here suggests this may be needlessly cautious.
Trial registration number: not applicable

P-740 The incidence of monozygonic twins in assisted reproduction technology

X. Feng[1], P. Liu[1]
[1]*Center for Reproductive Medicine, Department of Obstetrics and Gynecology-Peking University Third Hospital, Beijing, China*

Study question: Whether assisted reproductive technology effect the incidence of monozygonic twins
Summary answer: In assisted reproductive technology, blastocyst culture significantly increased the risk of monozygonic twins. However, the parental age, ICSI or assisted hatching had no signifcant impact.
What is known already: it is known that the incidence of monozygonic twin (MZT) in natural conception is about 0.4%. Previous report has shown that the risk of MZT has doubled after assisted reproductive technology. MZT can lead to miscarrige, increase the incidence of preterm birth and other adverse neonatal outcomes. Therefore, researchers have been take much attention to the incidence and reasons of MZT in assisted reproduction and found that maternal age, ICSI and blastocyst tranplantion may be associated with the happening of MZT.
Study design, size, duration: This study included 24777 fresh and frozen tranfer cycles in Peking University Third Hospital from 2015 to 2017.
Participants/materials, setting, methods: Maternal age, fertilization strategy and the embryos they transfered were analyzed between the MZT and non-MZT groups. All pregnant patients were confirmed by detection of fetal heart activity on the use of transvaginal ultrasound by early first-trimester. In all cases, a P-value was considered significant if <0.05. For the statistical analysis, SPSS software was used.
Main results and the role of chance: In fresh cycyles, the ratio of MZT in D3 cleavage stage was 0.49%(59/12060) while it was 1.52% (9/590) in blastocyst tranfer cycles. It is significantly higher in patients accepted blastocyst transfer. This trend is the same in frozen-thawn cycles of 0.63%(32/5042) with cleavage embryo transfer vs 1.96%(145/7085) with blastocyst transfer. In addition, maternal age seem to have no impact on MZT incidence. Moreover, for conventional IVF, the ratio of MZT was 0.52% and it was 0.57% in ICSI group with no significant difference. For assisted hatching, we found no significant difference in those with blastocyst hatching(2.24%, 59/2632) and those without hatching(1.83%, 16/872).
Limitations, reasons for caution: This is a retrospective research and more data from randomized trial are required.
Wider implications of the findings: This research indicated the risk of blastocyst transfer and give us more thinking about whether blastocyst transfer should be widely used.
Trial registration number: No

P-741 Predictive factors for dizygotic twin pregnancies after single embryo transfer: a retrospective analysis of a large-scale nationwide database study

T. Takahashi[1], I. Takehara[2], K. Ota[1], H. Mizunuma[1], S. Nagase[2]
[1] *Fukushima Medical University, Fukushima Medical Center for Children and Women, Fukushima, Japan*
[2] *Yamagata University, Obstetrics and Gynecology, Yamagata, Japan*

Study question: What are the risk factors for dizygotic twin pregnancies after single embryo transfer (SET)?
Summary answer: There were three independent risk factors as following: unexplained infertility, the frozen-thawed embryo transfer (FET) cycle, and the type of luteal support.
What is known already: The dizygotic twin pregnancies after SET might be the simultaneous pregnancies by assisted reproductive and natural conception. It remains unknown the predictive factors for dizygotic twin pregnancies after SET.
Study design, size, duration: A retrospective cohort study was performed, based on 1404648 treatment cycles in registered assisted reproductive technology (ART) data from JSOG between 2007 and 2012.
Participants/materials, setting, methods: A total of 1509 twin pregnancies after 595226 SET cycles were included in the analysis. The sex-discordant twin pregnancies are always dizygotic. Then, we analyzed the predictive factors for dizygotic twin pregnancies after SET based on the data of sex-discordant twin by multivariate analysis.
Main results and the role of chance: The numbers of sex-concordant and discordant twin pregnancies were 1391 and 118, respectively. The rate of sex-discordant twin pregnancies was 7.8% (118/1509). According to Weinberg's differential rule, the rate of dizygotic twin pregnancies accounted for 15.6% of the total twin pregnancies after SET. In the multivariate analysis, there were three independent predictive factors for dizygotic twin after SET as following: unexplained infertility (adjusted odds ratio (aOR), 1.47; 1.01-2.15, p=0.04), the FET cycle (aOR, 1.73; 95%CI, 1.07-2.79; p=0.03), and the luteal support with estrogen and progesterone (aOR 0.29; 95% CI, 0.14-0.62, p=0.001).
Limitations, reasons for caution: In the FET cycles, information about ovarian stimulation and fertilization methods did not include.
Wider implications of the findings: Clinicians should explain to the patients the possibility of causing the spontaneous conception during ART. Mainly, in the case of unexplained infertility, the FET cycle, and the specific type of luteal support, we had better explain the necessity of contraception during ART in the point of avoiding multiple pregnancies.
Trial registration number: not applicable

P-742 Safety of originator follitropin alfa (GONAL-f) for fertility treatment – Frequency of OHSS and thromboembolism in the scientific literature and the Merck KGaA safety database

E. Velthuis[1], J. Hubbard[2], S. Longobardi[3], T. D'Hooghe[3]
[1] *Merck B.V., Global Patient Safety, Schiphol Rijk, The Netherlands*
[2] *EMD Serono, Research & Development Institute, Billerica, U.S.A.*
[3] *Merck KGaA, Global Medical Affairs Fertility, Darmstadt, Germany*

Study question: Based on systematic review of published data and the Merck KGaA Safety Database, what is the frequency of OHSS and thromboembolism with GONAL-f?
Summary answer: Reporting rates of OHSS and thromboembolism demonstrate that the risk after ovarian stimulation treatment with GONAL-f (Merck KGaA, Darmstadt, Germany) is low.
What is known already: Recombinant-human follicle-stimulating hormone (r-hFSH) is used for ovarian stimulation as part of treatment with assisted reproductive technologies (ART), with dosing (both starting dose and during treatment) individualized to optimize safety and efficacy. Owing to its mechanism of action there is a risk for OHSS with r-hFSH treatment, and there is also a risk for thromboembolic events, which is increased in the presence of pregnancy and OHSS.
Study design, size, duration: MEDLINE and Embase were systematically searched from inception to 19-Oct-2018 for clinical studies using GONAL-f. Keywords were 'GONAL-f' and 'r-hFSH' and their variants.

Reports of OHSS and thromboembolism were obtained from the Merck KGaA Global Safety Database from 29-Nov-2000 to 19-Oct-2018. This database includes reports from healthcare professionals, patients, health authorities, clinical trials, non-interventional studies and literature. Number of treatment-cycles were estimated from sales data based on an average 1875 IU administered per treatment-cycle.
Participants/materials, setting, methods: There were no exclusion criteria for the Global Safety Database search. The systematic review included clinical studies of patients with infertility receiving GONAL-f for ovulation induction or ART, with a starting dose within the range included in the SmPC. Case reports/series were excluded from the systematic review as they are included in the Global Safety Database. Data extracted were: number of patients exposed to GONAL-f, number of treatment cycles, incidence of OHSS, incidence of thromboembolism.
Main results and the role of chance: Data are presented separately for the systematic review and Global Safety Database search.

The systematic review identified 45 studies, including 5186 patients exposed to GONAL-f and 5240 treatment-cycles. Overall 272 reported cases of OHSS (reporting rate: 5190 per 100,000 treatment cycles; 5.19%) and 10 cases of severe OHSS (reporting rate: 191 per 100,000 treatment cycles; 0.19%) were identified; no fatal cases. No reports of thromboembolism were identified. The OHSS reporting rate may be high because of enhanced monitoring for adverse events in clinical trials and the characteristics of the patients included, which may not fully reflect clinical practice.

In the Global Safety Database, there were 1110 reported cases of OHSS (using MedDRA preferred term=OHSS) and 80 reported cases of thromboembolic events (MedDRA SMQ = Embolic and thromboembolic events). Overall, there have been an estimated 16,525,975 treatment cycles since 29-Nov-2000. This resulted in reporting rates for OHSS and thromboembolism of 6.7 per 100,000 treatment cycles (0.007%) and 0.48 per 100,000 treatment cycles (0.0005%), respectively. Three fatal cases were recorded; two fatal cases of OHSS and one fatal case of thromboembolism. The OHSS frequency reported from the Safety Database may be lower than the systematic review as it reflects spontaneous reporting.
Limitations, reasons for caution: The cases reported in the Global Safety Database were either submitted voluntarily or obtained from the literature. There may therefore be some duplication of cases between the Global Safety Database and the systematic review. In addition, the number of treatment-cycles in the post-marketing setting was estimated from sales data.
Wider implications of the findings: GONAL-f has been used for more than 18 years, with low rates of OHSS and thromboembolism. This provides reassurance about using GONAL-f for ovarian stimulation.
Trial registration number: not applicable

P-743 Lack of consistency in the execution and reporting of sperm FISH poses potential problems for clinical interpretation and patient counselling

M. Esbert[1], J. Rodriguez[1], D. Wells[2], L. Bassas[3], I. Loiudice[4], A.B. Casas[5], M. Joumady[5], A. Guerin[5], A. Ballesteros[5], E. Fragouli[2]
[1] *IVI RMA Barcelona, IVF laboratory, Barcelona, Spain*
[2] *IVI RMA Global Oxford, Research laboratory, Oxford, United Kingdom*
[3] *Fundació Puigvert, Laboratory of Andrology and Embryology, Barcelona, Spain*
[4] *IVI RMA Rome, Gynecology department, Rome, Italy*
[5] *IVI RMA Barcelona, Gynecology department, Barcelona, Spain*

Study question: To what extent are strategies for sperm aneuploidy testing and the reporting of results standardized?
Summary answer: Comparison of FISH reports from multiple laboratories in nine different countries confirms a remarkable lack of consistency in technical, analytical and reporting methods.
What is known already: Improper segregation of chromosomes during meiosis results in the generation of genetically unbalanced sperm or oocytes. If these gametes participate in fertilization, the resulting embryo will be aneuploid and will consequently be at greatly elevated risk of implantation failure, miscarriage or the birth of a chromosomally abnormal child. Multiple studies have indicated that some infertile men with normal karyotypes,

and in many cases normal semen parameters, display increased sperm aneuploidy.

Fluorescence *in situ* hybridization (FISH) analysis with chromosome-specific DNA probes is capable of evaluating aneuploidy rates in human sperm and has been employed for this purpose by many laboratories.

Study design, size, duration: This is a descriptive study comparing a large number of FISH sperm reports issued by 46 different laboratories, located in nine countries. The patients that provided the sperm samples attended 11 ART clinics (part of a single network) between 2017 and 2018. Sperm-FISH was undertaken for specific couples when physicians wished to obtain a more complete picture of the male factor, using molecular methods to supplement routine semen analysis.

Participants/materials, setting, methods: The reports analysed were generated in laboratories that offer sperm FISH, located in Spain (n=28), France (n=6), Italy (n=6), Argentina (n=1), Norway (n=1), Portugal (n=1), Switzerland (n=1), Australia (n=1) and Turkey (n=1). Information from the reports was extracted, and a data sheet was created to analyse all the variables.

Main results and the role of chance: The data reported varied between laboratories. Reported parameters included disomy rate (50.0% of laboratories), X and Y bearing sperm ratio (41.3%), diploidy (45.6%), nulisomy (29.8%) and monosomy rates (21.7%). The number of sperm analised was reported by 84.8% of laboratories (mean 1914.8, range 200-104887). In 82.6% of the cases five chromosomes were examined (13,18,21,X,Y), 2.1% screened a different set of five (12,18,21,X,Y), 8.7% analysed seven chromosomes (13,15,16,17,18,21,22,X,Y), and 6.5% examined only three chromosomes (18,X,Y).

The test result was clear in 41 (89.1%) reports, with about half (56.1%) yielding an abnormal outcome. Reference values were given in 58.7% of the reports, but the control population was only well-defined in one laboratory (normozoospermic fertile men). In 10.9% of reports, it was stated that the reference values were obtained from publications, whereas no information about the control population was given for the rest. The test was considered normal when the percentage of abnormalities was lower than the control group (89.1%) or when the difference in abnormality rates reached statistical significance (10.9%).

When disomy was assessed, gonosomes showed higher abnormality rates (17.6%) followed by chromosomes 13 (11.8%), 18 (8.8%) and 21 (5.9%). A high percentage of reports (33.3%) indicated an increased diploidy rate.

Limitations, reasons for caution: While we were able to carry out a full assessment of the way clinical data was reported, we were only able to make inferences about certain aspects of the laboratory method (eg, number of sperm analysed, chromosomes tested, etc). We were unable to examine the accuracy of the FISH protocol.

Wider implications of the findings: Variability in FISH methodology and reporting is challenging for physicians who must interpret results to counsel patients. The creation of a Best Practice Guideline by a panel of experts and the participation in pilot schemes for sperm FISH should be encouraged, in order to maximize diagnostic accuracy and consistent reporting.

Trial registration number: Not applicable

P-744 Frozen-thawed transfer increases birth weight of female babies only, but not male babies from our analyses of 2578 neonates in a solo practice

N. Isshiki[1], H. Matsumoto[1], S. Mizuno[1], A. Fukuda[1], Y. Morimoto[2]

[1] *IVF Osaka Clinic, Department of Obstetrics and Gynecology, Higashi Osaka, Japan*

[2] *HORAC grand front osaka clinic, Department of Obstetrics and Gynecology, Osaka, Japan*

Study question: What causes the neonates born after frozen-thawed embryo transfers (FET) heavier than fresh embryo transfers (fresh ET). Is there any difference between female and male babies?

Summary answer: The factors to increase birth weight after FET on each gender were different.Female babies by the process of FET, but male babies by other factors.

What is known already: The previous studies have shown birth weight of babies born after FET is heavier than fresh ET. However, there are no reports to investigate what caused babies born after FET are heavier than fresh ET. Birth weight also is correlated with gestational age and maternal age. Therefore, in the present study, the influence of FET was investigated between male and female neonates to determine if there is any causative factor to increase birth weight in each gender with reference to multivariate analyses adjusted for those parameters.

Study design, size, duration: A total of 2,578 full term neonates (37–41 weeks of gestation) born after FET (n=1959) and fresh ET (n=619) from 2008 to 2016 were investigated. All analyses were carried out both in male (n=1276) and female (n=1302) newborns.

Participants/materials, setting, methods: Birth weight (g), gestational age (weeks) and maternal age (years) were compared between singletons born after FET and fresh ET using student's t-test. Multiple regression analyses were performed to reveal the variables relevant to birth weight among gestational age, maternal age, type of IVF (IVF or ICSI) and type of ET (FET or fresh ET).

Main results and the role of chance: Birth weight, gestational age and maternal age of male babies born after fresh ET vs FET were 3089.0 ±386.2 vs 3153.6 ±390.5 ($p<0.05$), 38.8 ±1.1 vs 39.0 ±1.3 ($p<0.01$), 35.4±4.0 vs 35.7 ±3.6 (ns), respectively. In addition, birth weight (g), gestational age (weeks) and maternal age (years) of female babies born after fresh ET and FET were 2971.2 ±363.4vs 3056.1 ±389.8 ($p<0.01$), 39.1 ±1.2vs 39.1 ±1.3 (ns), 35.1±3.7vs 35.8 ±4.1 ($p<0.01$), respectively. Multiple linear regression identified only gestational age ($p<0.01, \beta=0.42$, 95%CI=116.91-148.57) as a parameter associated with male birth weight. Gestational age ($p<0.01$, $\beta=0.41$, 95%CI=105.76-135.53), maternal age ($p<0.05$, $\beta=0.07$, 95%CI=1.45-11.02) and type of ET ($p<0.01$, $\beta=0.08$, 95%CI=29.91-119.08) were independently associated with female birth weight. The present study showed that cryopreservation was not associated with male birth weight.

Limitations, reasons for caution: Several factors such as BMI, smoking and birth order were not included as potential confounders in the present study.

Wider implications of the findings: It was revealed that the relevance of cryopreservation and maternal age to neonatal birth weight is unequivocal in females compared with males. Though the mechanisms in which those parameters influence baby development are still unclear, it is suggested that female embryos are more susceptible to those factors than males.

Trial registration number: not applicable

P-745 Fibrin (Fibrinogen) degradation products (FDPs) in late pregnancy and estradiol levels: a case-control study

C. Li[1,2], Y. Su[1,2], X. Liu[1,2], H. Huang[1,2]

[1] *Shanghai Jiao Tong University- School of Medicine, International Peace Maternity and Child Health Hospital, Shanghai, China*

[2] *Shanghai Jiao Tong University- School of Medicine, Shanghai Key Laboratory of Embryo Original Diseases, Shanghai, China*

Study question: What are risk factors for elevated FDP, a clinical indicator of the risk of venous thromboembolism and hemorrhage, in late pregnancy among women undergoing ART?

Summary answer: Fresh embryo transfer(ET) and >10 oocytes retrieved were risk factors for elevated FDP levels in late pregnancy among women undergoing ART.

What is known already: Normal pregnancy is linked to changes in hemostasis and fibrinolysis, characterized mainly by a hypercoagulable state. This can help prepare for the hemostatic challenge at delivery and maintain normal placental function, but can also predispose pregnant women to thromboembolism and other vascular complications. ART procedures can further exacerbate the process by increasing the risk of venous thromboembolism and antepartum and postpartum hemorrhage.

Study design, size, duration: This retrospective case-control study included infertile women who underwent ART procedures and gave birth at International Peace Maternity and Child Health Hospital from January through May in 2016.156 pregnant women with elevated FDP levels and 58 pregnant women with normal FDP levels in the third trimester were included. Only infertile women who underwent ART procedures and gave birth at the same hospital were analyzed to avoid bias.

Participants/materials, setting, methods: 5 μg/mL was chosen as the threshold value of serum FDP during late pregnancy. Pregnant women who had a serum FDP level higher and lower than 5 μg/mL in the third trimester were enlisted in the case(n=156)and control group(n=58). Odds ratios (ORs) and their 95% confidence intervals (CIs) were calculated to estimate the relationships between elevated FDP levels and ART procedures and were adjusted for confounding factors in multivariate logistic regression analyses.

Main results and the role of chance: Serum FDP levels are much higher in late pregnancy among women undergoing ART compared with spontaneous conception(9.78 ± 11.72μg/mL versus 3.09 ± 1.96μg/mL, p<0.001). Among women undergoing ART, fresh embryo transfer (aOR=3.33, 95%CI, 1.57-7.03) and >10 oocytes retrieved (aOR=2.09, 95%CI, 1.10-3.99) were associated with elevated FDP levels in late pregnancy after adjusting for confounders. Serum estradiol(E2) levels in late pregnancy and on the day of hCG trigger were higher in the high-FDP group than in the low-FDP group. A positive correlation was found between serum E2 levels on the day of hCG trigger and FDP levels in late pregnancy for both fresh (r=0.67, p<0.001) and frozen embryo transfer (r=0.53, p<0.001).No correlation was found between serum E2 levels before embryo transfer and FDP levels in late pregnancy for frozen embryo transfer (r=-0.13, p=0.17).

Limitations, reasons for caution: We were unable to design this study as a prospective cohort study to confirm the influence of estrogen on coagulation and fibrinolysis in late pregnancy since we could not make all participants who underwent ART procedures participate in a follow-up with the obstetrician at our hospital during their pregnancy.

Wider implications of the findings: Fresh ET and higher E2 on hCG trigger day can probably increase the risk of venous thromboembolism in late pregnancy and antepartum and postpartum hemorrhage. Deferring fresh ET to frozen ET may be a better option for patients with a high level of E2 on hCG trigger day.

Trial registration number: not applicable

P-746 Perinatal outcomes in 1134 singletons conceived after frozen embryo transfer (FET); true natural cycle (tNC-FET), modified natural cycle (mNC-FET) and artificial cycle (AC-FET), from 2006-2014.

L.L. Asserhøj[1], A.L. Pedersen[1], R. Beck Jensen[2], A.K. Aaris Henning[1], A. Pinborg[1]

[1]*Rigshospitalet, Fertility Clinic, Copenhagen, Denmark*

[2]*Rigshospitalet, Department of Growth and Reproduction, Copenhagen, Denmark*

Study question: Are perinatal outcomes different for singletons born after varying FET stimulation regimens?

Summary answer: Perinatal outcomes were similar after different FET-protocols, however, the tNC-FET group had significantly higher risk of very preterm birth (VPTB) compared with the mNC-FET group.

What is known already: Children conceived after assisted reproductive technology (ART) treatment have increased risk of being born preterm and small for gestational age (SGA) compared with spontaneously conceived (SC) children.

Furthermore, children conceived after FET have increased risk of being born large for gestational age (LGA) compared with children conceived after fresh embryo transfer and SC. Whether this altered risk profile is due to the ART hormone treatment or the embryo freezing/thawing is unclear. Studies suggest that pregnancy and live birth rates are similar after tNC-FET, mNC-FET and AC-FET in ovulating women. Perinatal outcomes for these three FET stimulation regimes are scarcely explored.

Study design, size, duration: A national register-based cohort study including all singletons conceived after FET (n=1,134) with information on the FET stimulation regimes; tNC-FET (n=167), mNC-FET (n=496) and AC-FET (n=471), in Denmark from 2006-2014. Data were extracted from the national ART and medical birth register and were cross-linked based on the maternal and child unique personal identification numbers.

Participants/materials, setting, methods: Perinatal outcomes were compared using regression analyses with tNC-FET as reference group. The multiple regression analyses were adjusted for the following confounders; fertilization method of the frozen embryos (IVF/ICSI), sex, parity (0 or > 1), maternal age (continuous variable), year of childbirth (categorical variable), blastocyst or cleavage stage transfer, single embryo transfer (sET), and for FET treatment group (tNC-FET, mNC-FET or AC-FET).

Main results and the role of chance: Most children were conceived after either mNC-FET (43.7%) or AC-FET (41.5%) treatment, while only 14.7% of the children were conceived after tNC-FET treatment. Crude analyses on background characteristics showed that sET was less used in the tNC-FET treatment group compared with both the mNC-FET and the AC-FET treatment groups. In addition, more tNC-FET children were conceived after ICSI-treatment and more tNC-FET children were born of nullipara women compared with children conceived after mNC-FET.

In the adjusted multiple regression analyses children conceived after tNC-FET had a significant higher risk of VPTB (before week 32) (aOR 3.30 (95% CI 1.06; 10.30)) compared with children conceived after mNC-FET. No altered risks were found when investigating preterm birth (before week 37), mean birth weight, SGA, LGA, stillbirth after week 28, perinatal or neonatal death**.**

Limitations, reasons for caution: Due to the retrospective design residual confounding may occur. Adjusting for BMI, smoking, cryopreservation technique and cause of infertility were not possible.

The group of tNC-FET is small.

Wider implications of the findings: Hormonal treatment (mNC-FET or AC-FET) was not associated with poor perinatal outcomes. This is important knowledges, as the effect of hormone substitution, for women with regular menstrual cycle, during ART treatment is frequently debated. mNC-FET and AC-FET are often logistically preferred, although tNC-FET may be clinically advantageous.

Trial registration number: Not applicable

P-747 Involvement of serum and glucocorticoid-regulated kinase 1 (SGK1) in term and preterm labor

J.J. Chen[1], D. Zhang[2], Y. Ruan[1]

[1]*the Hong Kong Polytechnic University, Department of Biomedical Engineering, Hong Kong, Hong Kong*

[2]*Zhejiang University, Women's Hospital, Hangzhou, China*

Study question: Does the glucocorticoid-regulated kinase 1 (SGK1) play a role in term and preterm labor/birth?

Summary answer: SGK1, by mediating glucocorticoid-induced epithelial sodium channel (ENaC) upregulation and its downstream inflammatory signaling, may play a role in term and preterm labor.

What is known already: We have previously shown in humans and mouse models that ENaC and its regulated inflammatory signaling play essential roles in term and preterm labor. The surge in cortisol levels, a major glucocorticoid in humans, is observed in women as approaching towards the end of pregnancy. SGK1 is phosphorylated/activated by glucocorticoids and promotes ENaC expression in many systems including fetal lung tissues.

Study design, size, duration: Women with spontaneous preterm labor (n=14) and term labor (n=15) were recruited and placental tissues were collected for SGK1 expression. A previously published human transcriptome database from maternal–fetus interface tissues/blood collected at onset of term and preterm labor was used for analysis of SGK1 expression and its correlation with ENaC-regulated signaling. In addition, knockdown of SGK1 was performed in human endometrial epithelial cells in vitro and the regulatory role of SGK1 in ENaC was examined.

Participants/materials, setting, methods: The expression of SGK1, phosphorylated SGK1 (pSGK1), ENaC subunits and inflammatory factors was assessed by immunoblotting or real-time PCR. Comparisons were done between term and preterm women. Correlation tests were performed between different genes. siRNA based knockdown technology was used in vitro.

Main results and the role of chance: Uterine SGK1 is activated at labor in mice. Placental SGK1 expression is upregulated in women with spontaneous preterm labor as compared to those with term labor. Analysis of the human transcriptome database reveals significant and positive correlation of SGK1 with ENaCalpha as well as labor-associated pro-inflammatory factors in labored birth groups (both term and preterm), but not the non-labored group. In vitro in human endometrial cells, treatment with cortisol

enhances ENaCalpha and COX-2 expression, which is attenuated by SGK1 knockdown.
Limitations, reasons for caution: The involvement of SGK1 in animal models of preterm labor in vivo awaits further investigation. Possible role(s) of SGK1 on fetus during preterm labor awaits more detailed study.
Wider implications of the findings: These results have showed that SGK1 may play an important role in labor, suggesting it as a potential target for diagnosis and treatment of preterm labor/birth.
Trial registration number: Not applicable.

P-748 Exposure to gonadotropin-releasing hormone agonist during early pregnancy is associated with increased risk of ectopic pregnancies

R. Nie[1], Z. Guijin[1], J. Lei[1]
[1]*Reproductive Medicine Center, Tongji Hospital, Wuhan, China*

Study question: What is the effect on pregnancy and neonatal outcomes of exposure in early pregnancy to a gonadotropin-releasing hormone (GnRH) agonist?
Summary answer: Exposure to a GnRH agonist during early pregnancy may increase the risk of ectopic pregnancies, but does not affect fetal development.
What is known already: Pituitary downregulation with the GnRH agonist is widely used in *in vitro* fertilization (IVF). A potential drawback is that the patient undergoing IVF may conceive naturally during the mid-luteal phase of downregulation with the GnRH agonist. There is concern that exposure to a GnRH agonist in early pregnancy may adversely affect pregnancy outcomes and neonatal outcomes. However, few individual case reports have been published, and with conflicting results.
Study design, size, duration: This retrospective study with a large cohort analyzed data collected from June 2010 to January 2018. The outcomes of women who conceived naturally prior to IVF treatment (NC) and during downregulation with the GnRH agonist were evaluated relative to women who conceived by IVF, intrauterine insemination (IUI), or artificial insemination by donor (AID).
Participants/materials, setting, methods: The final analysis included 116, 140, 325, and 183 women in the NC, IVF, IUI, and AID groups, respectively. Pregnancy outcomes and neonatal outcomes were compared among the four groups.
Main results and the role of chance: Nine of 129 women in the NC group were lost to follow-up, and pregnancies were ongoing in four women at the end of the study period, leaving 116 for this analysis. The live birth rate of the NC group (57.8%) was lower than that of the IUI (70.9%) and AID (74.3%) groups, but similar to the IVF group (71.2%). However, after adjusting for maternal age, body mass index, type of infertility, and history of previous caesarean section, the live birth rates of the NC and AID groups were comparable. In both the unadjusted and adjusted analyses, the rate of ectopic pregnancies of the NC group (17.5%) was significantly higher than that of the IVF (1.4%), IUI (3.7%), or AID (0.6%) groups. In both the unadjusted and adjusted analyses, all the groups were statistically similar with regard to rates of biochemical pregnancy, pregnancy loss, and birth defects, and gender ratio of newborn, gestational age at delivery, mode of delivery, and birth weight.
Limitations, reasons for caution: This retrospective cohort study is vulnerable to all the associated inherent biases. In addition, the development of the newborns was judged by gross external anatomy and parents' perceptions, and not validated by physical or neurological examination.
Wider implications of the findings: These data provide valuable guidance for both physicians and patients when GnRH agonist is used during the luteal phase. Patients should be informed about the small chance of natural conception and the increased risk of ectopic pregnancies. Physicians should be cautious when applying GnRH agonist for luteal support in IVF.
Trial registration number: not applicable

P-749 Obstertric and perinatal outcome of babies born after Elective Fertility Preservation (EFP).

A.C. Cobo Cabal[1], J. García Velasco[2], J. Domingo[3], M. Nohales[4], A. Coello[5], P. Gamiz[4], A. Pellicer[6], J. Remohí[6]
[1]*IVIRMA-Valencia, IVF laboratory-Criopreservation unit, Valencia, Spain*
[2]*IVIRMA Madrid, Ob/Gyn, Madrid, Spain*
[3]*IVIRMA-Las Palmas, Ob/Gyn, Las Palmas, Spain*
[4]*IVIRMA-Valencia, IVF laboratory, Valencia, Spain*
[5]*IVIRMA-Valencia, IVF laboratory- Criopreservation Unit, Valencia, Spain*
[6]*IVIRMA-Valencia, Ob/Gyn, Valencia, Spain*

Study question: Is there a compromise in the obstetric and perinatal outcome of the children born after EFP trough oocytes vitrification?
Summary answer: Obstetric and perinatal outcome following EFP is comparable to the results observed in autologous fresh ICSI cycles.
What is known already: There is evidence about the obstetric and perinatal results obtained after IVF cycles conducted with vitrified oocytes in the overall population. However, although there is increasing demand in EFP there is a lack of information about the results achieved by women who electively had their oocytes vitrified for fertility preservation (FP) and returned to attempt pregnancy.
Study design, size, duration: Retrospective multicentric study, January 2008-September 2018.
Participants/materials, setting, methods: Private university-affiliated IVF center. Obstetric outcome was obtained from 170 pregnant EFP women who delivered 185 children. Control group included 12262 women who achieved pregnancy after fresh autologous ICSI cycles during the same period and delivered 14914 babies. Chi-square and Student's t-test were used when appropriate. Adjusted odds ratios and their 95% confidence intervals were estimated with each method to evaluate the relative odds for vitrified oocytes compared to the reference group of fresh oocytes.
Main results and the role of chance: Mean age was older for EFP patients (38.5 ± 3.8 vs. 34.8 ± 3.5) $p<0.005$. Delivery route was similar (50.3% vs. 50.7% vaginal delivery) (NS). EFP women and controls delivered during week 39.1 ± 2.9 and 38.5 ± 3.8 respectively ($P<0.005$). There were no differences in terms of preterm births (12.1% vs 16.4%), very preterm births (7.1% vs. 4.3%), perinatal mortality (0.5% vs.0.3%), birth defects (0.5% vs. 0.6%), admission to NICU (5.4% vs 3.3%) and sex of the baby (47.6% vs 49.8% for female neonates) (NS). Birth weight was higher in EFP group (3046.7 ± 722.9 g vs. 2865.9 ± 663.7 g) ($p<0.05$). Low birth weight (LBW:<2500 g) was higher in controls (14.8% vs. 26.3%) $p<0.05$) and very low birth weight (VLBW:1500 g) was comparable (5.4% vs 3.0%) (NS). The impact of EFP on the following variables was rule out as shown by the OR (95%CI): LBW=0.854 (0.337-1.091);VLBW: 1.849 (0.337-1.091); Preterm birth: 0.703 (0.449-1.01); very preterm birth: 1.701 (0.963-3.008); perinatal mortality: 1.795 (0.246-13.089); Birth defects: 0.773 (0.107-5.573); Route for delivery; 1.017 (0.756-1.368) and sex of the baby:1.124 (0.837-1.510);(NS).
Limitations, reasons for caution: Although this study compiles a large series, sample size is still small in EFP group.
Wider implications of the findings: This study suggests that there is no increased risk of adverse obstetric and perinatal outcome in children conceived from vitrified oocytes in elective fertility preservation, thus confirming the safety of the approach. Further analysis as the sample size continues to grow will be mandatory in order confirm our findings.
Trial registration number: N/A

P-750 Reassuring results on the chance of a live born child in women with multiple sclerosis receiving assisted reproduction

L.R. Jølving[1], M.D. Larsen[2], J. Fedder[3], B.M. Nørgård[2]
[1]*Researcher, Center for Clinical Epidemiology- Odense University Hospital, Odense, Denmark*
[2]*Odense University Hospital, Center for Clinical Epidemiology, Odense, Denmark*
[3]*Odense University Hospital, Centre of Andrology and Fertility Clinic, Odense, Denmark*

Study question: What is the chance of a live birth after assisted reproductive technology (ART) treatment in women with multiple sclerosis (MS)?
Summary answer: Women with MS did not have a decreased chance of a live born child per embryo transfer, compared to women without MS undergoing ART.
What is known already: The results in women with other autoimmune diseases as ulcerative colitis, Crohn's disease and rheumatoid arthritis, have suggested a reduced chance of live birth after ART treatment. Whether ART treatment affects the disease course in MS is controversial, but women with

MS are more likely to refrain from pregnancy and infertility and MS may also coincide. No previous studies have examined the efficacy of ART in women with MS, in terms of live birth. Therefore, we examined the chance of live birth after embryo transfer in women with MS, compared to women without MS.

Study design, size, duration: A nationwide register-based cohort study comprising all embryo transfers in Denmark during 24 years (1994 to 2017), including follow-up on pregnancies until November 2018.

Participants/materials, setting, methods: Women undergoing ART treatment included 2,297 embryo transfers in 826 women with MS (the exposed cohort), and 203,862 embryo transfers in 68,105 women without MS (the unexposed cohort). We used multilevel logistic regression analysis to compute the crude and the adjusted risk estimates with 95% confidence intervals (CI) adjusting for a number of important confounders. In sub-analysis we examined a potential impact of the use of corticosteroids prior to embryo transfer.

Main results and the role of chance: There were 508 (22.1%) live births in the exposed cohort and 49,185 (24.1%) live births in the unexposed cohort. The adjusted odds ratio (aOR) for a live born child in women with MS, relative to women without MS undergoing ART, was close to unity (aOR = 0.92 (95% CI 0.82-1.03)). Use of corticosteroids within 3 month prior to embryo transfer did not have an impact on the chance of a live birth. This is the first study to examine the impact of maternal MS on the chance of a live born child after ART treatment. On the whole, the study design prevents selection- and information bias, and we obtain relative risk estimates with good statistical precision. Our results are novel, and it is reassuring that the chance of livebirth after ART in women with MS, are equal to women without this chronic disease.

Limitations, reasons for caution: Although this study includes all relevant patients, procedures and diagnoses from the national Danish registries, we did not have access to information on disease severity, and use of MS-modifying medication in relation to ART treatment.

Wider implications of the findings: This is the first study to examine the impact of MS on efficacy of ART, and our results must be confirmed in other settings. The chance of a live birth is similar between women with MS and without MS. These are important information for women with MS and their clinicians.

Trial registration number: The study is notified at the Danish Data Protection Agency under the current joint notification of the Region of Southern Denmark (ref.no. 2012-58-0018).

P-751 A randomized controlled trial comparing the number of mature oocytes following automated-3D versus manual-2D ultrasound follicle assessment, in high-risk for OHSS patients triggered with GnRH-agonist

G. Lainas[1], T. Lainas[1], I. Sfontouris[1], S. Kyriaki[1], I. Zorzovilis[1], J. Bosdou[2], G. Grimbizis[2], A. Chatzimeletiou[2], C. Venetis[3], E. Kolibianakis[2]

[1]Eugonia IVF Unit, Unit of Human Reproduction, Athens, Greece
[2]Aristotle University of Thessaloniki- Unit of Human reproduction, 1st Department of OB/Gyn, Thessaloniki, Greece
[3]University of New South Wales, School of Women's and Children's Health UNSW Medicine, Sydney, Australia

Study question: Is the number of mature oocytes(MII) different following automated-3D versus manual-2D ultrasound follicle assessment, in high-risk for OHSS patients undergoing ICSI, triggered with GnRH agonist?

Summary answer: A significant, but clinically irrelevant, increase in MII oocytes was observed following automated-3D versus manual-2D follicle assessment in high-risk for OHSS patients triggered with GnRH-agonist.

What is known already: Accurate assessment of size and number of follicles during ovarian stimulation is important for determining the day of triggering final oocyte maturation and oocyte retrieval, in order to retrieve an optimal number of mature oocytes. Previous studies have shown that timing final oocyte maturation using 3-dimensional SonoAVC (automated-3D) and conventional 2-dimensional (manual-2D) ultrasound assessment is associated with similar numbers of mature oocytes in normal responders. However, no data are available on the comparative efficiency of manual-2D and automated-3D ultrasound for determining the day of triggering final oocyte maturation with GnRH-agonist in high responders at risk of OHSS.

Study design, size, duration: Random patient allocation to automated-3D (SonoAVC;GE Medical Systems) or manual-2D ultrasound assessment was performed at initiation of stimulation by a nurse using a computer-generated randomization list in a single center between 8/2018 and 1/2019. Primary outcome was the number of MII oocytes retrieved. A sample size of 26 patients in each group was required to yield 80% power to detect a difference of 4 MII oocytes, assuming a mean number of COCs retrieved=18 and SD=5.

Participants/materials, setting, methods: This study included women ≤40 years with AMH>3 ng/ml at high risk for OHSS treated with GnRH-antagonists and recombinant-FSH. When three follicles≥17mm were present based on manual-2D or automated-3D ultrasound assessment, 0.2mg triptorelin was administered to trigger final oocyte maturation. Oocytes were fertilised with ICSI and all blastocysts were cryopreserved. Clinicians deciding when to trigger, embryologists and patients were blinded to the method of follicular assessment. Values are expressed as median (interquartile range).

Main results and the role of chance: Age, BMI, AMH and baseline FSH, LH, oestradiol and progesterone levels were similar in the two groups.Compared to manual-2D, automated-3D assessment was associated with a similar duration of stimulation [11 (95%CI: 11.0-12.0) vs 12 (95%CI: 11.0-12.0, respectively] and total dose of recFSH [1787 (1500-1988) vs 1800 (1736-2007), respectively]. Serum hormone levels in the 2D and 3D group on the day of trigger were similar for oestradiol [4567 (3269-4928) vs 3718 (3014-5512)], progesterone [1.1 (0.8-1.6) vs 1.3 (0.94-1.62)] and LH [1.3 (1.2-2.7) vs 1.7 (0.83-2.7)] respectively.

However, compared to manual-2D , automated-3D assessment was associated with significantly more follicles ≥11mm on the day of trigger [22 (21.0-24.0) vs 26.5 (20.9-31.5), p=0.037, respectively], more cumulus-oocyte complexes (COCs) retrieved [18 (7) vs 18.5 (5), p=0.041, respectively), more mature oocytes [14.0 (10.0-16.0) vs 15.0 (14.0-17.0), p=0.016, respectively] and more 2PN oocytes [9.5 (7.4-12.1) vs 12.0 (11.0-14.5), p=0.010, respectively].

Limitations, reasons for caution: Although significantly more COCs and mature oocytes were retrieved and more 2pn oocytes were available after fertilization in the automated-3D vs the manual-2D group, the detected differences appear to be clinically irrelevant. This is a small albeit powered RCT, necessitating studies with a larger patient population.

Wider implications of the findings: The decision to trigger using automated 3D follicle measurement was associated with significantly more mature oocytes compared with conventional 2D ultrasound, in high-risk for OHSS patients triggered with GnRH-agonist. However, these differences were small and potentially clinically irrelevant. The choice of method depends on equipment availability in each clinic.

Trial registration number: NCT03610009

P-752 Modeling of Low Level and Common Embryotoxic Volatile Organic Compounds (VOCs)–Their Relationship to Concentrations Within the Culture Media, Human Embryo, and Mechanisms of Cytotoxicity

K.C. Worrilow[1], A.R. Urrutia[2], H.T. Huynh[3], J.T. Fox[4]

[1]LifeAire Systems / Penn State University - Lehigh Valley, Biological Sciences, Fogelsville, U.S.A.
[2]LifeAire Systems / Cornell University, Engineering, Ithaca, U.S.A.
[3]LifeAire Systems / Pa College of Health Sciences, Health Education, Lancaster, U.S.A.
[4]Lehigh University, Engineering, Bethlehem, U.S.A.

Study question: To better understand mechanisms of embryotoxicity, can airborne concentrations of VOCs be modeled as concentrations within the supporting culture media and embryo?

Summary answer: Henry's Law and octanol-water partitioning coefficients define the relationship between concentrations of specific VOCs in the gaseous and aqueous phase, and within the embryo.

What is known already: VOCs, organic compounds with a high vapor pressure and thus, a high level of volatility, are a common airborne con-

stituent of outside source air, recirculated laboratory air, HVAC components, tissue cultureware, and IVF procedures. VOCs are ubiquitous and unique in their polarity, molecular weight and biochemical structure. VOCs are embryotoxic and play a critical role in preimplantation toxicology and epigenetic processes. Research has clearly demonstrated that a large range of VOCs exist within the IVF laboratory and exert a negative impact on zygote to blastocyst conversion rates, implantation rates, and clinical pregnancy rates in IVF laboratories.

Study design, size, duration: Henry's Law was used to model VOC mass transfer from the air to the water/culture phase. This model uses the air-water partitioning coefficient and the definition that the ratio between the liquid concentration and the air phase concentration is equivalent to a dimensionless constant. The octanol-water partitioning coefficient was used to correlate the mass transfer from the water/culture phase to the embryo using the ratio between the octanol concentration and the water concentration.

Participants/materials, setting, methods: The 34 most common VOCs in IVF laboratories were studied. Henry's Law and octanol-water calculations determined the relationship between concentrations of each VOC in the culture media, embryo, and time to thermodynamic equilibrium. The VOCs in the air phase were assumed to be dilute and at three constant concentrations (10ppb, 100ppb, 1ppm). The concentration in the embryo was compared to the median lethal dose (LD50), the dose at which 50% of living cells survive.

Main results and the role of chance: Extensive testing demonstrated that total VOC (TVOC) levels range between 100ppb and 1ppm in IVF laboratories. The concentration of each VOC within the embryo at 10ppb in air was compared to LD50 values. Many of the concentrations within the embryos were higher than documented LD50 values indicating these VOCs to be cytotoxic. Research has demonstrated an average concentration of 11.3 $\mu g/m^3$ of formaldehyde as measured in numerous IVF laboratories. The concomitant formaldehyde concentration within the embryo was 19.36 times higher than the LD50 value. Low level airborne VOCs increased in concentration as they partitioned from the air to the cell culture medium, and ultimately, into the embryo. Research has demonstrated that VOCs can exert an embryotoxic effect by disrupting the cellular membrane, increasing intracellular calcium, impairing mitochondrial function, decreasing spindle formation/chromosome alignment, interfering with DNA/RNA replication, and increasing DNA oxidative damage and fragmentation. This model correlates the measured concentration of various airborne VOCs to the final concentration within the embryo. The presence of low level TVOCs is concomitant with reduced cellular metrics and clinical outcomes. This information, in conjunction with LD50 values, can be used to understand, and remove VOCs as a cytotoxic variable in the cell culture process.

Limitations, reasons for caution: The specific density of the human embryo is not clearly known and an approximation for standard cell density was used. Variations in cell density will impact the calculated concentration of each VOC in the culture media and embryo.

Wider implications of the findings: These findings are applicable to all cultured cellular processes utilizing living cells. A deeper understanding of the cytotoxic mechanisms of VOCs in relationship to the living cell culture will provide a paradigm shift in the definition of the optimal *in vitro* culture environment for the living cell.

Trial registration number: Not Applicable

P-753 The influence of advanced paternal age on offsprings' intelligence following assisted reproductive technology

W. Wang[1], Y. Zhu[1]

[1] *Women's Hospital school of Medicine Zhejiang University, Department of Reproductive Endocrinology, hangzhou, China*

Study question: Is advanced paternal age a cognitive risk for the offspring born after assited reproductive technology(ART)?

Summary answer: Our study suggests advanced paternal age may result in higher offspring Verbal intelligence quotient(IQ) and Full IQ scores in ART population

What is known already: Recent investigations suggest that advanced paternal age has many deleterious effects on offsprings' developmental outcomes ,especially cognitive, emotional and neuropsychiatric outcome,but there is debate about the relationship between fathers' age and children's intelligence.Few studies have examined the impact of paternal age on offsprings' intellectual development,especially children born after assisted reproductive technology.

Study design, size, duration: The study was divided into four groups based on the age of the fathers:≥40 years;35∼39 years;30∼34 years;25∼29 years(control), The follow-up assessments were taken place between 2009.09 and 2017.07 at ART Offspring Health Monitoring Center 4-6 years old children who born in 2003-2012 was recurited in our Reproductive Center to have a intelligence test-Chinese Version of the Wechsler Intelligence Scale for Children (C-WISC)

Participants/materials, setting, methods: Participants who underwent IVF/ICSI and achieved live births included.Exclusion criterias for parents:

1)sperm and oocyte donation donation,PGD/PGS;

2)mutiple pregnancy,one member of a couple smoked or abused alcohol before pregnancy;

3) serious diseases;

4) data missed in database.

After exclusion,a total of 1934 parents agreed to participate and 1914 singletons completed the intelligence tests(C-WISC).

Adjusted linear regression or logistic regression analyses were used to evluate cognition after control for certain confounders.

Main results and the role of chance: After controlling for multiple possible confounding factors, including the other parent's age,parental education, pregnancy complications,sex ,birth weight and birth complications,singletons' Verbal IQ and Full IQ whose fathers' age ≥40 ,35∼39,30∼34 years are higher than paternal ages 25∼29 years.There are no difference among the four groups in Performance IQ.Our study suggests advanced paternal age may result in higher offspring Verbal IQ and Full IQ scores in IVF/ICSI population.This result is similar to a previous study which suggests advancing paternal age is associated with higher GI in offspring.Older father age may not only bring some deleterious devlopment outcome,but it also has some advantageous developmental outcomes.

Limitations, reasons for caution: This study also has some limitations,the parents' income is not a factor in our confounding factors,because of it is a private information for Chinese pepole.Family economic status always show correlation with childrens' education levels.Therefore ,we considered area as a confounding factor,to some extent ,it represents economic level.

Wider implications of the findings: Most investigations suggest that advanced paternal age has deleterious effect on offsprings' intelligence.Our result show disagreement with most researches.It could be due to different population and participant numbers in these studies.

Trial registration number: Z15H040001

P-754 Conversion of in vitro fertilization cycles to intrauterine inseminations in patients with a poor ovarian response: risk of multiple pregnancies.

S. Abnoun[1], C. Verhaeghe[1], H. El Hachem[2], R. Corroenne[1], G. Legendre[1], P. Descamps[1], P. May-Panloup[1], P.E. Bouet [1]

[1] *Gynécologie-Obstétrique- Centre Hospitalier Universitaire d'Angers, Reproductive Medicine, Angers, France*

[2] *Clemenceau Medical Center- Beirut- Lebanon, Reproductive Medicine, Beirut, Lebanon*

Study question: What is the risk of multiple pregnancies following conversion of in vitro fertilization cycles to intrauterine insemination when a poor ovarian response (POR) is diagnosed during controlled ovarian stimulation (COS)?

Summary answer: In in vitro fertilization (IVF) cycles converted to intrauterine inseminations (IUI) for poor response, the risk of multiple pregnancy (MP) is acceptable (12%).

What is known already: There are no studies that have estimated the risks of MP in IVF cycles converted to IUI for POR. Conversion to IUI can be offered to women with one to four mature follicles. Two factors usually lead physicians to favor IVF over IUI: 1) the hypothetic lower success rates with IUI compared to IVF, 2) the hypothetic risk of MP with IUI in cases with more than two mature follicles. We aimed to assess the risks of MP following conversion to IUI in

patients with POR and to evaluate the MP rates according to the number of mature follicles.

Study design, size, duration: We undertook a retrospective study in our teaching hospital from January 2007 to December 2017. Overall,205 IVF cycles that were converted to IUI in 128 patients were analyzed.

Participants/materials, setting, methods: The inclusion criteria were: (1) age ≥18 and <43 years; (2) IVF cycles, with and without Intracytoplasmic sperm injection, following COS using an agonist (long and short) or an antagonist protocol, with only ≤ 4 mature follicles (≥14 mm) on ovulation trigger day; (3) Serum estradiol level <1000 pg/mL on ovulation trigger day.

Main results and the role of chance: Mean age was 34.1 ± 4.6 years, mean antral follicle count was 11 ± 5.3 and meanAMH was 1.8 ± 2.9 ng/L. The main causes of infertility were unexplained (41%) (84/205) and premature ovarian insufficiency (35%) (72/105). The mean daily dose of gonadotropins was 321.1 ± 89.5 IU. On the day of ovulation triggering, the mean number of follicles ≥14 mm was 2.5 ± 1.3, and the mean level of serum estradiol was 465.9 ± 247.1 pg/mL. Of all the cycles converted to IUI, 53 (26%) had one mature follicle on trigger day, 56 (27%) had 2, 56 (27%) had 3, and 40 (20%) had 4. The live birth rate was 7.3% (15/205) and the miscarriage rate was 40% (10/25). There were 3 twin pregnancies, but no higher order pregnancies; the MP rate was 12% (3/25). One twin pregnancy occurred in a cycle with 1 mature follicle on trigger day, one in a cycle with 2 mature follicles and one in a cycle with 4 mature follicles. All twin pregnancies were bichorial-biamniotic. Finally, there was no significant difference in the MP rate between patients with 1-2 mature follicles and patients with 3-4 mature follicles (15.4% vs 8.3%, p=0.99, respectively).

Limitations, reasons for caution: The main limitation is the retrospective design. Moreover, despite including a considerable number of cycles, the number of live births was not high enough to allow us to compare outcomes between different subgroups and draw more significant conclusions, mostly because of the poor overall prognosis of patients with POR.

Wider implications of the findings: In IVF cycles converted to IUI,the risk of MP is acceptable, even with 3 or 4 follicles ≥ 14 mm on trigger day. Conversion to IUI can be offered to patients when there are ≤4 mature follicles on trigger day with a serum estradiol level < 1000 pg/ml.

Trial registration number: Not applicable

P-755 Factors affecting the quality of successful implantation of thawed cryopreserved embryos: the Welsh experience

B. Davies[1], G. Jose[2], Z. Shehadeh[2], G. Kalra[2], A. Ibrahim[2], A. D'Angelo[2]

[1]*Cardiff University, Wales Fertility Institute, Cardiff, United Kingdom*

[2]*University Hospital of Wales, Wales Fertility Insitute, Cardiff, United Kingdom*

Study question: What are the factors that affect the success rates of thawed frozen embryo implantation?

Summary answer: The greatest implantation success was seen in ages 30-34, 2-embryo transfer (p≤0.05), day-5 thaw, 18-21 days of HRT stimulation, male infertility (p≤0.05), ICSI and vitrification.

What is known already: Although frozen embryo transfer (FET) appears promising, the success rates are not idyllic with only 20-25% of embryos transferred resulting in a birth. Some predictors of success include maternal age, infertility duration, tubal infertility, damage during the freeze-thaw process, embryo quality and quantity, and maternal body mass index (BMI).

Study design, size, duration: A retrospective analysis of patients who underwent FET (after in-vitro fertilisation [IVF] or intra-cytoplasmic sperm injection [ICSI]) at a University Hospital, between January 2007 and December 2017, was carried out.

Participants/materials, setting, methods: Records from 1325 patients were reviewed for factors affecting implantation. Primary outcomes analysed were positive pregnancy tests (PPT) and clinical pregnancy rate (CPR) per embryo transfer cycle and embryo transferred. The variables scrutinised were maternal age and BMI, cycle number, number of embryos transferred, embryo stage at thaw, endometrial thickness, HRT duration, HRT versus natural cycle, infertility type and cause, IVF, ICSI and slow freezing or vitrification. Logistic regression was performed using SPSS Statistics.

Main results and the role of chance: 181 (13.6%) patients were excluded due to failure to thaw (95), incomplete data (53) and other reasons (33). The CPR per embryo transferred and per embryo transfer cycle, were 14.38% and 21.69%, respectively. The biochemical pregnancy rate was 8.0%. The PPT rate and CPR for a 2-embryo transfer (odds ratio [OR] 1.850 and 1.818, respectively) and the CPR for male factor infertility (OR 1.87) were statistically significant (p≤0.05).

The maternal age ranges with the highest (24.69%) and lowest (17.65%) proportion of CPR were 30-34, and greater than 40, respectively. The OR for age was 1.004 for CPR and 1.009 for PPT. One cycle was inferior to multiple cycles (ORs 0.802 for CP and 0.891 for PPT). Thawing on day 5 produced the highest CPR (OR 1.75). HRT cycles yielded a higher PPT rate and CPR than natural cycles (38.50% vs 30.43% [OR 0.957], and 23.34% vs. 19.57% [OR 0.863], respectively). 18-21 days of HRT stimulation produced the highest PPT rate (45.7%) and CPR (27.3%). The optimum endometrial thickness for implantation was 8.1-13mm (ORs 0.979 for PPT and 1.004 for CPR). ICSI was superior to IVF (ORs 1.38 for CPR and 1.05 for PPT).

Limitations, reasons for caution: This study was retrospective, and, thus, the relationships found could be associative: confounding bias may have affected the results, such as lifestyle factors. Also, there could have been a degree of selection bias as incomplete patient records were required to be removed from the analysis.

Wider implications of the findings: Both PPT and CPR reflected other studies. Young age, 2-embryo transfer, and day-5 thaw increased pregnancy rates. Alleviating the debate surrounding HRT, stimulation for 18-21 days produced the greatest success. Contrary to previous results, male infertility had higher implantation rates, possibly due to increased use of, and improved, ICSI technique.

Trial registration number: Not applicable since this was a retrospective audit.

P-756 Obstetric and neonatal outcome of assisted reproductive technology (ART) in patients with polycystic ovaries (PCO): in vitro maturation (IVM) of oocytes versus controlled ovarian stimulation

L. Mostinckx[1], I. Segers[2], F. Belva[3], R. Buyl[4], S. Santos-Ribeiro[5], C. Blockeel[2], J. Smitz[6], E. Anckaert[7], H. Tournaye[2], M. De Vos[2]

[6]*Vrije Universiteit Brussel, Follicle Biology Laboratory FOBI- Vrije Universiteit Brussel, Brussel, Belgium*

[7]*UZ Brussel, Laboratory of Clinical Chemistry and Radioimmunology- UZ Brussel, Brussel, Belgium*

Study question: Does in vitro maturation (IVM) of immature oocytes in women with polycystic ovaries (PCO) have an impact on obstetric and neonatal outcome compared to controlled ovarian stimulation (COS)?

Summary answer: Obstetric and neonatal outcomes after IVM appear to be similar to those after COS.

What is known already: Women with polycystic ovary syndrome (PCOS) have an increased risk of adverse pregnancy outcomes and congenital malformations in their offspring. For patients with PCOS who require in-vitro fertilization (IVF), IVM of germinal vesicle (GV)-stage oocytes retrieved from antral follicles has been adopted as a mild approach assisted reproductive technology (ART), with improved pregnancy rates over the last two decades. Although reports of obstetrical and neonatal outcome after IVM have been reassuring, the limited sample size in previous studies precludes firm conclusions and warrants further study.

Study design, size, duration: This is a retrospective observational study analysing obstetric and neonatal data from 1574 pregnancies in patients with PCO who conceived following a cycle of IVM or conventional ovarian stimulation (COS) between January 2010 and December 2016 in a tertiary reproductive centre. In total, 857 pregnancies with a gestational age beyond 20 weeks were included. A phenotypic approach was used for the diagnosis of PCOS. Patients requiring pre-implantation genetic testing (PGT) or testicular biopsy were excluded.

Participants/materials, setting, methods: Outcomes of 209 singleton pregnancies beyond 20 weeks after IVM were compared with those of 648 singleton pregnancies after COS. Pregnancies in the IVM group were obtained after minimal ovarian stimulation and no hCG trigger before oocyte retrieval. Outcomes included obstetric complications and neonatal health parameters, in particular birthweight, prematurity, small/large-for-gestational age, perinatal death and major/minor malformation rates. Data were analysed by multiple linear and logistic regression, adjusted for relevant treatment variables and maternal characteristics.

Main results and the role of chance: The IVM and the COS groups differed significantly ($p<0.001$) for maternal characteristics, including circulating AMH levels and PCOM/PCOS phenotype distribution, with an overweight of PCOS phenotype A in the IVM group and a predominance of PCOM in the COS group.

With regard to obstetric complications in singleton pregnancies, in the unadjusted analysis, mothers to infants in the IVM group had more often hypertensive disorders of pregnancy (HDP) (33/193 (17.1%) vs. 44/568 (7.7%)) than mothers to infants in the COS group. Singletons born after IVM showed a tendency toward higher standard deviation score (SDS) (0.54 ± 0.98 vs. 0.39 ± 1.02, $p=0.09$) and a significantly higher preterm (32–36.9 weeks; 24/191(13.3%) vs. 37/562 (6.8%)) and early preterm birth rate (<32 weeks; 5/191 (2.8%) and 15/562 (2.7%)), compared with peers born after COS ($p=0.02$). The total malformation rate was comparable between IVM (3.5%) and COS (3.9%), $p=0.85$. Multivariate linear regression analysis accounting for relevant confounders demonstrated that parity was the only independent predictive factor ($p<0.001$) for birthweight SDS. Multivariate logistic regression analysis showed that BMI and parity were significantly correlated with the incidence of HDP. The risk of HDP was also increased in patients with PCOS phenotype A following IVM.

Limitations, reasons for caution: The study is limited by its retrospective nature and loss to follow up of a subset of children with no information regarding congenital malformations. Furthermore, data from consecutive pregnancies in the same patient were not excluded from the analysis.

Wider implications of the findings: This study provides further evidence that IVM of oocytes derived from small antral follicles does not adversely affect the neonatal health of the offspring of patients with PCOS compared to COS. The observed increased risk of HDP in patients with PCOS phenotype A following IVM treatment requires further scrutiny.

Trial registration number: The study was approved by the institutional review board of Universitair Ziekenhuis Brussel on March 21st 2018 (B.U.N. 143201835600).

P-757 A prospective RCT sibling study to test the efficacy and safety of the calcium ionophore GM508 in two different indication groups – preliminary results.

M. Schuff[1], A. Stecher[2], B. Wirleitner[2], A. Damko[2], F. Kentros[2], M. Bach[2], A. Neyer[2], M. Murtinger[2]

[1]NEXTCLINIC IVF Centers Prof. Zech - Bregenz, Bregenz, Austria

[2]NEXTCLINIC IVF Centers Prof. Zech, Bregenz, Bregenz, Austria

Study question: Does application of artificial oocyte activation (AOA) by calcium ionophore impact on neonatal outcome in IVF patients?

Summary answer: Preliminary results show no evidence for any negative impact on neonatal health due to AOA in this two-armed sibling study.

What is known already: AOA is widely applied in IVF, mainly to overcome failed or impaired fertilization. However, besides globozoospermia, there is no proven indication for AOA. Hence, large prospective studies are needed to prove efficiency and validated indications. As AOA does not result in physiological Ca(2+) oscillations, the question of neonatal health after AOA-therapy is of utmost importance. To date, there are only few studies reporting neonatal outcome after AOA. Additionally, different chemicals inducing Ca(2+) waves by different mechanisms were applied in these studies.

Study design, size, duration: A prospective 2-arm randomized sibling study was conducted in 2016. Inclusion criteria were female age < 44 y; $\geq$ 2MII oocytes and an indication for AOA (male factor infertility or previous IVF-cycles with reduced fertilization/blastocyst rate). Embryo culture was performed with one half of the oocytes undergoing AOA and the other half serving as non-treatment group. Preliminary results of neonatal outcome were evaluated by analyzing data of 43 returned questionnaires

Participants/materials, setting, methods: In all fresh or frozen transfers, the morphologically best-rated blastocyst(s) were chosen for transfer, blinded for AOA treatment. Thereby 18 patients received a transfer with AOA blastocyst(s), 11 with non-AOA blastocyst(s) and 14 two blastocysts one from each group. IVF outcome and clinical outcome were analyzed. Pregnancy course and neonatal health were evaluated by questionnaire encompassing 20 questions including patient's medical history, lifestyle factors, pregnancy course, social environment as well as delivery and obstetric outcome.

Main results and the role of chance: Mean number of transferred blastocysts/transfer in the AOA group was 1.4, in the non-AOA group 1.6 and in the mixed group 2.0. Mean female and male age at oocyte pick-up was: 35.1 and 41.0 years; 35.9 and 41.4 years; 36.7 and 38.6 years, respectively. In the AOA group 25 children were born (11 singletons and 7 twins) with two preterm deliveries in the twin group (28 and 32 gestational week). One twin pair was monozygotic. All children were healthy and experienced normal development during the first months. Syndactyly was reported in one girl as single minor malformation. In the non-AOA group 12 healthy children were born on term (10 singletons and 1 twin pair). In the mixed transfer group 16 healthy children were born (15 singletons and on triplet after double blastocyst transfer). One singleton and the triplet were born preterm. One boy was reported with syndactyly in this group. All children experienced normal development during the first months.

Limitations, reasons for caution: AOA was applied with GM508 Cultactive according to the manufacture's protocol, thus results might be not applicable for other AOA-protocols. Further limitations are the preliminary dataset of this ongoing study.

Wider implications of the findings: Our results encourage that the application of AOA by this protocol does not negatively impact on the obstetric outcome. Thereby, application might be enlarged in patients with risk for reduced fertilization rates due to severe male infertility or other factors.

Trial registration number: DRKS00010456 registered in 2016. This study has received ethical approval by the Ethical Committee of Vorarlberg (Austria)

P-758 Germline transmission of donor mitochondrial DNA in rhesus macaques produced via mitochondrial replacement therapy

C. Van Dyken[1], H. Ma[1], H. Darby[1], H. Sidener[2], N. Marti-Gutierrez[1], A. Koski[1], Y. Li[1], T. Hayama[1], E. Kang[3], Y. Lee[3], C. Ramsey[2], P. Amato[4], S. Mitalipov[1]

[1]Oregon Health and Science University, Center for embryonic cell and gene therapy, Portland, U.S.A.

[2]Oregon Health and Science University, Oregon National Primate Research Center, Portland, U.S.A.

[3]ASAN Institute for Life Sciences, Stem Cell Center, Seoul, Korea- South

[4]Oregon Health and Science University, Department of Obstetrics and Gynecology, Portland, U.S.A.

Study question: To define health and fertility of adult trans-mitochondrial monkeys produced by mitochondrial replacement therapy (MRT).

Summary answer: Both male and female MRT macaques are fertile and donor mitochondrial DNA (mtDNA) was passed on from the female MRT monkey to offspring.

What is known already: MRT is a form of germline gene therapy developed to prevent transmission of mtDNA mutations from mothers to children. In a previous study, mature oocytes were collected from female rhesus macaques of diverse genetic backgrounds. The cytoplasm and mtDNA complement of one oocyte was removed and replaced with mtDNA from a different background. MRT oocytes were fertilized and implanted into surrogate females. Trans-mitochondrial monkey offspring have now reached sexual maturity and are being studied.

Study design, size, duration: Four male MRT monkeys were produced in our lab in 2009, followed by an MRT female in 2012. Fertility in adult males was analyzed through sperm collection and analysis as well as natural breeding. Fertility and germline transmission of donor mtDNA were studied in the female MRT monkey and mature oocytes and live offspring were produced by natural breeding.

Participants/materials, setting, methods: This study was performed at the Oregon National Primate Research Center with rhesus macaques used as animal models. All studies were approved on an IACUC protocol. Analysis

started when monkeys were about 5-6 years old, the time of sexual maturity. All births were the result of natural breeding through the time-mated breeding program. MtDNA was analyzed with the amplification- refractory mutation system quantitative PCR (ARMS qPCR) and MiSeq.

Main results and the role of chance: Sperm from MRT monkeys was analyzed for volume, count, motility and morphology and were not distinguishable from controls. MRT males were paired naturally with females and resulted in healthy offspring.

57 mature oocytes were collected from the MRT female and 56 showed entirely donor mtDNA while one showed 1.6% of maternal mtDNA. The female monkey was paired with a male from the time-mated breeding program and also produced a healthy infant. All analyzed peripheral tissues from the infant showed exclusively donor mtDNA haplotype demonstrating successful germline transmission.**Limitations, reasons for caution:**

The number of animals used in this study is small including a sole female.

Wider implications of the findings: MRT clinical trials are ongoing in some countries. Our results on adult MRT monkeys and their offspring provide critical safety assurance. Results show that MRT does not affect fertility in males or females and that donor mitochondria will be passed on from mother to offspring.

Trial registration number: not applicable

P-759 Human and communication errors are the main cause of non-conformances in an IVF laboratory

C. Bisioli[1], M. Papayannis[1], M. Gomez Peña[1], G. Terrado Gil[2], E. De Martino[1], I. De Zúñiga[2], L. Kopcow[2], F. Sobral[2], A. Oubiña[2], M. Horton[2]

[1] *Pregna Medicina Reproductiva, Embryology, Buenos Aires, Argentina*
[2] *Pregna Medicina Reproductiva, Fertility Department, Buenos Aires, Argentina*

Study question: How frequent non-conformances are in the IVF laboratory and why do they occur?

Summary answer: Non-conformances in the IVF laboratory are not frequent and associated mainly to human and communication errors.

What is known already: Notwithstanding the complex procedures normally performed in an ART laboratory, and the emphasis given to quality control measures, reports and analysis of non-conformances in the IVF setting are scant. Likewise it has been noticed in other fields of medicine and human activities such as aviation, the few reports in ART indicate that the majority of the errors are of human and communication origin.

Study design, size, duration: We reviewed all non-conformances reported in our database between January 2012 and December 2018. The 29,357 procedures performed in this period included egg retrievals, fresh and frozen embryo transfers, vitrification, pre-implantation genetic testing and andrology practices. Non-conformances were divided according to the literature into four impact grades (minimal, significant, moderate and major) and eight categories (communication, documents/records, external, facilities, equipment/supplies, human, patient problem/complaint and quality control (QC)/statistical).

Participants/materials, setting, methods: Retrospective study of non-conformances registered in our IVF laboratory database.

Main results and the role of chance: A total of 64 non-conformances were documented during the study period (99.78 % with no non-conformances in all categories). When we analyzed them according to their impact, 50.00 % (32/64) were minimal, 18.75 % (12/64) moderate, 31.25 % (20/64) significant, with no major errors reported. We observed that 43.75 % (28/64) of the non-conformances were due to human errors, 29.69 % (19/64) to communication problems, 15.63 % (10/64) to failures in equipment or supplies, 7.81 % (5/64) to patient problems or complaints and 3.13 % (2/64) external. No facilities, documents/records or QC/statistical non-conformances were reported. The embryology laboratory was the site of the 53.13 % (34/64) of the errors, while 31.25% (20/64) of them occur in the cryopreservation/storage unit, 12.50 % (8/64) in the andrology sector, 1.56 % (1/64) in the PGT laboratory and 1.56 % (1/64) were external. If we consider only moderate and significant errors, non-conformances rates were 1 per 917 procedures (0.11 %) and 1 per 399 cycles (egg retrievals and frozen embryo transfers) (0.25 %).

Limitations, reasons for caution: It would perhaps be unwise to directly extrapolate or compare our results to other laboratories due to different settings, culture systems and classifications in use. With the improvement of our QC programme, the non-conformances documentation has been more precise over the years.

Wider implications of the findings: Our results provide more information about the origin of non-conformances. The coincidence of our data with other published reports suggests that our results could be useful for other embryologists and clinicians to anticipate and minimize risks.

Trial registration number: Not applicable.

P-760 Defining which serum Progesterone cut off levels on day of human chorionic gonadotropin (hCG) trigger can affect implantation in IVF/ICSI: evaluating the quality of service.

K. Kalra[1], C. Ariti[1], A. Ibrahim[2], Z. Shehadeh[2], G. Kalra[2], A. D'Angelo[2]

[1] *Cardiff University, School of Medicine, Cardiff, United Kingdom*
[2] *University Hospital Wales, Wales Fertility Institute, Cardiff, United Kingdom*

Study question: What is the level of serum Progesterone on the day of hCG trigger that can affect the clinical pregnancy rate (CPR) in IVF/ICSI treatments?

Summary answer: Serum Progesterone levels ≥5nm/L on day of hCG trigger reduces CPR. Frozen embryo transfers (FET) in a subsequent cycle gives better outcomes.

What is known already: Progesterone is a key hormone for IVF to succeed, it changes the endometrium to become receptive, facilitating embryo implantation. A spike in Progesterone levels on the day of hCG trigger in a controlled ovarian hyper stimulated cycle is known as premature luteinisation (PL). Although the pathogenesis is unclear, its detrimental effect on pregnancy has been documented in many papers. However, it is still unclear which cut-off Progesterone level is negatively affecting implantation. It has been suggested that each Unit should audit its practice, generating a reliable cut off level for freezing which could be applied to its patient's population.

Study design, size, duration: Retrospective quantitative data collection was done between September 2017 to April 2018. All patients undergoing IVF or ICSI cycles at Wales Fertility Institute (WFI) had their serum Progesterone levels measured, on the day of the hCG trigger. If the Progesterone levels were >7nm/L, patients were offered embryo freezing and subsequent transfer in a frozen embryo transfer cycle. All other patients with Progesterone levels ≤7nm/L had a fresh embryo transfer.

Participants/materials, setting, methods: A total of 527 patients had their serum Progesterone levels measured on the day of hCG trigger. 133 patients were excluded due to missing data and needing embryo freezing for other reasons such as ovarian hyper stimulation syndrome. Data from 394 patients was therefore used for service evaluation at WFI. Progesterone levels were split into ranges 1-4 nm/L, 5 -7nm/L and >7nm/L. Data was analysed using Chi-squared tests and logistic regression adjusted for confounders.

Main results and the role of chance: Initial analysis showed 37% CPR in the Progesterone 1- 4nm/L and 19% in the 5-7nm/L. This showed that there is a significant drop in the CPR when the Progesterone levels are greater than 4nm/L. CPR was 40% in the >7nm/L group post FET, suggesting that it is beneficial to freeze embryos when Progesterone levels are >7nm/L. There may also be a benefit from freezing embryos with Progesterone levels ≥5nm/L. However, there was weak evidence of an association with CPR due to the small size of the 5-7nm/L group ($p=0.2$). Logistic regression was used to identify women at a higher risk of having high Progesterone levels on the day of the hCG trigger. Three potential groups were identified: women with >15 follicles on the day of the hCG trigger (*OR (odds ratio)= 2.2, 95% CI (confidence interval): 1.0-5.0, p=0.064*), > 11 follicles > 15mm in size on the day of the hCG trigger (*OR=3.6, 95% CI: 1.6-8.2, p=0.022*) and women who had serum oestradiol (E2) levels >10,000pg/mL on the day of the hCG trigger (*OR=8.5; 95% CI: 2.6-27.9, p<0.001*). These are seemingly associated with high serum Progesterone levels on the day of the hCG trigger, the latter two being statistically significant*(p<0.05)*.

Limitations, reasons for caution: The main limitation was a relatively small sample size and some missing data on some variables. Furthermore, the potential risk factors identified are proxy variables for each other which means they are likely to be co-linear. To overcome this, three separate logistic regression models were used in the analysis.

Wider implications of the findings: From this retrospective service evaluation there seems to be a definite benefit to electively freezing embryos when

hCG trigger day Progesterone levels are ≥5nm/L. There are three main patient subgroups seemingly at higher risk. It could be suggested to limit the serum Progesterone assessment only to these groups.
Trial registration number: not applicable

P-761 Is the application of elective single embryo transfer (e-SET) in freeze-all cycles a good strategy?

P.A. Monteleone[1,2], P. Petersen[2,3], P. Peregrino[2,3], S. Gonçalves[2,3], J. Miorin[3], M. Fujii[4], A. Gomes[4], H. Martin[4], T. Bonetti[5,6]
[1]*Centro de Reproducao Humana Monteleone, Clinical director, Sao Paulo / SP, Brazil*
[2]*Universidade de São Paulo - Faculdade de Medicina FMUSP, Obstetrics and Gynecology Department - Discipline of Gynecology, São Paulo, Brazil*
[3]*Centro de Reprodução Humana Monteleone, Clinical, São Paulo, Brazil*
[4]*Centro de Reprodução Humana Monteleone, Embryology, São Paulo, Brazil*
[5]*Universidade Federal de São Paulo, Gynecology Department, São Paulo, Brazil*
[6]*Centro de Reprodução Humana Monteleone, Scientific, São Paulo, Brazil*

Study question: Is the application of elective Single Embryo Transfers (eSET) a good strategy, compared to elective double embryo transfer (eDET), in freeze-all cycles?
Summary answer: Two sequential eSET compared to eDET in IVF cycles using freeze-all strategy result in similar clinical pregnancy rates with the advantage of no multiple gestation.
What is known already: The success of IVF treatment is reliant on embryo, endometrium and interaction between them. Conventionally, embryo transfer is placed in the same cycle of oocyte collection, what is called fresh embryo transfer. However, studies have indicated that fresh transfers can result in endometrium impairment due to supraphysiologic hormone levels, and that better implantation outcomes could be obtained when vitrified embryos are transferred in a later hormone replacement cycle. The freeze-all strategy, where the entire cohort of embryos are vitrified, has been increasing in the last years, but it is still uncertain in which population and situation it is effective.
Study design, size, duration: Retrospective cohort study reviewed 4654 cycles performed between 2011 and 2018 in a private center. A total of 409 cycles were selected for this study as fullfilled the inclusion criteria: ICSI cycles using own oocytes and ejaculated or epididymal sperm, no embryo biopsy for genetic diagnosis, freeze-all embryos (no fresh embryo transfer) and existence of one or two frozen-thawed embryos transferred (ET) in a later cycle with at least one surplus embryo available.
Participants/materials, setting, methods: Patients underwent IVF cycle as routine and were split into two groups: eSET (n=165) and eDET (n=244). For the eSET, 35 women who failed in the 1st eSET had a 2nd SET and the cumulative clinical pregnancy rate (CPR) was calculated by the formula: [CPR at 1steSET + CPR at 2ndSET ∗ (1 - CPR at 1steSET)]. Demographic characteristics and clinical pregnancy rates (CPR) after a transfer of two embryos in each group were compared.
Main results and the role of chance: The choice about the number of embryos to be transferred was performed as a shared decision-making process between patients and doctors, after an explanation of advantages and disadvantages of each situation as routine. Groups were homogeneous to age (eSET: 35.6±4.0 versus eDET: 35.0±4.1; p=0.163), basal FSH measurement (eSET: 6.3±5.9 versus eDET: 6.3±3.2; p=0.907), dose of gonadotropin administered (eSET: 1785.3±402.3 versus eDET: 1866.3±488.0; p=0.088), number of oocytes recovered (eSET: 18.6±11.9 versus eDET: 17.1±9.5; p=0.154), number of embryos vitrified (eSET: 9.2±4.9 versus eDET: 9.1±4.6; p=0.695) and survival rate after thawing (eSET: 92.3% versus eDET: 94.8%; p=0.090). After the 1st frozen-thawed ET, the CPR was statistically similar between groups (eSET: 32.7% versus eDET: 37.3%; p=0.342). When we evaluated the cumulative-CPR in the eSET group after a 2nd ET for patients who did not become pregnant in the 1st ET, the eSET-SET group presented the cumulative CPR (44.2%) slightly higher than eDET (37.3%; p=0.848) despite no statistical significance. Additionally, while the eSET group had no multiple gestation, the eDET group had 29.7% of multiples (p<0.001).
Limitations, reasons for caution: The retrospective characteristic of this study is a limitation. Other points to be considered are that freeze-all strategy was performed mainly when patients presented ovarian hyperstimulation syndrome risk, high levels of estrogen or thin endometrium. Also, not all patients who received an eSET and failed had a second SET.
Wider implications of the findings: Studies have indicated that CPR can be higher in frozen-thawed than in fresh ET, which provide a basis for freeze-all strategy. We demonstrated that freeze-all strategy associated to eSET can be a good option compared to eDET, reducing drastically the multiple pregnancy rate and does not negatively affect the CPR.
Trial registration number: N/A

P-762 ICSI outcome in treated HIV-infected women: a retrospective cohort study

I. Mateizel[1], M. Pletincx[2], S. Allard[2], G. Verheyen[1]
[1]*Vrije Universiteit Brussel VUB- Universitair Ziekenhuis Brussel UZ-Brussel, IVF labo-CRG, Jette- Brussels, Belgium*
[2]*Vrije Universiteit Brussel VUB- Universitair Ziekenhuis Brussel UZ-Brussel, Department of Internal Medicine-Infectiology, Jette- Brussels, Belgium*

Study question: Does HIV infection in women affect the embryological and clinical outcome in Intra Cytoplasmic-Sperm-Injection (ICSI) cycles?
Summary answer: The ICSI outcome in treated HIV-infected women was similar to the outcome in matched HIV-uninfected women.
What is known already: As a consequence of improved overall health, quality of life and life expectancy, many HIV-infected patients of reproductive age desire children. Although anti-retroviral treatment (ART) is recommended for all individuals, regardless of $CD4^+$ T-cell count, little is known about possible differences in ICSI outcomes between ART treated HIV-infected women and uninfected women. Large prospective trials are lacking.
Study design, size, duration: In the present study, embryological and clinical outcomes were evaluated in ART treated HIV-infected women attending ICSI cycles (HIV+ group) between May 2012-September 2017. A similar number of HIV-uninfected ICSI cycles (CTRL group) were matched for female age, oocyte retrieval date, stimulation protocol, ethnicity and rank of cycle. Frozen embryo transfer, preimplantation genetic testing or oocyte donation cycles were excluded from the analysis. Women with ongoing hepatitis B or C infections were also omitted.
Participants/materials, setting, methods: A number of 96 ICSI cycles were analysed: 48 HIV+ cycles and 48 CTRL cycles. Fertilization rate (per mature oocytes) and embryo utilization rate (number of embryos frozen and transferred per fertilized oocyte) on day 3 and/or 5 were evaluated and compared between the two groups. The clinical pregnancy rate (per embryo transfer) was also reported. The data were analyzed using the chi-square test. The level of significance was set at $p<0.05$ for all comparisons.
Main results and the role of chance: The mean total amount of gonadotrophin units used per ICSI cycle was 2132.7 ± 898.6 IU in the HIV+ group , comparable with the control group (2426.4 ± 1107.6, $p>0.05$). A number of 787 oocytes were retrieved, of which 390 from the HIV+ group and 397 from the CTRL group.

No statistically significant difference in maturation (309/397 vs 296/397 p= 0.1202) and fertilization rate (225/309 vs 212/296; p=0.7431) was observed between the HIV+ and CTRL groups, respectively. In addition, utilization rate on day 3 (83/225 vs 94/212; p=0.1128) or day 5 (47/225 vs 45/212; p=0.9311) showed similar results in both groups.

In total, 15 cycles had no embryo transfer (ET) due to medical reasons (n=8), insufficient embryo quality for ET (n=3) and abnormal fertilization (n=4). From the 81 cycles with ET (39 from HIV+ group and 42 from the CTRL group), 28 resulted in positive hCG (11 and 17 cycles, respectively). In total, 24 cycles ended in clinical pregnancy with fetal heart beat (10 cycles in HIV+ group and 14 cycles in CTRL group), with no statistically significant difference (p=0.4487) between the two respective groups. Eventually, 20 babies were live born: 8 from HIV+ group and 12 from CTRL group.
Limitations, reasons for caution: To confirm this data, patient numbers need to be enlarged, if possible by conducting a multi-center study. This larger study should also investigate the effect of the antiretroviral treatment (type of medication and length of administration) on embryo quality and clinical outcome.
Wider implications of the findings: The present results reassure that treated HIV infection in women has no deleterious effect on embryological and clinical outcome following ICSI.
Trial registration number: not applicable

P-763 The number of oocytes retrieved is not associated with adverse obstetric and perinatal outcomes in IVF/ICSI cycles with antagonist protocol and fresh embryo transfer

M. Nicolielo[1], M. Cavagnoli[2], M. Roque[3], A.L.S. Rossi[4], A.R. Lorenzon[5], J.R. Alegrettl[6], E.L.A. Motta[7]

[1]Huntington Medicina Reprodutiva, Embryology, Sao Paulo / SP, Brazil
[2]Huntington Medicina Reprodutiva, Clinical Medicine Department, São Paulo, Brazil
[3]Clinica Origen, Scientific Director, Rio de Janeiro, Brazil
[4]Huntington Medicina Reprodutiva, Embryology, Campinas, Brazil
[5]Huntington Medicina Reprodutiva, Scientific Coordinator, São Paulo, Brazil
[6]Huntington Medicina Reprodutiva, Embryology Director, São Paulo, Brazil
[7]Huntington Medicina Reprodutiva/Federal University of São Paulo, Clinical Director/Department of Gynecology, São Paulo, Brazil

Study question: Is there an association between the number of oocytes retrieved and adverse obstetric and perinatal outcomes in IVF/ICSI cycles with fresh embryo transfer?

Summary answer: The number of retrieved oocytes has no impact on the perinatal and obstetric outcomes after a fresh embryo transfer in GnRH antagonist protocols.

What is known already: There are increasing concerns regarding the adverse effects of controlled ovarian stimulation (COS) upon the uterine environment, that would lead to poorer clinical and also in obstetric and perinatal outcomes. However, as more oocytes are retrieved higher is the cumulative live birth per cycle. However, few data with controversial results are available evaluating if there is an association between the number retrieved oocytes and obstetric/perinatal outcomes after a fresh embryo transfer. Moreover, the studies evaluating this correlation are based on large national registries with no adjustments for some possible confounders such as stimulation protocol, triggering and luteal phase support.

Study design, size, duration: This is a cohort study evaluating the offspring of IVF/ICSI cycles performed in a private IVF center between 2011 and 2015. Data were collected from 1035 newborns after fresh cleavage (n= 197) or blastocyst (n= 838) embryo transfers in cycles performed with GnRH antagonist protocol, hCG triggering, and vaginal progesterone for luteal phase support.

Participants/materials, setting, methods: Outcomes measure were: low birthweight (LBW), small and large-for-gestational-age (SGA, LGA), preterm birth, congenital anomalies, preeclampsia, gestational diabetes and perinatal mortality. Logistic regression analysis was performed to evaluate the association of the number of the oocytes retrieved (continuous variable) with these outcomes. Adjusted odds ratio (aOR) was performed for all outcomes after adjusting for confounding factors, i.e., female age, BMI, the cause of infertility, embryo developmental stage, fertilization method, and the number of embryos transferred.

Main results and the role of chance: There were no significant association in singleton between the number of retrieved oocytes and LBW (aOR 1.03, 95% confidence interval (CI) 0.98-1.09), macrosomia (aOR 0.97, 95% CI 0.87-1.08), SGA (aOR 1,00, 95% CI 0.94-1.06), LGA (aOR 1.01, 95% CI 0.94-1.07), preterm (aOR 0.97, 95% CI 0.92-1.03), congenital anomalies (aOR 0.97, 95% CI 0.98, 95% CI 0.80-1,18), preeclampsia (aOR 0.60, 95% CI 0.34-1.06), gestational diabetes (aOR 1.03, 95% CI 0.93-1.13), placenta accreta (aOR 0.60, 95% CI 0.22-1.61), and perinatal mortality (aOR 0.67, 95% CI 0.37-1.23). Even when evaluating twin newborns, there was no association between the number of oocytes retrieved and all the perinatal and obstetric outcomes evaluated.

Limitations, reasons for caution: As this is a cohort study, although the outcomes were adjusted for confounding factors, some unknown confounders may affect the outcomes.

Wider implications of the findings: This study allowed to evaluate the correlation between the number of retrieved oocytes and obstetric/perinatal, adjusting the outcomes for maternal and embryological confounders. Moreover, the patients evaluated performed the same stimulation protocol, triggering and luteal phase support, thus eliminating some additional confounders and improving the reproducibility of the findings.

Trial registration number: Not applicable.

P-764 Obstetric and perinatal outcomes of cleavage and blastocyst embryos in antagonist protocol after fresh and frozen-thawed embryo transfer

J. Fioravanti[1], M. Cavagnoli[2], M. Roque[3], B. Barros[4], A.R. Lorenzon[5], J.R. Alegretti[6], E.L.A. Motta[7]

[6]Huntington Medicina Reprodutiva, Embryology Director, São Paulo, Brazil
[7]Huntington Medicina Reprodutiva/Federal University of São Paulo, Clinical Director/Department of Gynecology, São Paulo, Brazil

Study question: Are there differences in obstetric/perinatal outcomes among antagonist protocol cycles when comparing cleavage and blastocyst embryo transfer in a fresh and frozen-thawed embryo transfer (FET)?

Summary answer: Fresh blastocyst transfer presents a higher chance of newborns with lower birthweight and gestational age when comparing to vitrified blastocyst after hormonal replacement endometrial priming.

What is known already: Observational studies and meta-analysis have associated adverse obstetric/perinatal outcomes when comparing blastocyst to cleavage embryos transfers. Moreover, FET cycles have been associated with better obstetric and perinatal outcomes when compared to fresh cycles. However, most of these data are based on large databases and meta-analysis studies, being impossible to exclude potential bias such as the type of stimulation protocol, i.e. long-agonist or antagonist, type of endometrial priming for FET, and also the embryo developmental stage. Thus, there is a need for evaluating the obstetric and perinatal outcomes in specific scenarios that are commonly used in current assisted reproduction practice.

Study design, size, duration: This is a cohort study evaluating the offspring of IVF/ICSI cycles performed in a private IVF center between 2011 and 2015. Data were collected from 1934 newborns after fresh cleavage (n= 197) or blastocyst (n= 838) embryo transfers, and after FET cycles in cleavage (n= 48) and blastocyst (n= 851) stage. All the IVF/ICSI cycles performed in GnRH antagonist protocol and the FET cycles were performed after hormonal replacement.

Participants/materials, setting, methods: Data from 1151 singletons and 783 twins were evaluated. Outcomes measure were: birthweight, low birthweight (LBW), small-for-gestational-age (SGA), large-for-gestational-age (LGA), gestational age, preterm birth, congenital anomalies, preeclampsia, gestational diabetes, and perinatal mortality. Multiple linear and logistic regression were performed, and the adjusted odds ratio (aOR) was obtained after adjusting for maternal characteristics and treatment variables. To adequately size the effect of gestational age and newborn gender on birthweight, we standardized birthweights using z-scores.

Main results and the role of chance: Singletons born after vitrified-warmed blastocyst transfer presented a significantly higher z-score ($P<0,0001$) and gestational age ($P<0,0177$) in comparison with a fresh blastocyst transfer. Although statistically significant, it is questionable whether these differences present a clinical significance as the mean difference (MD) in birthweight was 157.1g and in gestational age was 2.31 days. When evaluating SGA, LGA, preterm birth, congenital anomalies, preeclampsia, gestational diabetes, and perinatal mortality, the multivariable regression analysis adjusting for maternal confounders (aOR) did not present statistical differences among cleavage vs. blastocyst embryo transfer in fresh neither in FET cycles and also when comparing fresh to FET blastocyst transfers. These findings also were observed in twin pregnancies.

Limitations, reasons for caution: This was an observational study of a single center, making the generalization of its results questionable. Moreover, the sample of newborns after cleavage stage embryo transfer was smaller than the blastocyst stage. Therefore the results from the comparison among cleavage and blastocyst embryo transfers should be interpreted cautiously.

Wider implications of the findings: The findings of this study allow clinicians to select the stage of embryonic development and whether the embryo transfer will be performed in a fresh or frozen cycle embryo based on clinical criteria, without the need for concern with obstetric and perinatal outcomes.

Trial registration number: Not applicable.

P-765 Type 1 Diabetes in Children born after Assisted Reproductive Technology: a register based national cohort study

[7]Institute of Clinical Sciences- Sahlgrenska Academy- University of Gothenburg- Reproductive Medicine- Sahlgrenska University Hospital, Obstetrics and Gynecology, Gothenburg, Sweden

Study question: Is there an increased risk of type 1 diabetes in singletons born after ART as compared with singletons born after spontaneous conception?

Summary answer: ART children did not have increased risk of type 1 diabetes, but an association between type 1 diabetes and frozen embryo transfer (FET) was found.

What is known already: Recent studies have raised concerns to whether fertility treatments may have an impact on long-term morbidity in ART children. Elevated blood pressure and altered glucose metabolism have been found both in animal studies and in a few studies in ART children. Type 1 diabetes is one of the most frequent chronic pediatric diseases, showing a markedly increased incidence in childhood during the past decades. Two Danish studies have analyzed the risk of type 1 diabetes in children born to women with fertility problems or fertility treatment. No association between fertility status or fertility treatment and type 1 diabetes was found.

Study design, size, duration: This was a retrospective, register based national cohort study that included all singletons born in Sweden between 1985 and 2015, in total 3,138,540 children with follow-up for onset of type 1 diabetes until 2017.

Participants/materials, setting, methods: The study was population based and all live-born singletons born after ART (n=47,938) or spontaneous conception (n=3,090,602) were included. Several national health registries were cross-linked with data from Statistics Sweden (SCB). The unique personal identification numbers enable linkage of registries and of child and parents.

Main results and the role of chance: In total, 202 children born after ART and 17,916 children born after spontaneous conception developed type 1 diabetes, corresponding to 43.4and 35.5 per 100,000 person-years at risk (hazard ratio [HR] 1.23, 95% confidence interval [CI] 1.07 to 1.42). After adjustment for calendar year of birth the HR for type 1 diabetes was 1.13, (95% CI 0.98 to 1.30), and after full adjustment for sex, year of birth, smoking, parental ethnicity and educational level, and diabetes in the parents, the HR was 1.08, (95% CI 0.94 to 1.24). In a subgroup analysis, an association was found between FET and type 1 diabetes in the child (adjusted HR 1.52, 95% CI 1.08 to 2.14). When comparing ICSI vs IVF no difference was found (adjusted HR 1.08, 95% CI 0.77 to 1.52).

Limitations, reasons for caution: Limitations of the study are the retrospective design, missing data and residual confounding caused by unknown confounders

Wider implications of the findings: With the high number of ART children born globally and the fast introduction of new ART techniques, elucidation of important health problems is of utmost importance. The higher rate of diabetes among children born after FET is a concern in view of the present trend of increasing embryo freezing/thawing.

Trial registration number: ISRCTN 11780826

P-766 External quality controls using the Internet for andrology and embryology laboratories

A. Senn[1], V.L. Lângaro Amaral[2], R.A. Salvador[3], D. Til[4], M. Van den Bergh[5], M. Frajblat[6]

[5]QUARTEC GmbH, Quality in Assisted Reproductive Technologies, 5442 Fislisbach, Switzerland

[6]Federal University of Rio de Janeiro, Center for Health Sciences, Rio de Janeiro, Brazil

Study question: Can the Internet be a reliable support to verify, compare and confirm laboratories performances of analyses in andrology and embryology?

Summary answer: Online Internet Quality Control schemes allow establishing inter- and intra-laboratory quality controls of important semen, oocyte, and embryo parameters.

What is known already: Although very few papers have discussed this subject, very large coefficients of variation between laboratories have been reported: with CVs for concentrations >30%, for total motility >70%, for morphology >40%. The main reasons are: 1) the difficulty to achieve homogeneous dispatching of sperm samples and 2) the non-availability of oocytes and embryos for quality control purposes, and 3) the differences in assessment methods from one laboratory to the other.

Study design, size, duration: Inter-laboratory study of 30 professionals involved in andrology and embryology, in Europe, and North- and South-America. Online access to images and videos was granted during six weeks.

Participants/materials, setting, methods: Images of gametes (sperm, oocyte, embryos), videos (sperm motility), are presented as quality control schemes on a web-based application. Thirty professionals trained in andrology and/or embryology were invited to participate in the schemes. The online produced and saved data were analyzed at the end of the test period. Coefficients of variation (CV) for andrology schemes (semen parameters) and for embryology (degree of agreement on morphological characteristics) were calculated.

Main results and the role of chance: For the andrology schemes, the CVs were for concentration 12.8%, total motility 8.7%, morphology according to strict criteria 73.5% and vitality 4.2%. For the embryology schemes, the CVs were for oocytes 19.2%, cleavage stage embryos 15.6% and blastocysts 20.4%.

Limitations, reasons for caution: As a limited number of experienced professionals participated in this study, the CVs obtained on a larger less experienced population are likely to be higher. Furthermore, better inter-observer agreements could have been achieved through training.

Wider implications of the findings: Compared to external quality controls based on a distribution of biological samples, the online system allows assessing the laboratory performances in a more precise way. Lower CVs can be achieved as all users assess the same images. Higher CVs for sperm, oocyte and embryo characteristics stress the need regular controls.

Trial registration number: None

P-767 Risk of morbidity in pregnancies and deliveries after In Vitro Fertilization: a French comparative observational cohort of 43,084 IVF versus non-IVF deliveries 2013-2016

M. Valentin[1], S. Epelboin[2], R. Levy[3], F. Merlet[4], M. Bergère[4], F. Pessione[5]

[3]Hôpital Tenon- Assistance Publique Hôpitaux de Paris- Université Paris 6 Pierre et Marie Curie, Embryology Reproductive Biology, Paris, France

[4]Agence de la Biomédecine, Procreation Embryology Genetics, Paris, France

[5]Agence de la Biomédecine, Procreation Embryology Genetics Biostatistics, Paris, France

Study question: Is there an excess of maternal morbidity (MM) in ongoing pregnancies and deliveries after In Vitro Fertilization (IVF) techniques when compared to spontaneous conceptions (SC)?
Summary answer: In this 4-years cohort study, univariate and multivariate analysis identified increased risks of obstetrical complications after IVF and fresh transfer pregnancies, compared to non-IVF population.
What is known already: Large observational studies identified that Assisted Reproductive Techniques (ART) pregnancies are associated with a significant risk of complications as compared with pregnancies after SC. These complications include preterm delivery, gestational diabetes, pre-eclampsia and placental anomalies, leading to increased fetal loss, intrauterine growth restriction, and low birthweight for neonates, all events being a significant concern. Although initially it was believed that these complications were more prevalent after ART due to the high incidence of multiple pregnancies, a high risk was also demonstrated in ART singleton pregnancies (Pinborg, 2013, Ombelet, 2016, Wang, 2016, Qin, 2016, Luke, 2017, Vermey, 2018).
Study design, size, duration: This is an observational, exposed-unexposed national cohort study comparing deliveries and births following IVF, standard or using Intra Cytoplasmic injection (ICSI), and fresh transfers, to non-IVF controls. The study included all 2,832,578 national deliveries registered between 2013 and 2016 in France, among which 1.5% (43,084) from IVF. Births were considered when occurring beyond 22 weeks of gestation (WG), and a term birth was defined when it occurred at 37 WG and beyond.
Participants/materials, setting, methods: Pregnancies and deliveries were analyzed by extracting the Information Systems Medicalization Program (PMSI) French database. The main identified MM indicators for 43084 IVF and 2 789 494 non-IVF pregnancies were: venous and arterial thrombosis (VT, AT), gestational diabetes mellitus (GDM), pre-eclampsia (PE), placenta praevia (PP), placenta abruption (PA) hemorrhage at delivery (HD). The risks of MM in IVF were estimated in multivariate analysis after adjustment for maternal age, smoking and obesity, primiparity and multiple deliveries.
Main results and the role of chance: The mean maternal age was 33.2 and 29.9 years in the IVF and control groups ($p < 0.0001$). The rate of multiple deliveries was 1.68%, of which 13% if IVF conception. Diabetes and hypertensive disorders during pregnancy were more common in the IVF *vs* non-IVF group: 1.01% *vs* 0.9% ($p = 0.01$) and 1.04% *vs* 0.9% ($p < 0.001$). Tobacco dependence and obesity were less common in the IVF *vs* non-IVF group (2.2% *vs* 4.5%, and 3.9% *vs* 4.3%, $p < 0.001$). The frequency of premature deliveries was higher in IVF *vs* non-IVF: 19.3% *vs* 6.9% ($p < 0.0001$), persistent for single births (9.0% *vs* 5.7%, $p < 0.001$). The risk of MM (GDM, PE, PP, PA) was higher in IVF *vs* non-IVF (20.9% *vs* 14.3%, $p < 0.0001$), even if single pregnancies (19.6% *vs* 14.1%, $p < 0.0001$) except arterial thrombosis. The risk of MM increased significantly with age for all events except for PE. In multivariate analysis, IVF is a significant risk factor for all MM events except arterial thrombosis. The adjusted risk of the occurrence of at least one concern after IVF is 1.20 [1.16-1.22] at all and 1.23 [1.20-1.27] in single deliveries. This risk is stable over the four years.
Limitations, reasons for caution: While the strength of this study lies in the number and completeness of subjects studied, its limitations are its retrospective and register-based nature, not allowing to refine the risk evaluation, according to 1.obstetrical events only notified if hospitalization, 2. Undetailed IVF data, such as technique or embryonic stage at transfer.
Wider implications of the findings: These large national cohort data provide evidence for increased adjusted risk of maternal morbidity after IVF, including single pregnancies, and essential tool for informing without worrying couples candidate for IVF, and analyzing neonatal health of IVF-children. Future developments should allow to refine the knowledge of more or less at-risk subgroups.
Trial registration number: not applicabe

P-768 Birth size in children born after cryopreservation of embryo in assisted reproduction compared to fresh embryo transfer and spontaneous conception

E. Landsverk[1], K. Westvik-Johari[2], L.B. Romundstad[3], S. Opdahl[4]

[1]Norwegian University of Science and Technology, Faculty of Medicine and Health Sciences, Trondheim, Norway;
[2]Trondheim University Hospital, Department of Fertility- St Olavs Hospital, Trondheim, Norway
[3]Norwegian Institute of Public Health, Centre for Fertility and Health, Oslo, Norway
[4]Faculty of Medicine and Health Sciences- Norwegian University of Science and Technology, Department of Public Health and Nursing, Trondheim, Norway

Study question: Is the previously observed high birthweight after cryopreservation of embryo (cryo-ART) associated with a corresponding increase in other measures of fetal growth?
Summary answer: Children born after cryo-ART had a higher weight, length and head circumference at birth compared to spontaneously conceived children, but a similar ponderal index.
What is known already: In pregnancies following cryo-ART, the risk of preterm birth and small for gestational age is lower than in ART pregnancies with fresh embryo transfer (fresh-ART). However, cryo-ART fetuses carry a higher risk of being born large for gestational age, as measured by birthweight. It is not known whether this is a result of increased longitudinal, but symmetrical, growth, as reflected by other measures of birth size.
Study design, size, duration: Nation-wide registry-based cohort study of 3838 singletons born after cryo-ART, 18 144 singletons born after fresh-ART and 1 390 259 singletons born after spontaneous conception from 1988 to 2016 in Norway.
Participants/materials, setting, methods: Data were collected from the Medical Birth Registry of Norway and the Norwegian National Education Database. Main outcome measures were: gestational age, birthweight, birthweight for gestational age, birth length, head circumference at birth, ponderal index (birthweight relative to birth length), placental weight and birtweight:placental weight ratio. We estimated mean differences between children born after spontaneous conception, fresh-ART and cryo-ART in linear regression models, reporting 95% confidence intervals (CIs) on differences between ART methods and SC.
Main results and the role of chance: Children born after cryo-ART had a higher weight (Δ=70 g, 95% CI 50 to 90), length (Δ=0.29 cm, 95% CI 0.19 to 0.38) and head circumference (Δ=0.23 cm, 95% CI 0.16 to 0.30) at birth compared to spontaneously conceived children, but a similar ponderal index (Δ=-0.002 95% CI -0.01 to 0.01). The larger size at birth after cryo-ART was more pronounced for boys than girls. Children born after fresh-ART had a lower weight (Δ=-94 g, 95% CI -103 to -84), length (Δ=-0.37 cm, 95% CI -0.42 to -0.33), head circumference (Δ=-0.26 cm, 95% CI -0.29 to -0.23) and ponderal index (Δ=-0.023 95% CI -0.027 to -0.019) at birth than spontaneously conceived children. Placental weight was larger in both cryo-ART and fresh-ART compared to spontaneously conceived pregnancies, also relative to birthweight. Adjustments were made for parity (0/1/2/3+), age of mother and child year of birth. In a sub-sample with available information, further adjustments for maternal pre-pregnancy body mass index, height, smoking and education did not alter conclusions.
Limitations, reasons for caution: We were unable to adjust for cause and duration of infertility, number of oocytes retrieved, good quality embryos available, total dose of gonadotropins, information on type of culture medium and method used for cryopreservation (i.e. slow-freeze or vitrification).
Wider implications of the findings: Our study suggests that the high birthweight seen in cryo-ART is associated with an overall increased, but symmetrical growth. However, the implications of these findings for the future health of children born after cryo-ART are unclear and warrant further investigation.
Trial registration number: None

P-769 assisted reproductive technology (ART) and neurodevelopmental outcome at 4 years of preterm infants

T. Freour[1], P.E. Bouet[2], P. Barriere[1], G. Gascoin[3], V. Rouger[4], M. Olivier[4], J.C. Roze[5], C. Flamant[5], J.B. Muller[5]

[1]CHU Nantes, reproductive medicine, nantes, France
[2]CHU Angers, reproductive medicine, Angers, France
[3]CHU Angers, neonatology, Angers, France
[4]CHU Nantes, Loire Infant Follow-up Team, nantes, France

[5]CHU Nantes, neonatology, nantes, France

Study question: Is assisted conception associated with neurodevelopmental impairment at 4 years age in preterm infants born before 34 weeks of gestational age?
Summary answer: At 4, fine motor skills are the most fragile domain of neurodevelopment in ART preterm and affect less than 10% of infants
What is known already: Some risk factors of neurodevelopmental impairment in ex preterm are well-known, such as gestational age, birthweight, severe neurologic complications of prematurity but also male sex and low socio-economic conditions. Assisted conception appears to increase the rate of preterm births, though few studies have analyzed late outcomes for these preterm infants.
Study design, size, duration: All infants born alive between 24+0 and 33+6 weeks of gestational age between 2003 and 2014 enrolled in the Loire Infant Follow-up Team (LIFT) prospective longitudinal cohort and assessed for neurodevelopmental outcome at 4 years are included. The neurodevelopmental outcome at 4 years of corrected age was determined by a physical examination and ASQ parental questionnaire.
Participants/materials, setting, methods: All infants born alive before 33+6 weeks of GA between 2003 and 2013 and included in LIFT are included. ART preterm was extracted and described for neonatal characteristics and 4 years ASQ outcome. ASQ is widely validated tools including 30 items exploring five domains of neurodevelopment: communication abilities, gross motor skills, fine motor skills, problem solving abilities and personal-social skills. ART and neurodevelopment association is explored matching 1:1 with preterm from LIFT cohort.
Main results and the role of chance: Among 378 preterm born after ART included who have reaching age of 4 years: 16 were non included, 1 died, 8 were lost of follow-up, 10 moved, 23 refused secondarily follow-up, 9 were out of follow-up for sequelae. 311 ASQ have been posted, 253 (81%) have been completed by parents. Neurodevelopmental difficulty at ASQ was revealed for 7.5%, 4.8%, 9.9%, 5.2% and 1.2% respectively for communication abilities, gross motor skills, fine motor skills, problem solving abilities and personal-social skills. According to ART, difficulty were highest for artificial insemination in communication abilities (12.5%), whereas it was highest for ovulation induction in gross motor skills (9.3%), fine motor skills (16.4%) and in problem solving abilities (9.1%). No neurodevelopmental difficulties were diagnosed for oocyte donation preterm excepted for fine motor skills (3.4%)and personal-social skills (3.4%).
Limitations, reasons for caution: Several limitations have to be take into account. Firstly, lost of follow-up preterm is a particular social high risk subgroup of neurodevelopment disabiliites. Secondly, although ASQ is a well-validated questionnaire; this tool may lack of sensibility. Considering these limits, long term disabilities of preterm in this cohort may be underestimated
Wider implications of the findings: At 4, neurodevelopmental disabilities remain unfrequent in ART preterm. Further studies are still necessary to assess later behavioral outcome of this specific preterm infants.
Trial registration number: NA

P-770 The role of Cabergoline and post-collection Gonadotropin Releasing Hormone – antagonist administration for Ovarian Hyperstimulation Syndrome prevention after agonist trigger.

M. Dahan[1], G. Shrem[2], N. Steiner[3], J. Balayla[4], A. Volodarsky-Perel[3], S. Tannus[3], W. Son[3]
[1]McGill University, McGill University Health Center Reproductive Center, Montreal-QC, Canada
[2]McGill University, Reproductive Medicine, Montreal, Canada
[3]McGill University, Reproductive MEdecine, Montreal, Canada
[4]McGill University, Ob Gyn, Montreal, Canada

Study question: What is the role of Cabergoline 0.5mg orally daily for 7-days and post-collection GnRH-antagonist 250mcg SQ daily for 7-days administration for OHSS prevention after GnRH-agonist trigger?
Summary answer: The addition of luteal phase GnRH-antagonists may reduce the risk of OHSS and manage discomfort beyond Cabergoline alone, which is better than agonist trigger alone.
What is known already: Induction of ovulation with GnRH-agonists is one of the most efficient methods to prevent OHSS (Mourad *et al.* 2017), Cabergoline has been proven in several studies to reduce the risk of OHSS (Tsunoda *et al.* 2003; Manno *et al.* 2005; Álvarez *et al.* 2007; Carizza *et al.* 2008). It has been shown that restarting GnRH-antagonists inhibit the expression of VEGF and thus may reduce the rate of vascular permeability.
Study design, size, duration: This is a retrospective cohort study of 480 patients who underwent IVF treatment at the University Health Centre from 2011 to 2018, with agonist trigger and freeze all embryos.
Participants/materials, setting, methods: IVF/ICSI patients at high risk of developing OHSS were treated with GnRH-agonists triggering. 208 patients received no other treatment (group-1). 167 patients were treated with Cabergoline 0.5mg for 7 days (group-2), and 105 patients (group-3), were treated with a combination of Cabergoline 0.5mg for 7 days and a GnRH-antagonist 250mcg for 7 days. Statistical analysis was performed with ANOVA with post hocks or Chi-Square testing. Normal distribution was confirmed. Data is mean±SD or percentage.
Main results and the role of chance: The three groups did not differ for female age, male age, basal serum FSH, and PCOS diagnosis (P>0.05). AFC was higher among group-3 than group-1 or 2 (p=0.0001). No severe OHSS occurred. For mild or moderate OHSS group-1 had more than group-2 (38% vs. 29%, p=0.048) or group-3 (38% vs. 18%, p=0.006) and group-2 had more than group-3 (29% vs. 18%, p=0.046) (total p=0.001). Group-3 had lower levels of haemoglobin (12.2±1.9 vs.13.8±1.0 vs. 13.3±1.2g/dl, p=0.0001), higher serum albumin (31.6±5.4 vs. 27.0±3.4 vs. 30.1±5.4 g/L, p=0.0001) than group-1 or 2, respectively. In group-3, 18% complaints of bloating/discomfort vs. 33% and 21% in group-1 and 2 (p= 0.005).Group-3 had higher serum sodium than did group 1 or 2 (135.3±2.0 vs. 132.9±1.4 vs. 133.5±1.9mEq/L, p=0.0001) and lower serum potassium (3.6±0.5 vs. 4.8±0.3 vs. 4.1±0.8mEq/L, p=0.0001). (Please note when group 1 is less than group 2 or groups 3 respectively post hock testing was significant (p<0.05).
Limitations, reasons for caution: As a retrospective cohort study, it may exhibit selection biases. The groups had significant differences in the AFC, which may influence OHSS development. However, the group with the highest mean AFC was group 3, which exhibited the lowest rates of OHSS and symptomatology.
Wider implications of the findings: The addition of Cabergoline to patients who received GnRH agonist trigger; minimizes hematologic abnormalities, decreases patient discomfort and prevents the development of mild and moderate OHSS. Adding the GnRH-antagonist to Cabergoline leads to further decreases in peritoneal fluid accumulation, hematologic abnormalities and most importantly increase patient comfort.
Trial registration number: not applicable

P-771 Higher risk of preeclampsia in singleton pregnancies, from donor versus autologous oocytes (AO) with similar endometrial preparation, in a healthy, young cohort: a prospective study

M. VARMA[1], S. Singh[2], S. Verma[3], H. Tuli[4], R. Kumar[4], T. Kaur[5]
[1]Sadbhavna Medical & Heart Institute, Obstetrics and Gynecology, Patiala, India
[2]Sadbhavna Medical & Heart Institute, Reproductive Medicine, Patiala, India
[3]Edwards Lifesciences, Marketing and Innovations, Irvine- California, U.S.A.
[4]Sadbhavna Medical & Heart Institute, Neonatology, Patiala, India
[5]Sadbhavna Medical & Heart Institute, Anaesthesia, Patiala, India

Study question: Is the risk of hypertensive disorders increased in healthy women ≤37 years with singletons from donor oocytes [fresh-transfer] versus AO [elective frozen embryo transfer (eFET)]?
Summary answer: Amongst the hypertensive disorders, there was a higher risk of preeclampsia, and an increased risk of iatrogenic preterm delivery (PTD) in donor oocyte (DO) pregnancies.
What is known already: Recent meta-analyses show an increased risk of hypertensive disorders and PTD in DO versus AO pregnancies. Most of the studies are retrospective and conducted in elderly women. Main confounding factors are age, parity, and plurality.

Very few studies highlight an increased risk of hypertensive disorders in DO pregnancies in younger women. Proposed etiologies are immunological and altered endometrial hormonal milieu. The latter, in itself could be a potential

confounder for perinatal outcomes when comparing DO with AO pregnancies with fresh embryo transfer. Limited studies, controlling for endometrial preparation, show a higher perinatal morbidity with DO FET compared with AO FET.
Study design, size, duration: A prospective cohort study conducted at a tertiary referral centre from October 2012 -December 2018

A total of 108 singleton pregnancies diagnosed on ultrasound at 10 weeks were studied. The DO group (n = 49) had fresh ET and AO group (n=59) had vitrification followed by eFET. Both groups were similar regarding ICSI, ET policy (2-3 cleavage stage) and programmed endometrial preparation. The IVF programme, antenatal care and deliveries were conducted at the same institution.
Participants/materials, setting, methods: All participants were ≤37 years old with a BMI <30kg/m2. Oocytes donors were <30 years, in good physical and mental health. Pregnancies were followed for hypertensive disorders as a primary outcome, including chronic hypertension, preeclampsia, eclampsia and superimposed preeclampsia. Additionally, PTD (<37weeks) both iatrogenic and spontaneous, was also studied.

Chi-square and t-tests were used to compare proportions, and means respectively. Adjusted odds ratios were calculated using logistic regression (significance was set at $P < .05$, two-tailed).
Main results and the role of chance: Mean age and BMI were comparable in DO and AO groups at 31.96 ± 3.20 versus 30.92 ± 2.64 years (*P*=.07), and 23.31 ± 1. 36 versus 23.69 ± 1.25 kg/m2 (*P*=.14) respectively. All women were non-smokers, with no history of chronic hypertension, and not on aspirin. Overall, there were 103(95.4%) nulliparas. There was no case of eclampsia.

Hypertensive disorders were significantly more in the DO group at 22.45% versus 8.47%, (OR 3.12; 95% CI 1.00-9.73; *P*.04). This difference could not be validated after adjusting for age (AOR 2.47; 95% CI 0.77-8.81; *P*=.13) This implies that the risk of hypertensive disorders in DO pregnancies, in a young cohort compared to an autologous group with comparable mean age, (*P*=.07), may still be age-dependent.

Amongst hypertensive disorders, preeclampsia was significantly higher in the DO group (14.29% and 3.39%, *P*=.04) while gestational hypertension was comparable (*P*=.52).

Although overall PTD rate was similar (*P*=.15), iatrogenic PTD was higher in the DO group at 26.53% versus 8.47% (OR 3.80; 95% CI 1.25 -11.55; *P*=.01) After adjusting for preeclampsia this difference lost statistical significance (AOR 2.41; 95% CI 0.68-10.52; *P*=.13), implicating preeclampsia to be a key risk factor for iatrogenic PTD in women with DO pregnancies.
Limitations, reasons for caution: We have compared pregnancies from DO with fresh ET to AO with eFET, as similar endometrial preparation was needed to study end points. Adequate number of patients with DO FET as a study group were not available. Vitrification may have affected our results. Also, larger studies are needed for confirmation.
Wider implications of the findings: Our results suggest an increased risk of preeclampsia in young, healthy woman with DO pregnancies. Therefore, they need to be counselled and require specialized care for optimum maternal and perinatal outcomes. Lowering the risk of preeclampsia with specific endometrial preparation protocols needs to be explored.
Trial registration number: Not Applicable

P-772 IVF incident reporting system: a customized tool for the application of the Quality management system in IVF laboratories

A. Nicoli[1], D. Morini[1], G. De Feo[1], B. Valli[1], M.L. Tranquillo[1], A. Sibahi[1], J. Daolio[1], P. Ragni[1]
[1]Azienda Unità Sanitaria Locale - IRCCS di Reggio Emilia- Italy, Obstetrics and Gynecology, Reggio Emilia, Italy

Study question: How to manage the approach to the clinical risk management in IVF laboratories in accordance with the Italian State-Regions Conference of March 15th, 2012?
Summary answer: The IVF incident reporting system enhances the safety level of procedures by monitoring non-conformances and/or adverse events that could be prevented with specific corrective measures.
What is known already: Quality measures require IVF laboratories to satisfy stringent criteria to document, track and report items ranging from minimal inconvenience to extreme harm that can impact on the outcome of IVF treatments or on gametes'/embryos'/patients' safety. In Italy, the Board of the Region of Emilia Romagna acknowledged the State-Regions Conference of March 15th/2012 throughout the deliberation n. 972/2013. It defines functional, structural and technological requirements that the Health Service hospitals must have in accordance with Quality Control and Quality Assurance rules of the Italian Law n.40/2004 referred to the donation, supplying, control, storage and distribution of human gametes and embryos.
Study design, size, duration: Based on 2013 regulations, an expert team of embryologists and Quality Referees designed a specific electronic database to record any non-intentional deviation from protocols adopted daily in our IVF Center by embryologists, gynecologists and nurses. Since the introduction in 2015, this tool is currently used as an incident reporting system defining three possible levels of detection: the IVF laboratory, the outpatients' room and the department of Obstetrics and Gynecology.
Participants/materials, setting, methods: Retrospective analysis of an electronic database monitoring and documenting non-conformances and adverse events at a large IVF Center with an average of 1300 IVF cycles per year. Events detected by the IVF laboratory were divided into three categories based upon their content regarding the management of samples prior to, during or after the analytical phase, the management of laboratory parameters or the operators training.
Main results and the role of chance: From January 2015 until December 2017, 330 non-conformances were recorded with an average of 110 events yearly. The 75% (245/330) of non-conformances regarded IVF laboratory responsibilities: the 82% (200/245) concerns the management of samples prior to, during or after the analytical phase demonstrating that this is the most critical part of the IVF treatment, the 17% (42/245) was about the management of laboratory parameters (forgetting to log daily maintenance, parameters of incubators or environmental controls) and 1% (3/245) concerns operators' deviations away from standard working procedures. The 23% (77/330) of non-conformances was assessed to the IVF laboratory-outpatients' room interface (incorrect patient ID assessment and/or documentation, communication problems with the surgical or nursing departments) and the remaining 2%(8/330) was due to inaccuracies of clinical engineering service and others. All non-conformances have been frequently discussed by the IVF team, who shared and introduced more than 10 corrective actions in clinical procedures. The same approach has been used to monitor subsequent outcomes. For example, in 2017, the number of non-conformances related to the partial integrity of clinical folders was quite null compared to 2016 following the introduction of a novel check list to be completed at the end of the IVF cycle.
Limitations, reasons for caution: It is important to keep on sensitizing and encouraging all the operators involved in clinical practice as the usage of the reporting system is founded on a voluntary attitude leading to the risk of underestimating errors.
Wider implications of the findings: A robust system of incident reporting mirrors what happens in clinical activity, impacting on the perception of clinical risk. This tool should be recommended to consciously increase the management of clinical risk and combined with other tools for the perspective and/or retrospective detection of errors.
Trial registration number: Not applicable.

P-773 Frozen-thawed embryo transfer is an independent risk factor for third stage of labor complications in singleton vaginal deliveries

Y. Shufaro[1], O. Sapir[1], E. Krispin[1], A. Ben-Haroush[1], G. Oron[1], E. Shlush[1], E. Altman[1], T. Schohat[1], A. Viznetser[1], A. Wertheimer[1]
[1]Infertility and IVF Unit- Beilinson Hospital- Rabin Medical Center- and the Felsenstein MRC- Tel-Aviv University, Beilinson Women's Hospital, Petach-Tikva, Israel

Study question: Is pregnancy conceived by frozen-thawed embryo transfer (FET) associated with an increased risk for third stage of labor complications in singleton vaginal deliveries?
Summary answer: Conception by FET is an independent risk factor for post-partum hemorrhage, requirement for manual lysis and revision of uterine cavity in singleton vaginal deliveries.

What is known already: IVF pregnancies are associated with a higher prevalence of perinatal complications than spontaneous gestations, even after correction of confounding factors. Little is known about the prevalence of third stage of labor complications in IVF pregnancies. In a previous study from our group, the prevalence of these complications was increased in gestations conceived through IVF and fresh embryo transfer. The endometrial preparation for FET varies from fresh cycles and the outcome of gestations conceived by FET is different from those conceived through fresh embryo transfer.

Study design, size, duration: Cohort study reviewing delivery files of all pregnancies conceived through FET and successfully delivered vaginally in the same tertiary medical center between 2007 and 2017. The study group consisted of 88 FET gestations (cases), and 176 matched parturients that conceived spontaneously (controls).

Participants/materials, setting, methods: The FET cases group were matched according to maternal age, gravidity, parity, and gestational age at delivery in a 2:1 ratio to a control group of women who conceived spontaneously and underwent a singleton vaginal delivery at our center during the same period. Women with multiple gestations, deliveries by cesarean sections, intrauterine fetal demise and missing data regarding the third stage of labor were excluded.

Main results and the role of chance: Baseline characteristics were similar in cases and controls except for a lower prevalence of induction of labor in the control group (36.3% vs. 23.3%, p=0.03). The rate of post-partum hemorrhage was 13.6% in cases and 5.7% in controls (OR=2.62, p=0.018). Manual lysis was required in 17% of the case deliveries and in 2.3% of the controls (OR=8.83, p<0.001). Revision of the uterine cavity was required in 21.6% of cases and 6.8% of controls (OR=3.76, p<0.001). Multivariable analysis adjusted for age, previous cesarean section, induction of labor and the type of anesthesia demonstrated that deliveries after FET were independently associated with an increased risk for the above mentioned third stage of labor complications (estimate OR=4.44, p=0.002).

Limitations, reasons for caution: Retrospective case-control design. FET group size number is limited due to the primary inclusion criteria (FET and successful singleton vaginal delivery in the same center). Nevertheless, our findings are clinically and statistically significant.

Wider implications of the findings: FET is an independent risk factor for third stage of labor complications warranting anticipating active management. Together with similar findings in deliveries following fresh transfers, this data suggests that the implantation of embryos created in-vitro adversely affect placental separation and uterine contraction after delivery, regardless of type of endometrial preparation.

Trial registration number: Retrospective study, IRB approved.

P-774 The effect of maternal pre-pregnancy BMI on intelligence and growth of singletons following IVF/ICSI: follow-up of a large sized, cohort study

H. Yan[1], M. Tang[1], Y. Fu[1], X. Hu[1], F. Zhang[1], L. Xing[1], D. Chen[1], Y. Zhu[1]
[1]Women's Hospital School of Medicine Zhejiang University, Department of Reproductive Endocrinology, Hangzhou, China

Study question: To evaluate the effect of raised maternal pre-pregnancy body mass index (BMI) on intelligence and growth of singletons following IVF with or without ICSI.

Summary answer: Maternal pre-pregnancy obesity is associated with increased risks for obesity, overweight and intellectual disability at early ages of offspring conceived through IVF/ICSI.

What is known already: Pregnancy in obese women is associated with escalating risks of complications for fetus, such as increased risks of preterm birth, macrosomia and fatal growth restriction. Besides, longer-term consequences of studies suggest that maternal obesity risks offspring's health later in life and increases susceptibility to adult disease. Offspring of obese mother increase the risks of obesity and metabolic syndrome, hypertension, asthma, central nervous system developmental problems, depression, attention-deficit hyperactivity disorder.

Study design, size, duration: This is a cohort study with 1904 singletons aged 3-6 years were followed up from 2009 to 2017, born to infertile couples who received autologous IVF/ICSI cycle from 2002 to 2012.

Participants/materials, setting, methods: Singletons at 3-6 years old who were consent to attend the follow-up study had the metabolic and Intelligent assessment. Age- and sex-specific BMI z-scores by Chinese standard were used to assess growth and development of children. Chinese Version of the Wechsler Intelligence Scale for Children (C-WISC) was performed to evaluate verbal intelligence quotient (VIQ), performance intelligence quotient (PIQ), and full intelligence quotient (FIQ) of children.

Main results and the role of chance: After adjusting for confounders, the obese women were more likely to have obese children (20.0% vs 5.1%, P =0.01) than normal BMI women, and overweight women had increased risks of having overweight children (13.6% vs 8.2%, P =0.02) or obese children (10.1% vs 5.1%, P =0.01) than normal weight women. Maternal BMI had no effect on serum lipids of IVF/ICSI offspring. When not adjusting for parental educational level, offspring of the overweight women scored lower in VIQ (97.72 vs 99.65, P =0.02), PIQ (111.33 vs 112.93, P =0.04) and FIQ (104.82 vs 106.71, P =0.02) than the normal weight women, while offspring of the obese women lower in both PIQ (109.28 vs 112.93, P =0.04) and FIQ (102.69 vs 106.71, P =0.03). However, after adjusting for parental educational level, this result was not consistently observed in four groups. But after adjusting for confounders, offspring of obese women showed increased prevalence of intellectual disability (IQ < 80) in VIQ (16.9% vs 8.5%, P =0.03) and FIQ (10.8% vs 3.9%, P =0.03) compared with normal BMI women.

Limitations, reasons for caution: The enrolled children were 3 to 6 years old whose intelligence levels were still in the rapid development stage whose intelligence levels were still in the rapid development stage. And it still wasn't clarified the mechanism of effect of maternal BMI on children obesity and decreased intelligence.

Wider implications of the findings: A growing number of obese women are appealing to ART for infertility, however maternal obesity has been found to impair ART outcomes and offspring's health. Nevertheless, it's quite important to inform public health policy in terms of advising women to manage weight and diet prior to and during ART.

Trial registration number: not applicable

P-775 The pregnancy outcomes of women with a congenital didelphus uterus after in vitro fertilization-embryo transfer

X. Li[1], Y. Ouyang[1], P. Cai[1], F. Gong[2]
[1]Reproductive & Genetic Hospital CITIC-Xiangya, Imaging Department, Changsha, China
[2]Reproductive & Genetic Hospital CITIC-Xiangya, Reproductive Department, Changsha, China

Study question: Are the pregnancy outcomes of women with a didelphus uterus worse than those of women with a normal uterus?

Summary answer: The didelphus uterus associated with increased risks of premature delivery and low birth weight (LBW), but with a similar live birth rate as normal uterus.

What is known already: Although normal pregnancies can occur in some patients with a clinically asymptomatic didelphus uterus, this condition has been reported to be in relation with miscarriage, premature delivery, perinatal mortality and other complications in ordinary population. The prevalence of didelphus uterus was estimated to be 0.2-0.5% in infertile women. Then, what about the pregnancy outcomes in infertile women with a didelphus uterus undergoing in vitro fertilization- embryo transfer (IVF-ET)?

Study design, size, duration: A retrospective, single-center case control study was conducted of 50 women with a didelphus uterus and 567 women with a normal uterus, who received IVF-ET treatment from January 2004 to December 2017.

Participants/materials, setting, methods: All included patients obtained singleton pregnancies via IVF-ET. A comparison of the pregnancy outcomes was conducted between the didelphus group and the control group. The main outcome measures included miscarriage, preterm delivery, LBW and so on. In order to avoid selection bias, only the first pregnancy of each patient was considered. Multiple pregnancy and spontaneous/selective reduction were excluded from analysis.

Main results and the role of chance: The didelphus group and the control group were statistically similar regarding the maternal age (p = 0.768), body mass index (p = 0.088), endometrium thickness on transfer day (p = 0.104),

infertility type (p = 0.51), cause of infertility (p = 0.052) and basic follicle-stimulating hormone (p = 0.390).

The presence of a didelphus uterus was associated with increased risks of premature delivery (16.0% vs. 3.9%, OR 4.72; p < 0.001) and LBW (12.2% vs. 2.6%, OR 5.28; p = 0.001); Additionally, significantly lower term delivery rate (66.0% vs. 78.7%, OR 0.53; p = 0.039) and live birth weight (3026.0 ± 573.0 vs. 3388.0 ± 451.0 g; p < 0.001) were also observed in the didelphus group. However, the live birth rate (82.0% vs. 81.3%; p = 0.904) was statistically similar in 2 groups. Furthermore, although the rates of miscarriage (18.0% vs. 14.3%; p = 0.476) and cesarean section (85.4% vs. 73.9%, OR 2.06; p = 0.106) were higher, and the gestational weeks at delivery (38.2 ± 2.1 vs. 38.9 ± 2.3 weeks; P = 0.064) and ectopic pregnancy rate (0 vs. 3.2%; p = 0.201) were lower in the didelphus group, the difference were not significant.

Limitations, reasons for caution: All pregnancy outcomes were tracked by telephone calls or faxes in our reproductive center. Thus, some obstetric complications were not detailed recorded. Additionally, the control group in this retrospective study was not screened randomly, which may cause selection and confounding biases.

Wider implications of the findings: Our findings can be used to counsel the pregnancies in women complicated by a didelphus anomaly and help guide appropriate antenatal treatment and surveillance.

Trial registration number: None.

P-776 The Assisted Reproductive Technology (ART) Capability Assessment: experiences from 24 pilot assessments with fertility clinics from 14 countries

P. Harrison[1], S. McArthur[2], D. Seidel[3]

[1]*Genea, Genea Consult, SYDNEY, Australia*

[2]*Genea, Genea, Sydney, Australia*

[3]*Freelance Consultant, Consulting, Mannheim, Germany*

Study question: To test our assessment in the field in order to evaluate whether it can detect and quantify capability variations between fertility clinics

Summary answer: The results of our pilot assessments suggest that there is a considerable amount of capability improvements to be made across many fertility clinics

What is known already: ART treatment is not without risk and unsuccessful treatment approaches can cause considerable psychological stress to patients. Treatment access, effectiveness and safety vary greatly between countries. Several factors are known to affect ART treatment outcomes, in particular the quality of the embryo and the woman's age. However, outcome variations between clinics are also due to different stimulation protocols, culture methodology and embryo transfer techniques used as well as the quality management and control systems in place

Study design, size, duration: The ART Capability Assessment is based on relevant international guidelines, scientific publications and input from leading experts in the field. It is conducted by a team of experienced consultants over the course of two days and involves interviews, observations as well as document analysis. Between May 2016 and November 2017, we piloted our assessment with fertility clinics from Europe (N=10), Asia (N=7), Australia (N=2), the Middle East (N=2), Latin America (N=2) and North America (N=1)

Participants/materials, setting, methods: Interviews were conducted with senior clinic staff, including clinicians, biologists, nurses and technicians. Processes, operations and management areas were also assessed by means of observations. The assessment comprised five major categories (clinical processes, clinical operations, laboratory processes, laboratory operations and management), 43 subcategories and more than 400 assessment criteria. The criteria were rated on a four point-scale (0%, 33%, 66% and 100%), allowing category scores and an overall assessment score to be calculated

Main results and the role of chance: The mean overall assessment score for all clinics was 72% (median 75%), ranging from 39% to 89%. The clinics achieved the highest mean score for clinical processes (77%) and the lowest for management (66%). Several areas were identified where many clinics performed very well, for example, endocrinology (when conducted in-house) (89%), laboratory cleaning (87%) and medication storage & handling (85%). On the other hand, there were also several areas where the performance of many clinics was significantly below best practise standards, particularly consumable selection and use (53%) and cryopreservation & storage (53%). In addition, one clinic each from Europe and Asia underwent re-assessment more than one year after the initial assessment. The clinics had been provided with the results of the initial assessment in the form of a detailed report, containing suggestions for improvement. According to the results of the re-assessment, mean overall assessment scores improved from 58% to 61% and from 75% to 80%, respectively. The improvements were attributable to various small incremental changes throughout multiple areas as opposed to any single major change. This suggests that the assessment results were meaningful, allowing the clinics to implement changes which lead to capability improvements

Limitations, reasons for caution: Our sample of fertility clinics was a so-called convenience sample that included clinics from various countries willing to participate in a pilot. Thus, the results cannot be considered representative. Moreover, we did not assess whether the capability improvements observed in our re-assessments were associated with improvements in clinical outcomes

Wider implications of the findings: There is a need for more standardised processes, operations and management across fertility clinics in order to increase the chances of a successful treatment, to reduce treatment-related risks and to decrease the psychological burden on patients. The ART Capability Assessment provides guidance as to how to accomplish this

Trial registration number: Not applicable

P-777 Pregancy outcomes of patients with a congenital unicornuate uterus: an analysis of 406 women following in vitro fertilization embryo transfer

J. Xiao[1], X. Li[1], Y. Ouyang[1], Y. Mao[1]

[1]*Reproductive & Genetic Hospital CITIC-Xiangya, Imaging Department, Changsha, China*

Study question: What are the pregnancy outcomes in women with a unicornuate uterus after in vitro fertilizaiton-embryo transfer (IVF-ET)?

Summary answer: The presence of a unicornuate uterus was associated with some adverse outcomes in singleton pregnancies, but the live birth rate was satisfactory.

What is known already: Unicornuate uterus is a rare form of uterine malformation with an estimated prevalence of 8.0–13.3% in infertile patients. Although normal pregnancies can occur in some patients clinically asymptomatic, most literature regarded this kind of anomaly to be associated with increased risks of maternal and neonatal complications as well as infertility. However, most studies were based on small sample or case studies and thus these analyses were not comprehensive enough.

Study design, size, duration: Four hundred and six women with a unicornuate uterus who obtained clinical pregnancies via IVF-ET from January 2012 to December 2017 were retrospectively analyzed. According to the number of gestations, the pregnancies were divided into singleton pregnancies (n = 279) and multiple pregnancies (n=127). Among the multiple pregnancies, there were 121 cases of twin pregancy (including 5 monochorionic twins), 5 cases of triplet pregnancy (including 4 dichorionic triplet pregnancies) and 1 case of quadruplet pregnancy.

Participants/materials, setting, methods: This study was conducted at the Reproductive and Genetic Hospital of CITIC-Xiangya (Changsha, China). Pregnancy outcomes including the rates preterm delivery, cesarean section, live birth and perinatal mortality, birth weight were analyzed in singleton and multiple pregnancy groups.

Main results and the role of chance: The total miscarriage rate of patients with a unicornuate uterus was 16.5% (67/406): the early pregnancy loss rate was 15.3% (62/406), and the late miscarriage rate was 1.2% (5/406). The rates of preterm delivery and term delivery were 21.9% (89/406) and 60.0% (244/406), respectively. The ectopic pregnancy rate was 1.0% (3/406) (2.4% (3/279) in singleton pregnancies and 0.8% (1/127) in multiple pregnancies. In addition, there were 2 cases of induced abortion due to congenital chromosomal abnormalities.

The number of babies born was 386, including 361 cases of live births and the live birth rate was 88.9% (361/406) (77.7% in singleton (213/274) and 85% in multiple (12/14) pregancies). The overall perinatal mortality was 6.2% (25/406), including 16 cases of still birth and 9 cases of neonatal death. There was a high cesarean section rate with 71.2% (275/386). Furthermore, the average gestational age at delivery was 37.2 ± 3.4 weeks of gestation.

Among the multiple pregnancies, there were 37 cases experienced spontaneous reduction and 26 cases received selective reduction. What is more, the 26 women with twin pregnancy who underwent selective reduction all resulted in live births.

Limitations, reasons for caution: This was a descriptive analysis and the results were not compared with women with a normal uterus. Additionally, all pregnancy outcomes were obtained via telephone calls or faxes in our center and thus some detailed information were not recorded.

Wider implications of the findings: The results can be used to guide appropriate antenatal treatment and surveillance for women who are pregnant or plan for a future pregnancy but complicated with a unicornuate uterus.

Trial registration number: None

P-778 Lower total gonadotropin dose per oocyte retrieved and top-quality embryos in the fresh cycle affect live birth rate in frozen-thawed embryo transfer

H. Joona[1], S. Mäkinen[2,3], K. Ahinko[4], A. Haltia[5,6], C. Hydén-Granskog[1], A. Perheentupa[7], N. Simberg[8], A. Tiitinen[1], H. Martikainen[9], J.S. Tapanainen[1,9], Z. Veleva[1]

[1]University of Helsinki and Helsinki University Hospital, Department of Obstetrics and Gynecology, Helsinki, Finland
[2]Ovumia Fertinova, Helsinki, Helsinki, Finland
[3]Väestöliitto Fertility Clinics, Helsinki and Oulu clinics, Helsinki, Finland
[4]University of Tampere and Tampere University Hospital, Department of Obstetrics and Gynecology, Tampere, Finland
[5]Felicitas Mehiläinen, Turku infertility clinic, Turku, Finland
[6]Väestöliitto Fertility Clinics, Turku clinic, Turku, Finland
[7]University of Turku and Turku University Hospital, Department of Obstetrics and Gynecology, Turku, Finland
[8]Dextra Fertility Clinic, Helsinki, Helsinki, Finland
[9]University of Oulu and Oulu University Hospital, Department of Obstetrics and Gynecology- Medical Research Center- PEDEGO Research Unit, Oulu, Finland

Study question: Which factors of the fresh cycle affect live birth rate (LBR) after frozen-thawed embryo transfer (FET)?

Summary answer: Lower total gonadotropin dose per oocyte (dose/oocyte) and presence of ≥1 top-quality embryo are associated with higher LBR in FET.

What is known already: Factors that are known to affect LBR include female age, number of oocytes retrieved, ovarian response and number of top-quality embryos created. It is known that high gonadotropin doses are associated with poor endometrial function in the fresh cycle but it is unclear if FET cycles are affected. Previous studies have evaluated the effect of characteristics of the fresh cycle on LBR after fresh transfer or cumulatively. Only a few analyses have focused on FET and little is known about fresh cycle characteristics that might affect LBR in FET.

Study design, size, duration: Retrospective cohort study of data from a national infertility database. A total of 9465 FET cycles with single embryo transfer performed in 2000 – 2017 were included in this study. Only cycles up to the first live birth (LB) after FET (gestational age >24 weeks) of 5905 women were analysed. Fresh cycle characteristics were matched to corresponding FET treatments.

Participants/materials, setting, methods: The study consisted of 1525 (16.1%) natural cycles, 4091 (43.2%) natural cycles with luteal support and 3849 (40.7%) hormonally substituted cycles. Blastocyst transfer was performed in 1064 (11.8%) cases. We analyzed the effect of characteristics of the fresh cycle, such as number of oocytes retrieved and number of top-quality embryos created on LBR using general estimating equations. Dose/oocyte was used as measure of ovarian response.

Main results and the role of chance: Overall, LBR after FET was 20.2% (1915/9465). It was highest in patients with low dose/oocyte in the fresh cycle (<200 IU/oocyte: 21.5%, 1434/6675) and lowest in those with 300-400 IU/oocyte (13.5%, 85/630, P<0.0001). In patients with no top-quality embryos created in the fresh cycle, LBR was only 17.1% (208/1219) but increased to 21.3% in those with >3 top-quality embryos (469/2200, P=0.002).

The final model showed that the chance of LB after FET was highest after stimulations with dose/oocyte <200 IU/oocyte and decreased in cases with 200-300 (odds ratio [OR] 0.79, 95% confidence interval [CI] 0.67-0.94) and 300-400 IU/oocyte (OR 0.58, 95% CI 0.45-0.74). Presence of ≥1 top-quality embryo in the cohort also increased the odds of LB in FET, compared with no top-quality embryos created (OR 1.39, 95% CI 1.36-1.66). Blastocyst transfer did not significantly affect results. Age >36 years decreased the odds of LB (OR 0.63, 95% CI 0.56-0.71). Compared with spontaneous cycles with luteal support, both purely spontaneous cycles (OR 0.80, 95% CI 0.66-0.98) and hormonally substituted treatment cycles (OR 0.65, 95% CI 0.57-0.75) were associated with lower chance of LB after FET. The number of oocytes collected was excluded from the final model.

Limitations, reasons for caution: It was not possible to evaluate the effect of different embryo freezing methods on results (vitrification vs. slow freeze). As there still is no consensus on embryo quality grading after thawing, the quality of the transferred embryo was not analysed.

Wider implications of the findings: Dose/oocyte reflects ovarian function and oocyte quality. Stimulation should be optimized so that dose/oocyte remains as low as possible because of lower LBR in FET with >200 IU/oocyte. Day of freezing does not affect LBR but even a single created top-quality embryo is associated with higher LBR in FET.

Trial registration number: Not applicable

P-779 Impact of oocyte donation on pregnancy complications at very advanced maternal age

R. Meyer[1], R. Orvieto[1], Y. Timerman[2], T. Gorodesky[2], S. Toussia-Cohen[3], A. Kedem[1], M.J. Simchen[1], R. Machtinger[1]

[1]The Chaim Sheba Medical Center, Obstetrics & Gynecology, Ramat-Gan, Israel
[2]St George's University of London, The Faculty of Medicine, London, United Kingdom
[3]Tel-Aviv University, The Sackler Faculty of Medicine, Tel-Aviv, Israel

Study question: We aimed to compare the complication rates between oocyte donation and spontaneously conceived singleton pregnancies at very advanced maternal age.

Summary answer: Oocyte donation pregnancies in the late 5th decade of life were associated with significantly higher rates of gestational hypertensive complications compared with spontaneous pregnancies.

What is known already: Deliveries in the fifth and sixth decades have risen in accordance with a shift in family planning trends and the increased use of assisted reproductive technologies. Oocyte donation has become a common treatment option among women at the edge of the age of fertility. Oocyte donation pregnancies have been linked with higher rates of obstetrical complications, including gestational diabetes, hypertensive disorders, placental abnormalities, preterm labor and cesarean deliveries. Still, it is unclear whether the reason for this is attributed to the advanced age of the recipients, to the IVF itself, or to the use of non-autologous gametes.

Study design, size, duration: A retrospective cohort study, consisting of all women aged 45 to <47 years old at time of delivery who gave birth to singletons in our hospital between March 1, 2011 and May 1, 2018. The final cohort included 150 women in the oocyte donation group and 76 women in the spontaneous conception group.

Participants/materials, setting, methods: All women aged 45 to <47 years old at time of delivery who gave birth to singletons at 24 weeks' gestation or later. The oocyte donation group included pregnancies achieved after IVF with donated oocytes. The spontaneous conception group included pregnancies achieved following coitus or intrauterine insemination. Exclusion criteria were multiple gestation pregnancies, pregnancies achieved by IVF with autologous oocytes or patients that underwent iatrogenic fetal reduction.

Main results and the role of chance: Women in the oocyte donation group were mostly nulliparous compared with those that conceived spontaneously (62.0% vs. 7.9%, p<0.001 respectively). The rates of gestational hypertension (14.7% vs. 5.3%, P=0.036, respectively) and preeclampsia (14.7% vs. 1.3% P=0.002, respectively) were significantly higher in the oocyte donation group compared with the spontaneous conception group, as well as the rate of cesarean delivery (83.3% vs. 35.5%, P<0.001, respectively). In the multivariate analysis, conducted to test possible association between the mode of conception and gestational hypertensive complications, oocyte donation pregnancies had almost four times the risk of gestational hypertensive complications compared with spontaneous conception group after controlling for age, parity, marital status and use of LMWH during pregnancy (OR 3.92; 95%CI 1.28-11.98; P=0.017).

Limitations, reasons for caution: First, it is possible that our oocyte donation population included women who are healthier compared with others at the same age. Second, the study groups differed in parity rates which is a risk factor for preeclampsia. We tried to overcome this confounder by including it in the multivariate analysis.
Wider implications of the findings: Oocyte donation pregnancies at very advanced maternal age were associated with a high risk of hypertensive complications. This may suggest an immunological imbalance as the culprit of hypertensive disorders in this population. The use of spontaneous pregnancies as a control group may help to isolate the effect of oocyte donation.

[10]University of Oulu and Oulu University Hospital, Department of Obstetrics and Gynecology- Medical Research Center- PEDEGO Research Unit, Oulu, Finland

Study question: How many singleton children do IVF/ICSI patients have and which factors affect the number of children born?
Summary answer: On the average, there were 1.14 children per couple, and this number was affected most strongly by age, total gonadotropin dose/oocyte retrieved (dose/oocyte) and BMI.
What is known already: The endpoint of most infertility analyses is the first pregnancy or live birth after IVF/ICSI. However, many infertile couples wish for more than one child. Factors that are known to affect outcome from treatment include female age, number of oocytes retrieved, total gonadotropin dose used, number of top-quality embryos created and tubal factor infertility. Dose/oocyte, a measure of estimating ovarian response, is inversely related to cumulative live birth rate, with higher values indicating lower chances of live birth. However, it is not known how this and other factors relate to the number of children born after one or several IVF/ICSI.
Study design, size, duration: Retrospective cohort study of data from a national infertility database. We analysed data of women with single embryo transfer in the first cycle who had ≥1 live birth of a singleton after 1-18 stimulations during 2000-2017. We examined the effect of background and treatment characteristics of the first stimulation cycle on the number of children born. Patients had 1-5 singletons but the main analysis was restricted to those with 1-3 deliveries (>90% of all).
Participants/materials, setting, methods: We analysed data of 5385 women who had a total of 9007 singleton deliveries after fresh or frozen-thawed embryo transfer. Dose/oocyte was used for evaluating ovarian response to stimulation. Other factors analysed included age, BMI, total gonadotropin dose, number of oocytes retrieved and number of top-quality embryos. Data were studied by ordinal logistic generalized linear models. Inclusion into final model was based on Akaike information criterion (AIC), in which lower values indicate a better model.
Main results and the role of chance: In all, 4685 (87.0%) patients had one child, 665 (12.3%) had two and 35 (0.6%) had three children after IVF/ICSI treatment. Women who had three children had similar numbers of oocytes retrieved (12.5±4.6 vs. 11.8±5.6, P=0.70), dose/oocyte (176.3±128.3 vs. 192.0±127.2, P=0.74) but had more stimulations (3.9±1.8 vs. 2.2±1.8, P<0.0001), compared with patients having one child.

Due to collinearity, the number of oocytes retrieved and dose/oocyte were included into separate analyses. The model featuring dose/oocyte had lower AIC and was chosen as the final model. Age >36 years (odds ratio [OR] 0.40, 95% confidence interval [CI] 0.30-0.54, vs. age ≤36 years), dose/oocyte >300 IU/oocyte (OR 0.62, 95% CI 0.46-0.84, vs. ≤300 IU/oocyte) and BMI 30-34.9 kg/m^2 (OR 0.56, 95% CI 0.37-0.85, vs. BMI 20-24 kg/m^2) were associated with lower odds for having several children. The chance of having several children increased with >3 stimulations (OR 5.08, 95% CI 3.96-6.51), compared to one. The odds of having >1 child also increased with the number of top-quality embryos (OR 1.09, 95% CI 1.05-1.14). In the final model, dose/oocyte, age and BMI were more important factors than the number of ovarian stimulations performed and the number of top-quality embryos.
Limitations, reasons for caution: It was not possible to determine whether each couple attained the desired number of children through IVF/ICSI treatment as reasons for discontinuation of treatment were not available. Characteristics of cryopreserved cycles and of subsequent stimulations were also not evaluated.
Wider implications of the findings: Modifiable factors for having more children are dose/oocyte and BMI. Both of these factors are more important for having >1 child from IVF/ICSI than multiple treatments. Dose/oocyte is more reflective of the overall quality of ovarian stimulation than the number of oocytes retrieved and should be kept low.
Trial registration number: Not applicable

P-781 Ovarian stimulation response and extended embryo culture, but not assisted zona hatching, correlate to monozygotic multiple pregnancies

R. Mättner[1], M.R. Maduro[1], E. Strehler[2], K. Sterzik[2]
[1]Nextclinic MVZ fuer Kinderwunsch und Praenatalmedizin GmbH Praxisklinik Frauenstrasse, Ivf-Laboratory, Ulm, Germany
[2]Nextclinic MVZ fuer Kinderwunsch und Praenatalmedizin GmbH Praxisklinik Frauenstrasse, Reproductive Medicine, Ulm, Germany

Study question: Are monozygotic twin pregnancies after assisted reproduction correlated to assisted zona hatching (AZH), extended embryo culture (EEC) or number of oocytes retrieved?
Summary answer: Monozygotic twin pregnancies (MTP) after assisted reproduction are correlated to ovarian stimulation response and EEC, but not to AZH.
What is known already: The increased incidence of MTP after assisted reproductive techniques (ART) has for long been a matter of debate, yet its causes are still controversial. Many factors, ranging from prolonged embryo exposure to the culture media, to the use of AZH or to intrinsic factors of the oocytes following ovarian stimulation, have been presented as potential causes. While the use of AZH has been reported to increase the chance of twins, blastocyst transfer is generally accepted to play a major role. In addition, higher levels of estradiol have been documented in early multiple pregnancies but this correlation during implantation is unknown.
Study design, size, duration: Retrospective analysis of 1596 clinical pregnancies after ovarian stimulation and conventional in vitro fertilization or intracytoplasmic sperm injection, of which 4% corresponded to MTP. Pregnancies were grouped according to the number of embryos transferred (ET) and the number of fetal heart rates (FHR) detected. For each of the groups, data referring to the use of AZH, the day of transfer and the number of oocytes retrieved was collected.
Participants/materials, setting, methods: Participants undergone ART treatment at Next Clinic Praxisklinik Frauenstrasse in Ulm, Germany. Assisted zona hatching was performed on day 3 of culture using the OCTAX pulse laser. Intrauterine embryonic transfer of 1 or 2 embryos took place either early (day 2-3) or after extended embryonic culture (day 5-6). Fetal heart rate was monitored by Doppler ultrasound starting at 4 weeks after intrauterine embryonic transfer. Statistical multivariate analysis was performed by Chi-Square Test.
Main results and the role of chance: Our results indicate a 10-fold increased incidence of MTP after ART, compared to the normal population.

Analysis of 61 MTP versus 1535 non-MTP controls showed a correlation of MTP to EEC (93% MTP had EEC versus 69% of controls). MTP were also positively correlated to a higher number of oocytes retrieved, corresponding to a higher estradiol environment during oocyte intra-follicular development (>3,000pg/ml). MTP presented a statistically significant ($p<0.01$) increased incidence of cases with >15 oocytes retrieved (43%), compared to controls (16%). AZH was slightly more frequent in the MTP group (28%) than in the controls (22%). When the pregnancies were further subdivided into single ET leading to single pregnancies (control A, n=233) or MTP (group A, n=10) and 2 ET leading to 2 FHR (control B, n=1302) or >2FHR (group B, n=51), the correlation of MTP to ovarian stimulation response was reconfirmed ($p<0.01$), with higher response present in 20% of group A (control A, 9%) and 47% of group B (control B, 17%). EEC was more frequent in MTP, although statistical power was lacking for one group (group A, 60%; control A, 49%, $p>0.1$; group B 100%; control B, 72%, $p<0.01$). Interestingly, no correlation was found between AZH and MTP.

Limitations, reasons for caution: This is a multivariate analysis study that limits the ability to determine the consequence of a single variable (AZH, EEC or the effect of ovarian stimulation) on the outcome (MTP). The term monozygotic also needs to be taken with caution as genetic analysis of the twins was not performed.

Wider implications of the findings: Single embryo transfer is advisable to patients with more than 15 oocytes retrieved to avoid the risk of MTP. AZH performed on day 3 does not show a correlation to MTP, in contrast to previous reports. EEC benefits should be balanced with MTP possibility in patients with health risks.

Trial registration number: not applicable

P-782 THIRD PARTY REPRODUCTION: THE ITALIAN SOCIETY OF HUMAN REPRODUCTION (SIRU) CONSENSUS MEETING

A. Guglielmino[1], P. Viganò[1], L. Montano[1], A. Allegra[1], A. Liprino[1], F. Giacone[1], S. Palini[1], A. Paffoni[1], M. Baldi[1], Z. Donarelli[1], F. Tomei[1], D. Carone[1], E. Papaleo[1], P. Inaudi[1], E. Somigliana[1]

[1]Italian Society of Human Reproduction SIRU, consensus meeting working group, Rome, Italy

Study question: What is the recommended assessment and management of reproductive treatments with donated gametes, based on the best available evidence and clinical expertise?

Summary answer: A consensus meeting was organized among all different professional figures involved in ART procedures, patients' associations and lawyers to promote evidence-based care on donor-assisted reproduction.

What is known already: In Italy donor-assisted reproduction is presently permitted by law. An increase in number of treatments (from 2800 to 6247,+123%), patients (from 2462 to 5450,+121%), and deliveries (from 601 to 1457,+142%) was observed from 2015 to 2016. However, since Annex III of EC Directive 17/2006 was only partially accepted, a dramatic lack of donors is currently observed. In 2016, 84.4% of sperm donation and 94% of oocyte donation treatments were performed with gametes imported from international banks. The Italian regulatory limitations negatively impact on the feasibility of treatments so that couples' needs are not being met and gaps still persist.

Study design, size, duration: The Italian Society of Human reproduction (SIRU) has organized a meeting in order to define the best scientific evidence for Italian healthcare professionals. The consensus conference was held in Lampedusa from 11 to 13 October 2018 involving 28 experts, equally distributed between public and private centers (55% vs 45%) and gender (59% men vs 41% women). Conflicts of interest were managed in order to guarantee transparency and disclosed by all the participants.

Participants/materials, setting, methods: SIRU organized a consensus conference based on the methodology derived from ESHRE Manual for development of recommendations for good practice. The Grading of Recommendations, Assessment, Development and Evaluation (GRADE) framework was applied for evaluation of 301 bibliographic references.

Main results and the role of chance: We have developed the first consensus meeting on third party reproduction based on a pre- and post-process rigorous methodology. The final document provided nine consensus statements, one clinical consensus recommendation and six clinical practice points aroused from discussion during the meeting. High quality GRADE statements referred to risks of treatments, number of embryos to transfer, recipients' clinical evaluation, risks of pregnancy in advanced maternal age and endometrial preparation before transfer. Moderate quality GRADE statement referred to outcomes of reproductive treatments with fresh or frozen oocytes. Low quality GRADE statements referred to genetic and psychological counselling for donors and recipients and reimbursement for donation. A clinical recommendation was proposed on the use of low dose aspirin during pregnancy in advanced maternal age. The clinical practice points suggested the minimum genetic tests required for donors and the number of oocytes useful for each patient. Finally, the expert working group discouraged the use of preimplantation genetic screening for donor-assisted reproduction, the routinely use of endometrial scratching, the use of donor sperm after repeated implantation failures in couples with normozoospermic men and the indication to reproductive treatments when the prognosis is very poor especially in advanced maternal age.

Limitations, reasons for caution: The consensus statements were developed in relation to the Italian practice. A different panel of international experts would likely have yielded subtly different statements. Embryo donation was not considered because it remains presently forbidden in Italy.

Wider implications of the findings: For the first time in Italy, a scientific society representative of all figures involved in donor-assisted procedures, has convened to evaluate the evidence on management of treatments using donor gametes. The impact of the consensus statements in reducing multiple pregnancies and increasing effectiveness of treatments should be evaluated prospectively.

Trial registration number: not applicable

P-783 Long term management of OHSS syndrome in a large patient population

E. Porcu[1], G. Damiano[1], L. Cipriani[1], F. Sacilotto[1], I. Roncarati[1], F. Vergine[2], G.M. Cillo[1]

[1]University of Bologna, Human Reproductive Medicine Unit, Bologna, Italy
[2]University of Pisa, Infertility and IVF center, Pisa, Italy

Study question: Does a different management of IVF cycle in a patient at risk of OHSS influence complication and pregnancy rate?

Summary answer: An accurate evaluation of individual risk factors for OHSS is the most important factor to prevent complications and improve IVF outcomes in hyper-responders.

What is known already: OHSS is the main complication of ovarian stimulation with a mortality of 3 out of 100.000 cases. The main risk factors are: young age (<30), BMI <19kg/m^2, antral follicles count higher than 24, AMH >3.4ng/ml, polycystic ovarian syndrome, number of follicles at the time of induction > 20, estradiol plasmatic levels >3500 pg/ml, personal history of OHSS.

Even though it is impossible to completely eliminate the risk of OHSS the strategies for OHSS prevention are: primary prevention, such as election of proper gonadotropin dose and antagonist protocol and secondary prevention such as GnRH agonist triggering and freeze all strategy.

Study design, size, duration: Retrospective cohort study. Among 14103 patients undergoing an IVF treatment 1318 were included because considered at risk for OHSS. The patients were divided into 3 groups based on the number of retrieved oocytes and estradiol levels at trigger day: Group A including 377 patients that underwent oocytes freeze all; Group B including 62 patients that underwent embryos freeze all; Group C including 879 hyper responders patients who underwent fresh embryo transfer.

Participants/materials, setting, methods: Participants treated at the IVF and Infertility Center of Bologna University from 1991 to 2018 had comparable age, FSH and AMH level. 1471 cycles of ovarian stimulation were performed using low dose of gonadotropin associated with GnRH antagonist protocol. Monitoring was performed with seriated estradiol blood tests and pelvic ultrasounds. hCG trigger 36 hours before pick-up was used. According to the profile risk of the patients, fresh embryo transfer or oocytes/embryos freeze all was performed.

Main results and the role of chance: AFC was significantly higher in group A compared to the other groups ($p<0,001$). Both days of stimulation and total

dose of gonadotropin were similar among the groups. Patients of group C had lower estradiol levels (pg/ml) on trigger day (2504±869 vs. B 2890±1036, vs. A 3919±1312 p<0,001). Furthermore, group C patients had lower number of follicles at the ultrasound (11±3.4 vs. B 12.6±6.6 vs. A 16.2±5.1 p<0,001) and lower number of oocytes retrieved (9.5±5.8 vs. B 14.9±6.1 vs. A 19.4±9.6 p<0,001). Based on these characteristics Group C had a relatively lower risk to developing OHSS, thus fresh embryo transfer was performed. The mean hospitalization rate for OHSS was 14.5%, but significantly higher in group B patients (38,1%), mainly due to mild and moderate cases. Whereas the rate of hospitalization for severe OHSS was significantly higher in group C compared to group A (15.5% vs. 5.6% p<0,001). The complication rate was low (6.8%) among all the groups and referable to clinical ascites (70%). Finally, pregnancy rate obtained from fresh or frozen embryo transfer was comparable in the three groups (A 39.6% vs. B 40% vs. C 41.8% p=ns).

Limitations, reasons for caution: The main limitation of the study is a possible bias of patient selection particularly in the fresh ET group. In fact, due to the long duration of the study the clinical criteria for choosing fresh ET could have changed as supported by reduction of OHSS rate over the years.

Wider implications of the findings: The main limitation of the study is a possible bias of patient selection particularly in the fresh ET group. In fact due to the long duration of the study the clinical criteria for choosing fresh ET could have changed as supported by reduction of OHSS rate over the years.

P-784 Outcome in singletons born after vitrification and slow-freeze – a CoNARTaS study of 11,773 singletons born after frozen embryo transfer in Sweden and Denmark

E. Ginström Ernstad[1], S. Opdahl[2], A.L. Spangmose[3], U.B. Wennerholm[1], C. Bergh[4], A. Pinborg[3], S.S. Malchau[1]

[1]Institute of Clinical Science- Sahlgrenska Academy- Gothenburg University- East Hospital- Sahlgrenska University Hospital, Department of Obstetrics and Gynecology, Gothenburg, Sweden

[2]Faculty of Medicine and Health Sciences- Norwegian University of Science and Technology, Department of Public Health and Nursing, Trondheim, Norway

[3]The Fertility Clinic- Rigshospitalet Copenhagen University Hospital, Department of Obstetrics and Gynaecology-, Copenhagen, Denmark

[4]Institute of Clinical Science- Sahlgrenska Academy- Gothenburg University- Reproductive Medicine- Sahlgrenska University Hospital, Department of Obstetrics and Gynecology, Gothenburg, Sweden

Study question: Is transfer of vitrified blastocysts associated with increased obstetric risks compared with slow-freeze cleavage stage embryos in frozen embryo transfer (FET)?

Summary answer: Transfer of vitrified blastocysts does not seem to alter the well-known risks described in singletons born after slow-freeze cleavage-stage transfer, as compared to fresh transfer.

What is known already: Transfer of frozen-thawed embryos have a central role in modern fertility treatment, limiting the risk of ovarian hyperstimulation syndrome and multiple pregnancies. However, several studies report higher risk of being born macrosomic and large for gestational age after FET. In recent years, the introduction of new techniques has increased treatment success. The slow-freeze technique combined with cleavage stage (CT) transfer has been replaced by vitrification and blastocyst transfer (BT). Only a few studies compare obstetric outcomes after vitrification and slow-freeze, most indicating similar perinatal outcome in the two groups. However, studies indicate higher risk of preterm birth after blastocyst transfer.

Study design, size, duration: This registry-based cohort study includes singletons born after fresh and frozen-thawed transfers following the introduction of vitrification in Sweden and Denmark, in 2002 and 2009, respectively. The study includes 3650 children born after vitrified BT, 8123 children born after slow-freeze CT and 4469 children born after fresh BT during 2002-2014. Obstetric outcome in singletons, born after vitrified BT, was compared with singletons born after slow-freeze CT and singletons born after fresh BT.

Participants/materials, setting, methods: Nordic collaboration study from the CoNARTaS (Committee of Nordic ART and Safety) group. Based on national registries in Denmark, Finland, Norway and Sweden, the ConARTaS cohort includes all children born after ART-treatment in public and private clinics. Obstetric outcomes were assessed with logistic multivariate regression analysis, adjusting for country, year of birth of child, maternal age, parity, BMI, smoking, parental educational level, fertilization method (IVF/ICSI), single embryo transfer, number of gestational sacs and child´s sex.

Main results and the role of chance: The adjusted odds ratio, aOR [95% CI], for preterm birth (PTB <37 weeks) was significantly higher in the vitrification BT group compared with the slow-freeze CT group 1.33 [1.09–1.62]. Similar risks for low birthweight (<2500 g) aOR 0.91 [0.70–1.19], for small for gestational age (SGA) aOR 0.85 [0.63–1.13], for macrosomia (>4500 g) aOR 0.93 [0.77–1.15] and for large for gestational age (LGA) aOR 1.10 [0.91–1.32] were observed. Moreover, similar risks for Apgar score <4 at 5 min aOR 1.28 [0.70–2.34] and malformation aOR 1.16 [0.91–1.47] were observed. Regarding maternal outcomes no differences were seen in the risk of hypertensive disorders in pregnancy (HDP) aOR 0.97 [0.81–1.17] and placenta previa aOR 1.48 [0.98–2.24]. When comparing vitrified BT with fresh BT, we found a higher risk for macrosomia (>4500g) aOR 1.77 [1.35–2.31] and LGA aOR 1.47 [1.18–1.84]. Further, the risk of HDP was higher in singletons born after vitrified BT aOR 1.47 [1.19–1.81]. However, the risk of SGA was lower aOR 0.58 [0.44–0.78] as was the risk of placenta previa, aOR 0.35 [0.25–0.48].

Limitations, reasons for caution: Since vitrification was introduced simultaneously as blastocyst transfer in Sweden and Denmark, it was not possible to explore the effect of vitrification or blastocyst transfer *per se* in this study. The number of singletons born after slow-freeze combined with blastocyst transfer was too small for sensitivity analysis.

Wider implications of the findings: Replacing slow-freeze CT with vitrified BT does not seem to alter obstetric risks in singletons conceived after FET, although this comparison includes two variables. The increase in risk of PTB is probably related to blastocysts. Increased risks of macrosomia and HDP remain increased compared with singletons born after fresh BT.

Trial registration number: ISRCTN11780826

P-785 Use of a subcutaneous catheter (I-port Advance) during ovarian stimulation in oocyte donors before IVF does not affect the clinical outcomes compared to conventional injections.

J.F. Solorzano Vazquez[1], L.G. Villar Munoz[1], I. Maldonado Rosas[2], E. Bonifacio Leon[3], I. Jimenez Medina[2], C. Torres[1]

[1]Centro de Innovación Tecnologia y Medicina Reproductiva CITMER, Medical Area, Mexico City, Mexico

[2]Centro de Innovación Tecnologia y Medicina Reproductiva CITMER, IVF Lab, Mexico City, Mexico

[3]Centro de Innovación Tecnologia y Medicina Reproductiva CITMER, Medical Area, Monterrey, Mexico

Study question: Does the placing of a subcutaneous catheter in donors' skin during the ovarian stimulation for hormones administration could impact negatively the in vitro outcomes?

Summary answer: The placing of a subcutaneous catheter in the donors' skin at any time of the ovarian stimulation does not impact negatively the in vitro outcomes.

What is known already: It is estimated that about 10% of the adults are afraid of needles. The use of port (I-port Advance, Medtronic) a subcutaneous catheter has resulted in a decrease of the number of needle sticks used, from 12.5 to 3.3 injections, during the ovarian stimulation without negatively impacting the stimulation length, gonadotrophic consumption, on number of retrieved eggs in oocyte donors. A small percentage of users have reported skin irritation or unease with the usage of the device, so they returned to regular injections. There is not information if the use of this catheter could put at risk the IVF outcomes.

Study design, size, duration: A prospective randomized study was performed form August 2017 to December 2018: 120 cycles of ovarian stimulation of 34 different donors were included to participate on this study. The subcutaneous catheter was used for a maximum time of 4 days before replacing it for a new port and the donated oocytes were used for In vitro fertilization.

Participants/materials, setting, methods: 120 Recipient´s husbands with normal semen parameters (WHO 2010), were included into this study. 3 groups were formed as following: Group A (40 oocyte donations) which used the I-port for only 8 days of the ovarian stimulation and the remaining part of the stimulation with regular injections. Group B (40 oocyte donations) used

the subcutaneous catheter during all ovarian stimulation and Group C (40 oocyte donations), which used subcutaneous catheters during all the ovarian stimulation.

Main results and the role of chance: 36 hours after the HCG trigger shot the egg collection of the donors was performed. According to our statistical analysis comparing the 3 groups (group A vs Group B vs Group C), we did not find any significant differences in the mean number of oocytes retrieved was (14.4± 4.3, 16.3±4.2 and 15.2±3.3) percentage of matured eggs (87%, 86% and 85%), fertilization rate (68 ,71 and 70%), number of good quality embryos at day 2 of the development (47%, 52% and 48%), blastocyst formation (50%, 46%, 49%), mean of embryos transferred (2.0, 2.1 and 2.0) and pregnancy rate (64%, 63%, 65%) $p>0.05$. For the first time we analyzed the impact of the clinical results when a subcutaneous catheter is used during all the ovarian stimulation and also when its use was canceled at the middle of the ovarian stimulation showing both similar results compared to the conventional ovarian stimulations using syringes.

Limitations, reasons for caution: We did not analyze the comfort and the psychological stress generated with the use of the syringes compared to the use of the subcutaneous catheter.

Wider implications of the findings: The use of a subcutaneous catheter during 4 days of ovarian stimulation showed similar clinical outcomes compared to the conventional use of syringes. The decrease from an average of 32 injections to only 4 injections (I-port advance) could improve the comfort during the in vitro fertilization cycles.

P-786 Pathogenic mtDNA mutations are abundant in oocytes but eliminated during fetal development

H. Ma[1], T. Hayama[1], C. Van Dyken[1], H. Darby[1], A. Koski[1], N. Marti Gutierrez[1], Y. Li[1], R. Ahmed[1], D. Liang[1], T. Gonmanee[1], P. Amato[2], S. Mitalipov[1]

[1]Oregon Health & Science University, Center for Embryonic Cell and Gene Therapy, Portland, U.S.A.

[2]Oregon Health & Science University, Department of Obstetrics and Gynecology, Portland, U.S.A.

Study question: Does purifying selection against deleterious mitochondrial DNA (mtDNA) mutations occur during oocyte development?

Summary answer: Purifying selection against mtDNA mutations does not function in female germline in ovary but operates during early fetal development depending on heteroplasmy levels of mutations.

What is known already: Inherited mtDNA mutations are common and associated with multiple diseases in humans. However, only few recurring mutations account for the majority of known familial cases. This phenomenon suggests the existence of intergenerational purifying selection. While the exact timing or developmental stage at which such negative selection operates is unknown, it has been suggested that most deleterious mtDNA mutations are eliminated in the female germline, during oocyte development.

Study design, size, duration: We performed whole mtDNA genome sequencing in mature oocytes and specific developmental stages in offspring of heterozygous *PolG*$^{mut/wt}$ females generated by paring with wild type *PolG*$^{wt/wt}$ males. The effect of specific protein-coding gene mutations on fetal development was examined in chimeric animals.

Participants/materials, setting, methods: Whole mtDNA sequencing (Miseq) was performed to examine the spectrum of mtDNA mutations in single skin fibroblasts of *PolG*$^{mut/wt}$ mothers, MII oocytes, *PolG*$^{wt/wt}$ blastocysts, *PolG*$^{wt/wt}$ viable fetuses at E9.5, *PolG*$^{wt/wt}$ live pups, and MII oocytes of *PolG*$^{wt/wt}$ pups. Embryonic stem cells (ESCs) carrying specific mtDNA mutations were generated and injected into host ICR embryos. Chimeric blastocysts were transferred to recipients to generate chimeric embryos and fetuses.

Main results and the role of chance: *PolG*$^{mut/wt}$ mother's somatic cells showed a mean 10.0±1.7 mtDNA mutations per skin fibroblast while *PolG*$^{wt/wt}$ live pups inherited a significantly lower 4.6±0.7 mutations. Remarkably, MII oocytes, *PolG*$^{wt/wt}$ preimplantation embryos and ESCs, but not viable fetuses of *PolG*$^{mut/wt}$ females, carried abundant deleterious mtDNA mutations. The yield of MII oocytes in *PolG*$^{mut/wt}$ mice was comparable to control *PolG*$^{wt/wt}$ mice, while the number of viable E9.5 fetuses in *PolG*$^{mut/wt}$ females was reduced. Moreover, the majority (95%) of mutations transmitted to the live pups were at low heteroplasmy (≤10%) levels, while most of the mutations with high and moderate heteroplasmy levels presenting in mothers were transmitted to their oocytes and to their fertilized embryos including blastocysts. High heteroplasmy of nonsynonymous mutations for *mt-Nd4l*, *mt-Nd5*, *mt-CoxI*, *mt-CoxII*, *mt-CoxIII* and *mt-Atp6* genes were abundant in mothers and MII oocytes, but not in the live pups. Conversely, high heteroplasmy mutations in other protein-coding and RNA-coding genes were transmitted to the live pups. Chimeric mice carrying *mt-CoxIII* gene mutations showed a high degree of fetal lethality before E9.5. These results demonstrate that the purifying selection against deleterious mtDNA mutations operates during early fetal development and acts on the specific genes resulting in embryonic and fetal demise.

Limitations, reasons for caution: Limitation may be due to the small number of ESC lines with specific mtDNA mutations and chimeric mice generated. More research in RNA-coding gene mutations and their impacts on embryonic and fetal development is needed.

Wider implications of the findings: Our data indicate that deleterious mtDNA mutations causing mitochondrial dysfunction are abundant in mammalian oocytes and may be responsible for unexplained pregnancy loss in humans.

Trial registration number: not applicable

P-787 New role of neogenin in the mammalian testis at the early phase of spermatogenesis

J.W. Park[1], L. Chan Hee, lch_1115@naver.com[2], K. Jung-Jae, highko@cha.ac.kr[3], K. Dae Keun, dkkim@chamc.co.kr[4], L. Sang Jin, leesj@syu.ac.kr[2], J.H. Lee, Ph.D.[3]

[2]Sahmyook University, Animal Biotechnology, Seoul, Korea- South

[3]CHA University, Biomedical Science, Seoul, Korea- South

[4]CHA fertility seoul center seoul sequare 3floor, Urology, Seoul, Korea- South

Study question: There is a lot of neogenin expression in the testicular tissue of mammals but remain unknown as the main role of Neogenin for spermatogenesis. What is the major role of neogenin in spermatogenesis?

Summary answer: Neogenin is specifically localized in the spermatogonial germ cells and it regulates with the early phase of spermatogenesis for differentiation.

What is known already: Neogenin has reported a gene level expression in the mammalian testis.

Study design, size, duration: This control study for the identification of the neogenin function during spermatogenesis in the seminiferous tubule of the mouse testis. And we performed the loss of the functional study with a male mouse that has been postnatal for 12days using the Crisper/CAS9 with the Neogenin knockdown gRNA.

Participants/materials, setting, methods: We performed immunohistochemical study to identify the neogenin expression of testis and expression analysis with western blot. Therefore, we designed that neogenin knockdown genetical edition with the Crisper/CAS9. Then we underwent spermatogenesis to analyze the seminiferous tubule of the Neogenin knockdown.

Main results and the role of chance: Neogenin abundant expression between the spermatogonia, primary and secondary spermatocyte differentiating phase. After advanced aging, testis (over 40weeks) decreased, compared to the one that has been postnatal for 24days based on Western blot data. And then other germ line development for related proteins like Oct4, SOX2 and Nanog shows the similar pattern of Neogenin expression. Especially SOX2 shows an abundant expression at the spermatocyte phase with neogenin. Nanog is highly expressive after the secondary spermatocyte phase compared with Oct4 and SOX2. Oct4 shows well matching with a pattern of neogenin expression. Therefore, Neogenin knockdown mouse

animals, we found a significant decrease in the early differentiation phase from type B spermatogonia compared with control testis. These study results suggest that neogenin may play an important role in initial spermatogonia differentiation.

Limitations, reasons for caution: Animal controlled experiment for spermatogenesis. We need confirm in the human testis whether the expression of neogenin and its defects were related spermatogonia arrest relationship.

Wider implications of the findings: We found the specific role of neogenin by loss functional study with Crisper/CAS9. This platform can apply for specific factor functional study with postnatal testis. And gene editing technology can apply defect gene replacement by normal gene for overcome for spermatogenesis arrest.

P-788 DNA demethylation accelerates the induced differentiation of human primordial germ cells from pluripotent stem cells

S. Yang[1,2], S. Ding[2], S. Peng[3], S. He[3], L. He[1], K. Gao[1], L. Leng[1], Y. Huang[1]

[1]*Department of Obstetrics and Gynecology, Shenzhen University General Hospital-Shenzhen University Clinical Medical Academy, Shengzhen, China*

[2]*The Center of Reproduction Medicine, The University of Hong Kong-Shenzhen Hospital, Shenzhen, China*

[3]*The Key Laboratory of Carcinogenesis and Cancer Invasion of the Chinese Ministry of Education- the Key Laboratory of Carcinogenesis of The Chinese Ministry of Health and Cancer Research Institute, Xiangya Hospital- Central South University, Changsha, C*

Study question: Can DNA demethylation accelerate the induction of human primordial germ cells (PGCs) from pluripotent stem cells (iPSCs) *in vitro*?

Summary answer: DNA methyltransferase inhibitor 5-aza-2-deoxycytidine (DAC) promoted the induced differentiation of human PGCs from iPSCs *in vitro*. The induced PGCs from iPSCs showed hypomethylated status.

What is known already: There are two waves of global demethylation in human PGCs from the migrating stage to the gonadal stage *in vivo*. The global erasure of DNA methylation creates a super-hypomethylated germline genome. It has also been confirmed that human iPSCs can differentiate into PGCs. But we did not know the methylation status of differentiated PGCs from iPSCs *in vitro*, and the relationship of DNA methylation and the induced differentiation of PGCs from iPSCs *in vitro*.

Study design, size, duration: VASA-GFP iPSCs were used for induction differentiation experiments. The induction efficiency of PGCs from VASA-GFP iPSCs were compared between two groups, which one is induction medium adding the DNA methyltransferase inhibitor (DNMTi) 5-aza-2-deoxycytidine (DAC) and other is no adding DAC. During inducted differentiation, the methylation status was analysed at day 4 and day 8.

Participants/materials, setting, methods: The DNMTi DAC is added after pre-induction for demethylation at day 5. The final concentration was 0.05 uM. These cells were cultured three days with DAC and PGC medium for downstream experiments. We analyzed the DNA demethylation dynamics in human PGCs at day 4 and day 8 by bisulfite sequencing in three imprinted genes *H19*, *HEG1* and *SNRPN*, and the efficiency of induced differentiation to ask whether the DNA demethylation accelerated the differentiation of human PGCs from iPSCs *in vitro*.

Main results and the role of chance: Our results showed the human PGCs derived from iPSCs at day 8 displayed much lower genome-wide 5mC level, indicating hypomethylation status, and also showed the percentage of VASA-GFP positive cells after 4 day induction using DAC and without DAC group was 17.42 ± 1.85%, 16.63 ± 1.73%, respectively; the percentage of CD38-positive cells after 4 day induction using DAC and without DAC group was 10.28 ± 1.85%, 9.21 ± 1.21%, respectively; after 8 day induction, the percentage VASA-GFP positive cells was 54.38 ± 3.75%, and 46.35 ± 2.27%, respectively; the percentage of CD38- positive cells was 36.21 ± 1.41%, 43.36 ± 1.89%, respectively, indicating DNA demethylation accelerated the induction of human PGCs from iPSCs *in vitro*.

Limitations, reasons for caution: In this study, the global epigenetic reprogramming process during induction differentiation of PGCs from iPSCs *in vitro* remains to be determined.

Wider implications of the findings: This provides a new and high-efficiency way for PGC induction differentiation from iPSCs *in vitro*.

Study question: To assess outcomes of ovarian function including therapeutic mechanisms by transplanted human placenta-derived mesenchymal stem cells (PD-MSCs) in a rat model with ovary dysfunction.

Summary answer: The findings offer insights into further understating of stem cell-based therapeutic mechanisms for reproductive system and provide new avenues to develop therapies in degenerative diseases.

What is known already: Premature ovarian failure (POF) is lack of follicle and infertility in women younger than 40 years of age. Because hormone replacement therapy (HRT) has limitations such as high risk of developing breast cancer are known, the development of new stem cell-based therapies for ovarian dysfunction is required. We reported that follicular development is promoted by mesenchymal stem cells (MSCs) transplanted into an animal models with ovarian dysfunctions. Recently, PD-MSCs, which have their activities for self-renewal and immunomodulation were higher than those of bone marrow- and adipo-derived MSCs, have emerged as new stem cell resources compared with others.

Study design, size, duration: The rats were randomly divided into three groups (NTx: non-transplantation; DTx: directly transplantation; TTx: tail vein transplantation). After all rats were anesthetized by Avertin, one ovary of rat was removed by excision. One week after the ovariectomy, PD-MSCs were transplanted directly into the ovary tissues (DTx) or by the tail vein transplantation (TTx), respectively. And then, the therapeutic mechanisms of PD-MSCs were analyzed at 1, 2, 3, and 5 weeks after transplantation, respectively.

Participants/materials, setting, methods: Blood and ovary tissue were analyzed after post-transplantation. The hormone levels in the plasma was measured by using ELISA. To analyze the engrafted human PD-MSCs in the ovary tissues, the expression of human specific Alu sequence was analyzed using qRT-PCR. The expression for folliculogenesis-related genes and PI3K/Akt signal pathway in the ovary tissues were analyzed using qRT-PCR and Western blot, respectively. The number of ovarian follicles in the ovarian tissues was evaluated by histological analysis.

Main results and the role of chance: The human Alu sequence gene expression was significantly increased in both DTx and TTx groups compared with NTx groups ($*p<0.05$). The levels of E2 and AMH in blood were increased both DTx and TTx groups compared with NTx groups ($*p<0.05$). The number of follicles in ovary tissues was increased in both DTx and TTx groups compared with NTx groups($*p<0.05$). In qRT-PCR analysis, the mRNA expression levels of Nanos3, Nobox, and Lhx8 were significantly increased in both DTx and TTx groups after PD-MSCs transplantation compared with NTx groups ($*p<0.05$). Their proteins expressions in both DTx and TTx groups were also significantly increased compared with NTx groups ($*p<0.05$). Interestingly, the mRNA expression of Lhx8 was increased in both DTx and TTx groups compared with NTx groups ($*p<0.05$). The number of ovarian follicles in the ovary tissues after PD-MSCs Tx was more significantly increased than NTx group ($*p<0.05$). Especially, the number of follicles in TTx group were significantly increased compared to DTx group at long-term periods after Tx. ($*p<0.05$). Furthermore, PD-MSCs trigger significantly activation of PI3K/AKT signal comparing to NTx groups, otherwise, the expression of caspase-3 and caspase-9 were significantly decreased ($p<0.05$).

Limitations, reasons for caution: We need further studies to analyze more in deep the molecular mechanisms by which secreted signal molecules of PD-MSCs for restore ovarian function in ovarian failure model.
Wider implications of the findings: Pooled results from evaluated studies suggest that engrafted PD-MSCs into ovary tissue of rat model with ovarian dysfunction can restore ovarian function by increasing folliculogenesis via the PI3K/AKT signal pathway. Our findings suggest that PD-MSCs could be used as an alternative therapy for patients with ovarian dysfunction, including infertility.

P-790 Stem cell therapy induces a shift from an inflammatory environment towards an immune tolerant scenario promoting endometrial tissue regeneration

L. De Miguel-Gómez[1], S. López-Martínez[1], A. Faus[1], D. Hervás[2], H. Ferrero[1], I. Cervelló[1]
[1]IVI Foundation, Research, Valencia, Spain
[2]Health Research Institute La Fe, Data Science- Biostatistics and Bioinformatics, Valencia, Spain

Study question: Could bone marrow derived stem cell (BMDSC) transplantation induce an immunomodulatory milieu helping tissue recovery in human and murine models with endometrial pathologies?
Summary answer: Differences in Neutrophil Elastase (NE) expression in treated women and a specific cytokine/chemokine profile in mouse models have evidenced a favourable ambient inducing endometrial regeneration.
What is known already: Asherman Syndrome and Endometrial Atrophy (AS/EA), producing endometrial destruction, are two of the most frequent causes of uterine-type infertility. Cell therapy using $CD133^+$BMDSCs has been described for treating these pathologies. It has been demonstrated that factors secreted by these cells stimulate tissue regeneration, for example in pathological situations where Neutrophil Elastase (NE) is overexpressed, creating a microenvironment based on pro-inflammatory and immunomodulatory processes. Our previous studies detected up- and down-regulated genes like SERPINE1/IL4/JUN and CXCL8/CCDND1 respectively. Interestingly, NE can be inhibited by SERPINE1 and increases the release of CXCL8, a potent chemoattractant, thus potentiating the inflammatory response.
Study design, size, duration: Our study design involves on one hand a retrospective study based on endometrial tissue analysis from 8 patients with endometrial pathologies (AS/EA) before and after autologous $CD133^+$BMDSCs treatment (ClinicalTrials.gov-NCT02144987): gene and protein analysis were performed to elucidate how the regenerative process occurred. On the other hand, uterus from immunocompromised mice with damaged endometrium, where human $CD133^+$BMDSCs were injected intrauterus (n = 5) or through the tail vein (n = 5), were analysed by Multiplex technologies.
Participants/materials, setting, methods: We collected 2 endometrial biopsies from each of these 8 women: before/Control and after the Treatment. Genetic analysis from our previous study was assessed with bioinformatic analyses (*t*-test), and validated by individual PCR. All samples were analysed by immunohistochemistry against NE (M0752, Dako), the differential expression was analysed using Image-ProPlus-6.0 (Mann-Whitney test). These results were also supported from the animal model (intrauterus and tail vein) where Multiplex Immunoassays (ProcartaPlex Mouse-26plex Cytokine&Chemokine, ThermoFisher) were carried out.
Main results and the role of chance: Bioinformatic analysis revealed 5 significant genes: JUN, SERPINE1 and IL-4, up-regulated, while CCND1 and CXCL8, down-regulated; when Treatment condition was compared to Control. These gene pattern correlates with the subsequent protein analysis we performed. Expression of NE protein resulted significantly lower in the Treatment group (p=0.0286) when compared to Control, which correlates with CXCL8 gene downregulation (p=0.036). The down-regulated expression of CXCL8 and NE (reliable markers of inflammation) in the human endometrium, caused by the transplantation of $CD133^+$BMDSCs, results in a diminished inflammatory cascade in AS/EA patients promoting probably endometrial regeneration. All together correlates with the NE inhibitory capacity of SERPINE1 (p=0.026), which in absence of NE turned to be up-regulated. This change from an inflammatory environment toward an anti-inflammatory/tolerant phenotype allows proliferation, differentiation, anti-apoptosis and chemotaxis events. We observed evidences of these pro-regenerative processes, when analysing in detail our animal model by Multiplex immunoassays, we obtained a specific cytokine/chemokine pattern (IL-27, MCP-1, MIP-1β and MIP2 among others) in the affected area after cell therapy. All these molecules seemed to be involved in tissue recovery after damage, pro-angiogenic events, wound healing and BMDSCs secretions, processes in that SERPINE1, IL-4 (p=0.041) and JUN (p=0.037) are also implicated.
Limitations, reasons for caution: The limitation of our study is the low quantity of tissue collected due to human endometrial biopsies were coming from women suffering from AS/EA. And, in our animal model the use of Formaldehyde Fixed-Paraffin tissues to perform the Multiplex assays.
Wider implications of the findings: These results support the regenerative effect of CD133+BMDSCs in endometrial pathologies like AS/EA via immune and inflammatory responses; what would bring us one step forward to understand the specific mechanisms of this cell therapy. The decrease of endometrial NE identified here may diminish the inflammatory response giving a proliferative scenario.

P-791 A novel mtDNA knockout approach to investigate mitochondrial gene mutations in mice

R. Ahmed[1], H. Ma[1], T. Hayama[2], C. Van-Dyken[1], N. Marti-Gutierrez[1], H. Darby[1], Y. Li[1], A. Koski[1], E. Kang[3], Y. Lee[3], D. Liang[1], P. Amato[1], S. Mitalipov[1]
[1]Oregon Health Sciece University, Center for Embryonic Cell and Gene Therapy, Portland, U.S.A.
[2]Department of OB & GYN- Saiseikai South Yokohama Hospital, Center for Reproductive Medicine- Department of OB & GYN Yokohama City University Medical Center, Yokohama, Japan
[3]ASAN Medical Center- Olympic-ro 43-gil- Songpa-gu, ASAN Institute for Life Sciences, Seoul, Korea- South

Study question: Can chimera-competent mouse embryonic stem cell (ESCs) with pathogenic mitochondrial DNA (mtDNA) mutations be generated?
Summary answer: Wildtype ESCs with specific mtDNA variants can be derived from heterozygous PolG mutator females, introduced into host embryos and disease phenotypes studied in chimeric mice.
What is known already: Mammalian mtDNA is critical for cellular energy production. It contains 37 genes encoding 13 subunits of oxidative phosphorylation (OXPHOS) complex, 2 rRNAs, and 22 tRNAs. Specific mtDNA mutations in humans are associated with severe syndromes. However, no animal model of human mtDNA disease exist due to limitations of directly manipulating mtDNA genome.
Study design, size, duration: Heterozygous $PolG^{mut/wt}$ females were bred with wt mice and resulting blastocysts were used for ESC isolation. Wildtype ESC lines were selected and screened for mtDNA mutations by whole genome sequencing. Mutant ESCs were compared with human mtDNA database to predict phenotypes.
Participants/materials, setting, methods: Whole mtDNA sequencing (Illumina Miseq) was used to determine mtDNA mutation profile in each wildtype ESC lines. DNA sequences were analyzed with NextGene software to identify mtDNA variants.
Main results and the role of chance: Multiple mutant ESC lines were generated and three lines (ND6-100, ND2-50, ATP8-62) carrying specific heteroplasmic and homoplasmic mutations were selected for studies in chimeras. Implantation, full-term and live pup development rates for ND6-100, ND2-50 and ATP8-62 high ESC-chimeras were comparable to controls. ND6-100 chimeras displayed significantly reduced complex I and IV activity, ATP8-62 chimeras were deficient for complex V while ND2-50 animals showed reduced complex I activity compared to controls. Glucose levels in all chimeras were significantly elevated compared to controls. The optokinetic response indicated vision impairments. The mean ejection friction of ATP8-62 chimeras was significantly lower than controls and the mean diastolic left ventricle volume was higher. These animals showed evidence of bi-ventricular failure, suggesting reduce pumping function with chamber enlargement.
Limitations, reasons for caution: Some specific mtDNA mutations are embryonic lethal and cannot be studied in adult chimeras. Other mtDNA mutations survive in chimeras but not transmitted to offspring due to lethality.

Wider implications of the findings: Our simple and effective approach provides a long sought mean of generating mtDNA mutant mouse chimeras and examination of in vivo phenotypes.
Trial registration number: 'not applicable'

P-792 Testicular sperm extraction derived cells conditioned medium as an in vitro niche supports germ cells development from human embryonic stem cells

F. Akyash[1], R. Aflatoonian[2], E. Farashahi Yazd[1], J. Golzadeh[1], S.S. Tahajjodi[1], H. Moore[3], B. Aflatoonian[1]

[1]Stem Cell Biology Research Center- Yazd Reproductive Sciences Institute- Department of Reproductive Biology, Shahid Sadoughi University of Medical Sciences, Yazd, Iran
[2]Department of Endocrinology and Female Infertility- Reproductive Biomedicine Research Center-, Royan Institute for Reproductive Biomedicine- ACECR, Tehran, Iran
[3]Centre for Stem Cell Biology CSCB- Department of Biomedical Sciences, The University of Sheffield- Western Bank- Alfred Denny Building, Sheffield S10 2TN, United Kingdom

Study question: Can testicular sperm extraction (TESE) derived cells conditioned medium (TCM) support male and female germ cells development from human embryonic stem cells (hESCs)?
Summary answer: TCM supports germ cell development from hESCs as assessed by gene expression profile.
What is known already: Embryonic stem cells (ESCs) can form post meiotic germ cells in mammals. Different growth factors and conditioned medium were used so far to direct this process. It has been reported previously that conditioned medium from testicular cells supports germ cell development in mice and Buffalo ESCs. Recently it was shown that co-culture with human testicular cells can facilitate germ cell progression from hESCs as shown by microarray analysis and gene expression.
Study design, size, duration: TCM was collected following culturing TESE-derived cells in different basal media including, DMEM+20%FBS and EB medium. TCM collected every 4 days following seeding cells. For germ cell development, embryoid bodies (EBs) from hESCs cultured for 4, 7 and 14 days. EBs were cultured in several induction conditions: (i) spontaneously differentiation (SD) using EB medium (SD-EB), (ii) EB medium/40% conditioned EBs medium (TCM-EB). (iii) EB medium/40%DMEM+20%FBS without conditioning (SD-DMEM), (iiii) EB medium/40% conditioned DMEM+20%FBS (TCM-DMEM).
Participants/materials, setting, methods: Yazd2 hESC line (46, XY) was used for *in vitro* generation of germ cells. Following differentiation in all groups, EBs were fixed and immunofluorescent (IF) staining was performed for evaluation the expression of SSEA-1, C-KIT, DAZL, VASA, and SCP3 markers. Moreover, Q-PCR for pluripotency (*NANOG, OCT4*), primordial germ cells (PGCs; *SOX17, DAZL),* pre-meiotic gonocytes *(VASA, SCP3*), and post-meiotic germ cells (*H1T, PRM1, GDF9* and *ZP3*) genes was performed. Experiments were performed in triplicate.
Main results and the role of chance: Interestingly, both TCM-EB and TCM-DMEM showed positive induction role for male and female germ cell development from hESCs in comparison with SD groups similar to previously reported in mice and Buffalo. Co-localization of C-KIT and DAZL as PGCs markers was revealed at days 4 and 7. SSEA-1 and VASA were expressed in differentiated cells after 4 and 7 days. Moreover, SCP3 was expressed at days 7 and 14. Q-PCR data revealed that lower expression level of *NANOG* and *OCT4* in TCM groups than other groups on days 4, 7 and 14. While, *SOX17* as master regulator of human PGCs which expressed from migrating to gonadal PGCs was increased significantly using TCM, similar to *SCP3* after 7 and 14 days ($P<0.05$). *DAZL* and *VASA* with similar expression patterns following differentiation, significant increase ($P<0.05$) was demonstrated in TCM groups. Moreover, high expression level of *H1T*, *PRM1, GDF9* and *ZP3* was detected 14 days following differentiation as post-meiotic developmental stage which was significantly increased in TCM groups ($P<0.05$) and confirmed potential of TCM groups to form an *in vitro* niche for germ cell development.
Limitations, reasons for caution: The major limitation of this study was obtaining TESE samples according to our including criteria.
Wider implications of the findings: Our results confirm previous reports in mice and Buffalo which indicates that TCM could be used as a suitable niche to mimic germ cells development from hESCs.
Trial registration number: Not applicable.

P-793 Cumulus cells conditioned medium as an in vitro niche for differentiation of human embryonic stem cells to female germ cells

S.S. Tahajjodi[1], E. Farashahi Yazd[1], R. Aflatoonian[2], A. Agharahimi[3], F. Hajizadeh-Tafti[1], F. Akyash[1], H. Moore[4], B. Aflatoonian[1]

[1]Stem Cell Biology Research Center- Yazd Reproductive Sciences Institute- Department of Reproductive Biology, Shahid Sadoughi University of Medical Sciences, Yazd, Iran
[2]Department of Endocrinology and Female Infertility - Reproductive Biomedicine Research Centre, Royan Institute for Reproductive Biomedicine, Tehran, Iran
[3]Research and Clinical Center for Infertility- Yazd Reproductive Sciences Institute- Department of Reproductive Biology, Shahid Sadoughi University of Medical Sciences, Yazd, Iran
[4]Centre for Stem Cell Biology CSCB- Department of Biomedical Sciences-, The University of Sheffield- Western Bank- Alfred Denny Building, Sheffield S10 2TN, United Kingdom

Study question: Can cumulus cells conditioned medium (CCCM) improve differentiation of human embryonic stem cells (hESCs) to female germ cells?
Summary answer: In comparison with spontaneously differentiation (SD) of embryoid bodies (EBs) formed from hESCs, CCCM improved the differentiation of hESCs to female germ cells.
What is known already: Embryonic stem cells (ESCs) in different mammals can form post meiotic germ cells either spontaneously or using different growth factors as confirmed using gene expression profile assessments. On the other hand, cumulus cells secret growth factors like BMP15 and VEGF which provide a niche to support oogenesis. It was shown previously that CCCM improve female germ cell development from Buffalo ESCs.
Study design, size, duration: EBs from Yazd4 (hESC line;46,XX) were divided into 4 groups: 1) spontaneously differentiation (SD) with 100%EB medium (SD-EB), 2) treated with 40%CCCM [40%EB medium (conditioned) +60%EB; CCCM-EB], 3) SD-DM with 40%DMEM (not conditioned) +60%EB and 4) treated with 40%CCCM [40%DMEM (conditioned)+60%EB; CCCM-DM]. EBs from all 4 groups were cultured for 14 days. Gene expression profile of EBs in 4 groups was evaluated using IF and Q-PCR at the time of days 0, 4, 7 and 14.
Participants/materials, setting, methods: EBs from SD-EB, CCCM-EB, SD-DM and CCCM-DM groups were collected at the time of days 0, 4, 7 and 14. Expression of *NANOG, SOX17, DAZL, DDX4 (VASA), CTDSPL (SCP3), GDF9* and *ZP3* were examined in EBs from each group by Q-PCR. In addition, immunofluorescent (IF) staining was done for pluripotency and germ cells markers, TRA-2-49, SSEA1, VASA, GDF9 and ZP3.
Main results and the role of chance: Q-PCR data revealed that between 4 groups, CCCM-EB had the best impact for female germ cell differentiation from hESCs. However, between groups with similar basal medium, CCCM-EB and CCCM-DM shown to provide a better condition for germ cell development in female. On the other hand, comparison between basal media revealed that EB medium provides a better condition for female germ cells development from hESCs. Using IF, co-localization of TRA-2-49 and SSEA1 in some parts of early differentiated cells were observed indicating primordial germ cell (PGC) formation. SSEA1 and VASA were expressed mainly in days 4 and 7 respectively in all groups. However, GDF9 and ZP3 were not observed in none.
Limitations, reasons for caution: Cumulus cells culture faced some difficulties such as contaminations in first attempts which were solved with more cautious in oocyte pick up procedures. High risk patients including HIV, HBS and HCV positive females were excluded from the study.
Wider implications of the findings: CCCM can improve the female germ cell development from hESCs as discovered by Q-PCR data. The basal medium itself plays a critical role for hESC differentiation.
Trial registration number: No applicable

P-794 Successful development of organoids from fresh and cryopreserved biopsy catheter derived endometrial tissue of subfertile women

B. Bui [1], M. Boretto [2], H. Kobayashi [3], M. Van Hoesel [4], N. Van Hoogenhuijze [1], F. Broekmans [1], H. Vankelecom [2], H. Torrance [1]

[1]University Medical Centre Utrecht, Department of Reproductive Medicine, Utrecht, The Netherlands

[2]KU Leuven University of Leuven, Department of Development and Regeneration-Cluster of Stem Cell and Developmental Biology- Unit of Stem Cell Research, Leuven, Belgium

[3]Yamagata University, Department of Anatomy and Structural Science, Yamagata, Japan

[4]University Medical Centre Utrecht, Regenerative Medicine Centre Utrecht, Utrecht, The Netherlands

Study question: Can organoids be established from minimal invasive endometrium biopsies of subfertile women, and are the organoid characteristics comparable between fresh and cryopreserved biopsies?

Summary answer: Organoids can be developed from fresh and cryopreserved catheter-derived endometrium from subfertile women and are comparable regarding morphology, formation efficiency, expandability, gene and protein expression.

What is known already: Organoids are three-dimensional *in vitro* structures that self-organize from tissue subunits or stem cells, recapitulating key features of the organ of origin, and are largely expandable while remaining phenotypically-genetically stable. They offer possibilities to mimic patient- and disease-specific pathologies and to develop personalized treatments. Previously, endometrial organoids have been established from fresh biopsy catheter derived tissue (Turco et al. 2017) and fresh laparoscopically obtained tissue (Boretto et al. 2017) (healthy and cancerous). Endometrial organoids have not yet been developed from subfertile women, nor been grown from cryopreserved biopsy catheter derived tissue and directly compared with organoids from matched fresh tissue.

Study design, size, duration: In two nested cohort studies within the SCRaTCH randomized controlled trials (RCT), endometrial tissue was obtained during scratching in the luteal phase of the natural cycle or during an oral contraceptive cycle, using an endometrial biopsy catheter (Pipelle®). Ethical approval was obtained for this pilot study, in which tissue of 6 subfertile patients was subjected to endometrial organoid development after obtaining patients' broad written consent.

Participants/materials, setting, methods: Women with unexplained infertility and a good prognosis for spontaneous conception were eligible for one RCT, while the other RCT included women undergoing in-vitro fertilization (IVF) who have not become pregnant in the first full cycle. Endometrial tissue was cultured for organoid development (as described by Boretto et al. (2017)) immediately after the biopsy and after at least 1 week of cryopreservation. Briefly, tissue was digested, embedded in Matrigel and cultured under 'wingless/integrated' (WNT)-activating conditions.

Main results and the role of chance: Organoids developed from both fresh and cryopreserved catheter derived endometrial tissue in a similar manner: glandular fragments self-organized during the first 24 hours and grew into endometrial organoids within 1 week of culture, which could be consecutively expanded every 10-14 days. The organoids from both conditions showed similar morphology (cystic structures with epithelial cell border), comparable formation efficiency (n=3, mean % (organoids ≥100 µm/seeded cells) ± SD, fresh vs cryopreserved tissue, 1.48% ± 0.74% vs 2.10% ± 3.31%, p=1.000 (day 7), and 5.15% ± 5.57% vs 8.00% ± 13.07%, p=1.000 (day 10)), expandability (both up to at least passage 13) and immunophenotype (expression of ERα, PAEP, PR, E-cadherin, acetylated α-tubulin). Proliferation was not statistically different (Ki67 immunoreactivity in fresh vs cryopreserved tissue derived organoids, mean ± SD (n=3): 15.5% ± 2.5% vs 9.1% ± 2.9%, p=0.2500 (cultured without hormones), 21.5% ± 5.8% vs 18.1 ± 10.5%, p=0.7500 (treated with estradiol) and 10.1% ± 1.2% vs 7.4% ± 1.9%, p=0.2500 (treated with progesterone)). Gene expression analysis by reverse transcription quantitative real-time polymerase chain reaction (RT-qPCR) showed no statistically significant differences between fresh and cryopreserved tissue derived organoids regarding the expression of several endometrial/epithelial markers (e.g. *FOXA2, ESR1, MUC1, PAEP*).

Limitations, reasons for caution: More patient samples may be needed for more solid conclusions of gene expression profiles, although the current sample size already clearly showed no effect on organoid morphology, expandability and immunophenotyping (protein expression).

Wider implications of the findings: The applicability of cryopreserved tissue to develop endometrial organoids allows organoid-based translation in fertility clinics when organoid research laboratories are not nearby. Furthermore, endometrial organoids will provide a valuable model to study many sorts of 'omics' in endometrial-related reproductive diseases and develop personalized treatments.

Trial registration number: 1. SCRaTCH trial, NTR5342, registered July 31st, 2015; 2. SCRaTCH-OFO trial, NTR6687, registered August 31st, 2017.

P-795 Autologous Mitochondria transfer to Improve Outcomes in Women With IVF Failures Due to Low Oocyte Quality: A Prospective Self-Controlled Study

L. Xiaolan[1], J. Lei[2], C. Guokun[2], F. Cong[2], H. Rui[2], L. Xiaoyan[2]

[1]he Sixth Affiliated Hospital of Sun Yat-Sen University, Reproductive Medicine Center, Guangzhou, China

[2]The Sixth Affiliated Hospital of Sun Yat-Sen University, Reproductive Medicine Center, Guangzhou, China

Study question: Can Bone marrow mesenchymal stem cell-Derived autologous mitochondria transfer into compromised oocyte change embryonic development kinetics and improve outcomes in Women With multiple IVF failures due to Low oocyte quality?

Summary answer: This study demonstrated that bone marrow mesenchymal stem cell-Derivedautologous mitochondria transfer doesn't alter embryonic development kinetics

What is known already: Qocyte quality plays an important role in fertilization and development to high -quality embryos. All of these development stages require high energy consumption, increasing the synthesis of mitochondrial adenosine triphosphate, which provides the energy necessary for the rupture of the germinal vesicle and the resumption of meiosis, for a normal fertilization, and for reducing the incidence of errors during the second meiotic division. Moreover, mitochondrial dysfunction has been suggested as a major cause of age-induced decline in oocyte quality.

Study design, size, duration: This Prospective Self-Controlled Study plans to conduct in our clinical center from August 2018 to August 2020. By means of a time-lapse system (EmbryoScope; Unisense FertiliTech, Aarhus, Denmark), this study determined the timing of a number of developmental parameters including cleavage timing from a zygote to a 8-cell embryo (t2, t3, t4, t5, t6, t7, t8) and assessed fragmentation at each stage.

Participants/materials, setting, methods: Infertile women <42 years of age, body mass index <30 kg/m2, at least one previous failed IVFdue to low embryo quality were included. Their oocytes were randomly and averagely divided into two groups i.e. Mitochondria transfer groups (MT) and control group. Mitochondria from bone marrow mesenchymal stem cell were isolated by differential centrifugation. In Mitochondria transfer groups (MT), 4000-5000 copies mitochondria DNA were injected into each oocyte during intracytoplasmic sperm injection.

Main results and the role of chance: A total of 18 patients were included and we got169 oocytes in total. till now. Their average age was 32.72 years old and antimullerian hormone leve was 3.28 ng/ml. 72.22% patients was primary infertility and the major cause of infertility was tubar factor. The results showed that the timings of all embryo cleavage stages (from t2to t8) together with fragmentation values showed no significant differences between embryos deriving from oocytes with MT or without MT. In addition , 2PN fertilization rate was similar between two groups (51.1% vs. 50%, P=0.959)

Limitations, reasons for caution: We will further follow up clinical pregnancy outcomes of embryos in two groups. A randomized clinical trial will be necessary to determine the true extent of any clinical benefits.

Wider implications of the findings: This is the first investigation to evaluate the impact of Bone marrow mesenchymal stem cell-derived Autologous mitochondria transfer on embryonic development kinetics. Results confirm that bone marrow mesenchymal stem cell-derived Autologous mitochondria transfer doesn't alter embryonic development kinetics. Autologous mitochondria injection is safe.

Trial registration number: NCT03639506

P-796 COMPARISON OF THE EFFECTS OF ALLOGENIC BONE MARROW AND ADIPOSA-DERIVED STEMCELLS TRANSPLANTATION ON REPRODUCTIVE FUNCTIONS OF MICE WITH CYCLOPHOSPAMIDE-INDUCED OVARIAN FAILURE

M. Suzanta[1], H. Tjahjanto[1], M. Prihadi[1]
[1]*Reproduction Endocrinology Fertility division, department of Obstetrics Gynecology-Indonesia, Semarang, Indonesia*

Study question: Is the ability of allogenic ADSCs (adipose-derived stem cells) better than BMSC (bone marrow derived stem cells) on reproductive function of POF (premature ovarian failure) mice model?
Summary answer: POF mice model that received ADSCs had higher effect on reproductive functions than those who received BMSC.
What is known already: Several studies have been conducted on the role of stem cells in repairing ovarian reserve, while the effect of administering stem cells on endometrial receptivity is still unclear. Researchs showed that stem cells from different sources can have the same effect in saving ovarian function. Previous research has shown that BMSC and ADSCs transplants increases follicle growth and maturation, improves microevironment in the follicles. These processes then rebuild normal hormone function and decreasing the apoptosis process. It is not clear yet which one is more optimal between BMSC and ADSCs in improving reproductive function.
Study design, size, duration: Randomized post test control group design. This study was divided; Pre-experimental (making POF model mice) and the experimental. The size of the sample was obtained by replicating the formula for a complete random randomized trial ($n \geq 6$). Dependent variables on this study; serum AMH (anti-mullerian hormone) levels, integrin $\alpha v\beta 3$ expression of endometrial tissue, and pregnancy outcomes (birth characteristics i.e. number, birth weight, birth length). This research had been done in 2 months (October-December 2016)
Participants/materials, setting, methods: 56 female mice (wistar strain *Micetus norvergicus*)on diestrus phase were outbred
1.C(-): intraperitoneal injection of 0.9% NaCl
2.C(+): injection of Cyclophosphamide (Cyc) and NaCl 0.9%
3.BMSC group: Injection of Cyc and BMSC
4.ADSCs group: injection of Cyc and ADSCs
were mated, then for two groups, 7 mice were terminated (day-4) to assess serum AMH and integrin levels and 7 other were performed cesarean sections (day-19) to assess the characteristics of the offspring born. Two mice from each group were labeled
Main results and the role of chance: Pre-experimental found ovarian histopathological findings showed no follicles with intraperitoneal dose of 15 mg/kgBW Cyc for 2 weeks. Experimental stage on 56 mice, found significant differences in the serum AMH levels ($p = 0.001$), with higher values observed for ADSCs and BMSC group compared to the C (+) group. serum AMH levels in the ADSCs group were higher than the BMSC group, but not significant ($p = 0.7$). There was 11 folds increase in serum AMH levels at ADSCs and a 9 folds increase in BMSC group.

There were significant differences in the integrin $\alpha v\beta 3$ expression of endometrial tissue ($p = 0.01$), with higher values observed for ADSCs and BMSC group compared to the C (+) group. There was an increase in integrin $\alpha v\beta 3$ expression of endometrial tissue 2.4 folds upon administration of ADSCs and a 2.2 folds increase upon administration of BMSC.

There were significant differences in the number of offspring ($p = 0.005$), birth weight ($p = 0.002$) and birth length ($p = 0.02$), with higher values observed for ADSCs group compared to the BMSC group.

Tissue sample from labelled mice was examined under fluorescence microscopy and showed higher endometrial and ovarian tissues "homing" in ADSCs compared to BMSC group.
Limitations, reasons for caution: In this study there was no histopathological examination to the extent of damage of endometrium due to cyc inj. It is not known how long the effect of stemcells settles (optimally homed) on the reproductive organs. Special examination is needed to determine the rejection reaction in this study.
Wider implications of the findings: Research shows that ADSCs have several advantages in easily available sources, are not invasive, minimal rejection reaction. Allogenic stem cells can be considered to be an alternative therapy for stem cells without host rejection reactions risk, although further clinical trials are needed in this matter.
Trial registration number: -

P-797 Transcriptome analysis reveals potential role of autophagy in embryo fragmentation

Q. Zhou[1,2], S. Lin[2], J. Mu[2], J. Guo[2], X. Yang[2], W.J. Wang[2]
[1]*University of Copenhagen, Department of Biology, Copenhagen, Denmark*
[2]*BGI-Shenzhen, BGI-shenzhen, Shenzhen, China*

Study question: Is the fragmentation of In *vitro* fertilized (IVF) embryos derived from assisted reproductive technology (ART) caused by abnormal autophagy?
Summary answer: Alterations in autophagy could lead to molecular changes in multiple processes, and may influence cell growth and development.
What is known already: For IVF embryos derived from ART, fragmentation is a common feature, which could generate embryos with poor quality and reduce the success rate of ART. After fertilization, the maternal mRNA and proteins stored in oocytes are rapidly degraded and new mRNA and proteins encoded by the embryonic genome are synthesized. The autophagy pathway can drive the rapid cellular changes necessary for proper development. Although it has reported that programmed cell death or apoptosis is triggered in arrested fragmented human embryos, the exact molecular mechanism of autophagy in maintaining the intracellular homeostasis in embryogenesis is still unclear.
Study design, size, duration: In the primary study, we *in vitro* activated and inhibited the autophagy pathway in mouse embryonic stem cells (mESCs), respectively. Next, we performed the RNA-sequencing for each group, as well as normal control (2 samples per group), and analyzed their expression profiles.
Participants/materials, setting, methods: We used a mTOR kinase inhibitor (AZD8055) to block the mTOR pathway and activated the autophagy in mESCs. In another group, the autophagy process was down-regulated by inhibiting the lysosomes using chloroform. After extracting the total RNA from cells and depleting the ribosome RNA, libraries were generated and sequenced with paired-end reads. Then the expression profile was analyzed and the comparison was performed for activation group (AZD) and inhibition group (Chl) separately.
Main results and the role of chance: After treatment, we observed a significant increase of mESCs death in the AZD group and defined 1495 differentially expressed genes (DEGs) in the transcriptome analysis. Besides, about 366 genes aberrantly expressed in the Chl *vs* control. The main biological processes regulated by these genes included cell kill (*Tap2*), growth (*Wisp1, Rarg, Pou4f2, Dmbx1, Bmp4, Ntn1, Prox1, et al*), biological adhesion (*Nckap1, Plau, Jam2, Ccdc80, Tgfb2, Tnc, et al*) and metabolic process (*Cbr3, Apoe, Atp2b2, Abca1, Fgf8, Ighbp3, Tll1, Wnt3, et al*). In addition, we found a shared set of down-stream pathways was regulated in both groups, such as MAPK signaling pathway, Rap1 signaling pathway, TGF-beta signaling pathway, ECM-receptor interaction, Cell adhesion molecules and tight junction, which are essential pathways for normal embryo development. These molecular changes caused by altering the process of autophagy may result in abnormal cell growth and development.
Limitations, reasons for caution: We have only conducted preliminary exploration in mESCs and investigated the consequence of abnormal autophagy. The further comparison can be carried out between arrested fragmented human IVF embryos and normal embryos.
Wider implications of the findings: Studying the molecular changes influenced by autophagy could help to understanding its importance in regulating the embryo development. Our results will provide a basis on how autophagy impact the fragmentation of IVF embryos and contribute a potential new insight on optimizing culture conditions to improve the treatment of infertility.
Trial registration number: Not applicable.

P-798 Genome editing by CRISPR-Cas9 reveals that pre-implantation development in the mouse is compromised in Pou5f1-null embryos

P. Stamatiadis[1], A. Boel[1], M. Van der Jeught[1], B. Bekaert[1], R. Reddy[1], M.X. Tang[1], P. De Sutter[1], P. Coucke[2], B. Heindryckx[1]

[1] *Ghent University, Department for Reproductive Medicine Ghent University Hospital, Ghent, Belgium*

[2] *Ghent University, Center for Medical Genetics- Department of Biomolecular Medicine- Ghent University Hospital, Ghent, Belgium*

Study question: What is the role of *Pou5f1* in mouse pre-implantation development?

Summary answer: In mouse, *Pou5f1* expression is required for successful development to blastocyst stage, as *Pou5f1*-null embryos, edited by CRISPR-Cas9, exhibited a significantly lower blastocyst formation rate.

What is known already: Early mammalian embryogenesis is controlled by mechanisms that govern the balance between pluripotency and differentiation. The transcription factor Oct4, encoded by *Pou5f1*, is a key component of the pluripotency regulatory network. At blastocyst stage, the outer cells of the embryo differentiate into the trophectoderm, and *Pou5f1* expression becomes downregulated and restricted to cells of the inner cell mass (ICM). CRISPR-Cas9 has been used to examine the role of OCT4 during mouse and human preimplantation development, but the details of its effect on mouse embryonic development remain unclear.

Study design, size, duration: We compared CRISPR-Cas9 component delivery in two developmental stages, as it was previously shown in human that gene editing at an earlier stage, resulted in increased editing efficiency.

The degree of mosaicism (gene-edited vs non-edited cells within the embryo), and the mutational spectrum (different mutations within the embryo) were evaluated by immunofluorescent detection of Oct4 (n=29), PCR Fragment size Analysis (n=44) and Next Generation Sequencing (NGS) (n=24).

Participants/materials, setting, methods: An sgRNA-Cas9 mixture targeting exon 2 of *Pou5f1*, encoding the Oct4 protein, was either microinjected in mouse zygotes (n=21), or was co-injected with mouse sperm during ICSI in Metaphase-II oocytes (MII) (n=19).

The control groups consisted of sham-injected zygotes/ICSI-oocytes (n=10) and non-injected media-control zygotes/ICSI-oocytes (n=10).

Reconstructed embryos were cultured for 5 days in sequential KSOM/Cook Blastocyst medium. Embryonic development was assessed daily, with detailed scoring at blastocyst formation on day 5.

Main results and the role of chance: Genomic analysis of embryos revealed a very high gene editing efficiency at the blastocyst stage, similar for both groups, with 95.2% of embryos being edited in the zygote group and 100% in the MII group.

Within the edited embryos, no mosaicism was detected. More specifically, the edited embryos contained only mutant alleles while no wild type alleles were identified.

In addition, the mutational spectrum was similar for both groups. In the zygote group, 30% of embryos contained 1 mutant allele, compared to 40% in the MII oocyte group. The majority of embryos harbored 2-4 mutant alleles, being 70% for the zygote-group vs 60% for the MII group.

We further observed a stereotypic pattern in the type of indels introduced in independently targeted embryos, including a 28 bp deletion present in 50% of the edited embryos.

The development of *Pou5f1*-targeted embryos was compromised. In both groups, an average of 55,35% of the reconstructed embryos were arrested at the morula stage, while 32,15% formed blastocysts with reduced size blastocoel cavity and 9,5% formed blastocysts with reduced ICM. Blastocyst formation rates in the control and sham-injected groups were 86% and 88%, respectively.

Immunofluorescence analysis of reconstructed embryos confirmed efficient loss of Oct4 expression.

Limitations, reasons for caution: One of the major hurdles of CRISPR-Cas9 genome-editing in mouse embryos is the presence of a wide mutational spectrum, which may complicate phenotypic analysis of the injected embryos.

Furthermore, the efficiency of genome modification depends on the intrinsic properties of the targeted locus, and the effects may vary between targeted regions.

Wider implications of the findings: Early injection of CRISPR-Cas9 components results in absence of mosaicism and a similar mutational spectrum compared to later stage injections.

Our study reveals that CRISPR-Cas9-technology can be efficiently applied in the mouse model, paving the way for further studies on the role of key gene regulators on pre-implantation development.

Trial registration number: Not Applicable

P-799 Erythroblast Differentiation of Human Endometrium derived Induced Pluripotent Stem Cells as a Source of Autologous Transfusion

J.H. Park[1], S. Cho[1], Y.S. Choi[2], B.S. Lee[2], K. Jeong[3], J.H. Lee[2]

[1] *Gangnam Severance Hospital- Yonsei University Medical College, Obstetrics and Gynecology, Seoul, Korea- South*

[2] *Severance Hospital- Yonsei University Medical College, Obstetrics and Gynecology, Seoul, Korea- South*

[3] *Ewha Womans University Mokdong Hospital- College of Medicine- Ewha Womans University, Department of Obstetrics and Gynecology-, Seoul, Korea- South*

Study question: Are human endometrium derived induced pluripotent stem cells (iPSc) compatible as a stable source of erythroblast cells for the development of a novel autologous transfusion strategy?

Summary answer: In an effort to develop autologous transfusion source, iPS cells driven from human endometrial cells stably yielded cells of eryhroid differentiation of upto orthochromatic normoblasts.

What is known already: Due to its regenerative potential and plasticity, endometrial tissue has been described in the literature as a favorable source of tissue regeneration. Human endometrium derived iPSc have been previously described as an efficient cell source for reprogramming into a pluripotent state. Resident adult stem cells in the basalis layer of the endometrium has been proposed as a source for in vitro differentiation into various lineages, owing to its high plasticity. Although erythroid differentiation has been attempted using embryonic stem cells or fibroblast driven iPSc, endometrium driven iPSc from hysterectomy patients are tested as a stable material for autologou transfusion.

Study design, size, duration: Discarded endometrial cells were obtained from 6 donor women receiving hysterectomies due to benign conditions. The endometrial layer was dissected from the myometrium and loose endometrial cells were dissociated enzymatically. By passaging these primary cells, endometrial stromal cells were allowed to dominate. A total of 15 iPSc lines were driven from these donors using the defined Yamanaka factors, followed by a two phase feeder and non-feeder hematopoietic differentiation procedure.

Participants/materials, setting, methods: pMIG-human sox2,oct4,klf4 and c-Myc vectors were used to transduce the endometrial stromal cells. Directed differentiation of established iPS cells were conducted in two phases, first on murine bone marrow stromal feeder cells(OP-9) followed by feeder free conditions with hydrocortisone, stem cell factor, interleukin-3, recombinant erythropoietin and poloxamer188. Expression profiles of KDR,CD235a+,CD34+,CD43+ and CD 71+ were analyzed by flow cytometry and Wright-Giemsa staining was performed for morphological analysis and differential counting.

Main results and the role of chance: The treatment of donor endometrial stromal cells with β estradiol at a concentration of 0.1μM/ml resulted in iPS cell reprogramming efficiency of approximately 166 ± 5% compared with the non-treated control cells set as 100%. As a result of inducing these cells to hematopoietic fate via a 9 day co-culture with murine stromal fibroblasts, yields ranging from 8-13% was observed depending on the donor. Because the potential of these co-cultured cells to further differentiate into erythroblastic fate may not be confined to defined cell surface markers, all of the OP-9 co-cultured cells were transferred to a feeder-free system composed of hydrocortisone, stem cell factor, interleukin-3, recombinant EPO and poloxamer 188 for 17 days, stably yielding over 80% of polychromatic and orthochromatic normoblasts. Flow cytometry expression profiles of KDR, CD235a+, CD34+, CD43+ and CD 71+ were compatible with the pattern of embyonic hematopoiesis and erythropoietic differentiation. A significant yield of 52 ± 4% polychromatic erythroblasts on day 7th and 30 ± 2% orthochromatic erythroblasts were observed on the 14th day of differentiation. The fraction of orthochromatic

erythroblasts further expanded to approximately 40% on day 17, showing clinically useful yields.

Limitations, reasons for caution: Erythropoietic differentiation up to the point of counting the ratio of polychromatic and orthochromatic normoblasts were evaluated. The process of retrieving enucleated reticulocytes was not selected as the end-point in this study and still requires refinement with further extension experiments.

Wider implications of the findings: A complete process of deriving iPSc with discarded human endometrium and consecutively directing differentiation into erythroid lineage was fully described. Significant yield of polychromatic erythroblasts on day7 and orthochromatic erythroblasts were observed on day 14, which may serve as a pilot study for developing a novel autologous source of transfusion.

Trial registration number: not applicable

P-800 Urine-derived stem cells facilitate endogenous spermatogenesis restoration of busulfan-induced non-obstructive azoospermia mice by paracrine exosomes

C. Deng[1], Y. Xie[2], Z. Chi[2], O. Bin[3], L. Xiaoyan[1], D. Chunhua[1], L. Guihua[1]

[1]The sixth affiliate hospital of Sun Yat-sen University, Reproductive medicine Center, Guangzhou, China

[2]the First Affiliated Hospital of Sun Yat-sen University, Department of Andrology, Guangzhou, China

[3]Guangzhou First People's Hospital- School of Medicine, Department of Andrology, Guangzhou, China

Study question: whether transplantation of USCs or USCs exosomes (USC-exos) could promote endogenous spermatogenesis restoration in a busulfan-induced NOA mice model.

Summary answer: USCs could facilitate endogenous spermatogenesis restoration of busulfan-induced NOA mice through paracrine exosomes, but could not protect the mice testicles at early stage of destruction.

What is known already: Non-obstructive azoospermia (NOA) is the most severe issue without effective treatments in male infertility. Urine-derived stem cells (USCs) possess multipotent differentiation capacity and paracrine effects to participate in tissue repair and regeneration.

Study design, size, duration: NOA mice devided into 8 groups: Normal group, groups treated with no injection, PBS or USCs on the 0 days after busulfan administration respectively, groups treated with no injection, PBS, USCs or USC-exos on the 36 days after busulfan treatment separately.Thirty days after USCs and USC-exos transplantation, all mice were sacrified to detect spermatogenic markers.

Participants/materials, setting, methods: USCs were cultured and indentified. High-density USCs were cultured in hollow fiber bioreactor for exosomes collection. USC-exos were isolated from USCs conditional media and identified by transmission electron microscopy, western blot and Flow NanoAnalyzer. USCs and USC-exos were transplanted into interstitial space in testes of NOA mice (40 mg/kg).Immunofluorescence staining and hematoxylin and eosin (H&E) staining, *qRT-PCR* and western blot analysis were used to detect spermatogenic markers.

Main results and the role of chance: Thirty days after USCs and USC-exos transplantation, the spermatogenesis was restored by both USCs and USC-exos in NOA mice of 36 days after busulfan-treated confirmed by immunofluorescence staining and hematoxylin and eosin (H&E) staining. Moreover, spermatogenic genes (Pou5f1, Prm1 and SYCP3) and spermatogenic protein UCHL1 were significantly increased in both USCs 36 and USC-exos36 group compared to PBS treated group demonstrated by using *qRT-PCR* and western blot analysis. However, transplantation of USCs at day 0 after busulfan treatment didn't improve the spermatogenesis of NOA mice.

Limitations, reasons for caution: Despite the encouraging effect of USCs and USCs exosomes on NOA mice, the mechanism remains mysterious.

Wider implications of the findings: Our study provides a novel insight in the treatment of NOA.

Trial registration number: SYSU-IACUC-2018-000258

P-801 Increased primordial germ cell (PGC) specification from human embryonic stem cells (hESC) derived in Activin A

[4]Ghent University, Laboratory of Pharmaceutical Biotechnology- Faculty of Pharmaceutical Sciences, Gent, Belgium

[5]Leiden University Medical Centre, Department of Anatomy and Embryology, Leiden, The Netherlands

Study question: Does pluripotency state affect differentiation of hESCs into PGC-like cells and can this be enhanced by supplementing with Activin A(ActA) or using hESCs derived in it?

Summary answer: HESCs derived in ActA, in '4i' state of pluripotency support best the derivation of PGC-like-cells, which is further enhanced by supplementation with ActA during differentiation

What is known already: Stem cell derived gametes can serve as a treatment as well as a model to understand gametogenesis and infertility. Human gamete precursors or PGC-like cells can be obtained from hESCs differentiated as embryoid bodies (EBs) in the presence of Bone Morphogenetic Protein4 (BMP4), Stem-Cell Factor (SCF), Epidermal Growth Factor (EGF), human-Leukemia Inhibitor Factor (hLIF) & Rho-Kinase inhibitor (ROCKi). In mouse, 'naive' ESCs cultured in ActA form a germline competent epiblast-like condition, eventually resulting in derivation of functional oocytes and fertile offspring. In human, it remains unclear if the pluripotency state or exposure to ActA affects PGC derivation.

Study design, size, duration: Female hESC lines, UGENT 11-2 and UGENT-11-4A (derived in ActA), cultured in distinct conditions (primed, Wnt-I (Wnt pathway inhibited) and naïve (4-inhibitors (4i) and RSeT). Another male line UGENT12-3A derived in ActA was cultured in the 'primed' condition without and with continuous supplementation of ActA (UGENT-12-A2) followed by conversion to '4i' state. PGC-like cells were derived all conditions, immunostained using cell surface antibodies and quantified using flow cytometry.

Participants/materials, setting, methods: HESCs in all conditions were force-aggregated (6500 cells/EB) and cultured 4 days in embryoid body differentiation medium (EBDM) containing BMP4, SCF, EGF, hLIF and ROCKi or in EBDM with ActA (20ng/ml) in hypoxic conditions. Day 4 EBs were immunostained for OCT4, SOX17 and PDPN to identify PGC-like cells, imaged as z-stacks and quantified using FIJI, followed by analysis with one-way ANOVA. Additionally, Day4 EBs were also dissociated, immunostained with TNAP and PDPN, quantified using FACS.

Main results and the role of chance: We found that the specific pluripotency state affects the germline induction potential of hESCs. PGC-like cells co-expressing OCT4, SOX17 and PDPN, were observed in EBs from all conditions, with 4i-hESCs showing highest competency. In UGENT 11-2, 4i-hESCs yielded significantly higher number of PGC-like cells per EB than primed-hESCs ($p=0.03$) and RSeT-hESCs ($p=0.002$). In ActA-derived UGENT11-4A, the number of PGC-like cells per EB was highest in 4i-hESCs ($p=0.0003$).

We found that ActA-derived lines responded better to germline derivation. The average PGC-like cells yield from the '4i' EBs of in the conventional UGENT 11-2 was 281 PGC-like cells per EB while the ActA-derived UGENT 11-4A was 1102 PGC-like cells per EB. EBDM+ActA increased this yield significantly ($p<0.0001$).

Continuous culture of primed ActA-derived hESC in ActA did not improve the PGC-like cell yield when converted to the '4i' state . Instead, it compromised their competence to form PGC-like cells in UGENT 12-A2. The '4i' UGENT 12-2A hESCs responded to EBDM with 56% TNAP-PDPN double-positive live single cells in Day 4 EBs and showed an increased yield of TNAP-PDPN double-positive cells to 71.7% with EBDM+ActA.

Limitations, reasons for caution: The trancriptome of the stem cells and PGC-like cells derived in EBDM and EBDM+ ActA are currently being analysed.

This data would add robustness to the study as well as highlight markers in ActA-derived lines which lead to increased yield of PGC-like cells

Wider implications of the findings: The current study aims to identify PGC markers and conditions to standardise the process of deriving gametes from human pluripotent stem cells. Adaptation of culture conditions based on this knowledge may ultimately advance efforts to derive germ cells in vitro for patients currently facing sterility.

Trial registration number: This study is funded by Innovation by Science and Technology in Flanders (IWT, Project Number: 150042). The authors declare they have.

P-802 Differentiating mouse embryonic stem cells into primordial germ cell-like cells and early meiotic stages by exposure to adult interstitial and neonatal testicular cells

A. Trout[1], P. Xie[1], Z. Rosenwaks[1], G.D. Palermo[1]

[1]Weill Cornell Medicine, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.

Study question: Does culturing mouse embryonic stem cells with adult interstitial and neonatal testicular cells increase efficiency of differentiation to primordial germ cell-like cells and induce meiosis?

Summary answer: Mouse adult interstitial and neonatal testicular cells were able to support differentiation of mouse embryonic stem cells (mESCs) into male germ cells.

What is known already: Multiple studies have been conducted outlining the differentiation of mESCs into epiblast-like cells (EpiLCs), primordial germ cell-like cells (PGCLCs), and later into spermatid-like cells, through cultured media. The spermatogenesis pathway has been replicated in vitro with the goal of treating and alleviating male infertility. Expressions of Oct3/4, Nanog, DAZL, and VASA at different times of the differentiation process can identify the stage of the cells. Interstitial cells from mouse testis are known to play an important role in the development of the reproductive system and support the completion of the spermiogenic process through secretion of hormones and other factors.

Study design, size, duration: Interstitial cells isolated from adult or neonatal testes of B6D2F1 mice were plated on mesh interphases. mESCs with mouse embryonic fibroblasts were plated below and differentiated in this conditioned medium. Three wells with increasing ratios of adult or neonatal testicular cells to mESCs were used (1:5, 2:5, 3:5). Three wells with no mesh interphase were the control. Each contained approximately $1.2x10^6$ mESCs. Germ cell stage-specific biomarkers were assessed after a few days of culturing.

Participants/materials, setting, methods: Over a 6-month period, mESCs were differentiated into EpiLCs and PGCLs. Interstitial cells were isolated from adult or neonatal mouse testes using differential plating and were plated on mesh interphases. After 7 passages, mESCs were plated and cultured in the mesh interphase system at 37°C and 5% CO_2. Immunofluorescence was used to analyze the efficiency and stages of differentiation by staining with Nanog, Oct4, DAZL, and VASA.

Main results and the role of chance: At day 3 of differentiating mESCs in mesh interphase-conditioned medium containing Activin A, bFGF, and KSR, and co-culture with interstitial cells derived from adult or neonatal testis, some cells were trypsinized and analyzed by immunofluorescence. A decreased positivity of Nanog indicated the successful differentiation of mESCs into EpiLCs. Continued expression of Oct3/4 was detected in the cells at day 3, suggesting the retention of stemness. Expression of DAZL in the cytoplasm at day 5 demonstrated differentiation to PGCLC, indicating progression to the germ cell lineage. On day 8, approximately 30% expressed VASA positivity, indicating entrance to meiosis. Cells cultured in wells with a 1:5 ratio containing adult interstitial cells had greater expression of DAZL and VASA. DAZL and VASA expression was negative in the control group, suggesting the important role of the supporting testicular cells. This indicates that the presence of interstitial cells may further differentiate the EpiLCs into PGCLCs earlier on.

Limitations, reasons for caution: Despite successfully differentiating mESCs into EpiLCs and PGCLCs and early meiotic stages, the efficiency of differentiation through culture with adult and neonatal cells into spermatid-like cells need to be confirmed. Additional studies on further differentiation should be conducted to more completely study spermatogenesis in vitro.

Wider implications of the findings: Coaxing the differentiation of mouse embryonic stem cells into the early male gamete can be accomplished in the presence of factors secreted from the testicles of adult mice. Reproducing spermatogenesis in vitro may provide valuable information on overcoming male infertility due to spermatogenic arrest or germ cell aplasia.

Study question: What is the role of Steroidogenic factor 1 (SF-1) in the development of two testicular somatic cell types, Sertoli cells and Leydig cells, in human?

Summary answer: SF-1 is required for guiding the differentiation of bipotential gonad stage cells into Leydig cell-like steroidogenic and Sertoli cell-like non-steroidogenic cells early in human development.

What is known already: Steroidogenic factor 1 (SF-1), an orphan nuclear receptor encoded by *Nuclear receptor subfamily 5 group A member 1* (*NR5A1*), is essential in the reproductive and adrenal development and in endocrine regulation. In mice, loss of *Nr5a1* (Sf-1) leads to gonadal and adrenal aplasia, and in human mutations in *NR5A1* (SF-1) have been identified in patients suffering from complete or partial gonadal dysgenesis. Sf-1 expression initiates in the bipotent genital ridge and persists in testicular pre-Sertoli and Leydig cells. In mice, Sf-1 is required for fetal Sertoli and Leydig cell development and for differentiation towards steroidogenic cell lineages.

Study design, size, duration: This study was conducted using human induced pluripotent stem cells containing a Tetracycline-inducible dead Cas9 (dCas9), a Trimethoprim (TMP)-regulatable destabilization domain and CRISPR guide RNAs for targeting the *NR5A1* (SF-1) promoter. Cells were differentiated for 10 days. The levels of steroidogenic hormones were measured from culture supernatants in triplicates and induction of cyclic adenosine 3', 5'-cyclic monophosphate (cAMP) from duplicate samples.

Participants/materials, setting, methods: Cells were differentiated in basal medium containing Activin A, CHIR-99021, Dorsomorphin and Y-27632 (1d), BMP-7 and CHIR-99021 (2d), followed by differentiation in basal medium supplied with/without doxycycline (DOX) and TMP for 6 days. At day 8 of differentiation cells were stimulated with follicle stimulating hormone (FSH) and luteinizing hormone (LH) for 1, 8 or 24 hours. Gene expression levels were monitored with quantitative polymerase chain reaction (qPCR) at 7-8 time points.

Main results and the role of chance: Cell differentiation into primitive streak (PS) -like stage and intermediate mesoderm (IM) was demonstrated by detecting an increase in the expression levels of respective markers; BRACHYURY for PS and PAX2, LHX1 and OSR1 for IM. By day 8 of differentiation, bipotential gonadal markers (GATA4, WT1, LHX9 and EMX2) were expressed in the differentiated cells of both non-treated (-DOX, -TMP) and treated (+DOX, +TMP) conditions. Conditional activation of SF-1 by DOX and TMP in cells differentiating towards gonadal fate initiated expression of SF-1 at day 6 of differentiation, and the expression persisted until the completion of culturing. Notably, in cells where SF-1 was activated (+DOX, +TMP) the expression levels of steroidogenic markers (STAR, CYP11A1, CYP17A1 and HSD17B3) were greatly increased relative to the undifferentiated cells. Furthermore, by day 8-10 of differentiation an increase in the expression levels of several testicular markers: anti-Mullerian hormone (AMH), inhibin alpha subunit (INHA) and SOX9 (specific markers of Sertoli cells), and luteinizing hormone receptor (LHR, a Leydig cell marker) could be detected. By contrast, in non-treated cells the expression of SF-1, steroidogenic, and testicular markers remained at basal level.

Limitations, reasons for caution: The cell identity could not be entirely resolved with the methods applied in this study and thereby, the differentiated cells likely represent a heterogeneous population.

Wider implications of the findings: This study demonstrates that SF-1 is required for the development of testicular steroidogenic cells and for the induction of Sertoli cell-specific gene expression in human. This is the first human *in vitro* model, in which endogenous activation of SF-1 defines the testicular steroidogenic and non-steroidogenic cell fates.

[4]Women's Health Dexeus, Unit of Biostatistics, Barcelona, Spain

Study question: How can microgravity affect frozen human sperm samples? Can frozen sperm samples be safely sent to space for possible future use under different gravitational conditions?
Summary answer: Frozen sperm samples preserved in cryostraws and stored in a specific nitrogen vapour cryoshipper do not suffer significant alterations after exposure to microgravity (μG).
What is known already: Microgravity affects lipid structures and enzymatic reactions in mammalian cells. The effects of microgravity on the cardiovascular system, muscular-skeletal apparatus, nervous system and male and female reproductive systems among others have been reported. There is relatively little known about the effects of different gravitational environments than that of Earth's gravity (1G) on human gametes/embryos. Some data suggest a significant decrease in the motility of human fresh sperm samples but nothing is known about the possible effects of gravitational differences on frozen human gametes, in which state they would be transported from earth to space.
Study design, size, duration: Prospective study carried out in a University-affiliated ART centre in collaboration with a Polytechnic University and an Aeroclub specialized in aerobatic parabolic flights for scientific research. A CAP10B plane that offers short-duration hypogravity exposure was chosen to obtain microgravity conditions. The plane executed series of 20 parabolic manoeuvres,x which means 8 seconds of microgravity for each parabola. Overall 10 sperm samples obtained from 10 healthy donors were analysed after exposure to microgravity and ground gravity.
Participants/materials, setting, methods: Samples were split in two and frozen using glycerol as cryoprotector, aliquoted in high security straws and stored in liquid nitrogen until the day of the experiment when they were exposed to μG and 1G conditions. After thawing, evaluation of sperm concentration and motility using a computerized semen motility analyzer, vitality(eosin-nigrosin staining), morphology (eosin-tiazin staining), DNA fragmentation (Sperm Chromatin Dispersion) and apoptosis degree by magnetic activated cell sorting using annexin-V microbeads were performed.
Main results and the role of chance: Comparing mean values between control group (1G) and study group (μG) no significant statistical differences were found in any of the parameters analysed ($p \geq 0.05$):

- Sperm concentration (M/ml) 48.15±41.20 vs 48.05±35.37 (0.10 95% CI [-5.56;5.76])
- Sperm motility (M/ml) 16.01±12.98 vs 17.16±13.78 (-1.14 95% CI [-4.33;2.05])
- Progressive a+b sperm motility (%) 23.95±13.17 vs 22.08±11.26 (2.22 95% CI [0.94;1.25])
- Sperm vitality (%) 43.23±10.21 vs 43.94±7.80 (0.97 95% CI [0.87;1.08])
- Morphologically normal spermatozoa (%) 8.54±3.93 vs7.40±2.97 (1.14 95% CI [0.96;1.35])
- DNA sperm fragmentation (%) 12.25±5.43 vs 12.38±5.07 (0.98 95% CI [0.83;1.16])
- Apoptotic spermatozoa (%) 19.55±14.24 vs 13.09±10.34 (1.39 95% CI [0.72;2.70])

100% concordance was observed in vitality diagnosis and DNA sperm fragmentation diagnosis after μG exposure in comparison with the initial diagnosis at 1G. 90% concordance was observed in sperm concentration and sperm progressive motility diagnosis according to the World Health Organization standards, and 80% in morphological assessment according to Kruger Criteria. Minor differences observed were more probably related to heterogeneity of the sperm sample than to the effect of exposure to different gravity conditions.
Limitations, reasons for caution: Aerobatic parabolic flights offer a limited time of microgravity (5-8 seconds) as well as short periods (1-3 seconds) of hypergravity preceding and following μG. Other platforms such as Random positioning machines or the Space Station could be considered. More cases have to be analysed to confirm the results.
Wider implications of the findings: The lack of differences observed in the sperm characteristics between frozen samples exposed to microgravity and those maintained in ground conditions open the possibility of safely transporting male gametes to space and considering the possibility of creating a human sperm bank outside Earth.
