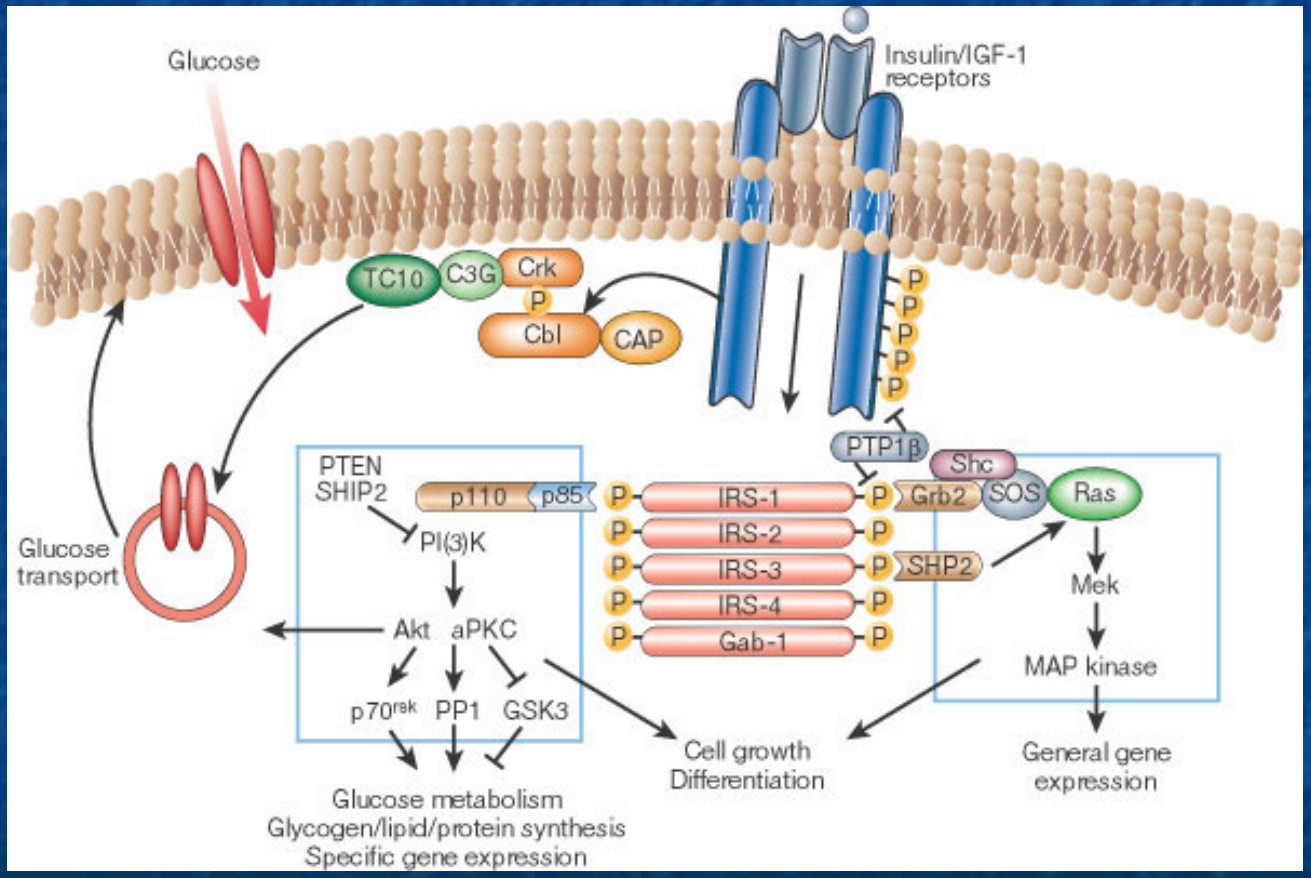
Defining Insulin Resistance and Metabolic Syndrome

Didier DEWAILLY, *M.D.*

Department of Endocrine Gynaecology and Reproductive Medicine, Hôpital Jeanne de Flandre, C.H.R.U., 59037 Lille, France

Insulin Resistance is a physiological, adaptative and selective phenomenon



Alan R. Saltiel and C. Ronald Kahn Insulin signalling and the regulation of glucose and lipid metabolism. Nature 414, 799-806(13 December 2001)

ADIPOTOXICITY
is the main cause of pathological IR

Genes
Environment

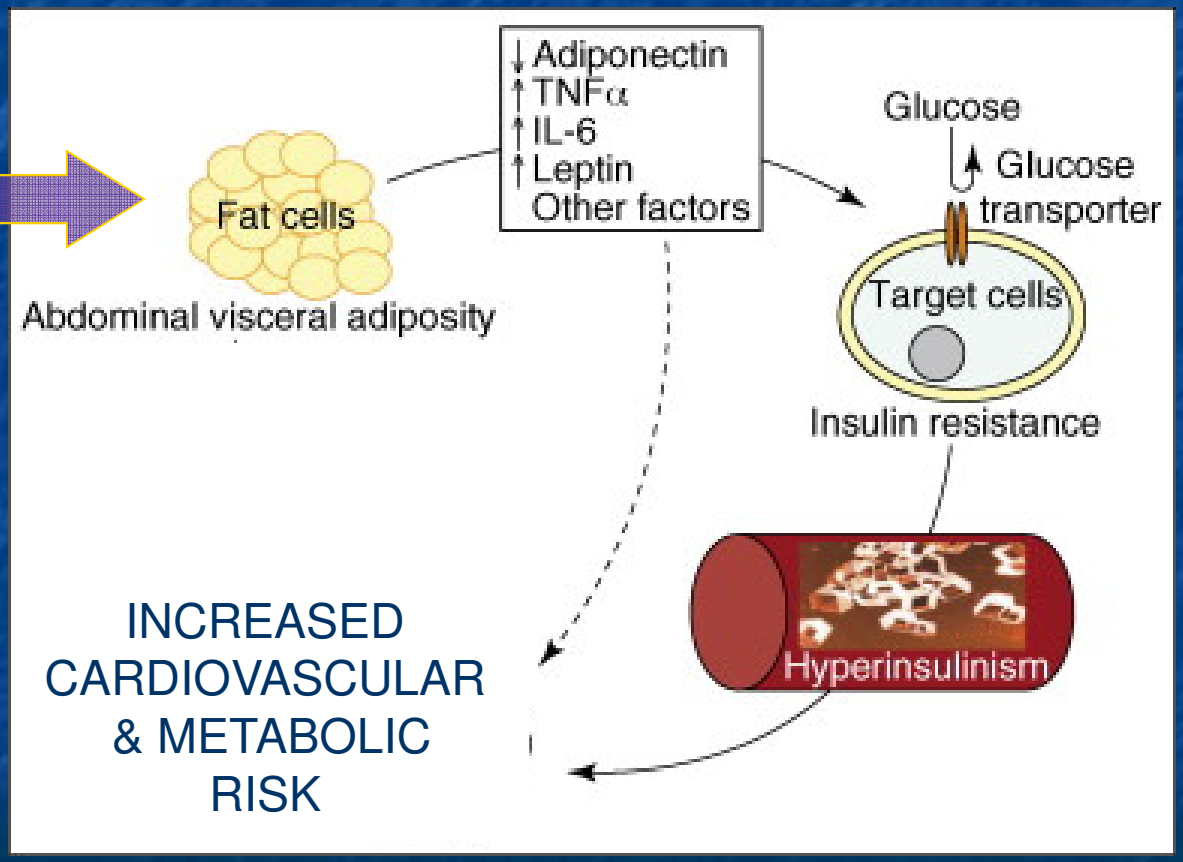


Table 1. *Current approaches for assessing insulin sensitivity and resistance in vivo*

Method	Measurement of Insulin Sensitivity
	Direct measurements
Hyperinsulinemic euglycemic glucose clamp	Steady-state GIR = M. SI_{Clamp} = M/(G × ΔI), where M is normalized for G (steady-state blood glucose concentration) and ΔI (difference between fasting and steady-state plasma insulin concentrations)
IST	SSPG concentration during constant infusions of insulin and glucose with suppressed endogenous insulin secretion
	Indirect measurements
Minimal model analysis – FSIVGTT	Minimal model uniquely identifies model parameters that determine a best fit to glucose disappearance during the modified FSIVGTT. S_I: fractional glucose disappearance per insulin concentration unit; S_G: ability of glucose per se to promote its own disposal and inhibit HGP in the absence of an incremental insulin effect (i.e., when insulin is at basal levels)
	Simple surrogate indexes
Surrogates derived from fasting steady-state conditions	
1/(Fasting insulin)	Reciprocal of fasting plasma insulin concentration, μU/ml
G/I ratio	Ratio of fasting plasma glucose (mg/dl) and insulin (μU/ml) concentration
HOMA	HOMA-IR = {[fasting insulin (μU/ml)] × [fasting glucose (mmol/l)]}/22.5
QUICKI	QUICKI = 1/[Log (fasting insulin, μU/ml) + Log (fasting glucose, mg/dl)]
Surrogates derived from dynamic tests (OGTT)	
Matsuda index	$ISI(Matsuda) = 10{,}000/\sqrt{[(G_{fasting\ (mg/dl)} \times I_{fasting\ (mU/l)}) \times (G_{mean} \times I_{mean})]}$
Gutt index: $ISI_{(0,\ 120)}$, $mg \cdot l^2 \cdot mmol^{-1} \cdot mIU^{-1} \cdot min^{-1}$	$ISI_{(0,\ 120)} = 75{,}000 + (G_0 - G_{120})_{(mg/dl)} \times 0.19 \times BW/120 \times G_{mean(0,\ 120)\ (mmol/l)} \times \mathrm{Log}\ (I_{mean\ (0,\ 120)})_{(mU/l)}$
Avignon index, SiM	SiM = [(0.137 × Sib) + Si2 h]/2, where $Sib = 10^8/(I_{0\ (mU/l)} \times G_{0\ (mmol/l)} \times VD)$ and $Si2\ h = 10^8/(I_{120\ (mU/l)} \times G_{120\ (mmol/l)} \times VD)$
Stumvoll index	$ISI_{Stumvoll} = 0.156 - 0.0000459 \times I_{120\ (pmol/l)} - 0.000321 \times I_{0\ (pmol/l)} - 0.00541 \times G_{120\ (mmol/l)}$

GIR, glucose infusion rate; M, glucose disposal rate; IST, insulin suppression test; SSPG, steady-state plasma glucose; FSIVGTT, frequently sampled intravenous glucose tolerance test; S_I, insulin sensitivity index; S_G, glucose effectiveness index; HGP, hepatic glucose production; G/I ratio, glucose/insulin ratio; HOMA, homeostasis model assessment; HOMA-IR, homeostasis model assessment of insulin resistance; QUICKI, quantitative insulin sensitivity check index; OGTT, oral glucose tolerance test; G_{mean}, mean plasma glucose concentration during OGTT; I_{mean}, mean insulin concentration during OGTT; G_o, plasma glucose concentration during fasting; G_{120}, plasma glucose concentration at 120 min; BW, body weight; I_o, plasma insulin concentration during fasting; I_{120}, plasma insulin concentration at 120 min; VD, glucose distribution volume (150 ml/kg BW).

RESEARCH

Muniyappa R et al., Am J Physiol Endocrinol Metab. 2008;294:E15-26.

Surrogate indexes of insulin sensitivity

using fasting basal determinations of G and I

- HOMA-IR:

  I (mIU/L) x G (mmol/L)/22.5

- QUICKI:

  1/ log I (mIU/L) + log G (mg/dl)

- G/I:

  G (mg/dl) / I (mIU/L)

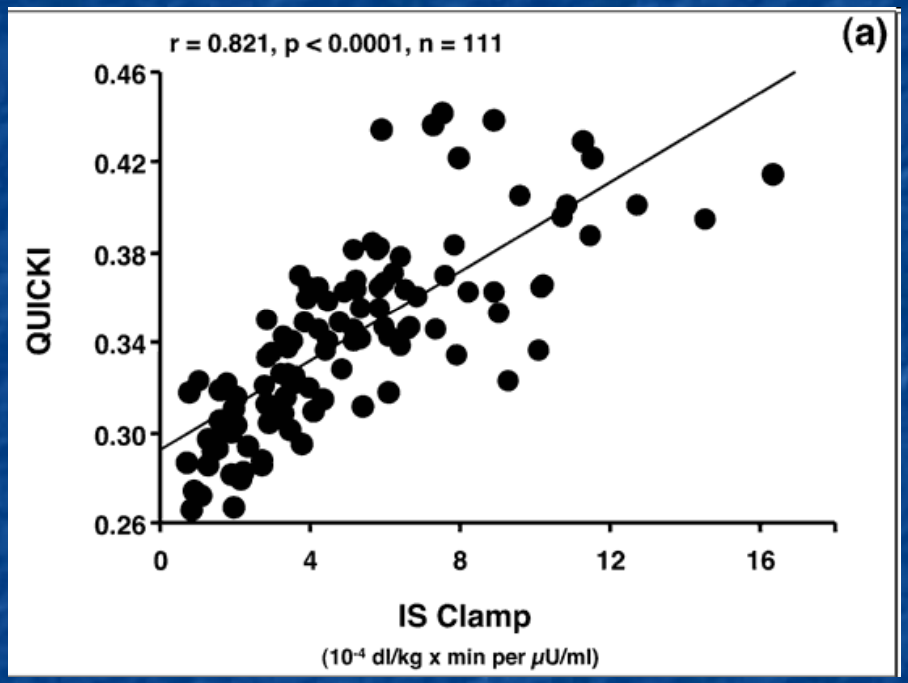
Table II

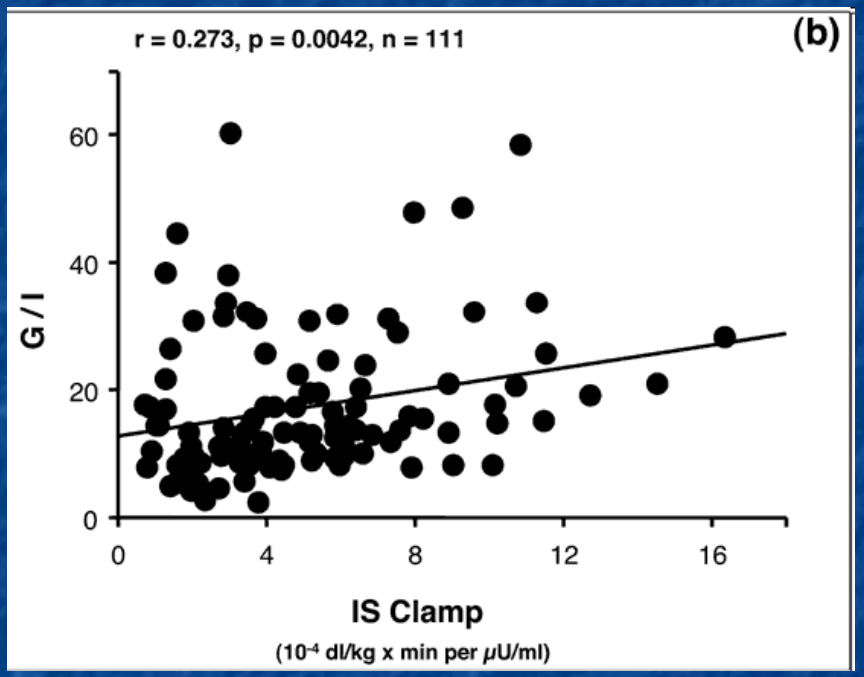
Univariate Spearman's correlation between simple measures of insulin resistance and directly-measured insulin sensitivity by hyperinsulinemic euglycemic clamp (n = 111).

Simple measures	Spearman's *r*	*p*
HOMA	– 0.820	< 0.0001
FIRI	– 0.820	< 0.0001
QUICKI	0.821	< 0.0001
G/I	– 0.273	= 0.0042
I/G	– 0.272	= 0.0043
40/I	– 0.701	< 0.0001

Bastard JP et al., Diabetes Metab 2003, 29:285-8

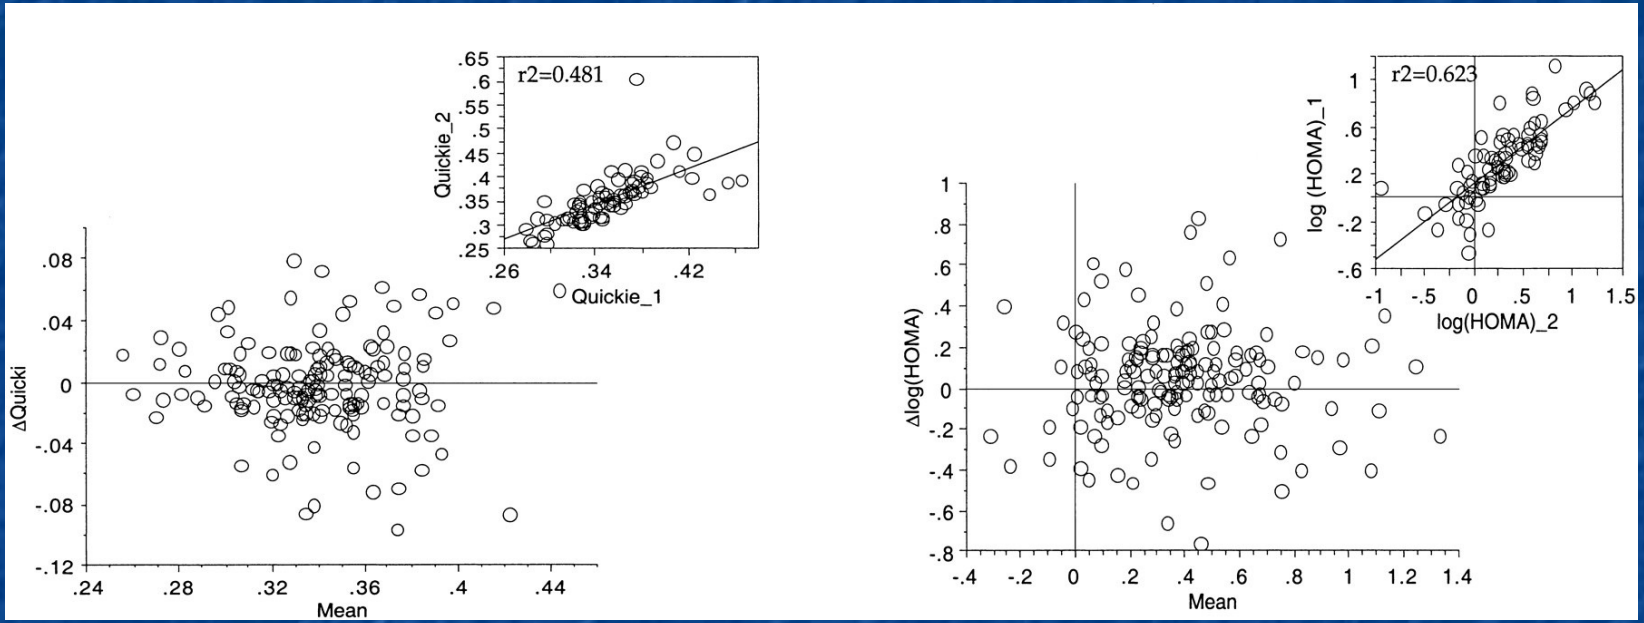
QUICKI is better than G/I





Bastard JP et al., Diabetes Metab 2003, 29:285-8

QUICKI and Log(HOMA) are similar



Mather, K. J. et al. J Clin Endocrinol Metab 2001;86:5457-5464

Surrogate indexes of insulin sensitivity

Caveats

- Depend on I assay that is not standardized
- Skewed distribution of I values (improved by log transformation)
- Not optimal in diabetic subjects (G/I)
- Not optimal in healthy insulin-sensitive subjects

Usefulness

- Epidemiological studies
- Research clinical studies (correlations)
- Follow up after therapeutic interventions

Detecting IR in clinical practice

Table 3. Familial, clinical and physical features as risks factors for IR in children and adolescents

Family history	Patient's history	Physical examination
Glucose intolerance or T2DM	Birth weight (small or large for gestational age)	Acanthosis nigricans
Overweight or obesity	Precocious pubarche	Striae
Hypertension	Evolution of obesity	Centripetal obesity
Metabolic syndrome	Dietary habits	Adipomastia
Hyperuricemia or gout	Physical activity	Hypertension
Coronary heart disease	Medication/drugs which affect appetite, glucose or lipid metabolism	Acne
Stroke		Hirsutism
Chronic pancreatitis		Tall stature
Gestational diabetes		Precocious puberty
Polycystic-ovary syndrome or hirsutism		Genu valgum
Nonalcoholic fatty liver disease		

Table 4. Medications associated with IR

Hormones	HIV therapy	Antipsychotic drugs	Immune suppressants	Others
Glucocorticoids	HIV nucleoside reverse-transcriptase inhibitors	Clozapine	Tacrolimus	Tiazides
Growth hormone	HIV protease inhibitors	Olanzapine	Cyclosporine A	Valproate
		Risperidone	Sirolimus	Glucosamine

The Metabolic Syndrome (MetS)

Requiescat in pace?

G. Reaven

2005

The « old » definitions of MetS

Table 1. WHO, EGIR and ATPIII definitions of the metabolic syndrome.

WHO 1999	EGIR 1999	ATPIII 2001
Diabetes or impaired glucose tolerance or insulin resistance*	Insulin resistance* or hyperinsulinaemia (only non-diabetic subjects)	
Plus two or more of the following:	Plus two or more of the following:	Three or more of the following:
1. Obesity: BMI > 30 kg/m² or WHR > 0.9 (M) > 0.85 (F)	1. Central obesity: Waist circumference ≥ 94 cm (M), ≥ 80 cm (F)	1. Central obesity: Waist circumference >102 cm (M), > 88 cm (F)
2. Dyslipidaemia: Triglycerides ≥ 150 mg/dl (1.7 mmol/l) or HDL-C < 35 mg/dl (0.9 mmol/l) (M) < 39 mg/dl (F) (1.0 mmol/l)	2. Dyslipidaemia: Triglycerides > 177 mg/dl (2.0 mmol/l) or HDL-C < 39 mg/dl (1.0 mmol/L)	2. Hypertriglyceridaemia: Triglycerides ≥ 150 mg/dl (1.7 mmol/l)
3. Hypertension: Blood pressure ≥ 140/90 mmHg or medication	3. Hypertension: Blood pressure ≥ 140/90 mmHg or medication	3. Low HDL -C: < 40 mg/dl (1.03 mmol/l) (M), < 1.29 mmol/l (50 mg/dl) (F)
4. Microalbuminuria: Albumin excretion ≥ 20 μg/min or albumin:creatinine ratio ≥ 30 mg/g	4. Fasting plasma glucose ≥ 110 mg/dl (6.1 mmol/l)	4. Hypertension: Blood pressure ≥ 130/85 mmHg or medication
		5. Fasting plasma glucose ≥ 110 mg/dl (6.1 mmol/l)

* defined as the top quartile of fasting insulin in the non-diabetic population.

Table 2. IDF Metabolic Syndrome World-wide Definition.

CENTRAL OBESITY
Waist circumference*– ethnicity specific (Table 2)

Plus any two of the following:

- RAISED TRIGLYCERIDES:
  ≥ 150mg/dl (1.7 mmol/l)
  or specific treatment for this lipid abnormality

- REDUCED HDL-CHOLESTEROL
  < 40 mg/dl (1.03 mmol/l) in males
  < 50 mg/dl (1.29 mmol/l) in females
  or specific treatment for this lipid abnormality

- RAISED BLOOD PRESSURE
  Systolic : ≥ 130 mmHg
  or Diastolic: ≥ 85 mmHg
  or treatment of previously diagnosed hypertension

- RAISED FASTING PLASMA GLUCOSE**
  Fasting plasma glucose ≥ 100 mg/dl (5.6 mmol/l)
  or previously diagnosed type 2 diabetes
  If above 5.6 mmol/l or 100 mg/dl, OGTT is strongly recommended but is not necessary to define presence of the syndrome.

* If BMI is > 30 kg/m^2 then central obesity can be assumed, and waist circumference does not need to be measured. Ethnic specific waist circumference are listed in table 2.

For women in western countries: 80 cm !

The metabolic syndrome and incidence of cardiovascular disease in non-diabetic subjects

a population-based study comparing three different definitions

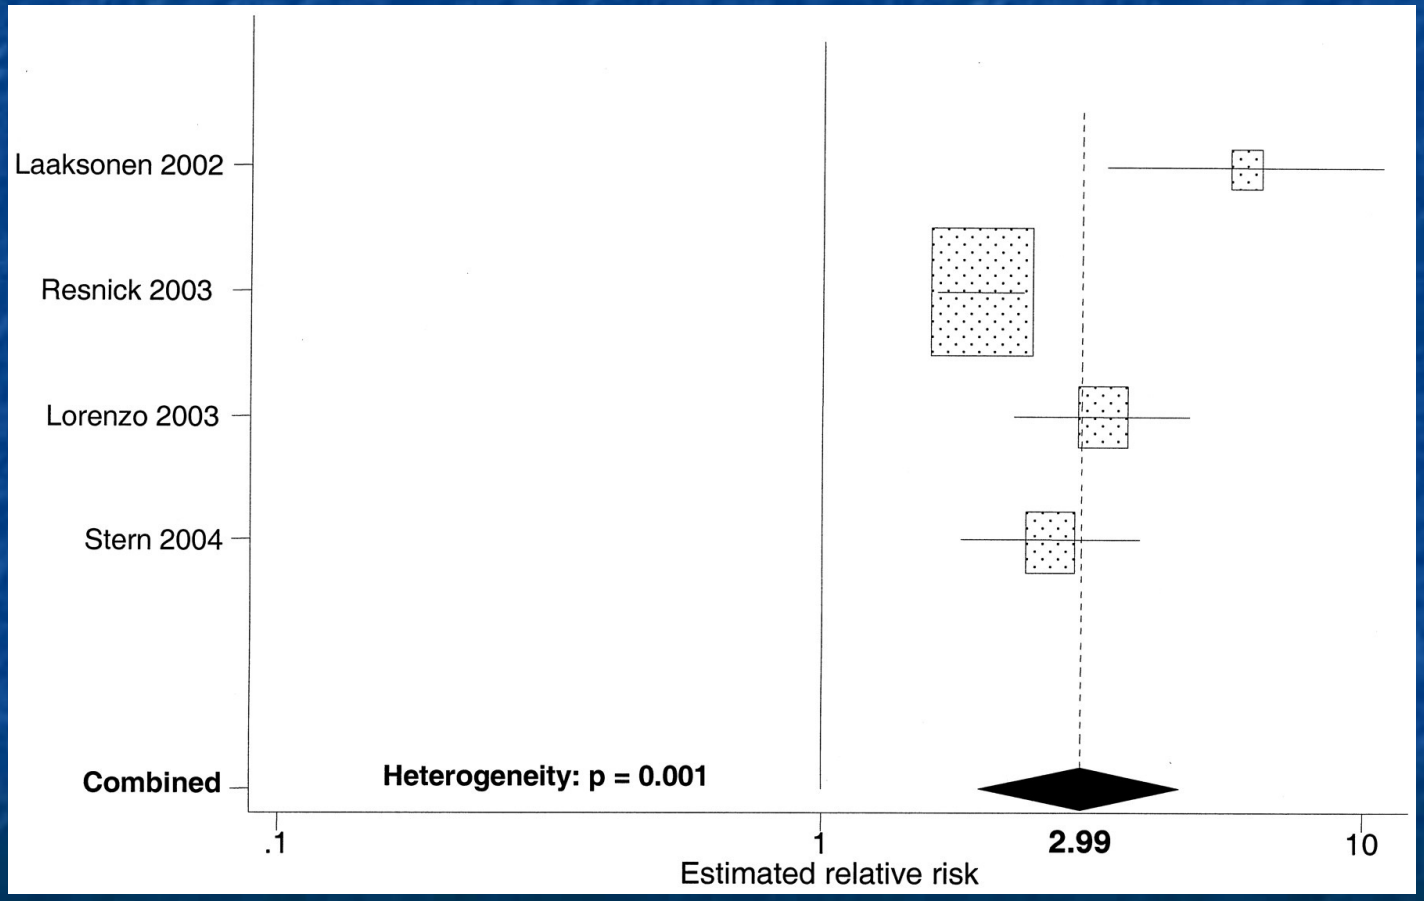
Nilsson PM et al., Diabetic Medicine, 2007, **24**, 464– 472

5,047 non-diabetic subjects (66% women), 11 years of follow-up.

	Prevalence (%)	HR* (95% CI)
MetS NCEP-ATPIII	21	1.95 (1.56–2.43)
MetS EGIR	19	1.55 (1.23–1.95)
MetS IDF	22	1.37 (1.09–1.72)
Hypertension (A, I)	79	2.97 (1.90–4.63)
Hypertension (E)	63	2.22 (1.67–2.95)
Obesity (A)	15	1.81 (1.42–2.31)
Obesity (E, I)	37	1.20 (0.97–1.48)
Low high-density lipoprotein (A, I)	30	2.01 (1.63–2.49)
Dyslipidemia (E)	21	1.65 (1.31–2.07)
Hypertriglyceridaemia (A, I)	22	1.37 (1.09–1.73)
Hyperglycemia (A, E, I)	14	1.39 (1.07–1.81)
Insulin resistance (E)	25	1.45 (1.16–1.81)
Current smoking	23	1.95 (1.55–2.45)

*RR adjusted for age and sex compared with those without the risk factor.
Variables included in the definition of metabolic syndrome (MetS): A, Adult Treatment Panel III (ATPIII); E, European Group for the study of Insulin Resistance (EGIR); I, International Diabetes Federation (IDF); based on criteria.

MetS as a predictor of T2DM



MetS: caveats

- Extremely abnormal values for any particular criterion receive the same weight as values that are barely abnormal
- Some patients may be misclassified as "normal" when indeed they have values that are close to the upper limit of normal.
- The selection of cutoff points has been arbitrary, in the most part, and not guided by biological and epidemiological principles of normality
- Not appropriate for early detection of IR in the young

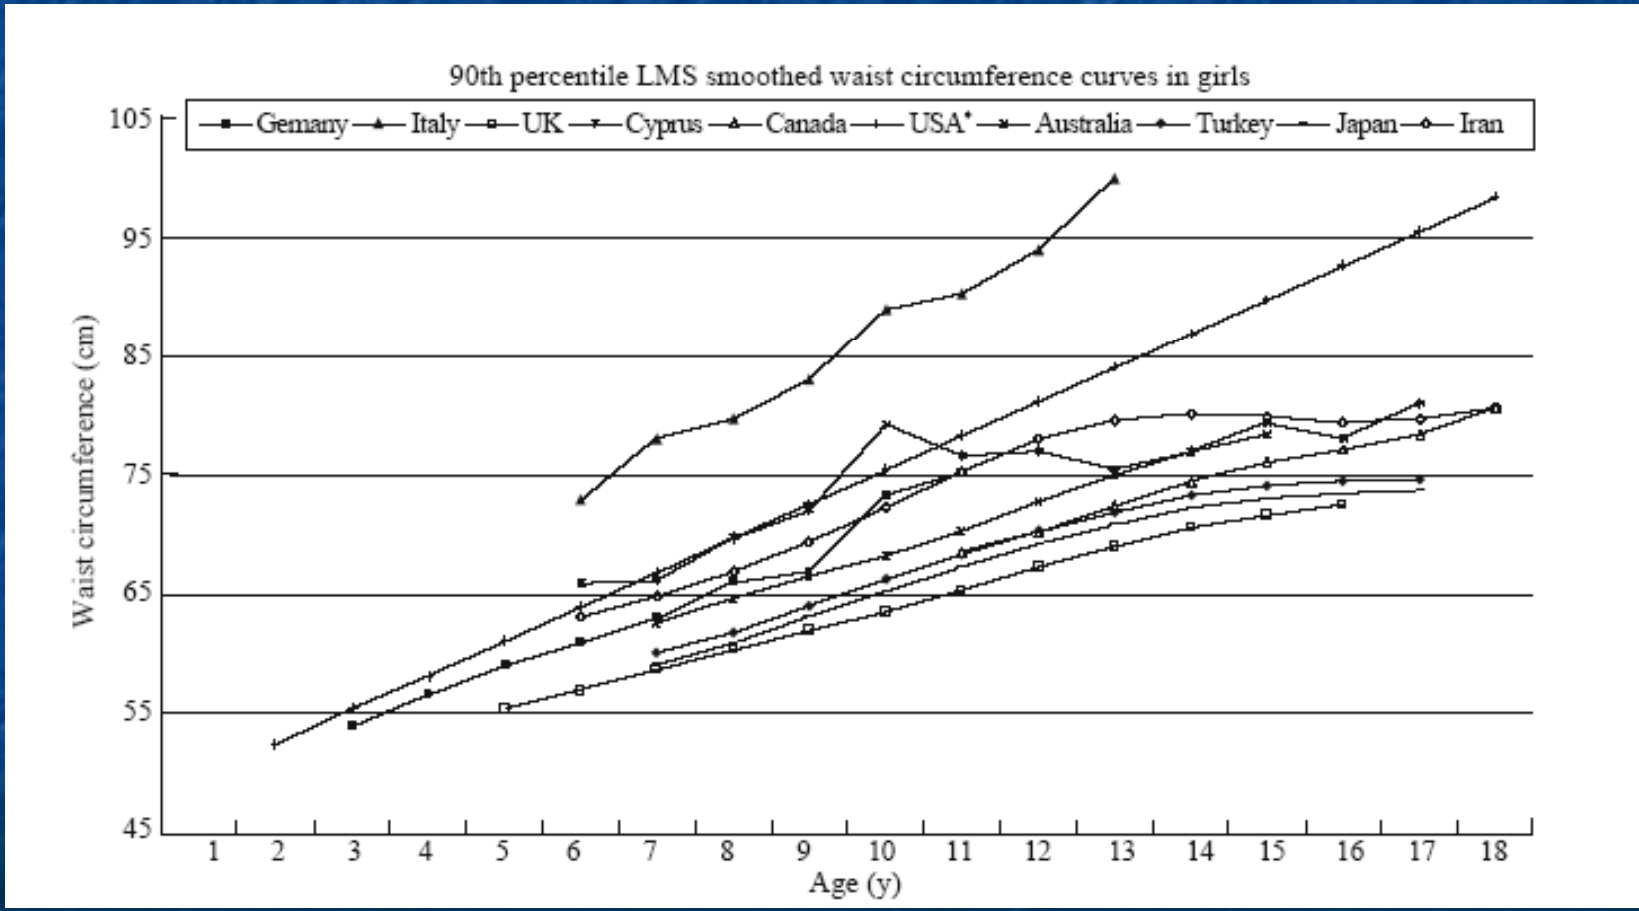
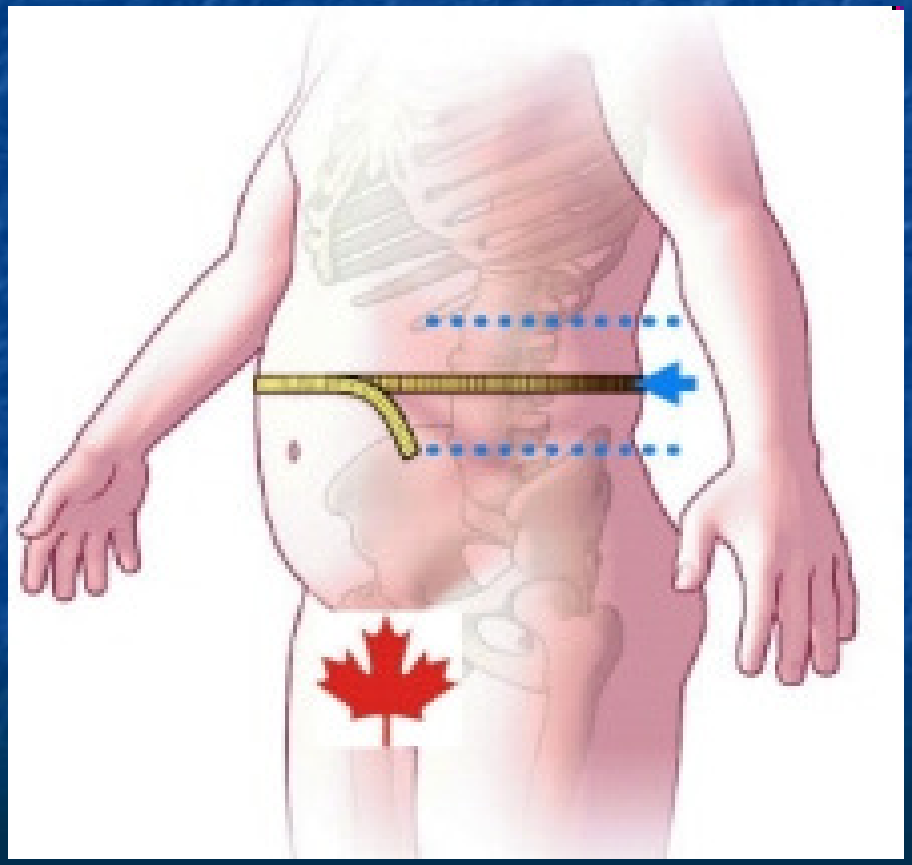
?

Upper normal limit for WC in adolescent girls: *similar to adults*



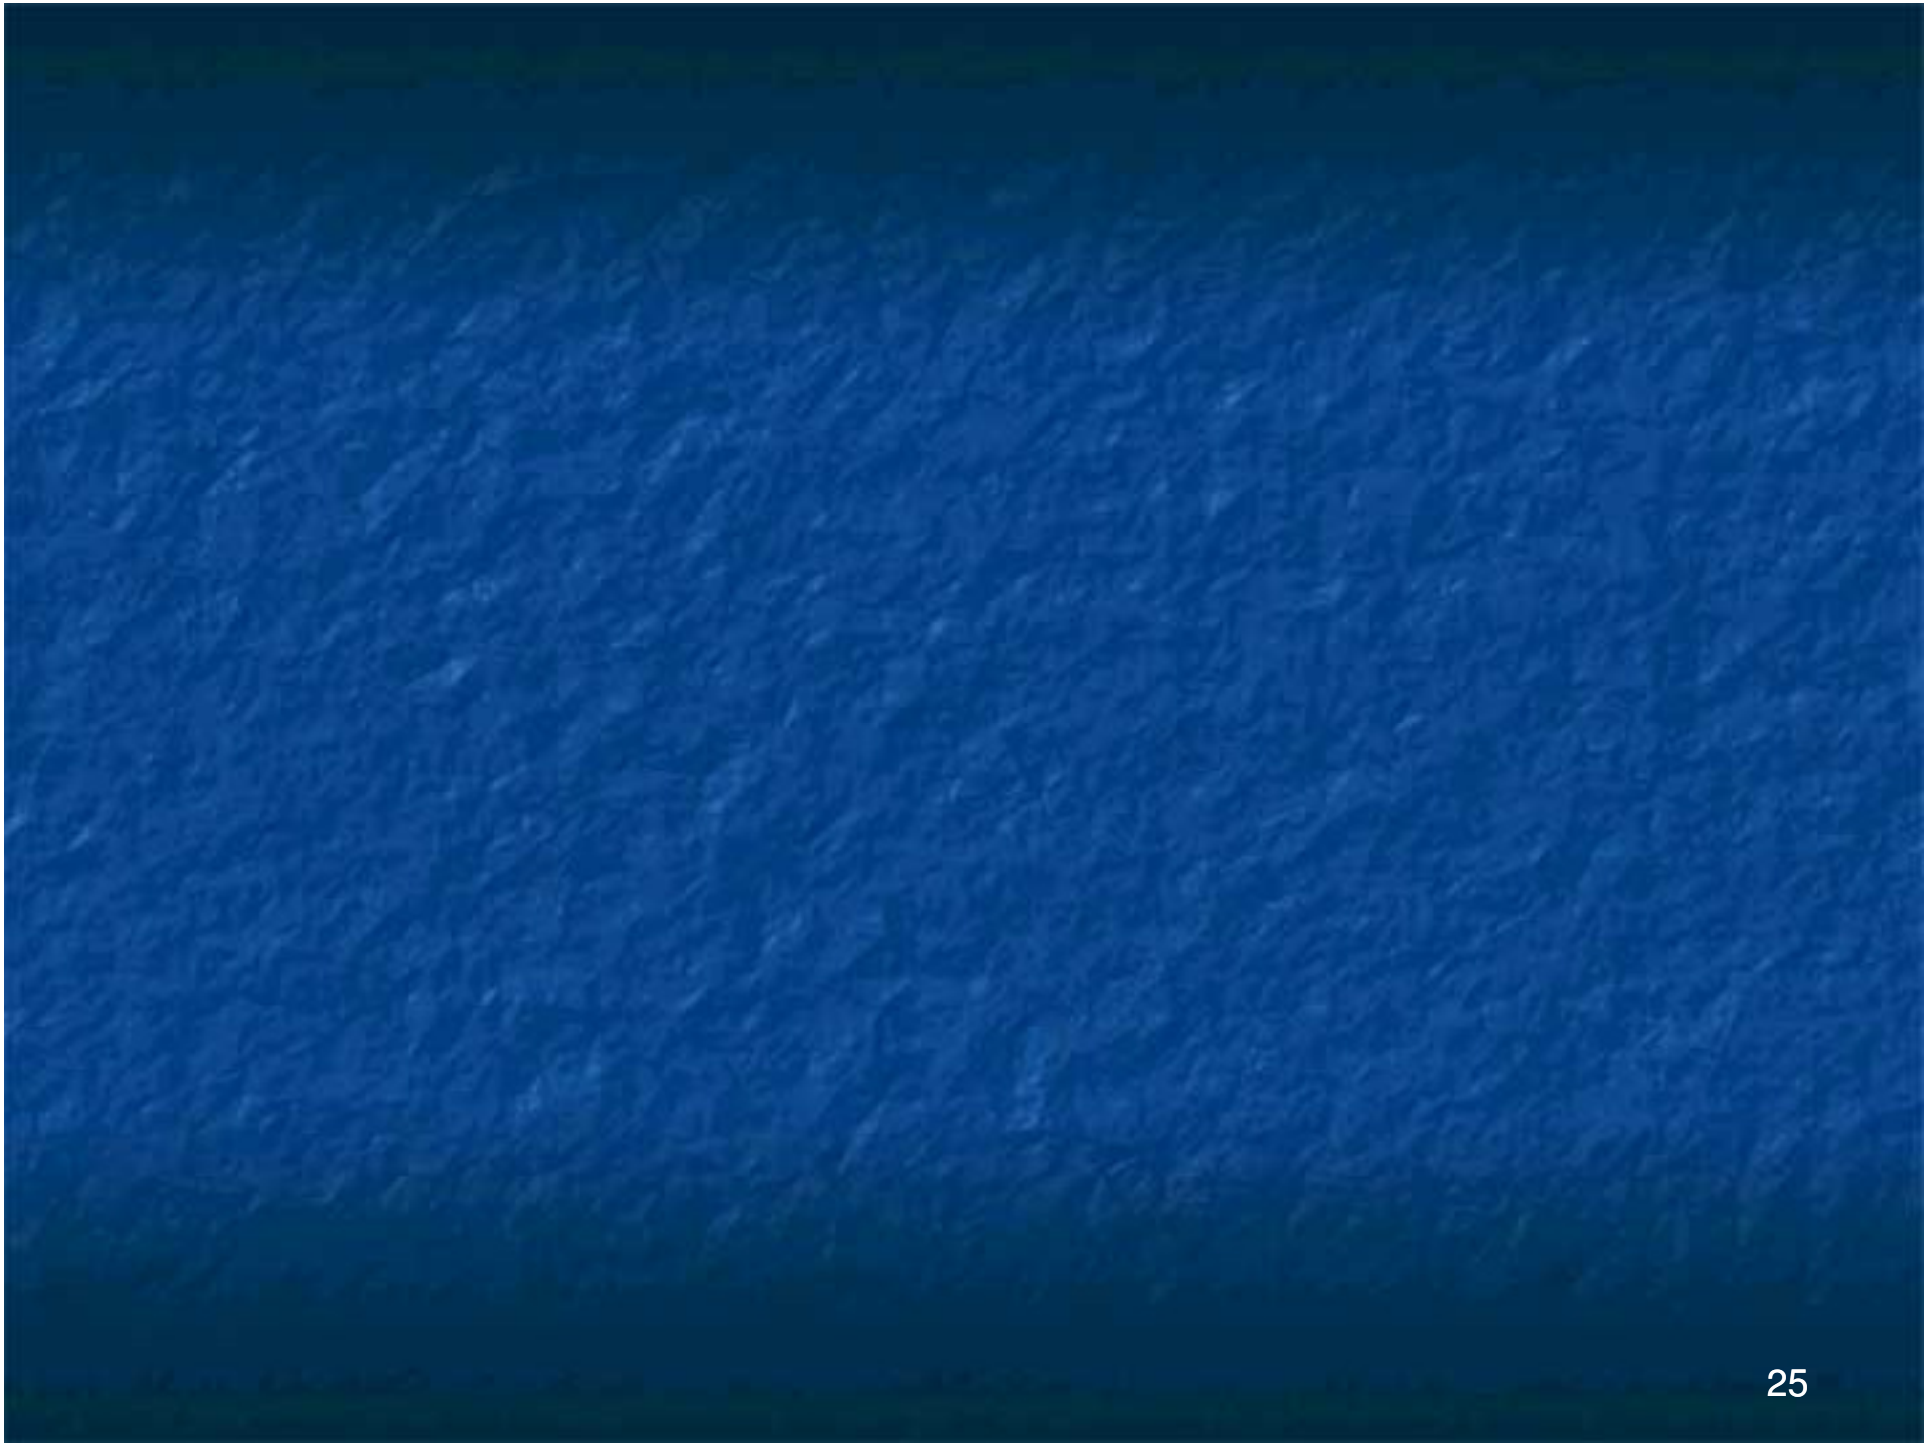
Waist circumference:

the most cost-effective predictor for insulin resistance and CV risk



CONCLUSIONS

- Detecting IR in clinical practice should rely on clinical data (WC+++);
- Defining IR in clinical research can rely on simple surrogate indexes;
- Stratifying patients according to the MetS yields an incomplete estimation of the CV&M risk.



CHD events and new-onset diabetes stratified by both CRP (</>=3 mg/L) and presence of absence of metabolic syndrome (MS)

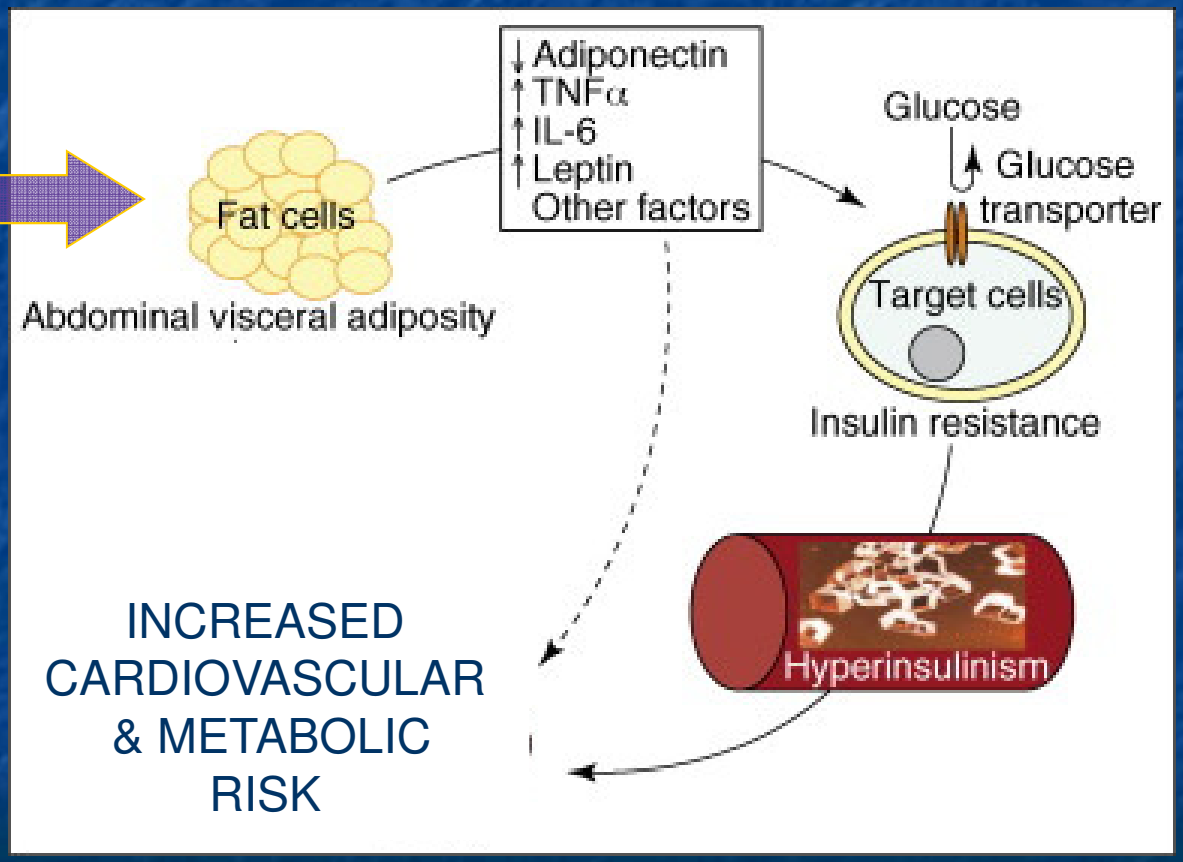
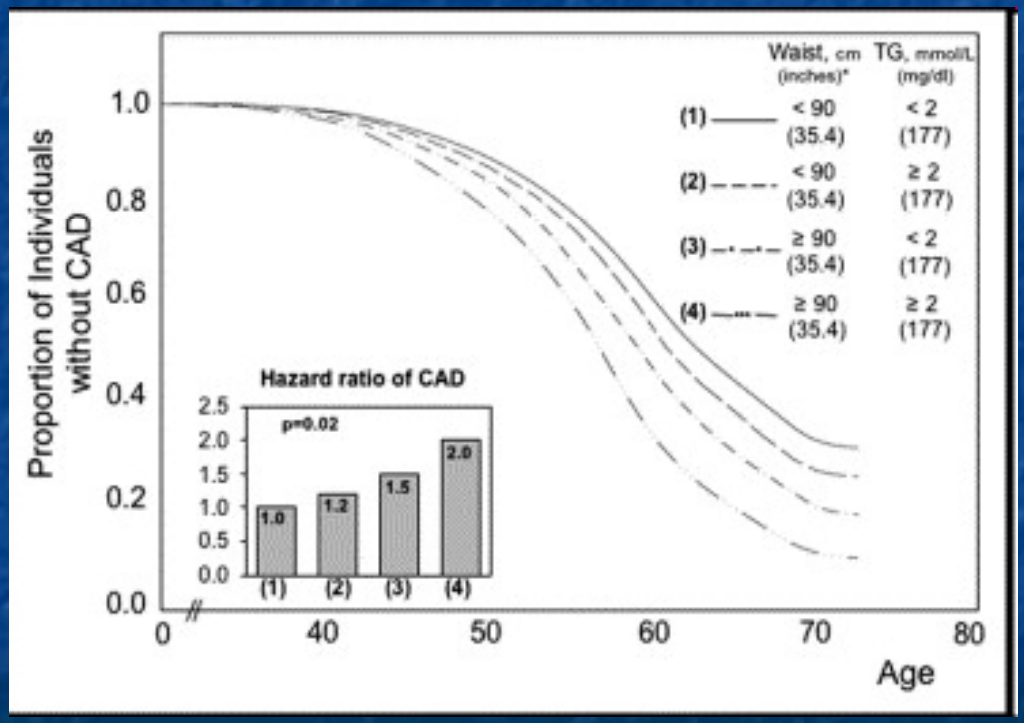
ADIPOTOXICITY

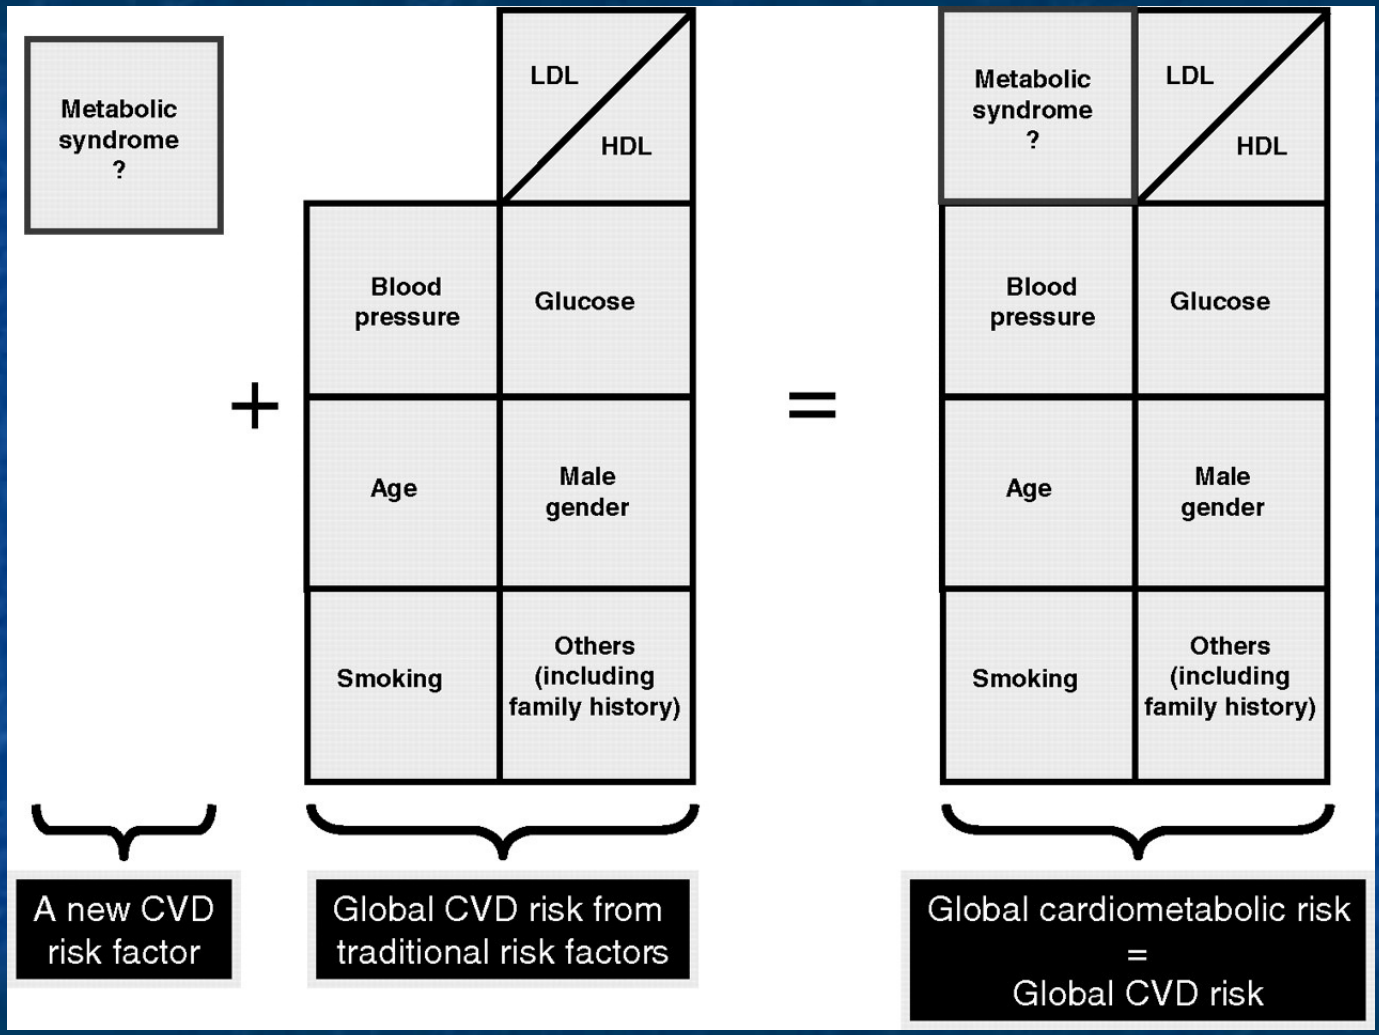
Genes
Environment



The hypertriglyceridemic waist phenotype



The "building blocks" of global cardiometabolic risk



Despres, J.-P. et al. Arterioscler Thromb Vasc Biol 2008;28:1039-1049

- MIRACLE score included: family history (early cardiovascular disease, type 2 diabetes, and hypertension), individual history (small for gestational age and ethnic origin), clinical features (BMI, waist circumference > 90th percentile and blood pressure > 95th percentile) and metabolic abnormalities (glucose intolerance or type 2 diabetes). It was assigned a value of 1 to "presence" and 0 to" absence" in every patient. The children were considered as having metabolic risk when at least 5 items were present. Triglycerides, HDL-cholesterol, apolipoprotein B, apolipoprotein A1, glucose and HOMA index, were measured too. The most frequent clinical features of MIRACLE score were: excess waist circumference (95.4%) and hypertension (41.8%). Family history criteria were frequent (55.3% for type 2 diabetes, 39.1% for hypertension and 31.3% for early cardiovascular disease). Individual risk factors were not frequent. Glucose intolerance was detected in 22.2% of the obese patients. A MIRACLE score > or = 5 was found in 37.4% of the children studied, being associated with a significant risk of dyslipidemia (triglycerides, p = 0.040; HDL-cholesterol, p = 0.006; LDL-cholesterol p = 0.038; apolipoprotein B, p = 0.008) only in females.
