

Annex 9: Number of embryos to transfer- Evidence tables

PICO 1: Which pregnancy-related risks should be considered before the transfer of more than one embryo?

Evidence Table

Reference	Study Type	Patients Include: No. of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Eapen A, et al., <i>Fertility and sterility</i> 2020;114: 690-714.	Meta-analysis	60 studies	up to February 2020.	maternal and fetal outcomes	<p>Maternal health risk: Antenatal hospitalisation (OR 2.6; 95%CI 1.9-3.5), caesarean section (OR 3.7; 95%CI 3.3-4.1), gestational diabetes (OR 1.2; 95%CI 1.1-1.3), preterm labour (OR 6.3; 95%CI 3.6-11.0), pregnancy-induced hypertension (OR 2.0; 95%CI 1.9-2.3), preeclampsia (OR 1.9; 95%CI 1.4-2.6), placental abruption (OR 1.3; 95%CI 1.2-1.5), placenta previa (OR 0.8 ; 95%CI 0.7-0.9) and postpartum haemorrhage (OR 2.2; 95%CI 1.2-4.1).</p> <p>Fetal and neonatal risks: Congenital anomaly (OR 1.1; 95%CI 1.0-1.2), preterm birth rate (OR 8.3; 95%CI 7.8-8.9), early preterm birth rate <32 gestational weeks (OR 3.5; 95%CI 3.1-3.9), very preterm birth rate <28 gestational weeks (OR 5.5; 95%CI 5.2-5.9), low birth weight (OR 10.6; 95%CI 9.9-11.4), NICU admission rate (OR 6.5; 95%CI 5.8-7.3), perinatal mortality rate (OR 2.4; 95%CI 2.1-2.8), and stillbirth rate (OR 2.2; 95%CI 1.8-2.6).</p>	With twin pregnancies, the higher maternal risks, the greatly increased risk of premature delivery for infants, and the higher health care costs that results are consistent among studies throughout the world. The data are compelling that a strategy of one healthy baby at a time should be the objective of every IVF-ICSI treatment cycle.	
Sites CK, et al., <i>Reproductive biology and endocrinology : RB&E</i> 2020;18: 68.	Retrospective study	21,188 births,	singleton (12,810) and twin (8378) live-births from autologous or donor eggs from 2005 to 2012.	Risk of Preeclampsia	<p>the transfer of multiple embryos increased the risk of preeclampsia [aRR = 1.10 (95% CI: 1.01–1.19)].</p> <p>Relative risks were greatest for fresh non-donor cycles [aRR = 1.14 (95% CI: 1.03–1.26)].</p> <p>Vanishing twin and number of prior ART cycles was not associated with preeclampsia among singleton births [aRR = 1.18 (95% CI: 0.91–1.53)], and aRR = 1.01 (95% CI: 0.96–</p>	Among ART births, the transfer of more than 1 embryo for singleton gestations and more than 2 embryos for twin gestations	

					1.05)], respectively. Considering all twin births, the transfer of > 2 embryos increased the risk of preeclampsia [aRR = 1.09 (95% CI: 1.001–1.19)]. Vanishing triplet and number of prior ART cycles were not associated with preeclampsia among twin births [aRR = 0.93 (95% CI: 0.69–1.264), and aRR = 0.98 (CI: 0.95–1.02)], respectively.	increased the risk for preeclampsia diagnosis.	
Luke B, et al., <i>Journal of assisted reproduction and genetics</i> 2021;38: 835-846.	Retrospective study	138,435 children	Children born 2004–2013 (Texas), 2004–2016 (Massachusetts and North Carolina), and 2004–2017 (New York) were classified by ET and Fetal heartbeat FHB: [ET=1, FHB=1] was defined as the reference group; [ET=2, FHB=1] and [ET=3, FHB=1] were the excess embryos transferred groups; and [ET≥2, FHB≥2] was the excess embryos transferred and excess fetal heartbeats group. For twin births, [ET=2, FHB=2] was defined as the reference group; [ET=3, FHB=2] and [ET≥4, FHB=2] were the excess embryos transferred groups; and [ET≥3, FHB≥3] was the excess embryos transferred and excess fetal heartbeats group	Major nonchromosomal birth defect, small-for-gestational age birthweight (SGA), low birthweight (LBW), and preterm birth (≤36 weeks), by excess ET, and excess ET + excess FHB, by plurality at birth (singletons and twins).	In singletons with [2 ET, FHB=1] and [≥3 ET, FHB=1]: risks [AOR (95% CI)] were increased, respectively, for major nonchromosomal birth defects (OR 1.13; 95%CI 1.00–1.27 and OR1.18; 95%CI 1.00–1.38), SGA (OR 1.10; 95%CI 1.03–1.17 and OR 1.15; 95%CI 1.05–1.26), LBW (OR1.09; 95%CI 1.02–1.13 and OR1.17; 95%CI 1.07–1.27) Preterm birth OR1.06; 95%CI 1.00–1.12 and OR1.14;95%CI 1.06–1.23). With excess ET + excess FHB, risks of all adverse outcomes except major nonchromosomal birth defects increased further for both singletons and twins.	Excess embryos transferred are associated with increased risks for nonchromosomal birth defects, reduced birthweight, and prematurity in IVF-conceived births	

<p>van Heesch M Met et al., <i>Acta obstetricia et gynecologica Scandinavica</i> 2014;93: 277-286.</p>	<p>Retrospective cohort</p>	<p>3041 singleton and 907 multiple pregnancies following IVF/ICSI. Groups comparable in terms of maternal age, parity, ethnicity, BMI, socio-economic status</p>	<p>Maternal and neonatal complications in singleton versus multiple pregnancies. Follow up till birth, mean 40 weeks.</p>	<p>Need for caesarean section, birthweight, gestational age, small for gestational age, NICU admission, perinatal mortality.</p>	<p>Singleton vs multiple: caesarean section 22.5% vs 41%; OR 2.49; 95%CI 2.19 - 2.84 birthweight 3362g vs 2441g gestational age in weeks 39.4 vs 36.3 Small for gestational age 11.5% vs 22.4%; OR 2.26; 95%CI 1.92 - 2.64 NICU admission 2.8% vs 12.2%; OR 5.01; 95%CI 3.80 - 6.61 perinatal mortality 0.4% vs 1%; OR 2.61; 95%CI 1.22 - 5.59</p>	<p>Perinatal outcomes in IVF/ICSI-conceived multiples are considerably poorer than in singletons.</p>	
<p>Pinborg A, et al., <i>Acta obstetricia et gynecologica Scandinavica</i> 2004;83: 75-84.</p>	<p>Retrospective cohort</p>	<p>236 twin pregnancies, 634 singleton pregnancies and 566 non-IVF twin pregnancies. Groups comparable in terms of parity, social class, duration of infertility and treatment.</p>	<p>Maternal and neonatal complications in singleton versus multiple pregnancies. Follow up till birth, mean 40 weeks.</p>	<p>Pregnancy induced hypertension, pre-eclampsia, gestational diabetes, admission to hospital, caesarean section, birthweight, prematurity <37 weeks</p>	<p>IVF twin vs non-IVF twin: pregnancy induced hypertension: OR 1.0; 95% CI 0.7 - 1.6 pre-eclampsia OR 1.6 95% CI 1.1 - 2.6; gestational diabetes OR 2.0 95% CI 0.9-4.2 admission OR 1.8 95% CI 1.3 - 2.5; caesarean section 58.1% vs 44.0%; birthweight 2509g vs 2578g prematurity 52.1% vs 49.3% </p> <p>IVF twins vs IVF singletons: pregnancy induced hypertension OR 1.3 95% CI 0.8 - 2.0 pre-eclampsia OR 2.3 95% CI 1.4-3.8 gestational diabetes OR 1.4 95% CI 0.7 - 2.7 admission OR 3.4 95% CI 2.5 - 4.7 caesarean section 58.1% vs 26.2% birthweight 2509g vs 3387g prematurity <37 weeks 52.1% vs 17.9%</p>	<p>Although this population study indicates that maternal risks in IVF/ICSI twin pregnancies are comparable with non-IVF/ICSI twin pregnancies, the IVF/ICSI twin mothers were more likely to be on sick leave or hospitalized during pregnancy. Furthermore, maternal risks were higher and obstetric outcome poorer in IVF/ICSI twin vs. IVF/ICSI singleton pregnancies.</p>	
<p>Makhseed M, et al., <i>International journal of gynaecology and obstetrics: the official organ of the International Federation of Gynaecology and Obstetrics</i> 1998;61: 155-163.</p>	<p>Retrospective cohort</p>	<p>31 twins, 22 triplets, 5 quads, 58 singletons. No data on baseline characteristics.</p>	<p>Maternal and neonatal complications in singleton versus multiple pregnancies. Follow up till birth, mean 40 weeks.</p>	<p>Gestational diabetes, pregnancy induced hypertension, gestation at birth, birthweight, caesarean section</p>	<p>Singleton vs twins vs triplets vs quads: gestational diabetes 13.8% vs 16.1% vs 11% vs 0%; pregnancy induced hypertension 18.9% vs 16.1% vs 33.3% vs 33.3% gestational age at birth 37.1 vs 35.8 vs 30.1 vs 33.6 weeks birthweight 3086g vs 2380g vs 1300g vs 1670g prematurity <37 31% vs 67.7% vs 100% vs 100% caesarean section 74.1% vs 90.3% vs 88.9% vs 100%</p>	<p>There was a significantly higher maternal and neonatal complication rate in the triplet group compared to singletons and twins, including threatened miscarriage, pre-eclampsia,</p>	

						antepartum haemorrhage, longer hospital stay and preterm labor.	
D'Souza SW, et al., <i>Archives of disease in childhood Fetal and neonatal edition</i> 1997;76: F70-74.	Retrospective cohort	278 children (150 singletons, 100 twins, 24 triplets and four quadruplets), conceived by IVF after three fresh embryos had been transferred, 278 naturally conceived singletons.	Maternal and neonatal outcomes in IVF singletons vs multiples vs natural singletons. Follow up till birth, mean 40 weeks.	Gestation at birth, birthweight, caesarean section	IVF singleton vs IVF multiple vs Natural singletons: gestation at birth 38.4 vs 35.2 vs 39.4; birthweight 3016g vs 2078g vs 3380g; caesarean section 26.7% vs 55.5% vs 6.8%	The outcome of IVF treatment leading to multiple births is less satisfactory than that in singletons because of neonatal conditions associated with preterm delivery and disabilities in later childhood. A reduction of multiple pregnancies by limiting the transfer of embryos to two instead of three remains a high priority.	
Gupta R, et al., <i>Journal of human reproductive sciences</i> 2020;13: 56-64.	Retrospective cohort	897 singleton and 382 twin pregnancies. Maternal age similar between groups.	Maternal and neonatal outcomes in IVF singletons vs multiples. Follow up till birth, mean 40 weeks.	Pre-eclampsia, premature rupture of membranes, antepartum haemorrhage, gestational diabetes, composite of maternal complications, gestation and birthweight at delivery	Singletons vs twins: pre-eclampsia OR 1.35 95% CI 0.93-1.96; premature rupture of membranes OR 2.32 95% CI 1.48-3.64 antepartum haemorrhage OR 1.94 95% CI 0.80-4.73 gestational diabetes OR 0.88 95% CI 0.34-2.26 composite maternal complications OR 1.53 95% CI 1.17-2.01 gestational age at delivery 37.2 vs 35 birthweight 2760g vs 2030g	Twin deliveries, following IVF/ICSI deliver at lower gestational age, have lower birth weight and have higher odds of stillbirth plus neonatal death as compared to singleton deliveries following IVF/ICSI	

Papers included as background information
(Kamath et al., 2020)

PICO 2. Which financial issues should be considered for couples/individuals planning a singleton or multiple pregnancy/birth?

Evidence Table

Reference	Study Type	Patients Include: No. of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Hernandez Torres E, et al., <i>Fertility and sterility</i> 2015;103: 699-706.	RCT	121 women (<38 years old), undergoing their first or second IVF cycles.	Women in group 1: SET + eSFET; Women in group 2: DET From January 2010 to December 2012		cLBR: eSET+ eSFET group vs DET: 38.60% vs 42.19% MPR: SET+eSFET vs. DET. 0 vs 25.9% The mean costs/ patient: eSET+ eSFET vs DET 5,614.11 vs vs 5,562.29 €, (NS)	This study does not show that eSET is superior to DET in terms of effectiveness or of costs.	
Lukassen HG, et al., <i>Human reproduction (Oxford, England)</i> 2005;20: 702-708.	RCT	107 patients with at least one good quality embryo available for transfer	2 cycles SET: 54 patients vs one cycle DET: 53 patients	Cumulative live birth rate Multiple pregnancy rate Medical cost/live birth	cLBR/woman: 2 consecutive SET vs DET: 41% (95% CI: 27–54] vs 36% (95%CI 23–49), NS MPR : SET vs DET: 0% vs 37% (95% CI 15–59)(P=0.002). Medical cost/live birth: SET vs DET: 13 438 € vs 13 680 €.	Two cycles with SET were equally effective as one cycle with DET, and the medical costs per live birth up to 6 weeks after delivery were the same. However, if lifetime costs for severe handicaps are included, more than €7000 per live birth will be saved after implementing SET.	

Lukassen HG, et al., <i>Fertility and sterility</i> 2004;81: 1240-1246.	Retrospective cost analysis	279 pregnancies 135 Singleton pregnancies 144 twin pregnancies	No intervention Medical costs per singleton and twin pregnancy after IVF Between 1995 and 2001	Medical costs per singleton and twin pregnancy after IVF	In patients pregnant with twins, the incidence of hospital antenatal care, complicated vaginal deliveries, and caesarean sections was higher and was associated with more frequent and longer maternal and neonatal hospital admissions. Maternal and neonatal hospital admissions were the major cost drivers. Total medical costs: singletons vs Twins: €2,549 vs €13,469.	The medical cost per twin pregnancy was more than 10,000 higher than per singleton pregnancy. A reduction in the number of twin pregnancies by elective single ET will save substantial amounts of money.	
Kjellberg AT, et al., <i>Human reproduction (Oxford, England)</i> 2006;21: 210-216.	RCT	661 women <36y, first or second IVF cycle with at least two good quality embryos	330 SET vs 331 DET	Maternal and Paediatric costs for health care Costs of productivity losses Quality of life	SET vs DET (330 women): Total health cost: €3069989 vs €4064837 Mean health cost per woman: €9309 vs €12318, p=0.002 Difference of additional cost for DET: €994848 Incremental Cost-effectiveness ratio ICER: €73307 per extra deliver live-born child Incremental ICER + productivity: €91701	The SET strategy is superior to the DET strategy, when number of deliveries with at least one live-born child, incremental cost-effectiveness ratio and maternal and paediatric complications are taken into consideration.	
Carpinello OJ, et al., <i>Applied health economics and health policy</i> 2016;14: 387-395.	Retrospective cohort study	Medical records of patients who conceived with IVF (n = 116)	No intervention between 2007 and 2011	Healthcare costs per cohort, extrapolated costs assuming 100 patients per cohort, and incremental costs per infant delivered	SET vs DET vs ≥3 embryos: Premature singleton deliveries: 6.3 % vs 9.1 % vs 10.0 %. caesarean delivery 26.7 % vs 36.6 % vs 47.1 %. Extrapolated costs per cohort US\$718,616 vs US\$1,713,470 vs US\$1,227,396	Attempting to improve IVF pregnancy rates by permitting multiple embryo transfers results in sharply increased rates of multiple gestation and preterm delivery. This practice yields a greater frequency of adverse perinatal outcomes and substantially increased healthcare spending.	
Gerris J, et al., <i>Human reproduction (Oxford, England)</i> 2004;19: 917-923.	prospective observational study	367 patients: 30.9y	206/367 (56.1%) SET vs 161/367 (43.9%) DET from January 1, 2000, until December 31, 2001	LBR Neonatal costs and Maternal costs Total costs	SET vs. DET: LBR: 37.4% vs. 36.6%. duration of pregnancy: 39.0 ± 1.4 vs 38.3 ± 2.2 weeks; P = 0.055), percentage prematurity: 8.5 vs 23.8%; P = 0.033 Percentage of neonates hospitalized:	transfer of a single top-quality embryo is equally effective as, but substantially cheaper than, double embryo transfer in women <38 years of	

					<p>5.7 vs 17.9%; P = 0.121</p> <p>Duration of neonatal hospitalization 6.3 ± 2.2 vs 10.3 ± 10.1 days; P = 0.01.</p> <p>Total cost: €4700 ±3239 vs €8613± 10 105; P = 0.105)</p> <p>Neonatal costs: €451± 957 vs €3453±8154; P < 0.001</p> <p>Maternal costs: €4250± 2882 vs €5160 ±4106; P = 0.152</p>	age in their first IVF/ICSI cycle.	
<p>Veleva Z, et al., Human reproduction (Oxford, England) 2009;24: 1632-1639.</p>	observational study	In the DET period, 826 women had 1359 fresh and 589 FET cycles; in the eSET period, 684 women had 1027 fresh and 683 FET cycles	the DET period (fresh cycles: 1995–1999, FET cycles: 1995–2000), in which eSET was used experimentally; and the eSET period (fresh cycles: 2000–2004, FET cycles: 2000–2005), in which eSET was more routinely practiced.		<p>cPR/OPU: 38.2 vs 33.1%, P = 0.01</p> <p>cLBR/OPU: 28.0 vs 22.5%, P = 0.002</p> <p>cLBR/woman: 41.7 vs 36.6%, P = 0.04.</p> <p>cMPR: 8.9 vs 19.6%, P = 0.0001.</p> <p>eSET vs DET: Total costs: €3837964 vs €4865304</p> <p>Costs of the fresh cycles: €3383250 vs €4473172 (OR 0.95 (95%CI 0.91-0.97))</p> <p>Costs of the FET cycles: €454714 vs €5890 (OR 1.03 (95%CI 0.997-1.07))</p> <p>Total costs per woman: €5611 vs €5890</p> <p>A term live birth in the eSET period was 19 889 euros less expensive than in the DET period.</p>	eSET with cryopreservation is more effective and less expensive than DET and should be adopted as a treatment of choice.	
<p>Velez MP, et al., Human reproduction (Oxford, England) 2014;29: 1313-1319.</p>	Prospective comparative cohort study	7364 IVF cycles performed in Quebec	<p>Period I: IVF treatment in Quebec during 2009, before implementation of the public IVF programme</p> <p>Period II: cycles performed at the same centres during 2011</p>	utilization, pregnancy rates, multiple pregnancy rates and costs.	<p>2009 vs. 2011: eSET transfer in 1.6% of the cycles vs 31.6% (P, 0.001).</p> <p>CPR 39.9% vs. 24.9% (P, 0.001),</p> <p>MPR: 29.4% vs. 6.4 (P,0.001).</p> <p>Government costs per IVF treatment cycle: CAD\$3730 vs CAD\$4759.</p> <p>Cost per live birth (up to 1 year post-delivery): CAD\$49 517 to CAD\$43 362 per baby conceived by either fresh and frozen cycles.</p>	Universal coverage of IVF increased access to IVF treatment, decreased the multiple pregnancy rate and decreased the cost per live birth, despite increased costs per cycle.	
<p>van Heesch MM, et al., Human reproduction (Oxford, England)</p>	Retrospective study	302 multiples and 278 singletons.	children born from IVF in 2003–2005,	Hospital resource utilization Hospital costs	<p>Multiples vs singletons: The risk of hospitalization: OR 4.9, 95% CI 3.3–7.0</p> <p>Outpatient visits: OR 2.6, 95% CI 1.8–3.6</p> <p>Medical procedures: OR 1.7, 95% CI 1.2–2.2</p>	Hospital costs from birth up to age 5 were significantly higher among IVF/ICSI multiple children compared with IVF/	

<p>2015;30: 1481-1490.</p>					<p>The average hospital costs: -during the birth admission period: €10 018 vs €2093 (P, 0.001) -After the birth admission period to the first birthday: €1131 vs €696 (n.s.) -From the second to the fifth life year: €1084 vs €938, (n.s.)</p> <p>Hospital costs from birth up to age 5 were 3.3-fold higher for multiples compared with singletons (P, 0.001).</p> <p>Among multiples and singletons, respectively, 90.8 and 76.2% of the total hospital costs were caused by hospital admission days and 8.9 and 25.2% of the total hospital costs during the first 5 years of life occurred after the first year of life.</p>	<p>ICSI singletons; however, when excluding the costs incurred during the birth admission period, hospital costs of multiples and singletons were comparable.</p>	
<p>Motohashi T, et al., <i>Reproductive medicine and biology</i> 2004;3: 159-164.</p>	<p>observational study</p>	<p>Control group: 58 singletons and 21 twins; High-order multiple group: 14 triplets and 1 quadruplets</p>	<p>No intervention: between 1997 and 2002</p>	<p>gestational ages: The average inpatient medical care cost for mother and child(ren), from maternal admissions after 12 weeks' gestation to the discharge of all family members from hospital,</p>	<p>gestational ages: 39.4 (singletons), 35.6 (twins), 31.9 (triplets) and 25.1 (quadruplets) weeks (P < 0.001 by ANOVA). Birthweights: 2886 ± 425 g, 2117 ± 623 g, 1430 ± 373 g, and 633 ± 77 g (mean ± SD), respectively (P < 0.001). The average inpatient medical care cost for mother and child(ren), from maternal admissions after 12 weeks' gestation to the discharge of all family members from hospital, was ¥703 279 yen (~US\$5861), ¥4 903 270 (~US\$40 861), ¥11 810 327 (~US\$98 419), and ¥44 961 000 (~US\$374 675), respectively (P < 0.001).</p>	<p>The present study outlined the high costs of medical care for HOM pregnancies.</p>	
<p>Koivurova S, et al., <i>Human reproduction (Oxford, England)</i> 2004;19: 2798-2805.</p>	<p>obs study</p>	<p>215 IVF mothers and 225 IVF neonates vs 662 control mothers and 388 control children</p>	<p>No intervention; 1990-1995</p>		<p>The total health care costs for an IVF singleton until the end of the neonatal period were 5780 euros and 15 580 euros for an IVF twin.</p> <p>The health care costs were 1.3-fold for IVF singletons and 1.1-fold for IVF twins compared to control singletons and twins.</p>	<p>The health care costs of an IVF singleton neonate were higher than those of a spontaneously conceived control neonate with similar backgrounds. For twins the health care costs were equal.</p>	

					The costs for twins were ~3-fold compared to singletons		
Chambers GM, et al., JAMA pediatrics 2014;168: 1045-1053.	Retrospective population cohort study	Conceived following ART: 1% of 226 624 singleton, 15.4% of 6941 twin, and 34.7% of 285 HOM infants.	No intervention	economic and health services assessment of the frequency, duration, and cost of hospital admissions during the first 5 years of life for singleton, twin, and higher-order multiple (HOM) children Contribution of ART to the incidence and cost of multiple births	Undesirable effect Twins and HOMs > singletons Stillbirth: 3.4 and 9.6 times; Neonatal death: 6.4 and 36.7 times Preterm birth: 18.7 and 525.1 times Small for gestational age 3.6 and 2.8 times The mean hospital costs of a singleton, twin, and HOM child to age 5 years were \$2730, \$8993, and \$24 411 (in 2009-2010US dollars), respectively.	Compared with singletons, multiple-birth infants consume significantly more hospital resources, particularly during the neonatal period and first year of life.	
Fiddellers AA, et al., Human reproduction (Oxford, England) 2006;21: 2090-2097.	observational study Cost analysis of a RCT (Van Montfoort et al., 2006)	308 couples, first IVF cycle with at least two embryos (2PN) available	154 SET vs 154 DET; January 2002 to December 2004	cost-effectiveness of one fresh cycle eSET versus one fresh cycle DET	Successful pregnancy rates were 20.8% for eSET and 39.6% for DET. Societal costs per couple were significantly lower after eSET (€7334) compared with DET (€10 924). The ICER of DET compared with eSET was €19 096, meaning that each additional successful pregnancy in the DET group will cost €19 096 extra.	One cycle eSET was less expensive, but also less effective compared to one cycle DET.	
Stillman RJ, et al., Fertility and sterility 2009;92: 1895-1906.	retrospective study	Infertile women undergoing 15418 consecutive IVF; good prognosis patients.	eSET: 583 autologous + 201 donor cycle vs DBT: 3300 autologous+ 783 donor cycle; January 2002 to December 2007		eSET vs. DET: PR: 65% vs. 63% MPR (Twin rate) 1% vs. 44%. Donor cycles PR 63% vs. 74% MPR: 2% vs. 54%. There was no decrease in overall pregnancy rates: 1.5% to 8.6% of all autologous transfers and 2.0% to 22.5% of all transfers to donor oocyte recipients	Selective eSET use among good-prognosis patients can significantly reduce twin pregnancies without compromising pregnancy rates. Patients are more likely to choose eSET when freed from financial pressures to transfer multiple embryos.

Wenze SJ. et al., <i>Archives of women's mental health</i> 2015;18: 163-176.	Systematic review	27 papers (between 1989-2014). More than 40.000 patients. parents of multiples vs parents of singletons	No intervention	mental health outcomes in the postpartum and early childhood periods: symptoms of depression, anxiety, and parenting stress		mental health outcomes in the postpartum and early childhood periods are, in general, worse for parents of multiples versus parents of singletons, and may be worse in the case of higher-order multiples versus twins. In contrast, we found no clear evidence for differences in mental health outcomes in the antenatal period between women expecting singletons versus multiples. Postpartum (but not early parenthood) outcomes may be worse for parents of multiples resulting from ART versus NC multiples, while maternal antenatal depressive symptoms may be higher among women with NC multiples versus ART.	
van den Akker O. et al., <i>Reproductive biomedicine online</i> 2016;33: 1-14.	Systematic review	8 papers, 1732 mothers.	No intervention	-depression, anxiety or stress of assisted reproductive technology twins/multiple birth mothers versus assisted reproductive technology singleton birth mothers;		Mothers of assisted reproductive technology multiple births exhibit significantly more stress and depression compared with mothers of assisted reproductive technology singleton births.	

				-depression, anxiety or stress of assisted reproductive technology twins/multiple birth mothers versus natural conception twins/multiple birth mothers.			
Porat-Zyman G. et al. <i>Women & health</i> 2018;58: 72-91.	Systematic review	2001-2012: 561 mothers	No intervention	maternal mental health (MMH) 1-month post-partum changes in MMH over 4 years in relation to birth circumstances (singleton/twins, full-term/pre-term infant/s, first/non-first child), internal resources (adult attachment styles), and external resources (marital quality and maternal grandmother's support) at 1 month post-partum.		Shortly after birth, mothers at risk for poorer MMH were those who gave birth prematurely or were characterized by insecure attachment styles, lower marital quality, younger age, or a higher level of education. The mothers with a good prognosis for improvement in MMH were those who had given birth prematurely or were younger, more highly educated, or multiparous. Women with insecure attachment or lower marital quality reported lower MMH one month after delivery that did not improve over time, and the MMH of older or less educated mothers deteriorated over time. Marital quality mitigated or exacerbated the effects of birth circumstances and insecure attachment style on MMH shortly after giving birth.	
Noy A, et al. <i>Women & health</i> 2014;54: 317-335.	Observational study	274 mothers. Of these, 127 were mothers of singletons and 147 mothers of twins.	No intervention	Mother's well-being and distress		being a mother of a singleton or twins did not contribute to the explanation of variance in well-being or distress. Marital quality provided the strongest explained variance for both well-being and distress. Mother's health, attachment anxiety and self-differentiation also explained significant amounts of the variance.	

De Roose M, et al. <i>Women and birth : journal of the Australian College of Midwives</i> 2018;31: e197-e203.	Observational study	151 singleton mothers and 101 twin mothers	No intervention	parenting stress levels		Coparenting seems to be a significant coping strategy reducing the level of parenting stress in singleton and twin mothers, irrespective of their personal and obstetric characteristics.	
Spinelli M, et al. <i>Journal of family psychology : JFP : journal of the Division of Family Psychology of the American Psychological Association (Division 43)</i> 2013;27: 873-883.	Observational study	125 mothers and their preterm infant	No intervention	Parenting stress and maternal interaction quality during play were measured at 4, 24, and 36 months corrected age.		Mothers of multiples and infants with more medical risks and shorter hospitalization, and mothers with lower education and more depressive symptoms, reported more parenting stress at 4 months of age. Parenting stress decreased over time for mothers of multiples and for mothers with lower education more than for mothers of singletons or for mothers with higher educational levels. Changes in parenting stress scores over time were negatively associated with maternal behaviours during mother-infant interactions.	
Boivin M, <i>Journal of child psychology and psychiatry, and allied disciplines</i> 2005;46: 612-630.	Observational study	Parents (2122 mothers and 1829 fathers) of 5-month-old infants, and parents of 5-month-old infant twins (510 families)	No intervention	parenting perceptions and behaviours: parental self-efficacy, perceived parental impact, parental hostile-reactive behaviours and parental overprotection genetic-environmental aetiology analysis			
Anderson KN et al., <i>Family process</i> 2017;56: 997-1011.	Observational study	57 families with eighty 6- to 12-year-old MAR twin and singleton children	No intervention	Parent-child relationships and interactional behaviours twins vs singletons			

Golombok S, et al., <i>Human reproduction (Oxford, England)</i> 2007;22: 2896-2902.	Observational study	10 families with triplets and matched groups of 15 families with twins and 30 families with singletons.	No intervention	Standardized measures of the mother's psychological well-being (parenting stress, depression and quality of marriage) and standardized measures of the child's psychological development (emotional/behavioural problems and general development) were completed by the mother.		The birth of triplets or twins does appear to cause difficulties for parents in the early years, however, the children themselves do not seem to experience markedly raised levels of psychological or developmental problems.

Couples/individuals undergoing ART with own oocytes							
Ma S, et al. Reproductive biology and endocrinology: RB&E 2022;20:20.	Systematic review and meta-analysis	14 RCTs and 71 observational studies	Studies published through to February 2021. SET vs DET; single IVF cycle with own oocytes	CPR, LBR, MPR, miscarriage rate, Preterm birth rate, gestational age at birth, low birth weight rate, Perinatal mortality, birth defect, NICU admission., caesarean section, gestational diabetes, PE, antepartum haemorrhage, Apgar score 1 <7.	LBR: Patients aged <35y: DET > SET (OR 0.71, 95%CI 0.61-0.84, I2= 85%, 12 studies) Patients aged 35-40y: DET >SET (OR 0.80, 95%CI 0.69-0.94, I2= 69%, 6 studies), Patients aged ≥40 years: No difference (OR 0.87, 95% CI 0.54–1.40, I2=69%, P=0.565, 4 studies). MPR: Patients aged <35y: DET > SET (OR 0.03; 95%CI 0.03-0.05, I2= 0%, P<0.0001, 11 studies) Patients aged 35-40y: DET>SET (OR 0.04, 95%CI 0.03-0.06, I2= 0%, P<0.001, 5 studies) Patients aged ≥40 years: No difference (OR 0.34, 95%CI 0.06-2.03, I2= 0%, P=0.236, 3 studies). Preterm birth: In all age categories: DET >SET (9.9% vs 31%, OR 0.25, 95%CI 0.21-0.30, I2=0%, P<0.001, 13 studies)	In women aged <40years or if any GQE is available, SET should be incorporated into clinical practice. While in the absence of GQEs, DET may be preferable. However, for elderly women aged ≥40 years, current evidence is not enough to recommend an appropriate number of embryo transfer;	

<p>Kamath MS, et al., The Cochrane database of systematic reviews 2020;8: Cd003416</p>	<p>Cochrane review</p>	<p>17 RCTs, 2505 women most women included in the studies were under 36 years of age, with a good prognosis.</p>	<p>A single cycle of SET was compared with a single cycle of DET in 13 studies, 11 comparing cleavage-stage transfers and three comparing blastocyst-stage transfers. One study reported both cleavage and blastocyst stage transfers.</p>	<p>Primary outcomes: LBR and MPR Secondary outcomes: CPR and Miscarriage rate.</p>	<p>LBR: DET>SET (RR 0.67, 95% CI 0.59 to 0.75; I2 = 0%; 12 studies, 1904 participants; low-quality evidence). MPR: DET>SET (Peto OR 0.16, 95% CI 0.12 to 0.22; I2 = 0%; 13 studies, 1952 participants; moderate-quality evidence).</p>	<p>Although DET achieves higher live birth and clinical pregnancy rates per fresh cycle, the evidence suggests that the difference in effectiveness may be substantially offset when elective SET is followed by a further transfer of a single embryo in fresh or frozen cycle, while simultaneously reducing multiple pregnancies, at least among women with a good prognosis.</p>	
<p>Mejia RB, et al. F&S reports 2021;2: 50-57.</p>	<p>retrospective study</p>	<p>49333 patients aged 21 to 45 years; with initial oocyte retrievals cycles Age categories: <35, 35–37, 38–40, and>40y; Gravidity: 0; Parity: 0</p>	<p>Initial eSET (n=17576) vs DET (n= 31757) January 2014 – December 2015 + subsequent frozen embryo transfers occurring through December 2016 that used embryos from the initial retrieval (n=725)</p>	<p>Primary outcomes: LBR, cLBR, Secondary outcomes: MPR, Preterm birth, cycle to pregnancy, infant birthweight, and perinatal mortality</p>	<p>eSET vs. DET: cLBR: In all age categories: 74% vs 57 % (AOR 1.32, 95% CI 1.26-1.38). < 35y: AOR 1.31, 95% CI 1.24-1.39 35-37y: AOR 1.27, 95% CI 1.15-1.40 38-40y: AOR 1.06; 95%CI 0.90-1.24 >40y: AOR 1.36; 95%CI 0.91-2.04 MPR: In all ages categories: 8% vs 34% (AOR 0.13; 95%CI 0.12-0.14) <35y: AOR 0.14; 95%CI 0.12-0.17 35-37y: AOR 0.10, 95% CI 0.06-0.16 38-40y: AOR 0.12; 95%CI 0.11-0.13 >40y: AOR 0.31; 95%CI 0.07-1.39 Preterm birth: 1.2 % vs 2.8%. Perinatal mortality: 0.5% vs 1.2%.</p>	<p>The association of initial eSET with a higher cLBR and markedly improved perinatal outcomes outweigh the relatively minor increase in time to pregnancy, reinforcing the guidance for eSET in initial transfer cycles, particularly in younger patients with a good prognosis.</p>	
<p>Veleva Z, et al., Human reproduction (Oxford, England) 2006;21: 2098-2102.</p>	<p>retrospective study</p>	<p>women 36-39 years</p>	<p>eSET vs. DET: 1224 fresh cycles; 828 frozen embryo transfer (FET): 335 eSET of top-quality embryo, 110 eSET of non-top-quality embryo (nt-eSET), 194 compulsory single embryo (cSET) and 585 DET</p>	<p>LBR and cLBR</p>	<p>eSET of top-quality embryo and nt-eSET of non-top-quality embryo vs. DET: LBR: 26% and 15.5% vs. 21.9% cLBR 41.8% and 29.1% vs 26.7% MPR: 1.7% and 2.8% vs. 16.6%</p>	<p>The eSET policy can be applied also to patients aged 36–39 years, reducing the risk of multiple birth and increasing the safety of assisted reproduction technique (ART) in this age group.</p>	
<p>Niinimäki M, et al., Human reproduction</p>	<p>retrospective</p>	<p>628 women 40-44 years. The characteristics</p>	<p>women treated between 2000-2009. eSET (n= 264) vs. DET (n=364)</p>	<p>LBR and cLBR MPR and cMPR (twins rate in fresh cycle and the cumulative</p>	<p>eSET vs. DET: LBR: 11 vs 13.6% cLBR: 13.2 vs 22.7%</p>	<p>An eSET policy can be applied with gratifying cumulative clinical pregnancy and live birth rates in older</p>	

ion (Oxford, England) 2013;28: 331-335.	cohort	of the two patients' groups are not comparable	In the subsequent frozen-thawed embryo transfer cycles, SET/DET was performed in both groups according to the number of embryos available and the opinion of the couple.	twins rate in subsequent cycles)	MPR: fresh cycle: 0% vs. 7.5% cMPR: 6.7% vs 8.3% All of the twin pregnancies in the eSET group resulted from frozen and thawed DET embryo transfer cycles.	women (40–44 years) with a good prognosis.
Tannus S, et al., Reproductive biomedicine online 2017;35: 733-738.	retrospective study	411 women aged 41- 43y.	SET vs DET in fresh blastocyst transfer cycles. eSBT	LBR, MPR, cLBR, cMPR	eSET vs. DET; Fresh cycles: LBR: 19.3% vs. 26.5%. MPR: 0% vs 17.5% eSET vs DET; frozen cycles: LBR: 9.4% vs. 13.7 %; cLBR: 28% vs 31.1%. cMPR: 0% vs. 14.9%, p= 0.03.	Women aged 40-43y, when fully expanded blastocysts are achieved, maternal age is not a predictor for live birth, and elective single blastocyst transfer can be performed without compromising cLBRs.
Lawlor DA, Nelson SM. Lancet (London, England) 2012;379: 521-527.	prospective study	124,148 IVF cycles; Age categories: 18-34 (53821); 35-37 (32178); 38-39 (18874); 40-42 (15145); 43-44 (3200); 45-50 (930)	between January 2003, and December 2007. SET (14749; 10.5%), DET (117378 (83.3%) or TET (8772 or 6.2%)	Outcomes: LBR, MPR, low birthweight (<2.5 kg), preterm birth (<37 weeks), and severe preterm birth (<33 weeks) in women younger than 40 years and those aged 40 years or older.	<40 years; SET vs. DET LBR: OR 2.33, 95% CI 2.20–2.46 MPR: OR 20.6; 05%CI 14.14-29.93 Preterm birth: OR 2.25; 95%CI 1.91-2.66 Severe preterm birth: OR 2.33; 95%CI 1.68-3.24 ≥40 years; SET vs. DET LBR: OR 3.12, 95% CI 2.58-3.77 MPR: OR 4.32; 05%CI 1.57-11.9 Preterm birth: OR1.27; 95%CI 0.72-2.23 Severe preterm birth: OR1.02; 95%CI 0.35-2.89	Transfer of three or more embryos at any age should be avoided. The decision to transfer one or two embryos should be based on prognostic indicators, such as age and the number of embryos successfully fertilised
Arab S, et al., Reproductive sciences (Thousand Oaks, Calif) 2020.	retrospective study	1140 FET cycles; 818 women aged up to 39y and 97 women aged 40y or older.	FET cycles between January 2008 and December 2019 in women aged ≤ 39y: 744 SET vs 74 DET; women ≥40y: 63 SET vs 34 DET	CPR, LBR and MPR	≤ 39y: SET (n=744) vs. DET (n=74) LBR: 20.21% vs 12,16% MPR: 1.63% vs 6.7% ≥40y: SET (n=63) vs DET (n= 34) LBR: 6.34% vs 0 MPR: 0% vs 0%.	Single embryo transfer should be offered even in women ≥ 40 years of age or transferring lower quality embryos since transferring more did not increase outcomes in this group, and SET is likely the safest path.
Mancuso AC, et al. Fertility and sterility 2016;106:	retrospective cohort	USA, 464 centres, Patient ages <35 and 35–37 years old	during 2013, eSET vs DET	LBR and MBR.	No significant differences in clinic level LBR for each age group (<35 y vs 35-37 y). There was a linear decrease in MBR with increasing eSET rate and no significant difference in clinic-level LBR for each age group. Cycle-level analysis found slightly higher LBR with DET, but this was mainly observed in women aged	A linear reduction in MPR, and important, little to no effect on clinic-level LBR with increasing rates of eSET -->eSET is effective in decreasing the high MPR associated with IVF and suggests that eSET should be used

1107-1114.					35–37 years or with four or more embryos available for transfer and confirmed the marked reduction in MBR with eSET.	more frequently than is currently practiced.	
Couples/individuals undergoing ART with donor oocytes							
Mersereau J, et al Fertility and sterility 2017;108: 750-756.	retrospective cohort	281660 patients age categories: 18-29; 30-34; 35-37; 38-40 and 41-43y;	2004-2013; SET vs DET. 181523 women with autologous fresh first cycle; 37,658 with fresh second cycles, and 35,446 with frozen thawed second cycles. 27,033 with fresh first oocyte donor cycles	LBR and MBR after SET DET were measured.	there was little to no effect of maternal age. LBR (in all age categories) No embryo cryopreserved, CST: SET vs DET: 20.1% vs. 41.7%; BT: 45.6% vs. 57.6% ≥1 embryos cryopreserved: CST: SET vs DET: 38.5% vs. 53.1%; BT: 56.1% vs. 66.6% MPR (in all age categories) No embryo cryopreserved, CST: SET vs DET: 4.3% vs. 27.4 %; BT: 0.9% vs. 38.1% ≥1 embryos cryopreserved: CST: SET vs. DET: 0% vs 35.3%; BT: 1.7% vs. 49.4%	This study reports a 10%-15% reduction in live birth rate and a 47% decrement in multiple birth rate with SET compared with DET in the setting of favourable patient prognostic factors.

PICO 11. In FET, should endometrial characteristics be considered a factor in deciding to apply DET instead of (e)SET for couples/individuals undergoing ART (with own gametes or with donated oocytes/embryos) (hormonal substitution vs. ovulatory cycle)? If yes, what is the appropriate cut off?

Evidence Table

Reference	Study Type	Patients Include: No. of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
El-Toukhy T, et al., Fertility and sterility 2008;89: 832-839.	Retrospective study	768 consecutive FER cycles The mean endometrial thickness recorded on the day of P supplementation was 9.3 ± 2.1 mm (range, 5–20 mm)	FER cycle between 1997 and April 2006	Implantation, clinical pregnancy, ongoing pregnancy, and LBR.	the clinical pregnancy rate in group B SET cycles (9-14mm) was double that in group A SET cycles (7-8mm) (19.5% vs. 9.5%, respectively; P= 0.1) but similar to the clinical pregnancy rate achieved in group A cycles where more than one embryo was replaced (n = 315; 19.4%; P=.87).	In medicated FER cycles, an endometrial thickness of 9–14mm measured on the day of P supplementation is associated with higher implantation and pregnancy rates compared with an endometrial thickness of 7–8 mm.

At cleavage stage transfer, there is no difference in live birth rates between the two groups.</p>	
<p>Hill MJ, et al., <i>Fertility and sterility</i> 2020;114: 338-345.</p>	<p>Retrospective cohort study</p>	<p>Patients with DET were 2.5 years older than those who received SET (P<.01). Patients with DET also had lower serum estradiol level on the day of trigger and fewer oocytes were retrieved. Patients in this primary analysis had no supernumerary</p>	<p>4640 autologous fresh IVF cycles SET vs. DET from 2013 to 2015 There were 889 double-embryo transfers with one good-quality blastocyst and a second poorer-quality embryo. Of those secondary embryos, 205 were a fair or poor blastocyst,</p>	<p>LBR MPR</p>	<p>The primary analysis: SET vs. DET LBR was 6% higher with transferring a second poor-quality embryo (44% vs. 50%, OR 1.28; 95% CI 1.28–1.90). MPR 1% vs. 16% DET with a second lower-quality embryo (P<.01).</p>	<p>Addition of a lower-quality embryo does not have a detrimental effect on a good-quality blastocyst and results in a small increase in live births. However, this is at the expense of a marked increase in the likelihood of multiple gestations.</p>	

		blastocysts for vitrification	455 were early blastocyst, and 229 were a morula to transfer. There were 3,751 controls with a good-quality blastocyst SET.		The singleton live birth rate: 43.5% in SET vs. 42% in the second lower-quality cohort (P=0.35)		
Theodorou E, et al., <i>Acta obstetricia et gynecologica Scandinavica</i> 2021;100: 1124-1131.	Cphort study	2145 women under the age of 40 years	2346 fresh blastocyst transfers between January 2013- June 2019 grade B for TE and ICM was further subcategorized into a B+ and a B- score based on both cell number and package. According to this, blastocysts graded as AA, AB+, AB-, B+A, B-A, B+B+ were classified as high-quality blastocystsHBQ, whereas blastocysts graded B-B+, B+B- or lower were considered low-quality blastocysts (LQB).	LBR MPR Miscarriage rate Outcomes were compared between single embryo transfers with a high-quality blastocyst (SET-H), double embryo transfers with two HQBs (DET- HH), and transfers with one high- quality and one low-quality blastocyst (DET- HL). Outcomes were also assessed between SET and DET when only low- quality blastocysts were available (SET-L vs. DET LL).	eSET-H vs. DET-HH: LBR: 51.0% vs. 61.0%; OR 1.8; 95%CI 1.4-2.2 MPR 1.9% vs. 42.5%; OR 49.3; 95%CI 24.7-98.3. eSET with mixed-quality DET LBR: 51.0% vs. 47.0%; OR 0.9; 95%CI 0.7-1.1), MPR: 1.9% vs. 28.7%; OR 20.9; 95%CI 10.2-42.9. SET-H with at least one or more high-quality blastocyst available to freeze vs. SET-H with no other HQB available: LBR: aOR 1.69; 95%CI 1.17-2.45 SET-L vs. DET-LL with no high-quality blastocysts available: LBR: aOR 3.20; 95%CI 1.78-7.703 MPR: aOR 3.72 *10 ¹⁰	When there is one HQB available, transferring an additional low- quality blastocyst would only slightly increase the LBR, but significantly increase the twin rate, therefore SET should be recommended. When two or more HQBs are available, ET- H would have a reasonably good chance of success without the very high twin rate associated with DET- HH. DET- LL when compared with SET- L, would increase the LBR, but increase the risk of multiple gestation.

<p>Le Lannou D, et al., <i>Reproductive biomedicine online</i> 2006;13: 368-375.</p>	<p>obs study paired case-control study</p>	<p>428 pt, 138 in the eSET group and 290 in DET group. Case-control study population: 130 pt eSET vs 130 pt for fresh transfer, 96 pt eSET vs 89 DET for frozen transfer. Inclusion criteria: <38y, 1° cycle, ≥ 2 good quality embryos. ET day 3.</p>	<p>eSET fresh vs DET fresh (eSET in frozen embryo transfer). eSET: embryos frozen singly in straws, DET: up to two embryos were placed in each straw. Stimulation with oestradiol valerate (6mg/day) and intravaginal micronized progesterone (600 mg/day).</p>	<p>Pregnancy, implantation, live birth multiple pregnancy and cumulative live birth rates.</p>	<p>SET vs DET: cLBR: 43% vs 45%, No difference</p> <p>MPR: 3.5% vs 34%, $p < 0.01$.</p>	<p>while twin pregnancies are not totally adverse outcomes in IVF-ICSI, it is possible to reduce their occurrence considerably by pursuing a policy of single embryo transfer that can be applied to a large majority of patients, but only if it is accompanied by widespread embryo cryopreservation.</p>	
<p>López Regalado ML, et al., <i>Journal of assisted reproduction and genetics</i> 2014;31: 1621-1627.</p>	<p>Retrospective cohort study</p>	<p>221 pt included, 105 pt in DET-FET group, 60 pt in cSET-FET group and 41 pt in eSET-FET group. Inclusion criteria: < 38 y, BMI 19-29 kg/m², FSH < 15mIU/ml, 1°-2°</p>	<p>eSET (cumulative) vs DET vs cSET in frozen transfer. From January 2010 to June 2013 Cryopreservation day 3 using ethylene glycol and 1,2-</p>	<p>Clinical, multiple pregnancy, miscarriage, ongoing pregnancy, live birth and cumulative live birth rates.</p>	<p>eSET vs DET: cLBR: 34.1% vs 30.0%</p> <p>MPR: 0% SET vs 32.5% DET, $p < 0.05$.</p>		

		cycle, no pregnancy in their fresh cycles and ≥ 2 vitrified embryos A/B quality.	propanediol in HTF culture medium fluid				
Racca A, et al., Gynecological endocrinology: the official journal of the International Society of Gynecological Endocrinology 2020;36: 824-828.	Retrospective cohort study	3601 pt included, 1936 pt in SET group, 16665 pt in DET group. Criteria for cryopreservation: ≥ 6 blastomeres and $< 20\%$ fragmentation.	SET (n= 1936) vs DET (n=1665) in frozen transfer. Natural or artificial cycle estradiolvalerate and micronized vaginal progesterone	Live birth and multiple birth rates.	Overall, 657/3601 (18.24%) had a live birth. SET vs DET: LBR: cleavage [100/757 (13.1%) versus 153/1032 (14.8%), p=.33] o blastocyst stage FET [256/1179 (21.7%) versus 148/633 (23.4%), p=.4]. OPR: 359/1936 (18.5%) vs. 316/1665 (18.9%) MPR: 7/359 (1.9%) vs. 53/316 (16.7%) p<.001.	the number of embryos transferred in the frozen cycle was not related to LBR. both SET and DET may result in similar LBR, albeit multiple pregnancy rates are significantly lower in case of SET.	
Zhu Q, et al., Frontiers in physiology 2020;11: 930.	Retrospective cohort study	26676 women 1st FET Inclusions: Autologous oocytes Each women included only 1 time in the study Exclusion: Women with previous fresh or FET Patients receiving mixes cleavage and blastocyst transfer	Between Jan 2011 – Dec 2017 Information on IVF/ICSI procedure, embryo culture, evaluation and freezing see other papers of this group. Embryos cultured until day 3 or day 5/6. Cleavage embryos: Grade I and grade II: 4cell on day 2 or 6 to 8 cells on day 3 with $<20\%$ fragmentation. Grade III or IV: 2cell on day 2 or <6 cell on day 3, $>20\%$	LB: infant born alive after 24 weeks of gestation surviving more than 28 days per FET (see remark) 2 major groups: cleavage vs blastocyst. 5 subgroups: SET-GQE SET-PQE DET-2GQE DET-GQE+PQE DET-2PQE	24613: FET using cleavage stage embryos 2063: FET using blastocyst cleavage stage embryos Blastocyst FET vs cleavage stage FET: LBR for SET: 38.64% vs. 24.72% LBR DET: 56.08% vs. 45.01% MPR for SET: 0.81% vs. 0.29% MPR for DET: 21.69% vs. 13.76% LBR was higher in blastocyst vs. Cleavage n all 5 subgroups. Cleavage stage FET DET2GQE: LBR:45.73%-MPR: 14.22% DET-GQE+PQE: 37.25%-MPR:8.7% DET-2PQE: 32.89%-MPR:6.14% SET-GQE: 25.55%-MPR:0.31% SET-PQE: 12.16%-MPR:0% LBR is significantly reduced in SET-PQE (OR: 0.49 (0.28-0.84) p=0.009 and significantly higher in DET-2GQE OR 1.62 (1.40-1.51) p<0.001 and in DET-GQE+PQE OR1.25 (1.04-1.51) p=0.018. No sign diff for LBR in DET-2PQE vs SET-GQE. Blastocyst stage FET	DET with GQE+PQE increases the LBR for cleavage stage FET but not for blastocyst FET for the 1st FET. DET with GQE+PQE increases MPR for both cleavage stage and blastocyst stage FET. Although DET with GQE + PQE leads to increasing LBR, but it leads to increased MPR in cleavage stage FET. For blastocyst FET, DET with GQE+PQE does NOT increase LBR, it only increases MPR. MPR is higher in DET vs. SET regardless of the transferred embryo quality and developmental stage of the embryo.	Results are expressed per ET or per warming? Is not described in the study – however in the discussion it is stated: per transfer

Zipori Y, et al., Reproductive	Meta-analysis	Total number 3209 patients in 24 studies. Conception	Triplets reduced to twins vs no reduction of	Preterm delivery, gestational diabetes, hypertensive	Preterm delivery <36 OR 0.14 95% CI (0.06, 0.35)	MPR of triplet pregnancies to twins is associated with a better	Limitation is inclusion of

biomedicine online 2017;35: 296-304.		not just using ART. Non substantial heterogeneity between the groups in most comparisons	triplets. Follow up to birth, mean 40 weeks.	disorders, small for gestational age, prenatal hospitalisation, rate of caesarean section, neonatal death	preterm delivery <34 0.16 (0.09, 0.28) Gestational diabetes 0.36 (0.19, 0.67) Hypertensive disorders 0.47 (0.31, 0.72) Small for gestational age 0.93 (0.63, 1.38) Rate of caesarean section 0.18 (0.10, 0.33) Neonatal death 0.32 (0.12, 0.84)	pregnancy outcome compared with that of non-reduced triplets. Single embryo transfer during ART, should remain the mainstay approach for triplet pregnancies. Should this fail, multifetal pregnancy reduction may be the appropriate alternative to reduce perinatal morbidity and mortality in trichorionic triplet pregnancies.	non-ART pregnancies
Dodd JM, et al., The Cochrane database of systematic reviews 2015: Cd003932.	Cochrane review	No RCTs to include					
Anthoulakis C, et al., Human reproduction (Oxford, England) 2017;32: 1351-1359.	Meta-analysis	Total number 1416 patients in 8 studies. Conception not just using ART. Some heterogeneity between studies.	Triplets reduced to twins vs no reduction of triplets. Follow up to birth, mean 40 weeks.	Miscarriage <24 and preterm birth <34	TCTA vs reduced: miscarriage 8.1 versus 7.4%, P = 0.661 and RR = 1.08, 95% 0.58–1.98; preterm birth 17.3 versus 50.2%, P <0.005 and RR = 0.36, 95% CI: 0.28–0.48. DCTA vs reduced: miscarriage 8.5 versus 13.3%, P = 0.628 and RR = 1.22, 95% CI: 0.38–3.95, respectively; preterm birth 51.9 versus 46.2%, P = 0.778 and RR = 0.5, 95% CI: 0.04–5.7, respectively	The principal finding of our study is that ER to twins in TCTA pregnancies reduces the risk of preterm birth (<34 weeks) without significantly increasing the risk of miscarriage (<24 weeks).	Limitation is inclusion of non-ART pregnancies
Groutz A, et al., Human reproduction (Oxford, England) 1996;11: 1334-1336.	Prospective cohort	10 quadruplets (group 1) and 30 triplets reduced to twins (group 2) and 30 spontaneous twins (group 3). Groups comparable in terms of maternal age and parity.	Reduction of multiple pregnancy to twins vs spontaneous twins.	Gestational age at delivery, caesarean section rate, birth weight and overall complications.	Insufficient data for effect size calculations. Group 1 vs. Group 2 vs. Group 3: Mean Gestational age at delivery: 33.2 w vs. 35.9 w vs. 36.9 weeks Mean Birth weight: 1843g vs. 2209g vs. 2361g Premature contractions rate: 50% vs. 27% vs. 13%, Pregnancy induced hypertension rate 40% vs. 23% vs. 7%.	The initial number of foetuses before reduction was inversely correlated with gestational age at delivery and birthweight, and positively correlated with pregnancy complications. Contrary to previous studies, we found a higher incidence of pregnancy complications after MFPR compared with spontaneous twins, especially PMC and PIH.	
Jin B, et al., Medicine 2020;99: e20730.	Systematic review and Meta-analysis	Six retrospective cohort studies involving 7398 participants	Between 2011 and 2019 A total of 530 twin gestations that	The primary outcomes of interest were preterm birth rate, birth weight, and miscarriage	MPR of DCDA twin pregnancy to singleton vs. expectant management: A lower risk of preterm birth (5 studies with 7297 participants;	Compared to expectant management, MPR of DCDA twin pregnancy to singleton prevents preterm birth and low	

			underwent MPR and 6868 controls that underwent expectant management	rate. The secondary outcomes were the rates of intrauterine growth retardation (IUGR), cesarean section, and gestational diabetes mellitus (GDM). T	RR: 0.30,95%CI: 0.22–0.40; P<.001) Higher birth weight (4 studies with 5763 participants; mean differences: 548.10g, 95% CI: 424.04–672.15; P<.001) No difference in the occurrence of miscarriages (5 studies with 7355 participants; RR: 1.57, 95% CI: 0.90–2.75; P=.11).	birth weight, without increasing the risk of miscarriages. Regarding perinatal morbidity related to preterm birth, MPR can be reserved as a remediation measure to improve the perinatal outcomes of DCDA twin pregnancies.	
Liu Y, et al., <i>Taiwanese journal of obstetrics & gynecology</i> 2019;58: 133-138.	Retrospective cohort	57 triplets, 670 triplets reduced to twins. Groups comparable in terms of maternal age, BMI, duration of infertility, treatment used.	Triplets reduced to twins vs no reduction. Follow up to birth, mean 40 weeks.	Abortion, live birth, caesarean section, preterm birth, gestation at delivery, perinatal mortality, birth weight	Triplets vs triplets reduced to twins: abortion 15% vs 5% p=0.071; live birth 85% vs 95% p=0.099; caesarean section 88% vs 93% p=0.51; preterm delivery 85% vs 53% p<0.001; gestation at delivery 34.6w vs 36.1w p<0.001; perinatal mortality 1% vs 1% p=0.73; birth weight 2083g vs 2432g p<0.001	For DCT and TCT pregnancies, MFPR application could reduce the miscarriage rate, while improving live birth and take-home baby rates compared to the expectant groups. Especially, when reduced to a single fetus, MFPR could provide the better perinatal outcomes.	
Yimin Z, et al., <i>Frontiers in endocrinology</i> 2022;13: 851167.	Retrospective cohort study	502 women underwent MFPR to twins or singletons and 9641 non-reduced women.	2002 – 2016 331 women with twins reduced from triplets at 6-13 weeks 45 women with singletons reduced from triplets at 7-12 weeks 126 women with singletons reduced from twins at 7-16 weeks Primary singletons: 6853 Primary twins: 2788 women	GA at delivery, the rates of preterm delivery before <32 weeks, <34 weeks, and <37 weeks of gestation, pregnancy loss < 24 weeks, abortion of one fetus and caesarean section as well as neonatal outcomes such as neonatal birth weight, the rates of at least one fetus LBW, at least one fetus very low birth weight (VLBW) and SGA.	Singletons reduced from triplets/twins vs primary singletons: higher rates of preterm delivery (15.8% vs. 7.3%, P<0.001), LBW (12.3% vs. 4.32%, P<0.001), VLBW (2.3% vs. 0.4%, P=0.002), and SGA (14.6%vs.6.6%, P<0.001) comparable pregnancy loss rate (5.3% vs. 5.4%, P=0.671).	the pregnancy loss rate is similar between reduction and non-reduction groups. MFPR improves pregnancy outcomes, including the risk of preterm delivery, LBW, and SGA, but still could not completely reverse the adverse pregnancy outcomes of multiple pregnancies.	
Kristensen SE, et al., <i>American journal of obstetrics and gynecology</i> 2022.	Retrospective cohort study	9735 dichorionic twin pregnancies	9563 dichorionic twin pregnancies 172 reduced twins. 16,465 primary singletons.	Primary outcome: adverse pregnancy outcome: miscarriage before 24 ⁺ weeks, stillbirth from 24 ⁺ weeks, or	Adverse pregnancy outcome was observed in 4.1% (95%CI 1.7%-8.2%) of reduced twin pregnancies, and 2.4% (95%CI 0.7%-6.1%) were delivered before 28	all dichorionic twin pregnancies, transabdominal fetal reduction by needle guide for fetal or maternal indication was shown to be safe, with good outcomes for the	

			<p>Fetal reductions were performed between 11 and 23 weeks between January 2008 and December 2018.</p>	<p>single intrauterine fetal death in the nonreduced twin pregnancies, preterm delivery before 28⁺⁰, 32⁺⁰, or 37⁺⁰ weeks, rate of live-born children, and gestational age at delivery. Secondary outcomes: pregnancy complications defined as preterm prelabour rupture of membranes (PPROM), preeclampsia, placenta previa, and placental abruption, and birthweight z-scores</p>	<p>weeks, and 4.2% (95% CI 1.7%-8.5%) before 32 weeks. When fetal reduction was performed before 14 weeks, adverse pregnancy outcomes occurred in only 1.4% (95% CI 0.0%-7.4%), and delivery before 28 and 32 weeks diminished to 0% (95% CI 0.0%-5.0%) and 2.8% (95% CI 0.3%-9.7%), respectively. In contrast, 3.0% (95%CI 2.7%-3.4%) of nonreduced dichorionic twins had an adverse pregnancy outcome, and 1.9% (95% CI 1.7%-2.1%) were delivered before 28 weeks, and 7.3% (95%CI 6.9%-7.7%) before 32 weeks. Adverse pregnancy outcomes occurred in 0.9% (95% CI 0.7%-1.0%) of primary singletons, and 0.2% (95% CI 0.1%-0.3%) were delivered before 28 weeks, and 0.7% (95%CI 0.6%-0.9%) before 32 weeks.</p>	<p>remaining co-twin. Results were best when the procedure was performed before 14 weeks.</p>	
<p>van de Mheen L, et al., <i>Human reproduction (Oxford, England)</i> 2015;30: 1807-1812.</p>	<p>Retrospective cohort study</p>	<p>118 women with a twin pregnancy that was reduced to a singleton, 818 women with an ongoing dichorionic twin pregnancy and 611 women with a primary singleton pregnancy.</p>	<p>From 2000 to 2010. Fetal reduction was performed trans-abdominally by intracardiac or intrathoracic injection of potassium chloride using a 20 Gauge or 22 Gauge needle.</p>	<p>Gestational age at delivery Neonatal birthweight Number of perinatal deaths.</p>	<p>Loss of the entire pregnancy ,24 weeks and preterm delivery occurred significantly more in the reduction group compared with the ongoing twin group (11.9 versus 3.1%, 24 weeks, P,0.001 and 18.6 versus 11.5% ,32 weeks, respectively, P, 0.001). In the reduction group, the percentage of women without any surviving child was significantly higher compared with the ongoing twin and primary singleton group (14.4, 3.4 and 0.7%, respectively, P, 0.001). Median gestational age was 38.9weeks (interquartile range (IQR) 34.7–40.3) for</p>	<p>Only when a lethal abnormality is threatening the normal co-twin, for instance in case of development of severe polyhydramnion, should selective feticide be considered. Parents need to be counselled that undergoing fetal reduction always exposes the healthy remaining fetus to a risk of serious complications possibly resulting in preterm birth.</p>	<p>indications for reduction were heterogeneous.</p>

					reduced pregnancies, 37.1 weeks (IQR 35.3–38.1) for ongoing twin pregnancies and 40.1 (IQR 39.1–40.9) for primary singletons (P, 0.001 for all comparisons).		
Wang C, et al., Reproductive biology and endocrinology: RB&E 2022;20: 71.	Retrospective study	5922 patients with embryo transfer	March 2011 to January 2021 DET Elective reduction to singletons SEFR group (n=390) and spontaneous reduction to singletons SPFR group (n=865) SET group (n=4667)	Clinical outcomes, including pregnancy outcomes, pregnancy complications, and newborn outcomes,	SEFR increased the risk of miscarriage (OR 2.368, 95% CI 1.423–3.939) and preterm birth (OR 1.515, 95% CI 1.114–2.060), and reduced the gestational age (β -0.342, 95% CI -0.544 - -0.140). SPFR increased the risk of gestational diabetes mellitus (GDM) (OR 1.657, 95% CI 1.215–2.261), preterm premature rupture of membranes (PPROM) (OR 1.649, 95% CI 1.057–2.574), and abnormal amniotic fluid volume (OR 1.687, 95% CI 1.075–2.648). Both SEFR and SPFR were associated with reduced live birth rate (OR 0.522, 95% CI 0.330–0.825; OR 0.671, 95% CI 0.459–0.981), newborn birth weight (β -177.412, 95% CI -235.115– -119.709; β -42.165, 95% CI -83.104– -1.226) as well as an increased risk of low-birth-weight newborns (OR 2.222, 95% CI 1.490–3.313; OR 1.510, 95% CI 1.092–2.087).	DET with subsequent fetal reduction was related to poor clinical outcomes.
