Summary answer: Differences are observed in the levels of normal vs abnormal spindle chromosome configurations, the chromatid exchange rate and the ultrastructure between fresh and vitrified embryos.

What is known already: Most studies in human vitrified embryos concentrate on assessing the success of the procedure on survival rates and clinical outcomes following transfer. Indeed several clinical trials have confirmed promising results. Limited studies have however examined the effects of vitrification on spindle structure and chromosome alignment, while no studies have looked into the sister chromatid exchange rate (SCE) or investigated in detail the ultrastructure of the cellular organelles in vitrified and fresh human embryos.
Study design, size, duration: This is an ongoing study, initiated in March 2013. Until today, 140 blastocysts, rejected for transfer following day 3 biopsy and PGD, were treated either fresh or following day 5 vitrification with DMSO/EG for cytoskeletal analysis (n = 25 fresh/n = 25 vitrified), Transmission Electron Microscopy analysis (TEM) (n = 25 fresh/n = 25 vitrified) and chromatid exchanges (SCE) (n = 20 fresh/n = 20 vitrified).
Participants/materials, setting, methods: Cytoskeletal analysis by immunostaining with α, γ, acetylated tubulin and DAPI was conducted in an academic hospital with IVF/PGD laboratory. TEM analysis was conducted in a Histology/Embryology Laboratory following fixation in glutaraldehyde osmium, uranyl and immersion in EPON. SCE assessment was performed following treatment with BrdU in a Biology Laboratory.
Main results and the role of chance: Cytoskeletal analysis by confocal laser scanning microscopy revealed that the majority of spindles examined in both groups were normal but the incidence of spindle abnormalities, was significantly higher in the vitrified blastocysts compared to fresh blastocysts ($P < 0.05$). In particular, in the vitrified vs the fresh group, 60.4% vs 73.2% of spindles were normal, 35.8% vs 22.4% were abnormally shaped occasionally with chromosome lagging, bridging or congression failure, while 3.8% vs 4.4 had abnormalities only in the number of poles. The sister chromatid exchange rate was also higher in the vitrified group compared to the fresh group. TEM analysis of vitrified blastocysts (24 h post-warming) showed an increased incidence of lipofuscin droplets (representative of apoptosis), higher number of vacuoles and distension of mitochondria compared to fresh blastocysts.
Limitations, reason for caution: The blastocysts used in this study were all diagnosed with either chromosomal abnormalities or single gene defects following PGD/S. The majority of the cells at the blastocyst stage are in interphase and therefore spindle chromosome configuration analysis and the SCE rate are inevitably based on a small number of mitoses.
Wider implications of the findings: This is the first study to compare the ultrastructure and SCE rate in biopsied fresh and vitrified human embryos. Mechanical stress sustained after exposure to cryoprotectants lead to the increased spindle/chromosome abnormalities observed in the vitrified group. Differences in mitochondrial number/morphology reflect alterations in embryo metabolism, but the increase in lipofuscins may indicate a 'rescue' process for the embryo, which in its attempt to fully recover and continue normal development following vitrification, eliminates damaged/abnormal cells.

P-254 Predicting live birth relies on different kinetic parameters depending on embryo transfer day

Y. Kumtepe Colakoglu[1], M. Cetinkaya[1], C. Pirkevi[1], Z. Atayurt[1], H. Yelke[1], A. Karahasanoglu[1], H. Akbas[1], S. Kahraman[1]
[1]*Istanbul Memorial Hospital, IVF Center, Istanbul, Turkey*

Study question: Is it possible to use the same ranges of morphokinetic variables for the prediction of live birth in patients transferred on different days?
Summary answer: Embryos transferred on day 3 and 4 and blastocysts transferred on day 5 behave differently on kinetic basis when early cleavage parameters are evaluated. Therefore, different models should be used to predict the live birth potential of embryos transferred on different days.
What is known already: Embryo implantation of embryos transferred on day 3 was predicted using the time of division to 5 cells, the time between division from 3 to 4 cells and the time between division from 2 to 3 cells (Meseguer et al., 2011). An aneuploidy risk classification based on the start of blastulation and the formation of a full blastocyst proved beneficial in correlation with live birth when applied to non-biopsied embryos transferred on day 5 (Campbell et al, 2013).
Study design, size, duration: This retrospective cohort study was conducted from October 2011 to December 2013. It included 149 infertile patients and 218 embryos achieving live birth (LB) and incubated in a time-lapse incubator (EmbryoScope™). A total of 66LB embryos transferred on day 3 and 4 and 152LB blastocysts transferred on day 5 were compared.
Participants/materials, setting, methods: The mean age was 33.04 ± 3.98 and 30.75 ± 3.99 for the first and second group, respectively. In the same order, the total number of retrieved oocytes was 8.44 ± 5.09 and 13.03 ± 6.36. Differences in early cleavage kinetics (before t8) were analyzed using a Mann Whitney test. Statistical significance was determined as $p < 0.05$.
Main results and the role of chance: As our policy, embryos were cultured to the blastocyst stage whenever possible (two good quality embryos on day 3 and on day 4). Patients transferred on day 3 and 4 have therefore different clinical characteristics than those transferred on day 5. When analyzing only embryos achieving LB, cleavage timings up to t8 were significantly different for those transferred on day 3 and 4 when compared to those transferred on day 5. Embryos developing into blastocysts are faster and the delay of LB embryos transferred on day 3 and 4 is increasing from t2 to t8, reaching a maximum of 4 h for t7. All p values were found to be below 0.05. The overall live birth rate was calculated as 19.50% for the cohort studied.
Limitations, reason for caution: Blastocyst transfers are obviously done for younger females with a good ovarian reserve. However, this does not change the fact that the embryos achieving the blastocyst stage have significantly different kinetic values beginning from the time to achieve at 2 to t8.
Wider implications of the findings: Separate time ranges should be used when working with absolute time points for cleavage and morulae transfers and blastocyst transfers. Female age and ovarian reserve are also two crucial parameters to take into consideration when building morphokinetic models.

P-255 Using time-lapse to study diploidization of human parthenogenetic haploid embryos

L. Z. Leng[1], X. Y. Kong[1], K. Tan[1], D. H. Cheng[2], S. T. Yang[1], M. Hao[1], G. X. Lu[2], G. Lin[2]
[1]*Institute of Reproductive and Stem Cell Engineering, Central South University, Reproductive Group, Changsha, Hunan, China*
[2]*Reproductive and Genetic Hospital of CITIC-Xiangya, Reproductive Group, Changsha, Hunan, China*

Study question: Do human parthenogenetic haploid embryos (hPHEs) undergo diploidization through specific cleavage behaviors?
Summary answer: hPHEs can actively undergo cleavage tendency (CT) or blastomere fusion (BF) in the first three divisions to realize self-diploidization.
What is known already: In animal models, partly parthenogenetic haploid embryos were induced to become diploid during preimplantation development, but the underline mechanism is unclear.
Study design, size, duration: A experimental study from August 2012 to May 2014 was conducted. A total of 96 *in-vitro* matured metaphase (MII) oocytes were collected and parthenogenetic activated. Then cleavage behaviors were analyzed by time-lapse. Further, we used Fluroescence in situ hybridization (FISH) to detect chromosome ploidy.
Participants/materials, setting, methods: Immature oocytes from patients receiving ICSI were collected and matured *in vitro* culture. Further parthenogenetic haploid oocytes obtained by calcium ionophore A23187 with puromycin were used for time-lapse observation. Meanwhile, 328 IVF/ICSI embryos were analyzed as the control. 20 hHPEs, occurring CT/BF or not, were tested by FISH in Day 3.
Main results and the role of chance: Compared to IVF/ICSI embryos, hPHEs had higher incidence in CT (18.8% vs. 1.2%, $P < 0.001$) and BF (7.3% vs. 0.9%, $P = 0.001$). Among hPHEs, 63.0% CT/BF behaviors occurred at the first division and 55.6% CT/BF embryos could cleavage normally in the next cell cycle. In addition, the compaction rate of D5 CT/BF embryos was 45.5% while

non-CT/BF embryos was 11.8%. FISH results showed that the hPHEs appeared CT/BF were diploid signals (100%, 9/9), while the non-CT/BF embryos all showed haploid signals (100%, 11/11), besides, when CT/BF occurred in the first division, almost all the blastomeres turned out to be diploid signals. Finally, for artificial diploidization in hPHEs at 2-cell stage, the blastocyst formation rate of electrofusion group was significantly higher than that of non-electrofusion group (39.3% vs 8.7%, $P < 0.01$).

Limitations, reason for caution: In our study, the chromosome ploidy of hPHEs tested by FISH using three-colour fluorescent DNA probes specific for three different chromosomes (16, 18, X) can not represent the whole chromosome ploidy exactly.

Wider implications of the findings: This study gives a better insight into the mechanisms involved in self-diploidization. hPHEs may possess the ability to correct aberrant chromosomal ploidy.

Study funding/competing interest(s): Funding by national/international organization(s) – National Science Foundation of China (No. 81222007).

Trial registration number: NA.

P-256 Cleavage synchronicity predicts increasingly live birth as women grow older

H. Yelke[1], M. Cetinkaya[1], C. Pirkevi[1], Z. Atayurt[1], Y. Kuimtepe[1], S. Unal[1], A. P. Cil[1]

[1]*Istanbul Memorial Hospital, ART and Reproductive Genetics Center, Istanbul, Turkey*

Study question: Is the cleavage synchronicity behaves the same regarding female age when predicting live birth?

Summary answer: Cleavage synchronicity from two to eight cells (CS2-8) predicts live birth in retrospective cohort of 537 patients ($p < 0.0001$). When women were categorized in three different age groups (<30; 30–35; 35–40) the live birth ratio increased by 1.86 fold in the young group and 16.2 fold in the oldest group.

What is known already: The relative timing CS2-8 = ((t3-t2) + (t5-t4))/(t8-t2)) has been found to be the best predictor available on day 3 for blastocyst formation and quality when compared to absolute time-points (AUC: 0.786; sensitivity: 83.43; specificity: 62.46) (Cetinkaya et al., 2014). However, the proposed expression need to be further tested in regard to implantation potential and live birth prediction in order to obtain specific models for patients with different clinical characteristics.

Study design, size, duration: This retrospective cohort study was conducted from October 2011 to December 2013. It included 904 embryos having a (t8) and with known live birth data (KLB) from 537 infertile patients. Patients were divided into three categories according to age (Group A: <30; Group B: ≥30 and <35; Group C: ≥35 and <40).

Participants/materials, setting, methods: Incubation was performed in time-lapse incubators (EmbryoScope™). Group A, B and C included 207, 401 and 296 KLB embryos, respectively. Each group was further investigated as having asynchronous (CS2-8 ≤ 0.6) or synchronous (CS2-8 >0.6) cleavages. Differences were then analyzed using a chi-square test. Statistical significance was determined as $p < 0.05$.

Main results and the role of chance: Cleavage synchronicity from 2 to 8 cells ((t3-t2) + (t5-t4))/(t8-t2) reflects the ratio of time the embryo spends from 2 to 4 cells over the time from 2 to 8 cells. Although each blastomere basically behaves independently during mitotic cell divisions, an embryonic synchronicity exists, such that uneven cell stages represent very short time frames during the 5 days of preimplantation embryo development.

The overall live birth rate (LBR) was calculated as 24.11 for the cohort studied. When analyzing by age categories, the LBR increased from 20.9% to 39.0% for group A when asynchronous and synchronous embryos were compared ($p = 0.0422$). Similarly for group B the LBR increased from 11% to 31% ($p = 0.0004$). The trend further increased for group C with a LBR of 1.1% for asynchronous embryos and a LBR of 17.9% for synchronous embryos ($p = 0.0001$).

Limitations, reason for caution: Embryos having a (t8) were exclusively included in the additive model, leaving out evaluation of day 2 embryo transfers. The cohort studied involved only infertile patients (female, male or combined) and is in this respect a heterogeneous population.

Wider implications of the findings: The synchronicity of mitotic divisions is a strong predictor of live birth in this retrospective cohort study. As a conclusion, the effect of synchronous cleavages is more prominent as women grow older, therefore CS2-8 can easily be implemented in the clinical practice when choosing embryos for transfer from time-lapse incubators to obtain high LBR.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Memorial Sisli Hospital/Turkey.

Trial registration number: Approved by Ethical Committee of Memorial Sisli Hospital, Istanbul.

P-257 Successful application of a single warming protocol for embryos cryopreserved by either slow freezing or vitrification techniques: can one method fit for all?

O. Coban[1], M. Serdarogullari[2], N. Findikli[3], O. Olcay[3], K. Boynukalin[4], B. Erzik[4], M. Bahceci[4]

[1]*Bahceci Cyprus IVF Centre, Embryology Laboratory, Famagusta, Cyprus*
[2]*Bahceci Umut IVF Centre, Embryology Laboratory, Istanbul, Turkey*
[3]*Bahceci Fulya IVF Centre, Embryology Laboratory, Istanbul, Turkey*
[4]*Bahceci Fulya IVF Centre, Infertility Clinic, Istanbul, Turkey*

Study question: This study asks whether sucrose gradient-based tri-step warming protocol can be efficiently adapted in a clinical setting as a universal warming protocol for previously cryopreserved and stored embryos by using both slow freezing and vitrification methods.

Summary answer: Our study shows that, irrespective of the methods of cryopreservation as well as freezing date, a sucrose-based common warming protocol can be effectively used and create acceptable cryosurvival as well as pregnancy rates in clinical IVF settings.

What is known already: Recent developments and improvements in cryopreservation technologies created a rapid shift from slow freezing to vitrification protocols in clinical IVF programmes worldwide. For this reason, many clinics have abandoned slow freezing protocols and adopted vitrification as the main technique in their cryopreservation facilities. However, depending on the duration of cryostorage, samples that had been previously cryopreserved by slow freezing method in the past can create problems as well as uncertainties upon warming in embryo viability due to the limited experience and the lack of warming materials/kits for this specific procedures when needed.

Study design, size, duration: This prospective cohort study had been performed between January 2013 and November 2014 in Bahceci Cyprus Assisted Reproductive Technology Center. A total of 497 human embryos from 153 patients that had previously been cryopreserved by slow freezing or vitrification protocols were included in the study.

Participants/materials, setting, methods: In non-donor cycles, a total of 254 embryos in 72 cycles that had previously been cryopreserved by slow freezing (before 2011) and 294 embryos in 81 cycles that had been vitrified (after 2011) were warmed by a single, sucrose gradient-based tri-step warming protocol. Upon warming, embryo and cellular viability was assessed and suitable embryos were cultured/used for embryo transfer. Where available, embryos that were cultured for day 5/6 embryo transfer were also scored for blastocyst development rate.

Main results and the role of chance: No significant differences ($p > 0.05$) were observed in patient characteristics such as female age at the time of cryostorage, BMI, sperm parameters etc. In all procedures, embryos were cultured in conventional human embryo culture media at least 2 h before embryo transfer. Data regarding the embryo survival, blastocyst development as well as pregnancy rates (PR) is shown in table. Although higher blastulation and pregnancy rates are observed in slow freezing/fast warming group, these differences were not statistically significant ($p > 0.05$).

			Survival after warming (%)					
	Cases (*n*)	Embryos (*n*)	100%	≥50%	<50%	0%	Blastulation rate (%)	PR (%)
Slow freezing	72	254	79.9	8.7	9.1	2.4	43.0	68.1
Vitrification	81	294	88.4	4.1	4.8	2.7	35.8	53.1

Limitations, reason for caution: The number of embryos and cycles analysed are the main limitations of our study. Further research and larger sample sizes with the current parameters and technical setting are required to confirm our findings. Slight variations in slow freezing procedures can also be addressed in a large study.

Wider implications of the findings: Current data on using a universal warming protocol for oocytes/embryos in different cryopreservation cycles are scarce. Our data, although underpowered, show important and acceptable embryo development and pregnancy results that can be created by a single, universal warming protocol that is easy and adaptable in any clinical setting.
Study funding/competing interest(s): Funding by hospital/clinic(s) – This study received no funding and no conflicts of interests to be declared.
Trial registration number: This study was not an RCT and therefore there is no registration number.
Keywords: embryo cryopreservation, slow freezing, vitrification/warming, clinical outcome

P-258 Similar implantation and pregnancy rates using a single medium versus sequential media for embryo culture: a randomized controlled trial

I. A. Sfontouris[1], E. M. Kolibianakis[2], G. T. Lainas[1], I. Z. Zorzovilis[1], G. K. Petsas[1], T. G. Lainas[1]
[1]*Eugonia, Assisted Reproduction Unit, Athens, Greece*
[2]*Aristotle University of Thessaliniki, 1st Department of Obstetrics and Gynecology, Thessaloniki, Greece*

Study question: Are implantation rates different after embryo culture in a single medium compared to sequential media?
Summary answer: Implantation rates are similar after embryo culture in a single medium compared to sequential media.
What is known already: Sequential media and single media represent two fundamentally different approaches for embryo culture, in principle and formulation. Several studies randomizing sibling oocytes showed that single media are associated with higher blastocyst formation rates compared to sequential media. However, despite the remarkable interest in the use of single media, reliable data on implantation and pregnancy rates are limited as available studies with patient randomization are currently scarce.
Study design, size, duration: RCT performed at Eugonia Assisted Reproduction Unit in Athens, between January 2014 and June 2014. A total of 100 patients were randomly allocated to embryo culture in ether a single medium (Global; $n = 50$ patients) or sequential media (ISM1/BlastAssist, Origio; $n = 50$ patients). Primary outcome was implantation rate.
Participants/materials, setting, methods: Patients ≤40 years, with ≤2 previous attempts were treated with GnRH antagonist protocol. Embryos were group-cultured in the assigned medium (Global or ISM1/BlastAssist) and transfers were performed on Days 2, 3 or 5. Media were changed on Day 3. Doctors and patients were blinded to the type of medium used.
Main results and the role of chance: Baseline patient characteristics were similar in the two groups. Implantation rates [35.6 ± 38.5% versus 35.8 ± 39.2%], positive hCG rates [72.7% (32/44) versus 75% (36/48)], clinical pregnancy rates [61.4% (27/44) versus 58.3% (28/48)], and ongoing pregnancy rates [50% (22/44) versus 50% (24/48)] per embryo transfer did not differ statistically in single and sequential media, respectively. No significant differences were observed in blastocyst formation rates per 2PN [55.9% (123/220) versus 54.3% (133/245)], embryo utilization rates per 2PN [63.7% (216/339) versus 58.9% (218/370)], number of 2PN [7.2 ± 4.9 versus 7.4 ± 4.8], number of good quality embryos [2.8 ± 1.8 versus 3.0 ± 2.6], and number of embryos transferred per patient [2.5 ± 0.7 versus 2.5 ± 0.7] in single and sequential media, respectively. All outcomes were similar when evaluated for Day-2, Day-3 and Day-5 transfers separately.
Limitations, reason for caution: The present study was powered to compare implantation rates as a marker of embryo viability. Powered RCTs reporting on live birth rates in single versus sequential media are necessary to verify the present findings.
Wider implications of the findings: Implantation and pregnancy rates, as well as blastocyst formation and embryo utilization rates were similar in single (Global) and sequential (ISM1/BlastAssist) embryo culture media. Both types of media appear to adequately support *in vitro* preimplantation embryo development, yielding embryos of similar viability and developmental competence, and similar reproductive outcomes.
Study funding/competing interest(s): Funding by hospital/clinic(s). Funding by commercial/corporate company(ies) – Eugonia Assisted Reproduction Unit, LifeGlobal.
Trial registration number: NCT02048527.
Keywords: single media, sequential media, implantation rates, pregnancy rates, embryo culture

P-259 Exploring mathematical vectors to predict embryo implantation: a model using the start of blastulation and the time to reach the expanded blastocyst stage

M. Cetinkaya[1], C. Pirkevi[1], Y. Kumtepe Colakoglu[1], H. Yelke[1], M. Aygun[1], S. Kahraman[1]
[1]*Istanbul Memorial Hospital, ART and Reproductive Genetics Center, Istanbul, Turkey*

Study question: Can mathematical vectors be a useful tool when modeling and predicting embryo implantation from tEB (time from insemination to expanded blastocyst) versus tSB (time from insemination to start of blastulation)?
Summary answer: A geometric approach was used to calculate the distance and angle of coordinates derived from tEB versus tSB in 599 KID (Known Implantation Data) blastocysts belonging to 385 patients. An increase of 2.29 fold was calculated when the lowest category was compared with the highest implantation group (24.16% vs. 55.41%, respectively).
What is known already: Since time-lapse has entered the IVF laboratory many models using kinetic expressions, e.g., cleavage timings, time intervals and time ratios have been proposed and have tried with variable reproducibility to predict blastocyst formation, implantation and live birth. However, predicting blastocyst implantation is a difficult objective to achieve since if embryos are able to develop into blastocysts of fair quality then the implantation potential is obviously driven by extrinsic factors like, among others, endometrial receptivity.
Study design, size, duration: This retrospective cohort study was conducted from October 2011 to November 2014, including 599KID blastocysts. For each embryo, a vector was drawn from the origin to the tEB vs. tSB intersection point and the length of the vector was determined. Also, the angle of this vector to the tEB axis was evaluated.
Participants/materials, setting, methods: Incubation was performed in time-lapse incubators (EmbryoScope™). Cut-offs were calculated by an area under curve (AUC) analysis (145.35 for the length of the vector and 0.72 for the angle of the vector to the x axis). Differences were then analyzed using a chi-square test. Statistical significance was determined as $p < 0.05$.
Main results and the role of chance: Time points that define precise embryo cleavage events may not be generalized to infertile patients with different etiologies, and may depend on the conditions applied in IVF units. Therefore, exploring unorthodox ways to approach embryologic developmental timings may give the flexibility required for each individual embryo's evaluation in relation to its implantation potential, by allowing an associative analysis of many time-points with each other instead of strict cut-off values resulting in grouping dissimilar embryos. In the study conducted, the overall KID rate was calculated as 37.73. When dividing the data into four quartiles according to the cut-off values obtained, the KID rate increased from 24.16% to 55.41%, with the two intermediate groups having a KID rate of 37.01% and 40.96% ($p < 0.0001$).
Limitations, reason for caution: Embryos cultured to the blastocyst stage were exclusively included in the additive model, leaving out evaluation of day 3 embryo transfers.
Wider implications of the findings: The use of mathematical vectors, although unconventional, is an approach that deserve to be explored as an option that may efficiently predict the implantation potential of blastocysts when integrated to time-lapse incubation.
Study funding/competing interest(s): Funding by hospital/clinic(s) – This retrospective study was funded by ART and Reproductive Genetics Center, Memorial Sisli Hospital, Istanbul, Turkey.
Trial registration number: This retrospective study was approved by the Ethics Committee of the Memorial Sisli Hospital, Istanbul, Turkey.
Keywords: ART, implantation, morphokinetics

P-260 Is everything about the morula? The time to achieve a morula and the period at which the embryo stays a morula predict implantation

C. Pirkevi[1], M. Cetinkaya[1], Y. Kumtepe Colakoglu[1], Z. Atayurt[1], H. Yelke[1], A. P. Cil[1], S. Kahraman[1]
[1]*Istanbul Memorial Hospital, Assisted Reproductive Technologies and Reproductive Genetics Center, Istanbul, Turkey*

Study question: Are the time to achieve a morula and the period at which the embryo stays a morula important predictors of implantation?
Summary answer: Five classes of implantation have been established based on time from insemination to a full morula (tM) and time period between a full

blastocoele where the blastocyst has not yet started expansion (tB) and tM. The KID rate (Known Implantation Data) was increased by nearly two-fold between the first and the fifth group.

What is known already: The aneuploidy status of embryos was related to the start of blastulation and the formation of a full blastocyst. The aneuploidy risk classification built proved beneficial in a correlation with live birth when applied to non-biopsied embryos (Campbell et al., 2013). Relative timings were found to be better indicators of blastocyst formation and quality when compared to absolute time-points (Cetinkaya et al., 2014). Therefore, time intervals and relative ratios may allow high predictivity of implantation.

Study design, size, duration: This retrospective cohort study was conducted from October 2011 to June 2014. It included 681 KID embryos having achieved the blastocyst stage and belonging to 427 infertile patients transferred on day 5. KID blastocyst were divided into five categories according to four parallels to the trendline of KID = 1 embryos.

Participants/materials, setting, methods: Incubation was performed in time-lapse incubators (EmbryoScope™). Group I, II, III, IV and V representing each 20% of the whole cohort included 103, 108, 113, 107 and 108 KID embryos, respectively. Differences were analyzed using a chi-square test. Statistical significance was determined as $p < 0.05$.

Main results and the role of chance: Time points that define precise embryo cleavage events may not be generalized to infertile patients with different etiologies, and may depend on the conditions applied in ART units. However, using relative equations such as time intervals generating a spectrum-like distribution may give the flexibility required for each individual embryo's evaluation, by avoiding impractical hierarchical classifications based on strict cut-off values that result in only a few subgroups in which more than one embryo can be located. When plotting tM against (tB-tM), five KID categories were defined. The KID rate was calculated as 46.21%, 42.96%, 34.07%, 31.79%, 23.48% for group I, II, III, IV and V, respectively ($p = 0.0010$). The relative increase between groups I–III and I–V was of 35% and 96%, respectively.

Limitations, reason for caution: The cohort studied involved only infertile patients (female, male or combined) and is in this respect a heterogeneous population.

Wider implications of the findings: The relation between the time to achieve a morula and the time the embryo stays as a morula is a predictor of implantation in this retrospective cohort study. Therefore, using time intervals in conjunction with selected developmental stages may allow an individualized ranking of embryos in relation to implantation for each patient.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Memorial Sisli Hospital.

Trial registration number: NA.

Keywords: ART, morphokinetics, morula, implantation

P-261 A prognostic model with two selected morphokinetic parameters accurately predicts the implantation potential of human embryos cultured in EmbryoScopeTM

D. Parvanov[1], I. Rangelov[2], I. Ivanova[2], K. Nikolova[2], S. Nikolova[2], V. Staykov[2], G. Stamenov[3], T. Chaushev[1]

[1]*Nadejda Fertility Clinic, Research Department, Sofia, Bulgaria*

[2]*Nadejda Fertility Clinic, Embryology Department, Sofia, Bulgaria*

[3]*Nadejda Fertility Clinic, Obstetrics/Gynecology, Sofia, Bulgaria*

Study question: Is it possible to predict the implantation potential of human embryos using morphokinetic parameters?

Summary answer: The logistic prediction model composed of synchrony of the second cell cycle (s2) and the period of time between the beginning of blastocyst formation and full blastocyst stage (Ssbb) has a powerful diagnostic capability for prediction of embryo implantation.

What is known already: Many candidate time-lapse markers have been studied regarding the selection of good quality embryos and improvement of pregnancy rates. The results of these studies highlight an adequate reproducibility about the successful implantation for only a few specific parameters, such as eight cells time point (t8), blastocyst formation time (tB), morula formation time (tM) and synchrony of the second cell cycle (s2). However, new sets of target parameters and better predictive models need to be developed.

Study design, size, duration: This retrospective study was conducted from January 2012 to November 2014. A total of 352 embryos from 223 patients were studied. 36 morphokinetic variables were analyzed.

Participants/materials, setting, methods: Embryos were cultured and analyzed in EmbryoScope™. The selection of variables was done by two-tailed *t*-test and backward stepwise regression. A logistic regression model was build and the discrimination and calibration was done by ROC analysis and Hosmer-Lemeshow test, respectively. All analyses were performed in SPSS19 and SigmaStat3.5 statistical software.

Main results and the role of chance: After two-step selection of all morphokinetic variables s2 and Ssbb were found to be the most significant parameters to be included in the model (Likelihood Ratio Test Statistic: 52,597 ($P = <0,001$)). The recall of the obtained model was 82.75%, while the fall-out was 82.85%.

Limitations, reason for caution: The developed prognostic model is not appropriate for embryos cultured until second or third day after ICSI procedure, because one of the selected parameters (Ssbb) is connected with later stages of embryonic development.

Wider implications of the findings: The use of morphokinetic parameters (synchrony of the second cell cycle and the time between the beginning of blastocyst formation and full blastocyst stage) would improve the selection of embryo with better implantation potential. This process will optimize the selection of embryos for single embryotransfer and could lead to reduction of negative effects observed in multiple pregnancies.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Nadezhda Fertility Clinic.

Trial registration number: NA.

P-262 Monopronucleated ICSI zygotes: *in vitro* development and morphokinetic evaluation

S. Mateo[1], F. Vidal[2], A. Veiga[1], V. Perez[1], I. Rodriguez[1], P. N. Barri[1], M. Boada[1]

[1]*Hospital Universitario Quiron Dexeus, Service of Reproductive Medicine, Barcelona, Spain*

[2]*Universitat Autònoma de Barcelona, Cell Biology Unit, Faculty of Biosciences, Barcelona, Spain*

Study question: What is the development capability of embryos derived from monopronucleated zygotes? Are kinetic parameters of ICSI monopronucleated (1PN) zygotes similar to those of normal zygotes (2PN)?

Summary answer: 1PN zygotes that reach blastocyst stage have similar kinetic behaviour to 2PN zygotes that give rise to pregnancy but different from those 1PN that arrest their development in earlier stages.

What is known already: Embryos from 1PN zygotes are not usually considered for embryo transfer due to possible anomalies during the fertilization process and a high incidence of aneuploidy.

The incorporation of time-lapse methodologies in ART laboratories provides constant information throughout embryo *in vitro* culture. The frequency of image capture and the number of focal planes are selected according to particular interest. The results obtained allow the identification of anomalies occurring during pronuclear formation, embryo cleavage and blastocyst formation.

Study design, size, duration: A prospective observational cross-sectional study performed between September 2012 and June 2014 with a total of 117 monopronucleated ICSI zygotes in the study group and 124 normal fertilized ICSI zygotes that resulted in ongoing pregnancies in the control group.

Participants/materials, setting, methods: Embryos were cultured in a tri-gas EmbryoScope™. Images were acquired at five focal planes every 15 min. Times of pronuclei appearance/disappearance, cleavage and cell cycles (Day 0 to Day 3) were analysed comparing both groups. Blastocyst formation was assessed in the study group. Statistical analysis was by Mann-Whitney/Chi-square test.

Main results and the role of chance: 21 monopronucleated ICSI zygotes (17.9%) developed to blastocyst stage and 96 (82.1%) arrested in early stages. Differences (median; $p < 0.05$) were observed between these two subgroups in time of PN disappearance (22 vs 24.4 h) and cleavage time to 2, 4, 6 and 7 cells (26.2 vs 29.6 h; 40.3 vs 47.2 h; 52.7 vs 57.7 h; 55.7 vs 62.4 h).

Cleavage times of monopronucleated ICSI zygotes that reached blastocyst stage were similar to those of the control group. Differences were only observed in time of PN disappearance (22 vs 24.2 h) and in the duration of the third cell cycle (11.4 vs 13.3 h).

Kinetics of 1PN ICSI zygotes that arrested their development were slower than those of both 1PN zygotes that reached blastocyst stage and 2PN zygotes that produced ongoing pregnancies.

Limitations, reason for caution: Despite the large number of monopronucleated zygotes included in the study, the subgroup of zygotes that reached blastocyst stage was limited. The control group was not followed up to the blastocyst stage and no comparison of kinetic parameters after Day 3 was done.
Wider implications of the findings: Not all 1PN zygotes have the same kinetic behaviour and developmental capability. Monopronucleated zygotes that achieve the blastocyst stage have similar kinetics to normal fertilized 2PN zygotes. In view of the results of this study, a new strategy could be considered rather than simply discarding such embryos. PGS of 1PN blastocysts would make it possible to determine their chromosomal constitution and thus their suitability for transfer or cryopreservation.
Study funding/competing interest(s): Funding by hospital/clinic(s) – "Cátedra de Investigación en Obstetricia y Ginecología" of the Department of Obstetrics, Gynecology and Reproduction, Hospital Universitario Quiron Dexeus.
Trial registration number: NA.
Keywords: monopronucleated ICSI zygotes, morphokinetic evaluation, time-lapse

P-263 Cilostazol improves oocyte competence and IVF outcomes in mice: ovulation of immature oocytes with higher developmental rates

A. M. Taiyeb[1], K. Khalaf[2], A. Alazzam[3], Bani A. Younes[4], M. E. Kjelland[5], A. Haji[6], S. A. Muhsen-Alanssari[6], M. T. Ridha-Albarzanchi[7]

[6]*BARZ IVF Center for Embryo Research and Infertility Treatment, IVF, Erbil, Iraq*
[7]*BARZ IVF Center for Embryo Research and Infertility Treatment, Andrology, Erbil, Iraq*

Study question: Can temporal arrest of oocyte maturation in superovulated mice synchronize oocyte meiotic and cytoplasmic maturation and improve oocyte competence and IVF outcomes?
Summary answer: Temporal arrest of oocyte maturation *in vivo* results in synchronization of oocyte meiotic and cytoplasmic maturation. The latter was observed to improve IVF outcomes and oocyte competence in superovulated mice.
What is known already: Temporal arrest of oocyte meiotic maturation *in vitro*, using phosphodiesterase 3A (PDE3A) inhibitors, can synchronize cytoplasmic and meiotic maturation and improve IVF outcomes. However, the beneficial effect of *in vivo* synchronization of oocyte maturation on IVF outcomes has not yet been addressed. Cilostazol is a PDE3A inhibitor with an established record of safe long-term use in patients. Cilostazol caused mice to ovulate immature oocytes at different stages based on time, dose, or frequency of administration.
Study design, size, duration: This study was designed as a mouse superovulated model for women undergoing hyperstimulation and IVF. No less than 10 mice were used in each group. This study was started in 2012 and finished in 2014.
Participants/materials, setting, methods: Swiss Webster mice were used in this study, and all materials were purchased from Sigma (St. Louis, MO). This study was of university laboratory setting and as follow: Ovulated or ovarian mature or immature oocytes were collected from superovulated mice treated with different doses of cilostazol.
Main results and the role of chance: Ovulated germinal vesicle (GV) oocytes had significantly higher rates of advanced chromatin configuration and cortical granule distribution than did ovarian GV oocytes collected from large antral follicles of hyperstimulated mice. Ovulated GV oocytes had lower levels of cAMP and consequently higher rates of germinal vesicle breakdown, first polar body emission, *in vitro* fertilization (IVF), and blastocyst formation than did ovarian GV oocytes ($P < 0.0001$). Ovulated MI oocytes had higher rates of normal spindles and chromosomes aligned at the metaphase plates than did ovarian MI oocytes collected from preovulatory follicles of superovulated mice ($P < 0.003$). Mice ovulating MI oocytes produced litter sizes greater than those observed in control mice ovulating mature oocytes ($P < 0.002$).
Limitations, reason for caution: The positive impact of CLZ on oocyte maturation and IVF outcomes need to be confirmed using other animal models that are more predictive to human reproduction.
Wider implications of the findings: The ovulated immature oocytes may substitute for ovarian immature oocytes and become an additional research resource. More importantly, the capability of a clinically approved medication to increase oocyte fertilization rates and litter sizes in mice, at doses extrapolated from human therapeutic doses, suggests the potential scenario of the inclusion of CLZ in human hyperstimulation programs to increase the live birth rate of IVF babies.
Study funding/competing interest(s): Funding by University(ies). Funding by hospital/clinic(s) – Texas A&M University and BARZ IVF Center for Embryo Research and Infertility Treatment.
Trial registration number: NA.
Keywords: cilostazol, immature oocytes, oocyte competence

P-264 Time-lapse analysis of 1264 embryo compaction: how many cells are necessary?

C. Splingart[1], A. Catteau[1], J. Lammers[1], A. Reignier[1], P. Barriere[1], T. Freour[2]
[1]*CHU de NANTES, AMP, Nantes, France*
[2]*EUGIN, Reproducción Asistida, Barcelona, Spain*

Study question: The aim of our study was to evaluate the morphokinetic parameters of embryo compaction and to observe how many cells were included in the compaction using the EmbryoScope®, a time lapse monitoring system.
Summary answer: In this study we showed that embryo compaction can occurred from the 3-cell stage to the ≥9-cell stage but the early cleavage development differs between groups and that obtention of good quality blastocyst is correlate with early cleavage development as well as the number of cells included in the compaction.
What is known already: The onset of compaction can occur on the third to the 4th day of embryo development that is concomitant with the activation of the embryonic genome. At this stage, blastomeres begin to compact tightly and cell boundaries progressively disappear until the fully compaction.
Study design, size, duration: We retrospectively analysed all the embryo compaction obtained after ICSI cycles performed with the EmbryoScope® between February 2011 and November 2014 in our IVF unit.
Participants/materials, setting, methods: Immediately after ICSI, oocytes were placed into the EmbryoScope®. Each embryo was investigated by detailed time-lapse analysis measuring the exact timing of the developmental events in hours after ICSI procedure. We particularly observed the time of compaction and the number of cells involved.
Main results and the role of chance: We observed that beginning of compaction occurred between 3-cell and ≥9-cell stage. Most of time, compaction occurred at the ≥9-cell stage (87.12%). Only 78 compaction occurred at the 8-cell stage (6.17%) and 84 occurred before the 8-cell stage (6.65%). When compaction happened with less than 8 cells we showed that PN visibility is longer (time between PN appearance and PN fading), 2 cell-stage (t2) to t7 are more precocious and that embryos stayed longuer at the morula stage until blastulation. Irregular division mostly occurred in <8-cell group and we observed more good quality blastocyst in ≥9-cell. 52.81% of ≥9-cell group were good quality embryos (transferred or cryopreserved), 39.74% in 8-cell group and 14.46% in <8-cell. Finally, pregnancy rate in higher in ≥9-cell group.
Limitations, reason for caution: Evaluation of early cleavage stage is easy but after the 9-cell stage, the precision to count cells is not relevant.
Wider implications of the findings: Time-lapse systems are known to optimize embryo culture thanks to uninterrupted culture and continuous surveillance. In this study we reported that the kinetic developmental pattern of embryo compaction depended of the number of cells at the initiation of compaction and that it also have an impact on the chance to obtain a good quality blastocyst.
Study funding/competing interest(s): Funding by University(ies) – CHU de Nantes.
Trial registration number: NA.
Keywords: time lapse, compaction

P-265 Outcome of vitrified-warmed blastocysts derived from poor-quality cleavage stage embryos

G. Cauffman[1], L. Van Landuyt[1], N. De Munck[1], H. Tournaye[1], H. Van de Velde[1], G. Verheyen[1]
[1]*UZ Brussel, Center for Reproductive Medicine, Brussels, Belgium*

Study question: Do supernumerary cleavage stage embryos that do not fulfil the freezing criteria on day 3 have the capacity to develop into good-quality blastocysts on day 5/6 and what is their implantation potential in blastocyst warming cycles?
Summary answer: One third of the embryos unsuitable for cryopreservation on day 3 were vitrified at the blastocyst stage. The clinical outcome of the warming cycles of blastocysts derived from these poor-quality embryos on day 3 is comparable to the outcome of warmed blastocysts derived from good-quality day 3 embryos.
What is known already: Embryo transfer on day 5 provides a better embryo selection and a higher implantation rate compared to day 3 transfer. In day 3 transfer and cryopreservation programs, often applied for poor prognosis patients, supernumerary embryos not fulfilling the day 3 cryopreservation criteria are discarded. Postponing vitrification of supernumerary day 3 embryos till the blastocyst stage and analysis of their clinical outcome in warming cycles might have implications for the cryopreservation policy after day 3 transfer.
Study design, size, duration: Retrospective study of 876 day 3 transfer cycles comparing extended blastocyst culture of 3918 supernumerary embryos suitable and not suitable for cryopreservation on day 3 from January 2010 until December 2013. The clinical outcome of 631 blastocyst warming cycles until November 2014 was analysed.
Participants/materials, setting, methods: Main day 3 cryopreservation criteria were ≥6 cells, ≤20% fragmentation, no multinucleation and no severe deviation in blastomere size. Clinical outcome parameters were positive hCG, clinical pregnancy rate (CPR), CPR with foetal heart beat (FHB) and implantation rate with FHB (IR). Chi-square test was performed for statistical analysis.
Main results and the role of chance: Out of 773 embryos that did not fulfil (group A) and 3145 that did fulfil (group B) the day 3 cryopreservation criteria, 247 (32%) and 1680 (53.4%) were vitrified on day 5/6, respectively ($p < 0.0001$). Survival rates after warming were comparable for both groups (87.2% and 89.1%). SET of warmed blastocysts of group A ($n = 67$) and group B ($n = 346$) resulted in 22.4% and 34.4% positive hCG, 19.7% and 28.8% CPR and 16.7% and 24.3% CPR or IR with FHB, respectively. Un-mixed DET cycles of group A ($n = 12$) and group B ($n = 206$) resulted in 41.7% and 42.2% positive hCG, 36.4% and 33.5% CPR, 36.4% and 29.9% CPR with FHB and 27.3% and 18.5% IR. The clinical outcome was not significantly different between both groups.
Limitations, reason for caution: The current findings are based on a retrospective analysis and, therefore, could not account for other potential confounding factors.
Wider implications of the findings: Poor-quality cleavage stage embryos that would normally be discarded on day 3 may form good blastocysts with acceptable implantation rates after warming. Therefore, we may consider postponing our selection of embryos for cryopreservation to the blastocyst stage in order to rescue embryos with implantation potential. The percentage of embryos suitable for cryopreservation on day 3 is almost reduced by half when cultured to day 5/6. The clinical significance of this loss requires further investigation.
Study funding/competing interest(s): Funding by hospital/clinic(s) – UZ Brussel.
Trial registration number: NA.

P-266 Follicular fluid biomarkers for oocyte quality in human *in vitro* fertilization: proof of principle

F. Chen[1], S. Carpentier[2], T. D'Hooghe[1], C. Spiessens[1]
[1]*Leuven University Hospital Campus Gasthuisberg, Leuven University Fertility Centre, Leuven, Belgium*
[2]*K.U.Leuven, Facility for Systems Biology Based Mass Spectrometry (SYBIOMA), Leuven, Belgium*

Study question: Is the peptide profile in individual follicular fluid (iFF) associated with oocyte quality in IVF/ICSI and can we use peptidomic techniques to identify potential biomarkers for oocyte quality in the future?
Summary answer: Our data demonstrate a set of 23 peptides that could discriminate fertilized oocytes and non-fertilized oocytes. It is also confirmed that using peptidomic techniques to identify potential biomarkers for oocyte quality is feasible.
What is known already: Follicular fluid (FF) is available during oocyte aspiration and theoretically represents an optimal source for non-invasive biochemical predictors of oocyte quality. Several studies have been published on the levels of peptides, with a known endocrinological function, in follicular fluid and their value for predicting embryo quality. Nonetheless, it is unlikely that a single peptide would be predictive. Peptide profiling of iFF and its potential use as an biomarker for oocyte quality has never been reported.
Study design, size, duration: A total number of 67 individual follicular fluid samples from couples undergoing IVF/ICSI treatment at the Leuven University Fertility Center were analyzed in 3 independent training groups and divided in two classes: 'fertilized'($n = 8$, 7 and 16) and 'non-fertilized' ($n = 9$, 11 and 16).
Participants/materials, setting, methods: iFF samples were collected during oocyte aspiration. Peptides were extracted using a filter assisted sample preparation and reverse solid phase extraction. Samples were dissolved in 10 ml of 5% acetonitrile in water and evaluated via LC-MS/MS (Orbitrap QExactive).The mean signal intensity was compared between fertilized and non-fertilized oocytes.
Main results and the role of chance: To avoid overfitting, three training groups were analyzed independently. A total number of 162 candidate peptides were found in the 1st training group, classifying 94.1% (16/17) of the iFF correctly. In the 2nd experiment, 236 candidate peptides were found, discriminating 88.2% (16/18) of the iFF. In the 3rd training group, 395 candidate peptides were found, with an accuracy of 84.4% (27/32). Of all the candidate peptides, 23 were confirmed by all the experiments, discriminating 88.23% (15/17), 83.33% (15/18), and 87.5% (28/32) iFF blindly in principle component analysis.
Limitations, reason for caution: To promote one or more of the candidate peptides as a biomarker(s) for oocyte quality and fertilization (relative) quantification has to be elaborated.
Wider implications of the findings: This study, for the first time, presents a set of peptides in iFF can be used as biomarker capable of predicting oocyte quality and fertilization. It also reveals that peptide profiling in individual follicular fluid samples can be a new promising innovative, non-invasive approach to predict oocyte quality and fertilization in clinical IVF practice.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Merck Serono Grant for Fertility Innovation.
Trial registration number: NA.
Keywords: peptide profile, human follicular fluid, oocyte quality, IVF outcome

P-267 Sperm DNA integrity and its effect on embryo development: a retrospective time lapse study

T. Lundberg[1], F. Hambiliki[1], F. Sonden[1], E. Åkerlund[1], M. Bungum[1]
[1]*Skanes University Hospital Reproductive Medicine Centre Malmö Sweden, Reproductive Medicine Centre, Malmö, Sweden*

Study question: Is there a correlation between the degree of sperm DNA fragmentation as measured by Sperm Chromatin Structure Assay and early embryo development?
Summary answer: There was no correlation between the degree of sperm DNA fragmentation as measured by Sperm Chromatin Structure Assay and of embryo development assessed by Time Lapse videography.
What is known already: A negative correlation has been shown between sperm DNA fragmentation and IVF and ICSI fertilisation rates. To our knowledge, no trial evaluating the correlation between the degree of sperm DNA fragmentation as measured by Sperm Chromatin Structure Assay (SCSA) and early embryo development has been undertaken.
Study design, size, duration: In this retrospective study oocytes from women assigned to IVF or ICSI were cultured in EmbryoScope and monitored by time lapse videography. Sperm sample was collected for SCSA.
Participants/materials, setting, methods: The study included 4000 oocytes from 697 couples treated by IVF or ICSI. Embryos were cultured in an EmbryoScope and monitored by time lapse videography until day 6. The semen was collected on the same day as ovum pick up and the sperm DNA fragmentation assessed by SCSA, expressed by DFI.
Main results and the role of chance: Oocytes/embryo were categorized into four groups according to DFI level (0–10%, 10.1–20%, 20.1–30%, and >30%). Mean values for all parameters were tested in a linear regression analysis model with the respective parameters as dependant and the four DFI categories as independent factors. For all endpoints; fertilization rate (2PN), extrusion of second polar body (2PBe), pronuclear appearance (PNa), pronuclear fading (PNf), early cleavage (t2), blastocyst development (tB) and blastocyst rate the mean numbers were equal between all four groups. No statistical difference between the groups was detected.

Limitations, reason for caution: None.
Wider implications of the findings: The combination of Time lapse technology and assays like SCSA may gave us insight in early embryo development. Since there is a correlation between sperm DNA fragmentation and outcomes of IVF and ICSI, one could speculate that there is a paternal influence on early embryo development.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Funded by Skane University Hospital, Malmö, Sweden.
Trial registration number: NA.

P-268 Are TrpV3 channels present in human oocytes to mediate strontium-induced artificial activation?

Y. Lu[1], M. Ferrer Buitrago[1], J. Neupane[1], W. H. De Vos[2], E. Van den Abbeel[1], M. Vander Jeught[1], P. De Sutter[1], B. Heindryckx[1]
[1]*Ghent University Hospital, Department for Reproductive Medicine Ghent Fertility and Stem Cell Team (G-FAST), Ghent, Belgium*
[2]*University of Antwerp, Department of Veterinary Sciences, Antwerp, Belgium*

Study question: Is the TrpV3 channel present and functional in mediating strontium-induced artificial activation in human oocytes as was recently reported in mouse?
Summary answer: The TrpV3 channels are distributed in *in vitro* matured (IVM) human oocytes. However, neither strontium nor the agonists of TrpV3 channels are able to induce calcium rises or activation in human oocytes.
What is known already: Calcium (Ca^{2+})-influx is the main signal for the start of oocyte activation in mammalian eggs. Selective activation of Transient receptor potential channel (TrpV3) by agonists promotes Ca^{2+}-entry and induces mouse oocyte activation. The absence of TrpV3 channels in mouse oocytes failed to provoke strontium-induced activation. Strontium is sometimes used to overcome fertilisation failure after ICSI in human, but its efficiency is controversial and the mechanism how it mediates the Ca^{2+}-influx has not been studied.
Study design, size, duration: The distribution of the TrpV3 channels was investigated in IVM metaphase I-II (MI-MII) human oocytes after 3 or 24 h of maturation and in *in vivo* matured (IVO) mouse MII oocytes. The TrpV3 agonists-induced Ca^{2+}-oscillations, activation rate and subsequent embryonic development was analysed in both human and mouse MII oocytes.
Participants/materials, setting, methods: MII oocytes from B6D2F1 mice as well as IVM human oocytes were used. The distribution of TrpV3 channels was determined by confocal microscopy and Ca^{2+}-pattern was measured by time-lapse imaging after exposure to TrpV3 agonists for 1 h. Embryo developmental potential was assessed after artificial activation with these agonists.
Main results and the role of chance: The distribution of TrpV3 channels in IVM human oocytes showed a similar homogeneous pattern as was observed in IVO mouse MII oocytes. In mouse oocytes, both agonists of TrpV3 (200 μM 2-aminoethoxydiphenyl borate (2-APB) and 200 μM of carvacrol) promoted a single broad Ca^{2+}-peak in the first hour of exposure. However, no Ca^{2+}-influx and release could be observed in IVM human oocytes after the exposure to these agonists. Moreover, the use of 200 μM 2-APB activated 85% of mouse MII oocytes with 83% of them developing to blastocyst stage. In contrast, neither activation nor blastocyst formation was observed in human IVM oocytes.
Limitations, reason for caution: IVO human MII oocytes were not available for research. The distribution and function of TrpV3 channels could be different in IVO and IVM human oocytes.
Wider implications of the findings: The dysfunction of TrpV3 channels might explain the inconsistency that is reported in human oocytes to induce artificial activation using strontium to overcome fertilisation failure.
Study funding/competing interest(s): Funding by University(ies) – Funding by national/international organization(s). China Scholarship Council and Special Research Fund from Ghent University (Bijzonder Onderzoeksfonds, BOF).
Trial registration number: NA.
Keywords: TrpV3 channels, Ca2+-release, strontium, human oocytes

P-269 Time-lapse versus bench incubator – a prospective randomized study comparing embryo outcome of sibling oocytes

D. Hadari[1], E. Kasterstein[1], D. Strassburger[1], O. Bern[1], B. Maslansky[1], Y. Gidoni[1], A. Raziel[1], I. Ben-Ami[1], Y. Barkat[1], R. Ron-El[1]
[1]*Asaf Harofe Medical Center, IVF Unit, Zerifin, Israel*

Study question: To determine whether culturing in the integrated EmbryoScope time-lapse incubator (TLI) with low oxygen improves embryo quality and blastulation rate in comparison with low oxygen bench incubator (LOI).
Summary answer: Cleavage stage embryo and blastocyst quality were comparable, whereas blastulation rate was significantly higher in the TLI system. The percentage of blastocysts suitable for freezing was similar in both groups.
What is known already: Previous retrospective studies showed higher pregnancy rates using embryos from TLI compared to standard incubators with atmospheric oxygen. Prospective randomized study comparing implantation and ongoing pregnancy found significant increased rates and decrease pregnancy loss with TLI system than with standard incubator, both with atmospheric oxygen supply. The authors admitted that they had no idea how much of this contribution was due to improved culture conditions.
Study design, size, duration: A prospective randomized sibling oocytes split study. Patients undergoing ICSI with ≥8 oocytes were enrolled between July and September 2014. Oocytes were randomly allocated into two groups after injection. Group A include 301 oocytes cultured in EmbryoScope, Group B 225 oocytes cultured in K-System. Oxygen in both systems was 6.0%.
Participants/materials, setting, methods: Oocytes were cultured in separate droplets of one step medium till D6. Group A oocytes were left in TLI till end of culture. In group B, evaluation of fertilization, Day 2, 3, 5 and 6 was done. Day 3 transfer was when <8 good quality embryos (I–II) were present. The suitable D3, D5 and D6 embryos for freezing were vitrified.
Main results and the role of chance: The percentage of D3 good embryos (6–10 cells, degree I–II) was borderline significant: in group A 27.0% of the embryos were with good quality and 36.5% in group B ($p = 0.0501$). The blastulation rate was statistically significantly increased in group A (51.8%, versus 30.3% in group B, $p < 0.001$). Blastulation rate on D5 was 30.4% and 14.7% ($p < 0.005$) and 21.4% versus 15.6% ($p = 0.294$) on D6. Day 3 supernumerary embryos of good quality were frozen: 8.3% of all embryos in group A and 13.3% in group B. ($p = 0.138$). Blastocysts were evaluated according to Gardner classification. Thirty good quality blastocyst out of 87 (34.5%) were frozen in group A and 11 of 33 (33.3%) in group B ($p = 0.923$).
Limitations, reason for caution: The size of the study group is limited, and so, conclusions and significance may not be well established. Implantation of embryos as a primary end point is impossible in this size of series, and thus, morphokinetics was not considered.
Wider implications of the findings: Our study compares, for the first time, the outcome of culture in TLI with this in conventional incubator, having the same a priori qualities, meaning dry chambers, same gas control conditions, low oxygen and same medium. The only investigated parameter was the exposure of embryos for evaluation with LOI. Under these conditions the percentage of good quality embryos was marginally better with LOI system, blastulation rate was significantly higher with TLI. However, the good quality blastocysts suitable for freezing were comparable in both systems. The advantages of TLI have still to be proven.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Assaf Harofeh Medical Center.
Trial registration number: NA.
Keywords: time lapse, blastulation, embryo culture, sibling oocytes

P-270 A higher cumulative pregnancy rate in elective cohort embryo freezing than fresh transfer with subsequent frozen embryo transfer in IVF/ICSI cycles in high responders

S. U. Chen[1], G. C. Jou[1], C. H. Chung[1], Y. T. Chiang[1], H. F. Chen[1], M. J. Chen[1], M. Y. Wu[1], Y. S. Yang[1]
[1]*National Taiwan University Hospital, Department of Ob/Gyn, Taipei, Taiwan R.O.C.*

Study question: Cumulative ongoing pregnancy rates (OPR) between elective cohort embryo freezing (freezing-all strategy) and first-cycle fresh embryo transfer (ET) with subsequent frozen ETs (FETs) for high responders in *in-vitro* fertilization/intracytoplasmic sperm injection (IVF-ICSI) cycles remain unclear.
Summary answer: Elective cohort embryo freezing could increase the cumulative second-trimester ongoing pregnancy rates in high responders.
What is known already: Elective cohort embryo freezing in high responders with subsequent FETs at better endometrial status is a safe and effective strategy for IVF-ICSI treatments. However, fresh ET used to be a norm in IVF/ICSI cycles considering the possibility of cryo-damage and its less procedure-related cost and time.

Study design, size, duration: This is a retrospective, cohort study. Analysis was performed on 180 patients with high response to ovarian stimulation (≥20 follicles bigger than 10 mm) with their first IVF/ICSI cycle during 2011–2014. The primary outcome measurement was cumulative second-trimester OPR. The secondary outcome was incidence of severe ovarian hyperstimulation syndrome (OHSS).
Participants/materials, setting, methods: Our study group consisted of 92 patients using elective embryo cryopreservation and subsequent FETs. The control group composed of 88 patients using fresh embryos at their first cycle of ETs, who would have another FETs if no successful ongoing pregnancy was achieved at the first cycle.
Main results and the role of chance: The ages were comparable between the two groups. Comparing to the control group, the study group had higher percentage of D5 ET (76.7% vs 32.2%, $p < 0.05$), and higher implantation rate (49.1% vs 29.8%, $p < 0.05$) in the first ET cycle. There were significant differences in clinical pregnancy rate (75.6% vs 67.8%, $p < 0.05$) and OPR (67.8% vs 56.3%, $p < 0.05$) between the study group and control group in the first ET cycle. In addition, a higher cumulative OPR (90.0% vs 82.8%, $p < 0.05$), especially noted in women with 20–25 follicles ≥11 mm (100% vs 81.5%, $p < 0.05$), and more surplus embryos were stored for further use in the study group comparing to the control group. Two cases (2.1%) of severe late OHSS developed in the control group.
Limitations, reason for caution: The sample sizes available in some analyses were small, limiting the power the study.
Wider implications of the findings: The use of cohort freezing might increase the chance of second-trimester ongoing pregnancy, especially for women with expected 20–25 oocytes. Therefore, when counseling to high-responders, we could offer them these data as well as the benefit of OHSS reduction.
Study funding/competing interest(s): Funding by University(ies) – Funding by National Taiwan University Hospital. All authors declare no conflicts of interests.

Keywords: cumulative pregnancy, cohort freezing

P-271 Time-lapse monitoring and morphokinetic parameters predictive of embryo implantation: the lack of inter cohort reproducibility

A. Reignier[1], J. Lammers[1], C. Splingart[1], A. Catteau[1], L. David[2], P. Barrière[1], T. Fréour[3]
[1]*CHU Nantes, Biologie et médecine de la reproduction, Nantes, France*
[2]*INSERM, UMR 1064, Nantes, France*
[3]*Clinica EUGIN, Reproducción Asistida, Barcelona, Spain*

Study question: Are Time-lapse monitoring parameters described as predictive of implantation in the literature able to predict implantation when applied in another center?
Summary answer: In this study, few morphokinetic parameters described as predictive of embryo implantation in previous retrospective studies were carried out to our database to check if they were still relevant when used out of their original laboratory context. As result, none was predictive of embryo implantation when applied to our database.
What is known already: Since time-lapse monitoring (TLM) had become a daily tool for many laboratories, numerous studies attended to highlight morphokinetic parameters correlated the best with embryo implantation. However, no evident-based consensus on which parameter to use exists and groups using TLM don't have similar practice, resulting variability in embryo selection among them.
Study design, size, duration: Eight morphokinetic parameters (defined in the results) described in recent studies were applied retrospectively to a database of 342 single transferred embryos (no matter the stage) resulting of ICSI cycles which culture was performed between February 2011 and July 2014 with the EmbryoScope® in the CHU of Nantes.
Participants/materials, setting, methods: Each embryo were previously prospectively annotated during the IVF process and selected with these criteria to be transferred. Implantation prediction was tested for each morphokinetic parameter, using a positive hCG blood test as relevant of embryo implantation. Statistical analysis consisted in Chi² and Student tests, performed in R using Rcmdr.
Main results and the role of chance: None of the following parameters showed itself as predictive of embryo implantation: PN fading <20.45 h ($n = 342$ embryos, $p = 0.49$), duration of 2-cells stage <11.9 h ($n = 336$ embryos, $p = 0.0503$), duration of 2-cells stage >5 h ($n = 336$ embryos, $p = 0.1507$), duration of 3-cells stage <0.76 h ($n = 182$ embryos, $p = 0.1559$), duration of third round of cleavage (from the 3-cells to 5-cells stage) between 9.7 and 21 h ($n = 323$ embryos, $p = 0.1925$), time to 5-cells stage between 48.8 and 56.6 h ($n = 330$ embryos, $p = 0.3538$), time to 8-cells stage ($n = 257$ embryos, $p = 0.1768$) and time to early blastulation ($n = 36$ embryos, $p = 0.3905$).
Limitations, reason for caution: These parameter had only been applied to a monocentric database making the results not as strong as if being found with several ones from different IVF centers, above the embryo growing speed can change depending on the media used.
Wider implications of the findings: In spite of TLM is now recognized as an innovative tool in the embryo assessment, this study reinforces that a large prospective study is needed to standardize the use of TLM and to highlight the most predictive morphokinetic parameters or algorithms which could be adaptive to any of ivf laboratory working with different culture media and/or incubators and gas conditions.

P-272 Impact of postovulatory oocyte aging on initiation of genome activation in murine 2-cell embryos

D. Dankert[1], H. Demond[2], B. Horsthemke[2], R. Grümmer[1]
[1]*University Hospital Essen, Anatomy, Essen, Germany*
[2]*University Hospital Essen, Human Genetics, Essen, Germany*

Study question: Does postovulatory aging of oocytes affect genome activation of murine 2-cell embryos after *in-vitro*-Fertilization (IVF)?
Summary answer: Fertilization of postovulatory aged oocytes has no impact on the number of resulting 2-cell embryos, but impairs transcriptional activation of the embryonic genome.
What is known already: Transcription in oocytes arrests during meiotic progression. Re-activation of transcription is essential for embryonic development and takes place in the 2-cell embryo in mice. Postovulatory aging of oocytes has been shown to reduce fertilization and implantation rates as well as embryonic development. So far, it is not known whether transcriptional activation in 2-cell embryos is impaired by postovulatory aging.
Study design, size, duration: Embryonic genome activation was determined in murine 2-cell embryos generated from control oocytes harvested and fertilized 14 h after ovulation induction ($n = 36$), and from oocytes after additional 4 h ($n = 32$), 6 h ($n = 34$) or 8 h ($n = 82$) of postovulatory aging.
Participants/materials, setting, methods: IVF was performed with oocytes from C57Bl/6J females. 24 h later, 2-cell embryos were counted and treated with fluorescence labelled BrUTP. The amount of incorporated BrUTP in nascent mRNA was evaluated by quantification of fluorescence intensity using Image J. Statistics were performed with Jarque-Bera and Mann-Whitney *U*-test.
Main results and the role of chance: Rate of 2-cell embryos after IVF was about 70 % in controls and remained stable after additional postovulatory aging of oocytes for up to 8 h. BrUTP incorporation was measured 24 h after IVF in early 2-cell embryos. Though fluorescence intensity of incorporated BrUTP did not change significantly in 2-cell embryos generated from aged oocytes, a decrease in number of embryos showing transcriptional activation was observed after 6 and 8 h of additional postovulatory aging compared to controls.
Limitations, reason for caution: Though the decrease in number of embryos showing genome activation was not significant, an effect of postovulatory aging on BrUTP incorporation can be assumed since concordant effects were seen after 6 as well as 8 h of postovulatory aging in two independent experiments.
Wider implications of the findings: Since genome activation is essential for embryonic development, postovulatory aging-induced reduction of transcriptional activation may lead to developmental defects of the embryo. Postovulatory aging of oocytes may occur in the course of assisted reproduction techniques. Thus these results could be of clinical relevance.
Study funding/competing interest(s): Funding by national/international organization(s) – Funded by DFG: GR 1138/12-1, HO 949/21-1, EI 199/7-1.
Trial registration number: None.

P-273 Zona pellucida mRNA expression in human oocytes is related to oocyte maturity, zona inner layer retardance and fertilization competence

S. Canosa[1], T. Adriaenssens[2], W. Coucke[3], P. Dalmasso[4], J. Smitz[2], A. Revelli[1]
[1]*Physiopathology of Reproduction and IVF Unit, Department of Surgical Sciences, Torino, Italy*
[2]*Follicle Biology Laboratory, Vrije Universiteit Brussel (VUB), Brussel, Belgium*
[3]*Scientific Institute of Public Health, Department of Clinical Biology, Brussel, Belgium*
[4]*Medical Statistics Unit, Department of Public Health and Paediatrics, Torino, Italy*

Study question: Is the mRNA expression of zona pellucida genes, ZP 1, 2, 3 and 4, in oocyte and cumulus cells related to the zona pellucida structure as observed by the Polarized Light Microscopy (PLM) and the oocyte quality as observed by the oocyte's maturity and fertilization capacity?
Summary answer: The ZP mRNA expression in human oocytes is related to oocyte maturity, zona inner layer retardance and fertilization competence. ZP3 expression in cumulus cells (CC) is related to the oocyte maturity.
What is known already: ZP structure and birefringence could provide useful information on oocyte cytoplasmic maturation, developmental competence for embryonic growth, blastocyst formation and pregnancy. In order to understand the molecular basis of morphological changes in the ZP, in the current study the PLM analysis was combined with the analysis of the expression of the genes encoding for ZP1, 2, 3 and 4, both in the oocytes and in the surrounding cumulus cells.
Study design, size, duration: This is a retrospective study comprising 98 supernumerary human cumulus oocyte complexes (COC) (80 MII, 10 MI and 8 GV) obtained from 39 patients after controlled ovarian stimulation. Single oocytes and their corresponding CC were analysed individually and results are corrected for the potential impact of patient and cycle characteristics.
Participants/materials, setting, methods: Patients were stimulated in a long protocol with GnRH-agonist and recombinant FSH. Mature and immature oocytes were examined using PLM. QPCR was performed for ZP1, 2, 3 and 4 in these individual oocytes and their CC. EFNB2 mRNA was measured in CC as control. Data were analysed using one-parametric and multivariate analysis.
Main results and the role of chance: PLM analysis revealed that both the inner layer (IL)-ZP area and thickness were significantly lower in mature oocytes (p = 0,016 and p = 0,002 respectively) compared to those of immature oocytes. Oocytes contained ZP1/2/3 and 4 mRNA while in CC only ZP3 was quantifiable. When comparing mature and immature oocytes or their corresponding CC, ZP1/2 and 4 expression decreased in mature oocytes (p = 0,02; p = 0,008 and p = 0,02 respectively) and ZP3 expression decreased in the CC of mature oocytes (p = 0,01). In MII oocytes IL-ZP retardance was significantly related with ZP expression in oocytes (e.g., ZP1 = p = 0.016). ZP3 expression in the MII oocytes was the main predictor for the fertilization capacity next to IL-retardance, EFNB2 expression in CC and the ovarian sensitivity.
Limitations, reason for caution: This is a retrospective study and the relation to fertilization capacity is indirect as oocyte gene expression analysis required the lysis of the oocyte.
Wider implications of the findings: Overall relations between PLM observations, gene expression changes and intrinsic oocyte competence were successfully documented. As such the PLM and cumulus cell gene expression are confirmed as valuable non-invasive techniques to evaluate oocyte competence.
Study funding/competing interest(s): Funding by University(ies) – University of Torino.
Trial registration number: NA.

P-274 Non-invasive metabolomic and chemometric analysis of human embryo culture medium at low oxygen pressure

R. Gonsálvez-Álvarez[1], J. Ten[2], B. Lledo[2], R. Bernabeu[2], F. C. Marhuenda-Egea[1]
[1]*University of Alicante Facultad de Ciencias, Agrochemistry and Biochemistry, San Vilente Del Raspeig, Spain*
[2]*Instituto Bernabeu Reproductive Medicine, Instituto Bernabeu Reproductive Medicine, Alicante, Spain*

Study question: Selecting the best embryo with the greatest potential to implant is the crucial step in all IVF centers. Metabolomic approach of embryo culture medium, together with the morphological criteria, has not produced satisfactory results. One of the major limitations is the technical complexity and cost.
Summary answer: We have not identified any metabolite in the culture medium at low pressures that is correlated with an increase/decrease in the pregnancy rate.
What is known already: Recent randomized controlled trials using commercial instruments failed to show a consistent benefit in improving pregnancy rates when metabolomics is used as an adjunct to morphology (Uyar and Seli, 2014). The High Pressure Liquid Chromatography with Mass Spectrometry (HPLC-MS) data have been analyzed with an approach developed in our group (Marhuenda-Egea et al., 2013) in order to found a relation between the implantation success and the metabolite concentration in embryo culture medium.
Study design, size, duration: Prospective study. We evaluated the metabolites presented in the culture media at low pressures of 121 embryos coming from 76 patients performed an IVF treatment with oocyte donation in our center during 2013.
Participants/materials, setting, methods: The embryos were cultured individually from day 3 to day 5 in 50 ml of Blastocyst Medium (Cook Medical, Ireland). The media were collected after embryo transfer and analyzed by HPLC-MS. The chemometric models were performed with Robust Principal Component analysis (RobustPCA) for samples from both, non-pregnancy and pregnancy cycles.
Main results and the role of chance: The global live birth rate of the recipients was 51.3%. The scores plot obtained by RobustPCA did not showed differences between the non-pregnancy and pregnancy samples. The distribution of the samples in the scores plot were determined by the loadings of the RobustPCA. These loadings were conditioned by the metabolite concentration.
Limitations, reason for caution: Although the use of metabolomics as a tool for embryo selection does not provide satisfactory results, the number of cases should be increased in order to check our detection method.
Wider implications of the findings: It seems that in the group of best reproductive prognosis (oocyte donation) and culture at low pressures which mimics the maternal environment, metabolomics is not useful. It would be interesting to test this analytical method in patients with poor reproductive prognosis like repeated implantation failure or recurrent pregnancy loss. Other steps could be the analysis of the metabolites in the uterus, since in this ambient could be the key to understand the pregnancy success.
Study funding/competing interest(s): Funding by University(ies). Funding by hospital/clinic(s) – Universidad de Alicante. Instituto Bernabeu Reproductive Medicine.

P-275 Preserving the integrity of the corona-oocyte-complex (COC), during *in vitro* preimplantation embryonic development, enhances embryonic quality and increase pregnancy and implantation rates

A. Ahumada Alvarez[1], F. Leocata Nieto[1], A. Torno[1], D. Rodriguez[2]
[1]*Procrearte, ART Laboratory, Buenos Aires, Argentina*
[2]*Procrearte, Statistics, Buenos Aires, Argentina*

Study question: Can we improve embryo quality and potential by preserving the biological interactions between the corona cells and the oocyte/embryo?
Summary answer: Keeping the integrity of the COC significantly increases embryo quality and improves implantation and pregnancy rates in embryos obtained in IVF procedures.
What is known already: The bi-directional communication existing between the human oocyte and COC is essential for the production of competent oocytes. The COC transmits signals by cytoplasmic extensions contacting oolemma through gap junctions. Despite this, little is known about the interactions of the COC and preimplantation embryos. COC has been used only as feeder cells, in a co-culture system.
Study design, size, duration: We conducted a prospective study involving 160 patients (from July 2012 to September 2013) who were candidates for *in vitro* fertilization due to different female factor. We excluded couples with severe male factor, history of fertilization failure and those who had less than 6 fertilized oocytes.
Participants/materials, setting, methods: When evaluating fertilization, zygotes were divided in two groups: Study group (GR+; n = 80), in which

COC were preserved; and Control group (GR-; $n = 80$), in which zygotes were completed denuded. In each group embryo quality was determined at the time of transfer. Quality embryo, pregnancy and implantation rates were compared.

Main results and the role of chance: Both groups of patients were comparable in age (36.9 vs. 36.5) and number of embryos transferred (2.15 vs. 2.22). Referred to embryo quality, the percentage of top quality embryos (grade I) was significantly higher in the GR+ group than in the GR- group (72% vs 28%, $p < 0.001$), while among grade II embryos, no significant differences were observed (54% vs. 46%, $p = 0.8156$). Meanwhile, the percentage of poor quality embryos (grade III and IV) was significantly higher in the GR– group (60% vs 40%, $p < 0.001$ and 71% vs. 29%, $p < 0.001$, respectively). Regarding pregnancy rates and implantation, both were significantly increased in the study group (46% vs. 31%, $p = 0.050$ and 24% vs 16%, $p = 0.034$, respectively).

Limitations, reason for caution: Our main limitation is that the better results in the study group could be related to the absence of stress experienced when zygotes are completely denuded. Furthermore, we analyzed only embryos from IVF procedures, discarding ICSI procedures.

Wider implications of the findings: This study demonstrated that maintaining the association between corona cells and oocyte improve the results of *in vitro* fertilization treatments. We suggest that these CS exert a trophic effect on embryo development, resulting in a higher embryo quality. These improvements in embryonic development induce an increase in the values of both implantation and pregnancy rates. We are currently conducting a similar study but in couples undergoing ICSI procedures in order to corroborate the results obtained.

Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Procrearte.

Trial registration number: None.

P-276 Which parameters affect the incidence of monozygotic twin pregnancies after single embryo transfer?

I. Mateizel[1], S. Santos-Ribeiro[1], W. Verpoest[1], H. Van de Velde[1], G. Verheyen[1]
[1]*UZ Brussel, IVF labo CRG, Jette Brussels, Belgium*

Study question: Does the manipulation of gametes or embryos during assisted reproductive technologies (ART) increases the chance of monozygotic twinning?

Summary answer: The overall monozygotic twin (MZT) pregnancy rate after fresh single embryo transfer (SET) was 2.7%. Blastocyst transfer was associated with an increased risk of MZT, while zona pellucida manipulation by ICSI, or day-3 embryo biopsy for pre-implantation genetic diagnosis (PGD) did not increase the risk for MZT pregnancy.

What is known already: Monozygotic twins have a higher risk for perinatal complications than dizygotic twins or singletons. Although an increased incidence of MZT pregnancies after ART (ranging from 1.5 to 5.6% vs 0.4% in the general population) has been previously reported, conflicting data regarding the possible impact of different laboratory procedures [e.g., ICSI, assisted hatching (AH), and prolonged embryo culture] have been described.

Study design, size, duration: All 4678 clinical pregnancies (CP; defined as the visualization of a gestational sac) after ART with fresh SET carried out in our IVF centre between 2004 and 2013 were retrospectively analysed for the incidence of MZT pregnancies. In addition, the effect of different laboratory procedures on the incidence of MZT was evaluated.

Participants/materials, setting, methods: MZT rates (MZTR) were assessed using multivariable logistic regression adjusting for oocyte age, the day of embryo transfer and the following laboratory procedures: type of insemination (conventional IVF vs ICSI), embryo biopsy (always ICSI and day-5 transfer) and AH on day-3 or day-5.

Main results and the role of chance: The overall MZTR was 2.7%. No significant differences were found between the MZT/no-MZT groups regarding oocyte age, use of ICSI or embryo biopsy. AH was performed in 35 cases without ever resulting in MZT. Blastocyst transfer was significantly higher in the MZT group (74.4% vs 59.3%, $p = 0.001$) and it was the only variable associated with an increased MZT risk (OR 2.08, CI 95% 1.35–3.20) after multivariable logistic regression.

Univariate subgroup analyses showed higher MZTR after day-5 compared to day-3 transfers (3.3% vs 1.8%, $p < 0.001$). Embryo biopsy did not increase MZTR when compared to day-5 ICSI without biopsy (3.3% vs 3.3%). Performing ICSI also did not have any significant impact on MZTR when compared to IVF in both day-3 (1.6% vs 2.6%) or day-5 transfers (3.3% vs 4.6%).

Limitations, reason for caution: This retrospective, monocentric study is limited by the fact that monozygosity was not confirmed by genetic testing. Furthermore, larger studies should be performed to investigate the influence of AH on MZT rates. When comparing our findings to other studies, variations in the definition of CP should be taken into account.

Wider implications of the findings: As long-term culture is associated with a higher risk of monozygosity, more studies on the effect of prolonged culture (both culture media composition and culture duration) should be performed to identify the possible mechanisms responsible for the induction of monozygosity after ART.

Study funding/competing interest(s): Funding by hospital/clinic(s) – University Hospital Brussel-UZ Brussel.

Trial registration number: NA.

P-277 Comparison of microRNA expression in mouse ovarian follicle culture before and after cryo-preservation; A pilot study

Y. J. Kim[1], S. M. Lee[1], K. W. Yi[1], H. T. Park[1], J. H. Shin[1], T. Kim[1], J. Y. Hur[1]
[1]*Korea University Medical Center, OB-GYN, Seoul, Korea South*

Study question: Does the cryopreservation affect the profile of microRNA in mouse ovarian follicle during *in vitro* culture?

Summary answer: Cryopreservation procedure may induce change in microRNA expression of mouse ovarian follicle.

What is known already: Cryopreservation of ovarian follicle has led to a great deal of interest as an alternative for fertility preservation. MicroRNAs are known to repress target genes at post-transcriptional level and play important roles in development and maturation of cell. However, the expression profiles and roles of microRNA in ovarian follicle during cryopreservation procedure have not been fully elucidated.

Study design, size, duration: Ovaries from 20 of 2-week-old C57BL6 mice were removed and preantral follicles were mechanically isolated. Recruited ovarian follicles were evenly divided into fresh (CTL) and vitrification (VT) groups.

Participants/materials, setting, methods: Total RNA was extracted from fresh ovarian follicles in CTL group and from vitrified and thawed ovarian follicles in VT group. The profiles of microRNA expression between two groups were analyzed by Exiqon miRNA array. Survival rate after *in vitro* culture of ovarian follicle was compared between CTL and VT groups.

Main results and the role of chance: Survival rate of CTL group was higher than that of VT group (72.2% vs. 24.4%, $P < 0.001$). Vitrification group showed 174 of over-expressed and 186 of down-expressed microRNAs compared to fresh group. Mmu-miR-182-5p, -5623-5p and -3473a were over-expressed and mmu-miR-878-3p, -375-5p and -138-2-3p were down-expressed in vitrification group compared to fresh group by more than 1.5-fold.

Limitations, reason for caution: The experiment of target gene confirmation for searched microRNAs is necessary as further study.

Wider implications of the findings: Our results suggest that vitrification of mouse ovarian follicle may induce change in microRNA expression and affect competence during *in vitro* culture. Further studies must be necessary to determine the effect of microRNA on survival rate of ovarian follicle after cryopreservation procedure.

Study funding/competing interest(s): Funding by University(ies) – Bumsuk Academic Research Fund in 2012.

Trial registration number: NA.

Keywords: microRNA, ovarian follicle culture, cryopreservation, mouse

P-278 Embryological KPIs significantly improved using SAGE 1-Step™ compared with the standard culture system in use, yet no subsequent difference in pregnancy rate was observed

S. Davies[1], K. H. Beilby[2], C. Karamalegos[1], M. Argyrou[1], E. Tsorva[3], M. Mastrominas[1]
[1]*c/o Embryogenesis, Embryology Department, Maroussi Athens, Greece*
[2]*ORIGIO a/s, Knardrupvej 2 Måløv, Denmark*
[3]*c/o Embryogenesis, Genetic Department, Maroussi Athens, Greece*

Study question: Introducing a new medium into the laboratory requires benchmarking against the current system in use. What parameters should be used as

benchmarks within a clinic? How does improvement in embryology outcome influence applied clinical outcome?
Summary answer: Improvements made in medium composition may improve some aspects of *in vitro* embryology including blastocyst rates and utilization rates (proportion of embryos either transferred or cryopreserved), yet this was not demonstrated to result in an increase in implantation rate.
What is known already: The composition of embryo culture media requires regular updating and subsequent clinical evaluation. Commonly, clinics will have a set of key performance indicators (KPIs) which they will benchmark new culture media against. KPIs need to, at a minimum, be maintained after changes in a culture system are introduced. However, the ultimate goal is to increase the baby take home rate of a clinic.
Study design, size, duration: This was a 2 arm, retrospective study comparing SAGE 1-Step™ medium (ORIGIO, Denmark) to the standard operational protocol currently used by the laboratory (Global Total, IVFOnline). Differences between the SAGE 1-Step™ ($n = 45$) and Global Total ($n = 83$) media systems were compared using a chi-square statistic.
Participants/materials, setting, methods: All patients undergoing IVF with stimulated cycle over a 2 month period in a busy IVF center were randomly allocated for culture in SAGE 1-Step™ medium or Global Total medium. All procedures were identical and ICSI was performed in all cases irrespective of sperm quality.
Main results and the role of chance: No difference was identified between treatment groups regarding the mean age (36,4 vs. 37,6) or the mean number of oocytes retrieved per patient (11,4 vs. 10,8) for the SAGE or Global groups, respectively, using a two-sample *t*-test. The cleavage (306/308 vs. 473/487), blastocyst (149/306 vs. 90/473) and embryo utilization (220/512 vs. 157/893) rates were all improved ($p > 0.001$) when embryos were cultured in SAGE 1-Step™ medium, compared to the currently validated system used by the clinic. Despite this improvement in embryology, no difference in implantation rate was observed between the two groups following embryo transfer (21/45 vs. 38/83; $p = 0.9$).
Limitations, reason for caution: Unequal replication across the two treatment groups; non-sibling design; and randomization according to time period could reduce the power of this comparison due to uncontrolled treatment factors (patient and environmental variations). The study should be repeated in different sites to look for developing trends, or extended with the above factors accounted for.
Wider implications of the findings: In conclusion, the compositional differences between SAGE 1-Step™ and Global Total media were shown to significantly improve standard embryological KPIs. Despite no difference in early pregnancy outcomes, improving any aspect of culture should be seen as a positive validation parameter for benchmarking the performance of new media products. While the ultimate aim of clinics is to improve the take-home baby rate (assuring healthy offspring) the clinical pregnancy rates may not accurately demonstrate improvements in laboratory outcome.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Embryogenesis IVF Unit, Greece.
Trial registration number: NA.

P-279 Polar body analysis by immunofluorescence staining in human multiple pronuclear embryos

M. Tokoro[1], N. Fukunaga[2], H. Kitasaka[2], T. Yoshimura[3], F. Tamura[2], H. Ohno[2], Y. Komori[2], H. Tsuji[3], Y. Hattori[3], Y. Wakahara[2], K. Kinoshita[3], M. Kondo[2], Y. Yakushi[3], Y. Hashiba[3], Y. Asada[2]
[1]*Asada Ladies Clinic Medical Corporation, Asada Institute for Reproductive Medicine, Kasugai, Japan*
[2]*Asada Ladies Clinic Medical Corporation, Asada Ladies Nagoya Clinic, Nagoya, Japan*
[3]*Asada Ladies Clinic Medical Corporation, Asada Ladies Kachigawa Clinic, Kasugai, Japan*

Study question: What is the cause of multi pronuclear (multi-PN) formation in human embryos after ICSI?
Summary answer: The main causes of multi-PN formation after ICSI are probably related to maternal chromosomal fragmentation or the failure of second polar body (PB) extrusion. However, in 14.3% of multi-PN embryos, insemination of immature oocytes was a cause of multi-PN formation as polar bodies were not present in the perivitelline space (PVS) of multi-PN embryos.
What is known already: Polyspermy, failure of second polar body formation and chromosomal fragmentation are regarded as the main causes of multi-PN formation. In our laboratory, 4.1% embryos showed multi-PN after ICSI. The causes of multi-PN formation differ across patients, and normal microscopical observation alone does not provide sufficient information to assess this phenomenon. In this study, we examined the cause of multi-PN formation by immunofluorescence staining especially focused on the existence of PB.
Study design, size, duration: From August 2013 to May 2014, we investigated, using immunofluorescence staining, 95 embryos which showed multi-PN (over 3 PN) after ICSI. The immunofluorescence results of these embryos confirmed that there was a first PB (or first PB-like cytoplasm) in PVS before insemination by ICSI. The Ethics Committee at our clinic approved this study before it started.
Participants/materials, setting, methods: Multi-PN embryos were stained with an anti-dimethylated lysine 9 on histone H3 antibody to detect the female chromosome, and DAPI to detect female and male chromosomes. After staining, embryos were observed using a CV1000, a box-type confocal microscopic system.
Main results and the role of chance: After immunofluorescence staining of 95 multi-PN embryos, 44 embryos (45.8%) had over 2 PB, 37 embryos (37.1%) have a single PB, and 14 embryos (14.3%) did not have a PB. Moreover, all multi-PN embryos used in this study had a single male pronucleus and multiple female pronuclei (over 2 pronuclei).
Limitations, reason for caution: Using the above techniques it was possible to ascertain the existence of PB and pronuclear sexing was possible. However, whether aneuploidy was present in PN embryos was not ascertained. Further studies are warranted to determine aneuploidy status of these multi-PN embryos.
Wider implications of the findings: First polar body presence is used as criteria of oocyte maturation. However, caution should be applied for assessing oocyte maturation by the existence of first PB, especially in patients with low rates of oocyte maturation, because there are PB-like cytoplasmic bodies in human oocytes.
Study funding/competing interest(s): Funding by hospital/clinic(s) – There was no specific funding for this study. The authors have no conflicts of interest to declare.
Trial registration number: NA.

P-280 Human oocyte exposure to 1,2-propanediol obtains similar results compared to the use of dimethyl sulfoxide during vitrification by cryotop method

H. Sierra Jimenez[1], M. Chirinos[2], I. Maldonado[1], M. E. Cuellar[1], E. Rodriguez[1], F. Camargo[1], L. Cedillo-Garcia[1], R. Sharma[3], A. Agarwal[3]
[1]*Instituto Ingenes, Embriology, Mexico City, Mexico*
[2]*Instituto Nacional de Ciencias Médicas y Nutrición "Salvador Zubirán", Reproduction Biology, Mexico City, Mexico*
[3]*Center for Reproductive Medicine Glickman Urological and Kidney Institute Cleveland Clinic, IVF Lab, Cleveland, OH, U.S.A.*

Study question: Does the presence 1,2-Propanediol (PrOH) mixed with Ethylene Glycol (EG), used as permeable cryoprotectants, impact negatively over clinical outcomes after human oocyte vitrification and warming by the cryotop method when compared to dimethyl sulphoxide (DMSO) and EG mix as components of the medium?
Summary answer: This study suggest that the exposure of human oocytes to PrOH obtains similar results to DMSO in terms of survival, fertilization, pregnancy, implantation and miscarriage rates as well as blastocyst formation when used during vitrification process by the cryotop method.
What is known already: Several studies conducted in mouse oocytes have previously reported that the use of PrOH as a component of the vitrification media induces zona pellucida hardening, cellular degeneration and proteome alterations that could result in higher risk of aneuploidies after mouse oocyte warming, compared with vitrification solutions containing DMSO instead PrOH.
Study design, size, duration: This retrospective study analyzed 536 vitrified and warmed donor oocytes during two periods. The first (2008–2009) employed homemade equilibration medium containing 7.5% PrOH and 7.5% EG followed by a 15% PrOH and 15% EG for vitrification. During the second period (2009–2010), PrOH was substituted by DMSO.

Participants/materials, setting, methods: 49 couples showing normal seminal parameters (WHO, 2010) were divided into two groups: 265 warmed oocytes from the first period were designated to 24 patients (Group A) and 267 warmed oocytes from the second period were designated to 25 patients (Group B). Survival, fertilization, pregnancy, implantation and miscarriage rates were evaluated.
Main results and the role of chance: No statistical differences ($P > 0.05$) were observed between treatments regarding the mean of designated oocytes per warmed cycle [265/24 (11.0) vs. 267/25 (10.6)], survival rate after oocyte warming [230/265 (87%) vs. 238/267 (89%)] and fertilization rate [175/230 (76%) vs. 187/238 (78%)]. Moreover, the mean of transferred embryos [50/24 (2.1) vs. 49/25 (1.96)] as well as pregnancy [16/24 (66%) vs. 17/25 (68%)], implantation [17/50 (34%) vs. 19/49 (38%)] and miscarriage rates [2/16 (12.5%) vs. 3/17 (17%)] were similar between both groups. The number of embryos that reached at least the blastocyst stage at day 5 of embryo development before transfer were also similar in both groups [79/175 (45%) vs. 95/187 (51%)].
Limitations, reason for caution: The impact of PrOH to human oocytes was only evaluated in terms of clinical outcomes as an indirect parameter of oocyte quality after warming. The obtained results from this study may not necessarily reflect its lack of toxicity to human oocytes.
Wider implications of the findings: The results of the present study suggest that human oocytes can be vitrified successfully using a mixture of PrOH and EG, expecting similar clinical results to those using DMSO, used commonly as permeable cryoprotectant in the commercial vitrification kits. Further analysis must be conducted to demonstrate these findings.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Instituto Ingenes, IVF Lab, Mexico City, Mexico. P-281 The role of *in vivo* and *in vitro* maturation time on oocyte nuclear-cytoplasmic dyssynchrony

N. Pereira[1], Q. V. Neri[1], J. P. Lekovich[1], A. P. Melnick[1], G. D. Palermo[1], Z. Rosenwaks[1]
[1]*Weill Cornell Medical Center, Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U. S.A.*

Study question: Although intracytoplasmic sperm injection (ICSI) largely achieves fertilization independent of spermatozoa characteristics, complete fertilization failure (CFF) occurs, albeit rarely. We question whether the timing of *in vivo* and *in vitro* maturation influences oocyte nuclear-cytoplasmic asynchrony.
Summary answer: Cycles with CFF were more likely to have a shorter time interval between human chorionic gonadotropin (hCG) trigger and oocyte retrieval, hCG trigger and removal of cumulus cells, and oocyte retrieval and removal of cumulus cells. Shorter *in vivo* and *in vitro* maturation time contributes to oocyte nuclear-cytoplasmic dyssynchrony.
What is known already: The ability of ICSI to overcome almost all forms of male infertility has enabled couples that would otherwise remain childless to achieve parenthood. Successful fertilization is not guaranteed, however; and in rare cases, CFF occurs even in ICSI cycles. CFF may possibly be attributable to delayed maturation of the ooplasm in relation to completed nuclear maturity.
Study design, size, duration: Retrospective, paired-comparison of ICSI cycles with CFF to index cycles with successful fertilization in the same patient during a 10-year period. Cycles that involved surgically retrieved spermatozoa or donor oocytes were excluded. Semen parameters, specifically spermatozoa count and motility, were comparable and within norm between CFF and index cycles.
Participants/materials, setting, methods: Eighteen ICSI cycles were analyzed for potential inclusion. Of these, 3 (16.7%) cycles were excluded due to the use of donor oocytes. Controlled ovarian stimulation (COS) using long or short protocols, hCG trigger, oocyte retrieval, semen analyses and processing were performed as per our standard protocols.
Main results and the role of chance: Fifteen patients met inclusion criteria. There was no difference in age, body mass index, total duration of COS, total dosage of gonadotropins, hCG trigger dose, peak estradiol level, or mature oocytes retrieved in cycles with CFF compared to cycles with successful fertilization. The overall fertilization rate was 77.7% in the index cycles. Compared to index cycles, cycles with CFF showed a shorter time interval between hCG trigger and oocyte retrieval [2029.0 (±15.5) min vs. 2195.0 (±9.5) min; $P < 0.001$], hCG trigger and removal of cumulus cells retrieval [2201.4 (±15.3) min vs. 2309.0 (±22.6) min; $P < 0.001$], and oocyte retrieval and removal of cumulus cells [171.8 (±15.4) min vs. 114.0 (±13.1) min; $P < 0.001$]. The interval between hCG trigger and ICSI, however, was comparable between the two groups.
Limitations, reason for caution: Our findings reveal novel patterns in the time intervals between hCG trigger, oocyte retrieval, removal of cumulus cells and ICSI. However, the retrospective design and small sample size are limitations. This study's insights may help to mitigate the devastating effect of CFF.
Wider implications of the findings: The occurrence of CFF despite ICSI with adequate spermatozoa and number of eggs suggests that there is an optimal timing for cumulus-bound *in vivo* and *in vitro* maturation. In this context, modulating the time intervals between hCG trigger, oocyte retrieval, removal of cumulus cells and ICSI to grant fertilization seems feasible. Altering hCG trigger doses or utilizing an adjuvant gonadotropin-releasing hormone agonist trigger in a prospective setting may be utilized to prevent CFF.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine.

Keywords: IVF, ICSI, oocyte nuclear-cytoplasmic dyssynchrony

P-282 An examination of embryo morphokinetics, utilization and pregnancy rates in single-step and sequential culture media systems

A. Barrie[1], E. Taylor[1], K. Schnauffer[1], C. Kingsland[1], S. Troup[1]
[1]*Liverpool Women's Hospital, The Hewitt Fertility Centre, Liverpool, United Kingdom*

Study question: Do embryo morphokinetics, blastocyst formation (BFR), utilisation rates (UR) and pregnancy rates differ between single-step and sequential culture media? Ultimately, this information will aid in the development of environment specific embryo scoring algorithms (ESAs) using time-lapse imaging provided by the EmbryoScope®.
Summary answer: These data suggest that embryos develop significantly faster in single-step medium. In addition, a higher number of 'usable' embryos were created from those in single-step medium with an increased BFR and UR. These preliminary results suggest that the biochemical (BPR) and clinical pregnancy rates (CPR) are equivalent.
What is known already: Two broad types of culture media are currently used in the IVF laboratory; single-step and sequential. Their effectiveness has been called into question owing to the existence of two theories regarding embryo nutrient use; 'let the embryo decide' and 'back to nature.' At present, both are used to varying degrees throughout IVF laboratories but their effect on embryo development in terms of morphokinetics remains to be elucidated.
Study design, size, duration: Embryos cultured in time-lapse from 09-06-14 to 08-09-14 were used to analyse sequential media use (group 1; $n = 3000$). Those from 09-09-14 to 08-12-14 were used to analyse single-step media (group 2; $n = 3392$). BFR, UR and morphokinetic parameters were analysed. BPR and CPR were analysed where data was available.
Participants/materials, setting, methods: Embryos from patients undergoing treatment within the Hewitt Fertility Centre were included. Embryos were cultured using either Vitrolife™ sequential media (G1 Plus™ and G2 Plus™) or single-step GTL™ medium at 5% O_2, 6% CO_2, 37°C throughout, in EmbryoScope® instruments. Morphokinetic data were derived retrospectively by manually annotating the captured images.
Main results and the role of chance: Group 1;4126 oocytes, 3000 embryos, 443 embryo transfers, average patient age; 35.1 ± 4.77, IVF:ICSI ratio; 1.10:1.0. Group 2; 4727 oocytes, 3392 embryos, 446 embryo transfers, average patient age; 34.5 ± 5.04, IVF:ICSI ratio; 1.12:1.0. All morphokinetic parameters revealed significant differences ($p < 0.0001$, unpaired *t*-test) with embryos cultured in single-step media developing faster; t2 (27.65 ± 0.09236 ($n = 2012$), 27.16 ± 0.08857 ($n = 2275$)), t3 (38.91 ± 0.1159 ($n = 1953$), 37.88 ± 0.1065 ($n = 2153$)), t4 (40.40 ± 0.1321 ($n = 1929$), 39.37 ± 0.1198 ($n = 2103$)), t5 (50.99 ± 0.1447 ($n = 2011$), 52.09 ± 0.1614 ($n = 1873$)). Analyses revealed the following results for group 1 and group 2, respectively; total number of

embryos cultured to day 5, 2797 vs 3153; 1616 vs 1935 reaching blastocyst, 915 vs 1188 good quality blastocysts (GQBs), BFR; 57.78% vs 61.37%, blastocyst UR; 37.33% vs 41.17%, overall UR; 39.3% vs 42.81%, BPR; 50.33% vs 50.67%, CPR; 37.47% vs 33.63% ($p > 0.5$, Chi-square test).
Limitations, reason for caution: Morphokinetic analyses are, by their nature, subjective therefore caution should be taken when considering the morphokinetic results. In addition, this study is a retrospective analysis and prospective trials are required to clarify the effect of different culture systems on embryo development.
Wider implications of the findings: These data suggest that an embryo's environment can affect its morphokinetic development adding to the increasing pool of evidence that environment-specific embryo scoring algorithms (ESAs) should be developed when time-lapse systems are in use. The use of published ESAs should be done so with caution and in-house derivation and validation is strongly advised. Embryo quality, as determined by UR, is also higher where single-step medium is used supporting the 'let the embryo choose' hypothesis.
Study funding/competing interest(s): Funding by hospital/clinic(s) – The Hewitt Fertility Centre.
Trial registration number: NA.

P-283 Successful *in vitro* fertilization and normal early embryo development after cryopreservation using a novel vitrification technique for epididymal spermatozoa

S. Catt[1], F. Horta[2], S. Jitanantawittaya[1], H. Alzobi[1], P. Chen[1], M. Pangestu[1], P. Temple-Smith[1]
[1]*Monash University, Education Program in Reproduction and Development, Department of Obstetrics and Gynaecology, Melbourne, Australia*
[2]*Clinica las Condes, Reproductive Medicine Unit, Department Obstetrics and Gynacology, Santiago, Chile*

Study question: Is vitrification of epididymalspermatozoa as effective in maintaining normal functions, including successful IVF and embryo development to blastocysts, as slow cooling.
Summary answer: Epididymal sperm vitrification using fibreplugs showed lower motility and viability post-warming but similar embryo developmental outcomes following IVF compared to slow-cooled or fresh spermatozoa. Vitrification with raffinose resulted in higher motility and viability scores than with sucrose, but sucrose vitrification gave better DNA integrity than slow cooling and vitrification with raffinose.
What is known already: Slow-cooling cryopreservation protocols for human spermatozoa are well established but not effective for small volumes. Vitrification shows promise for small volumes and is most effective when only non-penetrating cryoprotectants (CPAs) are used. Mouse sperm cryopreservation is challenging as the spermatozoa are very sensitive to chilling. In our preliminary study, epididymal sperm was vitrified using 0.25 ml straws, glass capillaries, fibreplugs (Cryologic) and open pulled straws but post-warm motility could only be achieved with fibreplugs.
Study design, size, duration: Four groups of mouse epididymal sperm samples ($n = 5$) were used and assessed for motility, viability (HOS) and DNA damage (TUNEL assay): fresh control (FC); slow freezing with 18%w/v raffinose (RS); and vitrification with 18%w/v raffinose (RV) or 0.25M sucrose (SV). Three groups were then selected (FC, RS and RV) to assess fertilization and embryo development.
Participants/materials, setting, methods: Prior to cryopreservation or IVF, epididymal sperm was prepared by swim up into KSOM + 1%w/v BSA (FC and SV) or into 18%w/v raffinose + 3%w/v skim-milk (RS and RV). Mouse eggs ($n = 267$) were inseminated using RV ($n = 102$), RS ($n = 86$) and FC spermatozoa ($n = 79$) and numbers of 2-cell embryos and blastocysts assessed.
Main results and the role of chance: Sperm motility [14 ± 1.4% (SV) and 30 ± 1.6% (RV) vs. 46.0 ± 3.0% (RS), $p < 0.01$, ANOVA, post hoc *t*-test] and viability (23 ± 4.2% (SV) and 39 ± 0.6% (RV) vs 57 ± 2.0% (RS); $P < 0.05$) were significantly lower after vitrification than slow-cooling. However, sperm vitrified with SV gave the lowest incidence of DNA fragmentation (15 ± 1.8% (SV) vs. 26 ± 2.8% (RV) and 27 ± 1.2% (RS), $p < 0.01$). The percentage of two–cell embryos produced by RV (66.7%), RS (61.6%) and FC (51.9%) spermatozoa was not significantly different. The proportion of blastocysts that developed *in vitro* from 2-cells, however, was significantly higher in FC (65.9%) than RV (36.8%, $P < 0.05$, Chi-square), but similar to the RC (50.9%). Expanded blastocyst rates were highest using RV spermatozoa (33.8%) than RS (17%, $P < 0.05$) and FC spermatozoa (19.5%).
Limitations, reason for caution: The tolerance to CPAs maybe specie-specific, therefore the type and concentration of CPAs selected for vitrification must be tested before translation of these results to clinical practice. Also, mouse embryo transfer trials are needed to further demonstrate the efficacy of each technique.
Wider implications of the findings: Vitrification using fibreplugs is simple, fast, and cost-effective and the warmed samples can be used directly for IVF or ICSI without further preparation, thus increasing the recovery rate of motile sperm. Fibreplugs are already used clinically for oocyte and embryo vitrification and thus can be conveniently and safely used for small volume vitrification of sperm. Also, the device does not come directly in contact with liquid nitrogen and thus is considered a safe technique.
Study funding/competing interest(s): Funding by University(ies) – Monash University.

P-284 Higher pregnancy rate of embryos with synchronous transition from the 2-cell stage to the 4-cell stage (t4-t3)

L. Sela[1], S. Mittenzwei[1], N. Rogenhofer[1], K. Friese[1], V. von Schönfeldt[1]
[1]*Klinikum der Ludwig-Maximilians-Universität, Hormon- und Kinderwunschzentrum, München, Germany*

Study question: How do different morphokinetic parameters affect the pregnancy rate? Is there any difference between stimulation protocols?
Summary answer: The duration of the 3-cell stage (t4-t3) is shorter in embryos that lead to a pregnancy in both the agonist and the antagonist group, being significant in the latter.
What is known already: The EmbryoScope™ allows the selection of embryos with the highest implantation potential based on diverse morphokinetic markers. Some of them, like the time of cleavage from the 2- to the 3-cell stage (t3), the time of cleavage from the 3- to the 4-cell stage (t4) and the duration of the 3-cell stage (t4-t3) are associated with high blastulation or implantation rates after transfer on day 3.
Study design, size, duration: We performed a retrospective analysis of the time-lapse annotations of 178 Patients undergoing ICSI from September 2013 to December 2014.
Participants/materials, setting, methods: Using the EmbryoScope™ (Unisense Fertilitech, Denmark) as a time lapse imaging device, we analysed different morphokinetic parameters (t3, t4 and t4-t3) of all transferred embryos depending on the stimulation protocol (antagonist vs. agonist). Transfers were performed either on day 3 or 5.
Main results and the role of chance: Embryos with a high implantation rate present a significantly shorter duration of the 3-cell stage (1.7 ± 1.6 h vs. 4.1 ± 4.9 h, $p = 0.027$) in the antagonist group (mean age 34.1 years). A similar trend was observed in embryos of the agonist group (mean age 37.2 years) without reaching statistical significance (2.0 ± 2.3 h vs. 2.6 ± 2.8 h, $p = n.s.$). This difference is probably due to the distinctly lower mean age of patients in the antagonist group.
Limitations, reason for caution: The embryo numbers are small and the study results are based on a retrospective time lapse movie evaluation that can be associated with certain inter and intra-observer variation.
Wider implications of the findings: The analysis of morphokinetic parameters of the early embryonic development allows a non-invasive selection of embryos with the highest implantation potential, even after prolonged culture until day 5 of development. Further studies are needed to investigate the effects of different stimulation protocols on morphokinetic parameters of early human embryogenesis *in vitro*.
Study funding/competing interest(s): Funding by University(ies) – None.
Trial registration number: NA.
Keywords: time-lapse, morphokinetic

P-285 Vitrif-augmentation: cumulative live birth rate per oocyte retrieval at first IVF cycle in a single embryo transfer policy

A. Guillaume[1], V. Poirier[1], N. Guyomard[1], S. Bonne[1], J. Ohl[1], K. Bettahar[1], C. Rongieres[1], L. Schindler[1], B. Feger[1], L. Moreau[1], M. Spizzo[1], I. Lichtblau[1], O. Pirrello[1]
[1]*CMCO-Hôpitaux Universitaires de Strasbourg, ART Center, Strasbourg, France*

Study question: The aim of this retrospective cohort study was to assess the cumulative live birth rate per oocyte retrieval in first IVF cycle using vitrification and a single embryo transfer policy (e-set).
Summary answer: Our study shows a cumulative rate of live birth of 38% after the third thawed embryo transfer in women undergoing a first IVF cycle with vitrification of embryos and a strict e-set policy.
What is known already: Embryos survival rate after vitrification is better than with slow cooling. An e-set politicy allows reduction in multiple pregnancies and better maternal and foetal outcomes with no reduction in the pregnancy and/or delivery rate in IVF program.
Study design, size, duration: Our study is a retrospective monocentric cohort study that included all the couples having a first oocyte retrieval from the 1st of January 2012 to the 31st of August 2013 at the ART center of Schiltigheim France. The main outcome was the cumulative live birth rate per oocyte retrieval.
Participants/materials, setting, methods: 541 patients undergoing a first oocyte retrieval for an IVF program and eligible for e-set (mandatory if <38 years old) were included. Exclusion criteria were oocyte or sperm donation, pre-gestational diagnosis and embryo cryopreservation. A closed vitrification system was used to freeze supernumerary embryos.
Main results and the role of chance: Women mean age was 32 years old [21–42]. Out of the 541 undergoing their first oocyte retrieval 93 (17%) had no embryo transfer (no embryos or no oocytes) and 348 couples had at least one frozen embryo. The live birth rate after the fresh embryo transfer was 30% per transfer and 25% per oocyte retrieval. The cumulative live birth rate after fresh and 3 thawed embryo transfer was 38%. The embryo survival rate after warming was 94.4%. The mean number of transferred embryos at frozen transfers was 1.14.
Limitations, reason for caution: Both the retrospective and the monocentric design of our study are limitations. In our study 26 women underwent a freeze all policy and thus with no fresh transfer (ovarian hyperstimulation syndrome or high progesterone level at ovulation induction) could not be included regarding our main objective. Another bias was the missing datas about the remaining frozen embryos. Only eight patients were lost in follow-up.
Wider implications of the findings: This evaluation needs to be completed with multiple pregnancy rates, to show the benefit of e-set policy. Over the past few years, e-set protocol has already spread widely in European recommendations. We believe that the parallel development of vitrification and the outstanding embryos survival rate after warming, support this policy.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Hôpitaux universitaires de Strasbourg.
Trial registration number: NA.
Keywords: vitrification, cumulative live birth rate, e-set

P-286 Rapid growth and grading system for assisted-hatching blastocysts to predict clinical outcome

T. Segawa[1], S. Teramoto[1], O. Miyauchi[1], K. Omi[1], Y. Watanabe[1], M. Kuroda[1], T. Okubo[1], M. Shozu[2]
[1]*Shinbashi YUME Clinic, Gynecology, Tokyo, Japan*
[2]*Chiba University, Gynecology, Chiba, Japan*

Study question: Gardner's grading system is popular for the assessment of blastocyst. It employed scoring hatching status and therefore may be less useful to clinical practice where all blastocysts performed assisted hatching. Hence, we reanalyzed morphometric measurements to developed a new grading system to predict developing competency of hatched blastocysts.
Summary answer: Receiver operating characteristic (ROC) analysis showed that our criteria consisting of a time to reach blastocysts (category A), duration from blastocyst formation to full expansion (category B), and cell number of trophectoderm on the maxim cross-section (category C) was superior to Gardner's scoring system to discriminate the live birth pregnancy.
What is known already: Gardner's criteria includes degree of expansion and hatching status, where all hating or hatched score is rated as the maximum score six. This is developed for spontaneous hatching and thus considering assisted hatching. Hence, it remains to be determined whether the criteria is useful for assisted-hatching blastocysts.
Study design, size, duration: We chart-reviewed 2335 blastocysts from infertility patients who performed IVF-ET on year 2013. Relationship between morphological assessment conducted just prior for cryopreservation and outcome (live birth rate: LBR) were analyzed by multiple logistic analysis and predictability of the criteria was assessed by area under the curve (AUC) of ROC analysis.
Participants/materials, setting, methods: Patients who collected oocytes were performed natural cycle or minimally stimulated cycle IVF. All cases after blastocyst transfer compared LBR by three new categories and Gardner's criteria (degree of expansion, inner cell mass grading, and trophectoderm grading) among each three groups.
Main results and the role of chance: We compared LBR into three categories; 45.9%, 40.5%, and 28.3% in category A, 52.5%, 39.8%, and 21.7% in category B, and 39.6%, 42.5%, and 31.2% in category C. There were significant difference among three groups into each category ($p < 0.01$). On the other hands, there was no correlation between LBR and the average diameter of blastocysts. In ROC analysis, including patient's age and endometrial thickness, the AUC was higher in new categories than in Gardner's criteria (0.738 vs. 0.697). In multiple logistic analysis, we found that patient's age, endometrial thickness, the duration from blastocyst to good blastocyst (category B), and cell number of trophectoderm on the maxim cross-section (category C) become independent factors. On the other hands, Gardner's grading system was not independent factors.
Limitations, reason for caution: This study was a retrospective study. Our cases were only cryopreserved-warmed blastocyst transfer using Cryotop method and all blastocysts were performed by laser assisted hatching before embryo transfer.
Wider implications of the findings: These findings suggest that the criteria of blastocyst quality needs not only inner cell mass and trophectoderm grading but also the duration from blastocyst to good blastocyst. The growth speed until expanded blastocyst formation may represent embryo quality.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Shinbashi YUME Clinic.
Trial registration number: NA.

P-287 Evaluation of the effect of various cryoprotectants and protocols on donor oocyte survival and embryo viability based on HOPE registry data

Z. P. Nagy[1], B. Hayward[2], M. C. Mahony[3]
[1]*Reproductive Biology Associates, Scientific and Laboratory Director, Atlanta, GA, U.S.A.*
[2]*EMD Serono Inc., US Medical Excellence, Rockland, MA, U.S.A.*
[3]*EMD Serono Inc., US Medical Affairs, Rockland, MA, U.S.A.*

Study question: To characterize oocyte survival rate (OSR), embryo quality, and implantation and pregnancy rates for donor oocytes cryopreserved by either slow freezing (SF) or vitrification (VIT), according to cryoprotectant use in the Human Oocyte Preservation Experience (HOPE) Registry in the US.
Summary answer: OSR (% of oocytes thawed/warmed that undergo intracytoplasmic sperm injection) and implantation rates (IRs) (% of embryos transferred developing foetal sacs) differ by cryoprotectants used during SF/VIT and thawing/warming.
What is known already: Oocyte cryopreservation is used for different indications including: fertility preservation (for medical or social reasons); for IVF patients as an alternative to embryo cryopreservation; and oocyte donation via donor banking. Efficiency of oocyte cryopreservation has been improved in recent years, but more clinical data on the effect of cryoprotectants on oocyte cryopreservation outcomes are warranted.
Study design, size, duration: This post-hoc analysis of the Phase IV prospective, multicentre (16 US centres), observational HOPE Registry data evaluated cryoprotectant use. Data from 136 patients (enrolled between June 2008 and September 2010), 18–50 years, receiving donor oocytes cryopreserved by either SF ($n = 41$, 302 oocytes) or VIT ($n = 95$, 704 oocytes) were analyzed.
Participants/materials, setting, methods: The HOPE Registry was established to collect clinical and laboratory information on ART cycle outcomes using cryopreserved oocytes (autologous and donor). We compared outcomes by various parameters in cycles using donor oocytes. Six centres (involving 85/145 [58%] patients) were audited and regular monitoring across all centres ensured clean patient data.
Main results and the role of chance: For SF, OSR and IR (both mean [SD]) differed significantly among cryoprotectant combinations (both $p < 0.05$); respectively, PROH/sucrose (91.9% [11.8%], 26.4% [28.3%]) vs PROH/sucrose/

synthetic serum substitute (54.1% [30.8%], 6.25% [17.7%]) or PROH/sucrose/choline (53.0% [22.2%], 0% [0%]). For VIT, OSR and IR differed significantly among cryoprotectant combinations (both $p < 0.05$); respectively, DMSO/sucrose/ethylene glycol (88.3% [17.6%], 58.7% [44.8%]) and PROH/ETOH/sucrose/other (88.0% [13.3%], 37.0% [48.4%]) vs ETOH/DMSO/sucrose (46.7% [25.4%], 0% [0%]). For thawing, with SF, OSR differed significantly among cryoprotectant combinations ($p = 0.0004$); PROH/sucrose, (85.2% [20.0%]) vs PROH/sucrose/synthetic serum substitute (54.1% [30.8%]) or sucrose (39.2% [20.1%]) (both $p \leq 0.05$); respectively, IRs were 20.1% [27.1%] and 6.3% (17.7%) or 0% [0%] (p = not significant). For warming following VIT, sucrose was used in 95.7% of cycles, with a mean (SD) OSR and IR of 87.5% (15.6%) and 52.7% (45.5%), respectively. Higher OSR and IR translated into higher pregnancy rates.

Limitations, reason for caution: General registry limitations include selection bias due to non-sequential patients, observational data only and missing data. Specific limitations include changes over time in cryopreservation techniques following the start of the registry. No corrections for multiple comparisons were performed on these analysis of variance results.

Wider implications of the findings: Recently, VIT has become a more widely used cryopreservation technique than SF. Effects of different cryoprotectants used could potentially influence outcomes from assisted reproductive technology cycles that use SF-thawed/VIT-warmed oocytes.

Study funding/competing interest(s): Funding by commercial/corporate company(ies) – EMD Serono, Inc., Rockland, MA, USA (a subsidiary of Merck KGaA, Darmstadt, Germany).

Trial registration number: NCT00699400.

P-288 Miscarriage rate tends to increase after fresh embryo transfer in hyper responders (>20 oocytes): a prospective observational study comparing fresh transfer vs freeze-all strategy

B. Gonzalez Marti[1], A. M. Junca[1], F. Olivennes[2], S. Alvarez[2], D. Cornet[2], J. de Mouzon[1], F. Entezami[1]

[1]*Laboratoire Eylau UNILABS, Assisted Reproduction Unit, Paris, France*

[2]*Clinique de la Muette, Assisted Reproduction Unit, Paris, France*

Study question: Does the freeze-all strategy enhance the chance of ongoing pregnancy in case of ovarian hyper response without clinical hyper stimulation?

Summary answer: The clinical outcome is similar between the first frozen ET (FRET) in the freeze-all group (A) and the fresh transfer (FT) group (B). The miscarriage rate (MR) is higher after FT with no statistical significance due to sample size. The MR is significantly reduced in FRET cycles of group B compared to the FT.

What is known already: It has been suggested that controlled ovarian hyperstimulation adversely affects clinical outcome in ART cycles with FT in comparison with the outcome obtained after FRET. Kyrou et al. (2009) demonstrated that patients with high estradiol concentrations have significantly higher progesterone levels and significantly more oocytes. The abnormal concentrations of these hormones alter endometrial receptivity. A meta-analysis of published data by Roque (2013), demonstrated that IVF outcomes may be improved by the freeze-all strategy compared with FT.

Study design, size, duration: Prospective observational study from January 2012 to September 2014, between two groups of patients ($n = 93$ in each) with ovarian hyper response and recovery of >20 oocyte at the time of pick-up. In group A all the embryos underwent vitrification. In group B a FT was performed and spare embryos were vitrified.

Participants/materials, setting, methods: Age, indication, rank and stimulation regimen were similar between groups. FRET were performed in natural cycles after vitrification. Pregnancy rate (PR) and MR were compared in the first FRET vs FT. Cumulative outcomes were compared between groups, inside group B (FRET vs FT) and in FRET cycles in group A + B vs FT.

Main results and the role of chance: PR and MR were similar between group A and B when comparing the first FRET to the FT (PR 32.3% vs 31.2%, $p = 0.87$ and MR 16.7% vs 31.0%, $p = 0.19$). Cumulative PR and MR were comparable between the groups when including all the FRET cycles (PR 55.9% vs 52.7%, $p = 0.66$ and MR 13.5% vs 20.4%, $p = 0.35$). In group B, FT yielded significantly higher MR compared to consecutive FRET cycles (31.0% vs 5.0%, $p = 0.05$). Computing the outcome of all the FRET cycles (group A + B) compared to FT showed a significantly higher MR after FT (11.1% vs 31%, $p < 0.02$).

Limitations, reason for caution: The absence of statistical difference in MR between the two groups is due to the small sample size. However, as there is a clear tendency to higher MR rate after FT in group B, the trial is still ongoing and would enroll more patients.

Wider implications of the findings: Adopting the freeze-all policy in case of high oocyte recovery (>20) in hyper responders yields the same clinical outcome compared to fresh transfer. Nevertheless, data suggest that the rate of take home baby may be enhanced by the freeze-all approach by reducing the abortion rate and the transfer of embryos in a more physiological environment with a better embryo-endometrium synchrony.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Laboratoire Eylau-UNILABS, Paris.

Trial registration number: NA.

P-289 Metabolomic analysis of culture media suggests a medium-chain fatty acid as an alternative energy source in preimplantation development

O. Seiji[1], T. Hamatani[1], M. Yamada[1], S. Wakamatu[1], H. Akutsu[2], H. Sasaki[1], T. Takemoto[1], S. Toda[1], O. Inoue[1], K. Sugawara[1], Y. Odawara[3], M. Tomita[4], A. Umezawa[5], M. Tanaka[6]

[4]*Keio University, Laboratory for Bioinformatics, Institute for Advanced Biosciences, Fujisawa, Japan*

[5]*National Research Institute for Child Health and Development, Reproductive Biology, Tokyo, Japan*

[6]*Keio University, Obstetrics and Gynecology, Tokyo, Japan*

Study question: Which medium-chain fatty acids (not listed on the composition list of the product data sheet) are present in commercial embryo culture media?

Summary answer: Five medium-chain fatty acids were identified in one-step culture media and especially, Octanoate is likely used as an alternative energy source in mitochondria throughout the preimplantation stages.

What is known already: Improvements in culture media formulations have led to an increase in the ability to maintain mammalian embryos in culture throughout the preimplantation stages. Recent development of culture media for human embryos is based on a characteristics switch in energy source preference. However, little has been reported regarding the direct measurements of global metabolites in preimplantation embryos.

Study design, size, duration: We studied metabolomic profiling of Mouse and Human culture media. The following four commercial human embryo culture media were included in this study: Continuous Single Culture Complete from Irvine Scientific, Sydney IVF Blastocyst Medium from Cook Medical, ONE STEP medium from NAKA medical and SAGE 1-step from ORIGIO.

Participants/materials, setting, methods: (1) 100 mouse embryos were cultured in KSOM (Millipore) until the blastocyst stage at the 120 h post hCG. These culture medium samples were measured by Capillary Electrophoresis Time-of-Flight Mass Spectrometer (CE-TOFMS). (2) All human media samples were analyzed by Gas Chromatograph Mass Spectrometer (GC-MS).

Main results and the role of chance: (1) 5 metabolites (pyruvate, lactate, glutamine, 5-Oxoproline, and octanoate) were significantly detected in both of the negative control and the embryo group. Compared to the negative control group, the embryo group showed significantly lower concentration of octanoete, suggesting it as an important energy substrate. Octanoate is not found in the component list of Millipore and is supposed to be carried into culture media by BSA. No embryos incubated in energy-depleted culture media reached the blastocyst stage. However, 76.9 ± 3.0% embryos incubated with octanoate alone reached the blastocyst stage. (2) 5 medium-chain fatty acids (octanoate, palmitate, palmitoleate, alienate and linoleatewere) were identified in all four commercial human embryo culture media.

Limitations, reason for caution: For four of the commercial embryo culture media only one batch was analyzed. However, this does not affect the overall conclusions.

Wider implications of the findings: Octanoate is likely used as an alternative energy source in mitochondria throughout the preimplantation stages. This study reveals metabolomic profiling of culture media in which preimplantation embryos were grown to understand metabolic demands of embryos towards further optimization of culture condition and exploration of a biomarker for embryo selection.

P-290 The insulin-like growth factor 1 receptor (IGF1R) expression is related to the activation of the embryonic genome during early bovine development *in vitro*

F. Poppicht[1], H. Grothmann[2], C. Wrenzycki[2]
[1]*University Hospital of Muenster, Centre for Reproductive Medicine and Andrology, Münster, Germany*
[2]*Clinic for Veterinary Obstetrics Gynecology and Andrology, Molecular Reproductive Medicine, Giessen, Germany*

Study question: The aim of the present study was to analyze the Insulin-like growth factor 1 receptor (IGF1R) expression during early bovine embryonic development *in vitro* on mRNA and protein level and to find out possible relations to the activation of the embryonic genome.
Summary answer: The mRNA and protein expression of the insulin-like growth factor 1 receptor showed a similar pattern during bovine early embryonic development. The stage-specific expression indicates a link to the maternal-embryonic transition, which takes place between the 8-cell and 16-cell stage in bovine embryos.
What is known already: The insulin-like growth factor 1 (IGF1) is a key regulator in early embryonic development, influencing physiological processes and stimulating growth and development. The signal transduction of IGF1 is performed by its binding to the insulin-like growth factor 1 receptor. On mRNA level, the IGF1R was already detected throughout preimplantation embryonic development and could be identified as a potential marker of good quality embryos. However, data on protein level is rare.
Study design, size, duration: *In vitro* derived embryos of different stages (2-cell, 4-cell, 8-cell, 16-cell stage, morula, blastocyst and expanded blastocyst) were either directly subjected to immunofluorescence staining or frozen at –80°C for use in RT-qPCR. Data were analysed by one-way ANOVA followed by a Tukey test using SigmaStat 3.5 Software.
Participants/materials, setting, methods: The mRNA expression of the IGF1R was analyzed by RT-qPCR using rabbit globin mRNA as an external standard. Immunofluorescence staining was performed with a peptide antibody against two peptide sequences of the bovine IGF1R alpha unit. Pixel intensity was measured and mean gray value was calculated using cellsens® software.
Main results and the role of chance: The detection of the IGF1R mRNA and protein was possible in all stages of embryonic development beginning at the 2-cell stage up to the expanded blastocyst. The maximal mRNA expression could be observed in 2- and 4-cell embryos. It significantly decreased to the 8-cell stage, followed by an increase up to the expanded blastocyst. The IGF1R protein was mainly localized in the plasma membrane of single blastomeres. Mean gray values were highest in the 2-cell stage, showing a significant decline up to the 16-cell stage and an increase again until the expanded blastocyst. The mRNA and protein expression showed similar patterns during early embryonic development, indicating a link to the maternal-embryonic transition.
Limitations, reason for caution: The analysis of gene expression by RT-qPCR and immunofluorescence staining in *in vitro* produced bovine embryos showed clearly that IGF1 plays an important role. But there are indications for differences to *in vivo* derived embryos, which have to be analyzed in future experiments.
Wider implications of the findings: The present study gives insides into basic knowledge of the IGF-system, which is influenced by the activation of the embryonic genome. Effects of IGF1 as conveyed by IGF1R play an important role in early embryonic development, as it is expressed throughout all stages.
Study funding/competing interest(s): Funding by national/international organization(s) – H. Wilhelm Schaumann Foundation (Hamburg, Germany).
Trial registration number: NA.

[6]*Clinic for Reproductive Medicine "Genesis Dnepr", Clinical Department, Dnipropetrovs'k, Ukraine*
[7]*Woman Hospital University of Cologne, Department of Obstetrics and Gynecology, Cologne, Germany*

Study question: Can *in vitro* culture of embryos with micro-vibration increase take-baby-home rate?
Summary answer: *In vitro* culture of embryos under micro-vibration conditions significantly increases take-baby-home rate for patients of 30 years old and older.
What is known already: The *in-vitro* culture of human embryos in a medium subjected to regular short intervals of micro-vibrations leads to increased development rates. This type of treatment tries to mimic the conditions which take place in the nature whereby oviductal fluid is mechanically agitated by the epithelial cilia.
Study design, size, duration: This work was performed from August 2010 to December 2013. Written informed consent was obtained from all the participating couples for the culture of non-fertilized and pronuclear oocytes and embryos. Patients were distributed on four age-groups: <29 years old, 30–34 years old, 35–39 years old and >40 years old.
Participants/materials, setting, methods: 4303 patients (mean age 35,5 + 4.6) prepared to IVF-/ICSI-cycles. The culture of oocytes/embryos performed under following conditions: micro-vibration with 20 Hz over 5 s/h (2152 patients, 4304 embryos) or static (2151 patients, 4302 embryos). Embryos transferred on Day 3/5 after oocytes retrieval. The data analyzed by ANOVA for categorical variables using the CATMOD Procedure (SAS).
Main results and the role of chance: The following take-baby-home rate was detected for Groups <29 years old, 30–34 years old, 35–39 years old and >40 years old, respectively (static vs. vibration): 29.3% vs. 32.9% ($P > 0.1$, increasing on the level of tendency), 27.1% vs. 38.7% ($P < 0.05$), 23.8% vs. 28.9% ($P < 0.05$), 9.1% vs. 14.5% ($P < 0.05$).
Limitations, reason for caution: This is a retrospective analysis and not all confounding factors could be considered.
Wider implications of the findings: Taking into account that *in vivo*, just after ovulation oocyte begins to be mechanically agitated, this agitation should be used also for IVF/ICSI.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Praxisklinik Frauenstraße, Frauenstr. 51, 89073 Ulm, Telefon: 0731/966510, Fax: 0731/9665130, E-Mail: info@kinderwunsch-ulm.de, Website: www.kinderwunsch-ulm.de.

P-292 Oocyte vitrification before or after *in vitro* maturation for fertility preservation? A cohort prospective comparative study

E. Kasapi[1], Y. Panagiotidis[1], N. Prapas[1]
[1]*Iakentro Fertility Centre, IVF, Thessaloniki, Greece*

Study question: The developmental competence of the *in vitro* matured human oocytes is more compromised when they are vitrified at the germinal vesicle (GV) or at the metaphase II (MII) stage?

Summary answer: There is no significant difference on the survival rate of the post thaw germinal vesicle (GV) and metaphase II (MII) stage oocytes. Still, the developmental competence of the GV-state human oocytes seems to be compromised by the vitrification procedure.
What is known already: Cryopreservation procedure compromises the developmental competence of the oocytes applied either before or after *in vitro* maturation (IVM) compared to the developmental competence of the post thaw *in vivo* matured human oocytes and to the *in vitro* matured human oocytes that are directly fertilized.
Study design, size, duration: A total of 408 GV sibling oocytes in three different groups of study, from 120 consenting IVF patients were included in the present cohort prospective comparative study performed from December 2013 until November 2014. The first group was the "GV vitrification" group, the second was the "MII vitrification" group and the third one was the "NO vitrification" group.
Participants/materials, setting, methods: The study was conducted in a private ART unit. The source of GVs was IVF cycles of patients younger than 38 years from which were retrieved at least three GVs. A commercial IVM medium (Sage, Copper Surgical, USA) supplemented with 75 mIU/ml FSH and LH was used. For vitrification the FertiPro media and the closed Vitrisafe device were used.
Main results and the role of chance: The results of the present study indicate that though the survival rate of the oocytes after vitrification at different developmental stages is the same (81,25% vs. 80,35% for group 1 and 2 respectively), the developmental competence of the oocytes vitrified at the GV stage is strongly compromised. The maturation rate is lower in the "GV vitrification" group compared to the "MII vitrification" group (44,23% vs. 87,5% respectively). Moreover, the fertilization and the blastocyst formation rate seem to be influenced by the vitrification procedure at the GVs. On the other hand, the developmental potential of the oocytes vitrified after IVM seems to be similar to those that have not been vitrified.
Limitations, reason for caution: the source of the GVs was stimulated cycles, while it's possible usage would be from unstimulated ones.
Wider implications of the findings: Cryopreservation of immature or *in vitro* matured oocytes derived from unstimulated cycles is an option for fertility preservation in cases of patients undergoing therapeutic treatments for malignant and non-malignant diseases. The developmental stage of the oocytes to vitrify is an important parameter for the success of the procedure.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Iakentro.
Trial registration number: NA.

P-293 Establishment and validation of a model for hCG stimulation in human mural granulosa cell culture

L. Ophir[1], Y. Yung[2], M. G. Yerushalmi[2], E. Maman[2], A. Hourvitz[2]
[1]*Tel Aviv University, Biochemistry, Petah Tikva, Israel*
[2]*Sheba Medial Canter, Gynecology, Ramat Gan, Israel*

Study question: To establish a standardized protocol for the culture of MGCs as a model for hCG effect.
Summary answer: In order to examine the effect of hCG on MGCs in culture, hCG should be administrated after 4 days in culture with daily medium exchange.
What is known already: Oocyte re-entry into the meiotic cell cycle and completion of maturation are triggered by increase in LH which is crucial for the final stages of oocyte maturation. Cell culture techniques of human mural granulosa cells serve as a major *in vitro* tool for understanding molecular signaling. However, the use of luteinized MGCs has major limitations due to their luteinized state hence a validated uniform model should be conducted in order to examine the effect of hCG in culture.
Study design, size, duration: luteinized MGCs were cultured with daily medium exchange. Cells were harvested and total RNA was purified for qRT-PCR analysis. Cell medium was obtained in order to examine progesterone secretion.
Participants/materials, setting, methods: Materials: Mural granulosa cell culture. Methods: qRT-PCR, ELISA for progesterone.
Main results and the role of chance: Our results indicate that after 4 days in culture with daily medium exchange MGCs demonstrate an increase in mRNA expression levels of LH downstream genes, Amphiregulin and Epiregulin and a decrease in sFRP4 mRNA expression. mRNA expression levels of the examined steroidogenesis genes, 3bHSD, 11bHSD and COX2 were also upregulated as a result of hCG administration on day 4 with daily medium exchange. We showed that luteinized MGCs response to hCG stimulation by upregulating LH downstream and upregulating steroidogenesis mRNA genes expression after 4 days of culture. On day 4, maximal effect of hCG on examined genes expression was observed 4–6 h after hCG administration. Progesterone secretion to the medium was increased as a response to hCG stimulation and reached the highest levels on day 4.
Limitations, reason for caution: MGCs were luteinized hence already exposed to hCG.
Wider implications of the findings: This novel model may provide an important standardized research tool for examining the effect of hCG on molecular processes occurring during the latter stages of follicular development in the human ovary.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Sheba Medical Center.
Trial registration number: 821/13/ANIM.
Keywords: mural granulosa cells, hCG, human, culture model

P-294 The effects of late ICSI on embryo quality

V. Nagornyy[1], P. Mazur[1], V. Zukin[1]
[1]*Clinic of Reproductive Medicine "Nadiya", Embryology Department, Kiev, Ukraine*

Study question: What are the reasons of decreased implantation potential of embryos derived after delayed ICSI?
Summary answer: If oocytes were fertilized by ICSI at 42 h or more after ovulation trigger the obtained embryos showed impaired developmental ability. This was revealed by reduced blastocyst quality, increased irregular division rate and abrupt morphokinetic pattern.
What is known already: Studies published so far defined empirically that prolonged storage of oocytes post retrieval is related to reduced embryo quality and significantly lower pregnancy rate. However the detailed explanation of this phenomenon is still missing.
Study design, size, duration: This cross sectional study included time-lapse embryo culture data from 410 fresh embryo transfer cycles, where oocytes originated from patient younger than 35 years. Of those in 140 cases comprehensive genetic screening was performed. Data was collected during 2 years in a private IVF centre.
Participants/materials, setting, methods: Oocyte fertilization was performed by ICSI or IMSI if needed. Time lapse culture was performed in EmbryoScope (Unisense Fertilitech, Denmark) and imaging data analysed with manufacturers software. Timings of development, presence of faulty cleavage patterns, morphological appearance were scored and compared depending on time spent by oocytes prior to fertilization.
Main results and the role of chance: Oocytes fertilised 42 h or more post ovulation triggering constituted 37% of cohort. The implantation rate in this subgroup was not significantly lower probably due to improvement of embryo selection with time-lapse embryo culture. Interestingly, after comparison of embryo division timings of the 'late ICSI' subgroup the faster dynamics was revealed. Additionally such embryos possessed increased incidence of poor prognosis predictor events such as divisions of blastomeres into three or more cells or production of two unevenly sized blastomeres. Although in the 'late ICSI' cohort transferred blastocysts were of comparable morphological quality the blastocyst formation rate was lower. Also, amongst all blastocysts obtained the percent of blastocyst having highest scores was reduced for this subgroup. No difference was observed regarding ploidy of embryos from delayed ICSI.
Limitations, reason for caution: This is a retrospective study and thus can be subject of bias. Amongst embryos derived by late fertilization there is a significant fraction with proper development dynamics and morphology. The efficiency of implantation of those can be the subject to further studies.
Wider implications of the findings: Our study reveals the importance of fertilization timing and complement previously published data. The accelerated cleavage of lately fertilized embryos can signify the existence of relation between the timing of oocyte maturation and subsequent embryo development.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Clinic of Reproductive Medicine 'Nadiya', Kiev, Ukraine.
Trial registration number: NA.
Keywords: ICSI, IMSI, embryo quality

P-295 Large scale comparison of morphokinetic timings of over 12,500 IVF and ICSI embryos from insemination to blastulation

A. Campbell[1], M. Laegdermand[2], S. Fishel[1], R. Smith[3], S. Montgomery[4], K. Berrisford[5], R. O. SmithB.[6], L. Nice[7], D. K. Griffin[8]
[1]*CARE Fertility Group, Corporate, Nottingham, United Kingdom*
[2]*Intus Analytics, Analytics, Viborg, Denmark*
[3]*CARE Fertility, Embryology, Sheffield, United Kingdom*
[4]*CARE Fertility, Embryology, Manchester, United Kingdom*
[5]*CARE Fertility, Embryology, Nottingham, United Kingdom*
[6]*CARE Fertility, Embryology, London, United Kingdom*
[7]*CARE Fertility, Embryology, Northampton, United Kingdom*
[8]*University of kent, BioSciences, Canterbury, United Kingdom*

Study question: Do IVF and ICSI embryos have different morphokinetics?
Summary answer: Mean time of pronuclear fading, following insemination, was 2 h delayed in IVF compared with ICSI but subsequent timings, durations and synchronicity of cell cycles, duration of compaction and blastulation did not differ between the two methods.
What is known already: Time lapse monitoring allows the detailed comparison of morphological and dynamic variables of development between embryos. Information comparing IVF and ICSI embryos using time lapse imaging is limited although one study suggests that the initial delay to early morphokinetic variables, in IVF compared with ICSI, is short-lived and that mean values for IVF embryos, reaching consecutive cell stages, align with those of ICSI embryos after the 8 cell stage.
Study design, size, duration: Morphokinetic data was retrospectively collected from 12939 embryos using EmbryoScope™ time lapse imaging from multiple sites using standardised laboratory practice and culture conditions (5%O_2; 5.5%CO_2), between May 2011 and December 2013. Insemination times were recorded: IVF time when gametes were mixed and ICSI time midway through the ICSI procedure.
Participants/materials, setting, methods: Mean values in hours (h) and standard deviations were calculated for the following: pronuclear fading (PNf); time to 2 cells (t2) from PNf (d1); t3-t2 (cc2a); t4-t3 (s2); t5-t4 (cc3a); t8-t5 (s3); duration of late stages (time to start compaction (tSC) from t8) (dLS); duration of compaction (dCom) and blastulation (dB).
Main results and the role of chance: A difference in means of 2.3 h between ICSI and IVF was observed in PNf. The mean (h) and standard deviation (in brackets) for ICSI and IVF PNf was 23.7 (5.1) (n = 9619) and 26.0 (4.2) (n = 3320) respectively. Ongoing morphokinetics were similar when comparing cell cycle, synchronicity and durations through to blastulation. Mean values and standard deviations were respectively as follows for ICSI: d1 3.0 (2.4); cc2 9.2 (5.2); S2 2.7 (4.8); cc3 9.5 (6.6); S3 11.3 (9.1); dLS 28.6 (11.2); dCom 12.3 (7.7); dB 11.2 (5.5) and IVF: d1 3.3 (2.6); cc2 9.3 (4.8); S2 2.7 (5.1); cc3 10.1 (6.6); S3 11.0 (9.1); dLS 28.1 (10.2); dCom 10.3 (6.3); dB 10.8 (5.0).
Limitations, reason for caution: Recording of insemination time may lack precision, particularly following ICSI where several oocytes are inseminated over several minutes, compared with IVF which is performed at a definitive time.
Wider implications of the findings: Morphokinetic algorithms, in order to be applicable to both IVF and ICSI embryos should avoid using time of insemination (t0), or direct derivatives of this, to assure accuracy. Durations, or relative time from pronuclear fading, provide more reliable variables for time lapse algorithm development considering the inevitable, but now measurable, delay in IVF embryos observed up to pronuclear fading.
Study funding/competing interest(s): Funding by hospital/clinic(s) – CARE Fertility Group.
Trial registration number: N/A.
Keywords: time lapse, morphokinetics, ICSI, IVF

P-296 S-Biopsy: a simplified, less invasive embryo biopsy technique for day 3 preimplantational genetic screening (PGS)

L. Cedillo Garcia Lascurain[1], I. Maldonado[1], J. Gomez[1], D. Guerrero[1], J. Cordero[1], A. Reyes[1], F. Camargo[1], E. Lopez-Bayghen[1], A. Ocampo[1], R. Sharma[2], A. Agarwal[2]
[1]*Instituto Ingenes, IVF Laboratory, Mexico City, Mexico*
[2]*Center for Reproductive Medicine Glickman Urological and Kidney Institute Cleveland Clinic, IVF Laboratory, Cleveland, OH, U.S.A.*

Study question: To report a stripper based, less invasive method for preimplantational genetic screening, comparing it to the conventional technique used for blastomere biopsy (aspiration of a blastomere by micromanipulation) to assess if this technique can obtain similar outcomes while making PGS more approachable to inexperienced personnel within the IVF laboratory.
Summary answer: When compared to the conventional biopsy method, the stripper based biopsy (S-biopsy) technique successfully removed the desired blastomeres for PGS while considerably reducing the invasiveness to the biopsied embryos and the performance time in which embryos are manipulated outside their incubators, even without extensive experience from the user.
What is known already: There is currently enough class I evidence provided by a series of randomized controlled trials to support preimplantational genetic screening (PGS) as a reliable tool to improve clinical outcomes by selecting chromosomally integral embryos for transfer. PGS requires nucleated cells for analysis; however, the conventional technique used for day three biopsy is extremely hard to master and has been noted to adversely impact the viability of the biopsied embryos if performed without extensive experience.
Study design, size, duration: 368 good quality day 3 embryos (7 or 8 cells, <10% fragmentation, no statistical differences) from PGS cycles were randomized within their own IVF cycles to be biopsied either by the conventional technique or S-biopsy to form two groups that were compared for blastomere integrity and blastocyst formation rate.
Participants/materials, setting, methods: S-Biopsy was performed using a laser to create a thin funnel in the zona pellucida next to the desired blastomere, which was then extracted by aspiration and release of the embryo with a 140 mm stripper capillary. The conventional method was performed as described in the literature.
Main results and the role of chance: Group A (188 embryos) was biopsied by the conventional aspiration technique, while Group B (180 embryos) was biopsied by S-Biopsy. All biopsied embryos were allowed to reach the blastocyst stage and a chi-square for concurrence was used to determine statistical differences (Alpha level: 0.05). There was no statistical difference for both groups regarding intact blastomeres (Group A: 95.7%, 180 embryos vs Group B: 95.0%, 171 embryos) or blastocyst formation rate (Group A: 70.7%, 133 blastocysts vs Group B: 72.7%, 131 blastocysts). However, there was a significant difference in performance times: 4 minutes (±30 seconds) for S-Biopsy vs 15 minutes (±60 seconds) for the conventional technique (3 biopsied embryos were considered as a mean in both techniques for all biopsies in each group, preparation and material set up times were included).
Limitations, reason for caution: The S-Biopsy has been proven to be safe. However it isn't completely risk free, as the embryo or the blastomere can be damaged if the technique is not performed properly (e.g., hitting the blastomere with the laser, doing a bigger or incomplete funnel, using a wrong sized capillary).
Wider implications of the findings: There are other aspects that add more value to the technique as it is extremely easy to learn and perform; and it doesn't involve the use of a micromanipulator, holding or biopsy pipettes or PGS media (Ca++ Mg++ free). It can also be performed within the culture dish without increasing embryo manipulation. This makes blastomere biopsy for PGS easier, cheaper, less time consuming and more accessible to a wider array of IVF programs.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Instituto Ingenes. No financial support was received for this study and there are no potential conflicts of interest.
Trial registration number: None.
Keywords: IVF, day 3 biopsy, PGS, embryo

P-297 The impact of abnormal mitoses and fragmentation from zygote to blastocyst on potential of blastocyst to result in a pregnancy

A. Azzarello[1], T. Hoest[1], A. L. Mikkelsen[1]
[1]*Copenhagen University, Holbaek Fertility Clinic, Holbaek, Denmark*

Study question: Do abnormal mitoses, large fragments and high fragmentation rate occur in embryos, which are able to develop to blastocysts with good morphology and do these blastocysts result in a pregnancy?
Summary answer: Abnormal mitoses, as direct cleavage (DC) and failed mitosis (FM) are compatible with pregnancy when occurring from 2nd cleavage and the blastomeres are integrated in blastocysts. High fragmentation (HF) and large fragments (LF) are frequently seen in embryos resulting in pregnancies.
What is known already: Blastocysts with a good morphology have high pregnancy rate. Embryos showing DC at the 1st cleavage can develop to blastocysts,

but their potential to result in a pregnancy is limited. The presence of a nucleus makes it possible to distinguish blastomeres from fragments. It is conventionally accepted to use a cut-off of 45 mm in diameter considering all cells less than 45 mm as a fragment. High fragmentation rate (>25%) is considered detrimental for embryo potential.
Study design, size, duration: Cohort study including 97 IVF/ICSI treatments. On day 2, the best embryo was transferred and remaining embryos were cultured to day 5. Blastocysts were vitrified and transferred after thawing in a subsequent cycle between January 2013 and October 2014. Pregnancy was assessed by ultrasound at gestational age 7 + 0.
Participants/materials, setting, methods: Embryos able to develop in good morphology blastocysts on day 5 were retrospectively assessed. Assessment was performed observing every mitosis and every nucleus in time-lapse. We recognized DCs; FMs (disassembling and reassembling of the nuclei without cytokinesis); LF (>45 µm); HF (>25%); and related to outcome.
Main results and the role of chance: Twenty-eight Blastocysts Resulted in a Pregnancy (BRP), 72 Blastocysts resulted in No Pregnancy (BNP). At the 1st cleavage (from 1 to 2 cells), DC and FM occurred respectively in 1 BNP and none BRP. Compared to 1st cleavage, FM occurred more frequently at the 2nd (2–4 cells), 3rd (4–8 cells), and 4th (8–16 cells) cleavages, in both BRP and BNP (2nd 2 vs. 5; 3rd 4 vs. 12; 4th 3 vs. 5). DC occurred less frequently than FM at any stage in both BRP and BNP (1st 1 vs. 2; 2nd 1 vs. 2; 3rd 0 vs. 0). LFs were released at 1st and 2nd cleavages in 9 BRP and 17 BNP. HF occurred in 1 BRP and 3 BNP. Fragments were never integrated in the blastocyst, while most of the blastomeres resulted after FM and DC were included.
Limitations, reason for caution: Blastocysts were vitrified. Few blastocysts did not survive the thawing, potentially selecting the ones with the highest potential. Fresh transfer blastocysts could have higher rate of abnormal mitosis. Abnormal mitoses could be underestimated at the 4th cleavage, due to the difficulties to assess this stage.
Wider implications of the findings: Embryos presenting DC and FM can result in good morphology blastocysts and, except at the 1st cleavage, in pregnancies. Embryos may have some self-repairing or recovering process. The occurring of DC and FM could be more frequent at earlier stage and that embryos select themselves when cultured till blastocyst at day 5. This supports the transfer of blastocysts instead of earlier embryo stage, in which the self-selection has not occurred yet.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Holbaek Regional Hospital.
Trial registration number: Approval number from the National Ethical Committee of Medical Science of Denmark: SJ-250.

P-298 The activities of aminopeptidase N (APN) and embryo quality

N. Gonzalez Espeja[1], A. Valdivia Palacín[2], N. Subirán Ciudad[3], M. Ferrando Serrano[4], Z. Larrategui Laiseca[1], J. Irazusta Astiazaran[3]
[1]*IVI Bilbao, IVF laboratory, Leioa Bizkaia, Spain*

[3]*Faculty of Medicine and Dentistry University of the Basque Country (UPV/EHU), Department of Physiology, Leioa Bizkaia, Spain*
[4]*IVI Bilbao, Department of Gynecology, Leioa Bizkaia, Spain*

Study question: The objective is to establish the relationship between the activity of aminopeptidase N (APN) enzyme and embryo quality.
Summary answer: The alterations in the metabolism of APN might be one of the factors which affect embryo quality.
What is known already: The sperm potential is determined by different factors and physiological processes. Most of these processes are regulated by biochemical signals necessary for cellular communication. Many of these molecules are peptides which act on receptors located on the sperm membrane. The effect of peptidases can be controlled by enzymatic hydrolysis. APN pathway is considered to be of great importance in the degradation of peptidases.
Study design, size, duration: 89 sperm samples of patients belonging to the program of assisted reproduction of the IVI Bilbao were analyzed.
Participants/materials, setting, methods: These samples were treated to obtain three different fractions (sperm cells, seminal liquid and prostasomes). Embryo quality (number of cell and fragmentation of the embryos) was evaluated by qualified embryologist.
The activities of APN were measured using fluorimetric aminoacid derivatives and were correlated with embryo quality.
Main results and the role of chance: The higher activity of APN in seminal liquid was negatively correlated with the number of cells on day 2 but positively correlated with the percentage of fragmentation. For the activity of APN in prostasomes the same correlations with above mentioned variables were founded.
Limitations, reason for caution: Therefore, the study of the metabolism of peptidases may be useful as a biochemical tool for the diagnosis of human fertility, but need to be more studied with a larger number of samples.
Wider implications of the findings: Previous studies about the metabolism of the APN and its influence on the embryo quality weren't founded. We suggest that mentioned enzyme could be a good predictor of the embryo quality.

P-299 Euploid-blastocyst formation and blastocyst implantation rate is higher for Eeva high than for low embryos: a multicenter blinded study in PGS and non-PGS trophectoderm-biopsy patients

M. D. VerMilyea[1], L. Tan[2], J. Conaghan[3], P. E. Chenette[3], K. Ivani[4], S. P. Willman[4], A. Le[5], R. Boostanfar[5], A. A. Chen[2], A. B. Copperman[6]

[3]*Pacific Fertility Center, IVF Unit, San Francisco, CA, U.S.A.*
[4]*Reproductive Science Center of the San Francisco Bay Area, IVF Unit, San Ramon, CA, U.S.A.*
[5]*HRC Fertility, IVF Unit, Encino, CA, U.S.A.*
[6]*Reproductive Medicine Associates of New York, Obstetrics and Gynecology, New York, NY, U.S.A.*

Study question: Do Eeva Test results, generated through the automated time-lapse analysis of early cell division parameters, correlate with the likelihood of euploid blastocyst formation? Furthermore, do Eeva Test results correlate with implantation after blastocyst transfer?
Summary answer: In patients seeking preimplantation genetic screening (PGS) of embryos derived from IVF, euploid blastocyst formation for Eeva High embryos was significantly higher than for Eeva Low embryos. In non-PGS patients, blastocyst implantation was significantly higher for Eeva High embryos than for Eeva Low embryos.
What is known already: Time-lapse imaging parameters have been correlated to aneuploidy risk (Chavez et al 2012, Campbell et al 2013) and shown in a recent RCT to improve IVF outcomes (Rubio et al 2014). The Eeva Test is an automated time-lapse analysis and embryo classification system that reduces the time needed to measure time-lapse parameters manually. Here, we perform an evaluation of the correlation of Eeva Test results with euploid blastocyst formation, and with blastocyst implantation.
Study design, size, duration: A total of 96 PGS trophectoderm biopsy patients from two centers (2012–2013) were prospectively enrolled to study the correlation between time-lapse parameters and embryo ploidy status. Known blastocyst implantation was retrospectively assessed in a separate group of 171 non-PGS blastocyst transfers from four centers (2011–2014).
Participants/materials, setting, methods: For PGS patients, blastocyst culture, biopsy and PGS were performed per standard protocols. Embryos selected for transfer were based on comprehensive-chromosomal-screening results. For non-PGS patients, standard morphological grading was used for embryo selection. Time-lapse images were collected using the Eeva System, but all Eeva results were blinded to embryologists.
Main results and the role of chance: In 96 PGS patients, 36% of the total 982 embryos were euploid blastocysts. Euploid blastocyst formation rates for Eeva High, Medium and Low embryos were 45% (95/213), 44% (115/263) and 27% (139/506), respectively. The difference in euploid blastocyst formation rates between Eeva High and Low embryos was statistically significant ($p < 0.0001$). In 171 non-PGS patients, 39% of the 233 transferred embryos with known implantation status implanted. Day 5 known implantation rates for Eeva High, Medium and Low embryos were 44% (43/98), 45% (28/62) and 26% (19/73), respectively. The difference in day 5 known implantation rates between Eeva High and Low embryos was statistically significant ($p = 0.02$).

Limitations, reason for caution: This was not a randomized, controlled study. Implantation was calculated using known implantation confirmed by ultrasound at 6–8 weeks. Known implantation may underestimate overall implantation rates by excluding some implanted embryos from multiple embryo transfer cases.
Wider implications of the findings: This multicenter blinded study demonstrated a positive correlation between Eeva Test results and two highly relevant clinical outcomes: euploid blastocyst formation and blastocyst implantation. Eeva Test results may therefore reflect the chromosomal integrity of human embryos and add valuable information to improve embryo selection and facilitate the trend towards eSET. The positive correlation between Eeva Test results and euploid blastocyst formation may also provide potential decision support for patients considering PGS trophectoderm biopsy.

P-300 Modified rapid thawing of oocytes can assure higher survival rates maintaining subcellular integrity

V. Furlan[1], M. T. Guerra[2], L. Parmeggiani[3], C. Magli[4], L. Gianaroli[4], F. Bertocci[5], V. Bianchi[5], V. Bianchi[1]
[1]*Casa di Cura città di Udine, Ob/Gyn, Udine, Italy*
[2]*Yale School of Medicine, Department of Internal Medicine, New Haven, CT, U.S.A.*
[3]*GynePro Medical Center, Reproductive Medicine Unit, Bologna, Italy*
[4]*Sismer, Reproductive Medicine Unit, Bologna, Italy*
[5]*Careggi Hospital, IVF Unit, Florence, Italy*

Study question: Can a faster thawing method result in a higher survival rate using slow freezing? Is the morphology of the oocyte preserved?
Summary answer: There is a significant increase in the survival rate within siblings using a faster thawing method. Rapid melting of ice crystals prevents oocyte degeneration. Cell morphology appears preserved by confocal microscopy of cellular structural elements. Together, these findings suggest that rapid thawing methods have potential for wider clinical application.
What is known already: In the clinical practice, oocyte cryopreservation is mainly used for fertility preservation and social freezing as well as egg donation programs.

Nevertheless, in the literature, there only have been few improvements in slow freezing protocols mainly due to the widespread use of vitrification procedures. In the past decade however, both survival and implantation rates have increased significantly due to a more balanced combination of sucrose, protein supplementation and exposure timing.
Study design, size, duration: This study involved 40 women undergoing *in vitro* fertilization (IVF) treatment who cryopreserved their oocytes and latter elected to donate these gametes for research. The mean age was 35 years old (range: 25–42). The operator froze all the spare metaphase II oocytes within 3 h post retrieval using slow freezing.
Participants/materials, setting, methods: Two warming methods were evaluate in sibling oocytes as follow: Group A) 30 sec air, 40 sec in a 30°C water bath Group B) 5 sec air, 5 sec in a 37°C water bath Survived oocytes were then fixed for tubulin and DNA fluorescence staining and imaged by confocal microscopy.
Main results and the role of chance: A total of 186 oocytes were divided in two groups of 93 oocytes to avoid inter individual variability bias. Sixty out of 93 eggs (64%) survived (group A) while 75/93 (group B) (81%) ($P < 0.025$). Two hours later survival was checked and 2 and 4 eggs were lysed in groups A and B respectively (P = ns). Confocal microscopy on a smaller number of the survived eggs of each group revealed similar mitotic spindle and chromatin distribution as shown by tubulin and DNA staining, which are compatible with previously reported data.

We tried to minimize the role of chance by splitting sibling oocytes for the thawing procedure. We speculate that a faster warming helps to minimize ice crystal formation and improve post thaw survival.
Limitations, reason for caution: The main limitation to widespread application of the current thawing methods is the lack of data on egg development therefore further evaluation of egg health is required before these procedures can be utilized in routine practice.
Wider implications of the findings: Oocyte cryopreservation techniques are associated with satisfactory clinical outcomes, but the long-term implications for egg health remain unknown. This study demonstrates that slow freezing protocols can be further improved. These findings may influence the choice of oocyte cryopreservation method and guide future optimization of different procedures.
Study funding/competing interest(s): Funding by hospital/clinic(s) – N/A.
Trial registration number: NA.

P-301 Comparative investigation of the effect of sage® media versus lifeglobal® media on human in vitro fertilization outcome after transfer of cryopreserved embryos

V. P. Apryshko[1], S. A. Yakovenko[2], N. V. Dmitrieva[3], A. A. Biryukov[1], A. I. Bolt[1], M. N. Troshina[1], M. A. Kharitonova[1], T. G. Khryapenkova[1], E. S. Kalinina[1], K. V. Kirienko[1], A. A. Klepukov[1], E. M. Savina[1], E. V. Uvarova[1], A. G. Mironova[1], A. A. Dolganova[1]
[1]*Altravita IVF Clinic, Department of Embryology, Moscow, Russia C.I.S.*
[2]*Altravita IVF Clinic, Lomonosov Moscow State University Department of Biophysics, Moscow, Russia C.I.S.*
[3]*Altravita IVF Clinic, Department of Obstetrics and Gynecology, Moscow, Russia C.I.S.*

Study question: The aim of this study was to compare the effectiveness of IVF cycles performed with Sage® media and LifeGlobal® media by assessing fertilization and blastocyst rates as well as outcomes of frozen embryo transfers (FET).
Summary answer: In our investigation the use of LifeGlobal® has shown better results comparing to Sage® medium, namely an increase in blastocyst rate, clinical pregnancy and implantation rates, thereby increasing the overall effectiveness of IVF program.
What is known already: Preimplantation embryos are able to develop in different culture media, which vary notably in their composition. On the other hand, in a number of experimental studies it has been shown that early embryo culture conditions might affect embryonic, fetal and newborn health.
Study design, size, duration: In the present retrospective study 442 treatment cycles from couples undergoing IVF or intra-cytoplasmic sperm injection (ICSI) from January 2011 to June 2014 were distributed between culture media Sage® and LifeGlobal®.
Participants/materials, setting, methods: A total of 438 patients aged between 20 and 39 years, not suffering from genetic infertility or cryptozoospermia were included. According to Gardner blastocyst grading system only embryos of good quality were cryopreserved using Vitrification Kit (Cryotech®) for subsequent transfer.
Main results and the role of chance: The 438 patients fitted the inclusion criteria; 213 of them were assigned to Sage® and the other 225 to LifeGlobal® media. Numbers of oocytes recovered (16.3 ± 8.1 for Sage® vs. 17.6 ± 8.5 for LifeGlobal®), an average number of transferred embryos (1.1 per FET) and fertilisation rates (77.8 ± 15.1 for Sage® vs. 76.0 ± 15.9 for LifeGlobal®) were similar between the two groups (P = NS). The same number of FET (n = 275) was perfomed in both groups. The blastocyst rate was significantly higher in the LifeGlobal® group (62.9 ± 21.5 vs 54.2 ± 23.3, $P < 0.05$) as well as the percentage of FET resulted in positive b-hCG (54.9 vs. 43.3%, $P < 0.01$), Clinical Pregnancy Rate (48.0 vs. 38.9%, $P < 0.05$) and Implantation Rate (46.1 vs. 36.8, $P < 0.05$). The difference in miscarriage rate before 12 weeks was not significant.
Limitations, reason for caution: Current study does not include take home baby and late term pregnancy loss rates as these data are still being collated on account of the ongoing pregnancies and patients lost to follow-up.
Wider implications of the findings: Due to the conflicting reports of the culture media effectiveness and the fact that manufacturers do not fully disclose their media composition it is reasonable to conduct an independent research in order to improve human embryo culture conditions. Having started with a simple comparison of embryological and pregnancy outcomes the investigation should be continued and deepened which might lead to better understanding of interactions of different aspects affecting embryos health in vitro.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Altravita IVF clinic.
Trial registration number: Not RCT.

P-302 Fragilis, Stella and Blimp1 gene expression progressively decreases in the ovaries as mice get older

M. Silva-de-Sá[1], D. B. Dentillo[1], A. C. J. S. Rosa-e-Silva[1]
[1]*Faculty of Medicine of Ribeirao Preto, Gynecology and Obstetrics, Ribeirao Preto, Brazil*

Study question: How Fragilis, Stella and Blimp1 gene levels change in mice ovaries according to the animals' age?
Summary answer: Fragilis, Stella and Blimp1 gene levels decrease in mice ovaries from neonatal to 65 days old and then decrease more when reaching 240 days.
What is known already: Fragilis, Stella and Blimp1, genes that are known to be involved in germ line cells differentiation, are expressed in the early development of mice ovaries and also during the adult life.
Study design, size, duration: Ovaries from Balb-c mice at different ages – neonatal (nn), 65 days (65d) and 240 days (240d) old – were evaluated regarding the expression of Fragillis, Stella, Blimp1 genes; the study lasted 3 months.
Participants/materials, setting, methods: RNA from ovaries of 10 animals of each mentioned age were isolated, the RNAs were reverse transcribed into cDNA, and gene expression levels obtained by real time PCR using relative quantification (RQ) method. B2m was the endogenous control. We used One Way ANOVA and Tukey's test to analyze the results (RQs).
Main results and the role of chance: Means of RQs and standard deviation for each gene were: Fragilis (nn: 3.16 ± 0.59; 65d: 1.98 ± 0.27; 240d: 1.45 ± 0.27); Stella (nn: 15.05 ± 1.55; 65d: 7.78 ± 2.82; 240d: 1.62 ± 1.11); Blimp1 (nn: 11.98 ± 2.18; 65d: 4.02 ± 1.19; 240d: 3.08 ± 1.77). We used One Way ANOVA and Tukey's test to analyze the results. The genes showed to be statistically different according to the mice ages at $p < 0.01$.
Limitations, reason for caution: This is a gene expression study and investigations regarding protein levels must be carried on.
Wider implications of the findings: Immediately after birth the three genes showed to be expressed at high levels compared to adult life; as the mice get older their expression decreases. This dynamic follows the decreasing fertility related to age in mammals, what may suggest that although adult ovaries harbor oocyte precursor cells, the reduction of their function along time may not support gametogenesis at older ages.
Study funding/competing interest(s): Funding by University(ies) – funding by national/international organization(s) – USP- University of São Paulo- Brazil – CNPq- National Counsel of Technological and Scientific Development- Brazil – CAPES-Coordenação de Aperfeiçoamento de Pessoal de Nível Superior- Brazil.
Trial registration number: CEUA (Ethics Committee in the use of Animals) - FMRP/USP-60/2014.

P-303 The category of embryo potential afforded by the automated time-lapse enabled EevaTM Test is strongly associated with the speed embryo development

C. Adam[1], C. Noble[1], N. Gibson[1], C. Paterson[1], S. Acharya[2], P. Mitchell[1], M. Gaudoin[2], R. Fleming[2]
[1]*GCRM Ltd, Embryology, Glasgow, United Kingdom*
[2]*GCRM Ltd, Clinical, Glasgow, United Kingdom*

Study question: The Eeva Test predicts the potential of an embryo to form a blastocyst based on automated time-lapse analyses of early cell divisions by determining 3 categories of embryo. How do these categories relate to cell number and developmental pace at assessment on day 3?
Summary answer: 'High potential' (HP) embryos showed a distribution of cell numbers strongly favouring rapid development with cell numbers greater than 7 predominating. In contrast 'low potential' embryos (LP) showed a distribution of cell numbers mostly less than 8 cells. 'Medium potential' (MP) embryos showed a mixed distribution of cell numbers.
What is known already: The Eeva Test, comprising automated time-lapse analyses of early embryo development, is able to indicate the potential of an embryo to develop into a blastocyst by categorisation to HP, MP or LP embryos. This categorisation has been shown to aid embryo selection achieving higher fresh pregnancy rates by comparison with use of morphology alone.
Study design, size, duration: This was a prospective examination of all 1470 embryos from 257 successive IVF and ICSI cycles in women < 40 years old, over 2 years in a single centre.
Participants/materials, setting, methods: Embryos were assessed on day-3 for cell count, regularity and degree of fragmentation, and the Eeva Test category was recorded. The blastomere count was categorised: 'less than 8 cells' (L8c), 8 cells (8c) or 'more than 8 cells' (M8c) and the 3 Eeva test categories were also recorded.
Main results and the role of chance: The distribution of categorisation of all embryos showed: L8c = 44% of the total, 8c = 42% and M8c = 14%. For the 720 LP embryos the distribution was L8c = 63%, 8c = 27% and M8c = 10%. For the 339 MP embryos the distribution was L8c = 35%, 8c = 55% and M8c = 10%. For the 411 HP embryos the distribution was L8c = 19%, 8c = 57% and M8c = 24%. These distributions differ significantly ($P < 0.01$) and imply that when the cell division timings lie within the ranges predictive of blastocyst formation (HP), the developmental capacity of embryos is more rapid – increased proportions of 8c and M8c embryos. This has implications for selection of embryos for transfer at the cleavage stage.
Limitations, reason for caution: This is a valid observational study of unselected embryos which may have implications for embryo selection in the absence of time-lapse evaluations. However, any such concept would require prospective controlled evaluation.
Wider implications of the findings: The timings of the initial cell divisions of an embryo appear to be critical for the pace of further development. Furthermore, as blastocyst formation appears to be associated with faster growing embryos, selection policies for cleavage stage embryos (whether to transfer 1 or 2 embryos) may take this into account.
Study funding/competing interest(s): Funding by hospital/clinic(s) – no external funding.
Trial registration number: NA.
Keywords: automated time-lapse, Eeva test, embryo selection, cleavage stage transfer

P-304 Mitochondrial oxygen consumption rates skyrocket at the blastulation in spite of constant mitochondrial DNA number during preimplantation development

H. Goto[1], S. Hashimoto[1], M. Yamanaka[1], T. Yamochi[1], A. Amo[1], Y. Takahashi[2], H. Iwata[3], M. Inoue[1], Y. Morimoto[4]
[1]*IVF Namba Clinic, Reserch Division, Osaka, Japan*
[2]*IVF Namba Clinic, Medical Office, Osaka, Japan*
[3]*Tokyo University of Agriculture, Department of Animal Science, Atsugi, Japan*
[4]*HORAC Grandfront Osaka Clinic, Medical Office, Osaka, Japan*

Study question: How does it change that mitochondrial DNA (mtDNA) copy number and mitochondrial function in human embryos during preimplantation development?
Summary answer: Mitochondrial oxygen consumption rates (mtOCRs) rise sharply at the blastulation in spite of constant mtDNA number during preimplantation development. In addition, mitochondria became mature and the CCO activity was detected at blastocyst stage.
What is known already: OCRs relate to the quantity of ATP production and mitochondrial respiration may be an effective index of mammalian embryo quality. The number of mtDNA has been shown to be a marker of mitochondria number. The number of mtDNA remains constant within preimplantation murine embryos, but not in cattle and pigs decreasing sharply from 2-cell to 4/8-cell stages. Moreover, the changes of mtOCRs of human embryos remain unknown.
Study design, size, duration: This experimental study was performed after obtaining informed consent of patients and an approval of ethical committee of JSOBGY using 21 MII oocytes, 12 day 3 embryos, 20 day 4 embryos and 20 blastocysts. We assessed the relationship among embryo developmental stage, their mtDNA number, and their mtOCRs.
Participants/materials, setting, methods: The mtOCRs and the mtDNA copy number of each sample were measured simultaneously using scanning electrochemical microscopy combined with a mito-toxin (cyanide) and by real time PCR, respectively. Morphological changes and cytochrome c oxidase (CCO) activities of mitochondria were assessed using 8 eggs. Data were compared using Tukey–Kramer method.
Main results and the role of chance: The copy number of mtDNA kept constantly from mature oocytes to blastocyst stage (155,702-222,511 copies). The mtOCRs didn't change from mature oocytes to day 4 embryos (0.5-1.5 fmol/sec). However, the mtOCR in blastocyst (4.3) was higher ($P < 0.05$) than others.

Round- or oval-shaped mitochondria transformed into elongated tubular forms, developing well-defined transverse cristae structure toward blastocyst stage at transmission electronic microscopy (TEM) observation. The mitochondrial CCO activity was detected at blastocysts stage based on TEM analysis, not but mature oocytes and cleavage embryos.

Limitations, reason for caution: Our data showed the number of mtDNA is constant during preimplantation development. This result is similar to those obtained in murine studies, but not bovine and porcine studies. Further studies need to clarify the species barrier and the relationship between the mtOCRs and mtDNA copy number in mammalian embryos.

Wider implications of the findings: Data of the present study showed mtOCRs rise sharply at the blastulation, that mitochondria became mature and that the CCO activity was detected at blastocyst stage. Blastulation requires more ATP depending on Na/K-ATPase. Thus, it is reasonable that mitochondria become mature and increase their OCRs at the timing of blastulation. This study provided new insights on the implications of a behavior of mtDNA copy number and mitochondrial function during human embryo development.

Study funding/competing interest(s): Funding by hospital/clinic(s) – no competing interests are declared.

Trial registration number: 142.

Keywords: embryo development, mitochondria, mitochondrial DNA, mitochondrial function

P-305 Is morphologically selected sperm injection (IMSI) useful in the case of performing IMSI and ICSI of sibling oocytes at the same time?

Y. Yamada[1], A. Yoshida[1], Y. Satou[1], K. Sano[1], K. Sakakibara[1], M. Tanaka[1]
[1]*Kiba Park Clinic, Tokyo, Japan*

Study question: Is there any difference of outcome between morphologically selected sperm injection (IMSI) and ICSI in non-selected patients? Is there any difference of outcome between IMSI and ICSI in patients with teratozoospermia, high sperm DNA fragmentation index and repeated implantation failure?

Summary answer: In non-selected patients and patients with teratozoospermia, high sperm DNA fragmentation index and repeated implantation failure, the normal fertilization rates by IMSI were significantly higher than those by ICSI. However, there were no differences of the blastocyst formation rate, the implantation rate and the delivery rate between the two groups.

What is known already: Morphological selection of fertilizing spermatozoa under a high magnification has been introduced to provide a better clinical outcome than the conventional ICSI. However, it is still a controversial issue whether human sperm head vacuoles affect ICSI outcome or not. Most of the earlier studies showed no effectiveness of IMSI in non-selected patients.

Study design, size, duration: This is a retrospective analysis of outcome in 11,215 with IMSI and 8,963 oocytes with ICSI conducted for women with all age from 2008 to 2012. In this study, we compared results of the two procedures on sibling oocytes. Embryo transfers were performed with only IMSI or ICSI derived embryos.

Participants/materials, setting, methods: Firstly, the comparison of outcomes between IMSI and ICSI in non-selected patients was performed. Among them, patients with teratozoospermia (Kruger test <4%), high sperm DNA fragmentation index (DFI ≥ 30%) and 2 times more than implantation failure were selected and the comparison of outcomes between IMSI and ICSI was performed.

Main results and the role of chance: In non-selected patients, the normal fertilization rate by IMSI was significantly higher than that by ICSI (71.1% vs 68.8%, $P < 0.01$). However, there was no difference of the good-quality embryo rate on day 3, the blastocyst formation rate, the implantation rate and the delivery rate between the two groups (good-quality embryo rate on the day 3: 45.5 vs 45.2%, blastocyst formation rate: 61.7 vs 61.9%, implantation rate: 38.0 vs 41.6%, the delivery rate: 26.4 vs 29.3%). In patients with teratozoospermia, high sperm DNA fragmentation index and repeated implantation failure, the normal fertilization rates by IMSI were significantly higher than those by ICSI. However, there were no differences of the good-quality embryo rate on day 3, the blastocyst formation rate, the implantation rate and the delivery rate.

Limitations, reason for caution: One of the reasons for the almost same results between IMSI and ICSI is that we performed IMSI and ICSI of sibling oocytes at the same time by one embryologist. Another reason is that selecting good-quality sperms by embryologists is possible even if low magnification because of introducing IMSI.

Wider implications of the findings: In non-selected patients and patients with teratozoospermia, high sperm DNA fragmentation index and repeated implantation failure, the ART outcomes excluding the normal fertilization rate by IMSI were almost comparable with those by ICSI in the case of performing IMSI and ICSI of sibling oocytes at the same time.

Study funding/competing interest(s): Funding by hospital/clinic(s). This study was not funded and there are no conflicts of interest.

Trial registration number: NA.

Keywords: intracytoplasmic sperm injection, intracytoplasmic morphologically selected sperm injection, outcome

P-306 Does the position of the inner cell mass during biopsy affects implantation?

A. Rodríguez-Arnedo[1], R. Bernabeu[2], H. Blanca[1], M. C. Díaz[1], I. Ochando[1], M. C. Tió[1], F. Sellers[2], J. Llacer[2], J. Ten[1]
[1]*Instituto Bernabeu, Embryology Dept., Alicante, Spain*
[2]*Instituto Bernabeu, Reproductive Medicine, Alicante, Spain*

Study question: The most common trophoectoderm biopsy technique requires assisted hatching (AH) on day 3, but this process makes the inner cell mass (ICM) can be inside, outside or in the herniation in the moment of biopsy. Therefore, the position of the inner cell mass could affect implantation and early fetal development.

Summary answer: The position of the ICM at the time of the biopsy does not affect embryo implantation, although there is a tendency to decrease implantation if it is in the herniation position.

What is known already: Trophectoderm biopsy allows more accurate genetic diagnosis without apparent embryo damage. The AH previous to the biopsy itself is performed on day 3 because it promotes embryo hatching and is easier to remove the cells. However, the ICM may have gone along with trophoectoderm cells through the hole hatching or stay in the herniation. In our knowledge there is any publication relating the position of the ICM with the implantation of euploid embryos.

Study design, size, duration: Prospective study. We include the known clinical results of 44 euploid embryos transferred coming from 39 women that underwent CCS treatments from September to December 2014.

Participants/materials, setting, methods: At least one euploid embryo was transferred to 39 patients. AH was performed on day 3 using laser pulses (Saturn Active, Research Instruments). On day 5 of development, conventional trophoectoderm biopsy was done. The position of the ICM in the moment of biopsy was recorded. Clinical outcomes were evaluated.

Main results and the role of chance: There was no statistically significant difference in the positive pregnancy test when the ICM was inside (group I), outside (group II) or in the herniation (group III) (55.6, 70.0 and 28.6%, respectively, $p = 0.24$). The position of the ICM did not affect implantation (41.7% in group I, 62.5% in group II and 28.6% in group III, $p = 0.40$). However, we can observe a tendency to decrease the clinical results when the ICM is in the herniation position.

Limitations, reason for caution: Study currently under development to increase the number of cases and test the study question.

Wider implications of the findings: The results obtained in this preliminary study confirm that the position of the ICM in the moment of trofoectoderm biopsy does not affect implantation. However, we observe a tendency to decrease implantation when the ICM is in the herniation, probably due to the manipulation during biopsy that makes the ICM would be subjected to more movement and pressure. So, we could suggest waiting longer for biopsy if we observe the ICM located in the herniation.

P-307 Morphokinetic data obtained until day 2 are not sufficient to predict blastocyst formation and quality

G. Koksal[1], M. Cetinkaya[1], C. Pirkevi[1], Z. Atayurt[1], Y. Kumtepe Colakoglu[1], H. Yelke[1], M. Aygun[1], H. Akbas[1], S. Kahraman[1]
[1]*Istanbul Memorial Hospital, IVF Center, Istanbul, Turkey*

Study question: Are morphokinetic data obtained until the 4-cell stage enough to predict blastocyst formation and quality?

Summary answer: Kinetic expressions of day 2 embryos were retrospectively compared with their blastocyst qualities on day 5. These exact timings of usable and unusable blastocysts were found to overlap by at least 30.2%, showing that kinetics of a day 2 embryo is not sufficient to predict blastocyst formation and quality.
What is known already: Blastocyst formation and quality were predicted using early cleavage parameters (time of division to 5cells (t5), time between division from 3 to 4cells (s2) and time between division from 2 to 3cells (cc2)) (Cruz et al., 2012). Furthermore, another time-lapse system is mainly based on timings of early cleavages (until the 4-cell stage) although the full scoring algorithm of the prediction of blastocyst formation and quality is not publically available (Conaghan et al., 2013).
Study design, size, duration: This retrospective cohort study was conducted from October 2011 to November 2014. It included 3503 embryos having achieved the blastocyst stage and belonging to 706 infertile patients transferred on day 5. Incubation was performed in time-lapse incubators (EmbryoScope™) and blastocysts were scored according to Gardner's classification (114-120 h post-ICSI).
Participants/materials, setting, methods: Blastocysts were classified into two groups: usable and unusable. The first one includes 3-4-5AA blastocysts, and also those graded as 3-4-5BB, AB or BA. Embryos of inferior quality and those manifesting a developmental arrest after the 8-cell stage were noted as unusable. Differences were analyzed by Mann Whitney test.
Main results and the role of chance: The studied kinetic parameters were: time of division to 2cells (t2), time of division to 3 cells (t3), time of division to 4 cells (t4), s2 and cc2. When usable (n = 2043) and unusable blastocysts (n = 1460) were retrospectively compared all timings apart from t3 were significantly different ($p < 0.001$). The mean usable blastocyst rate was calculated as 58.32%. The data were then divided into quartiles and the distribution of usable and unusable blastocysts was compared. For each of the five variables, two consecutive quartiles for which the usable blastocyst rates were the highest, were selected for further evaluation. The maximum increase in usable blastocyst rate was found for the second and third quartiles of cc2 and determined as only 11.48%. The gain in prediction was mediocre.
Limitations, reason for caution: The cohort studied involved only infertile patients (female, male or combined) and is in this respect a heterogeneous population.
Wider implications of the findings: The data gathered from cleavage timings until day 2 and the quartile approach have been described as the basis of some morphokinetic models published so far. However, the predictive power of these information is limited. Thus, data from late embryonic development phases are required for creating more robust inter-laboratory reproducible models.

P-308 Sperm Long noncoding RNA and mRNA profiling in poor embryo development patients identify central role of long noncoding RNAs in embryo development

W. Xu[1], M. Yang[1]
[1]*West China Second University Hospital, Laboratory For Reproductive Medicine, Chengdu Sichuan, China*

Study question: Do the long noncoding RNAs (LncRNAs) in sperm play roles in embryo development and could the expression of LncRNA be used as biomarker for poor embryo development?
Summary answer: Above four hundred of lncRNAs were up-regulated and more than six hundred of lncRNAs were down-regulated in sperm samples of poor embryo development. The expression of the most lncs were conformed with real-time PCR. Pathway analysis showed an upregulation of genes related to cell metabolism and genes related to stress response were overrepresented in the GO analysis.
What is known already: Recent evidence has shown that long noncoding RNA play critical roles in spermatogenesis. Long noncoding RNA could also be used as disease biomarker.
Study design, size, duration: The sperm samples of Three pairs of poor embryo development were chosen and sperm RNAs were extract and analyzed by microarray.
Participants/materials, setting, methods: Sperm were purified from the IVF failure patients and then human LncRNA Array v2.0 (8x60 K, Array star) was used to analysis the the expression of Lncs and mRNA in the RNA of the sperm sample. Real-time quantitative PCR was used to confirm the result. Bioinformatics analysis was used to check the possible function of the most significantly differentiated expressed LncRNA and mRNA.
Main results and the role of chance: Of the hundreds of differentiated LncRNAs identified in the microarray, two LncRNA, one is Lnc-CMPK1 and another one, Lnc, LA-16C390E6.5 was confirmed in the real time PCR with larger sample size. LA-16c390E6.5 as a human specific long noncoding RNA, has the best predictor value in the ROC analysis, with Cut-off value of 3.73 has the 100% sensitivity and specificity. Therefore further functional study could reveal whether could be used to further predict the embryo development.

GO analysis indicate that stress response represent the most significant part of the lnc-RNA in embryo loss of IVF patients. The down-regulated GO analysis shows that cell metabolism represent the major process related to the embryo development.
Limitations, reason for caution: The present method was validated only in small sample. Large samples with male infertility should be used and further confirm whether the LncRNA and mRNA could be a reliable biomarker for embryo development. Functional study could reveal the detailed mechanism of how the LncRNA regulate the function of embryo development.
Wider implications of the findings: Sperm lncRNA play important role in embryo development. The aberrant expression of LncRNA could impact on the embryo development. Lnc such as LA-16c390E6.5 could be a useful biomarker for the prediction of embryo development.
Study funding/competing interest(s): Funding by national/international organization(s) – National Basic Research Program of China (2012CB944903).
Trial registration number: NA.

P-309 Parameters associated with survival and implantation following vitrification(vit) of blastocysts (Blasts)

L. Chkonia[1], N. Kutchukhidze[1], T. Zhorzholadze[1], T. Charkviani[1], N. Kurashvili-Janelidze[1], D. H. McCulloh[2]
[1]*Georgian-American Center For Reproductive Medicine ReproART, IVF, Tbilisi, Georgia*
[2]*NYU Langone Medical Center, NYU Fertility Center, NY, U.S.A.*

Study question: It remains unclear whether Blast stages, grades and osmotic responses during vitrification (Vit) or rewarming (Wrm) are predictors of blastocyst survival or implantation.
Summary answer: Parameters associated with implantation (Im) were patient age (age), day of vitrification (day) and trophectoderm grade (TE). There was no significant association between Im and blast stage (S), inner cell mass grade (ICM), collapse, re-expansion (R), oocyte source, or uterus used.
What is known already: It was reported that there are significant associations between Im and S, ICM and TE when blastocysts are transferred fresh. For vitrified warmed blastocyst in frozen embryo transfer (FET) cycles it is remains controversial which parameters are most closely related to the implantation or survival.
Study design, size, duration: We have retrospectively applied multiple logistic regression (MLR) to Blast stages, grades and collapse during blast Vit and re-expansion after Wrm for FET at our facility from 2012 – February, 2014, to determine if they are associated with Blast survival or Im. We do not perform artificial collapse.
Participants/materials, setting, methods: Blasts were Vit on days 5 or 6 in Cryotips using Irvine Scientific solutions and protocol. MLR considered whether survival or Im were associated with age, day, S, ICM, TE, collapse of the Blast in Equilibration (C1) and Vitrification Media (C2), R, oocyte source or and uterus used.
Main results and the role of chance: 169 Blasts (2BB or better) from 97 patients were Wrm'd and transferred to patients or gestational carriers. Every Wrm'd embryo survived Vit and Wrm (100% survival) only 5 Blasts where lost in 4 cryotips that exploded. Transfer of Wrm'd Blasts yielded a clinical pregnancy rate of 64.5% (63/97) with an Im rate of 40.8% (69/169). None of the parameters was associated with Blast survival since all Blasts survived. Parameters associated with Im (via the Akaike Information Criterion) were age, day and TE:

$$\ln(ORIm) = -0.0237 \times age - 0.857 \times day - 0.534 \times TE + 5.67$$

where TE was made numeric (A = 1, B = 2, C = 3). There was no significant association between Im and C1, R, C2, oocyte source, or uterus used.
Limitations, reason for caution: The lack of association between Im and C1, R, C2 suggests that osmotic events are not required for survival or Im. We hope to compare results with other groups who benefit from artificial collapse in order to understand when artificial collapse provides a benefit.
Wider implications of the findings: Associations between Im and younger age, earlier day, better TE following Vit and Wrm revealed virtually no dramatic effect of Vit since the same parameters are associated with Im following fresh transfer of Blasts. Blast Vit without artificial collapse is capable of exceptional survival and adequate Im with no dependence on osmotic collapse.

P-310 Effect of embryo freezing process on birth weight

M. C. Tió[1], J. Ten[1], A. Rodríguez-Arnedo[1], J. Guerrero[1], B. Moliner[2], F. Sellers[3], J. Llácer[2], R. Bernabeu[2]
[1]*Instituto Bernabeu, Embryology, ALICANTE, Spain*
[2]*Instituto Bernabeu, Reproductive Medicine, ALICANTE, Spain*
[3]*Instituto Bernabeu, Obstetric Medicine, ALICANTE, Spain*

Study question: Are there differences between birth weights of children born after frozen embryo transfer (FET) and those coming from fresh embryos?
Summary answer: Singletons from FET lead to higher birth weights than embryos from fresh cycles.
What is known already: Recent investigations have showed that freeze-thawed embryos are related with a high incidence of macrosomia suggesting late consequences in the metabolic status of the offspring.
Study design, size, duration: In order to ascertain those finding we performed this transversal study including 121 births at term of single pregnancies from 60 FET and 61 fresh cycles carried out during 2013.
Participants/materials, setting, methods: One hundred and twenty one patients who gave birth at term, coming from single pregnancies after 61 IVF cycles and 60 FET cycles. Univariate analysis was performed to compare FET group versus fresh group including Fisher's exact test for quantitative variables and Student's *t*-test for categorical variables.
Main results and the role of chance: Birth weight of children coming from FET were higher than those coming from fresh embryos (p.0.034) being 3331 ± 416 g and 3125 ± 571 g respectively. Both groups had same age, parity, gestational age at birth and had no differences between own and donated oocyte proportion.
Limitations, reason for caution: On account of the small number of cases in this study it would be necessary perform a more extensive study.
Wider implications of the findings: The long term consequences of freezing should not be discarded. On the other hand women with known risk of low birth weight may benefit from postponing the transfer making a subsequent FET.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Instituto Bernabeu.

ENDOMETRIOSIS/ENDOMETRIUM

P-311 Predictability of frequency of uterine contractions in the early luteal phase after controlled ovarian stimulation in non-progesterone supplemented oocyte donors

B. M. Klein[1], L. Helmgaard[2], J. C. Arce[2]
[1]*Ferring Pharmaceuticals, Global Clinical R&D (Biometrics), Copenhagen, Denmark*
[2]*Ferring Pharmaceuticals, Global Clinical R&D (Reproductive Health), Copenhagen, Denmark*

Study question: To identify demographics, treatment cycle characteristics and endocrine profile predictors of the frequency of uterine contractions in the early luteal phase in non-progesterone supplemented subjects undergoing controlled ovarian stimulation.
Summary answer: Demographic variables or treatment cycle characteristics do not predict the frequency of uterine contractions in the luteal phase of controlled ovarian stimulation cycles. Endogenous progesterone levels are correlated with the frequency of uterine contractions in the luteal phase of controlled ovarian stimulation cycles, when following the long GnRH agonist protocol and no exogenous supplementation of progesterone is provided.
What is known already: Improving implantation of the transferred embryos/blastocysts is one of the major challenges in ART. It has been hypothesised that elevated uterine contractility at the time of transfer in women undergoing IVF/ICSI procedures could have a detrimental effect on implantation rates, and several compounds with anticipated impact on uterine contractility are currently in clinical development. However, the pathophysiology of the elevated uterine contractility during the luteal phase of controlled ovarian stimulation is not well understood.
Study design, size, duration: Retrospective investigation of baseline data from a randomised, double-blind, placebo-controlled trial in 84 oocyte donors who underwent controlled ovarian stimulation in the long GnRH agonist or antagonist protocol, triggering of final follicular maturation with hCG, and received no supplementation with progesterone after oocyte retrieval (OR).
Participants/materials, setting, methods: Demographic variables, type of protocol and total gonadotropin dose were recorded. Serum values for estradiol, LH and progesterone were obtained 2 days after OR (OR + 2). Transvaginal ultrasound recordings (Voluson i, GE Healthcare) of a continuous cine-loop image of at least 5 min were done on day OR + 2 in a standardised format. The frequency of uterine contractions was determined by a central independent assessor blinded to treatment allocation, using computer-assisted time series motion analysis software.
Main results and the role of chance: The median frequency of uterine contractions on day OR + 2 was 2.4/min (interquartile range: 2.1; 3.1). Correlations between the frequency of uterine contractions and age, body mass index, body weight and total gonadotropin dose were low and none were significant. The median frequency of uterine contractions was not significantly different between the two protocols. In subjects following the long GnRH agonist protocol, a significant negative correlation was observed between progesterone levels and the frequency of uterine contractions (r = -0.43, p = 0.002), but not in subjects following the GnRH antagonist protocol.
Limitations, reason for caution: Multicentre trial with multiple ultrasonographers.
Wider implications of the findings: Further research is needed to evaluate the pathophysiology of the elevated uterine contractility during the luteal phase of controlled ovarian stimulation cycles.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Ferring Pharmaceuticals.
Trial registration number: NCT01043120.

P-312 Predictability of frequency of uterine contractions in the early luteal phase after controlled ovarian stimulation in progesterone-supplemented oocyte donors

L. Helmgaard[1], B. M. Klein[2], J. C. Arce[1]
[1]*Ferring Pharmaceuticals, Global Clinical R&D (Reproductive Health), Copenhagen, Denmark*
[2]*Ferring Pharmaceuticals, Global Clinical R&D (Biometrics), Copenhagen, Denmark*

Study question: To identify demographics, treatment cycle characteristics and endocrine profile predictors of the frequency of uterine contractions in the early luteal phase in subjects undergoing controlled ovarian stimulation and supplemented with progesterone.
Summary answer: Demographic variables or treatment cycle characteristics do not predict the frequency of uterine contractions in the luteal phase of controlled ovarian stimulation cycles. The endocrine profile associated with the type of protocol may influence the frequency of uterine contractions in the luteal phase of controlled ovarian stimulation cycles supplemented with vaginal progesterone.
What is known already: Improving implantation of the transferred embryos/blastocysts is one of the major challenges in ART. It has been hypothesised that elevated uterine contractility at the time of transfer in women undergoing IVF/ICSI procedures could have a detrimental effect on implantation rates, and several

compounds with anticipated impact on uterine contractility are currently in clinical development. However, the pathophysiology of the elevated uterine contractility during the luteal phase of controlled ovarian stimulation is not well understood.
Study design, size, duration: Retrospective investigation of baseline data from a randomised, double-blind, placebo-controlled trial in 105 oocyte donors who underwent controlled ovarian stimulation in the long GnRH agonist or antagonist protocol, triggering of final follicular maturation with hCG, and were supplemented with vaginal progesterone 600 mg/day from day 1 to day 5 after oocyte retrieval (OR) (OR + 1 to OR + 5).
Participants/materials, setting, methods: Demographic variables, type of protocol and total gonadotropin dose were recorded. Serum values for estradiol, LH and progesterone were obtained 2 and 5 days after OR (OR + 2 and OR + 5, respectively). Transvaginal ultrasound recordings (Voluson i, GE Healthcare) of a continuous cine-loop image of at least 5 min were done on days OR + 1, OR + 2 and OR + 5 in a standardised format. The frequency of uterine contractions was determined by a central independent assessor blinded to treatment allocation, using computer-assisted time series motion analysis software.
Main results and the role of chance: A significant decrease in the median frequency of uterine contractions was observed in the early luteal phase: from 3.0/min on OR + 1 to 2.7/min on OR + 2 and to 2.0/min on OR + 5 ($p < 0.001$). Correlations between the frequency of uterine contractions and age, body mass index, body weight and total gonadotropin dose were low and none were significant. The median frequency of uterine contractions was not significantly different between the two protocols. However, in subjects following the GnRH antagonist protocol, a significant negative correlation was observed between LH levels and the frequency of uterine contractions on OR + 2 ($r = -0.46$, $p = 0.009$), and a significant positive correlation between estradiol levels and the frequency of uterine contractions on OR + 5 ($r = 0.36$, $p = 0.049$). No correlations were observed for the long GnRH agonist protocol.
Limitations, reason for caution: Multicentre trial with multiple ultrasonographers.
Wider implications of the findings: Further research is needed to evaluate the pathophysiology of the elevated uterine contractility during the luteal phase of controlled ovarian stimulation cycles.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Ferring Pharmaceuticals.
Trial registration number: NCT00587327.

P-313 Endometrial growth inhibition by natural compounds evaluated as new therapeutic agents for endometriosis

L. Ferella[1], J. I. Baston[1], M. Bilotas[2], J. J. Singla[3], A. M. Gonzalez[4], C. Olivares[1], G. F. Meresman[1]
[1]*Instituto De Bilogia Y Medicina Experimental, Laboratorio De Fisiopatologia Endometrial, Buenos Aires, Argentina*
[2]*Instituto De Bilogia Y Medicina Experimental, Laboratorio De Inmunología En Reproducción, Buenos Aires, Argentina*
[3]*Hospital De Clinicas, Servicio De Ginecología, Buenos Aires, Argentina*
[4]*Hospital Naval, Servicio De Ginecología, Buenos Aires, Argentina*

Study question: The objective of our study was to evaluate the effect on the development of experimental endometriosis both *in-vitro* and *in-vivo* of Wogonin (WG), an active constituent of Chinese Herbal Medicine, and two of the main antioxidant compounds found in rosemary leaves: Carnosic Acid (CA) and Rosmarinic Acid (RA).
Summary answer: All natural compounds evaluated exerted an inhibitory effect on endometrial cultured cells growth or endometriosis development. CA, RA and WG significantly inhibited cell proliferation of the human endometrial stromal cell line, T-HESC, and of primary cell cultures. In a murine model, these compounds diminished significantly the size of endometriotic-like lesions.
What is known already: Endometriosis is a chronic disease, with high levels of recurrence after standard medical therapy. The past few years have seen a renewed interest in the use of natural compounds due to their advantages: long term administration with minimal side effects. WG is known to inhibit proliferation and induce apoptosis in many kinds of cancerous cells. Similarly, antioxidant and antitumor activities have been reported after treatment with CA and RA.
Study design, size, duration: Primary cultures of stromal cells from endometrial biopsies of patients with endometriosis and controls and the T-HESC cell line were incubated with WG, CA or RA for 24-h. Endometriosis was surgically induced in BALB/c mice. Animals received WG, CA or RA daily from post-surgical day 14 until day 28.
Participants/materials, setting, methods: Cell proliferation was evaluated by MTS assay in primary and T-HESC cell cultures. Mice were randomly assigned to different treatment groups: RA-1mg/kg ($n = 11$); RA-3mg/kg ($n = 10$); CA-2mg/kg ($n = 11$); CA-20mg/kg ($n = 10$); WG-20mg/kg ($n = 12$) and Control ($n = 8$). Animals received CA or RA daily by intraperitoneal injection or WG daily by gastric gavage.
Main results and the role of chance: WG 40, 80 and 160 μM; CA 10, 12.5 and 25 μg/ml and RA 25, 50 and 100 μg/ml significantly inhibited cell proliferation in T-HESC cell line ($p < 0.01$, $p < 0.05$ and $p < 0.001$ vs. basal, respectively). All these compounds also inhibited cell proliferation of human endometrial stromal primary cultures ($p < 0.05$, $p < 0.01$ and $p < 0.05$ vs. basal for WG, CA and RA respectively). Wogonin induced an increase in the G2/M phase of the cell cycle in T-HESC, indicating an arrest at this stage. Furthermore, WG, CA and RA reduced the mean volume of established lesions in surgically induced endometriosis in mice ($p < 0.05$ vs. Control). The number of established lesions did not differ from those of the Control group. No evidence of toxicity was observed in mice.
Limitations, reason for caution: More studies should be addressed to fully understand the mechanistic behind the results obtained and to evaluate the safety of this type of compounds for endometriosis patients.
Wider implications of the findings: Nowadays, natural compounds are being considered for the treatment of diverse diseases. Amongst these is cancer which shares important similarities with endometriosis pathogenesis. All natural compounds evaluated in this study, WG, RA and CA, exerted an inhibitory effect on *in vitro* stromal endometrial growth and *in vivo* endometriosis-like lesions development. Our studies support the further investigation of novel, potentially safe and well-tolerated botanical products as future endometriosis treatments.

P-314 Imbalance Progesterone Receptor-A/-B ratio via +331G/A polymorphism enhance MMP-2, -9 expression in endometriosis

S. Mousazadeh[1], P. Afsharian[1], M. Shahhoseini[1], R. E. Z. A. Aflatoonian[2]
[1]*Royan Institute, Department of Genetics At Reproductive Biomedicine Research Center ACECR, Tehran, Iran*
[2]*Royan Institute, Department of Endocrinology and Female Infertility At Reproductive Biomedicine Research Center Royan Institute For Reproductive Biomedicine ACECR, Tehran, Iran*

Study question: Is there any significant association between the level of *MMP-2* and *MMP-9* gene expressions and altered ratio of *Progesterone Receptor-A/-B* (*PR-A/PR-B*) via +331G/A polymorphism in endometriosis?
Summary answer: Imbalance ratio of *PR-A/PR-B* via +331G/A polymorphism in endometriotic tissue may be able to consequence Matrix MetalloProteinases 2 and 9 (*MMP-2, MMP-9)* overexpression, which can be important in etiology and pathogenesis of endometriosis.
What is known already: MMPs degrade extracellular matrix components to provide normal remodeling and contribute to pathological tissue destruction in endometriosis. It is accepted that MMPs are resistant to suppression by progesterone in endometriosis. The capacity of progesterone affect to gene expression is dependent on PR-A/PR-B. Imbalanced ratio of PR isoforms may cause progesterone resistance in endometriosis. Many studies have investigated the role of +331G/A in the etiology of various cancers, which can elevate the expression of PR-B isoform.
Study design, size, duration: Blood samples were recruited from 98 women undergoing laparoscopy for endometriosis and 102 healthy fertile women at Royan Institute, Iran in 2013-2014. Ectopic and eutopic tissue samples were prepared from twenty endometriosis (stages III and IV) and endometrial tissue from 20 non-endometriosis women at Royan Institute.
Participants/materials, setting, methods: After DNA extraction from blood samples, allele and genotype frequencies were determined by PCR-RFLP. Then, RNA was extracted from tissue samples to analysis of *PR-A, PR-B*, *MMP-2* and *MMP-9* mRNA expression by Real-time PCR.

Main results and the role of chance: We were able to demonstrate significantly low expression level of *PR-B* isoform in ectopic tissues ($p = 0.002$). Although, *PR-A* expression was higher in the same ectopic samples compared to control group ($p > 0.05$). This method permitted us to demonstrate significant overexpression of *MMP-2* and *MMP-9* in ectopic samples compared to control endometrial tissues, as well ($p > 0.05$ and $p = 0.014$, respectively). Our data showed the frequency distributions 98.04%, 1.96% for GG, G/A genotypes in +331G/A polymorphism and 97.96%, 2.04% in patients and control groups respectively ($p = 0.968$). Although our data didn't show any significant association with +331G/A in our groups, however, we were able to demonstrate higher expression level of *PR-B* in patients with G/A compared to patients with GG genotypes.
Limitations, reason for caution: The frequency of A allele in +331G/A polymorphism is very low between different population. Therefore, we need higher sample size to study the association of this polymorphism with levels of PR-B isoform expression in Iranian women with endometriosis.
Wider implications of the findings: Many studies have been shown that the expression level of *PR-B* reduced during endometriosis, which can affect the function of progesterone. Patients with G/A had high expression level of *PR-B* compared to GG genotypes. Therefore, +331G/A have been found to lead increased transcriptional activity of *PR-B* by favoring G/A or AA. Our findings support this observation; *PR-A/PR-B* ratio was altered in ectopic tissues, which may cause *MMP-2,-9* overexpression that can be important in pathogenesis of disease.
Study funding/competing interest(s): Funding by hospital/clinic(s). This work was supported by a grant from the Royan institute, Reproductive biomedicine group, Tehran, Iran [91000358].
Trial registration number: There is no trial work.
Keywords: endometriosis, MMPs, PR-A/PR-B ratio, +331G/A polymorphism

P-315 Endometrioma and Artificial Reproductive Techniques (ART) outcomes: Results from Meta-Analysis and Systematic review

Y. Cheong[1], M. Hamdan[1], G. D. Dunselman[2], T. C. Li[3]
[1]*Complete Fertility Centre Princess Anne Hospital, Human Development and Health, Southampton, United Kingdom*
[2]*Research Institute GROW, Obstetrics and Gynaecology, Maastricht, The Netherlands*
[3]*The Chinese University of Hong Kong, Obstetrics and Gynaecology, Hong Kong, Hong Kong*

Study question: Does endometrioma influence ART outcomes and is surgical treatment to endometrioma prior to ART beneficial?
Summary answer: Women with endometrioma undergoing ART have similar reproductive outcomes compared to those without the disease, although the cycle cancellation rate is significantly higher. Given that the reduced ovarian reserve may be attributed to the presence of endometrioma per se, with additive detrimental impact from surgical intervention, individualisation of care in women with endometrioma prior to ART may help optimise their ART results.
What is known already: Endometriosis is a disease known to be detrimental to fertility. Women with endometriosis and the presence of endometrioma may require ART to achieve a pregnancy. Surgical treatment of endometriosis and endometrioma prior to ART is widely practiced even though very little evidence exists to provide robust guidance to clinicians. The specific impact of endometrioma alone and the impact of surgical intervention of endometriosis on the reproductive outcome of women undergoing ART are areas that require further clarification.
Study design, size, duration: We performed systematic review and meta-analysis. We searched studies published between 1980 and 2014 on endometrioma and ART outcomes. We performed electronic and manual search. Published cohort or case controlled studies (retrospective or prospective), and randomized controlled trials were eligible for inclusion.
Participants/materials, setting, methods: We included studies that had women who underwent ART with the presence of endometrioma in one of the comparison groups and at least a control group. Main outcome measures are Live birth rate (LBR), Clinical pregnancy rate (CPR), mean number of oocyte retrieved (MNOR) and adverse effects of treatment.
Main results and the role of chance: 33 studies were included for the meta-analysis. The majority of the included studies were retrospective studies (30/33) and 3 were RCTs. Compared to women with no endometrioma undergoing ART, women with endometrioma had a similar LBR (OR 0.98 95% CI [0.71, 1.36], 5 studies, 928 women, $I^2 = 0\%$), CPR (OR 1.17 95% CI [0.87, 1.58], 5 studies, 928 women, $I^2 = 0\%$), a lower MNOR (SMD -0.23 95% CI [-0.37, -0.10] 5 studies, 941 cycles, $I^2 = 37\%$) and a higher cycle cancellation rate compared to those without the disease (OR 2.83 95% CI [1.32, 6.06], 3 studies, 491 women, $I^2 = 0\%$). Compared to women with no surgical treatment, women who had their endometrioma surgically treated before ART had similar LBR, CPR and MNOR.
Limitations, reason for caution: Our study may be confounded by the high clinical heterogeneity of the included studies. The majority, with the exception of 3 studies, were all non-randomised controlled trials. We have however assessed and included only studies with either high or moderate quality according to Ottawa Scoring Systems.
Wider implications of the findings: Given that the reduced ovarian reserve may be attributed to the presence of endometrioma per se, with additive detrimental impact from surgical intervention, individualisation of care in women with endometrioma prior to ART may help optimise their ART results.
Study funding/competing interest(s): Funding by hospital/clinic(s) – funding by national/international organization(s) – Ministry of Education, Malaysia; Complete Fertility Centre Southampton.

[3]*Hopital Des Bluets, Service De PMA, Paris, France*

Study question: Is a preconceptional endometrial immune evaluation able to identify the uterine immune mechanisms generating repeated embryo implantation failures? Can we, based on the documented immune endometrial profiles, correct the deleterious mechanism to promote subsequent effective embryo implantation ?
Summary answer: From a cohort fertile control, we defined an immune endometrial 'equilibrated profile' and documented deregulations in patients with repeated embryo implantation failures (RIF) after IVF/ICSI or oocyte donation (IVF-OD). We personalized accordingly to the identified mechanism their treatments before the following IVF/ICSI or IVF-OD and assessed the clinical pregnancy rate at the subsequent embryo transfer.
What is known already: The embryo implantation remains the main limiting factor during in vitro fertilization (20% of success). Uterine remodeling events are required before implantation for a successful pregnancy. During the implantation window, uterine NK cells (uNK) and Th1/Th2 cytokines balance are crucial for implantation. This unique immune reaction is essential to promote embryo adhesion and regulate the invasion phase. Disequilibrium of such a vital reaction may impede implantation.
Study design, size, duration: The study design was a prospective cohort study including 411 RIF patients (311 after IVF/ICSI and 100 after IVF-OD). Patient were included between 2012 and 2014 with a prospective follow-up during 1 year.
Participants/materials, setting, methods: An endometrial biopsy was performed classically with a cormier pipelle in the luteal phase. After confirmation by a datation of the luteal phase, we quantified uNK by immunohistochemistry using anti-CD56 $^{+}$IgG and mRNA expression of IL-15 (uNK cells activation/maturation state), IL-18 (Th-1/Th-2 cytokines balance) and TWEAK/Fn-14 (immuno-regulation) by Real-Time PCR. Based on these biomarkers, we identify if a deregulation (low or over-immune activation) was present and personalized further treatments either to promote or control the immune activation before the next subsequent embryo transfer.
Main results and the role of chance: Endometrial immune profiles appeared to be deregulated in 85% of the RIF IVF/ICSI patients and in 60% of the RIF IVF-OD patients. In RIF-IVF/ICSI patients, an over activation was diagnosed in 60% whereas a low activation was diagnosed in 25%. In RIF IVF-OD patients, an over activation was diagnosed in 51% whereas a low activation was

diagnosed in 9%. Accordingly, we advised personalized cares and assessed their effects by the ongoing pregnancy rate (PR) and live birth rate (LBR) occurring after the first following embryo transfer. We report a LBR of 40% in deregulated-treated IVF/ICSI patients while LBR stagnate at 15% if no deregulation was diagnosed. The PR in RIF-IVF/OD patients was 50% with no difference between deregulated or no deregulated patients (ongoing results).
Limitations, reason for caution: RIF and early miscarriages have been suggested to be inducible by stress, so we cannot exclude that the 'new scientific evaluation' proposed had a positive influence for some of these patients. Scientifically, only a randomized controlled trial may prove that a preventive uterine immune profiling may increase subsequent LBR.
Wider implications of the findings: Approximately 80% of the Human embryo implantations fail to implant. Multiple factors may contribute to this failure, but the majority of the implantation failure cases are attributed to a poor uterine receptivity conjugated with a poor oocyte quality. Before conception, endometrial immune profiling appears as a real and affordable solution able to explain a RIF history but also to correct the deleterious mechanisms and hence may increase significantly the chance of a subsequent live birth.

P-317 Transvaginal Sonographic diagnosis and grading of endometriosis: A three year study

M. Niknejadi[1], M. Javam[2], F. Niknejad[3], M. Chehrazi[4]
[1]*Royan Institute For Reproductive Biomedicine ACECR, Reproductive Imaging At Reproductive Biomedicine Research Center, Tehran, Iran*
[2]*Royan Institute For Reproductive Biomedicine ACECR, Reproductive Imaging At Reproductive Biomedicine Research Center, Tehran, Iran*
[3]*Royan Institute Reproductive Biomedicine ACECR, Reproductive Imaging At Reproductive Biomedicine Research Center, Tehran, Iran*
[4]*Royan Institute For Reproductive Biomedicine ACECR, Reproductive Epidemiology, Tehran, Iran*

Study question: Is transvaginal sonography (TVS) accurate for diagnosis and grading of endometriosis in comparison with laparoscopy?
Summary answer: Our study demonstrated that TVS has a reliable accuracy and sensitivity in diagnosis and grading of endometriosis.
What is known already: Sonographic depiction of Endometrioma.
Study design, size, duration: Prospective study on 101 infertile women during 3 years.
Participants/materials, setting, methods: This was a prospective study at Royan Institute, Iran, from April 2010 till March 2013. All infertile women who showed at least one of the endometriosis symptoms or detected signs via clinical examination (TV) were recruited in the study. Patients underwent preoperative TVS by a single radiologist and all sonograms and videos were captured in a DVD for each sample. Patient's documents, TVS findings and laparoscopy results (which were video captured) were assessed to collect data. Grading of endometriosis based on TVS findings was as follow: mild (superficial: echogenic calcified points on serosal surface of ovaries), moderate (endometrioma: low level hemogenic cystic lesion) and sever (DIE: by detection of fixation and deviation of ovaries and distance between them). Agreement between sonography findings & laparoscopy results, sensitivity, specificity, positive & negative predictive values, and accuracy of TVS in diagnosis of endometriosis, regarding laparoscopy as gold standard, were calculated by SPSS16 software using McNemar's & Kappa tests, logistic regression model and other statistic tests.
Main results and the role of chance: Totally, 101women were recruited in the investigation. Patients aged 30.78 ± 4.79 years in average and the duration of infertility was 4.2 ± 2.91 years among them. Endometriosis was detected in 78 cases by laparoscopy. Overall accuracy, sensitivity, specificity, PPV and NPV of the TVS in diagnosis of endometriosis were calculated 72.3%, 67.2%, 79.1%, 81.3 and 64.2% respectively. Sensitivity and PPV of TVS in grading of endometriosis were as follow: 43.2% and 57.6% in mild, 77.4% and 82.8% in moderate, and 85.8% and 94.7% in severe endometriosis.
Limitations, reason for caution: none.
Wider implications of the findings: Our study demonstrated that TVS has a reliable accuracy and sensitivity in diagnosis and grading of endometriosis. Furthermore, "ovarian position" and "fixation of ovaries", particularly when they are detected both together, strongly suggest severe endometriosis (odds ratio of 14.78 and 46.89 respectively). Therefore, they can be used as important criteria for radiologists & gynecologists.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Royan Institute for reproductive biomedicine research center.
Trial registration number: NA.
Keywords: transvaginal sonography (TVS), laparoscopy, endometriosis, infertility

P-318 Extinction of S100A protein affects apoptosis of endometrial epithelial cells, a mechanism probably involved in patients with multiple implantation failures

D. Haouzi[1], L. Bissonnette[2], Y. Antoine[2], S. Bringer-Deutch[3], F. Entezami[4], S. Hamamah[5]
[1]*Hôpital Arnaud De Villeneuve, Inserm U1203, Montpellier Cédex 5, France*
[2]*IRMB, INSERM U1203, Montpellier Cédex 5, France*
[3]*Hôpital Arnaud De Villeneuve, Biologie De La Reproduction, Montpellier Cédex 5, France*
[4]*Laboratoire Eylau Unilabs, Clinique La Muette, Paris, France*
[5]*Hôpital Arnaud De Villeneuve, INSERM U1203, Montpellier Cédex 5, France*

Study question: We investigated function(s) of one endometrial receptivity biomarker, a S100A family member expressed in epithelial cells, using shRNAs. We analyzed the S100A protein extinction impact in relation to apoptosis. We also assessed mRNA expression level of S100A during the implantation window of patients with multiple implantation failures (MIF) after IVF.
Summary answer: Serum withdrawal in S100A protein knockdown-primary endometrial epithelial cells induced apoptosis compared with scrambled shRNA cells. This candidate was down-regulated during the implantation window in patients with MIF.
What is known already: Many biomarkers of human endometrial receptivity have been previously reported. However, few studies i) investigated the relevance of their biomarkers in patients with MIF, and ii) performed functional analyses to identify their role(s) and function(s) during the implantation window of fertile patients.
Study design, size, duration: The epithelial endometrial cells were isolated. An approach by shRNAs was used for stable gene silencing of the candidate. Serum withdrawal-induced apoptosis was investigated in shRNA S100A epithelial cells compared with scrambled shRNA cells. Endometrial biopsies from 27 patients with MIF were used for mRNA S100A expression quantification.
Participants/materials, setting, methods: ShRNA S100A and scrambled shRNA epithelial cells were culture in Dulbecco's modified Eagle medium supplemented with 1 or 10% heat-inactivated fetal bovine serum. After three days, apoptotic cells were detected by both immunofluorescence staining of activated caspase 3 and DAPI nuclear staining. S100A was quantified by qRT-PCR in endometrial biopsies.
Main results and the role of chance: In epithelial cells, serum withdrawal induced apoptosis only in shRNA S100A epithelial cells compared with scrambled shRNA cells. 50% of cells were positive for activated caspase 3 and fragmented nuclei according to the DAPI staining in shRNA S100A epithelial cells compared with scrambled shRNA cells. In addition, patients with MIF were characterized by a down-regulation of S100A mRNA expression level compared with fertile patients (p-value = 0.0012). As apoptosis plays a central role in the endometrium during the period of establishment of the implantation window, a deregulation of this signaling pathway due to the down-expression of the S100A mRNA can explain implantation failures in MIF.
Limitations, reason for caution: The mechanism by which the under-expression of the S100A mRNA affects apoptosis, and consequently implantation, must be investigated.
Wider implications of the findings: This study should open new perspectives in the understanding of mechanisms regulating human endometrial receptivity of infertile patients.
Study funding/competing interest(s): Funding by commercial/corporate company(ies). This work was partially supported by a grant from the Ferring Pharmaceutical Company.
Trial registration number: NA.
Keywords: endometrial receptivity, biomarker, MIF, primary endometrial cells, shRNAs

P-319 Hypoxia involves in endometriosis by regulating microRNAs expression

D. Yongdong[1], Ni. Huijuan[2], X. Tong[1], L. Shi[1], Y. Jiang[1], L. I. U. Liu[1], F. E. N. G. Zhou[1], C. H. A. O. Li[1], X. Jin[1], X. Lin[1], H. Zhu[1], S. Zhang[1]
[1]*Sir Run Run Shaw Hospital College of Medicine Zhejiang University, Reproductive Center, Hangzhou, China*
[2]*China Medical University Shaoxing Hospital, Department of Gynaecology and Obstetrics, Shaoxing, China*

Study question: Does hypoxia regulated microRNAs (miRs) involve in endometriosis development?
Summary answer: Hypoxia treatment in endometrial stromal cells dramatically changed several miRs expression, including miR-29c-5p, miR-200b, miR-199a and miR-126.
What is known already: Dysregulated miRs expressions in endometriosis tissues were well documented. And hypoxia was recently reported involved in the pathogenesis of endometriosis. But whether hypoxia regulated miRs participate endometriosis development is widely unknown.
Study design, size, duration: Endometrial stromal cells were isolated from normal endometrial tissues. Desferroxamine (DFO), CoCl2, 1% O2 were used to mimic hypoxia cell culture condition.
Participants/materials, setting, methods: Hypoxia induce factor 1a (HIF-1α) and VEGF expression were tested by immunofluorescence (IF) and western blot (WB) respectively to verify hypoxia effect. Quantitative real-time PCR (qRT-PCR) was applied to determine the expression changes of miRs in endometrial stromal cells with or without hypoxia treatment.
Main results and the role of chance: HIF-1α protein was accumulated in nucleus and VEGF protein expression was increased in endometrial stromal cells treated by hypoxia (1% O2, DFO and CoCl2) for 4, 8, 12 and 24 h, compared to the untreated cells. To determine whether miRs expression may be changed by hypoxia in endometriosis, miRs reported to be aberrantly expressed in endometriosis tissues were determined by qRT-PCR. Our results demonstrated that miR-29c-5p, miR-200b, miR-199a and miR-126 were all significantly upregulated in hypoxia-treated endometriosis stromal cells compared to those untreated cells.
Limitations, reason for caution: Only 4 miRs were tested in this study. MiRs expression profile should be determined by miR-array or miR-sequencing in endometrial stromal cells treated with or without hypoxia. Moreover, hypoxia regulated miRs' function should be further validated in vitro and in vivo.
Wider implications of the findings: The present findings demonstrated that hypoxia regulated several miRs expression in endometrial stromal cells, suggesting that those miRs may be involved in the pathogenesis of endometriosis.

P-320 Tracking the implantation window: synchronizing endometrial preparedness for implantation with stage of blastocyst to be transferred in antagonist IVF cycles involving single blastocyst transfers

B. N. Chimote[1], N. M. Chimote[2]
[1]*Vaunshdhara Clinic & Assisted Conception Centre, Embryology Biochemistry, Nagpur, India*
[2]*Vaunshdhara Clinic & Assisted Conception Centre, Embryology Endocrinology, Nagpur, India*

Study question: Is it absolutely irrelevant to take into account the day of menstrual period in IVF cycles? We sought to track the relevance of 'implantation window' by contemplating a correlation between stage of blastocyst transferred and endometrial preparedness for implantation with respect to day of menstrual period in antagonist IVF cycles.
Summary answer: Synchrony between stage of blastocyst transferred and endometrial preparedness for implantation with respect to day of menstrual cycle has a definitive influence on clinical pregnancy rates (CPR) in IVF cycles. Asynchrony and out of phase blastocyst transfer may lead to missing out the implantation window and unnecessarily hamper CPR.
What is known already: Debating the existence of the mythical implantation window (~day 18-22 of natural cycle) or considering day of menstrual period may not hold much significance in IVF cycles involving day 3 embryo transfers. However, with an excellent blastocyst gradation system available and a rising trend towards day 5/6 blastocyst transfers, it seems pertinent to investigate whether stage of blastocyst transferred has any influence on clinical pregnancy rates if this transfer is synchronized with day of menstrual period.
Study design, size, duration: Retrospective analysis of 443 cycles (February 2012 to September 2014) in women undergoing antagonist treatment protocol followed by oocyte retrieval approximately on day 14 ± 2 of their menstrual period. All cycles involved day 5/6 single blastocyst transfer (sBT) of top (AA) or good (AB/BA) quality blastocysts (BC) of various stages.
Participants/materials, setting, methods: Slightly modified Gardiner's system for Blastocyst stage grading was followed. Stage 1: early BC; 2: Full Blastocyst; 3: Expanded BC; 4: BC with point of hatching; 5: Hatching BC; 6: Hatched BC. Inner cell mass, Trophectoderm were graded A, B, C as per Gardiner's system. Clinical Pregnancy rate was main outcome measure.
Main results and the role of chance: Overall CPR = 26.64% (118/443). CPR was heavily influenced by transfer of various stages (1 to 6) of BCs on different days of menstrual period (days 18-23 ± 1, covering the implantation window) as follows:

Day 17: 1 = 0%; 2 = 20%; 3 = 22.22%; 4 = 6.66%; 5 = 0%, 6 = 0%
Day 18: 1 = 0%; 2 = 0%; 3 = 37.14%; 4 = 27.03%; 5 = 16.66%; 6 = 0%
Day 19: No stage 1 BT; 2 = 0%; 3 = 30.77%; 4 = 31.03%; 5 = 22.22%; 6 = 0%
Day 20: 1 = 0%; 2 = 0%; 3 = 30.44%; 4 = 30%; 5 = 35.71%; 6 = 42.86%
Day 21: 1 = 0%; 2 = 0%; 3 = 16.67%; 4 = 36.67%; 5 = 44.44%; 6 = 40%
Day 22: No stage 1 BT; 2 = 0%; 3 = 18.75%; 4 = 50%; 5 = 50%; 6 = 50%
Day 23: No stage 1 BT; 2 = 0%; 3 = 21.05%; 4 = 25%; 5 = 66.67%; 6 = 66.67%
Day 24: No stage 1, 2 BTs; 3 = 0%; 4 = 0%; No stage 5 BT; 6 = 100%

Evidently, as the day of menstrual period advances, higher stage blastocyst Transfer gives better pregnancy rates.
Limitations, reason for caution: This study took into account transfer of only top and good quality blastocysts in an effort to minimize the factor of embryo quality on CPR. Also, it would be better to segregate and compare cycles where all women have undergone oocyte retrieval on similar days of menstrual period.
Wider implications of the findings: This study provides a non-invasive insight into the so called 'mythical' implantation window and endometrial preparedness for implantation. Accordingly, if embryo development leads or lags w.r.t endometrial receptivity, blastocysts may be frozen and transferred in the next conducive coordinated natural cycle. The results may help establish a new paradigm for synchronized development of embryo and endometrium for better pregnancy rates in IVF cycles.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Self funded: by our own IVF centre – Vaunshdhara Clinic and Assisted Conception Centre, Nagpur, India.
Trial registration number: NA.
Keywords: blastocyst, implantation window, antagonist cycles, clinical pregnancy, endometrial receptivity

P-321 Use of an endometriosis model in rats to reveal new non invasive biomarkers

C. Munaut[1], J. Leenders[2], S. Labied[3], M. Martin[4], B. Govaerts[4], P. De Tullio[2], M. Nisolle[3]
[1]*University of Liège, Laboratory of Tumor and Developmental Biology GIGA-R, Sart Tilman (Liège), Belgium*
[2]*University of Liège, Department of Medicinal Chemistry Center For Interdisciplinary Research On Medicines (CIRM), Sart Tilman (Liège), Belgium*
[3]*University of Liège, Department of Obstetrics and Gynecology, Sart Tilman (Liège), Belgium*
[4]*Université Catholique of Louvain, Institute of Statistics (ISBA), Louvain, Belgium*

Study question: Biomarker research for early diagnostic of endometriosis is emerging but so far a non-invasive test is not yet available, therefore we decided to use an experimental endometriosis model in rats combined to metabolomics and miRNA analysis in body fluids to reveal new biomarkers.
Summary answer: Metabolomics profiles and miRNAs expression are differentially expressed in rats with endometriosis as compared to normal rats.
What is known already: Endometriosis is believed to be multifactorial and emerging data provide evidence that dysregulation of miRNA expression could be involved in the development of the pathology.

Study design, size, duration: Endometriosis was surgically-induced in twenty female Sprague–Dawley rats as described by Sharpe-Timms (*N Y Acad Sci,* 2002, *955*(1), 318-327).
Participants/materials, setting, methods: Endometriosis was surgically induced in 20 female Sprague–Dawley (Endo) rats by implantation of six autologuous pieces (5 mm^2 byopsy punches) from the distal two thirds of the left uterine horn to the arterial blood supply of the small intestine. Twenty female Sprague–Dawley rats underwent a control surgery with removal of the uterine horn and sutures, without tissues, were placed around arteries in the arterial cascade of the intestinal mesentery (Sham). During the next four weeks blood samples were collected weekly and submitted to nuclear magnetic resonance analysis (NMR). After post-treatment of NMR data, orthogonal partial least squares discriminant analysis (OPLS-DA) were performed. After 4 weeks all rats were sacrificed. Circulating miRNAs were firstly analyzed after four weeks.
Main results and the role of chance: In the course of the induction and development of the pathology, metabolics analysis displayed a significant discrimination between rats with endometriosis and Sham operated as early as after one week. This continues throughout the 3 other time points analyzed. Discriminant pics revealed that lipoprotein, LDL and VLDL, and lactate are increased in endo rats whereas glucose is decreased. Several miRNAs are also found differentially expressed between Endo and Sham rats (miR 22, miR145* and miR195).
Limitations, reason for caution: Experimental results in rat model with implantation of autologuous endometrial tissue need to be confirmed in human samples.
Wider implications of the findings: The present preliminary results will be useful to test those potential non invasive biomarkers in women.
Study funding/competing interest(s): Funding by University(ies) – Funding by national/international organization(s) – University of Liège and F.R.S.-FNRS.
Trial registration number: NA.
Keywords: biomarkers, diagnosis, miRNAs, metabolomics, rat model

P-322 miR-133b reverses hydrosalpinx-induced impairment of endometrial receptivity and embryo implantation through down-regulating serum- and glucocorticoid-inducible kinase 1(SGK1)

C. Kong[1], Z. Diao[1], L. Ding[1], X. Zhen[1], Y. Hu[1], H. Sun[1], G. Yan[1]
[1]*The Affiliated Drumtower Hospital, Reproductive Medicine Center, Nanjing Jiangsu, China*

Study question: To explore the mechanism of microRNA-133b (miR-133b) involved in regulation of endometrial receptivity and embryo implantation.
Summary answer: Our results suggest that miR-133b up-regulates HOXA10 expression through down-regulating SGK1 expression via directly targeting SGK1 3'UTR, and reverses hydrosalpinx-induced impairment of BeWo spheroid attachment in Ishikawa cells.
What is known already: Previous studies have demonstrated that hydrosalpinx interferes with endometrial receptivity and embryo implantation by decreasing the expression of HOXA10, a transcription factor which has been demonstrated to be essential for endometrial receptivity and embryo implantation. Our previous study has demonstrated that Ishikawa cells treated with hydrosalpinx alters the expression of miR-133b, a member of microRNAs (miRNAs) which play crucial roles in endometrial receptivity and embryo implantation.
Study design, size, duration: Mid-secretory endometrial tissue samples were collected from 11 subjects with hydrosalpinx and 11 disease-free women as control. Ishikawa cells treated with or without hydrosalpinx, then infected with Ad-LacZ, Ad-miR-133b and Ad-flag-SGK1 adenovirus or transfected with CTL inhibitors and miR-133b inhibitors at the indicated dose for 48 h.
Participants/materials, setting, methods: Luciferase reporter assay was performed to identify SGK1 as the target gene for miR-133b. The expression of SGK1, HOXA10 mRNA and miR-133b were determined by qRT-PCR. Western blot was used to measure SGK1 and HOXA10 levels. Moreover, attachment assay of BeWo spheroids to Ishikawa cells was performed to measure embryo implantation.
Main results and the role of chance: miR-133b and HOXA10 were down-regulated whereas SGK1 was up-regulated in a concentration-dependent manner in Ishikawa cells treated with hydrosalpinx at concentrations of 0, 25 and 50% for 48 h. As expected, the mid-secretory endometrium from subjects with hydrosalpinx had lower expression of miR-133b and HOXA10 and higher expression of SGK1. Moreover, Luciferase assay results showed that miR-133b directly targeted SGK1 3'UTR and down-regulated SGK1 protein expression, subsequently increased HOXA10 expression. Furthermore, BeWo spheroid adhesiveness was inhibited by SGK1 over-expression in Ishikawa cells (27.56 ± 4.94 vs $37.56 \pm 3.63\%$, $p < 0.05$, $n = 3$), whereas over-expression of miR-133b or HOXA10 could reverse the impairment of embryo adhesiveness mediated by hydrosalpinx (41.88 ± 3.93 vs $24.35\% \pm 2.72\%$, $p < 0.05$, $n = 3$ and $45.64 \pm 3.13\%$ vs $22.94 \pm 2.81\%$, $p < 0.05$, $n = 3$, respectively).
Limitations, reason for caution: Our study is performed mainly in vitro for now, the effect of miR-133b on endometrial receptivity and embryo implantation in vivo and the regulation between miR-133b and SGK1 in mouse model is to be further investigated.
Wider implications of the findings: Our present findings provide a novel mechanism that miR-133b improves endometrial receptivity marker genes expression and embryo implantation through reducing SGK1 expression, leading to reverse hydrosalpinx-induced impairment of endometrial receptivity and embryo implantation. These data suggest miR-133b might be a potential target for treatment of infertility subjects with hydrosalpinx.
Study funding/competing interest(s): Funding by national/international organization(s). This work was supported by The National Natural Science Foundation of China Grant 81170570 and 81370683.
Trial registration number: NA.
Keywords: miR-133b, SGK1, hydrosalpinx, endometrial receptivity, embryo implantation

P-323 Expression of endometrial vascular endothelial growth factor-A, -C and placental growth factor in women with elevated progesterone on the day of and after hCG administration

X. Chen[1], L. Liu[2], C. C. Wang[1], G. C. W. Man[1], T. C. Li[1], S. Zhang[2]
[1]*The Chinese University of Hong Kong, Department of Obstetrics and Gynaecology, Hong Kong, Hong Kong*
[2]*Sir Run Run Shaw Hospital, Center For Reproductive Medicine, Hang Zhou, China*

Study question: Is the expression of endometrial angiogenesis related factors affected by progesterone level on the day of and the day after hCG administration in controlled ovarian stimulation cycles?
Summary answer: Endometrial expression levels of VEGF-A, VEGF-C and PLGF were significantly altered in the women with elevated progesterone level on the day of and the day after hCG administration.
What is known already: Elevated serum progesterone on the day of hCG administration in controlled ovarian stimulation is associated with reduced endometrial receptivity. Endometrial angiogenesis activity plays a critical role around the time of embryo implantation.
Study design, size, duration: We investigated VEGF-A, VEGF-C and PLGF in precisely timed endometrial biopsies (hCG + 7, where the day of hCG administration is hCG + 0) obtained from 20 women with elevated progesterone (P4 ≥ 1.7 ng/ml on hCG + 0 and ≥9.5 ng/ml on hCG + 1) and compared the results with 20 women with normal progesterone in cancelled fresh ET cycles.
Participants/materials, setting, methods: The protein expression levels of VEGF-A, VEGF-C and PLGF were examined by immunohistochemistry. A semi-quantitative analysis was performed by H-score analysis of staining intensity in the luminal epithelium, glandular epithelium and stroma, separately. We also correlated expression of VEGF-A, VEGF-C and PLGF with progesterone level on hCG + 0 and hCG + 1.
Main results and the role of chance: VEGF-A expression in glandular epithelium in women with elevated progesterone level was higher ($P = 0.001$) than in women with normal progesterone level. A significantly higher stromal expression of VEGF-A ($P = 0.017$), VEGF-C ($P = 0.023$) and PLGF ($P = 0.033$) was found in women with elevated progesterone level than in women with normal progesterone level. There was a significant correlation between the serum progesterone level on the day of hCG administration and endometrial glandular epithelial expression of VEGF-A ($r = 0.537$, $P = 0.010$) and PLGF ($r = 0.411$, $P = 0.044$). No correlation was seen between the serum progesterone level and VEGF-C expression in any compartment.
Limitations, reason for caution: Immunohistochemistry and H-score analysis for staining intensity are semi-quantitative methods to determine the amount of protein expression. The study could potentially be strengthened by the quantitative RT-PCR measurement.

Wider implications of the findings: The significantly altered expression of endometrial VEGF-A, VEGF-C and PLGF around the time of embryo implantation provides a molecular explanation for the observed reduction of endometrial receptivity in the women with high progesterone level around the time of hCG administration.
Study funding/competing interest(s): Funding by national/international organization(s) – CHEN X. is a recipient of Hong Kong PhD fellowship from Hong Kong Research Grants Council.
Trial registration number: NA.

P-324 Fertility in patients with untreated colorectal endometriosis

I. Erasmo[1], F. Sozzi[1], A. Racca[1], U. Leone Roberti Maggiore[1], P. L. Venturini[1], V. Remorgida[1], S. Ferrero[1]
[1]*IRCCS San Martino Hospital and National Institute For Cancer Research University of Genoa, Obstetrics and Gynaecology Unit, Genoa, Italy*

Study question: Which is the pregnancy rate in patients with colorectal endometriosis who did not undergo surgery?
Summary answer: Patients with colorectal endometriosis have a spontaneous pregnancy rate of about 30% and a total pregnancy rate of about 50%.
What is known already: Reproductive outcomes after surgical treatment of colorectal endometriosis are well documented both in infertile women and in those with unknown fertility status. However, the pregnancy rate of patients with untreated bowel endometriosis is unknown.
Study design, size, duration: This prospective single-centre cohort study was performed between May 2009 and December 2014. It included 55 patients with colorectal endometriosis wishing to conceive.
Participants/materials, setting, methods: Colorectal endometriosis was diagnosed by magnetic resonance imaging enema. Criteria for exclusion from the study were: bowel stenosis > 60%, previous surgery for endometriosis or adnexal diseases, infertility, ureteral stricture, doubtful ovarian cysts, abnormal semen parameters of male partners. Data were presented according to intention to treat.
Main results and the role of chance: The median age of the patients was 33 years (range, 24-41 years). 78.2% of the patients were under hormonal therapy that was discontinued. Five patients interrupted the research of pregnancy because of change of partner, health problems or change of plans. 17 patients (30.9%) conceived spontaneously; the median time required to conceive was 9 months (range, 2-32 months). 12 patients (21.8%) conceived by intrauterine insemination or by in vitro fertilisation; the median time required to conceive was 21 months (range, 9-46 months). The total pregnancy rate in the study population was 52.7% (29/55; 95% C.I., 38.8-66.3%) after a median follow-up of 21.5 months (range, 2-54 months). After the first pregnancy, there were 3 conceptions among the 7 patients who tried to conceive again.
Limitations, reason for caution: The major limitation of the study is the small sample size. Patients wishing to conceive must interrupt hormonal therapies that are contraceptive and may have to tolerate severe pain and intestinal symptoms.
Wider implications of the findings: Patients with colorectal endometriosis should be informed on the possibility to conceive either spontaneously or by assisted reproductive technologies without undergoing surgical excision of endometriosis.

P-325 A comparison of pelvic magnetic resonance imaging, trans-vaginal and trans-rectal sonography with laparoscopic findings in diagnosis of deep infiltrating endometriosis

S. Alborzi[1], A. Rasekhi[2], G. Madadi[3]
[1]*Shiraz University of Medical Sciences, Head of The Gynecologic Endoscopy Division- Laparascopy Research Center- Department of Obstetrics and Gynecology-School of Medicine, Shiraz, Iran*
[2]*Shiraz University of Medical Sciences, Department of Radiology- School of Medicine, Shiraz, Iran*
[3]*Shiraz University of Medical Sciences, Division of Infertility- Infertility Research Center- Department of Obstetrics and Gynecology- School of Medicine, Shiraz, Iran*

Study question: To compare the sensitivity, specificity and accuracy of pelvic magnetic resonance imaging (MRI), trans-vaginal and trans-rectal sonography (TVS and TRS) with laparoscopic findings in diagnosis of deep infiltrating endometriosis (DIE).
Summary answer: The advantages of TRS, which makes it a reasonable substitute for TVS as a first-line imaging modality, include its supremacy in diagnosis of DIE lesions based on its more favorable sensitivity, negative predictive values, accuracy and likelihood ratios. TVS was found to be superior to pelvic MRI for sensitivity, while pelvic MRI turned to be the most specific technique in diagnosis of pelvic DIE.
What is known already: As far as we know, previous similar investigations have not sufficiently compared the performance and diagnostic value of TVS, TRS and MRI in endometriosis in a large population scale. Comprehensive studies which assess the diagnostic significance of such modalities and classify the results for each anatomical location of DIE, would possibly encourage gynecologists to consider revision in previous results.
Study design, size, duration: A cross-sectional prospective study conducted from March 2010 to late December 2014.
Participants/materials, setting, methods: A total of 317 patients with endometriosis undergoing operative laparoscopy were enrolled. Pelvic MRI, trans-vaginal and trans-rectal sonography were performed prior to operation. Sensitivity, specificity and accuracy of pelvic MRI, TRS and TVS were measured with regard to the diagnosis of DIE lesions.
Main results and the role of chance: Regardless of anatomical location, TRS possessed a better sensitivity for diagnosis of DIE lesions as compared to TVS and MRI (81.12 vs. 80.14 and 77.87, respectively). Meanwhile, the specificity was higher for MRI as compared to TVS and TRS (97.14 vs. 96.65 and 95.77, respectively). The accuracy was marginally higher in TRS as compared to TVS and MRI (93.28 vs. 93.14 and 92.79, respectively).
Limitations, reason for caution: Although over 500 cases underwent laparascopic surgery for endometrosis in the setting of this study, only non-virgin subjects could be enrolled since TVS evaluation was not possible in virgins.
Wider implications of the findings: Providing evidence to suggest the best imaging modality (TVS, TRS or MRI) in the diagnosis of deep infiltrating endometriosis.
Study funding/competing interest(s): Funding by University(ies) – Laparascopy Research Center, Department of Obstetrics and Gynecology, School of Medicine, Shiraz University of Medical Sciences, Shiraz, Iran.
Trial registration number: CT-P-92-4095-SUMS.

P-326 Aquaporin-2 Expression as predictor of endometrial receptivity in ICSI cycles

M. Salama[1], A. Ali[1], A. Ammar[1], M. El-Maraghy[1], K. Moussa[1], A. El-Helaly[1]
[1]*Ain Shams University Faculty of Medicine, Obstetrics and Gynaecology Dept., Cairo, Egypt*

Study question: Can endometrial expression of Aquaporin-2 (AQP-2) be used as predictor of endometrial receptivity in patients undergoing ICSI cycles?
Summary answer: This study have demonstrated that endometrial AQP-2 expression during the window of implantation (WOI) is strongly correlated to endometrial receptivity.

Using a semi-quantitative scoring system, an AQP-2 expression score of 2 was proved to have a validated predictive value for implantation, as well as biochemical and clinical pregnancy.
What is known already: Aquaporin-2, a small trans-membrane water channel, is expressed in the epithelium of human endometrium in a cycle-dependent manner, peaking in the mid-secretory phase, coinciding with the 'window of implantation'. The few available studies, mainly on animals, have indicated that this redistribution of AQP-2 might influence the endometrial receptivity.
Study design, size, duration: A pilot study investigating the expression and predictive value of endometrial AQP-2 expression. Fifty patients were recruited over one year, at a tertiary hospital. No reference-test for endometrial receptivity is available for comparison.

The assessors of AQP-2 expression and the data analysts were blinded to the patients' outcomes.

Participants/materials, setting, methods: Fifty couples with unexplained or male infertility planned for ICSI were included. Those with endometrial pathology were excluded.

Endometrial biopsies, by suction catheters, were obtained on day (LH + 7) prior to ICSI. Immuno-histochemical staining for AQP-2, using semi-quantitative scoring (0 to 4) was used. Patients were followed up for pregnancy.

Main results and the role of chance: Our results showed that endometrial AQP-2 expression was positively correlated to both the biochemical and clinical pregnancy rates. With positive AQP-2 expression, the OR for biochemical pregnancy was 7.03 (95% CI 1.91-25.91), and for clinical pregnancy 10.73 (95% CI 2.23-51.58).

The best predictive parameters were achieved with the AQP-2 expression cut-off score of 2. The sensitivity for predicting biochemical and clinical pregnancy rates were 58.06% (95% CI 39.1-75.5) and 92.86% (95% CI 66.1–99.8), the specificity 84.21% (95% CI 60.4–96.6) and 77.78% (95% CI 60.8–89.9), the positive predictive value 85.7% (95% CI 63.7–97.0) and 61.9% (95% CI 29.0–96.3), and the negative predictive value 55.2% (95% CI 35.3–73.9) and 96.6% (95% CI 81.8–99.9), respectively.

Limitations, reason for caution: This study was a pilot study. No previous studies on humans were available for sample size calculation or for comparing the results. Also, the endometrial expression of AQP-2 might be altered by the hormonal treatments of the subsequent ICSI cycles.

Wider implications of the findings: We suggest that testing the implantation window endometrial AQP-2 expression can help predict the success of subsequent ICSI cycles, and hence, directs clinical decision into either performing fresh embryo transfers, or, alternatively, vitrification of the embryos, and subsequent transfers when endometrial receptivity becomes more favourable.

We also hope that with deeper understanding of molecular biology and genetics of the implanting endometrium, medications could be developed that enable enhancing its receptivity through upregulating AQP-2 expression.

Study funding/competing interest(s): Funding by University(ies) – Faculty of Medicine, Ain Shams University, Cairo, Egypt.

Trial registration number: NA.

Keywords: aquaporin-2, implantation, endometrial receptivity, prediction of IVF success

P-327 Jagged-1 protein related signaling pathway effects on embryo implantation

P. W. Chu[1], G. J. Wu[1]

[1]*Tri-Services General Hospital, Obstetrics and Gynecology, Taipei City, Taiwan, R.O.C.*

Study question: To investigate the relationship between the Jagged-1 protein and the embryo implantation rate, mouse embryos were cultured and implantation competency was quantified.

Summary answer: Generally, an in vitro model should show a time delay in implantation compared with the timing of embryo implantation in vivo. The addition of rJagged-1 seemed to partially decrease the time gap between the *in vitro* and the *in vivo* model.

What is known already: Jagged-1 protein triggered Notch 1 signaling pathway has been studied for decades and its important role on the reproductive tract had been proved.

Study design, size, duration: For the collection of embryos we raised female ICR mice aged 4 to 5 weeks and male ICR mice aged 3 to 12 months for use in these experiments. Ovulation are induced in female mice by an intraperitoneal injection of pregnant mare serum gonadotropin (PMSG) followed by human chorionic gonadotropin (hCG) 48 h later. The following morning, the females exhibiting vaginal copulatory plugs are separated for the proposed experiments. The day of appearance of a vaginal plug are set as 0.5 dpc and 8-cell embryos were collected on 2.5.dpc The embryos are cultured in HTF-BSA (4mg/ml) or HTF-BSA with recombinant Jagged-1 protein. By matrigel assay we observed the growth competency and implantation ability.

Participants/materials, setting, methods: Western blotting analysis of N_1ICD of embryos cultured in HTF, HTF + rJagged-1(rJag-1). Fifty embryos per group were analyzed. The embryo spreading and invaded areas were observed and compared between different culture medium (HTF vs HTF + rJagged-1) on 5.5 dpc and 6.5 dpc. On 6.5 dpc, the invaded areas were stained with hematoxylin for further quantification. Quantification of the spreading and invaded areas of embryos cultured in different culture medium (HTF vs HTF + rJagged-1). Finally, the spreading and invaded areas were quantified using Motic Images Plus 2.0.

Main results and the role of chance: Generally, an in vitro model should show a time delay in implantation compared with the timing of embryo implantation in vivo. The addition of rJagged-1 seemed to partially decrease the time gap between the *in vitro* and the *in vivo* model.

Limitations, reason for caution: animal model may not reflect human embryo implantation completely.

Wider implications of the findings: This finding may be further applied on conception and even contraception.

Study funding/competing interest(s): Funding by national/international organization(s) – National Defense Medical Center Medical Research.

Trial registration number: NA.

Keywords: jagged-1 protein, embryo implantation

P-328 Measurement of oxidative stress in the follicular fluid of infertility patients with an endometrioma

R. Sugiyama[1], K. Nakagawa[1], M. Kaneyama[1], Y. Nishi[1], Y. Ojiro[1], K. Yamaguchi[2]

[1]*Sugiyama Clinic, Division of Reproductive Medicine, Tokyo, Japan*

[2]*National Center For Child Health and Development, Department of Maternal-Fetal Biology, Tokyo, Japan*

Study question: In order to measure the oxidative stress in the follicular fluid (FF) from a single follicle of patients with unilateral endometrioma (EM) in assisted reproductive technology (ART) treatment, we evaluated whether an EM might affect the environment of follicular growth.

Summary answer: The oxidative stress and antioxidant potential in the FF of the patients with unilateral EM showed values similar to those without an EM. Therefore, we concluded that EMs do not affect the environment for follicle growth during ART treatment.

What is known already: FF reflects its environment during oocyte growth, and, the evaluation of oxidative stress in the FF could be used to predict oocyte quality. Endometriosis is believed to affect the environment during follicular growth in ART, because endometriosis produces several cytokines that interfere with reproduction. EMs are located in the ovaries; hence, both follicular growth and oocytes could be directly affected by this condition. However, no report has evaluated the environment of a single follicle.

Study design, size, duration: Between December 2011 and July 2013, 26 patients with a unilateral EM (EM group) and 29 without EM (control group) were enrolled in this study. The FF was obtained during the first puncture of follicular aspiration, and was stored at -30? until it could be assayed.

Participants/materials, setting, methods: Oxidative stress was measured using a Free Radical Elective Evaluator (WISMERLL, USA). The d-ROM and BAP tests were used to measure oxidative stress (U.CARR) and anti-oxidant power (μmol/L), respectively.

Main results and the role of chance: The d-ROM values in the EM and control groups were 328.7 ± 97.8 and 414.9 ± 84.2, respectively, and the BAP values in the EMC and control groups were 2,474.3 ± 432.0 and 2,552.8 ± 435.58, respectively, and these two values were similar in both groups. In the EM group, there were no significant differences in the d-ROM and BAP values obtained from the right and left measurement of FF for any single patient. The number of patients whose modified BAP/d-ROM ratio < 1.0 in the EM and control groups were 16 and 15, and the percentage was similar (61.5 and 51.7%).

	EM group	Control group
d-ROM (U.CARR)[#]	328.7 ± 97.8*	414.9 ± 84.2
BAP (mmol/L)[#]	2,474.3 ± 432.0	2,552.8 ± 435.58

[#]mean ± SD.

Limitations, reason for caution: It is difficult to prevent the mixing of blood with the FF after a second puncture during follicle aspiration, and, therefore, we had only the first puncture on which to base our evaluation of the oxidative stress and the anti-oxidant power of the follicle.

Wider implications of the findings: There were no differences in the values (d-ROM and BAP) of the FF taken from the ovaries with or without an EM in the same women who had a unilateral intraovarian EM. The measurements of oxidative stress in the FF for a single follicle might reflect the complete amount

of oxidative stress in an ovary. Therefore, an EM might not affect the environment of follicle growth.
Study funding/competing interest(s): Funding by hospital/clinic(s) – The authors have received no funding for this study, and they have no financial interest in any companies. There are no competing interests.
Trial registration number: This study had no RCT status, and, therefore, it received no trial registration number.
Keywords: oxidative stress, anti-oxidant power, follicular fluid, endometriosis, ART

P-329 JNK and p38 inhibition suppresses PGE2-stimulated aromatase and estrogen receptor levels in human endometriosis

C. Zeng[1], J. N. Xu[1], Y. Zhou[1], Y. F. Zhou[1], Q. Xue[1]
[1]*First Hospital of Beijing University, Department of Obstetrics and Gynecology, Beijing, China*

Study question: The aim of this study was to investigate the molecular and cellular mechanism by which PGE2 regulates aromatase and ER β ((ERβ) expression in endometriosis. A better understanding of the common mechanism responsible for regulation of estrogen biosynthesis may lead to the discovery of new therapeutic targets for endometriosis.
Summary answer: We indicates that PGE2 activates p38 and JNK signaling pathways, further stimulating c-Jun and ATF2 binding to aromatase and ERb promoter regions with elevated estradiol production. Inhibition of p38 and/or JNK could impede or halt the growth of endometriomas and limit estrogen biosynthesis.
What is known already: Endometriosis is an estrogen-dependent disease. Aromatase is the key enzyme for estrogen biosynthesis, and estrogen's action is mediated primarily by nuclear estrogen receptors (ERs). Elevated levels of aromatase mRNA have been found in ovarian endometriomas. A strong association exists between prostaglandin E2 (PGE2) levels and development/severity of endometriosis. Mitogen-activated protein kinase (MAPK) pathways are implicated in the regulation of cellular proliferation and inflammation in endometriosis.
Study design, size, duration: Aromatase and ERb mRNA were examined by real-time RT-PCR. Aromatase activity was measured by Radioimmunoassay (RIA).ERβ, p38, JNK, ERK1/2, ERK5, ATF2 and c-Jun protein expression were detected by western blot assay. Estrogen production was measured by ELISA kits. The association between ATF2 and c-Jun were assessed by coimmunoprecipitation assay.
Participants/materials, setting, methods: Chromatin Immunoprecipitation assay was performed to investigate the effect of PGE2 on the interaction of ATF2 and c-Jun with aromatase and ERb promoter region. The effects of inhibiting p38 or JNK in the presence of PGE2 on estradiol synthesis and xenograft growth were investigated in endometriosis xenografts.
Main results and the role of chance: Aromatase and ERb mRNA levels in ESCs were 2240 fold and 23 fold higher than in the same endometrial cells. PGE2 treatment resulted in a significantly increase in aromatase mRNA (5.9-fold) and activity (11.3-fold). PGE2 also significantly stimulated ERβ expressions and estradiol levels. Bt2cAMP treatment resulted increased aromatase and ERβ mRNA. The P38, JNK, ERK1/2, ERK5 pathways were rapidly phosphorylated following PGE2 stimulation. Addition of p38 or JNK inhibitor/siRNA markedly reduced PGE2 induced aromatase and ERβ expression. PGE2 induced ATF2 translocation and enhances its association with c-Jun. Further, PGE2 enhances binding of ATF2 and c-Jun protein to the aromatase and ERβ promoter region. P38 and JNK inhibition in vivo abrogates PGE2-induced aromatase and ERb expression, estradiol production ($p < 0.05$) and growth of endometriosis grafts.
Limitations, reason for caution: none.
Wider implications of the findings: Inhibition of p38 and/or JNK could impede or halt the growth of endometriomas and limit estrogen biosynthesis. Thus, p38, JNK and their downstream transcription factors, c-Jun and ATF2, may be potential new drug targets for tissue-specific ablation of aromatase and *ERB* expression in endometriosis. Further studies about p38 and JNK inhibitors in the treatment of human endometriosis are still needed.
Study funding/competing interest(s): Funding by national/international organization(s) – This work was supported by the National Natural Science Foundation of China (Grant 81270674) and the Natural Science Foundation of Beijing, China (Grant 7132204).
Trial registration number: NA.
Keywords: endometriosis, aromatase, estrogen receptor

P-330 Free circulating levels of the endogenous immunoregulatory cytokine granulocyte colony stimulating factor (GCSF) correlate with implantation and clinical pregnancy in IVF cycles

N. M. Chimote[1], N. M. Nath[2], B. N. Chimote[3]
[1]*Vaunshdhara Clinic & Assisted Conception Centre, Embryology & Reproductive Endocrinology, Nagpur, India*
[2]*Vaunshdhara Clinic & Assisted Conception Centre, Biochemistry, Nagpur, India*
[3]*Vaunshdhara Clinic & Assisted Conception Centre, Embryology and Biochemistry, Nagpur, India*

Study question: We addressed the question whether serum levels of the unbound, free GCSF on day of blastocyst transfer (BT) and on day 7post BT correlate with implantation and clinical pregnancy in conventional IVF cycles.
Summary answer: Free G-CSF levels in serum, unbound to its receptor, on day of blastocyst transfer (BT) and day 7 post BT are reliable non-invasive prognostic factors for implantation and clinical pregnancy respectively in young women undergoing conventional IVF involving day 5 expanded blastocyst transfer.
What is known already: GCSF is endogenously produced in different tissues/cells including endothelium and decidual cells of endometrium. GCSF may be involved in immunoregulation by promoting T-cell tolerance towards the embryonicallograft. GCSF is produced by endometrial cells only when epithelial and stromal cellular elements are mutually interactive i.e. during the implantation window. It mediates embryo-endometrium dialogue and has direct trophic effect on the trophoblast cells by binding to its natural receptor, c-fms, expressed on the trophoblast.
Study design, size, duration: Prospective pilot study of fresh non-donor conventional IVF cycles ($n = 44$, mean age = 31.71 ± 3.96 years) carried out from June 2013 to December 2013. Standard controlled ovarian stimulation with r-FSH and antagonist protocol was followed. All cycles involved expanded blastocyst transfer (BT) (mean: 1.9 ± 0.4) on day 5 after oocyte retrieval.
Participants/materials, setting, methods: Serum levels of GCSF were measured in equal number of pregnant and non-pregnant cycles on day of blastocyst transfer (BT) and day 7 post BT. Serum β-hCG > 25mIU/ml on day 7 of BT indicated implantation whereas appearance of gestational sac in sixth week with cardiac activity established clinical pregnancy.
Main results and the role of chance: Serum GCSF levels differed significantly between pregnant ($n = 22$) and non-pregnant ($n = 22$) groups on day of BT (69.50 ± 6.7 vs. 127.8 ± 31.0 pg/ml, $p = 0.04$) and day 7 BT (46.92 ± 4.9 vs. 95.22 ± 14.00 pg/ml, $p < 0.0008$).A significant inverse correlation was observed between day of BT serum GCSF level and implantation (Pearson $r = -0.31$) and of day 7 BT serum GCSF with clinical pregnancy (Pearson $r = -0.5$). Interestingly, serum GCSF levels showed a significant decline from day of BT to day 7 of BT in the pregnant group (69.5 ± 6.7 vs. 46.92 ± 4.9, $p = 0.0093$) whereas the decline in levels was statistically non-significant in non-pregnant group (127.8 ± 31.0 vs. 95.22 ± 14.00 pg/ml, $p = 0.36$).
Limitations, reason for caution: This pilot study is limited by a small sample size. Moreover, since it is widely known that there is a redundancy in the roles of various cytokines; an intricate understanding of specific functions of the plethora of cytokines involved during the embryo-endometrial cross-talk is essential before carefully interpreting the results.
Wider implications of the findings: Endogenously produced GCSF facilitates implantation by binding to its receptor on trophoblast cells. Since it is impossible to analyze the activity of bound GCSF, it will be worthwhile to estimate circulating levels of the free unbound GCSF. Moreover, since this binding specifically occurs during the 'window' period, the estimation of free GCSF may give us more insight and understanding of the as yet enigmatic 'implantation window'.
Study funding/competing interest(s): Funding by hospital/clinic(s) – The study was self funded i.e by our own IVF centre.
Vaunshdhara Clinic and Assisted Conception Centre, Nagpur, India.
Trial registration number: NA.
Keywords: implantation, cytokines, GCSF, IVF, clinical pregnancy

P-331 Ovarian tissue surrounding endometrioma function: vascular inmunohistochemichal analysis

M. Vilela[1], D. Paz[2], G. Marconi[3]
[1]*PREGNA, Infertility, Buenos Aires, Argentina*
[2]*Buenos Aires University, Biology, Buenos Aires, Argentina*
[3]*IVI Buenos Aires, Infertility, Buenos Aires, Argentina*

Study question: To assess ovarian tissue surrounding endometrioma function by evaluating vascularization, follicle count and proliferation index.
Summary answer: Endometrioma affects surrounding ovarian tissue function as primordial follicle count, vascularization and proliferation cell index are diminished compared with contralateral non-endometrioma ovaries. These changes are not associated with endometrioma size.
What is known already: There are historical controversies about the influence of endometrioma surgery on subsequent ovarian function, but little research about the influence of endometrioma on the ovarian tissue that surrounds it prior to the actions of surgery. The hypothesis that there may be an alteration of ovarian endometriotic cyst adjacent histology with compromised blood supply and irrigation of follicular apparatus arises.
Study design, size, duration: Prospective study. 32 patients less than 40 years with clinical ovarian unilateral > 3 cm endometrioma diagnosis were operated by laparoscopy. After ovarian stripping cystectomy, an ovarian surrounding endometrioma tissue sample was taken (study group); another ovarian tissue sample from contralateral ovary without endometrioma was taken as control group.
Participants/materials, setting, methods: Samples were processed for histological primordial follicle count, inmunohistochemical vascular assessment with monoclonal CD34 antibody specific for endothelial cells and proliferation cellular index with PCNA. Both groups main outcome measures were compared by x^2 and non-parametric tests. Statistical correlation between ovarian endometrioma size and inmunohistochemical parameters was also performed.
Main results and the role of chance: Patients average age was 30. 5 ± 4.1years. 7 endometriomas were from right ovary and 25 from left ovary. Endometrioma average size was 5 ± 1.5 cm (3.5 a 8 cm rank). There was significantly less primordial follicular count (2.18 ± 2.7 vs 6.21 ± 6.2, $p < 0.05$), less vascular inmunostained area (2.87 ± 1.65 vs 4.46 ± 2.4, $p < 0.05$) and less proliferation cell index (5.2 ± 1.8 vs 7.4 ± 4.2, $p < 0.05$) in ovarian parenchyma surrounding endometriomas compared with ovarian contralateral tissue without endometrioma. No correlation was found between endometrioma size and primordial follicular count, vascular inmunostained area, nor proliferation cell index of the endometrioma surrounding tissue [Pearson coefficient: -0.24 (IC 95%: -0.44 to 0.11, NS); -0.054 (IC 95%: -0.39 to 0.30, NS) and 0.129 (IC 95%: -0.45 to 0.22, NS) respectively].
Limitations, reason for caution: None.
Wider implications of the findings: These results reopen the debate about whether patients with endometrioma to be submitted to assisted reproduction should be previously operated with the risk of generating even greater damage over the ovarian reserve; or stimulate better without surgery. While there is wide clinical experience and literature on the subject, has not yet reached an uniform consensus.
Study funding/competing interest(s): Funding by hospital/clinic(s) – None.
Trial registration number: NA.
Keywords: endometrioma, CD34, immunohistochemical, ovarian-function, ART

P-332 Myofibroblasts polarised arrangement and TGFß receptors spatial expression in the peritoneal endometriosis – reappraisal of the microenvironment of the superficial peritoneal endometriosis

M. G. Ibrahim[1], V. Chiantera[1], S. Frangini[1], S. Younes[1], S. Mechsner[1]
[1]*Charite Universitaetsmedizin, Gynaecology, Berlin, Germany*

Study question: Do the myofibroblasts and TGFß receptors follow a spatial arrangement in the superficial peritoneal endometriosis (EM)? Do the peritoneal fluid (PF), oestrogen (E_2) and TGFß1 affect cellular proliferation of fibroblasts and epithelial cells? Does TGFß1 level differ in PF in EM patients than control?
Summary answer: The myofibroblasts and TGFß receptors are spatially arranged in the peritoneal endometriosis microenvironment. The centre exhibited more contractile phenotype of the myofibroblasts and higher TGFßR1 and 3. PF and E_2 favour the profibrotic evolution of the lesions while TGFß1 inhibits the epithelial cell proliferation. TGFß1 did not differ in both.
What is known already: The shedded endometrium is affected by the peritoneal fluid in endometriosis patients in its retro-grade journey to the abdominal cavity. It stimulates the stromal cell proliferation. The shedded endometrium implants itself on the peritoneum where it develops through an EMT process into EM. TGFß1 is usually involved and induces the transformation of fibroblast into myofibroblasts. Myofibroblasts have been seen before in different EM lesions.
Study design, size, duration: In a pro- and retrospective study eighty-six premenopausal patients (EM patients = 55 and non-EM patients = 31) were included. PF, superficial peritoneal EM lesions, healthy peritoneum and unaffected peritoneum from EM patients were collected during laparoscopy at Charite University of Medicine between 2012 and 2014.
Participants/materials, setting, methods: Immunohistochemistry staining for TGFß receptor 1, 2, 3, collagen I and calponin was done. The proliferation rate of L-929 and 12Z cell lines incubated with PF, E_2 and TGFß1 was studied. ELISA kit for measuring TGFß1 level in PF in EM and control patients was used.
Main results and the role of chance: The collagen I immunoexpression was higher in the peripheral peritoneum and tend to decrease towards the centre of the lesion. Contrarily, calponin was higher expressed on the endometriotic stromal cells and tend to decrease towards the peripheral peritoneum. Both were higher expressed in the peritoneum of EM than non-EM. The unaffected peritoneum from EM patients and the healthy peritoneum did not show any difference. TGFßR1 and 3 were higher in the centre than in the peripheral compartment. TGFßR2 was always higher expressed than the other two receptors. PF from EM patients as well as E_2 stimulated the proliferation rate of L-929 cell line, while TGFß1 inhibited that of 12Z cell line. TGFß1 level did not show any difference between EM and non-EM patients.
Limitations, reason for caution: It is a descriptive study and further in-vitro modulation of the different TGFß receptor subunits and its possible linkage to calponin and collagen I expression is recommended. Isolation of the cells from the different compartments of this polarised microenvironment could be of value for individual in-vitro studies.
Wider implications of the findings: Our data could support the presumption of the polarisation of the microenvironment of the peritoneal endometriosis. The higher TGFßR1 and 3 in the centre might be linked to the more calponin expression. This could open question for further targeting the receptor subunit to control the myofibroblastic activity and hence fibrosis and pain.
Study funding/competing interest(s): Funding by University(ies) – funding by commercial/corporate company(ies) – the first author was granted a promotion-scholarship from the Ernst Schering Foundation and Humboldt University in Berlin, Germany.
Trial registration number: NA.
Keywords: peritoneal endometriosis, TGFß1, collagen I, myofibroblasts, peritoneal fluid

P-333 Metabolome of recurrent implantation failure versus recurrent implantation success: exploring the feasibility of implantation marker(s) identification in serum

B. N. Chakravarty[1], S. Roychoudhury[2], S. K. Goswami[1], R. Chattopadhyay[1], S. Ghosh[1], N. J. Gupta[1], H. S. Sarkar[1], M. V. Joshi[3], S. Srivastava[3], K. Chaudhury[2]
[1]*Institute of Reproductive Medicine, ART, Calcutta, India*
[2]*Indian Institute of Technology, SMST, Kharagpur, India*
[3]*Tata Institute of Fundamental Research, National Facility For High-field NMR, Mumbai, India*

Study question: Is there any difference in serum metabolic expression of women with repeated implantation success (RIS) compared with repeated implantation failure (RIF)? If any, whether these metabolites hold merit to be considered as pre-determined set of marker(s) and can help in predicting the chances of a successful pregnancy in women undergoing IVF?
Summary answer: Several metabolites were found to be significantly altered on comparing women with RIS and RIF. Among these metabolites, adipic acid, urea and D-glucose showed highest predictive values in discriminating the two groups.
What is known already: RIF, commonly encountered during IVF-ET, is defined as the failure to implant in at least three consecutive IVF attempts, despite transfer of good quality embryos at each cycle. In contrast, RIS refers to the group of women who conceive each time over multiple IVF-ET cycles, irrespective of whether average quality, fresh, or frozen embryos are transferred. Nuclear magnetic resonance based metabolomics involves reproducible quantification of intracellular metabolites and is helpful in identifying promising predictive biomarkers.
Study design, size, duration: Age, BMI and indication matched 24 women with RIS, who conceived each time during their multiple IVF-ET cycles and 28 women with RIF (≥ 3 IVF-ET attempts) were recruited from January 2004 to October 2014.

Participants/materials, setting, methods: Serum samples were collected during implantation window from RIS and RIF patients undergoing IVF-ET. Carr-Purcell-Meiboom-Gill spin-echo spectra were obtained and processed data was subjected to statistical analysis. Several multivariate and univariate statistical analyses were performed for group discrimination and marker(s) identification, respectively.
Main results and the role of chance: Principal component analysis, partial least squares discriminant analysis (PLS-DA) and orthogonal-PLS-DA show distinct classification between RIS and RIF based on the differently expressed metabolites. The metabolites, adipic acid, urea and D-glucose contributed most towards this differentiation and were significantly up-regulated in RIF as compared to RIS ($p < 0.05$). Oxidative stress is known to be associated with poor endometrial receptivity. Increased adipic acid levels, a byproduct of lipid peroxidation, is likely due to elevated ROS in RIF. Higher levels of urea in RIF indicate imbalance in nitrogen metabolism which may interfere with the normal inductive effects of progesterone on the uterine microenvironment. Up-regulated D-glucose in RIF is not surprising since it is well established that high glucose environment is not conducive to embryo implantation.
Limitations, reason for caution: This study needs to be extended to a larger sample size for data reproducibility and accurate predictability. Alterations in expression of these metabolites need further validation in a larger cohort of samples using biochemical tests.
Wider implications of the findings: Implantation marker(s) identification in serum of women during the IVF treatment cycle will be a major breakthrough in predicting the possibility of success in IVF cycles. Women unlikely to have successful implantation may be identified early and treatment protocol planned accordingly.
Study funding/competing interest(s): Funding by hospital/clinic(s) – the study was funded by our own private infertility centre: Institute of Reproductive Medicine. The authors have no conflict of interest.
Trial registration number: NA.

P-334 Serum nitric oxide on day 7 post transfer may indicate a receptive endometrium and is a non-invasive marker in ongoing IVF cycles

S. Ghosh[1], R. Chattopadhyay[1], P. Chakraborty[1], G. Bose[1], M. Chakravarty[1], B. N. Chakravarty[1]
[1]*Institute of Reproductive Medicine, ART, Calcutta, India*

Study question: To determine if serum nitric oxide (NO) level on day of embryo transfer (ET) and day 7 post ET (d7ET) reflects optimum endometrial vascularization and whether it can be interpreted as a non-invasive marker; if so does it correlate with *in vitro* fertilization (IVF) outcome?
Summary answer: Serum NO level with a threshold value of > 4.2 nm/ml on d7ET correlates well with clinical pregnancy and may be considered as a non-invasive marker for embryo implantation in ongoing IVF cycles.
What is known already: It is known that controlled ovarian stimulation adversely affects receptivity in assisted reproductive techniques (ART) cycles. It causes suboptimal synchrony between endometrium and transferred embryos and therefore can be responsible for many IVF cycle failures. As many aspects of IVF-ET have already become optimized, other aspects, such as possible alterations in endometrial development and receptivity, implantation and/or early placentation have become the focus of modifiable factors that may further enhance success and safety.
Study design, size, duration: A prospective cohort study was conducted from October 2013 to November 2014, including 227 patients stratified on the basis of favorable/unfavorable issues of IVF (Fertility & Sterility 19: 2011). All patients underwent IVF using standard downregulation with GnRH agonist and gonadotropins. 8 cycles were cancelled due to inadequate endometrial thickness.
Participants/materials, setting, methods: Serum NO was measured on day of ET and d7ET using spectrophotometric methods. Endometrial flow velocimetry was assessed on day of ET. Cycles were initially divided on the basis of pregnancy while subsequent stratification was based on d7ET NO levels. Clinical pregnancy and implantation rate were the main outcome measures.
Main results and the role of chance: Overall clinical pregnancy and implantation rate was 36.98% and 31% respectively. NO level on dET correlated strongly with endometrial vascularity (Spearman $r = 0.5709$, 95% CI: 0.3920–0.5011; $p < 0.001$) and clinical pregnancy (Spearman $r = 0.6655$, 95% CI: 0.4732–0.7972; $p < 0.0001$). Serum NO level on d7ET (5.11 ± 2.19 *vs*. 0.82 ± 0.21 nm/ml; $p < 0.001$) was significantly higher in pregnant ($n = 81$) than in non-pregnant ($n = 138$) group. High (> 4.2) d7ET NO group ($n = 108$) illustrated significantly much higher clinical pregnancy rate (43.51% vs. 32.43) compared to low d7ET NO population ($n = 111$). Threshold value of serum d7ET NO to achieve clinical pregnancy was found to be > 4.2 nm/ml (Sensitivity 91.89%, Specificity 77.53%, Likelihood ratio 3.51, ROCAUC 81.35%).
Limitations, reason for caution: The predictability of serum NO levels on d7ET as a biomarker in envisaging live birth outcome are limited to patients with favorable criteria for IVF. Moreover keeping an eye over the sample size it warrants the results to be proved in a randomized controlled trial.
Wider implications of the findings: d7ET serum NO level stands as a novel non-invasive marker for clinical pregnancy and implantation rates in ongoing IVF cycles as against human endometrial study which constitutes an invasive method for embryo implantation assessment and cannot be applied to an ongoing cycle. It has wide implication in clinical practice and has a good prognostic accuracy for predicting clinical pregnancy in the index cycle.
Study funding/competing interest(s): Funding by hospital/clinic(s) – The study was funded by our own private infertility centre; Institute of Reproductive Medicine. The authors have no conflict of interest.

P-335 A novel role for microRNA miR-218 in regulating invasiveness of endometriotic cells

M. Götte[1], I. Pino[1], A. K. Urbanowitz[1], A. B. Richling[1], L. Kiesel[1], A. N. Schüring[1]
[1]*Universitätsklinik Münster, Dept. of Gynaecology, Münster/Westf., Germany*

Study question: What is the functional impact of miR-218 dysregulation in endometriosis?
Summary answer: miR-218 regulates endometriotic cell invasiveness, possibly by targeting the EGFR and the TGFbeta-modulating proteoglycan decorin.
What is known already: microRNAs are small noncoding RNAs implicated in the posttranscriptional regulation of gene expression. miR-218 is downregulated in endometriosis (Wang WT, JCEM 2013;98:281), suggesting a potential involvement in the pathogenetic process.
Study design, size, duration: *In vitro* study on the endometriotic cell line 12Z, the endometrial stroma cell line ST-T1b, and on primary stroma cells derived from the eutopic endometrium of 3 patients with laparoscopically confirmed endometriosis.
Participants/materials, setting, methods: Cells were transiently transfected with miR-218 precursors to study the effects of miRNA upregulation in vitro. The impact of miR-218 on cell viability was studied by MTT assay, whereas invasiveness was assayed in matrigel invasion chambers. Predicted targets of miR-218 were identified by microRNA.org database analysis, and target regulation was confirmed by quantitative real-time PCR and Western blotting.
Main results and the role of chance: Matrigel invasiveness was reduced by 62% ($n = 6$, $p = 0.01$) in miR-218 transfected 12Z cells. miR-218 transfection moderately reduced ST-T1b cell viability by 10% ($p < 0.05$, N = 6). qPCR revealed significant downregulation of EGFR and decorin mRNA expression by > 50% in the two cells lines and in patient-derived primary cells ($p < 0.01$ for 12Z, $p < 0.05$ for stroma cells, $n = 6$). Decorin downregulation by miR-218 was confirmed by Western blotting in St-T1b cells.
Limitations, reason for caution: This is an in vitro study based on a transient transfection approach. Additional targets may be involved in the phenotypic changes.
Wider implications of the findings: This study demonstrates a role for miR-218 in regulating endometriotic cell invasiveness, which may be mechanistically linked to downregulation of the EGFR and the TGFbeta binding proteoglycan decorin. Upregulation of miR-218 may be a possible therapeutic approach worth exploring in additional preclinical models of endometriosis.
Study funding/competing interest(s): Funding by University(ies) – Münster University Hospital.
Trial registration number: NA.

P-336 Oxidative stress biomarkers in follicular fluid of women with endometriosis and tubal factor infertility- Is there a correlation with in-vitro-fertilization (IVF) outcome?

N. Malhotra[1], R. Dada[2], A. Tiwari[3], K. Gongadshetti[3]
[1]*AIIMS All India Institute of Medical Science, ART Centre Department of Obstetrics and Gynecology, New Delhi, India*
[2]*AIIMS All India Institute of Medical Science, Department of Anatomy, New Delhi, India*
[3]*AIIMS All India Institute of Medical Science, ART Centre Department of Obstetrics and Gynecology, New Delhi, India*

Study question: Does oxidative stress (OS) affect outcome during in-vitro-fertilization cycles (IVF)? The objective was to compare oxidative stress (OS) biomarkers in follicular fluid of women with endometriosis and tubal factor infertility undergoing in-vitro- fertilization (IVF) and correlate them with assisted reproductive technique (ART) outcome including oocyte fertilization, embryo cleavage and quality.
Summary answer: Women with endometriosis have lower pregnancy outcome during IVF cycles. There are altered levels of OS bio-markers in the follicular fluid of women with endometriosis undergoing IVF cycles. This may be responsible for lower pregnancy rate in women with endometriosis undergoing IVF.
What is known already: Oxidative stress may play a role in oocyte development and maturation which gets disturbed in endometriosis. The oocyte competence is lowered when levels of Reactive oxygen species (ROS) exceed the ability of the follicular fluid and the oocyte to counterfeit them with insufficient anti-oxidants, leading to lower oocyte potential and embryogenesis and consequently lower pregnancy rates. Levels of various OS bio-markers explored in follicular fluid during IVF cycles, but results do not convincingly suggest role of OS. A novel marker 8-Isoprostane has not been studied as it has better potential to define OS.
Study design, size, duration: Cross-sectional study. One hundred and seven women with endometriosis and tubal factor infertility undergoing IVF cycles at a tertiary fertility center. Sample size was calculated to 45 women in each group based on literature review. The study was conducted from July 2012 to June 2014.
Participants/materials, setting, methods: Follicular fluid from women with endometriosis (n = 50, group I) and tubal factor infertility (n = 57, group II) were evaluated for OS bio-markers including Reactive oxygen species (ROS), Total anti-oxidant capacity (TAC), eight-hydroxy-2-deoxyguanosine (8-OHdG) and 8-Isoprostane (8-IP) levels. ROS levels were detected by chemiluminesence, TAC, 8-OHdG and 8-IP by enzyme immunoassay.
Main results and the role of chance: Levels of ROS [(39.6cpm vs 54.8 cpm) (p = 0.2] and 8-OHdG [(6157.9 pg/mll vs 5393.0 pg/ml) (p = 0.05)] were comparable in both groups. Levels of 8-IP were significantly higher in group I as compared to group II [85.2 pg/ul vs 39.2 pg/ul) (p = 0.01)]. Levels of TAC were significantly higher in women with endometriosis as compared to tubal factor [(5.4 vs 4.1 mM of trolox) (p = 0.005) and could explain comparable ongoing clinical pregnancy rate in both groups (24.0 vs 24.5%, p = 0.34). There was no correlation of OS biomarkers with ART outcome in tubal factor. Follicular fluid from endometriosis revealed a negative correlation of ROS (-0.42; p = 0.002)with cleavage rate and positive correlation of TAC with fertilization rate (0.44; p = 0.001, cleavage rate (0.42; p = 0.03) and good grade embryos (0.4; p = 0.001).
Limitations, reason for caution: The study needs to be done on a larger sample size to validate the results.
Wider implications of the findings: OS may have a role in endometriosis related IVF outcome as revealed by higher levels of 8-IP in follicular fluid. OS bio-markers could be useful in prognosticating IVF outcome in women with endometriosis. Presence of adequate anti-oxidants in follicular fluid is required to counterfeit the effects of OS on oocyte competence. This could have wider implications to add anti-oxidants as supplements in women with endometriosis undergoing IVF cycles.
Study funding/competing interest(s): Funding by hospital/clinic(s) – All India Institute of Medical Sciences, New Delhi.

P-337 Induction of post-menstrual regeneration by ovarian steroid withdrawal in the functionalis of xenografted human endometrium

P. Coudyzer[1], P. Lemoine[1], C. Po[2], B. Jordan[2], P. Van Der Smissen[1], P. Courtoy[1], P. Henriet[1], E. Marbaix[1]
[1]*Université Catholique De Louvain (UCL), De Duve Institute, Brussels, Belgium*
[2]*Université Catholique De Louvain (UCL), Louvain Drug Research Institute, Brussels, Belgium*

Study question: Does the endometrial functionalis have the potential to undergo self-renewal after menstruation and how is this process controlled by ovarian steroids?
Summary answer: Endometrial xenografts subjected to withdrawal of estradiol and progesterone shrink but also show signs of proliferation and tissue repair. New estradiol supply blocks apoptosis, prevents atrophy but is not sufficient to increase volume graft.
What is known already: Menstruation, i.e. cyclic proteolysis of the extracellular matrix of endometrial functionalis, is induced by a fall in estrogen and progesterone concentration and is followed by tissue regeneration. However, there is debate about whether regenerating cells must originate from the basalis or from stem cells and whether new estrogen supply is required for the early repair concomitant with menstruation.
Study design, size, duration: Fragments from human endometrial functionalis (from 24 hysterectomy specimens) were xenografted in ovariectomized SCID mice and submitted to a 4-day estradiol and progesterone withdrawal (to mimic menstruation) followed by reexposure to estradiol (to mimic the proliferative phase). We measured signs of proliferation and changes in graft volume.
Participants/materials, setting, methods: Endometrium was collected from spontaneously cycling women. Cell proliferation was examined by immunolabeling Ki-67, cyclin D1 and phosphorylated-histone H3. Xenograft volume was measured by magnetic resonance imaging. Xenograft histomorphometry was performed to determine how the different tissue compartments contributed to volume change.
Main results and the role of chance: Hormone withdrawal induced a rapid decrease in graft volume mainly attributable to stroma condensation and breakdown, concomitant with an increase of proliferation markers. Reinsertion of E pellets after induced menstruation blocked volume decrease and apoptosis and stimulated epithelial and stromal growth, but, surprisingly, did not induce graft enlargement.
Limitations, reason for caution: Mechanisms of endometrial remodeling are different in women and mice and the contribution of circulating inflammatory cells in both species remains to be clarified. Moreover, during human menstruation, endometrial fragments resulting from tissue proteolysis can be expelled by the menstrual flow, unlike in this model.
Wider implications of the findings: Menstruation is a multifocal event within the functionalis. This is the first evidence that endometrial fragments that are not shed after menstrual tissue breakdown can support endometrial regeneration. Endometriosis is commonly thought to result from the retrograde migration of menstrual fragments of the degraded functionalis into the peritoneal cavity. Our study supports their potential to regenerate as ectopic endometrium.
Study funding/competing interest(s): Funding by University(ies) – Funding by national/international organization(s) – This work was supported by the Fonds de la Recherche Scientifique Médicale, Concerted Research Actions, Communauté Française de Belgique, Région wallonne, Région bruxelloise and Loterie nationale. P-338 An in vitro implantation model reveals morphologic and functional details of human blastocyst attachment to uterine epithelium

P. T. Ruane[1], P. A. Babbington[2], S. C. Berneau[1], S. J. Kimber[3], M. Westwood[4], D. R. Brison[4], J. D. Aplin[4]
[1]*St Mary's Hospital–5th Floor, Maternal and Fetal Health Research, Manchester, United Kingdom*
[2]*Central Manchester University Hospitals NHS Trust, Department of Reproductive Medicine, Manchester, United Kingdom*

[3]*University of Manchester, Faculty of Life Sciences, Manchester, United Kingdom*
[4]*St. Mary's Hospital, Maternal and Fetal Research, Manchester, United Kingdom*

Study question: What are the morphological details of early human blastocyst implantation events, specifically pertaining to trophectoderm breaching of the endometrial epithelium and trophectoderm outgrowth?
Summary answer: Human blastocysts of varying grades attach readily to the endometrial Ishikawa cell line in an in vitro model of implantation. Subsequent fluorescence microscopy revealed apoptosis in Ishikawa cells interacting with the blastocyst. Trophectoderm syncytialisation was also seen upon outgrowth on top of, and into, the Ishikawa cell layer.
What is known already: Apoptosis in the endometrial epithelium has been suggested as a mechanism for breaching this barrier during human embryo implantation. Human trophectoderm syncytialisation has also been observed upon blastocyst invasion beyond the endometrial epithelium and into the underlying stroma.
Study design, size, duration: We used an in vitro model of the initial stages of human embryo implantation, which allowed detailed fluorescent microscopic interrogation of morphology. Fifty-nine human blastocysts consented for research (with ethical approval and a licence from the HFEA) from fresh IVF/ICSI cycles and long term-storage were used.
Participants/materials, setting, methods: Day 6 human blastocysts were co-cultured with the endometrial Ishikawa cell line for 48 h. Blastocyst attachment was monitored at 24 and 48 h by gentle agitation, and attached blastocyst sites were fixed at 48 h, processed for immunofluorescence and imaged using an Apoptome-equipped Zeiss Axiophot microscope.
Main results and the role of chance: Attached blastocysts that exhibited fully expanded blastocoels were considered to be at an early attachment stage with limited trophectoderm outgrowth. Five of these attachment sites were labelled with the apoptosis marker anti-cleaved caspase3, with four of these revealing multiple apoptotic Ishikawa cells directly underneath the attached blastocyst. Co-labelling with phalloidin and DAPI also revealed morphological details at these sites, such as potential trophectoderm syncytialisation in contact with Ishikawa cell apical surfaces. Attached blastocysts which had collapsed after 48 h co-culture were considered to be at a later stage of attachment, with outgrowing trophectoderm. Nine of these attachment sites were labelled with the cell-cell adhesion marker anti-E-cadherin, alongside phalloidin and DAPI, which demonstrated syncytialisation in outgrowing trophectoderm in contact with Ishikawa cells.
Limitations, reason for caution: In vitro models are the only method for studying human embryo implantation. Our model was designed for microscopy and for screening interventions into implantation, and is highly simplified. The use of the Ishikawa cell line as a surrogate endometrial epithelium may not reflect dynamic receptivity in the in vivo endometrium.
Wider implications of the findings: We provide the first direct evidence for human blastocyst-induced endometrial epithelium apoptosis as a mechanism for breaching the epithelial barrier in early implantation. Furthermore, we document the formation of the initial syncytiotrophoblasts in human placental development. We show that these can form during early outgrowth into, and on top of, endometrial epithelium in the Ishikawa model. Importantly, this study highlights the potential of Ishikawa cells for further mechanistic investigation of the earliest stages of implantation.
Study funding/competing interest(s): Funding by national/international organization(s) – The study was funded by Wellbeing of Women grant RG1442 and a postgraduate studentship from the Anatomical Society of Great Britain and Ireland. The authors declare no competing interests.
Trial registration number: NA.
Keywords: human blastocyst, implantation, in vitro model, fluorescence microscopy

P-339 Granulocyte colony stimulating factor(G-CSF) : Does it really improve the endometrial thickness in women with persistent thin endometrial thickness undergoing frozen endometrial transfer?

S. Swati[1], S. Sankalp[1], C. M. Ashraf[1]
[1]*Craft Hospital and Research Center, Reproductive Medicine, Thrissur, India*

Study question: Does a persistently unresponsive endometrium improves in thickness with administration of granulocyte colony-stimulating factor (G-CSF) in frozen embryo transfer cycle?
Summary answer: The study failed to show a significant improvement in the endometrial thickness after administration of G-CSF.
What is known already: Endometrial thickness less than 7 mm has been shown in studies to hamper pregnancy rates. Many women continue to have unresponsive thin endometrium despite using all available modalities of treatment. Few small studies have reported the use of G-CSF to be efficacious in increasing the endometrial thickness in women with thin endometrium. None of the reported studies are randomized controlled trials (RCT) though.
Study design, size, duration: Prospective observational cohort study of 250 women with persistent unresponsive endometrium < 7 mm was conducted in craft hospital from 2012-2014.These women have tried and failed high dose estradiol therapy, long duration estradiol therapy, different routes of estradiol, natural cycle endometrial preparation, sildenafil citrate and vitamin E before they were offered off label use of G-CSF.
Participants/materials, setting, methods: Endometrial preparation was done with estradiol valerate 2 mg three times a day and escalated in phased manner. On day 20th of estradiol, if the endometrium was less than 7 mm, they were recruited for the study. Intrauterine G-CSF infusion was done and endometrial thickness was assessed 2 days later.
Main results and the role of chance: Overall, there was no significant increase in the endometrial thickness at 48 h post infusion.(p = 0.09).73/220 women (33.18%) had their endometrium improved to above 7 mm. They underwent embryo transfer and resulted in clinical pregnancy rate of 34.2% (25/73) per embryo transfer and implantation rate of 18%.
Limitations, reason for caution: Despite the fact that it is one of the largest reported study till now, it was not a randomized controlled trial. Also, since pregnancies have been reported with endometrium as thin as 3.7 mm,7 mm cut off for thin endometrium is at best arbitrary.
Wider implications of the findings: The persistently thin endometrium can be improved by G-CSF in only approximately 1/3rd of the women. This raises questions over the previous studies showing significant benefit of the intervention. The solution for the ongoing controversy can be achieved only by a large preferably multicentric RCT.
Study funding/competing interest(s): Funding by hospital/clinic(s) – craft hospital.
Trial registration number: NA.

P-340 Transcriptome pattern comparison between endometrium and peripheral blood

J. Huang[1], X. Y. Chen[1], C. C. Wang[1], T. C. Li[1]
[1]*the Chinese University of Hong Kong, Obstetrics and Gynaecology, Hong Kong, Hong Kong*

Study question: Can the transcriptome in peripheral blood reflect gene expression pattern in the endometrium around the time of implantation?
Summary answer: Preliminary results based on clustering analysis and gene pathway analysis suggest it is possible that the transcriptome in peripheral blood may be used to study changing gene expression in the endometrium around the time of implantation.
What is known already: Endometrium becomes receptive 6-9 days after luteinizing hormone surge, which is considered as the window of implantation. Transcriptome studies showed distinctive gene expression profiling of endometrium in the window of implantation. However, it is unclear if transcriptome in the peripheral blood may reflect the changes in the endometrium.
Study design, size, duration: This is a prospective, cross-sectional study with 8 subjects. Endometrium biopsy and blood collection were both timed precisely on day LH+ 7, following written consent.
Participants/materials, setting, methods: Subjects were recruited from the IVF clinic in Prince of Wales Hospital. RNA was extracted from endometrium and blood, investigated with gene expression array (Agilent Sureprint G3 8 × 60 k), and analyzed with GeneSpring 13.0. Differentially expressed genes were identified by using moderate T-test.
Main results and the role of chance: Clustering analysis of four pairs (endometrium and peripheral blood) of samples showed similarity in clustering pattern. Venn diagram and pathway analysis showed similar regulation pattern with 11 genes in 6 pathways, suggesting that peripheral blood may reflect endometrium gene expression in the peri-implantation period.
Limitations, reason for caution: Additional samples will be performed to confirm the preliminary findings.

Wider implications of the findings: The above findings suggest that it may be possible to utilize the transcriptome pattern in peripheral blood to reflect the gene expression profile in the endometrium around the time of implantation.
Study funding/competing interest(s): Funding by University(ies) – The Chinese University of Hong Kong.
Trial registration number: CRE Ref. No. 2014.637.

P-341 Role of 3D Ultrasound and Power Doppler in the prediction of IVF/ICSI outcome

A. Rao[1], P. Giridharan[1], D. Rao[1], S. Rao[1]
[1]*Rao Hospital, Centre For Assisted Reproduction and Endoscopy, Coimbatore, India*

Study question: Do endometrial parameters like endometrial volume & vascularity indices by 3D US & Power Doppler have any predictive value in IVF/ICSI outcome?
Summary answer: Miscarriage rate was higher when endometrial volume was <2 ml. Vascularity indices by 3D US& Power Doppler showed no significant difference in pregnant and non-pregnant group.
What is known already: 3D US volume calculation of the endometrium helps to correlate the cycle outcome with quantitative parameter than endometrial thickness. Pregnancy and implantation rates were previously demonstrated to be significantly lower when endometrial volume was < 2 ml and no pregnancy was achieved when endometrial volume was < 1 ml.
Study design, size, duration: Retrospective study of 161 ART cycles with 88 stimulated IVF/ICSI cycles & 73 recipient cycles over a period of 12 months.3D Ultrasound &Power Doppler done on the day of HCG in stimulated IVF/ICSI cycles & on the progesterone supplementation day in recipient cycles to assess the endometrial volume and endometrial perfusion.
Participants/materials, setting, methods: Endometrial volume assessment done on VOLUSON 730 (WIPRO GE) using transvaginal 3D probe& VOCAL software..Patients were divided according to endometrial volume into 3 subgroups; < 2 ml, 2–4 ml and > 4 ml..3DPowerDoppler & volume histogram done to obtain vascularity index (VI), Flow index (FI),& Vascularity flow index (VFI). Pregnancy rates were compared between all groups.
Main results and the role of chance: Pregnancy rates between 3 groups of endometrial volume in stimulated cycles; < 2 ml, 2-4 ml and > 4 ml was 55, 44.1, 40% respectively.& miscarriage rate was 36.6, 10.5,10.0%, respectively. In recipient cycles pregnancy rates in; < 2 ml,2-4 ml, > 4 ml.
Groups were; 55, 61.5 and 85.7%, respectively&miscarriage rate was 13.3, 12.5 and 0%. No significant difference in pregnancy rates between the three groups in stimulated & recipient cycles. Endometrial volume failed to predict outcome of IVF/ICSI. 2 pregnancies seen with < 1 ml endometrial volume. Increased miscarriage rate seen in stimulated & recipient cycles with < 2 ml endometrial volume. In stimulated IVF/ICSI cycles, VI/FI/VFI mean values were 4.6/26.9/1.4 respectively in pregnant group & 4.3 /26.7/1.6 in non-pregnant group. In recipient cycles, VI/FI/VFI mean values were 3.6/25.9/1.0.respectively in pregnant group & 1.7/24.2/0.6 in non- pregnant group. No significant difference in endometrial vascularity between pregnant &nonpregnant groups.
Limitations, reason for caution: Three Dimensional ultrasound has been proposed as a promising tool for evaluating endometrium accurately.3D Power Doppler indices seem to reflect endometrial perfusion. But its exact relationship with real blood flow is not fully understood. More studies using larger groups are necessary to draw firm conclusions.
Wider implications of the findings: Present study shows that there is no correlation between endometrial volume and pregnancy rates in stimulated cycles & recipient cycles. Contrary to the fact that no pregnancy was achieved If endometrial volume is < 1 ml, 2 pregnancies we had in < 1 ml endometrial volume., gives hope of conception in women having poor endometrium.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Rao Hospital, 120, West Periyasamy Road, R. S Puram, Coimbatore – 641002, Tamil Nadu, India.
Trial registration number: NA.

P-342 Vitamin D and endometriosis: the serum level and its anti-inflammatory and anti-proliferative effects

M. Miyashita[1], K. Koga[1], M. Nagai[1], T. Makabe[1], F. Sue[1], A. Taguchi[1], Y. Urata[1], G. Izumi[1], M. Takamura[1], M. Harada[1], T. Hirata[1], Y. Hirota[1], T. Fujii[1], Y. Osuga[1]
[1]*The University of Tokyo, OBGYN, Tokyo, Japan*

Study question: How much proportion of vitamin D (VD) deficiency among patients with endoetriosis? Does VD have the anti-inflammatory and anti-proliferative effects on endometriosis *in vitro*?
Summary answer: VD deficiency was associated with the progression of endometriosis. On endometriotic stromal cells (ESC), VD had an anti-inflammatory effect: repressing the production of cytokine, PGE_2, and the expression of its synthesis/degradative enzymes, and VD also showed an anti-proliferative effect. These effects were suggested to be mediated through NFkB activation pathway.
What is known already: Endometriosis is a chronic inflammatory disease and controlling its inflammation and immune responses can be a therapeutic strategy. VD is known to modulate the immune system and associations between VD deficiency and disease risks have been reported in many chronic inflammatory diseases. Regarding endometriosis, the circulating level of VD is controversial, and only one *in vivo* mouse study demonstrated that the VD receptor agonist reduced endometriosis by inhibiting peritoneal inflammation.
Study design, size, duration: Under informed consents, sera were taken from control ($n = 37$), patients with stage 1-2 ($n = 17$) and stage 3-4 ($n = 22$) endometriosis. All samples were collected from October to March, from 1998 to 2014. Endometriosis tissues were obtained from ovarian endometriomas ($n = 35$) for ESC isolation.
Participants/materials, setting, methods: Serum 25-(OH)VD, 1,25-$(OH)_2VD_3$ were measured by RIA. ESC were stimulated with IL-1β and VD (1,25$(OH)_2D_3$). RT-PCR, ELISA and Western blotting were used to measure IL-8 and PGE_2 synthesis/degradative enzyme mRNA expression, IL-8 and PGE_2 productions and IkBα expression respectively. Cell proliferation was analyzed by BrdU incorporation and Cell Counting Kit-8.
Main results and the role of chance: Serum 25-(OH) VD level in stage 3-4 endometriosis (17.2 ± 1.1 ng/ml) was significantly lower than control (21.8 ± 1.3 ng/ml, $p < 0.05$) and stage 1-2 endometriosis (21.5 ± 1.4 ng/ml, $p < 0.05$). Serum 1,25-$(OH)_2$ VD_3 levels were not different among groups. VD (10^{-7} M) reduced IL-1b (5 ng/mL) -induced IL-8 mRNA expression at 6 h ($p < 0.05$), and IL-8 production ($p < 0.05$). VD reduced IL-1β-induced PGE_2 secretion ($p < 0.05$), and IL-1β-induced PGE2 synthesis (COX-2, mPGES-1 and mPGES-2) and degradative (15-PGDH) enzyme mRNA expression ($p < 0.05$). VD decreased the number of ESC to 84.0% ($p < 0.05$) and BrdU incorporation to 73.5% ($p < 0.05$), but VD did not affect apoptosis. VD significantly decreased TNF-α increased IkBα in endometriosis ($p < 0.05$).
Limitations, reason for caution: Although the number of patients is not large enough to obtain conclusive results, the data showed striking evidences that VD deficiency may cause endometriosis. Serum VD level may be influenced by races and the duration of sunshine, and our results can not be generalized to other population than Japanese women.
Wider implications of the findings: Our results showed that VD deficiency is associated with the progression of endometriosis and VD has anti-inflammatory and anti-proliferative effects on endometriosis, which may be mediated through NFkB activation pathway. Current medical treatment for endometriosis is limited to hormonal agents and cannot be used for women who wish to conceive. Our study suggest that VD: a natural substance in the body that do not affect female hormonal milieu, could be an alternative medicine for preventing or controlling endometriosis.

P-343 Endometrial volume measurement in prediction of IVF/ICSI outcome

F. Ahmadi[1], F. Akhbari[1]
[1]*Royan Institute, Department of Reproductive Imaging At Reproductive Biomedicine Research Center Royan Institute For Reproductive Biomedicine ACECR Tehran Iran., Tehran, Iran*

Study question: To investigate the role of estimating endometrial volume, on the day of hCG, in prediction of IVF outcome.
Summary answer: The findings of the present study suggest that, analysis of endometrial volume on the day of the hCG administration had no predictive value for conception in IVF cycles.
What is known already: Successful implantation in ART cycles depends on multiple factors among which is endometrial receptivity, one of them is endometrial volume. Some studies reported relationship between endometrial volume on the day of hcg administration and positive pregnancy rate and some others say not.
Study design, size, duration: In this prospective study endometrial volume were measured in 167women undergoing an IVF/ICSI cycle, on the day of HCG,(between 2009 and 2011).
Participants/materials, setting, methods: In this prospective study endometrial volume were measured in 167women undergoing an IVF/ICSI cycle, on the day of HCG,(between 2009 and 2011). Using eXtended Imaging Virtual Organ Computer-aided Analysis (3D XI VOCAL) method volume was digitally manipulated to display a multiplanar view in longitudinal view of the endometrium in order to obtained the images manually in 10 sections, which showing simultaneously three orthogonal planes (axial, longitudinal, and coronal).Patients were divided into 3 groups, according to endometrial volume calculated. Group 1endometrial volume < 2cc, Group 2 with endometrial volume of 2-4.5cc, and Group 3 with endometrial volume > 4.5cc.
Main results and the role of chance: The study included 167 women with no significant difference in background characteristics between all subgroups. The overall pregnancy rate was 39.8%. Participant's age ranged from 20-38 year old and the mean age was 29.9 ± 4.23. Pregnancy rates between the three groups of endometrial volume was 26.7%,37.8% and 50% in group 1,2 and 3 respectively. Although there is no statistically significant difference between positive pregnancy rate and endometrial volume, likelihood ratio of pregnancy in group 3 is higher than another two groups.
Limitations, reason for caution: More sample size with balanced size in three groups is more valuable for analysing the data.
Wider implications of the findings: Further study with larger sample size is needed.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Imaging department of Royan institute.
Trial registration number: NA.
Keywords: pregnancy rate, IVF, endometrial volume

P-344 In silico, in vitro and in vivo analysis identifies a potential role for steroid hormone regulation of FOXD3 in endometriosis associated genes

D. Mathew[1], J. A. Drury[1], A. J. Valentijn[1], O. Vasieva[2], D. K. Hapangama[2]
[1]*Liverpool Women's Hospital, University Department of OB/GYN, Liverpool, United Kingdom*
[2]*Institute of Integrative Biology, University Department of Biosciences, Liverpool, United Kingdom*

Study question: Can bioinformatics analysis of publically available microarray datasets be utilised in identifying potentially important transcription factors (TF) in the hormonal regulation of the endometrium?
Summary answer: We have predicted a central role for the novel transcription factor, FOXD3 in secretory phase/endometriosis by bioinformatics analysis of endometrial microarray datasets, and confirmed its presence for the first time in healthy human endometrium; demonstrated that FOXD3 is differentially expressed in endometriosis and regulated by progesterone *in-vivo and in-vitro*.
What is known already: The reported endometriosis-associated endometrial aberrations are confined to the progesterone-dominant secretory phase and progesterone-resistance is a proposed causative factor. Bioinformatics is used to collate gene expression data to identify the key players in a disease process.
Study design, size, duration: The study was initially an '*in-silico*' study, with confirmatory 'wet lab' data. Endometrial samples from women with (n = 30) or without (n = 30) endometriosis not on hormonal therapy, 20 women with endometriosis treated with Mirena™-IUS and ectopic endometriosis lesions from 9 women were also analysed. Ishikawa endometrial cell line was also used.
Participants/materials, setting, methods: Initial mining and Bioinformatic analysis of microarray datasets identified key transcription factors, and FOXD3 expression levels were examined in human endometrial samples by western blotting (WB), immunohistochemistry (IHC), and PCR. The progesterone regulation of endometrial FOXD3 levels was examined *in vivo* and in a cultured human endometrial cell-line *in vitro*.
Main results and the role of chance: Initial mining and subsequent bioinformatics analysis of human endometrial microarray datasets identified FOXD3 to be a key regulator of gene expression specific to secretory phase/endometriosis. FOXD3 was dynamically expressed in healthy endometrium and differentially expressed in endometriosis. Progestagen (Levonorgestrel) treatment reduced the high endometrial FOXD3 protein ($p < 0.01$) and mRNA levels seen in untreated women with endometriosis, with a shift of epithelial FOXD3 from the nucleus to the cytoplasm. Treatment of Ishikawa cell-line with Medroxyprogesterone acetate for 72 h also down-regulated FOXD3 mRNA and protein.
Limitations, reason for caution: The quality of Bioinformatics analysis and results depends on the published micro-array data. The wet laboratory experiments are only descriptive without functional analysis of FOXD3 in the establishment of endometriosis.
Wider implications of the findings: FOXD3 in endometrium is regulated by progesterone and an in depth analysis of FOXD3 might provide insights into proliferative disorders of the endometrium.
Study funding/competing interest(s): Funding by University(ies) – Funding by hospital/clinic(s) – Funding by national/international organization(s).

P-345 Analysis of transcriptional expression of extracellular proteins in the endometrial stromal or epithelial cells during estrus

S. T. Lee[1], H. J. Park[1], M. H. Park[1], N. R. Han[1], M. S. Kim[1], J. I. Yun[1]
[1]*College of Animal Life Sciences, Kangwon National University, Chuncheon, South Korea*

Study question: To date, development of non-cellular niche has been not reported in endometrial stromal (ES) and epithelial (EE) cells. Therefore, as a basic study for constructing endometrial non-cellular niche, we analyzed transcriptional expression of extracellular proteins in the ES and EE cells, respectively.
Summary answer: We could identify type of extracellular proteins showing significant transcriptional up-regulation in ES and EE cells.
What is known already: ES and EE cells consisting of endometrium experience a variety of alterations during the estrus cycle by lots of hormones secreted in the sexual organs. Simultaneously, this hormonal regulation makes it difficult to investigate precisely effects of a specific treatment on ES and EE cells. Accordingly, construction of artificial endometrium using non-cellular niche of ES and EE cells is requested for eliminating chaotic treatment effects detected in the implantation-related studies.
Study design, size, duration: This study was designed prospectively. Post-isolation of ES and EE cells from mouse uterus, expression of extracellular proteins, including extracellular matrix-, cell-to-cell interaction- and integrin-related proteins, were investigated transcriptionally. All experiments were independently replicated 5 times.
Participants/materials, setting, methods: ES and EE cells were isolated enzymatically from 6-weeks-old ICR female mouse uterus in estrus phase and transcriptional level of extracellular matrix-, cell-to-cell interaction- and integrin-related proteins was measured by real-time PCR.
Main results and the role of chance: In case of extracellular matrix-related proteins, ES and EE cells showed significant increase in the expression of 4 (*FN*, *NID*, *ColI*, and *ColIII*) and 7 (*FN*, *NID*, *LN*, *TN*, *ColI*, *ColIII*, and *ColV*) genes, respectively. Moreover, in the cell-to-cell interaction-related proteins, significant increase of 4 (*Cdh2*, *Cdh3*, *Icam1* and *Pecam1*) or 3 (*Cdh1*, *Icam1* and *Pecam1*) genes transcription were observed in ES or EE cells. Finally, transcriptional level of 5 integrin alpha (*Itga2*, *Itga5*, *Itga6*, *Itga9* and *ItgaV*) and 3 integrin beta subunit genes (*Itgb1*, *Itgb3* and *Itgb5*) were significantly increased in ES cells, whereas EE cells showed significant transcriptional up-regulation of 6 integrin alpha (*Itga2*, *Itga5*, *Itga6*, *Itga7*, *Itga9* and *ItgaV*) and 5 integrin beta subunit genes (*Itgb1*, *Itgb3*, *Itgb4*, *Itgb5* and *Itgb6*).

Limitations, reason for caution: Based on these transcriptional expressions, studies on translational expression of extracellular proteins should be progressed further in order to confirm precisely type of extracellular proteins expressed in ES and EE cells.
Wider implications of the findings: These results will contribute greatly to develop non-cellular niche mimicking microenvironment of endometrium.
Study funding/competing interest(s): Funding by national/international organization(s) – This study was supported by a grant of the Korea Health Technology R&D Project (A121515-1201-0000100), Ministry of Health and Welfare, Republic of Korea.
Trial registration number: NA.
Keywords: extracellular proteins, transcriptional level, endometrial stromal cells, endometrial epithelial cells

P-346 Personolized embryo transfer (pET) after Endometrial Receptivity Array (ERA) in patients with recurrent implantation failure –an observational study

G. Arikan[1], N. Findikli[2], E. Yagmur[1], G. Karlikaya[1], M. Gultomruk[3], M. Bahceci[1]
[1]*Bahceci Fulya ART Centre, Infertility Clinic, Istanbul, Turkey*
[2]*Bahceci Fulya ART Centre, Embryology Laboratory, Istanbul, Turkey*
[3]*Bahceci Fulya ART Centre, R&D Laboratory, Istanbul, Turkey*

Study question: This observational study has been performed in order to determine the state and the impact of window of implantation (WOI) determined by endometrial receptivity array (ERA) on clinical outcome in patients with recurrent implantation failure (RIF).
Summary answer: Our results indicate that 1/3rd of the RIF patients (34%) in our study has displaced WOI which can be attributed for their reproductive failure. Assessing WOI before an ART cycle could help the clinician to address the nature of the problem as well as possible treatment strategies in such patients.
What is known already: Recurrent implantation failure is a poorly characterized and defined outcome with a wide spectrum of pathologies. While many of these pathologies can be corrected, the underlying implantation problem due to a possible molecular asynchrony of embryo-endometrium interactions can still remain. A microarray-based molecular diagnostic test, called as Endometrial Receptivity Array has been developed to detect such synchronies and, based on ERA results to determine personalized embryo transfer (pET) day in order to maximize the clinical outcome.
Study design, size, duration: This observational study was performed between November 2013 – December 2014. ERA test was offered to candidate patients with ≥ 2 previous IVF failures with no observed endocrinological or uterine pathologies.
Participants/materials, setting, methods: For those who accepted the test (n = 78), an endometrial tissue sampling has been taken during natural cycle (7 days after LH surge) or 5 days after progesterone replacement has commenced during hormone replacement therapy cycles. Biopsied tissue samples were stored, shipped and processed for RNA expression analysis according to the manufacturer's recommendations. According to the ERA test results, blastocyst-stage frozen embryo transfers were performed in 40 patients.
Main results and the role of chance: A total of 90 ERA tests were performed in 78 patients. In 83 of 90 samples (90%), valid RNA was obtained for analysis. There were no intra or port-operative complications. Twenty eight patients has a non-receptive (pre- or post-receptive) endometrium at the day of endometrial biopsy (34%). In 40 frozen embryo transfers that were performed according to ERA results, 20 gestations were achieved (50%). The rate of gestation remained the same in the subgroup of patients who had pET due to displaced WOI.
Limitations, reason for caution: The main limitation is the number of patients that were included in the study. As the number of cases included in this study as well as other studies are increased, the significance and the possible impact of ERA test-based pET programs can be assessed and validated in more realistic clinical scenarios.
Wider implications of the findings: Our results, being in parallel with the limited number of reported cases in the current literature, can indicate that assessment of endometrial receptivity prior to a frozen embryo transfer cycle can be beneficial for clinical outcome in cases with RIF.
Study funding/competing interest(s): Funding by hospital/clinic(s) – This study received no funding and there are no conflicts of interests to be declared.
Trial registration number: NA.
Keywords: endometrial receptivity, personalized embryo transfer, recurrent implantation failure

P-347 Cytokines related with implantation window can be increased with Metformin treatment in endometrial stromal cells on hyperinsulinemic and hyperandrogenic environment

S. Weber[1], A. B. Machado[2], G. D. Ferreira[2], T. Strowitzki[1], A. Germeyer[1], H. V. E. Corleta[3], I. S. Brum[2], E. Capp[2]
[1]*Universitätsklinikum Heidelberg, Frauenklinik, Heidelberg, Germany*
[2]*Universidade Federal Do Rio Grande Do Sul, Physiology, Porto Alegre, Brazil*
[3]*Hospital De Clínicas De Porto Alegre, Gynecology, Porto Alegre, Brazil*

Study question: Evaluate the effects of Metformin on IL-8 and IL-1β gene expression in a model of hyperinsulinemia and hyperandrogenism in endometrial stromal cells *in vitro*.
Summary answer: Metformin increases IL8 and IL1b gene expression levels in hyperinsulinemia and hyperandrogenism in endometrial stromal cells.
What is known already: The preparation of the endometrium for implantation involves a complex sequence of events and a variety of signaling molecules. The concentrations of IL-8 and IL-1β are correlated to the implantation process. The failure rate of this process is high in PCOS patients that affects from 6 to 8% of women in reproductive age. Despite the uncertainty about the primary cause of PCOS, there are reports about the importance of hyperinsulinemia and hyperandrogenism in infertility promoting.
Study design, size, duration: The present study was an experimental study in vitro. The endometrial cells were obtained from patients undergoing hysterectomy. We analyzed seven (N = 7) primary cultures of endometrial stromal cells with hyperinsulinemic and hyperandrogenic environment during 14 days in 24 and 48 h of Metformin treatment.
Participants/materials, setting, methods: The stromal cells were cultivated: (EP) estradiol, progesterone; (EPM) estradiol, progesterone, 10^{-3} M metformin; (EPI) estradiol, progesterone, 100 ng/mL insulin; (EPD) estradiol, progesterone, 10^{-6} mol/L dihydrotestosterone; (DI) estradiol, progesterone, insulin, dihydrotestosterone; (DIM) estradiol, progesterone, insulin, dihydrotestosterone, metformin. The IL-8 and IL1b gene expression was evaluated by real time PCR.
Main results and the role of chance: Increased gene expression of IL-8 was observed in EPM group treated for 48 h compared to the same group treated for 24 h (P < 0,05). Similarly, the EPM group showed higher IL-1b gene expression compared to all other groups treated with metformin for 48 h (P < 0.05). However, the DIM group, also metformin treated, did not show statistically significant difference in treatment time of any studied genes. It suggests an inhibitory action of insulin on these genes expression in the hyperinsulinemic and hyperandrogenic groups.
Limitations, reason for caution: These results are regarding to cell cultures, therefore physiologic influences were not measured.
Wider implications of the findings: Similarly to other results we have demonstrated higher interleukins genes expression when cells were treated with Metformin, not only in an hyperinsulinemic environment, but also in an hyperandrogenic environment. Additionally, our study demonstrated that even if acute treatment were carried out (24 h), there was higher IL8 gene expression.
Study funding/competing interest(s): Funding by University(ies) – Funding by hospital/clinic(s) – Universitätsklinikum Heidelberg, Universidade Federal do Rio Grande do Sul, Hospital de Clínicas de Porto Alegre.
Trial registration number: NA.

P-348 Intrafollicular iron and ferritin in women with ovarian endometriomas

A. Mangiarini[1], L. Benaglia[1], A. Paffoni[1], L. Restelli[1], C. Guarneri[1], N. Bettinardi[2], E. Somigliana[1]
[1]*Fondazione Ca' Granda Ospedale Maggiore Policlinico, Infertility Unit, Milan, Italy*
[2]*Fondazione Ca' Granda Ospedale Maggiore Policlinico, Central Laboratory, Milan, Italy*

Study question: to evaluate whether iron contained in ovarian endometriomas may diffuse through the cyst wall to follicular fluids and affect ovarian function.
Summary answer: Iron content did not differ in follicular fluids belonging to ovaries with and without endometriomas, while ferritin concentration resulted significantly higher in affected gonads compared to controls.
What is known already: Endometriotic cysts contain huge amount of free iron that can mediate the production of Reactive Oxygen Species (ROS) potentially harmful to the surrounding cells. The amount of oxidative stress in the ovarian cortex surrounding an endometrioma and in granulosa cells from patients with endometriosis was shown to be higher compared to controls. It has been hypothesized that factors present in the endometriomas, and iron in particular, may diffuse in the surrounding tissue causing ROS generation.
Study design, size, duration: A prospective case series, between January 2012 and January 2013. Sample size was decided considering as biologically relevant an Odds Ratio of having levels of iron/ferritin in the affected gonad above the 90th percentile of the distribution in the intact gonad ≥ 3. On these bases, thirty-nine women were recruited.
Participants/materials, setting, methods: Women undergoing IVF/ICSI with unilateral ovarian endometriomas (≥ 10 mm) at transvaginal ultrasound the month preceding the stimulation; age 18-42 years; absence of non-endometriotic ovarian cysts. Iron and ferritin were measured on an automatic platform in pools of follicular fluids obtained from affected and contralateral intact gonads.
Main results and the role of chance: The median (IQR) concentration of iron in the affected and unaffected ovaries was 59 (44-74) and 59 (47-73) µg/dL, respectively ($p = 0.77$). The median (IQR) concentration of ferritin was 57 (31-146) and 33 (23-67) µg/mL, respectively ($p = 0.026$). Ferritin concentration was above the 90th percentile of the distribution in unaffected ovaries (132 µg/mL) in 3 (8%) intact and 11 (28%) affected gonads ($p = 0.021$). No differences emerged when considering iron. Follicular concentration of iron correlated between the two ovaries (Rho = 0.76, $p < 0.001$). A similar figure emerged for follicular ferritin (Rho = 0.55, $p < 0.001$). A significant correlation was documented when correlating ferritin and iron in the 78 available gonads (Rho = 0.42, $p < 0.001$). No statistically significant correlations emerged between follicular iron and ferritin and variables reflecting ovarian responsiveness and oocyte developmental competence.
Limitations, reason for caution: We lack an histological diagnosis of endometriosis but his limitation is of scanty relevance given the high accuracy of transvaginal ultrasound. We exclusively recruited women with indication to IVF. Inferences of our findings to the whole population of women with ovarian endometriomas should therefore be made with caution.
Wider implications of the findings: Iron may diffuse from ovarian endometriomas into the adjacent ovarian tissue. However, this phenomenon does not markedly affect ovarian function because of some effective biological mechanisms such as ferritin storage that properly counterbalance the potentially highly detrimental effects of free iron.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Fondazione IRCCS Ca' Granda.
Trial registration number: NA.
Keywords: endometrioma, endometriosis, follicular fluid, iron, ferritin

P-349 sperm oviduct interaction in the human – new insights using live cell imaging

B. Hughes[1], S. Koelle[1]
[1]*University College Dublin, School of Medicine, Dublin, Ireland*

Study question: How do spermatozoa interact with the oviductal epithelium under near in vivo conditions?
Summary answer: Only spermatozoa with high membrane integrity bind to the cilia of the oviductal epithelium. As soon as sperm quality is impaired by a disruption in general health, sperm binding is also impaired. Inflammation of the fallopian tube also results in decreased sperm binding.
What is known already: In animals spermatozoa form a sperm reservoir in the isthmus by binding with their head to the cilia of the uterine tube. Thus they maintain their capacity to fertilize for days (most mammals), months (birds) or even years (reptiles). Due to the lack of imaging technologies for investigating the human fallopian tube under *in vivo* conditions, the sperm oviduct interaction has not been investigated in the human fallopian tube up to now.
Study design, size, duration: Using a digital video microscopic system, this pre-clinical randomized study was designed to characterize the human sperm-oviduct interaction under near *in vivo* conditions. Experiments were performed, over 9 months, on the ampulla and isthmus of 5 premenopausal women undergoing hysterectomy and in one pregnant woman undergoing caesarean section.
Participants/materials, setting, methods: The fallopian tubes of the premenopausal women and the pregnant woman were investigated immediately after surgery. Ampulla and isthmus with and without co-incubation with a) fresh and b) frozen thawed spermatozoa were examined qualitatively and quantitatively using a digital video microscopic analysis system and scanning electron microscopy (SEM).
Main results and the role of chance: Human spermatozoa bind to the epithelial cells of the fallopian tube as soon as they enter the oviduct. This binding capacity is not confined to the isthmus – it also takes place in the ampulla. Where there is a disruption in general health, e.g., inflammatory joint disease, sperm binding is impaired. Similarly inflammations of the fallopian tube, which in most cases are only seen microscopically, reduce sperm binding and sperm survival time. Accumulations of mucus in the fallopian tube, which may be drug related, result in the 'sticking' of sperm and thus decreased sperm vitality.
Limitations, reason for caution: Medications and in particular hormones influence the sperm oviduct interaction and have to be taken into account.
Wider implications of the findings: Our studies show movies of the human sperm oviduct interaction for the first time, under near *in vivo* conditions. The fact that only spermatozoa of high quality are able to bind to the oviduct point to it playing a pivotal role in sperm selection. Impairments in general health, both in male and in female result in reduced sperm binding and survival time- a major cause of decreased fertility.
Study funding/competing interest(s): Funding by University(ies) – School of Medicine, University College Dublin, Ireland.
Trial registration number: NA.
Keywords: human, sperm, fallopian tube

P-350 Review of performance of patients with endometriosis in in-vitro-fertilisation (IVF) as compared to tubal factor infertility-Retrospective Cohort study

M. Bapir[1], H. Mostafa[2]
[1]*The James Cook University Hospital, Obstetric and Gynaecology, Middlesbrough, United Kingdom*
[2]*North Tees and Hartlepool NHS Foundation Trust, Obstetric and Gynaecology, Stockton-on-Tees, United Kingdom*

Study question: To compare the performance of patients with endometriosis related infertility in IVF to patients with tubal factor infertility.
Summary answer: In comparison to tubal factor infertility, patients with endometriosis perform well in IVF with a reasonable clinical pregnancy rate, comparable implantation rate and number of good quality embryos generated.
What is known already: There is debate in the studies about IVF performance in endometriosis patients. Some studies are quoting reduced pregnancy rate and poor quality embryo in patients with endometriosis. However, data emerging from larger database such as human fertilisation and embryology authority (HFEA) suggests better performance.
Study design, size, duration: Retrospective review of the women undergoing IVF treatment between January 2012 to December 2013 in the assisted reproductive unit (ARU) at Hartlepool university Hospital. 41 patients with endometriosis were identified and compared to 321 patient with tubal factor infertility matched for age and duration of infertility.
Participants/materials, setting, methods: Endometriosis was confirmed by laparoscopy and staging following the American Society for Reproductive Medicine (ASRM), 73% minimal to mild endometriosis and 27% moderate to severe. The outcome measures were clinical pregnancy, implantation, embryo quality, on going pregnancy and multiple pregnancy rates. Statistical analysis was completed using GraphPad Prism ® 2015.
Main results and the role of chance: There was no statistically significant difference between the two groups regarding the clinical pregnancy rate per cycle started (*P*: 0.53, Relative Risk (RR): 0.83, 95% Confidence Interval (CI): 0.52–1.3), per cycle completed (*P*: 0.63, RR 0.87, 95% CI: 0.55–1.4), Implantation rate (*P*: 0.10, RR: 1.4, 95% CI: 0.96–2.1), miscarriage rate (*P*: 1.00, RR: 0.74, 95% CI: 0.10–5.2), ongoing pregnancy rate (*P*: 1.00, RR: 0.97, 95% CI: 0.61–1.5), and Twin pregnancy rate (*P*: 0.64, RR: 1.4, 95% CI: 0.37–5.5).

Endometriosis patients had a comparable percentage of good quality embryos (Grade 1 and 2) generated (83% versus 80%).

Limitations, reason for caution: The study is retrospective in nature. The sample size of endometriosis group is small as compared to the tubal factor group; however, all the patients were diagnosed with Laparoscopy. We also identified an unequal distribution of the severity of endometriosis in the study group.

Wider implications of the findings: The findings from our study suggest that women with endometriosis perform fairly well in IVF in term of embryo quality, implantation, and multiple pregnancy rates as compared to women with tubal factor infertility. Clinical pregnancy and ongoing pregnancy rates in endometriosis patients are lower but not statistically different from patients with tubal factor infertility.

Study funding/competing interest(s): Funding by hospital/clinic(s) – North Tees and Hartlepool NHS Foundation Trust.

Trial registration number: This study was registered with clinical audit department (CG 156).

P-351 miRNA expression of the endocervix as a biomarker for endometrium receptivity in patients undergoing assisted reproductive technologies

F. P. Rodrigues[1], T. C. S. Bonetti[2], F. Vigo[2], C. V. Carvalho[2], R. Fraietta[3], E. L. A. Motta[4]

[1]*Huntington – Reproductive Medicine/Gynecology Department of Federal University of Sao Paulo, Clinical/Gynecology-Endocrinology Discipline, São Paulo, Brazil*

[2]*Gynecology Department of Federal University of Sao Paulo, Gynecology-Endocrinology Discipline, São Paulo, Brazil*

[3]*Urology Department of Federal University of Sao Paulo, Human Reproduction Sector, São Paulo, Brazil*

[4]*Huntington – Reproductive Medicine/Gynecology Department of Federal University of Sao Paulo, Head of Clinical/Gynecology-endocrinology Discipline, São Paulo, Brazil*

Study question: To compare the miRNA expression in the endocervix and the endometrium during implantation window in patients undergoing *in vitro* fertilization (IVF) treatment? Could endocervix miRNA expression be a new less-invasive method to assess the implantation window of infertile patients undergoing *in vitro* fertilization (IVF) treatments?

Summary answer: The miRNA expression in endocervix was not totally concordant with the endometrium in infertile patients during the implantation window. However, we identified five microRNAs differentially expressed in both the endometrium and in the endocervix in patients who became pregnant and may be considered potential candidates for biomarkers of endometrium receptivity.

What is known already: Despite of high technology used to IVF treatments, the function of endometrium remains little explored in the assisted reproductive field. The endometrial gene expression has been recently used to identify the implantation window. miRNA are small molecules and may act as a post-transcriptional gene expression regulator. Endometrial biopsy constitutes an invasive method and cannot be applied to an ongoing cycle. Biomarkers for endometrial receptivity in the endocervix could represent a less-invasive approach and may be performed during the IVF treatment.

Study design, size, duration: This prospective cohort study included 32 good prognosis infertile women undergoing fresh IVF treatment cycles using standard conventional protocol, at an University Center from July 2012 to December 2013.

Participants/materials, setting, methods: Women candidates to IVF treatment underwent an endometrial biopsy and endocervical brush during the luteal phase (implantation window) in the menstrual cycle prior to IVF treatment. The endometrial and endocervix samples were submitted to RNA purification and were analyzed by miRNA PCR-array (miScript miRNA PCR Array, Qiagen).

Main results and the role of chance: It is interesting to note that among 86 miRNA evaluated, 14 miRNA were significantly downregulated in the endocervix in relation to endometrium, 11 miRNA were significantly upregulated in the endocervix in relation to endometrium, and 61 miRNA were similar between two kind of samples. We can suppose that about one-third of miRNA evaluated were differentially expressed between endometrium and endocervix, and hence, endocervix miRNA expression does not accurately represent the endometrium. On the other hand, when comparing pregnant and non-pregnant patients, pregnant patients revealed five miRNA downregulated in endometrium and upregulated in endocervix. So, those miRNA in the endocervix, could represent, in an inverse way, a possible new biomarker profile of implantation window, since the endocervical cells are not suitable for invasion. If the efficiency of those markers would be proved, it is also possible to perform the exam during the cycle.

Limitations, reason for caution: This study is a screening of miRNA expression in endometrium and endocervix of infertile patients undergoing IVF cycles in a limited sample size. The concordant miRNA expressed can represent a biomarker profile in the endocervix, and must be validated in a higher number of samples in an ongoing cycle.

Wider implications of the findings: Considering that human endometrial study constitutes an invasive method for embryo implantation assessment and cannot be applied to an ongoing cycle, this study offers endocervix miRNA expression as a less-invasive possible marker for implantation window. It may have wide implication in clinical practice and could be a decisive factor for either transferring embryos in same cycle and cryopreserving them and postponing transfer to subsequent cycle if endometrium is not well prepared.

Study funding/competing interest(s): Funding by national/international organization(s) – This study was funded by "Fundação de Amparo à Pesquisa do Estado de São Paulo", Brazil (FAPESP) Proc. number 2012/16911-0. There is no interest conflict related to this study.

Trial registration number: NA.

P-352 Ethanol sclerotherapy of ovarian endometriomas before IVF: long term data on safety and efficacy

C. Yazbeck[1], S. Cohen Scali[1], A. L. Margulies[1], S. Falcone[1], V. Kahn[1], C. Gout[1], C. Patrat[1], D. Luton[1], P. Madelenat[1]

[1]*Bichat Claude Bernard University Hospital, Obstetrics Gynecology and Reproductive Medicine, Paris, France*

Study question: To evaluate long-term safety and efficacy of ethanol sclerotherapy (EST) in the treatment of ovarian endometriosis before IVF.

Summary answer: EST of endometriomas appears to be a safe procedure associated with a low recurrence rate and a good fertility outcome.

What is known already: Conventional surgical treatment of endometriomas may decrease ovarian reserve and response to subsequent fertility treatments. This is particularly true in patients with advanced stage endometriosis, who have had multiple previous ovarian surgeries. In recent years, minimal invasive techniques like ethanol sclerotherapy were developed to minimize the effect of surgery on ovarian tissue. However, reports on safety and efficacy are still lacking.

Study design, size, duration: A prospective cohort study was conducted from October 2004 to December 2014, including a total number of 107 patients undergoing 129 ethanol sclerotherapy procedures. The mean follow-up period was about two years (range from 0.5 to 7.5 years). Six patients were lost to follow-up.

Participants/materials, setting, methods: Candidates for IVF presenting with severe endometriosis and one to four endometriomas with a large diameter of 25 to 65 mm, were included in the study. After 12 days of pituitary desensitization by GnRH agonists, EST was performed in an outpatient basis and ovarian stimulation was started 15 days later.

Main results and the role of chance: The mean patients' age was 33.2 years. The mean diameter of endometrioma was 44.6 mm. The procedure was successful in 95.4% of cases, and was globally well tolerated (visual analog scale of 2.9) under local anesthesia. We did not observe any major complication (infection, hemorrhage, ...), and all cysts' fluid cytologies were benign.

Recurrence rate, defined on ultrasound as a cystic image of more than 20 mm on the previously treated ovary, was estimated at 7.0% (8/115) on the 3-months' visit and at 13.8% (16/116) at the end of follow-up. Risk factors for recurrence were analysed by a Cox proportional hazards model. Pregnancy rate was 45.6% (36/79) after the first cycle of IVF and cumulative pregnancy rate at 1 year was 64.4% (47/73), including nine spontaneous pregnancies.

Limitations, reason for caution: Follow-up period which varied between patients and cases lost to follow up might underestimate recurrence rate. Analysis of survival data accounting for censored observations was consequently done.

Wider implications of the findings: This is one of the biggest series of EST in women undergoing fertility treatments. Results on safety and efficacy encourage us to consider this treatment as an alternative option to conventional surgery prior to IVF in future randomized trials.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Authors declare no competing interests. Data collection and analysis was funded by the obstetrics and gynecology department of Bichat Hospital.
Trial registration number: NA.

P-353 Correlation between the ultrasound elastographic features of endometriotic rectovaginal nodules infiltrating the rectum and symptoms

N. Bizzarri[1], V. Ghirardi[1], I. Erasmo[1], F. Sozzi[1], A. Racca[1], S. Ferrero[1]
[1]*IRCCS San Martino Hospital and National Institute for Cancer Research University of Genoa, Obstetrics and Gynaecology Unit, Genova, Italy*

Study question: Do the elastographic features of endometriotic rectovaginal nodules infiltrating the rectum correlate with symptoms?
Summary answer: The stiffness of endometriotic rectovaginal nodules infiltrating the rectum assessed by elastography correlates with the intensity of dyschezia and the severity of intestinal symptoms.
What is known already: Transvaginal ultrasonography has high specificity and sensitivity in diagnosing rectovaginal nodules infiltrating the rectum. No data is available on the elastographic features of these nodules.
Study design, size, duration: This prospective study was performed between June 2014 and December 2014 and included 16 patients with rectovaginal nodules infiltrating the rectum diagnosed by transvaginal ultrasonography. A standard ultrasonography machine (Voluson E6, GE Healthcare) equipped with transvaginal probe and software for elastography was used.
Participants/materials, setting, methods: Patients with previous surgery for bowel endometriosis and those under hormonal therapies were excluded from the study. The elastograms were classified into 5 patterns according to the distribution of the blue area in the nodule (from score 1, low stiffness to score 5, high stiffness).
Main results and the role of chance: The mean (±SD) age of the study population was 33.3 (±6.2) years. The mean largest diameter of the endometriotic nodule was 27.8 (±7.8 mm); the mean volume of the nodule was 6.6 (±5.1) cm^3. The mean intensity of dyschezia (measured on a VAS scale) was 4.2 (±2.4) cm. The mean total gastrointestinal symptoms score was 28.6 (±15.7) cm. The elasticity score was ≤3 in 5 patients, 4 in 4 patients and 5 in 7 patients. The elasticity score was significantly correlated with the intensity of dyschezia (Spearman's correlation coefficient = 0.839; $p = 0.01$) and with the gastrointestinal symptoms score (Spearman's correlation coefficient = 0.774; $p = 0.01$).
Limitations, reason for caution: Only patients with rectal nodules were included in the study; therefore, the findings of this study cannot be applied to patients with endometriotic nodules located in other bowel segments. Another limitation of this study is the small sample size.
Wider implications of the findings: If the findings of this study will be confirmed by larger investigations, elastography should be introduced in the ultrasonographic evaluation of rectal endometriotic nodules. Future studies should assess the changes in the elastographic features of these endometriotic nodules during hormonal therapies.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Piazza della Vittoria 14 S.r.l.
Trial registration number: NA.

P-354 Old and new "protagonists" on the ultrasound "scene" for the diagnosis of deep pelvic endometriosis: evidence-based algorithm based on systematic literature review and meta-analysis

M. Quaranta[1], S. Gizzo[2], M. Noventa[2], A. Vitagliano[2], C. Zicchina[2], F. Esposito[2], B. Abdulrahim[3], C. J. Aldrich[3], M. Gangemi[2], G. B. Nardelli[2], A. Andrisani[2], C. Saccardi[2]

[2]*University of Padua, Woman and Child Health, Padua, Italy*
[3]*NHS Trust – Northampton General Hospital, Obstetrics and Gynecology, Northampton, United Kingdom*

Study question: In the suspicion of deep-pelvic-endometriosis (DPE), which is the most appropriate ultrasound technique for diagnosis in each specific anatomical location? Beginning from evidences in literature, is it possible to establish a diagnostic algorithm with relation to the accuracy, reproducibility and required skill/learning-curve of each of the proposed techniques?
Summary answer: Transvaginal sonography (TVS) is an easily reproducible and well tolerated and is widely considered as first line diagnostic technique to evaluate patients with a suspicion of DPE. When TVS is inadequate for diagnosis, second-line "modified techniques" are recommended. However, these techniques, though fascinating, require further validation especially with regards to reproducibility.
What is known already: Evidences have suggested TVS as a good method to identify DPE as it is well accepted and widely available. However, its accuracy is generally lower for an accurate assessment of DPE severity when compared to MRI (magnetic-resonance-imaging). Considering the high prevalence of DPE, a routine MRI to evaluate DPE may not be cost-effective. For this reason, new proposals regarding "modified-technique" rather than "standard-TVS" are emerging to the reach MRI accuracy using ultrasound imaging.
Study design, size, duration: We have performed a Systematic literature review and meta-analysis (interval-time 1998–2004) of all prospective, observational and retrospective studies that provided clear and complete data regarding the sensitivity, specificity, positive/negative predictive value (PPV, NPV), accuracy and likelihood ratio of all ultrasound imaging techniques for the diagnosis and localization of DPE.
Participants/materials, setting, methods: The ultrasound techniques described in this systematic review are TVS, RES (rectal ultrasonography)and "TVS-modified technique" such as SCSV (saline-contrast-sonovaginography), TG-TVS (tenderness-guided-TVS), RWC-TVS (rectal-water-contrast TVS), TVS with bowel preparation, TVS sliding sign. The methodological quality of each study was evaluated with QUADAS-2. The odds-ratio was reported as 95% CI using both random-effect and fixed-model.
Main results and the role of chance: Using our key search strategy 35 manuscripts resulted eligible for systematic review and, of these, 32 were eligible for statistical evaluation. Specificity of TVS technique was greater than 85% for all DPE-sites while sensitivity ranged between 50% (bladder, vaginal-wall and recto-vaginal-septum) and 84% (rectum-sigmoid). Regarding the modified-TVS-techniques, the TG-TVS demonstrated the best accuracy for the diagnosis of bladder lesions. RES and RWC-TVS seems superior to TVS in detecting Recto-sigmoid-endometriosis with a sensitivity and specificity of 92.6 and 95%. Furthermore promising data was reported in the use of RCW-TVS (97.1% sensitivity) and SCVS (84.5% sensitivity) in the assessment of recto-vaginal septum endometriosis While SCVS seems to be the most accurate method for the diagnosis of USL, VW and VF endometriosis, the RES and TVS-sliding sign showed a sensitivity twice higher than TVS in evaluating POD endometriosis.
Limitations, reason for caution: The main limitation of this study is the small sample size of available studies and the lack of confirmed reproducibility of the technique itself. Furthermore, a great number of the "modified techniques" show excellent accuracy in detecting DPE in certain anatomical locations as opposed to others.
Wider implications of the findings: Our data allows us to suggest that TVS-modified techniques and RES should be performed by highly skilled and trained sonographers in a dedicated setting for diagnosis and management of endometriosis. These techniques should be offered when standard TVS is "non-conclusive" in the evaluation and specification of DPE localization. In adequate settings, trained clinicians may offer second level ultrasound-scans with a similar or better accuracy than MRI.
Study funding/competing interest(s): Funding by University(ies) – Authors declare no funding. Authors declare no competing of interest.
Trial registration number: Not required.
Keywords: deep pelvic endometriosis, ultrasound imaging, evidence based medicine, diagnostic accuracy, patient satisfaction

P-355 Concomitant endometriosis in malignant and borderline ovarian tumours

E. Oral[1], S. Ilvan[2], O. Aydin[2], H. Yilmaz[1], B. Kumbak[3], T. Bese[1], F. Demirkiran[1], M. Arvas[1]
[1]*Istanbul University Cerrahpasa Medical School, Obstetrics and Gynecology, Istanbul, Turkey*
[2]*Istanbul University Cerrahpasa Medical School, Pathology, Istanbul, Turkey*
[3]*Istanbul Medipol University Medical School, Obstetrics and Gynecology, Istanbul, Turkey*

Study question: What is the prevalence of concomitant endometriosis in malignant and borderline ovarian tumours?
Summary answer: The prevalence of endometriosis coexisting in women with malignant and borderline ovarian tumours is 7.3%; concurrent endometriosis is seen in 12% of women with borderline ovarian tumours and 6% of those with malignant ones.
What is known already: Clear evidence exists in the literature revealing that endometriosis is strongly linked to ovarian cancer. However, risk increase varies widely among studies. Clinical characteristics of the patients included are different. Moreover, risk factors and clinical utility of this association are ill-defined. On the other hand, counselling and treating women with endometriosis who are at high risk for cancer coexistence or conversion is encouraged.
Study design, size, duration: Retrospective cohort study. A total of 661 patients with malignant and borderline ovarian tumours were recruited between 1995 and 2011.
Participants/materials, setting, methods: A total of 661 patients with borderline and malignant ovarian tumours were evaluated and endometriosis association was sought. Clinical characteristics of patients with endometriosis-associated borderline ovarian tumours were compared to those of endometriosis-associated malignant ones. Clinical characteristics of patients with endometrioid and clear cell ovarian tumours with or without endometriosis were further analysed.
Main results and the role of chance: Forty-eight (7.3%) of the 661 malignant and borderline ovarian tumours had been associated with endometriosis. The most frequently endometriosis-associated subtypes were endometrioid (33%) and clear cell (18%) histologies. Concomitant endometriosis in endometrioid/clear cell carcinoma did not evoke poor prognosis. Of endometriosis-associated endometrioid and clear cell ovarian tumours, 70% were early stage, at younger age and 60% premenopausal. The prevalence of concomitant endometriosis in borderline tumours (12%) was significantly higher than that in malignant ovarian tumours (6%; $p = 0.02$). Of 48 endometriosis cases, 73% were atypical and 27% were typical. Of 32 endometriosis cases associated with malignant ovarian tumours, 69% were FIGO stage I-II and 31% were FIGO stage III. Infertility was noted in 38% of endometriosis-associated ovarian tumours.
Limitations, reason for caution: None.
Wider implications of the findings: The results are in accordance with the literature. Endometriosis association with borderline ovarian tumours is significantly high. Future research is warranted to identify clinical or biochemical tools for borderline ovarian cancer development or association in endometriosis cases.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Istanbul University, Cerrahpasa University Hospital.
Trial registration number: NA.

Study question: Are there any proteomic differences between endometrium of healthy women and PCOS patients?
Summary answer: There is a difference signature between proteome profile of endometrium obtained from normal women and PCOS patients.
What is known already: Endometrial receptivity seems to be the major limiting factor for the success of pregnancy in polycystic ovarian syndrome (PCOS).
Study design, size, duration: This study was a basic proteomic analysis of human endometrial biopsies taken from twelve PCOS patients and twelve healthy fertile women in the proliferative (on day 2 or 3 before ovulation, $n = 6$) and secretory (on day 3–5 after ovulation, $n = 6$) phases.
Participants/materials, setting, methods: In this study, for the first time, a 2-DE based proteomic approach coupled with mass spectrometry was used to identify the changes in whole proteins between PCOS and normal endometrium. We analyzed proteome of endometrium during proliferative ($n = 6$) and luteal phases ($n = 6$) from healthy women and PCOS patients ($n = 12$). To validate this investigation western blot and quantitative real time PCR were performed.
Main results and the role of chance: Out of about 802 ± 10 protein spots reproducible detected on gels, 170 proteins showed different intensities between PCOS, proliferative and luteal endometrium. Mass spectrometry analysis of differentially expressed proteins resulted in identification of 70 proteins involved in cellular metabolism, apoptosis and immunological process. Expression of annexin A5 (ANXA5), 14-3-3 protein, antitrypsina, cathepsin D proteins was validated by western blot. The gene expression profile of these proteins was confirmed by real time PCR. The results obtained in the western blot and real time PCR followed a similar regulation of proteomic analysis.
Limitations, reason for caution: The main limitation of this study is a low number of human endometrial samples for the proteomic analysis.
Wider implications of the findings: This study provide the first insight into the global protein expression in the endometrium of PCOS patients as compared to normal women which might affect endometrial receptivity in women with PCOS.
Study funding/competing interest(s): Funding by national/international organization(s) – This study was financed by Royan Institute.
Trial registration number: NA.

P-357 Interactive impact of metformin, dexamethasone and testosterone on endometrial tissue in vitro

A. Freis[1], T. Renke[2], J. Jauckus[2], T. Strowitzki[2], A. Germeyer[2]
[1]*Heidelberg University Women's Hospital, Department of Obstetrics and Gynecology, Heidelberg, Germany*
[2]*Heidelberg University Women's Hospital, Department of Gynecologic Endocrinology and Fertility Disorders, Heidelberg, Germany*

Study question: What are the effects of androgens and its treatment options (dexamethasone and metformin) on functional changes within endometrial stromal cells.
Summary answer: In our study, we demonstrate that the negative testosterone effects, like reduction of endometrial stromal cell proliferation, can be compensated by dexamethasone in vitro under certain conditions. Furthermore dexamethasone alone augmented stromal cell decidualization and proliferation, while metformin exhibits similar effects as androgens do and fortifies their action.
What is known already: Polycystic ovary syndrome (PCOS) is the most common female endocrine disorder, concerning 5–10 % of all women in reproductive age. Its main features are hyperandrogenism, cycle abnormalities with anovulation and distinct ovarian sonographic features. It is often associated with insulin resistance. Treatment options include dexamethasone, as well as metformin to reduce ovarian hyperandrogenism and to restore ovulation. The impact of these therapeutics on the local microenvironment of endometrial cells however remains to be elucidated.
Study design, size, duration: In order to evaluate effects of various concentrations of these medications in a hyperandrogenic microenvironment we used 13 endometrial biopsies from regularly cycling women without endometrial abnormalities or endometriosis after informed consent.
Participants/materials, setting, methods: Endometrial stromal cells were isolated after enzymatic digestion and cultured with serum containing media. Cells were treated with or without testosterone (T-8, T-6), dexamethasone (D-8, D-6) and metformin (1, 0.1, 0.01 mM), either alone or combined. Cells were then decidualized over 2 weeks and thereafter assessed for proliferation, and decidualization capacity.
Main results and the role of chance: Testosterone and low dosed dexamethasone showed no impact on decidualization, determined by stromal prolactin secretion. In contrast, high doses of dexamethasone alone increase the prolactin secretion. This effect vanished under hyperandrogenic conditions. High doses of metformin alone showed a negative effect on decidualization, which intensified under hyperandrogenic conditions and could not be compensated by dexamethasone. While low dose testosterone showed a tendency of proliferation

inhibition, high doses of testosterone significantly reduced proliferation, an effect which could be compensated by addition of high doses of dexamethasone. High doses of dexamethasone alone even promoted proliferation above baseline. While low concentrations of metformin left proliferation unaffected, high doses significantly reduced proliferation. This negative metformin effect could be partially abolished by high-dosed dexamethasone.

Limitations, reason for caution: These effects resemble the conditions in an in vitro culture with a single cell type, namely endometrial stromal cells. We can therefore not give a concrete prediction of effects on the endometrial microenvironment in vivo, if the drug components are systemically applied.

Wider implications of the findings: We confirmed in our study, that a hyperandrogenic state, which is often associated with PCOS lead to a decreased proliferation and decidualization of endometrial cells. This effect however can be partially compensated by treatment with dexamethasone, particularly, when hyperandrogenism is abolished. Metformin on the other hand also decreased proliferation and reinforced the effect observed under hyperandrogenic conditions. The decreased proliferation of metformin could only be partially compensated by dexamethasone.

Study funding/competing interest(s): Funding by University(ies) – Funding by commercial/corporate company(ies). Department of Gynecologic Endocrinology and Fertility Disorders at Heidelberg University Women's Hospital, Germany. Merck Serono Funding supported this trial.

Trial registration number: NA.

P-358 Adverse childhood experiences (ACE) – a risk factor for the development of endometriosis?

B. Leeners[1], T. Charpidou[2], M. M. Wölfler[3], P. Imesch[4], K. Geraedts[1], A. Kohl-Schwartz[5], C. Liebermann[1]

[1]*Clinic for Reproductive Endocrinology, University Hospital Zürich, Zürich, Switzerland*

[2]*District Hospital Baden, Baden, Switzerland*

[3]*Gynecology and Obstetrics, University Hospital Graz, Graz, Austria*

[4]*Gynecology, University Hospital Zürich, Zürich, Austria*

[5]*Clinic for Reproductive Endocrinology, University Hospital Bern, Bern, Switzerland*

Study question: Childhood abuse experiences (CAE) are very common and known to be associated with different general as well as psychiatric diseases/pain symptoms in later life. We aimed to investigate whether CAE might play a role in the development of endometriosis.

Summary answer: Traumatic experiences such as childhood sexual abuse, emotional abuse/neglect and inconsistency in the family of origin were strongly associated with a diagnosis of endometriosis. No such correlation was found for physical abuse/neglect and further adverse experiences (i.e., physical abuse of the mother, drug abuse in family, etc.).

What is known already: Traumatic childhood experiences are associated with adult diseases such as asthma, diabetes, cardiac diseases and many more. Chronic pelvic pain, fatigue and depression, i.e. symptoms of endometriosis, are also correlated with CAE. A possible pathophysiological mechanism could be through immunological modifications found as a consequence of CSA and known to be involved in the development of endometriosis. Therefore, several factors give emphasis to a role of CAE in the development of endometriosis.

Study design, size, duration: The study was designed as a multicenter retrospective case control study. Each control women was matched to a woman with a diagnosis of endometriosis with regard to age and nationality. The study is still ongoing; a total of 423 matched pairs was included for the present evaluation.

Participants/materials, setting, methods: Women with endometriosis and control women (routine annual control) were recruited in university and district hospitals in Germany/Switzerland. A modified version of the childhood trauma questionnaire was used to evaluate adverse childhood experiences. Diagnosis of endometriosis was confirmed by histology and classified according to ASRM criteria.

Main results and the role of chance: Women with endometriosis experienced significantly more often sexual abuse (20/14%, $p = 0.0197$), emotional abuse (44/28%, $p < 0.0001$), emotional neglect (50/42%, $p = 0.0123$) and inconsistency in the family of origin than control women. No statistically significant differences could be demonstrated for physical abuse/neglect (31/26%, $p = 0.1738$). Also combinations of these abuse/neglect experiences were reported significantly more often in women with endometriosis. Further adverse childhood experiences i.e. physical abuse of the mother (8/7%, $p = 0.8222$), drug abuse in the family (5/3%, $p = 0.0943$), mentally handicapped family members (1/1%, $p = 0.7271$), suicidal ideation in the family of origin (6/4%, $p = 0.2879$) and family members in prison (1/1%, $p = 0.1597$) were not statistically more frequent in women with endometriosis than in control women.

Limitations, reason for caution: Recall bias might have influenced our results. Also, some of the control women might present asymptomatic endometriosis, which would likely result in underestimation of our findings. A lack of conscious memories on abuse experiences should have no serious impact on our results as it probably affects both groups.

Wider implications of the findings: On the one hand the present findings, especially when taking the prevalence of for example childhood sexual experiences into account, add an important factor to the list of risk factors of endometriosis. On the other hand they confirm once more that traumatic childhood experiences have a serious impact on adult health. As there are effective strategies to avoid long-term consequences of abuse experiences such experiences should be asked for and treated as early as possible.

Study funding/competing interest(s): Funding by hospital/clinic(s) – No funding.

Trial registration number: USZ_11412.

Keywords: endometriosis, adverse childhood experiences, sexual abuse, emotional abuse, risk factor

P-359 Identification and mapping of somatostatin receptors (ssts) in endometriotic tissues

A. Fasciani[1], M. Rutigliani[2], G. Bocci[3]

[1]*Galliera Hospital, Department of Gynecology and Obstetrics, Genova, Italy*

[2]*Galliera Hospital, Department of Pathology, Genova, Italy*

[3]*University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy*

Study question: Could the presence of human somatostatin receptors in endometriotic tissues be considered a pathogenetic factor leading to the colonization of several female organs by ectopic endometrium ?

Summary answer: Somatostatin receptors sst_1 and sst_5 are highly expressed in ovarian endometriomata, in peritoneal lesions, in cervical adenomyosis, in subcutaneous endometriotic nodules and in the forms of deeply infiltrating endometriosis as vaginal, intestinal or bladder nodules.

What is known already: Somatostatin is a peptide hormone with affinity for a family of G protein-coupled receptors (sst1–sst5) that acts as inhibitory regulator of cellular functions including hormone secretion, motility, and proliferation. Moreover, sst agonists exert a direct cytostatic effect on normal (i.e., endothelial cells) and tumor cells expressing (ssts) or indirectly by inhibiting the release of growth factors. At the moment there is no data available regarding the status of sst in different forms of endometriosis.

Study design, size, duration: This descriptive study encompass observations from tissues of 50 women that underwent surgery. These patients were among those referred to our Unit for possible endometriosis, chronic pelvic pain and infertility for the last 9 years.

Participants/materials, setting, methods: Immunohistochemistry of sst1, sst2, and sst5 was performed with standard protocols; two pathologists evaluated and graded immunohistochemical staining by scoring separately the percentage of positive cells (endometrial glandular and stromal) using a proportion score (PS) and an intensity score (IS).

Main results and the role of chance: A well-defined sst1, sst2, and sst5 immunoreactivity was demonstrated both in epithelial and stromal cells of endometriotic lesions in superficial layer of peritoneum, ovarian endometriomata, cervical cystic adenomyosis, subcutaneous endometriotic nodules and in all the forms of deeply infiltrating endometriosis as vaginal, intestinal or bladder nodules. All the analyzed lesions with immunohistochemistry were studied *in vivo* by nuclear magnetic resonance and photographed during surgery. Microscopic pictures show a significantly stronger sst1 and sst5 positive staining (PS + IS scores) in endometriotic lesions (sst1: 6.4; sst5: 4.2) compared with the healthy part of the tissues (sst1: 3.1; sst5: 0.8) ($P < 0.05$). The sst2 immunoreactivity appears to be non specific being present ubiquitously and with comparable PS and IS scores both in colonized and disease-free tissues.

Limitations, reason for caution: Our findings may suggest the use of molecules such as somatostatin analogues used for years in other diseases; unfortunately somatostatin plays both physiological and pathological roles in the

female reproductive system and therefore remains difficult to understand its functional relevance in endometriosis.
Wider implications of the findings: Our data show that somatostatin receptors are expressed in all forms of endometriosis and interestingly the sst1 and sst5 receptors characterize the endometriotic lesions in comparison to surrounding healthy tissue both over and under the peritoneal layer. Endometriosis still remains a great challenge for those who attempt to treat it however the presence of these receptors could lead to the use of target therapies for patients affected by the disease.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Galliera Hospital.
Trial registration number: The study was approved by the local committee on human research; no trial registration number was requested for this observational study.
Keywords: endometriosis, somatostatin

P-360 Galectin-1 is over-expressed in endometriotic lesions from patients with minimal to mild endometriosis and promotes eutopic endometrial stromal cell proliferation

J. Bastón[1], L. Ferella[1], D. O. Croci[2], P. Hidalgo[3], M. A. Bilotas[4], A. G. Ricci[4], R. I. Barañao[4], J. J. Singla[5], A. M. Gonzalez[6], M. C. Johnson[3], G. A. Rabinovich[2], G. A. Meresman[1]
[1]*Institute of Biology and Experimental Medicine, Endometrial Pathophysiology Laboratory, Buenos Aires, Argentina*
[2]*Institute of Biology and Experimental Medicine, Immunopathology Laboratory, Buenos Aires, Argentina*
[3]*University of Chile, Institute of Maternal and Child Research, Santiago, Chile*
[4]*Institute of Biology and Experimental Medicine, Immunology of Reproduction Laboratory, Buenos Aires, Argentina*
[5]*Buenos Aires University, "José de San Martín" Clinical Hospital, Buenos Aires, Argentina*
[6]*Buenos Aires Navy Hospital, Tocogynecologic Department, Buenos Aires, Argentina*

Study question: The main objectives were to evaluate the Galectin-1 protein expression in endometriotic lesions and eutopic endometrium from patients with endometriosis, and to study the potential role of this endogenous lectin to promote cellular proliferation in primary cultures of eutopic endometrial stromal cells from patients with endometriosis and controls.
Summary answer: The protein expression of Galectin-1 was significantly higher in endometriotic lesions than eutopic endometrium, this increase occurred in patients with minimal to mild degree of endometriosis. The endogenous knock-down of Galectin-1 expression diminished cellular proliferation in eutopic endometrial stromal cells from patients with endometriosis but not from control women.
What is known already: The pathophysiologic mechanisms involved in the aetiology of endometriosis are not entirely known yet. Galectin-1 is an endogenous lectin with binding-affinity for multiple *N*-acetyllactosamine disaccharides comprised on *N*- and *O*-glycans involved in several events of tumor biology. The potential pathophysiologic role of this lectin in human endometriosis has not yet been completely elucidated; however, we recently reported that Galectin-1 substantially contributes to endometriotic-like lesions growth and vascularization in an experimental endometriosis mouse model.
Study design, size, duration: All subjects were infertile women undergoing diagnostic laparoscopy, showed regular menstrual cycles and had not received any hormonal medical treatment for the last three months. Endometriotic ($n = 41$) and endometrial biopsies ($n = 27$) were taken from women with endometriosis, and control women with tubal factor infertility, unexplained infertility or leiomyomas ($n = 27$).
Participants/materials, setting, methods: Biopsies of endometriotic lesions and eutopic endometrium were mechanically homogenized and Galectin-1 protein expression was assessed by Western blot. Knock-down of endogenous Galectin-1 expression was performed by RNA interference assay in primary cultures of eutopic endometrial stromal cells, and the cellular proliferation was measured by MTS method.
Main results and the role of chance: There were no differences in the levels of Galectin-1 expression between eutopic endometrium from patients with endometriosis and controls ($p = 0.1037$), but there was a significant increase of Galectin-1 expression in endometriotic lesions compared to eutopic endometrium from patients with endometriosis ($p = 0.0320$). This increase occurs in patients with minimal to mild degree of endometriosis ($p = 0.0368$), since in patients with moderate to severe endometriosis the endometriotic expression of this lectin did not differ significantly from eutopic endometrium ($p = 0.5573$). In addition, the transient reduction of Galectin-1 expression in eutopic endometrial stromal cells has no apparent effect on cellular proliferation in primary cultures from control patients ($p = 0.2335$), but the transient decrease of Galectin-1 expression caused a significant reduction of cellular proliferation in cultures from endometriosis patients ($p = 0.0061$).
Limitations, reason for caution: More studies should be addressed to fully understand the mechanistic behind the results obtained and to evaluate the role of Galectin-1 in other events involved in the endometriosis pathophysiology.
Wider implications of the findings: It is known that at early stages of the endometriosis development the ectopic lesions are highly metabolically active. The increased expression of Galectin-1 in endometriotic lesions from patients with minimal to mild degree of the disease, besides the reduced cellular proliferation observed in Galectin-1 knock-down endometrial stromal cells from patients with endometriosis, support the potential involvement of Galectin-1 in the endometriosis pathophysiology and validate this lectin as a possible target for future therapeutic strategies.
Study funding/competing interest(s): Funding by national/international organization(s) – National Agency for Promotion of Science and Technology (ANPCYT), National Council for Scientific and Technological Research (CONICET) and Roemmers Fundation; Buenos Aires, Argentina.

P-361 Human embryo co-culture up to day 14 on a two-dimension in vitro model

A. Aberkane[1], W. Essahib[1], G. Verheyen[2], H. Van de Velde[2]
[1]*Vrije Universiteit Brussel, Reproductive Immunology and Reproduction, Jette, Belgium*
[2]*UZ Brussel, Centre of Reproductive Medicine, Jette, Belgium*

Study question: Does co-culture of human embryos with Ishikawa cells sustain embryo implantation and trophoblast (TB) outgrowth *in vitro* until day (D) 14 of development?
Summary answer: Human embryos were successfully co-cultured with Ishikawa cells until D14 of development *in vitro*. The embryos attached to the Ishikawa cells and showed outgrowth formation. This outgrowth displayed markers for trophoblast formation and differentiation. More experiments are ongoing to further characterise the outgrowth (specific TB markers, hCG secretion, apoptosis).
What is known already: Implantation models have been set-up, using embryos or blastocyst-like spheroids and different endometrial cells. Ishikawa cell line is a human endometrial epithelial cell line and is considered to be a good model to study normal endometrial function. As far as we know, there is a lack of knowledge in the literature on sustained early embryonic trophoblast outgrowth and the characterisation of this process.
Study design, size, duration: High quality human blastocysts ($n = 35$) were warmed after vitrification. After 2.5 h of recovery, embryos were treated with pronase in order to remove the zona pellucida. On D6, 20 embryos were put into co-culture with the Ishikawa cells to maximum D14 of development *in vitro.*
Participants/materials, setting, methods: This study was approved by the Local and Federal Ethical Committees for research on human embryos. Embryos used for the study were obtained from patients who signed an informed consent to donate their embryos for research after the legal storage period. Embryos were morphologically evaluated and analysed by immunohistochemistry(IHC).
Main results and the role of chance: Blastocysts attached firmly (80%), through polar or mural TB, to the Ishikawa cells after co-culture for 48 h (D8). Following attachment, the blastocysts collapsed and showed outgrowth formation on D9/10. This outgrowth kept on expanding and changing morphologically until D14. Co-culture of embryos on GFP^+-Ishikawa cells confirmed the embryonic origin of the outgrowth. To characterise embryo implantation and outgrowth, IHC-staining for vimentin and E-cadherin was performed. D8 embryos' TB stained positive for nuclear vimentin, except for the attachment site. E-cadherin was found in all TB cells. Co-staining of E-cadherin and nuclear vimentin is an indication for TB invasiveness. Both proteins were absent in D14 outgrowths. The lack of vimentin at this stage might indicate TB differentiation. Preliminary TUNEL-assay analysis indicates that the outgrowth isn't apoptotic.

Limitations, reason for caution: This study is limited by the use of a two-dimension *in vitro* model and the absence of stromal cells. The effect of the cryopreservation on the process of embryo implantation and/or development cannot be excluded.
Wider implications of the findings: A better understanding of the human implantation process and TB differentiation will open doors to study the biology of human reproduction, in particular implantation failure and recurrent miscarriage. It may lead to the development of embryo culture and/or transfer medium to improve implantation and to develop non-hormonal contraceptives to prevent implantation. The outgrowth centre consists of a dark core of cells (most likely post-implantation epiblast and/or hypoblast) that needs to be further characterised.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Funding by national/international organization(s). Agentschap voor Innovatie door Wetenschap en Technologie (IWT). Wetenschappelijk Fonds Willy Gepts (WFWG) University Hospital.

P-362 Molecular alterations relevant to cancer stem cell markers in a subset of endometriosis patients: A potential link towards endometriosis associated ovarian cancers

P. G. L Lalitkumar[1], P. S. Srinivasan[1], S. Varghese[1], K. Andersson de-Cladio[1], R. Green[1], K. Gemzell-Danielsson[1]
[1]*Karolinska Institutet, Women's and Children's Health, Stockholm, Sweden*

Study question: Could endometriotic stem cells under go molecular alterations leading to endometrioma associated ovarian cancer?
Summary answer: For the first time, we report increased expression of cancer stem cell (CSC) markers in endometriotic mesenchymal stem cells (MSC) in a subset of endometriotic patients. These genes are known to be involved in pre-malignant functions in ovarian cancer, cancer metabolic pathway and epithelial-mesenchymal transition.
What is known already: Endometriosis is considered as a precursor of ovarian endometrioid and clear cell ovarian carcinoma. Epidemiological studies show a 2- to 3-fold higher risk for ovarian cancer among endometriosis patients. Endometrial adult stem/progenitors have been suggested to be involved in pathogenesis of endometriosis.
Study design, size, duration: MSC from endometrium and endometrioma from patients (paired, $n = 9$; unpaired $n = 5$) and endometrium from healthy volunteers ($n = 14$) were isolated using stem cell markers CD90, CD73 and CD105 by FACS and cultured up to seven passages in monolayer or 3D spheroids to explore CSC phenotypes.
Participants/materials, setting, methods: FACS and quantitative PCR (QPCR) were used to study proliferation and cell cycle. Custom made QPCRs relevant to MSC/CSC was performed and analysed using IPA. Immunofluorescence of spheroids performed in the following combinations: OCT3/CD133, CD44/CD133, ALDH1/CD133 to co-localise MSC and CSC markers. Paired T- test/Wilcoxon test were applied.
Main results and the role of chance: Endomtrioma from 3 patients (high risk group) showed had higher expression levels of Notch3 (FC: 11.19; $P < 0.05$), TP53 (FC: 2.02: $P < 0.05$), mTOR (FC: 1.75; $P < 0.05$). FOS (FC: 1.37; $P < 0.05$), BMI1 (FC: 2.15; $P < 0.05$) and EPAS1/HIF2α (FC: 4.04; $P < 0.05$) were deregulated in cyst MSCs. Eutopic MSCs from patients showed increased cells in S phase and decreased of G0-G1 phase and higher expression ($P < 0.05$) of NOTCH3 (FC: 7.64), CTNNB1/β-catenin (FC: 1.46), TGFβ (FC: 7.41), cKIT/CD117 (FC: 9.38).
Limitations, reason for caution: This study is conducted in a small population of endometriosis patients. A follow up of these 'high risk' patients for ovarian cancer related symptoms is required, if ethics permits.
Wider implications of the findings: This study throws light on understanding the molecular mechanism behind endometriosis associated ovarian cancer. It also opens up possibility to identifying high risk endometriosis patients for ovarian cancer and gives them the opportunity to undergo prophylactic surgery and thus reduce the rate of ovarian cancer, pain and suffering.
Study funding/competing interest(s): Funding by University(ies) – Funding by national/international organization(s). KID grants from Karolinska Institutet, and research grant from Swedish research council (VR) Stockholm, Sweden.
Trial registration number: NA.

P-363 The impact of presence of endometrioma and laparoscopic cystectomy on ovarian reserve tests in comparison to non-endometriotic cysts

K. N. Salihoglu[1], B. Dilbaz[1], D. Akdag[1], E. Ozkaya[2], L. Mollamahmutoglu[1]
[1]*Etlik Zubeyde Hanim Maternity and Women's Health Training and Research Hospital, Obstetrics and Gynecology, Ankara, Turkey*
[2]*DR.Sami Ulus Maternity and Women's Health Training and Research Hospital, Obstetrics and Gynecology, ankara, Turkey*

Study question: Are pre- and post-operative ovarian reserve tests different in women who had endometrioma from the women with non-endometriotic benign cysts after laparoscopic cystectomy?
Summary answer: Presence of endometrioma is related with lower preoperative anti-Mullerian hormone levels (AMH) and antral follicle count and the postoperative values of both tests are statistically significantly lower in these patients while this change was not observed in non-enometriotic cysts after surgery.
What is known already: The negative impact of both presence of ovarian endometrioma per se and cystectomy on ovarian reserve has been reported by various authors. These changes were not evaluated in comparison to the non-endometriotic cysts by evaluating the most widely used ovarian reserve tests and the subfactors such as age and bilaterality.
Study design, size, duration: A prospective study including women of reproductive age; 34 with endometrioma and 33 with benign non-endometriotic cysts ≥4 mm followed up for 2 months.
Participants/materials, setting, methods: The day-2 FSH, LH, E2, AMH levels, ovarian volume, antral follicule counts (AFC) of patients with endometriomas (Group 1) and with benign non-endometrotic cysts (Group 2) were determined preoperatively and 2 months after the surgery. The pre- and post-operative values were compared within the same group and between the two groups.
Main results and the role of chance: There was no statistically significant difference between two groups in terms of age (27.1 ± 5.3 vs 24.5 ± 5, $p = 0.058$) and the median cyst diameter (72.5 vs 70.0 mm $p = 0.59$). The incidence of bilaterality was 35.2 and 21.2% respectively. The pre-operative AMH level and AFC were statistically significantly lower in Group-1 in comparison to Group 2 (3.1 ± 1.9 vs 5.7 ± 3.7 ng/ml $p = 0{,}004$, 5 vs 7 $p = 0.025$). The change in pre-post operative AMH levels were similar in patients aged ≥ 35 and <35 in both groups. The pre-operative ovarian volume and AFC were statistically significantly lower in patients who had bilateral cysts in both groups ($p < 0.05$). The post-operative AMH and AFC were statistically significantly lower in Group 1 in comparison to the pre-operative values ($p = 0.004$) while no significant change was found in all ovarian reserve tests in Group 2.
Limitations, reason for caution: A larger sample size is required to generalize the results. A longer follow-up period is required in order to confirm that the decline in AMH levels is not temporary. A non-treated control group from both arms is lacking, so it is not possible to comment on the long-term progressive detrimental effect of presence of endometrioma on ovarian reserve.
Wider implications of the findings: The decrease in AMH level and AFC should be discussed with the patients with endometrioma before surgery without underestimating the negative impact of presence of ovarian endometrioma on ovarian reserve. Bilaterality of ovarian cysts is related with lower ovarian volume and AFC, and this should also be considered before surgery.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Etlik Zubeyde Hanim Maternity and Women's Health Training and Research Hospital.
Trial registration number: Not a RMC study.

P-364 Fas and fas-ligand in eutopic and ectopic endometrium of women affected by endometriosis: the possible immuno privilege of ectopic endometrium

M. Sbracia[1], C. Valeri[2], G. Antonini[3], H. Selman[2], A. Pacchiarotti[2]
[1]*Hungaria, IVF, Rome, Italy*
[2]*Praxi Provita, IVF, Rome, Italy*
[3]*University of Sapienza, Department of Science, Rome, Italy*

Study question: In this study we analyzed the concurrent expression of Fas-Ligand and Fas antigen in the eutopic and ectopic endometrium of women affected by endometriosis throughout the menstrual cycle.

Summary answer: The reduced expression of Fas in the ectopic endometrium with the contemporary higher expression of Fas-Ligand in the corresponding cells suggests a possible immuno privilege of this tissue.
What is known already: The Fas/Fas-Ligand system is an important mediator of apoptosis and it is involved in the maintenance of immuno privilege in several tissues. Immunohistochemical studies showed a stronger staining for Fas and Fas-L in human endometrium epithelial cells during the secretory phase than in the proliferative phase. Few data have been reported in the literature about the expression of Fas and Fas-L in the ectopic endometrial tissue in endometriosis.
Study design, size, duration: This is retrospective study. Tissue specimens were obtained from 33 women who underwent laparoscopic surgery for severe endometriosis and from 18 healthy women. The surgical procedures were carried out from September 2009 through May 2012. The immunohistochemical process was performed at Tor Vergata University Hospital from 2012 to 2014.
Participants/materials, setting, methods: The eutopic endometrium, ovarian endometriomas and peritoneal implants were obtained from 33 women with severe endometriosis (stage IV). Endometrial tissues of 18 healthy women in different phases of the menstrual cycle, obtained during hysteroscopy procedures, were used as controls. Biopsy sample were immunostaining for Fas and Fas-ligand.
Main results and the role of chance: Immunostaining for Fas-Ligand in the eutopic endometrium was positive mostly in the epithelial cells throughout the menstrual cycle, with a stronger staining in the secretory phase. The epithelial cells of endometriotic lesions showed a significantly stronger staining for Fas-Ligand independently from the menstrual phase with respect to the eutopic tissue ($P < 0.01$). Immunostaining for Fas in the eutopic endometrium showed a reduced staining during the entire proliferative phase, whereas it was strong in the secretory phase. The epithelial cells of the ectopic endometrium showed a reduced staining for Fas independently from the menstrual phase with respect to the eutopic tissue that was statistically significant ($P < 0.01$).
Limitations, reason for caution: The limitation of this study is the small number of the analyzed patients. These data should be confirmed in more extensive studies.
Wider implications of the findings: These findings may explain previous reports showing elevated soluble Fas-L levels in peritoneal fluids of women with endometriosis, and suggest that the ectopic endometrium may be a tissue with immune privilege, which may induce apoptosis in Fas positive immune cells.
Study funding/competing interest(s): Funding by University(ies) – Funding by commercial/corporate company(ies). Praxis DS, Praxi Provita.
Trial registration number: This is not RCT.
Keywords: endometriosis, Fas-ligand, Fas, ectopic endometrium, eutopic endometrium

P-365 Fourier transform infrared (FTIR) spectroscopy as a new tool to assess molecular changes of human granulosa cells induced by endometriosis

G. Gioacchini[1], E. Sereni[2], C. Zacà[2], V. Notarstefano[1], L. Vaccari[3], E. Giorgini[1], A. Borini[2]
[1]*Polytechnic University of Marche, Department of Life and Environmental Sciences, Ancona, Italy*
[2]*Tecnobios Procreazione, Center of Reproductive Health, Bologna, Italy*
[3]*Elettra Synchrotron, SISSI Beamline, Trieste, Italy*

Study question: Could the FTIR spectroscopy represent a new, reliable and comprehensive tool to evaluate molecular, biochemical and morphological changes on human granulosa cells (HGCs) induced by endometriosis?
Summary answer: This tool applied for the first time on HGCs, provided unique biochemical and morphological information elucidating the effects of ovarian endometriotic cysts on concentration and distribution of several molecules of interest (lipids, proteins, carbohydrates and nucleic acids), on cellular metabolism and not least on epigenetic control.
What is known already: Several studies demonstrated a reduced fecundity of 2–10% among patients with endometriosis associated with a poor ovarian reserve, reduced oocyte retrieval, lower oocyte and embryo quality and impaired implantation. Although endometriosis is generally thought to be related to infertility, its actual impact on fecundity and the molecular mechanisms activated on follicle cells underlying this detrimental effect are less clear.
Study design, size, duration: The study has been conducted between July 2013 and September 2014 on women undergoing a COH for an IVF treatment at Tecnobios Procreazione Bologna, Italy. 18 women had a diagnosis of ovarian endometriosis (staged as moderate to severe (stages III–IV); 16 women referred male infertility and represented the control.
Participants/materials, setting, methods: GCs from follicular fluid aspirates were isolated by Percoll layering. FTIR analysis was performed by using a Bruker Vertex 70 Interferometer with an Hyperion 3000 Vis-IR microscope and an FPA detector. Expression of selected genes was evaluated by Q-PCR and lipids were localized by using BODIPY®FL C16.
Main results and the role of chance: Endometriosis induced changes on HGCs: lipids metabolism and storage: FTIR evidenced an increase of total lipids (25.35% ± 1.27 vs 28.38 ± 0.63%; $P < 0.01$), phospholipids (0.78 ± 0.12 vs 1.71 ± 0.11%; $P < 0.001$) and unsaturated-lipids (1.27 ± 0.14 vs 1.53 ± 0.09%; $P < 0.05$) amount, validated by the increase of Peroxisome-Proliferator-Activated-Receptorg (1.3 ± 0.1 vs 8.12 ± 0.5a.u.; $P < 0.05$), Sterol-Regulatory-Element-Binding-Protein1 (1.35 ± 0.25 vs 6.02 ± 0.35a.u.; $P < 0.001$) and Fatty-Acid-Synthase (1.29 ± 0.38 vs 4.13 ± 0.42a.u.; $P < 0.01$) expression. The different localization and distribution evidenced by FTIR was supported by BODIPY analysis. *Carbohydrates metabolism*: the decreased concentration (6.72 ± 0.32 vs 3.89 ± 0.21%; $P < 0.05$) and distribution of carbohydrates evidenced by FTIR were validated by the decrease of Glucose-Transporter-Type1 (6.23 ± 0.6 vs 1.24 ± 0.2a.u.; $P < 0.05$) gene expression. *Apoptosis/Autophagy:* the increase of cell death spectral biomarker (25.35 ± 1.27 *vs* 28.38 ± 0.63%; $P < 0.05$) evidenced by FTIR were confirmed by the modulation of molecules involved on apoptosis (Caspase3 1.92 ± 0.61 vs 6.57 ± 0.85a.u.; $P < 0,05$, Survivin 33.89 ± 3.21 vs 1.8 ± 0.58a.u.; $P < 0.01$) and on autophagy (Beclin1 1.32 ± 0.22 vs 9.90 ± 1.04a.u.; $P < 0.001$, LC3 1.45 ± 0.31 vs 11.69 ± 1.12a.u.; $P < 0.05$). *Epigenetic control*: the increase of DNA methylation (5.43 ± 0.09 vs 6.98 ± 0.11%; $P < 0.05$) evidenced by FTIR was confirmed by the increase of DNA-Methyltransferase3a (1.32 ± 0.21 vs 7.71 ± 1.76a.u.; $P < 0.01$) expression.
Limitations, reason for caution: This is a preliminary but promising study conducted on a limited number of patients but the enrollment is still on going and study is not concluded.
Wider implications of the findings: This preliminary study, carried out on HGCs, represents the first vibrational approach to evaluate the macromolecular and biochemical changes associated with endometriosis. The findings, obtained by FTIR analysis and validated by conventional molecular tools, deeper elucidated the molecular mechanisms activated by ovarian endometriotic cysts on GCs and increased scientific knowledge in follicle damage due to inflammation. This could be useful in developing new strategies to prevent detrimental effects of endometriosis on fertility.
Study funding/competing interest(s): Funding by University(ies) – Funding by hospital/clinic(s). Tecnobios Procreazione, Bologna Italy. Università Politecnica delle Marche, Ancona Italy.
Trial registration number: Not requested as basic study.
Keywords: granulosa cells, endometriosis, Fourier Transform Infrared spectroscopy

P-366 Perfusion of intralipids may be an alternative treatment to control an endometrial over-immune activation resistant to corticoids in patients with previous repeated embryo implantation failures

M. Petitbarat[1], M. Rahmati[2], F. Turki[3], A. Metni[3], R. Balet[3], S. Dubanchet[2], K. Vezmar[1], L. Chevrier[1], H. Gahery[2], A. Bensussan[2], N. Ledee[1]
[1]*MatriceLab Innove, Hopital Saint Louis, Paris, France*
[2]*INSERM UMRS 976, Hopital Saint Louis, Paris, France*
[3]*Service de PMA, Hopital des Bluets, Paris, France*

Study question: Which alternative treatment can be proposed by physicians in case of endometrial over immune activation not controlled by corticoids for patients experiencing repeated implantation failures (RIF)?
Summary answer: Perfusion of Intralipids (IL) may be useful to control excess of Th-1 cytokines and hyper-activation of immune cells through a stimulation of local endometrial immunoregulators as TWEAK (TNF weak inducer of apoptosis). After observation of their impact on endometrial biomarkers used to establish the immune profile, observed pregnancy rates were significantly improved.
What is known already: Uterine NK cells (uNK) are crucial for implantation but If they are over activated, uNK cells become cytotoxic (over immune activation) and prevent the embryo implantation. Majority of RIF patients, we previously documented, shows such deregulation of over-immune local activation with some cases inefficacy of corticoids. In such context, Intralipids were

previous described as a therapy able to control the hyper-activation of circulating NK cells and to control excess of Th-1 cytokines.
Study design, size, duration: The study design was a cohort study including 34 RIF patients with a documented over-immune activation resistant to corticoids.
Participants/materials, setting, methods: An endometrial biopsy was performed in the luteal phase on two distinct cycles. The first biopsy for the basic diagnosis of over-immune activation, the second one to assess the impact of intralipids. We quantified uNK cells by immunohistochemistry and mRNA expression of IL-15 (uNK cells maturation state), IL-18 (Th-1/Th-2 cytokines balance) and TWEAK/Fn-14 (immuno-regulation) by RT-PCR. Pregnancy Outcome at the subsequent embryo transfer under IL was recorded for these patients.
Main results and the role of chance: Under intralipids, we observed a significant increase of 76% of the TWEAK mRNA expression ($p < 0.006$, paired sample *T*-test). The increase of local immunoregulator allowed a better local control of Th-1 cytokines (assessed by the IL-18 and -15 expression) and therefore a control of local cytotoxicity. 76% (28/34) were pregnant at their subsequent embryo transfer under IL despite their long story of unexplained RIF.
Limitations, reason for caution: We cannot exclude that the use of a new treatment can have a placebo effect in these patients. Only a randomized controlled trial with placebo may prove that intralipids are an effective treatment of local cytotoxicity in these specific immune profiles.
Wider implications of the findings: Developing preventive personalized strategies based on a clear understanding of each patient's endometrial immune prof is an emerging area of innovation in Reproduction. On that regards, intralipids may be very useful especially in some patients showing an over-immune activation with low expression of local immunoregulators. IL were able to control the cytotoxicity before any embryo transfer.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – MatriceLAB Innove.
Trial registration number: No trial number.
Keywords: embryos implantation failures, uterine receptivity, endometrium, over immune activation, intralipids treatment

P-367 *In vitro* differentiation of human endometrial stromal cells: effect of endocannabinoids in insulin-like growth factor-binding protein-1 and prolactin levels

B. M. Fonseca[1], M. Diniz-da-Costa[2], G. Correia-da-Silva[1], M. Almada[1], M. A. Costa[1], N. A. Teixeira[1]
[1]*UCIBIO REQUIMTE Laboratório de Bioquímica, Departamento Ciências Biológicas Faculdade de Farmácia da Universidade do Porto, Porto, Portugal*
[2]*Faculdade de Ciências da Universidade do Porto, Biologia, Porto, Portugal*

Study question: Does the major endocannabinoids (eCBs), anandamide (AEA) and 2-arachidonoylglycerol (2-AG), interfere with human decidualization?
Summary answer: The CB1 and TRPV1 receptors are expressed in both undifferentiated and decidualized human endometrial stromal cells. We also observed that the major eCBs and also the TRPV1 agonist capsaicin, affected human decidualization. The pre-treatment with the CB1 antagonist attenuated the effects induced by AEA and 2-AG.
What is known already: The endometrial stromal cells differentiate and proliferate into morphological and functional distinct decidual cells, which produce bioactive compounds. However, little information is available concerning the critical molecular molecules involved in decidual progress. There is growing evidences that eCBs are important mediators in reproduction, namely in hormonal control and uterine tissue remodelling. Although CB1 is expressed in endometrial stromal cells, the role of endocannabinoids in decidualization process remains unknown.
Study design, size, duration: To investigate the role of the major eCBs, AEA and 2-AG, on *in vitro* decidualization, we used a human immortalized endometrial stromal cell line (St-T1b).
Participants/materials, setting, methods: Decidualizing St-T1b cells were established using medroxyprogesterone acetate and 8-Br-cAMP for 2 and 5 days. The decidual response was characterized by transcriptional activation of prolactine (PRL) and insulin like growth factor binding protein 1 (IGFBP-1). The effects of eCBS in cell viability of undifferentiated and differentiated endometrial stromal cells were analysed by MTT. The expression of cannabinoid receptors was analysed by immunoblotting and their involvement studied with specific antagonists.
Main results and the role of chance: The eCBs, AEA and 2-AG, have no significant effects on cell viability of either undifferentiated or differentiated endometrial stromal cells in the conditions used. Additionally, these eCBs induced a significant down-regulation of IGFBP1 and PRL expression in either day 2 and 5 treated cells. CB1 and TRPV1, but not CB2, are expressed in both primary human endometrial stromal cells and in St-T1b cell line. The pretreatment with CB1 antagonist attenuated the reduction in IGFBP1 and PRL expression induced by AEA and 2-AG. Furthermore, the TRPV1 agonist capsaicin also affected decidual differentiation process. These results reinforces our previous observations showing eCBs-inhibition of rat decidualization either in vitro or in vivo.
Limitations, reason for caution: Our results were obtained with *in vitro* studies performed in cultures of immortalized endometrial stromal cells (St-T1b) by the transfection of telomerase. Further studies are required to support the effects of eCBs in *in vivo* human differentiation. Furthermore, the studies of the signalling pathways affected by eCBs requires additional research.
Wider implications of the findings: Here we present evidences that both eCBs interfere with decidualization process by reducing the mRNA levels of decidual markers, such as, IGFBP1 and PRL, proteins that are relevant for decidual function and, consequently, for pregnancy outcome. Additionally, our findings identify human decidual cells as potential targets for exocannabinoids resulting from cannabis consumption, which may affect endometrial stromal cell differentiation through interference with endocannabinoid system.
Study funding/competing interest(s): Funding by national/international organization(s) – The authors thank Fundação para a Ciência e Tecnologia (FCT) for the grant attributed to Fonseca BM (SFRH/BPD/72958/2010), Costa M (SFRH/BD/70721/2010)and Almada M (SFRH/BD/81561/2011).
Trial registration number: NA.

P-368 A Comparison of Hysterosalpingo-foam sonography (HyFoSy) and Hysterosalpingo-contrast sonography (HyCoSy) in the assessment of tubal patency

S. Lim[1], H. Rajesh[1], J. Jung[1], S. L. Yu[1]
[1]*Singapore General Hospital, Obstetrics and Gynaecology, Singapore, Singapore*

Study question: To compare the efficacy of ExEm foam (HyFoSy) with saline solution (HyCoSy) as a contrast medium for hysterosalpingsonography in subfertile patients.
Summary answer: HyFoSy with ExEm foam medium increased diagnostic confidence in the evaluation of tubal patency and reduced the proportion of false occlusion results in tubes examined by HyCoSy.
What is known already: HyCoSy is operator- dependent with a high false occlusion rate. It is not possible to differentiate between true tubal occlusion and occlusion due to tubal spasm or suboptimal visualisation. It is often only possible to demonstrate proximal patency with HyCoSy by visualising paracornual flow. Tracing the flow of saline through the entire tubal length is more informative but difficult. A positive contrast agent may allow better delineation of tubal anatomy and reduce false occlusion results.
Study design, size, duration: A single- blind pragmatic randomised cross- over trial was done to compare the efficacy of saline (HyCoSy) with foam medium consisting of ExEm-gel and water (HyFoSy) for hysterosalpingsonography in 40 subfertile patients from April 2014 to January 2015.
Participants/materials, setting, methods: Randomisation was done using computer- generated block randomization. Quality of visualisation was assessed as follows: peritoneal spillage of contrast, forward flow along the entire tubal length and forward flow at the paracornual region. Absent cornual flow suggested possible tubal occlusion and prompted sequential crossover testing with the other medium.
Main results and the role of chance: 36 participants were recruited. There were no significant differences in baseline characteristics between the two groups. A higher proportion of tubes in the HyFoSy group demonstrated good evidence of complete tubal patency (peritoneal spillage or forward flow along the entire tubal length) (60.0 vs 29.5%, $p = 0.045$). A higher proportion of tubes in the HyCoSy group demonstrated possible tubal occlusion (47.7 vs 25.7%, $p = 0.045$). After crossover evaluation, 43.5% of possibly occluded tubes in the HyCoSy group were re- classified as patent when examined with ExEm foam,

compared to 9.1% of possibly occluded tubes in the HyFoSy group examined with saline (p = 0.052). No significant complications were reported. Results subject to change pending recruitment of target sample size and further statistical evaluation.
Limitations, reason for caution: Evaluation of diagnostic accuracy was not possible because of small sample size and lack of comparison with gold standard tests. Selective crossover without a washout period may cause bias when evaluating the effect sizes of each study arm on results. However this is more clinically applicable and avoids additional testing when tubes are patent.
Wider implications of the findings: HyFoSy with ExEm foam medium is more efficacious as a first- line test for tubal patency and may lead to a smaller proportion of patients requiring second- line tubal evaluation by increasing diagnostic confidence and reducing the proportion of false occlusion results.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Neuvital Pte Ltd – provided HyFoSy samples.
Trial registration number: U1111-1165-7309.
Keywords: hysterosalpingosonography, tubal patency testing

P-369 VIP induces the decidualization program on human endometrial stromal cells and conditions dendritic cells profile

E. Grasso[1], S. Gori[2], D. Paparini[1], G. Salamone[2], G. Martinez[3], M. Irigoyen[3], C. Ruhlmann[3], C. Pérez Leirós[1], R. Ramhorst[1]
[1]*Iquibicen-Conicet, Immunopharmacology Laboratory, School of Sciences University of Buenos Aires., C.A.B.A., Argentina*
[2]*Institute of Experimental Medicine National Academy of Sciences, Immunology Laboratory, C.A.B.A., Argentina*
[3]*Instituto de Fertilidad San Isidro IMAC, C.A.B.A., Argentina*

Study question: To investigate VIP (vasoactive intestinal peptide) contribution into the decidualization program, from phenotypic and functional aspects and its effect on dendritic cells (DC) immune-profile. Here, we used an in vitro implantation model based in the co-culture of blastocyst-like spheroids from trophoblast cells cultured on hESC monolayer decidualized with VIP.
Summary answer: Our results suggest that VIP contributes to the decidualization process on hESC cells inducing phenotypic markers and chemokines expression. From the functional aspect, VIP-decidualizated hESC cells allow the blastocyst-like spheroides invasion and condition Dendritic cells to a tolerogenic profile preventing the increase of costimualtory molecules and inducing IL-10 secretion.
What is known already: The decidualization program involves phenotype and functional changes on endometrial cells that facilitate the attachment and invasion of the blastocyst. Although progesterone is a key hormone, the trigger of this process is an intracellular cAMP increase. The decidualization involves the modulation of different mediators such as cytokines, chemokines and growth factors. Particularly, vasoactive intestinal peptide (VIP) is a neuropeptide produced by endometrial stromal cells among others, and displays multiple target circuits that allow immunotolerance.
Study design, size, duration: We used an in vitro implantation model based in the co-culture of blastocyst-like spheroids from trophoblast cells line Swan71 cultured on hESC monolayer decidualized with VIP.
Participants/materials, setting, methods: Human endometrial stromal cell line (hESC) was cultured with/without VIP or MPA + dbcAMP. VIP/VPAC system and decidualization markers were evaluated by RTPCR and ELISA. Blastocyst-like spheroids (BLS) were obtained from Swan71cells and cultured on hESC monolayer. Monocytes were isolated from PBMCs, differentiated to DC and studied by FACS.
Main results and the role of chance: The MPA + dbcAMP decidualization increased VIP expression and secretion ($p < 0.05$). When decidualization was induced by VIP, we observed an increase of markers IGFBP1, PRL, KLF13/KLF9 ratio, IL-8 and SDF1 expression in a concentration-dependent manner ($p < 0.05$). To evaluate functional aspects of VIP-decidualization, an invasion assay was performed. BLS were able to invade hESC monolayer decidualizated with VIP or MPA + dbcAMP. When these assays were performed with conditioned media obtained from human blastocyst we found an increase in BLS invasion on VIP-decidualizated hESC ($p < 0.05$). Finally, we evaluate the immunomodulatory effects of decidualized cells on DC and monocytes. Decidualized hESC conditioned media induced a semi-mature profile on DC preventing the induction of CD83 and CD86 expression, and increasing IL-10 secretion ($p < 0.05$). Monocytes profile was not modulated by conditioned media.
Limitations, reason for caution: The present results were studied using immortalized cell lines. Further studies are necessary to elucidate the precise mechanisms involve and the role of VIP in decidualization.
Wider implications of the findings: Our results suggest that VIP may have an important role during the decidualization process as it is able to induce the differentiation on the stromal cells, not only from the phenotypic aspect but also from a functional one, by allowing blastocyst invasion while contributing to control the immune micro-environment by inducing a tolerogenic profile on DC. We propose that VIP may be a new participant in this differentiation program.

P-370 Interleukin-7 (IL-7), Interleukin-17 (IL-17) and their receptors' (IL-7R and IL-17R) endometrial expression during implantation window, in fertile women and infertile patients

M. Rahmati[1], M. Petitbarat[2], S. Dubanchet[3], H. Gahery[3], R. Balet[4], A. Bensussan[3], G. Chaouat[3], N. Ledee[2]
[1]*London Women's Clinic, Reproductive Medicine, London, United Kingdom*
[2]*Matrice Lab Innove, Hopital Saint Louis, Paris, France*
[3]*INSERM UMRS-976, Hopital Saint Louis, Paris, France*
[4]*Hopital des Bluets, Reproductive Medicine, Paris, France*

Study question: Can we identify endometrial expression differences for IL-7, IL-17 and their receptors (IL-7R and IL-17R) between fertile women and patients experiencing repeated implantation failures or repeated miscarriages?
Summary answer: We found a significant lack of endometrial expression for the receptors IL-7R and IL-17R in infertile patients, with repeated implantation failures or repeated miscarriages.
What is known already: Switch of endometrial immune actors from an adaptative to an innate type of immunity during the implantation window is essential for both Human implantation and placentation. IL-7 like cytokines are identified in maternal-foetal interface where they are expected to promote dendritic cells and a Th2 oriented environment, crucial for a successful implantation. IL-17 is also localised in this interface and is foreseen to regulate local immunological homeostasis.
Study design, size, duration: To help understanding their hypothetical implication on embryo implantation, we decided to identify endometrial mRNA expression differences for IL-7, IL-17 and their receptors between fertile women and patients experiencing repeated implantation failures or repeated miscarriages. 51 patients were included after informed consent and Institutional Review Board approval.
Participants/materials, setting, methods: We included 17 fertile women, 19 patients with repeated implantation failures and 15 patients with repeated miscarriages. Total RNA extractions were made on middle luteal phase endometrial biopsies (days 21–24 of a natural cycle). Endometrial mRNA expression for IL-7, IL-17, IL-7R and IL-17R were studied by Real Time-PCR.
Main results and the role of chance: Endometrial mRNA expressions for IL-7 and IL-17 were very low and we observed no variation between infertile patients and the control fertile group. For the receptors, IL-7R and IL-17R, we found at significantly lower mRNA levels in infertile patients, either with implantation failures or miscarriages ($p = 0.02$ for IL-7R and $p = 0.01$ for IL-17R).
Limitations, reason for caution: Pathways of endometrial actions of IL-7 and IL-17 still need to be elucidated.
Wider implications of the findings: The endometrial lack of expression observed in infertile patients suggests the involvement of the local immune regulation systems linked to IL-7 and IL-17 in a successful implantation. These pathways seem crucial for the communication between innate immune cells and endometrial stromal cells. Defining the optimal endometrial environment at the time of implantation may involve biomarkers documenting pathways related to dendritic and T regulatory cells. The observed deregulations may be informative in that regard.

P-371 Endometrial injury performed during the cycle preceding ovarian stimulation increases the biochemical pregnancy rate in unselected infertile women undergoing in vitro fertilization: a randomized placebo controlled trial

S. Y. Zhao[1], Y. Liu[1], L. P. Yu[1], H. Chao[1], M. H. Liu[1], Y. Y. Zhao[1]
[1]*Beijing Obstetrics and Gynecology Hospital Capital Medical University, Department of Reproductive Medicine, Beijing, China*

Study question: Does endometrial injury has an effect on reproductive outcome, performed during the cycle preceding ovarian stimulation in unselected infertile women undergoing in vitro fertilization (IVF)?
Summary answer: Local injury to the endometrium during the cycle preceding ovarian stimulation for IVF in unselected infertile women increases the biochemical pregnancy rate.
What is known already: Endometrial injury is defined as intentional damage to the endometrium, such as biopsy or curettage, in women undergoing assisted reproduction technology (ART) to improve endometrial receptivity. Significant improvements in implantation rates, clinical pregnancy rates and/or live birth rates on women with repeated implantation failure following endometrial injury performed in the preceding cycle were reported.
Study design, size, duration: This randomized placebo controlled trial recruited 145 unselected infertile women scheduled for IVF/ICSI treatment between March 2012 and August 2014. Subjects were randomized into endometrial injury group (n = 73) and placebo group (n = 72) according to a computer-generated randomization list.
Participants/materials, setting, methods: Subjects were recruited and randomized in the Department of Reproductive Medicine at Beijing Obstetrics and Gynecology Hospital, Capital Medical University. A total of 145 patients, <40 years old, in their first *in vitro* fertilization (IVF) cycle were randomized to two groups: endometrial injury group and placebo group. In 73 patients, endometrial biopsies were performed using a Pipelle catheter on days 9–12 or 21–24 of the menstrual cycle preceding IVF treatment. In 72 control patients, a same catheter was performed as the endometrial injury group without taking biopsy. All women were treated with a cycle of IVF/ICSI. Pregnancy outcomes were compared.
Main results and the role of chance: There were no significant differences in baseline or cycle characteristics between the two groups. The biochemical pregnancy rates of endometrial injury group [53.4% (39/73)] was significantly higher than that of placebo group [33.3% (24/72)] [RR 2.294 (95% CI 1.172–4.492), P = 0.015]. The implantation rates [23.9% (38/159) versus 18.4% (28/152); RR 1.391 (95% CI 0.804–2.407), P = 0.238], clinical pregnancy rates [37.0% (27/73) versus 30.6 (22/72); RR 1.334 (95% CI 0.669–2.662), P = 0.413], miscarriage rates [15.4% (6/39) versus 16.7% (4/24), RR 0.917 (95% CI 0.142–5.925), P = 0.927], live birth rates [26.0% (19/73) versus 23.6% (17/72), RR 1.138 (95% CI 0.535–2.421), P = 0.736] and multiple pregnancy rates [29.6% (8/27) versus 22.7% (5/22), RR 1.432 (95% CI 0.392–5.226), P = 0.586] were all compared between the endometrial injury group and placebo group.
Limitations, reason for caution: All of our recruited women were having their first IVF cycles, the results may not be generalizable to all women undergoing IVF. The mechanism of endometrial injury on endometrial receptivity need to be studied further.
Wider implications of the findings: According to the results of this study, local injury to the endometrium during the cycle preceding ovarian stimulation for (IVF) in unselected infertile women increases the biochemical pregnancy rate and may have a positive impact on endometrial receptivity.
Study funding/competing interest(s): Funding by national/international organization(s) – This project was funded by National Natural Science Foundation Project (81471520), State Scholarship Fund (2011911033), Beijing Natural Science Foundation Project (5122015), and Beijing Project of Training High-level Medical Technical Personnel in Health System. The authors declare no conflict of interest.
Trial registration number: No.

P-372 Soft microenvironments inactivate the fibrotic phenotype of endometriotic stromal cells

S. Matsuzaki[1], C. Darcha[2], C. Vachias[3], R. Botchorishvili[1], J. L. Pouly[1], M. Canis[1]
[1]*CHU Clermont-Ferrand, Department of Gynecology, Clermont-Ferrand, France*
[2]*CHU Clermont-Ferrand, Department of Pathology, Clermont-Ferrand, France*
[3]*University of Auvergne, GReD, Clermont-Ferrand, France*

Study question: Are deep infiltrating endometriotic fibroblasts influenced by changes in extracellular matrix (ECM) stiffness?
Summary answer: Increased matrix stiffness may promote cell proliferation, collagen synthesis and induce myofibroblasts differentiation of endometriotic stromal cells. Soft microenvironments may preserve the quiescent fibroblast phenotype of endometriotic stromal cells.
What is known already: Deep infiltrating endometriosis is histologically characterized by dense fibrous tissue. Tissue stiffening is a hallmark of fibrosis. However, previous in vitro studies typically analyzed cells grown on rigid plastic or glass substrates with stiffness in the Giga-Pascal (GPa) range, which are much stiffer than those occurring in vivo. To investigate how changes in ECM stiffness affect endometriotic fibroblasts, it is critical to model in vivo tissue compliance conditions in vitro.
Study design, size, duration: For this laboratory study, endometrial and/or endometriotic samples from 38 patients who had histological evidence of deep infiltrating endometriosis were analyzed.
Participants/materials, setting, methods: Expression of F-actin, alpha smooth muscle actin, ki67 and procollagen type I in endometriotic stromal cells on polyacrylamide gel substrates of varying stiffness (between 2 and 30-kPa) were determined by immunofluorescence confocal microscopy. mRNA expression of collagen type I, Cyclin D1, MMP-1 and MMP-14 was measured by real-time PCR.
Main results and the role of chance: Increased matrix stiffness induced F-actin stress fiber formation and expression of alpha smooth muscle actin in stress fibers in endometriotic stromal cells. Furthermore, increased stiffness promoted cell area, ki67 expression, cyclin D1 and collagen synthesis and decreased MMP-1 and MMP-14 mRNA expression in endometriotic stromal cells. Treatment with transforming growth factor-β1 increased collagen synthesis. On soft substrates, endometriotic stromal cells exhibited a small rounded morphology with diffuse labeling for F-actin. Expression of ki67, procollagen type I, collagen type I and Cyclin D1 were significantly decreased, whereas that of MMP-1 and MMP-14 was significantly increased, in endometriotic stromal cells cultured on a soft substrate (2-kPa) compared to those on a stiff substrate (30-kPa).
Limitations, reason for caution: A tremendous gap remains between the present in vitro model and in vivo endometriotic tissues. Cell cultures more closely mimics the cellular complexity typical of in vivo endometriotic tissues are required to develop novel strategies for treatment of deep infiltrating endometriosis.
Wider implications of the findings: Hormonal suppressive therapy is not usually very effective for deep infiltrating endometriosis. Interrupting mechanical interactions between endometriotic fibroblasts and aberrant ECM may be a novel strategy for treatment of deep infiltrating endometriosis.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – This study was supported in part by Karl Storz Endoscopy & GmbH (Tuttlingen, Germany).

P-373 A Mock Embryo transfer is as effective as an Endometrial Scratching to aid Implantation

T. K. Cunningham[1], C. Leary[2], P. Lesny[1], S. D. Maguiness[1]
[1]*The Hull IVF Unit, The Hull IVF Unit, Hull, United Kingdom*
[2]*The Hull IVF Unit, Embryology, Hull, United Kingdom*

Study question: To determine whether a Mock Embryo Transfer (ET) performed the cycle before an IVF/ICSI treatment cycle is as effective at aiding implantation as a formal endometrial scratching using an endometrial biopsy catheter (Pipelle de Cornier) following a Mock-ET the cycle before an IVF/ICSI treatment cycle**.**
Summary answer: A Mock-ET performed in the luteal phase the cycle prior to commencing IVF/ICSI is as effective as a formal endometrial scratching. Subgroup analysis demonstrated that endometrial scratching resulted in statistically significant lower clinical pregnancy rates in the second cycle and had no benefit in those with recurrent failed implantation.

What is known already: Endometrial scratching causes physical trauma to the endometrium using devices such as a biopsy pipelle, aiming to improve implantation rates. It is believed this trauma results in a significant release of cytokines, growth factors and interleukins inducing decidualisation and receptivity of the endometrium creating a favourable environment for implantation. This should not be performed during the same cycle as the ET, however when in the menstrual cycle and degree of injury is still being debated.
Study design, size, duration: A retrospective cohort study of all fresh IVF and ICSI cycles performed between the 1st of January 2013 and 31st of December 2014 at the Hull IVF unit. 622 fresh cycles were performed during this period and no patients were lost to follow-up.
Participants/materials, setting, methods: In 2013 all patients underwent a Mock-ET during the luteal phase of the cycle before IVF, to measure the length of the uterine cavity and to document any difficulties that maybe experienced at the time of ET. In 2014 endometrial scratches were performed after the Mock-ET the cycle before IVF.
Main results and the role of chance: 622 fresh IVF/ICSI cycles were performed. There was no significant difference in patient demographics between the 2 groups comprising age, BMI, AMH, endometrial thickness and embryo quality. There were 133 clinical pregnancies in the mock-ET group and 105 in the Mock-ET and endometrial scratching group demonstrating no significant difference $p = 0.099$.

Subgroup analysis highlighted that there was a significant difference in pregnancy rates in the 2nd cycle between the two groups $p < 0.03$, indicating that the endometrial scratching resulted in a significant fall in clinical pregnancy rates. Endometrial scratching patients with repeated failed implantation, cycles 3 to 5 demonstrated no significant increase in clinical pregnancy rates compared to the Mock-ET only group, $p = 0.414$. This was also true for patients undergoing their 1st cycle of IVF/ICSI, $p = 0.518$.
Limitations, reason for caution: This study does not take into account conflicting variables such as ease/difficulty of embryo transfer, rigidity of catheter and cervical dilatation.
Wider implications of the findings: We feel that a Mock-ET cause's sufficient injury to the endometrium to aid implantation, thus avoiding an endometrial scratching that is not without complications such as infection and uterine perforation, and in some instances may require cervical dilatation. The literature remains divided on endometrial scratching but we feel we are the first group to highlight that it is no more beneficial than a mock-ET and in sub-group analysis may in fact be detrimental.
Study funding/competing interest(s): Funding by hospital/clinic(s) – The Hull IVF Unit.
Trial registration number: NA.
Keywords: implantation, mock embryo transfer, endometrial scratching

P-374 A prospective randomized controlled study (RCT) of Intra-uterine administration of Granulocyte Colony-Stimulating Factor (G-CSF) before embryo-transfer on resistant thin endometrium in IVF cycles

R. Singh[1], M. Singh[1], A. Jindal[1], P. C. Jindal[1]
[1]*Bhopal Test Tube Baby Centre, Infertility, Bhopal, India*

Study question: Does intrauterine administration of G-CSF (granulocyte colony-stimulating factor) prior to Embryo Transfer in patients with resistant thin endometrium improve endometrial thickness and pregnancy rate in IVF cycles?
Summary answer: Yes, intrauterine administration of G-CSF (granulocyte colony-stimulating factor) before embryo transfer in patients with resistant thin endometrium increases endometrial thickness and improves the pregnancy rate in IVF cycles.
What is known already: Optimal endometrial thickness reflects an adequate maturation, which is a key factor for embryo implantation. Proliferative and secretory changes in the endometrial lining are the result of a complex intrauterine environment where sex steroid hormones and different local factors play an important role for endometrial thickening. Lucena and Moreno-Ortiz found that the uterine infusion of G-CSF quickly increased endometrial thickness resulting in a successful pregnancy and healthy born baby. Li *et al*. aimed to evaluate the effectiveness of G-CSF administration for infertile women with a thin endometrium in a frozen ET program. These results suggested that G-CSF is a factor that participates during endometrial remodeling enhancing the synchronization between uterine environment and embryo development.
Study design, size, duration: 48 Infertile patients with thin endometrium younger than 42 years from Jan.2014 to Dec.2014 were included in this study. All using traditional treatments with estradiol and sildenafil citrate (Viagra) had been unsuccessful. Patients were randomly divided into two groups using a computer generated list. The study group received intrauterine administration of G-CSF (300 mg/ml) and control group received placebo-saline before Embryo Transfer in IVF cycles. *Primary Outcome Measures:* Endometrial thickness, implantation rate and pregnancy rate. *Secondary Outcome Measure:* Miscarriage rate.
Participants/materials, setting, methods: The study group ($n = 24$) received intrauterine infusion of 300 µg/ml of G-CSF, and the control group ($n = 24$) underwent placebo-saline infusion before Embryo Transfer. G-CSF was administered per intrauterine catheter by slow infusion before noon on the day of hCG administration. If the endometrium had not reached at least a 7-mm within 48 h, a second infusion was given following oocyte retrieval.
Main results and the role of chance: The endometrial growth was significantly different within the two groups. An improvement was shown between the control and G-CSF infused groups. Endometrial expansion to minimal thickness occurred within approximately 48 – 72 hour from G-CSF infusion. In all the subjects at the time of infusion of G-CSF, endometrial thickness was 6.49 ± 1.65 mm, and, after infusion, it increased significantly to 8.79 ± 1.57 mm. The IR and PR were statistically significantly higher in the group that received intrauterine infusion of G-CSF (23 and 33%, respectively) as compared with the control group (12 and 16%, respectively).
Limitations, reason for caution: A relatively new concept in thin endometrium, requiring more multicentric trials worldwide. Our study is not without limitations. Firstly, we did not have a large number of patients. Secondly, we applied Aspirin and/or Sildenafil citrate which also could have a positive effect on endometrial thickness. We can only speculate that the other factors could have impact on endometrial thickness. But we do not believe that this could have essential impact on our results. Wider implications of the findings: Uterine perfusion with G-CSF represents a promising new tool for the currently mostly intractable problem of inadequate, thin endometrium. A thin endometrium is one of the most difficult problems encountered in assisted reproduction every day practice. Several methods were proposed, to increase thin endometrium in women undergoing IVF. These therapies included tocopherol, pentoxifylline, low-dose aspirin, sildenafi l citrate, estradiol administration and hCG priming. Endometrial perfusion with G-CSF may be effective in expanding chronically unresponsive thin endometrium, which was resistant to traditional remedies. This treatment also deserves further investigation for its potential to improve implantation chances in association with IVF and, therefore, pregnancy rates.
Study funding/competing interest(s): Funding by hospital/clinic(s) – BTTB CENTRE.
Trial registration number: BTTBC/2014/12
Keywords: thin-endometrium, IVF-ICSI, intrauterine-infusion, G-CSF (granulocyte colony stimulating factor), embryo-transfer

P-375 ER map: re-defining the transcriptomic signature of endometrial receptivity. Validation of a new method for endometrial receptivity evaluation

I. Jurado[1], J. P. Carrascosa[1], M. C García-Poyo[2], L. Medrano[2], S. Rogel[2], S. Munné[3], L. Werlin[4], J. Aizpurua[1], J. A. Horcajadas[1]
[1]*Universidad Pablo de Olavide, Genetics, Seville, Spain*
[2]*IVF Spain, Fundación IVF Spain, Alicante, Spain*
[3]*Reprogenetics, New Jersey, U.S.A.*
[4]*Coastal Fertility Center, Irvine, California, U.S.A.*

Study question: To re-define the human endometrial receptivity signature by gene expression analysis of a new set of genes specifically involved in the development of the endometrial receptivity and immune response. Validation of these biomarkers with a new method of gene expression analysis.
Summary answer: A new method for endometrial receptivity gene expression analysis has been generated. It combines a new list of genes involved in endometrial receptivity and immune response with the use of new platform of digital PCR.
What is known already: The endometrium reaches a receptive status for embryonic implantation around day 20–21 of the menstrual cycle. This period of time is known as the window of implantation (WOI) and it occurs 7 days after the peak of endogenous LH (LH + 7). It is known that the endometrium shows

a specific gene expression profile during the WOI and that its transcriptomic signature can be used for the evaluation of the endometrial function.
Study design, size, duration: Sixty endometrial samples at LH + 2 (*n* = 30)and LH + 7 (*n* = 30) were collected in the period of March to November, 2014. Endometrial biopsies were collected from fertile women (<37 years) by a pipelle catheter. Oligonucleotide primers for gene expression analyses of one hundred and 192 genes were designed.
Participants/materials, setting, methods: Total RNA from every sample was purified by using Trizol protocol. RNA quality was assessed by using Agilent Bioanalyzer. Gene expression was measured by quantitative real time PCR (RT-PCR) using BioMark platform from Fluidigm for the 192 endometrial receptivity and immune response genes. Oligonucleotide pairs were designed by using GeneFisher 2.0 platform.
Main results and the role of chance: A list of 185 genes with functional relevance in the process of endometrial receptivity and immunological response related with embryonic implantation has been generated. These genes have been selected doing a strict review of the literature since 2008. Another 7 housekeeping genes have been included in the list for normalization of gene expression data. Gene ontology analyses have revealed that cellular proliferation and migration, apoptosis, cellular communication and immune response are the most over-represented biological terms in this group of genes. Validation analysis by standard PCR has shown the correct of 88.5% of the oligonucleotide. The resting 11.5% showed no amplification, double amplification or amplification of incorrect sequences. Sequencing of PCR products was performed for the verification of gene identity.
Limitations, reason for caution: Further studies with more samples are needed to reduce the biological variability shown for some genes. New oligonucleotide have to be designed to replace those oligonucleotide pairs that produced non-specific amplifications.
Wider implications of the findings: A new system for human endometrial evaluation based on has been created. This new tool has been designed with 192 genes not previously used for this purpose and a new algorithm for gene expression analysis. This new molecular tool has been developed in a new system, BioMark platform from Fluidigm, a cost-effective method for gene expression analyses.
Study funding/competing interest(s): Funding by national/international organization(s) – The original study has been funded by SINAERE, Seville, Spain.
Trial registration number: NA.
Keywords: endometrial receptivity signature, gene expression, endometrium, immune response, biomarker

P-376 A prospective randomised controlled study(RCT)comparing the effect of Pre-IVF treatment with Dienogest vs GnRH-Analogue in improving pregnancy outcome in Endometriosis

P. C. Jindal[1], M. Singh[1], R. Singh[1], A. Jindal[1]
[1]*Bhopal Test Tube Baby Centre, Infertility, Bhopal, India*

Study question: Is the IVF outcome with Dienogest Pre-IVF treatment in endometriosis comparable with GnRH analogue?
Summary answer: Yes, the IVF outcome with Dienogest pre-IVF treatment in endometriosis is comparable with GnRH analogue. What is known already: Dienogest is an oral progestin that has been investigated extensively in the treatment of endometriosis and studies have demonstrated that dienogest 2 mg daily effectively reduces endometriotic lesions, and improves quality of life. Dienogest also show a favorable safety and tolerability profile, with predictable adverse effects, better patient compliance, and low withdrawal rates. GnRH agonists are an established therapy for endometriosis. Although GnRH agonists provide effective pain relief and reduce the progression of endometriotic implants, the hypoestrogenic state that they induce is associated with several side effects. Therefore, the use of GnRH agonists requires 'add-back' therapy.
Study design, size, duration: Our study involved 46 infertile patients below 42 years old, who were treated at our hospital between Mar. 2014 to Dec.2014. After confirming the diagnosis of endometriosis, the patients selected for IVF were randomly divided into two groups, using a computer generated list.The study group of 23 patients received oral Dienogest 2mg per day for 12 weeks and the control group of 23 patients received GnRH-Analog before IVF. *Primary Outcome Measure:* Implantation rate and cumulative pregnancy rate. *Secondary Outcome Measures:* Gonadotropin usage, number of oocytes retrieved and miscarriage rate.
Participants/materials, setting, methods: This is a prospective randomised controlled study (RCT) of 46 women with endometrioss. The study group of 23 patients received oral Dienogest 2 mg/day for 12 weeks and the control group of 23 patients received GnRH Analog as pre-IVF treatment.
Main results and the role of chance: Cumulative clinical pregnancy rates were comparable in both the groups – 35% in study group (Dienogest) vs – 39% in the control group (GnRH Analogue.) Implantation rates and miscarriage rates were also comparable. Though the total Gonadotropin usage was lower in study group (Dienogest), it was not statistically significant.
Limitations, reason for caution: Adverse drug reactions with Dienogest were breast discomfort nausea and irritability. Other adverse drug reactions included fatigue, weight gain, headache, depression and breast engorgement. These side effects were those typical of progestins with no major safety concerns. A relatively new concept in IVF in endometriosis, requiring more multicentric trials worldwide.
Wider implications of the findings: Women with endometriosis treated with IVF have lower pregnancy rates compared to women with no endometriosis. Many treatment regimens have been suggested prior to performing IVF for these women. The present study confirms the fact that pretreatment of women with endometriosis with a GnRH Analogue or Dienogest yields similar IVF outcomes with the latter giving a better patient compliance. There was no significant difference in the amount of gonadotropin required between women in the two groups. Our study indicate that Dienogest Pre-IVF Treatment can safely replace GnRH-Analogue in endometriosis.
Study funding/competing interest(s): Funding by hospital/clinic(s) – BTTB CENTRE.
Trial registration number: BTTBC/2014/04.
Keywords: endometriosis, IVF-ICSI, dienogest, pregnancy-rate, GnRH-analogue

P-377 Postoperative oral contraceptives (OCs) may help maintain fertility-enhancing effects after laparoscopic removal of endometrioma

T. Makabe[1], K. Koga[1], A. Takeuchi[1], F. Sue[1], M. Miyashita[1], Y. Urata[1], G. Izumi[1], N. Yamamoto[1], M. Takemura[1], A. Hasegawa[2], M. Harada[1], T. Hirata[1], Y. Hirota[1], T. Fujii[1], Y. Osuga[1]
[1]*The University of Tokyo, Obstetrics and Gynecology, Tokyo, Japan*
[2]*Sanraku Hospital, Obstetrics and Gynecology, Tokyo, Japan*

Study question: Young women with endometrioma who desire pregnancy in the future may opt to plan the laparoscopic removal at a later date, right before seeking conception, concerning the time-dependent diminishing of fertility-enhancing effects of laparoscopy. However, it is not known whether postoperative OCs can maintain the fertility-enhancing effects.
Summary answer: The cumulative pregnancy rate after removal of endometrioma was not lower in women who started to seek conception after having laparoscopic removal of endometrioma followed by postoperative OCs, in comparison with women who immediately sought conception after laparoscopy, indicated that postoperative OCs may help maintain fertility-enhancing effect after laparoscopy.
What is known already: Endometriosis may cause infertility. Laparoscopic removal of endometriosis improves spontaneous pregnancy rate, however, this fertility-enhancing effects may diminish in a time-dependent manner. Postoperative OCs reduces recurrence of endometrioma, and OCs prescription is recommended after removal of endometrioma for women not immediately seek conception.
Study design, size, duration: 112 patients who underwent laparoscopic removal of endometrioma between January 2009 and December 2011 were analyzed. Patients who sought conception immediately after laparoscopy (*n* = 87, Group A) were compared with patients who eventually sought conception after having taken postoperative OCs (*n* = 25, Group B). The mean observation period was 19.1 months.
Participants/materials, setting, methods: The cumulative pregnancy rates after starting to seek conception (after laparoscopy in Group A, after ceasing OCs in Group B) were analyzed using the Kaplan-Meier method and the Log rank test. In Group B, the correlation between the duration of OCs use and pregnancy rate was analyzed using Wilcocxon test.
Main results and the role of chance: Patients' backgrounds such as rASRM score at laparoscopy and age at seeking pregnancy were not different between groups. The cumulative pregnancy rate in Group B (52.0%, 13/25) was not lower than that in Group A (39.1%, 34/87). The average time to conception was

also equivalent between groups (11.2 ± 8.3 months in Group A and 12.0 ± 7.1 months in Group B). In Group B, the period of OCs use was not associated with the cumulative pregnancy rate (19.4 ± 9.5 months in the pregnancy group and 15.1 ± 6.7 months in the non pregnancy group).
Limitations, reason for caution: This is the retrospective study and therefore results may be biased. The sample size is also relatively too small to draw conclusive data.
Wider implications of the findings: Our results indicate that postoperative OCs help maintain fertility-enhancing effects of laparoscopy. Given the inherent risks of endometrioma such as rupture, infection or ovarian damage, laparoscopic removal of endometrioma followed by OCs may be recommended for the management of young patients with endometrioma who desire pregnancy in the future.
Study funding/competing interest(s): Funding by University(ies) – Funded by Ministry of Education, Culture, Sports, Science and Technology/none.

P-378 Retrospective observational cohort study of endometrial receptivity array (ERA)

S. Gupta[1], K. Rani[1], S. Sharma[1], P. Naidu[1], H. Yadav[1], M. Bhushan[1], S. Talwar[1], P. Arora[1], N. Mahajan[1]
[1]*NOVA IVI Fertility, Reproductive Medicine, Delhi, India*

Study question: To evaluate the role of endometrial receptive array (ERA) in patients with recurrent implantation failure, previous one IVF failure and thin endometrium.
Summary answer: There was an improvement in reproductive outcome in all the three groups (Recurrent implantation failure (RIF), 1 failed IVF and thin endometrium).
What is known already: The endometrial window of implantation (WOI) is a short period in menstrual cycle, 5–9 days post-ovulation. Displacement of window prevents embryo implantation, resulting in implantation failure. Endometrial receptivity array [ERA] – a diagnostic test based on specific transcriptomic signature that identifies receptive endometrium in natural and artificial (hormonal replacement therapy) cycles. This identification of WOI allows personalization of embryo transfer. Personalized embryo transfer (pET) improves implantation and pregnancy rate in patients with RIF.
Study design, size, duration: This retrospective study examined 182 infertile women who underwent ERA between August 2013 to October 2014. The primary end point was ongoing pregnancy rate (OPR).
Participants/materials, setting, methods: Patients were divided into three groups. Group I (RIF)-76 patients, group II (one failed IVF) – 93 patients and group III (thin endometrium ≤6 mm)-13 patients. Patients with receptive ERA underwent frozen blastocyst transfer (BET) in hormonal replacement cycle. Patients with non receptive ERA, underwent repeat ERA, followed by pET.
Main results and the role of chance: ERA was non receptive in 28% in group I, 15% in group II and 23% in group III. In group I – 53 (70%) patients, group II – 68 (73%) and in group III – 9 (69%) patients underwent BET, giving overall OPR of 37, 58 and 66.7% respectively. After pET, OPR in group I was 45%, group II – 16% and group III – 100%. In patients where 1st ERA was receptive the OPR in group I was 35%, group II – 62% and group III – 57.1%. Further subgroup analysis done in 15 RIF patients who failed at least one frozen BET at our centre (to eliminate centre bias). Incidence of non receptive ERA was 40%. OPR was 50% after pET and 44.4%in patients with 1st ERA-receptive.
Limitations, reason for caution: The numbers are very small to draw any definite conclusion. Further larger studies are warranted.
Wider implications of the findings: In patients with 1st ERA receptive, improvement in reproductive outcome was found even when we removed centre bias (quality of embryo and transfer technique). This post ERA increase in Pregnancy rate needs further evaluation. Also, failure to conceive post pET needs to be further investigated. Both clinician and patient, in thin endometrium, proceeded with embryo transfer more confidently after finding it receptive.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – nova ivi fertility Delhi.
Trial registration number: NA.

P-379 Assessment of clinical features of neuropathic pain in women with chronic pelvic pain

L. H. R Whitaker[1], J. Reid[2], A. Choa[3], K. Vincent[4], A. W. Horne[1]
[1]*University of Edinburgh, MRC Centre for Reproductive Health, Edinburgh, United Kingdom*
[2]*NHS Fife, Foundation Program, Edinburgh, United Kingdom*
[3]*University of Edinburgh, Medical School, Edinburgh, United Kingdom*
[4]*University of Oxford, Nuffield Department of Obstetrics and Gynaecology, Oxford, United Kingdom*

Study question: Do women with chronic pelvic pain (CPP) have a neuropathic pain (NeP) component to their painful symptoms?
Summary answer: Clinical features of NeP are present in >50% of women with CPP. Rates of NeP are not significantly affected by associated intra-pelvic pathology. Features of NeP can be assessed by questionnaires that are acceptable to women. NeP questionnaires as well as modified QST could be used to predict response to treatment of CPP with neuromodulators.
What is known already: CPP affects 5–24% women. 55% have no obvious pathology and 40% have associated endometriosis. NeP is defined as pain arising as a consequence of a lesion/disease affecting the somatosensory system. The prevalence of NeP in women with CPP is not known. Diagnosis of NeP is challenging because there is no gold-standard assessment. Questionnaires have been used the clinical setting to diagnose NeP and QST has been used in a research to identify abnormal sensory function.
Study design, size, duration: This was a prospective cohort study. The sample size was calculated assuming an expected 70% negative diagnosis for the presence of NeP (based on previous clinical audit data) for the presence of NeP and was powered for specificity of 85±10% (based on validation of NeP questionnaires outside the reproductive tract).
Participants/materials, setting, methods: Women (aged 18–55) attending a university hospital with a diagnosis of CPP underwent a clinician completed questionnaire (DN4) and completed the S-LANSS and PainDETECT® questionnaires. They underwent QST testing by a trained clinician. They also completed a patient acceptability questionnaire. Patient notes were interrogated for underlying aetiology, and drug use.
Main results and the role of chance: Clinical features of NeP were identified by both questionnaires and QST. Of the women who were NeP positive, 56, 35 and 26% were identified by the S-LANSS, DN4 and PainDETECT® respectively. When NeP was identified by questionnaire, the associated laparoscopy findings were similar irrespective of which questionnaire was used. No subject had entirely unchanged QST parameters. There were distinct loss and gain subgroups as well as mixed alteration in function but this is not necessarily clinically significant in all patients. 80% of patients were confident that questionnaires could diagnose NeP in the setting CPP and 90% found them easy to complete.
Limitations, reason for caution: NeP questionnaires have not been validated within the context of CPP. The lack of gold standard means formal validation is likely to be challenging. A modified QST-protocol was used to facilitate testing in our clinical setting but this reduces ease of comparison with previously published NeP literature out with the pelvis.
Wider implications of the findings: Early identification of NeP in women with CPP with a simple questionnaire could facilitate targeted therapy with neuromodulators, which are cheap, readily available and with good safety profiles. Furthermore, this could prevent unnecessary or fertility-compromising surgery and prolonged treatment with hormones.
Study funding/competing interest(s): Funding by University(ies) – University of Edinburgh.
Trial registration number: REC No: 12/SS/0149. Lothian R&D approved: 2012/R/RM/47.
Keywords: neuropathic pain, endometriosis, chronic pelvic pain

P-380 Developmental disturbances caused by endometriosis and normalizing effects of aromatase inhibitors on embryo morphokinetics: a pilot study

F. Boynukalin[1], M. Serdaroglu[2], N. Findikli[2], T. Aksoy[2], G. Oktayer[3], C. Celik[4], S. Sezginsoy[4], O. Sahin[5], M. Bahçeci[1]
[1]*Bahceci Fulya IVF Center, Reproductive Endocrinology, Istanbul, Turkey*
[2]*Bahceci Fulya IVF Center, Embryology Laboratory, Istanbul, Turkey*
[3]*Bahceci Fulya IVF Center, A&D Laboratory, Istanbul, Turkey*

[4]*Bahceci Umut IVF Center, Reproductive Endocrinology, Istanbul, Turkey*
[5]*Bahceci Umut IVF Center, Embryology Laboratory, Istanbul, Turkey*

Study question: This study asks whether any effect of endometriosis as a cause of infertility on embryo development kinetics and also evaluates if aromatase inhibitors can create developmental amelioration in cases with endometriosis by time-lapse analysis.
Summary answer: Compared to controls, endometriosis can significantly disturb embryo morphokinetics, cause retardations in early embryo dynamics. In cases where aromatase inhibitors were included in ovarian stimulation protocols, although such disturbances can partially be masked during early cleavage, apparent albeit not significant differences in morphokinetic parameters.
What is known already: It is well known that women with endometriosis have lower success with IVF, which is postulated to be related with impaired follicular microenvironment and reduced endometrial receptivity. Although such an impaired microenvironment has been known to have an impact on oocyte quality and embryo development, little is known about its effects on human embryo morphokinetics.
Study design, size, duration: In order to minimize confounding factors, cases which endometriosis was sole indication of infertility were included. Morphokinetic parameters of 119 embryos (18 cycles) with endometriosis were retrospectively analysed and compared with 48 embryos (4 patients) with unexplained infertility using time-lapse monitoring between January 2012-August 2014 in Bahceci Fulya-Umut IVF Centers.
Participants/materials, setting, methods: Embryos derived from endometriosis patients that used antagonist protocol (11 cycles, 78 embryos, Group I), endometriosis patients that used letrozole-antagonist protocol (7 cycles, 41 embryos, Group II) and control group that used antagonist protocol (4 cycles, 48 embryos, Group III) were analyzed. Analyzed parameters were: extrusion of the 2nd polar body, pronuclei appearance, pronuclear fading, early cleavage time points and duration in each cleavage from two cells – until hatching blastocyst stages, time interval between cleavages, PN duration and duration of blastulation.
Main results and the role of chance: Embryos of endometriosis patients showed significantly perturbed early and late cleavage timings compared to controls ($p > 0.05$). Compared with Group II and III embryos, embryo development in Group I embryos delayed at from tPB2 to t5 parameters. In Group II, inclusion of aromatase inhibitors minimized these perturbations and resulted in improved early embryo morhokinetics. On the other hand, although the pace of early embryo development was found to be similar with the controls, embryos in group II were found to reach tEB and tHB stages significantly earlier ($p > 0.05$).
Limitations, reason for caution: The number of embryos and cycles analysed are the main limitations of our study. Further research with larger sample sizes, according to the stage of endometriosis and technical setting are required to confirm our findings.
Wider implications of the findings: Our preliminary study indicates that there can be significant disturbances on embryo morphokinetics in patients with endometriosis. To the best of our knowledge, this is the first study that analyse human embryo morphokinetics in such cases. As the number of cases increase, a better understanding of the possible effects, degree of disturbances with respect to the stage of endometriosis as well as the possible corrective approaches can be obtained.
Study funding/competing interest(s): Funding by hospital/clinic(s) – This study received no funding and no conflicts of interests to be declared.
Trial registration number: This study was not an RCT and therefore there is no registration number.
Keywords: endometrosis, time-lapse monitoring, letrozole

P-381 A significant association between CCR5 and voltage gated sodium channel SCN3A in endometriotic lesions may allow communication between inflammation and sensory nerves

B. McKinnon[1], V. Kocbek[1], N. Bersinger[1], M. Mueller[1]
[1]*University of Bern, Department of Clinical Research, Berne, Switzerland*

Study question: Is there a relationship between inflammation and the regulators of nociceptive action potentials in sensory neurons in endometrial and endometriotic tissue?
Summary answer: A significant positive correlation between the expression of the RANTES receptor CCR5 and the voltage gated sodium channel SCN3A exists in endometriotic lesions.
What is known already: Nerve fibers have been identified in eutopic endometrium of women with endometriosis and are present around endometriotic lesions. Endometriosis creates a chronic inflammatory response and inflammatory cytokine receptors are present on sensory nerves. By binding to their receptors cytokines can influence the activity of sensory nerve through the expression and activity of voltage gated ion channels. An association between peritoneal inflammation and sensory nerve ion channel expression may be important in pain signals.
Study design, size, duration: A total of 30 women (17 with endometriosis, 13 without) undergoing laparoscopic surgery were included in the study. No hormonal treatment was reported at least 3 months prior to surgery and all samples were collected during the proliferative stage. Both eutopic endometrial biopsies and ectopic endometriotic tissue was collected.
Participants/materials, setting, methods: mRNA was isolated from both eutopic and ectopic endometrial tissue and gene expression determined with quantitative PCR. Cytokine receptors (TNFR1, CCR2, CCR5 LepR), purinergic ion channels (P2X2, P2X3, P2X4) and voltage gated sodium channel (SCN3A, SCN9A and SCN11A) mRNA expression was determined via quantitative Real-time PCR.
Main results and the role of chance: CCR5, the receptor for RANTES, was significantly increased in the peritoneal ectopic lesions compared to either the matching eutopic tissue and the ovarian lesions. The purinergic receptors were present in eutopic tissue with no significant difference between their eutopic and ectopic expression. The voltage gated sodium channels however were either not present, or present at very low levels in eutopic endometrial tissue and significantly increased in the ectopic lesions. Furthermore analysis between cytokine receptors and voltage gated ion channel identified a significant correlation between the cytokine receptors (CCR and TNFR1), the voltage gated sodium channels (SCN3A and SCN9A) and importantly between the cytokine receptor CCR5 and the SCN3A voltage gated sodium channel.
Limitations, reason for caution: The current results only show an association between cytokine receptors and voltage gated ion channels and not a cause-and-effect. Further *in vitro* experiments on sensory nerve cells will be needed to confirm a direct association between CCR5 and the SCN3A voltage gated sodium channel.
Wider implications of the findings: As voltage gated sodium channels were only present in ectopic tissue these results suggests that either sensory nerve are not present in the endometrium of endometriotic women, or that expression of these ion channels is induced in sensory nerves in an ectopic, inflammatory environment. A significant relationship between CCR5 and SCN3A raises the possibility that RANTES may induce SCN3A expression in endometriotic associated sensory nerves and thus could contribute to the painful response.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Frauenklinink, Inselspital Berne.
Trial registration number: 149/03.

P-382 Genome-wide pathway analysis highlights the role of Wnt signaling in endometriosis

O. Uimari[1], N. Rahmioglu[1], D. R. Nyholt[2], C. M. Becker[3], A. P. Morris[1], G. W. Montgomery[4], K. T. Zondervan[1]
[1]*University of Oxford, The Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom*
[2]*QIMR Berghofer Medical Research Institute, Neurogenetics, Brisbane, Australia*
[3]*University of Oxford, Nuffield Department of Obstetrics and Gynaecology, Oxford, United Kingdom*
[4]*QIMR Berghofer Medical Research Institute, Molecular Epidemiology, Brisbane, Australia*

Study question: Do endometriosis genome-wide association study (GWAS) data provide insight in novel endometriosis-associated biological pathways, and to what extent do they provide evidence for the causal involvement of previously hypothesised pathways such as steroidogenesis or immune responses?
Summary answer: Pathway analysis of the largest GWAS conducted to date, in women of European ancestry, uncovers multiple interesting pathways that are statistically enriched for genetic endometriosis association signals. Hypothesis-free analysis involving all independent loci genome-wide uncovers the *Wnt signaling pathway* as the top pathway associated with endometriosis.

What is known already: Endometriosis is a complex disease with an estimated heritable component of ~51%. GWA studies have so far identified nine genome-wide significant ($P < 5 \times 10^{-8}$) common risk variants for endometriosis, which explain <4% of heritability, where as half of the heritability is estimated to such risk variants. Pathway analyses of GWAS data combine the evidence of single variants into gene-based measures, and adding to the evidence for certain pathways to be involved in disease pathogenesis.
Study design, size, duration: We conducted hypothesis-free and hypothesis-driven pathway analyses utilising the International Endogene Consortium GWAS data, comprising of 3,194 surgically confirmed endometriosis cases and 7,060 controls with genotype data imputed up to Phase3 1000-Genomes. Endometriosis cases were grouped into stage I-II, and stage III-IV (rAFS classification) for sub-phenotype analysis.
Participants/materials, setting, methods: We used two major pathway databases, MSigDB and PANTHER and tested for enrichment of genetic variants in (1) all curated pathways (Hypothesis-free), (2) pre-selected pathways defined by over-representation of endometriosis candidate genes and literature review of endometriosis biology (Hypothesis-driven). Genetic enrichment analysis within these pathways was performed in MAGENTA software.
Main results and the role of chance: Hypothesis-free analysis showed 72 genetically enriched pathways with a nominal $P < 0.05$, with the most significantly associated the *Wnt signaling pathway* (nominal $P = 0.018$, FDR = 0.018) comprising 80 known genes. In the hypothesis driven analysis *Insulin/IGF pathway-MAPK cascade* showed significant genetic enrichment for stage I-II endometriosis, and *Androgen oestrogen progesterone biosynthesis* –pathway for stage III-IV endometriosis (FDR < 0.05). There were no immunology-related pathways that showed significant enrichment of genetic variants associated with endometriosis, suggesting that immune response – although an important characteristic of disease progression and symptomatology – does not play a major part in initial causality. Results on sub-phenotype analyses (stage I–II and stage III–IV cases) will be presented at the meeting.
Limitations, reason for caution: The analysis is restricted to the gene-based pathway definition as registered in the databases, and by current knowledge of the constituting parts of these pathways. Only SNP associations within genes can be attributed to pathways, and are therefore included in the analysis.
Wider implications of the findings: The top ranked genetically enriched pathways for endometriosis are steroid hormone metabolism and steroid hormone related cell signalling pathways. Our highest ranked enriched pathway, *Wnt signalling* is involved in sex-hormone homeostasis and female tract development, offering us more knowledge on the underlying biology of endometriosis. With a recognised important role in endometrium biology, there should be an increased focus on the causal role of *Wnt signaling* in endometriosis pathogenesis.
Study funding/competing interest(s): Funding by national/international organization(s) – The Wellcome Trust.
Trial registration number: NAD.

[3]*Obstetrics and Gynecology, Seoul Rachel Fertility Center, Seoul, Afghanistan*
[4]*Geno Life Care division, Biocore Co. Ltd., Seoul, South Korea*

Study question: To analysis the endometrial gene expression related to the signaling network for uterine receptivity and implantation in patients with repeated implantation failure (RIF).
Summary answer: Gene expression pattern associated with signaling network for uterine receptivity and implantation can be used clinically in patients with RIF. This identification of the optimum window of implantation by using endometrial receptivity biomarkers can help to rescue repeated pregnancy failure resulting from misplaced dating of the endometrial WOI.
What is known already: Repeated implantation failure (RIF) is determined when embryos of good quality fail to implant following IVF-ET cycles in a minimum of 3 times. RIF is the most common cause of infertility couples. Many other studies that analyzed the human gene expression during different menstrual cycle have been published.
Study design, size, duration: Prospective controlled study. Analysis of the gene signature related to the signaling network for uterine receptivity and implantation in patients ($n = 3$) with repeated implantation failure.
Participants/materials, setting, methods: Human endometrial samples were collected throughout the menstrual cycle (LH + 5, LH + 7 and LH + 9) in patients with RIF. The profiling of transcriptomic signature and histologic evaluation were accomplished. Each total RNA sample was labeled and amplified. Labeled aRNA were placed on Agilent Sureprint G3 Human GE 8X60K array and analyzed.
Main results and the role of chance: There are different gene expression patterns between receptive and non-receptive histologically observed endometrium obtained on the same day of menstrual cycles. And its patterns were slightly different at each patient. Comparison of the data sets defined a common set were slightly different, also. In addition, in comparison with endometrial receptivity related 30 genes, various fold change were showed in endometrium of each patient with repeated implantation failure. From 6 to 15 genes were changed at LH + 5 phases versus LH + 7 phases and from 10 to 16 genes were changed at LH + 5 phases versus LH + 9 phases. Furthermore, there were strong different patterns in PCO patient with RIF.
Limitations, reason for caution: Since this was a prospective study with small sample size, randomized study in a larger scale will be necessary.
Wider implications of the findings: This result of the expression patterns of endometrial receptivity related genes are helpful for diagnosis and personalized embryo transfer in patient with RIF. Further more research is need to confirm and better understanding our data.
Study funding/competing interest(s): Funding by hospital/clinic(s) – This study was funded by our own private infertility center.
Trial registration number: NA.

P-384 Increased expression levels of metalloprotease, tissue inhibitor of metalloprotease, metallothionein, and p63 in ectopic endometrium: an animal experimental study

J. Rosa-e-Silva[1], V. C. M Brandao[1], C. M. Bonocher[1], J. Meola[1], S. B. Garcia[1], F. J. Candido-dos Reis[1], O. B. Poli-Neto[1], A. A. Nogueira[1], R. A. Ferriani[1]
[1]*Faculty of Medicine of Ribeirao Preto, Obstetrics and Gynecology, Ribeirao Preto, Brazil*

Study question: To characterize the patterns of cell differentiation and tissue invasion in topic and ectopic endometria of rabbits with induced endometriotic lesions via a well-known experimental model, 4 and 8 weeks after the endometrial implantation procedure.
Summary answer: Ectopic endometrial lesions seem to express greater power for cell differentiation and tissue invasion, compared with topic endometrial lesions, demonstrating a potentially invasive, progressive, and heterogeneous presentation of endometriosis.
What is known already: The etiopathogenesis of endometriosis is controversial and studies suggest that the endometrium of patients with endometriosis have an invasive and aggressive behavior, and higher expression levels of substances related to cellular invasion, cellular differentiation, and proliferation.
Study design, size, duration: Animal experimental study. Twenty-nine female New Zealand rabbits.
Participants/materials, setting, methods: Twenty-nine female New Zealand rabbits underwent laparotomy for endometriosis induction through resection of one uterine horn, isolation of the endometrium, and fixation of tissue segment to the pelvic peritoneum. Two groups of animals (14 and 15 animals in each group) were sacrificed 4 and 8 weeks after endometriosis induction. The lesion was excised together with the opposite uterine horn for endometrial gland and stroma determination.
Main results and the role of chance: Immunohistochemical reactions were performed in topic and ectopic endometrial tissues for analysis of the following markers: metalloprotease (MMP-9) and tissue inhibitor of metalloprotease (TIMP-2), which is involved in the invasive capacity of the endometrial tissue; and metallothionein and p63, which are involved in cell differentiation and proliferation. The intensity of the immunostaining for MMP 9, TIMP-2, metallothionein, and p63 was higher in the ectopic endometrium than in the topic endometrium. However, when the ectopic lesions were compared at

4 and 8 weeks, no significant difference was observed, with the exception of the marker p63, which was more evident after 8 weeks of evolution of the ectopic endometrial tissue.

Limitations, reason for caution: The results of an animal experimental study should be viewed with caution.

Wider implications of the findings: In this study, we demonstrated that the ectopic endometrial lesions showed higher expression levels of cellular invasion markers (MMP-9 and its inhibitor TIMP-2) and molecules involved in cellular proliferation and differentiation (MT and p63) than did topic the endometrial lesions in a rabbit experimental model of endometriosis, with good reproducibility and effectiveness. This indicates the invasive and progressive power of the illness, corroborating the other evidence described.

P-385 Mesenchymal stem cell-conditioned medium enhances trophoblast cell proliferation, migration and invasion: possible applications in improving implantation rate in assisted reproductive technology

C. Y. Liao[1], S. C. Hung[2], H. Y. Li[3]

[1]*National Yang-Ming University, Institute of Anatomy and Cell Biology, Taipei city, Taiwan R.O.C.*

[2]*National Yang-Ming University, Institute of Clinical Medicine, Taipei city, Taiwan R.O.C.*

[3]*Taipei Veterans General Hospital, Department of Obstetrics and Gynecology, Taipei city, Taiwan R.O.C.*

Study question: Embryo implantation is a complex process that requires adequate proliferation, migration and invasion of trophoblast cells. Since mesenchymal stem cell-conditioned medium (MSC-CM) can stimulate skin cell proliferation and migration, we investigated whether MSC-CM can enhance trophoblast cell proliferation, migration and invasion, and the underlying mechanisms.

Summary answer: Using mouse blastocysts and trophoblast stem (TS) cells, we found that MSC-CM could enhance trophoblast cell proliferation, migration and invasion. MSC-CM was found to be abundant in various growth factors and cytokines, among which thrombopoietin mediated MSC-CM-enhanced trophoblast outgrowth. ERK activation was shown to mediate MSC-CM-stimulated trophoblast cell proliferation.

What is known already: Our previous study has shown MSC-CM could significantly enhance skin cell migration. Sufficient migration capacity is crucial for trophoblast invasion to endometrium, and inadequate trophoblast invasion results in implantation failure or abortion. MSC-CM may provide a potential means to promote trophoblast functions, thereby increasing implantation rates and preventing abortion in assisted reproductive technology (ART).

Study design, size, duration: We first determined the effects of MSC-CM on mouse blastocyst outgrowth and on the proliferation, migration and invasion of TS cells. Then we analyzed growth factors and cytokines contained in MSC-CM. Finally, underling molecular mechanisms of MSC-CM-enhanced trophoblast cell proliferation and migration were studied.

Participants/materials, setting, methods: Mouse blastocyst outgrowth was assessed by measuring areas of trophoblast outgrowth at day4. Migration and invasion of TS cells were determined by Transwell assay. MTT was used to determine cell proliferation. Western blot and appropriate inhibitors were employed to study underlying mechanisms. Protein array detected protein contents in MSC-CM.

Main results and the role of chance: MSC-CM dose-dependently enhances blastocyst outgrowth, suggesting that MSC-CM could promote trophoblast cell migration. Transwell assays also revealed that MSC-CM promoted TS cell migration and invasion. Furthermore, MSC-CM significantly stimulated TS cell proliferation. MSC-CM was abundant in various growth factors and cytokines, including thrombopoietin. Anti-thrombopoietin antibody significantly inhibited the enhancing effect of MSC-CM on trophoblast outgrowth, and recombinant thrombopoietin also promoted trophoblast cell migration, indicating a role of thrombopoietin in MSC-CM-enhanced trophoblast cell migration. Extracellular signal-regulated kinases (ERK) were activated by MSC-CM, and ERK inhibitor PD98059 could block the MSC-CM-enhanced TS cell proliferation, indicating that ERK was involved in MSC-CM-enhanced trophoblast cell proliferation. This study suggested that MSC-CM could enhance trophoblast functions, findings that may be applied to increase implantation rate in ART.

Limitations, reason for caution: These findings were based on *in vitro* studies using mouse blastocysts and TS cells. Further studies using human TS cells may be performed after ethical issues are settled. Mouse model of recurrent miscarriage (CBA/J female X DBA/2 male) may be utilized to examine whether MSC-CM could prevent recurrent abortion.

Wider implications of the findings: Since MSC-CM significantly enhanced trophoblast cell proliferation, migration and invasion, it may be added in the embryo transfer medium to promote trophoblast functions, thereby enhancing implantation rate in ART.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Funding by national/international organization(s). National Science Council (NSC101-2314-B-010 -031 -MY3). Taipei Veterans General Hospital (V102C-142).

Trial registration number: NA.

P-386 Combined treatments of intrauterine perfusion with G-CSF and injection of hCG enhance the endometrial growth, implantation and pregnancy rates in thin endometrium patients

Y. H. Jung[1], S. S. Kim[2], Y. Y. Kim[1], Y. J. Yoo[1], M. H. Kim[1], S. H. Kim[1], J. D. Jo[1]

[1]*Elle Medi, Infertility Clinic, Changwon Gyongnam, South Korea*

[2]*Pusan National University Hospital, Pusan, Korea South*

Study question: Intrauterine perfusion with G-CSF (granulocyte colony-stimulating factor) and intrauterine injection of hCG improved the endometrial growth and implantation rates, respectively. This study was examined the efficiency between endometrium perfusion of G-CSF and a combination of G-CSF and intrauterine injection of hCG in the patients.

Summary answer: For patients who had a thin endometrium (<8 mm) on the hCG day, the combined treatments of endometrium perfusion of G-CSF on the day of hCG and intrauterine injection of hCG before embryo transfer significantly improved the endometrial thickness, implantation and pregnancy rates.

What is known already: An adequate endometrial thickness is necessary for successful implantation. The treatment of Vitamin E, l-arginine, or sildenafil citrate was not sufficient to improve the endometrial growth in patients with a thin endometrium, but intrauterine perfusion with G-CSF was effective to patients showing a resistance to the treatment. More recently, intrauterine injection of hCG before the embryo transfer improved significantly both the implantation success and the pregnancy rates of the patients with recurrent implantation failure.

Study design, size, duration: Prospective study was examined using 58 patients who had a thin endometrium (<8 mm) on the hCG day and failed to conceive with high-quality embryos in previous IVF cycles in a private fertility clinic from 2011 to 2014. Groups were established according to the treatments.

Participants/materials, setting, methods: Group A (n = 34) was received G-CSF (filgrastim 300 μ/mL) by slow intrauterine infusion using embryo transfer catheter on the day of hCG. Group B (n = 24) was received G-CSF on the day of hCG and 500 IU of hCG intrauterine administration approximately 7 min before embryo transfer.

Main results and the role of chance: There were no significant differences in endometrial thickness on the day of hCG among both groups (Group A vs. Group B; 6.9 ± 0.8 vs.6.8 ± 7.2) whereas both groups showed significant increase of the endometrial thickness on the day of embryo transfer (8.6 ± 1.0 vs. 8.5 ± 0.8). The endometrial thickness was gradually increased from the hCG to the ET day, but it was not significantly differed on the day of ET in both groups. Interestingly, the rates of implantation (13.0 vs. 22.6%) and clinical pregnancy (29.4 vs. 41.7%) were significantly higher in Group B than those in Group A (P < 0.01). Thus, the combined treatments of G-CSF and hCG intrauterine infusion enhanced the endometrial thickness, implantation and pregnancy rates of the patients.

Limitations, reason for caution: The clinical results are necessary to confirm its efficacy and safety via further studies. Thus, further large cohort studies are required.

Wider implications of the findings: This study shows the most recent finding that the combined treatments of G-CSF and hCG intrauterine infusion enhance the increase of endometrial thickness as well as the implantation and pregnancy

rates in patients with thin endometrium. The combined treatments will improve the efficacy for patients with recurrent implantation failure.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Ellemedi infertility clinics.
Trial registration number: NA.

ETHICS AND LAW

P-387 Oocyte banking for future mother-to-daughter donation; how to assess these requests?

F. Mol[1], E. M. E. Balkenende[1], C. B. Lambalk[2], M. Goddijn[1], W. Dondorp[3]
[1]*Academic Medical Center, Center for Reproductive Medicine, Amsterdam, The Netherlands*
[2]*VU University Medical Center, Department of Obstetrics and Gynecology, Amsterdam, The Netherlands*
[3]*Maastricht University, Department of Health Ethics and Society Research Schools CAPHRI and GROW, Maastricht, The Netherlands*

Study question: How should requests for oocyte banking for future mother-to-daughter donation be assessed in the light of relevant ethical considerations?
Summary answer: Oocyte banking for future mother-to-daughter-donation is challenging and needs special ethical attention of the fertility specialists involved. Requests should be handled with thorough screening and psychological counselling. Further guidance is needed, especially with regard to concerns that those for whom oocytes were banked, may feel obligated to use them.
What is known already: The ethical aspects of gamete donation by family members ('Intrafamilial Medically Assisted Reproduction'; IMAR) have been discussed in ESHRE and ASRM documents. However nowadays, oocyte vitrification opens the door for a new form of IMAR: banking of mothers' oocytes for a possible future donation to her daughter in situations where premature ovarian insufficiency (POI) is diagnosed in girls and young women. This form of intergenerational IMAR raises additional concerns not yet discussed in those documents.
Study design, size, duration: We performed a systematic review of the literature regarding mother-to-daughter donation to extract the ethical dilemma's involved. We collected 3 requests of mothers who asked for oocyte banking for future donation to their daughters with POI in two academic fertility centres from 2011 up to 2014.
Participants/materials, setting, methods: Studies were identified by searching Medline, ISI Web of Science and Google scholar until January 2015. Studies were eligible when intergenerational donation or banking of oocytes was discussed. We identified 197 studies from the literature, of which 5 were included in the systematic review.
Main results and the role of chance: Three publications were ESHRE and ASRM documents on IMAR. One review discussed the possibility of oocyte banking for young galactosemic girls. One case-report described a mother who banked oocytes for her daughter with Turner syndrome. The reported ethical considerations were risk of role-confusion and coercion. The risk of role-confusion might be lower in mother-to-daughter-donation compared to sister-to-sister-donation, since the donor's life expectancy is limited. The risk of coercion might be reduced since the donor is in the more powerful position. No permission was given to the three mothers who requested oocyte banking in our hospitals. The staff was reluctant to bank oocytes since guidance was lacking with regard to their major concern: that young girls can feel obligated later in life to use the oocytes.
Limitations, reason for caution: The systematic review of literature revealed a limited number of studies. The search for requests for mother-to-daughter donation was limited to two academic fertility centres.
Wider implications of the findings: Overall; there is a shortage of literature regarding this specific form of IMAR. On the one hand, the mother's gift may help fulfill a later childwish of her daughter. On the other hand, young girls do not yet know if they want to have children and can feel obligated later in life to use the oocytes. The specific ethical dilemmas of oocyte banking for future mother-to-daughter donation should be further explored.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Academic Medical Center, Center for Reproductive Medicine.
Trial registration number: NA.
Keywords: mother-to-daughter-donation, fertility preservation, ethics, IMAR

P-388 The technological imperative in reproductive medicine

H. Mertes[1]
[1]*Bioethics Institute Ghent BIG Ghent University, Department of Philosphy and Moral Sciences, Gent, Belgium*

Study question: As in many areas of medicine, also reproductive medicine is not immune to the dogma 'we can so we should'. Why is this ethically problematic, how can we explain it and what can be done about it?
Summary answer: Given the rising health care costs and given the increasing pressure on research funding, a more critical attitude towards new innovations should be adopted. Both on the level of individual treatment and on the level of research, responsibility is shared by several parties involved.
What is known already: It has previously been argued that technology is no longer merely a tool that is used to respond to challenges and demands in health care, but that technological possibilities also create demand. Moreover, new medical technology is the dominant driver of increasing health care costs.
Study design, size, duration: Existing literature on the technological imperative in health care was gathered and an assessment was made of whether or not this phenomenon is ethically problematic in the field of reproductive medicine, with a focus on recent achievements such as uterus transplantations and derivation of gamete precursors from stem cells.
Participants/materials, setting, methods: The model that is used to bring empirical data (as found in literature research) and normative ethics together is the Wide Reflective Equilibrium. This is essentially a coherence theory, where the justification of the components (moral judgments, moral principles and background theories) is achieved by their coherence.
Main results and the role of chance: The technological imperative is at play on two different levels in reproductive medicine. First, individual patients often wish to exhaust all treatment options to avoid future regrets. A rational assessment of success rates and risks is easily undermined. There is a shared responsibility of policy makers (reimbursement schemes), physicians and patients to weigh the pros and cons of each treatment option rather than 'trying everything possible'. Second, also research is not exclusively steered by patients' needs. Besides the technological imperative, factors such as prestige, publication pressure and commercial interests contribute to the trend to focus on groundbreaking new technologies, rather than – for example – making existing ARTs more affordable. In this case, responsibility stretches out to funding bodies, researchers, pharmaceutical companies, scientific journals and academic institutions.
Limitations, reason for caution: This is a philosophical assessment, not an empirical study.
Wider implications of the findings: Today more than ever before, the theoretical possibilities in health care are enormous. At the same time, research funding is limited and new treatment options are oftentimes very costly. Thus, we are evolving towards a society in which much will be technically feasible, but not necessarily affordable or desirable. Also in reproductive medicine, there is an increasing responsibility of several actors to maintain the right priorities for technological innovation and to resist the technological imperative.

P-389 The moral and legal status of human parthenogenetic entities and parthenogenetic derived stem cells after the ruling of the European court of justice

T. Faltus[1]
[1]*Translational Centre for Regenerative Medicine, University Leipzig, Leipzig, Germany*

Study question: The research project aims to clarify the legal and moral status of human parthenogenetic entities and parthenogenetic derived stem cells taking into account the patent ruling of the European Court of Justice.
Summary answer: At least in patent law human parthenogenetic entities have a different moral and legal status than human totipotent entities. This patent law related findings can be a blueprint for the overall determination of the moral and legal status of human parthenogenetic entities.
What is known already: Within the member states of the European Union (EU) there it is controversial whether early human totipotent entities have such a moral

status which protects them from purposeful production and destruction for stem cell research and/or medicine. Whilst techniques based on human embryonic stem cells extracted from human totipotent entities are unpatentable within the EU, techniques based on stem cells from human parthenogenetic entities are patentable, because human parthenotes are not considered to be totipotent.
Study design, size, duration: None.
Participants/materials, setting, methods: None.
Main results and the role of chance: The ruling of the European Court of Justice in its parthenote patent case indicates that human parthenogenetic entities have another moral status than human totipotent entities. This different moral status is connected to a smaller protection scope than the moral status of human totipotent entities provides. Whilst techniques based on embryonic stem cells extracted from human totipotent entities are unpatentable in the EU, techniques based on stem cells from human parthenogenetic entities are patentable. Therefore, therapies based on embryonic stem cells extracted from totipotent human entities are considered not to be in compliance with the ordre public of the EU as well as the related patent issues, therapies based on stem cells extracted from human parthenotes seem to be in compliance with current morals standards.
Limitations, reason for caution: None.
Wider implications of the findings: Since therapies based on embryonic stem cells extracted from human totipotent entities could cause moral and legal problems, therapies based on stem cells extracted from human parthenotes could be a viable alternative if such stem cells meet the necessary scientific and medical quality standards.
Study funding/competing interest(s): Funding by University(ies) – Funding by national/international organization(s). Translational Centre for Regenerative Medicine (TRM) Leipzig, funded by the German Ministry of Education and Research (BMBF 1315883).
Trial registration number: NA.

P-390

Abstract withdrawn by the author

P-391 The interest of gynaecologists in potential future fertility treatments involving artificial gametes for couples with ovarian failure

S. Hendriks[1], T. M. D'Hooghe[2], M. van Wely[1], F. van der Veen[1], S. Repping[1], E. A. F Dancet[1]
[1]*Academic Medical Center, Center for Reproductive Medicine, Amsterdam, The Netherlands*
[2]*Leuven University Hospital, Leiven University Fertility Centre, Leuven, Belgium*

Study question: What characteristics define whether gynaecologists would recommend potential fertility treatments with artificial gametes to couples with ovarian failure?
Summary answer: Gynaecologists are interested in treatments with artificial gametes allowing infertile patients to have genetically related children. Clinical introduction of such treatments would mainly depend on effectiveness and safety for the child. In addition, curing infertility, moral acceptability, naturalness, burden, safety for patients, costs, and diagnostic value are important characteristics.
What is known already: New fertility treatments with artificial gametes allowing infertile patients to have genetically related children are being developed in model organisms. Gynaecologists need to reflect on the conditions deemed necessary for introducing new treatments in clinical practice. Effectiveness, safety, costs and burden are classically considered relevant. Patients additionally value treatments' resemblance to natural conception and feeling cured. Which treatment characteristics define whether gynaecologists would recommend the use of artificial gametes to their patients is unknown.
Study design, size, duration: Exploratory qualitative study conducted in 2014. Ten gynaecologists selected by purposive sampling took part in a single face-to-face in-depth interview of 45–70 min. This sample size was sufficient to reach data saturation, defined as not identifying new treatment characteristics during three subsequent interviews.
Participants/materials, setting, methods: Gynaecologists were updated on the progress of developing artificial gametes and asked to reflect on treatment characteristics determining which treatment to prescribed to heterosexual couples with ovarian failure. The interviews were performed according to a semi-structured interview guide, recorded, transcribed and subjected to content analysis by two researchers.
Main results and the role of chance: The ten gynaecologists (6 women, 4 men) worked in University clinics in Belgium (n = 5) and the Netherlands (n = 5), had on average 17.2 (±9.9) years of experience. All participants had genetically related children, one had experienced fertility treatments herself and one had stepchildren. The gynaecologists were interested in artificial gametes and considered ten treatment characteristics as relevant: safety for the child, pregnancy rates, genetic parenthood, curing infertility, moral acceptability, naturalness, burden, safety for the patient, costs, and diagnostic value. The characteristics most commonly receiving their top-3-priority were: safety for the child (n = 10/10), pregnancy rates (n = 7/10) and genetic parenthood (n = 5/10). All gynaecologists indicated that the decision to offer artificial gametes in clinical practice would require reflection of and discussion among professionals from various fields.
Limitations, reason for caution: Data-saturation indicated that all treatment characteristics important to gynaecologists have been identified. Insight in how these treatment characteristics are traded-off against each other requires quantitative research on a large sample of gynaecologists.
Wider implications of the findings: Gynaecologists' interest encourages further research into fertility treatments with artificial gametes.
Study funding/competing interest(s): Funding by University(ies) – University of Amsterdam, Academic Medical Center.
Trial registration number: NA.
Keywords: artificial gametes, implementation, stem-cell based treatments, qualitative research

P-392 Time-lapse in reproductive medicine: outlining ethical prospects and challenges

C. Munthe[1], S. Järvholm[2], K. Lundin[3]
[1]*University of Gothenburg, Department of Philosophy Linguistics and Theory of Science, Gothenburg, Sweden*
[2]*University of Gothenburg & Salhrenska University Hospital, Department of Psychology & Centre for Reproductive Medicine, Gothenburg, Sweden*
[3]*University of Gothenburg & Salhrenska University Hospital, Department of Obstetrics and Gynecology & Centre for Reproductive Medicine, Gothenburg, Sweden*

Study question: What are the ethical prospects and challenges of using time-lapse (TL) for different purposes in research, clinical service, care and commercial marketing in the assisted reproductive context? What possible professional or public policy implications follow from these?
Summary answer: The ethics of TL depends on its more exact use. Current knowledge indicates possible clinical benefits, but premature clinical application should be resisted. TL opens for, e.g., patient demands regarding embryo selection and implementation of TL involving display to patients mandates extra caution regarding care, counseling and marketing exploits.
What is known already: Using TL to capture the process of in vitro embryo development has quickly entered reproductive medicine, with prospective uses in research and clinical service. It has also been picked up as a possible marketing tool by commercial providers, and as an add-on of patient care and counseling. Assessment of the effects and efficiency of TL is ongoing and, as yet, displaying complex and partly unclear or contradictory results. care and counseling aspects remain uncharted.
Study design, size, duration: Explorative theoretical analytical applied ethics study.
Participants/materials, setting, methods: Systematic analysis of ethical aspects using literature on TL and relevant aspects of the ethics of assisted reproduction and reproductive medicine.
Main results and the role of chance: TL is valuable for research, but trials of TL-interventions aiming at improved IVF should not be launched prematurely or allowed to sneak into routine practice. Offering display of TL documentation of embryo development to patients during *ongoing* treatment has unclear benefits and risks from a care and counseling perspective and arises the issue of what to display. It may be a vehicle for increasing patient involvement, but may also create conflict between patients and clinicians regarding embryo selection, and will introduce care and counselling challenges as patients form their own reactions. *Retrospective* offers appear less risky, but may fuel into uncertainty

about the outcome. Marketing services with such offers risks biasing patients towards an "entertainment" view and away from more important considerations counseling wise.
Limitations, reason for caution: There are many unknowns regarding the more detailed effects on patient experience of incorporating TL display as part of assisted reproductive services. Such additions also have unknown cultural dimensions by making the living in vitro embryo more widely and intimately visible and acquaintable.
Wider implications of the findings: Besides the need to structure, monitor and limit attempts at using TL to boost IVF results, the idea of displaying TL output to patients is in need of much probing, not least regarding patient experience and structural effects on the perception of assisted reproductive services, but also clinical policy and counseling requirements. Professional and scientific organizations should act to prevent premature and reckless clinical use.

P-393 Pre-implantation genetic diagnosis and the European convention on human rights: applying the 'consensus' and 'margin of appreciation' principles

M. Bayefsky[1]
[1]*National Institutes of Health, Department of Bioethics, Bethesda, Maryland, U.S.A.*

Study question: Is a national ban on preimplantation genetic diagnosis (PGD) compatible with the European Convention on Human Rights (ECHR)?
Summary answer: No, by applying the 'consensus' and 'margin of appreciation' principles commonly employed by the European Court of Human Rights (ECtHR), an absolute ban on PGD falls outside the allowable margin of variation in European countries' laws and is therefore incompatible with the European Convention on Human Rights.
What is known already: In the 2013 case *Costa and Pavan v. Italy*, the ECtHR struck down Italy's ban on PGD because it was internally incoherent; Italy permitted pregnancy termination if the resulting child would suffer from a serious genetic disease but would not permit the use of PGD to select for an embryo without the same disease. The Court did not address the legal question of whether a PGD ban would violate the ECHR *per se*.
Study design, size, duration: To determine whether a PGD ban violates the ECHR *per se*, I apply the principle that a high level of consensus among European national laws delineates a margin of appreciation for acceptable legal variation. I survey national laws in Europe on PGD in order to ascertain if consensus exists.
Participants/materials, setting, methods: The legal approach towards PGD was examined in the ECHR's 47 Contracting states. Existing national legislation or regulation on PGD was surveyed. A number of countries lacked explicit rules for the use of PGD, but fertility clinics freely offering PGD were identified, indicating that no ban was in place.
Main results and the role of chance: Of the 47 Contracting states to the ECHR, PGD is explicitly legal or otherwise available in 40. Only five prohibit PGD, and one is in the process of modifying its ART law to allow for the limited use of PGD. The final two countries do not appear to have IVF clinics. In the countries where PGD is available, the conditions for which it is performed varies, but at a minimum, it is utilized to select against serious heritable disorders. Based on these results and an analysis of the 'consensus' concept, I argue that consensus exists among the Contracting states that PGD should be allowed, at least for selection against serious genetic conditions. An outright ban on PGD would thus be in violation of the ECHR.
Limitations, reason for caution: The 'consensus' and 'margin of appreciation' concepts are not precisely defined by the ECtHR or ECHR experts. Determining how many Contracting states constitutes a sufficient consensus for arguing that a national measure falls outside the margin of appreciation, and hence violates the ECHR, is therefore a matter of judgment.
Wider implications of the findings: While an outright ban violates the ECHR, the Convention likely protects variation regarding the conditions for which PGD may be performed, given the lack of consensus in national laws. Legal diversity results in reproductive tourism, as couples seeking PGD travel abroad to obtain services forbidden at home. Reproductive tourism puts patients at risk for legal and health complications, and is already occurring within Europe and between Europe and the US, where PGD is not regulated.
Study funding/competing interest(s): Funding by University(ies) – This study was conducted under the auspices of Yale University's Department of Political Science, but did not require departmental funding.
Trial registration number: NA.
Keywords: PGD, European convention on human rights, reproductive rights, margin of appreciation, consensus

FEMALE (IN)FERTILITY

P-394 Comparative results of PGS cycles in patients needing two or three stimulations to provide for sufficient embryos for PGS

C. Barbed[1], F. Martinez[1], M. Parriego[1], M. Solé[1], I. Rodriguez[1], P. N. Barri[1], B. Coroleu[1]
[1]*Quiron-Dexeus, Reproduction, Barcelona, Spain*

Study question: Are different the results of Preimplantation Genetic Screening (PGS) cycles in patients needing to undergo two or three ovarian stimulations to yield at least ten mature oocytes?
Summary answer: Oocyte vitrification is a good strategy in patients with an inadequate response to PGS to improve their chances of a successful pregnancy. Patients who underwent 2 or 3 ovarian stimulations have different characteristics but the final outcomes were very similar.
What is known already: The main cause of infertility in recurrent miscarriage, implantation failure, severe mail factor and/or advanced maternal age is the high rate of embryo aneuploidy. PGS is a useful tool for improving treatment results in these couples. At least 10–12 mature oocytes (MII) are required to assured the availability of at least two normal embryos for transfer. Many women would need to undergo 2–3 ovarian stimulation cycles and oocyte accumulation to achieve this goal.
Study design, size, duration: An observational study of 112 patients undergoing two (2OS = 83) or three (3OS = 29) successive ovarian stimulations, oocyte accumulation, ICSI for PGS and fresh embryo transfer (ET) cycles performed between January 2012 and March 2014.
Participants/materials, setting, methods: Women undergoing several ovarian stimulations for PGS by CGH at Hospital Universitario Quiron-Dexeus. Ovarian stimulation was performed with rec-FSH or rec-FSH + HMG and GnRH-antagonist. Euploid embryos were transferred on day 5. Patient characteristics, ovarian response and clinical outcomes after two or three stimulations (20S vs 3OS) were compared by an apropriate statistical analysis.
Main results and the role of chance: Patients underwent a mean of 2.3 ± 0.4 stimulation cycles. Comparative characteristics of 2OS vs 3OS patients were: age 39.1 ± 3.4 vs 39.8 ± 4.0 years (*n*.s.), AMH 1.6 ± 1.2 vs 0.7 ± 0.7 ng/ml ($p < 0.5$); AFC 11.0 ± 5.0 vs 9.0 ± 4.0 ($p < 0.5$) respectively. Patients in 2OS group produced significantly more oocytes during second stimulation (7.5 ± 1.9 vs 10.3 ± 4.1; $p < 0.00$) regardless repeating the same stimulation protocol in 80.1% of the cases. Among patients in 3OS group, the mean number of oocytes recovered was identical in the three stimulation cycles (6.2 ± 2.5). Comparing 2OS vs 3OS, there were no significant differences in number of total oocytes (17.8 ± 4.7 vs 18.5 ± 6.3), number of embryos biopsied (9.0 ± 3.0 vs 7.0 ± 3.0), euploid embryos rate (17.6%vs18.6%) and number of embryos transferred (1.6 ± 0.5 vs 1.3 ± 0.5). There were no differences in clinical pregnancy rates per patient (34.9 vs 31.0%) and per embryo transfer (56.8 vs 60%) between 2OS vs 3OS patients.
Limitations, reason for caution: This is an observational study, performed at a single center, in a limited number of cases, with our population of patients, under our local stimulation protocols and our laboratory of oocyte cryopreservation and PGS.
Wider implications of the findings: Our results suggest that patients needing to undergo two or three ovarian stimulation cycles can expect similar results after the transfer of one or two euploid embryos. The accumulation of oocytes for PGS in patients with suboptimal ovarian response to stimulation

seems a feasible strategy to achieve the transfer of euploid embryos and clinical pregnancy.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Reproduction Department of Quiron Dexeus Hospital, Barcelona, Spain
Trial registration number: NA.
Keywords: DGS, oocyte vitrification, aneuploidies, ovarian stimulation

P-395 The impact of thyroid stimulating hormone (TSH) on Anti Mullerian hormone (AMH) levels in infertile women. Does TSH affect follicular recruitment?

A. Weghofer[1], V. A. Kushnir[2], D. H. Barad[2], N. Gleicher[2]
[1]*Medical University Vienna, Obstetrics and Gynecology, Vienna, Austria*
[2]*The Center for Human Reproduction, New York, U.S.A.*

Study question: Recent animal studies demonstrated impacts of thyroid function on follicular recruitment. Thyroxin co-culture within physiological ranges resulted in accelerated growth and reduced apoptosis of preantral follicles. To investigate whether thyroid function also influences follicular recruitment in humans, the impact of thyroid function on AMH in euthyroid infertility patients was investigated.
Summary answer: Euthyroid infertility patients with TSH ≥ 2.5µIU/mL demonstrated significantly lower AMH levels than euthyroid women with TSH < 2.5µIU/mL. These results suggest that thyroid function may influence follicular recruitment in infertility patients.
What is known already: Thyroid disorders are associated with menstrual irregularities and may cause anovulation. Even overt and/or subclinical hypothyroidism has been associated with female infertility. These observations have led to the commonly adopted practice of supplementing thyroxin in women with TSH ≥ 2.5 µIU/mL, desirous of pregnancy.
Study design, size, duration: All 225 infertility patients underwent AMH and thyroid function testing at a University-affiliated private fertility center between 2009 and 2014.
Participants/materials, setting, methods: In 225 infertile women the association of AMH and stratified TSH levels (TSH< vs. ≥2.5 µIU/mL) was investigated. Analyses were adjusted for patient age, sex hormone binding globuline levels and thyroid autoimmunity. Only euthyroid women with normal prolactin concentrations were eligible for enrollment.
Main results and the role of chance: Mean patients' age was 38.4 ± 5.0 years, mean AMH levels were 1.3 ± 2.0 ng/mL (median 0.4 ng/mL, [0.1–11.0 ng/mL]), mean TSH levels were 1.8 ± 0.9 µIU/mL. Adjusted for age and SHBG, women with TSH <2.5 µIU/mL presented with significantly higher AMH levels (1.4 ± 2.1 ng/mL) compared to those with TSH ≥2.5 µIU/mL (0.9 ± 1.5 ng/mL; $P = 0.02$), a finding remaining significant when the analysis was further adjusted for laboratory evidence of thyroid autoimmunity ($P = 0.02$).
Limitations, reason for caution: Women included in these study were predominantly of advanced reproductive age. Whether these findings are applicable to women of all ages remains to be elucidated.
Wider implications of the findings: The here presented significant association of AMH and TSH levels among euthyroid infertile women offers an explanation for previously observed effects of thyroid hormone supplementation on pregnancy potential in euthyroid women with TSH levels above 2.5 µIU/mL. Our findings also contribute to the ongoing discussion of whether thyroid function or thyroid autoimmunity represents the more important factor in affecting female reproduction. Further research is needed to evaluate whether L-thyroxin supplementation may have a beneficial effect on oocyte yield in the course of IVF.
Study funding/competing interest(s): Funding by national/international organization(s) – The Foundation for Reproductive Medicine.
Trial registration number: NA.
Keywords: thyroid function, anti Mullerian hormone (AMH), thyroid stimulating hormone (TSH), functional ovarian reserve, follicular recruitment

P-396 Prevalence of HPV infection in oocyte donors and women treated for infertility: a prospective study

H. Ondryasova[1], B. Zborilova[2], V. Koudelakova[3], I. Oborna[4], J. Brezinova[5], J. Vrbkova[3], M. Hajduch[3]
[1]*Faculty of Medicine and Dentistry Palacky University Olomouc, Institute of Molecular and Translational Medicine, Olomouc, Czech Republic*
[2]*Fertimed Ltd., Fertimed Ltd., Olomouc, Czech Republic*
[3]*Faculty of Medicine and Dentistry Palacky University Olomouc, Institute of Molecular and Translational Medicine, Olomouc, Czech Republic*
[4]*Department of Obstetrics and Gynecology, University Hospital Olomouc, Olomouc, Czech Republic*
[5]*Arleta IVF Ltd., Arleta IVF Ltd., Kostelec nad Orlici, Czech Republic*

Study question: What is the prevalence of Human Papilloma Virus (HPV) infection in oocyte donors and women treated for infertility? Is there any correlation between HPV status, childlessness and female infertility?
Summary answer: In this study, HPV prevalence in oocyte donors was 26% compared to 15% in women treated for infertility.

The prevalence of HPV in oocyte donors was significantly higher than the prevalence in women treated for infertility. Younger childless oocyte donors were significantly more often HPV+ than donors who were parous. Length of infertility treatment was negatively related to HPV prevalence. Further studies are needed to clarify this issue.
What is known already: HPV infection could play a role in human fertility like other sexually transmitted diseases (STDs). Higher risk of spontaneous abortion and possible mother-fetus transmission has been also described in HPV positive women. Moreover, *in vitro* studies demonstrated increased apoptosis and delayed development in HPV positive embryos. Unlike other STDs, HPV is not tested obligatorily for gamete donors or infertile couples, although it could significantly affect fertility, pregnancy or the fetus itself.
Study design, size, duration: This was a prospective laboratory based study. Cervical smears of oocyte donors ($n = 158$) and women treated for infertility ($n = 610$) were collected between April 2013 and October 2014. All participants filled a questionnaire focused on their health status and sexual behavior.
Participants/materials, setting, methods: Cervical smears were analyzed for presence of 14 high-risk (hrHPV) genotypes by Cobas 4800 HPV system (Roche) and PapilloCheck HPV-Screening system (Greiner Bio-One) detecting 18 hrHPV. Data from questionnaires, clinical data and HPV screening results were analyzed by statistical software R.
Main results and the role of chance: Forty-one (26%) of oocyte donors were HPV+. Childlessness in HPV+ oocyte donors was more frequent than in the HPV- group (39 vs. 20%; $p = 0.016$). The average age was 25.6 in HPV+ vs. 27.4 in HPV-($p = 0.023$). HPV infection was detected in 90 (15%) women from infertile couples and increased with the number of sexual partners (median 4 vs. 5; $p = 0.002$). Interestingly, women treated for infertility ≤6 months were more frequently HPV+ than women treated ≥48 months (32.4 vs. 7.5%, $p = 0.001$). The prevalence of HPV was twice as high within oocyte donors as in infertile women (26 vs. 15%), which could be related to the lower age of oocyte donors (27.0 vs. 32.7; $p < 0.001$).
Limitations, reason for caution: Only cervical smears have been analyzed in this study. No data on embryos/fetus/child development of HPV positive women or recipients of oocyte from HPV positive donor were evaluated, which could contribute to clarification of the relation between HPV infection and female fertility.
Wider implications of the findings: The significantly higher prevalence of HPV infection in the group of oocyte donors is disconcerting. According to the literature, HPV positivity is a risk factor for pregnancy. HPV positive oocyte donors may be therefore a risk for the oocyte recipient and for the further development of the fetus.
Study funding/competing interest(s): Funding by national/international organization(s) – IGA_LF_2014_009, CZ.1.05/3.1.00/14.0307, CZ.1.05/2.1.00/01.0030.

P-397 Direct ovarian stimulation (DOS) by intra-ovarian injection of corifollitropin-a for the patients with poor ovarian response in IVF-ET program

H. C. Kwon[1], J. Y. Jung[1], S. J. An[1], S. J. Lee[1], J. H. Park[1], K. S. Jung[1]
[1]*Miraewaheemang Hospital, Department of OB/GYN, Seoul, South Korea*

Study question: The effects of DOS by intra-ovarian injection of Corifollitropin alfa on oocytes recovery, embryo development and pregnancy outcomes for patients with a history of poor response in previous IVF-ET cycles.
Summary answer: After DOS cycle, the number of good quality oocytes retrieved, good quality embryos and transferred embryos were significantly

increased. The clinical and ongoing pregnancy rates were statistically higher in DOS cycle (37.0 and 33.3%, respectively) compared with prior conventional GnRH antagonist cycle (0%). Our study showed that there was a significant improvement of IVF-ET outcomes in poor responders undergoing DOS.
What is known already: Poor ovarian response (POR) to stimulation usually indicates a reduction in follicular response resulting in a reduced number of retrieved oocytes. In general, these poor responders have reduced pregnancy rates compared with normal responders. There are numerous strategies that have been suggested to improve the probability of pregnancy in POR. However, pregnancy rates after in vitro fertilization (IVF) remain disappointingly low, with studies reporting around 10%
Study design, size, duration: This prospective study is conducted in the private infertility clinic between January and December 2013. Total thirty patients were enrolled and the criteria for the patient selection were as follows. a. Five or less retrieved oocytes in prior two consecutive IVF-ET cycles with conventional GnRH antagonist protocol. b. Serum AMH levels equal to and <1.0 ng/mL. c. And visible ovaries by TVS on the second day of menstruation.
Participants/materials, setting, methods: We conducted direct ovarian injection of FSH on aforementioned patients, and compared the reproductive outcomes with prior conventional IVF cycle. The outcome variables were the number of good quality oocytes retrieved (MI, MII) and embryos (G1, G1-1, G2), the number of embryos transferred, clinical pregnancy rate and ongoing pregnancy rate.
Main results and the role of chance: The effect of DOS was verified through comparison with the results of prior conventional GnRH antagonist protocol in the same study population. IVF-ET outcomes after DOS were significantly improved compared to their prior cycles. The number of retrieved oocytes (*3.37 ± 1.42* vs. *7.41 ± 3.34*), good quality oocytes (*2.19 ± 1.24* vs. *6.37 ± 3.20*), and good quality embryos (*1.37 ± 0.97* vs. *2.81 ± 1.24*) and successfully transferred embryos (*1.63 ± 0.74* vs. *3.00 ± 1.07*) were all increased to about two folds by DOS. Clinical and ongoing pregnancy rates improved up to 37.0 and 33.3%, respectively (Table 1).

Table 1 | IVF-ET and clinical outcomes

	Prior cycles (n = 27)	DOS cycles (n = 27)
No. of retrieved oocytes	3.37 ± 1.42[a]	7.41 ± 3.34[a]
No. of good quality oocytes (M1, M2)	2.19 ± 1.24[a]	6.37 ± 3.20[a]
No. of good quality embryos(G1, G1-1, G2)	1.37 ± 0.97[b]	2.81 ± 1.24[b]
No. of transferred embryos	1.63 ± 0.74[b]	3.00 ± 1.07[b]
Clinical pregnancy rate (%)	0	10 (37.0%)
Ongoing pregnancy rate (%)	0	9 (33.3%)

Mean ± SD; [a]$p < 0.001$ by Paired t-test; [b]$p < 0.05$ by Wilcoxon signed rank test.

Limitations, reason for caution: The limitation of the present study is that small number of patients would make it difficult to consider the available evidence for DOS. And the additional dose of rFSH or rLH might have influenced on the results. In spite of the limitations described above, the current attempt showed the remarkable outcomes for poor responders, which have not been suggested in most other studies. Furthermore, Cochrane reviews and meta-analysis revealed limited successes on quality of oocytes and embryos, pregnancy outcomes in patients using either numerous stimulation protocols or adjuvant therapy like GH and rLH in poor responders.
Wider implications of the findings: DOS by intra-ovarian injection of Corifollitropin alfa, as an alternative approach to ovarian stimulation, enhances the ovarian response, and thereby improves the number and quality of transferred embryos and clinical outcomes. This may be due to increased FSH concentration and sensitivity for early antral follicles with concomitant augmentation of angiogenesis by sufficient estrogen secreted in the treated ovaries. Consequently, it may enhance the ovarian response to the subcutaneous injected gonadotropins, several days later.
Study funding/competing interest(s): Funding by hospital/clinic(s) – None.
Trial registration number: NA.

P-398 Evaluation of transvaginal hydrolaparoscopy (THL) as a first line investigation for tubal pathology: feasibility and prognostic capacity

M. van Kessel[1], R. Coenders-Tros[2], J. Oosterhuis[3], W. Kuchenbecker[4], B. Mol[5], C. Koks[6]

[1]*University Medical Center Groningen, Obstetrics and Gynecology, Groningen, The Netherlands*
[2]*VU University Medical Center Amsterdam, Obstetrics and Gynecology, Amsterdam, The Netherlands*
[3]*St. Antonius Hospital, Obstetrics and Gynecology, Nieuwegein, The Netherlands*
[4]*Isala, Obstetrics and Gynecology, Zwolle, The Netherlands*
[5]*Robinson Research Instute School of Paediatrics and Reproductive Health, Obstetrics and Gynecology, Adelaide, Australia*
[6]*Maxima Medical Center, Obstetrics and Gynecology, Veldhoven, The Netherlands*

Study question: What is the prognostic capacity of THL as a first line investigation for tubal pathology to predict natural conception?
Summary answer: In an unselected group of subfertile women who undergo THL, the incidence of bilateral tubal occlusion and peritubal disease are 4.9 and 19.2%. These abnormalities strongly reduce natural fecundity.
What is known already: THL is a safe method to investigate tubal patency and explore the pelvis in subfertile women. It can be performed as an outpatient procedure and is well tolerated.
Study design, size, duration: Between 2000 and 2011, we performed THL as a first line diagnostic test in 952 subfertile women in four large hospitals in the Netherlands. Follow-up on fertility outcome during 36 months after the procedure was derived by examining medical records.
Participants/materials, setting, methods: We studied women with primary or secondary subfertility trying to conceive for at least 12 months. Cumulative treatment independent ongoing pregnancy rates were calculated for each category of findings, using Kaplan-Meier analysis. Furthermore we calculated fecundity rate ratios (FRR) to express the relative risk on natural conception.
Main results and the role of chance: Bilateral tubal patency was found in 82.7% One-sided tubal occlusion in 12.6% and bilateral tubal in 4.7% Cumulative spontaneous pregnancy rates after 36 months were 52% for women with bilateral patent tubes, 48% for women with one-sided tubal occlusion and 7% for women with bilateral tubal occlusion. Corresponding FRRs were 0.93 (95% CI 0.71–1.23) for one-sided tubal occlusion, and 0.10 (95% CI 0.03–0.31) for bilateral tubal occlusion. Endometriosis and adhesions were diagnosed in respectively 6.4 and 9.1 % of women, and both endometriosis and adhesions in 3.8%. Corresponding FRRs are 0.73 (95% CI 0.49–1.02), 0.62 (95% CI 0.43–0.90), and 0.35 (95% CI 0.19–0.71).
Limitations, reason for caution: In this prospective cohort, THL was used in a clinical setting and abnormalities at THL had medical consequences, thus generating informative censoring. We controlled this by doing time to event analysis.
Wider implications of the findings: The results of our study show that when bilateral tubal occlusion of peritubal disease are diagnosed at THL, chances of natural conception are significantly reduced. THL is a feasible procedure and because of its prognostic capacity it can be used as a first-line diagnostic test for tubal patency in subfertile women.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Not applicable.
Trial registration number: NA.

[3]*Hillel Yaffe Medical Center, IVF Unit, Hadera, Israel*
[4]*Hillel Yaffe Medical Center, Obstetrics and Gynecolgy, Hadera, Israel*

Study question: We sought to determine whether ovarian stimulation leads to myeloid cell population alterations as seen in other proangiogenic inflammatory states.

Summary answer: In close similarity to changes observed in the placenta before labor, ovarian stimulation is associated with reciprocal alterations in myeloid cell populations within the follicular fluid (FF) that correlate with ovarian response to gonadotropins.

What is known already: Immature myeloid cells (IMCs) are bone marrow-derived cells that normally differentiate into granulocytes, macrophages, and dendritic cells (DCs) but expand in proangiogenic inflammatory states such as malignancy and pregnancy. For example, labor is preceded by a decrease in IMCs and an increase in DCs populating the placenta.

Ovarian stimulation and ovulation are associated with follicular inflammation and angiogenesis. The presence of inflammatory cell population shifts as seen in other proangiogenic conditions remain unexplored.

Study design, size, duration: An observation study; We analyzed 12 FF samples from 10 patients undergoing IVF. Patients received standard ovarian hyperstimulation protocols, and oocyte retrieval was performed 34 hours after hCG. In order to minimize blood contamination, only FF from the first aspirated follicle was analyzed. FFs with bloody contamination were discarded.

Participants/materials, setting, methods: FF single cell suspensions were immunostained with anti CD45; HLA-DR; lin-2; CD33 antibodies. The samples were run on FACS Calibur and analyzed using FloJo software. Bone marrow derived hematopoietic cells were detected by expression of CD45. DCs were defined as $CD45^+$ $lin2^-HLADR^+$ cells and IMCs were defined as $CD45^+$ $lin2^-$ $HLADR^-CD33^+$ cells.

Main results and the role of chance: FFs (n = 12) from 10 patients were analyzed. Patients were all normal responders 33.5 ± 0.9 years of age, BMI 26.7 ± 0.8 kg/m^2, day 3 FSH was 6.0 ± 0.3 IU/L, estradiol levels at day of hCG trigger was 1181 ± 111 pg/ml, number of eggs retrieved was 9.6 ± 1.0. We observed that both IMCs and DCs are highly abundant myeloid cell populations within the FF: 41.7 ± 4.5% and 20.2 ± 5.0% of total $CD45^+$ bone marrow derived hematopoietic cells respectively. We detected a significant negative correlation between IMCs and DCs in the FF (r = -0.60, p = 0.038), possibly indicating a process of differentiation of IMCs into DCs. Interestingly, the presence of DCs in FF correlated with the response to ovarian stimulation as reflected by estradiol levels at the day of hCG triggering of ovulation (r = 0.58, p = 0.044).

Limitations, reason for caution: This is an observational study and only associations can be determined. In vitro culture studies and mouse studies are underway to determine whether IMCs indeed differentiate into DCs upon follicular maturation.

Wider implications of the findings: Our study indicates that ovarian stimulation is accompanied by alterations of IMCs and DCs in the FF in a reciprocal fashion that correlates with ovarian response. Similar population shifts were observed by our group upon maturation of the placenta before labor, pointing at a universal phenomenon of sterile inflammation that accompanies physiologic angiogenesis. Specifically, in the ovary, differentiation of IMCs into DCs may lead to healthy development, angiogenesis and maturation of the ovarian follicle.

Study funding/competing interest(s): Funding by national/international organization(s) – Israel Science Foundation 142/09.

Trial registration number: NCT01083745.

Keywords: ovarian stimulation, myeloid cells, angiogenesis

P-400 Long-term effects of methamphetamine exposure in adolescent mice on the future ovarian reserve in their adulthood: a randomized controlled study

L. Wang[1], K. Huang[1], X. Dong[1], L. Ji[1], WANG, Y[1], J. Yao[1], H. Zhang[1]

[1]*Tongji Hospital Affiliated to Tongji Medical College Huazhong University of Science and Technology, Reproductive Medicine Center, Wuhan, China*

Study question: Does a long-term exposure of methamphetamine (MA) in adolescent mice have negative impacts on their future ovarian follicle number and anti-Mullerian hormone (AMH) level?

Summary answer: Eight weeks of methamphetamine abuse from adolescent days significantly decrease the primordial and growing follicle number and increase the atretic follicle number in their later reproductive age. We also found a lower AMH secretion per cell after granulosa cell culture in the treatment group compared with the control group.

What is known already: Several studies have demonstrated that MA, alongside its adverse impact on nervous system, is teratogenic as well as embryotoxic. What's more, it could also negatively affect the male fertility by disrupting the function of hypothalamic-pituitary-testicular axis, decreasing levels of luteinizing hormone, and damaging sperm function as well as testicular structure. As for adult women, a long-term abuse of MA could result in the disruption of menstrual cycles and dysfunction of hypothalamic-pituitary-gonadal axis.

Study design, size, duration: This is a randomized controlled cross sectional study with a sample size of 11 mice of the treatment group and 11 of the control group. The duration of MA administration lasted for 8 weeks. Ovaries and blood serum of each mouse were obtained and further processed after MA/saline treatment.

Participants/materials, setting, methods: Methamphetamine (5 mg/kg) or saline was administered to ICR mice from the 21st PD for 8 weeks. Serum AMH level was measured by ELISA. Ovarian follicle numbers were counted after HE-staining. Expression of AMHR2 was valued by realtime-PCR and western-blotting. Granulosa' secretion of AMH was investigated by cell culture.

Main results and the role of chance: A significantly lower number of ovarian primordial follicles per section (22.5 ± 6.3 vs. 38.4 ± 6.0, p = 0.001), and growing follicles(5.4 ± 3.0 vs 10.0 ± 3.5 p = 0.001) as well as higher number of atretic follicles per section (13.6 ± 3.3 vs. 10.9 ± 3.7, p = 0.038) in the treatment group were found than those in the control group. After ovarian dissociation and cell culture, we found that granulosa cells from the treatment group showed a lower secretion of AMH per cell after rFSH stimulation (0.08 ± 0.02 vs. 0.11 ± 0.02 pg/L, p = 0.021). However, no significant difference was found in the serum AMH level, and the expression of mRNA and protein of ovarian AMH receptor-2 between the two groups.

Limitations, reason for caution: The long-term impact of methamphetamine to adolescents on their future ovarian reserve was only shown in murine with a relatively small sample size. A perspective RCT on human is difficult because of ethical restrictions.

Wider implications of the findings: It's generously accepted that methamphetamine abuse causes neurodegeneration. Some of the affected neurological pathways also contribute to the neuroendocrine system relating to fertility. But the potential effects of MA on the female reproductive functions have not been extensively studied. From a public health point of view, this is also an interesting topic as a considerable portion of the juvenile is consuming such a drug which could possibly compromise their future reproductive ability.

Study funding/competing interest(s): Funding by University(ies) – Funding by hospital/clinic(s). Tongji Hospital of Tongji Medical College, Huazhong University of Science and Technology.

P-401 Enrichment of functional pathways in cumulus cells surrounding oocytes whose embryos successfully implant

T. Burnik Papler[1], L. Lovrecic[2], A. Maver[2], A. N. Kopitar[3], E. Vrtacnik Bokal[1]

[1]*University Medical Center Ljubljana, Department of Human Reproduction, Ljubljana, Slovenia*

[2]*University Medical Center Ljubljana, Clinical Institute of Medical Genetics, Ljubljana, Slovenia*

[3]*Medical Faculty Ljubljana, Institute of Microbiology and Immunology, Ljubljana, Slovenia*

Study question: The main objective of the study was to determine biomarkers expressed in human granulosa (GC) and cumulus (CC) cells that could be used for the prediction of pregnancy in IVF procedures.

Summary answer: There were no biomarkers expressed in GC or CC that could be used for the prediction of pregnancy after embryo transfer (ET) in IVF procedures. However, gene ontology (GO) analysis revealed pathways connected with embryo development are significantly overrepresented in CC samples whose embryos achieved pregnancy.

What is known already: The oocyte plays a dominant role in regulating GC and CC functions during folliculogenesis and it is believed that functions of GC and CC indirectly reflect oocyte's competence. For this reason, several published studies in recent years suggested that genes expressed in GC and CC have the potential to serve as biomarkers of pregnancy in IVF procedures. However, potential candidate genes differ between the studies and thus, a universal biomarker is still to be found.

Study design, size, duration: Forty-seven infertile women were included in the study. The study was approved by National Ethics Committee and all patients signed informed consent. Genome wide gene expression analysis of 64 individual GC and CC samples was performed using microarrays, followed by a qPCR validation of microarray data.
Participants/materials, setting, methods: GnRH antagonist protocol was used for ovarian stimulation in women with tubal and unexplained cause of infertility. Follicles were aspirated individually. After that, GC and CC were stored separately and oocytes cultured individually. Elective single embryo transfer was performed. Microarrays were used for genome wide gene expression analysis, followed by a functional analysis of gene expression profiles using Gene Set Enrichment Analysis (GSEA).
Main results and the role of chance: There were no significantly differentially expressed genes between non-implanted and implanted embryos in either of the cell types after the correction for multiple testing. Also, qPCR analysis was in accordance with microarray analysis and there were no differentially expressed genes. GSEA analysis revealed pathways as ectoderm and epidermis development, and keratinocyte differentiation are significantly overrepresented in CC samples, surrounding oocytes whose embryos achieved pregnancy. There were no overrepresented pathways in GC samples. This finding implies, that processes of embryogenesis are regulated already during folliculogenesis and perhaps the flaws in these processes lead to the development of less competent embryos with a lower ability to implant.
Limitations, reason for caution: Relatively small number of patients included in the study.
Wider implications of the findings: It has already been proposed that there are advantages of using the complete set of up and down-regulated genes gained from a microarray experiment, rather than focusing on the most affected ones, as physiological changes are often not translated into large gene expression variations. Therefore, genes from the same pathway moving in a cluster can serve as a better indication of the physiological condition studied than expression of a single gene.
Study funding/competing interest(s): Funding by national/international organization(s) – Slovene Research Agency, grant number P30326.
Trial registration number: NA.

P-402 Anti-Mullerian hormone (AMH) as predictor of natural conception

S. Ferrero[1], F. Sozzi[2], U. Leone Roberti Maggiore[2]
[1]*University of Genova and Piazza della Vittoria 14 S.r.l., Obstetrics and Gynecology Unit, Genova, Italy*
[2]*Piazza della Vittoria 14 S.r.l., Obstetrics and Gynecology Unit, Genova, Italy*

Study question: Does AMH predict the chances of natural conception and time to conception in women with unknown fertility status?
Summary answer: AMH does not predict the chances of conception in women <40 years and the time to conception independently from the age of women. AMH predicts the chances of conception in women aged 40 years or older.
What is known already: AMH is a marker of ovarian reserve and response to gonadotropins. Very few data are available in the literature on the use of AMH in predicting natural fecund ability.
Study design, size, duration: This was a prospective cohort study. Enrolment was offered to all women attending our clinic who were about to start trying to conceive between May 2012 and September 2014. Out of 191 couples enrolled in the study, 169 couples completed the follow-up and were included in the analysis.
Participants/materials, setting, methods: The study included women of reproductive age with no previous reproductive experience. Patients with risk factors for infertility were excluded from the study. A secretary contacted the patients by email or by telephone every 3 months up to 1 year from the enrolment in the study.
Main results and the role of chance: The median female age was 34 years; the median male partner age was 37 years. One hundred twenty-one couples conceived during the study period (63.4%; 95% CI, 56.1–70.2%). The mean (±SD) time to conception was 4.7 (±2.8) months. AMH levels were similar in women who conceived and did not conceive ($p = 0.129$). AMH levels were similar in patients who conceived and did not conceive when the analysis was restricted to women <30 years ($p = 0.255$), ≥30 and <35 years ($p = 0.569$) and ≥35 and <40 years ($p = 0.741$). In women ≥40 years, AMH levels were higher in patients who conceived (2.0 ± 1.5 ng/ml) than in those who did not conceive (1.0 ± 0.9 ng/ml; $p = 0.032$). There was no significant correlation between AMH levels and time to conception ($p = 0.610$).
Limitations, reason for caution: The major limitation of the study is the small number of women ≥40 years ($n = 29$).
Wider implications of the findings: If the results of this study will be confirmed by investigations including a larger number of women aged 40 years or older, measurement of AMH might be offered to these patients in order to predict the chances of natural conception.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Piazza della Vittoria 14 S.r.l.
Trial registration number: NA.
Keywords: anti-Mullerian hormone, time to pregnancy, fecundity, natural conception, age

P-403 Pregnancy outcomes of intrauterine injection of human chorionic gonadotropin before frozen embryo transfer in *in vitro* fertilization

N. Li[1], J. Z. Shi[1], W. H. Shi[1], W. Zhao[1], B. Meng[1], H. Y. Zhou[1], Xue, X.[1], Tian, L.[1]
[1]*Maternal and Child Health Care Hospital of ShaanXi Provence, Assisted Reproduction Centre, Xi'an, China*

Study question: To investigate potential effects of intrauterine injection of human chorionic gonadotropin (hCG) before frozen embryo transfer (FET) in *in vitro* fertilization.
Summary answer: The clinical pregnancy rate and live birth rate were decreased in hCG treated group. No birth defect was found in this group.
What is known already: HCG is the first embryonic signal secreted by the embryo before implantation. It has been demonstrated that hCG played an important role in embryo invasion, implantation and uterine immune tolerance. Several previous studies have declared intrauterine administration of hCG before embryo transfer could increase the pregnancy rate *in vitro* fertilization/intracytoplasmic sperm injection in fresh cycles. However, its potential benefits in frozen embryo transfer cycles have not been investigated.
Study design, size, duration: This was a case control study of 143 cycles from 143 patients performed between May and September 2012. Primary endpoint was live birth rate. Secondary endpoints included clinical pregnancy rate, implantation rate, miscarriage rate and ectopic rate. Safety endpoint was birth defect.
Participants/materials, setting, methods: Infertility patients younger than 42 years endured at lest one failed cycle of either fresh or frozen embryo transfer. Thirty-eight patients in the study group received 500 IU of hCG via intrauterine administration before FET, and 115 patients in the control group underwent FET without hCG.
Main results and the role of chance: The clinical pregnancy rate was statistically significantly decreased in the hCG administration group compared with the control group (26.3 vs.46.1%, $P = 0.032$). The live birth rate (18.4 vs. 34.8%, $P = 0.058$) and implantation rate (13.0 vs.22.4%, $P = 0.054$) were lower in the hCG group than the control group, but with no statistical significance. There were no significant difference in miscarriage rate (20.0 vs. 24.5%, $P = 1.000$) and ectopic rate (10.0 vs.0%, $P = 0.159$) between the study group and the control group. None of birth defect infant was found in the hCG group.
Limitations, reason for caution: This was a retrospective case control study of limited samples from a single IVF center. Prospective analysis of large data sites from a multicentre study is necessary to confirm the effect on intrauterine injection of hCG.
Wider implications of the findings: The miscarriage rate and ectopic rate were not influenced by hCG intrauterine administrated before FET.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Maternal and child health care hospital of Shaan Xi province.
Trial registration number: NA.
Keywords: frozen embryo transfer, human chorionic gonadotrophin, intrauterine administration, pregnancy outcome

P-404 Preeclampsia in autologous and oocyte donation pregnancy: is there a different pathophysiology?

L. E. E. Lashley[1], A. Buurma[2], G. Swings[3], M. Eikmans[3], J. Anholts[3], J. Bakker[4], F. H. J. Claas[3]
[1]*Leiden University Medical Center, Gynaecology and Obstetrics, Leiden the Netherlands, Neth. Antilles*

[2]*Leiden University Medical Center, Pathology, Leiden the Netherlands, Neth. Antilles*
[3]*Leiden University Medical Center, Immunohematology and Blood Transfusion, Leiden the Netherlands, Neth. Antilles*
[4]*Leiden University Medical Center, Clinical Chemistry and Laboratory Medicine, Leiden the Netherlands, Neth. Antilles*

Study question: Is the extent of complement activation in pregnancies after oocyte donation (OD) complicated by preeclampsia different from complement activation in preeclamptic and uncomplicated autologous pregnancies?
Summary answer: In line with autologous preeclampsia pregnancies, there is excessive activation of complement in preeclamptic OD pregnancies. However, in contrast to autologous pregnancies this is not associated with a counterbalancing upregulation of complement regulatory proteins, suggesting another trigger or regulatory mechanism involved in placental C4d deposition in preeclamptic OD pregnancies.
What is known already: OD is accompanied with an increase in early and late obstetrical problems. The pathophysiological mechanism underlying these complications is thought to differ from autologous pregnancies, based on differences in histocompatibility, pathological findings and neonatal birth weight. However, both in autologous and OD pregnancies, the pathogenesis of preeclampsia is poorly understood. In autologous pregnancies, increasing evidence suggests that preeclampsia is associated with excessive complement activation.
Study design, size, duration: Case control study.
Participants/materials, setting, methods: Patients were selected who conceived by oocyte donation and delivered at our hospital. Thirty-three pregnancies were uncomplicated, 9 pregnancies were complicated by pre-eclampsia. We furthermore included 46 autologous pregnancies with preeclampsia and 20 autologous and uncomplicated pregnancies as controls. Paired samples of decidua basalis, maternal peripheral blood and umbilical cord blood from all pregnancies were obtained within 24 h after delivery.
Main results and the role of chance: A significantly ($p < 0.03$) higher incidence of C4d deposition was observed in placentas from women with preeclampsia compared to uncomplicated pregnancies, both in OD and autologous pregnancies. The level of complement factors in serum did not differ between the groups. We observed no fetal growth restriction in our preeclamptic OD group. The main difference between OD and autologous pregnancies was the significantly lower placental mRNA expression level of complement regulatory proteins in both uncomplicated and preeclamptic OD pregnancies.
Limitations, reason for caution: A limitation is the low number of included patients with OD. In the Netherlands commercial and anonymous donation is forbidden by law, which affects the number of women that apply for OD. Furthermore, many patients wish to conceal the fact that their pregnancy was conceived artificially and will not mention the OD to medical personnel.
Wider implications of the findings: To unravel the, possibly different, pathophysiological mechanism underlying preeclampsia in OD pregnancies. We hypothesize that the allogeneic nature of the fetus in OD pregnancies plays a role in the development of these pregnancy complications.
Study funding/competing interest(s): Funding by national/international organization(s) – now.
Trial registration number: No RCT.
Keywords: oocyte donation, pregnancy complication, complement activation

P-405 DEHP may alter ovarian function by induced mitochondrial fragmentation, increased reactive oxygen species and DRP1 expression in mouse granulosa cells

K. L. Wang[1], C. H. Chen[1], C. W. Wang[1], C. R. Tzeng[1]
[1]*Taipei Medical University, Center for Reproductive Medicine and Sciences, Taipei City, Taiwan R.O.C.*

Study question: Evaluate the effects of phthalates (PAEs) on mitochondrial function in ovarian granulosa cells (GCs).
Summary answer: Di-(2-ethylhexyl) phthalate (DEHP) affects female fertility by changing the steroidogenesis and altering mitochondrial function of GCs.
What is known already: PAEs are very widely used as plasticizers and solvents. Di-(2-ethylhexyl) phthalate (DEHP) is the most abundant PAEs used in the world. Previous studies have demonstrated that DEHP interferes with reproductive system by inhibiting steroid hormone production.
Study design, size, duration: Six-week-old female ICR ovarian granulosa cells (GCs) were used to evaluate of DEHP on female reproductive system. Mice were treated with different concentration of DEHP for 2 or 4 weeks. Eighty mice were used in the study.
Participants/materials, setting, methods: Plasma estradiol and anti-Müllerian hormone (AMH) were measured by ELISA. Mitochondrial activity including oxygen consumption rate (OCR), glycolytic flux (extracellular acidification rate, ECAR) and ATP production rate were measured by a Seahorse XF24 extracellular flux analyzer. Mitochondria morphology of GCs was investigated by staining with MitoView green under confocal fluorescent microscope. Cell proliferation rate was determined by colorimetric MTT assay.
Main results and the role of chance: Oral administration with DEHP (0.05–500 mg/kg/day) for 2 weeks increased mouse estradiol levels. In contrast, a decreased estradiol levels was found after 4 weeks of DEHP treatment. Moreover, OCR and ATP production rate were also increased in GCs obtained from the mice treated with DEHP (5 and 500 mg/kg/day). The OCR was increased by 3-folds in the highest concentration of DEHP treatment group (347.0 ± 53.1 pMoles/min) compared with control (102.7 ± 32 pMoles/min). In contrast, ECAR of GCs was reduced after 2 weeks of DEHP treatment. DEHP treatment (5 and 500 mg/kg/day, respectively) showed a decrease of elongated mitochondria (43.9 and 46.2 vs. 54.2% as compared with vehicle group). Increased mitochondrial fragmentation were observed significantly after DEHP treatment. Moreover, expression of mitochondrial fission factor, dynamin-related protein 1 (Drp1) was elevated after 4 weeks of DEHP exposure. *In vitro* study of GCs, OCR also increased after DEHP (10 and 100 mM) treatment. The higher concentration of DEHP (100 mM) treatment inhibited the cell proliferation of GCs.
Limitations, reason for caution: It is hardly to distinguish the order or the correlation of ROS production and mitochondrial fragmentation.
Wider implications of the findings: PAEs could affect female fertility as time goes by.
Study funding/competing interest(s): Funding by national/international organization(s) – Ministry of Science and Technology.
Trial registration number: LAC-101-0022.

P-406 A randomized double blind comparison of two hormone replacement regimens for thawed blastocyst transfer

S. Taguchi[1], M. Funabiki[1], T. Hayashi[1], Y. Tada[1], M. Karita[1], Y. Iwaki[1], Y. Nakamura[1]
[1]*Oak Clinic Inc., Infertility Center, Osaka, Japan*

Study question: The two regimens of hormone replacement protocols used in thawed blastocyst transfer show different clinical outcomes?
Summary answer: There were significant differences for the clinical outcomes of thawed blastocyst transfer in the two regimens of hormone replacement protocols.
What is known already: The clinical outcomes of thawed blastocyst transfer in various regimens of hormone replacement protocols are controversial because large prospective randomized controlled trial is not yet conducted. A few observational studies suggested that the use of Estrogel (®) may be more effective for the clinical outcomes than Premarin (®).
Study design, size, duration: A large prospective, double-blind, randomized controlled trial in order to evaluate the outcomes in two different hormone replacement regimens for thawed blastocyst transfer was performed. A total of 1,000 women (median age 38.3 years), undergoing IVF at a clinic in Japan, were enrolled from July 2014 to October 2014.
Participants/materials, setting, methods: Participants were randomized according to a computer-generated randomization list as follows. Premarin (®) group ($n = 500$; 2.492 mg/day; from the second day of menstruation to the fifth day and 4.98 mg/day, after the sixth day). Estrogel (®) group ($n = 500$; 2.16 mg/day in Estrogen conversion, after the second day of menstruation).
Main results and the role of chance: Serum estradiol (E2) levels were 305.71 ± 7.70 pg/ml in Premarin (®) group, 783.31 ± 30.11 pg/ml in Estrogel (®) group. Therefore, serum E2 levels in Estrogel (®) group were higher than those in Premarin (®) group ($P < 0.001$). Furthermore, the pregnancy rate in Estrogel (®) group was higher than those in Premarin (®) group (39.0 versus 27.0%, $P = 0.0001$, rate ratio 1.73, 95% confidence interval: 1.32–2.26).

Moreover, the miscarriage rate in Estrogel (®) group was lower than those in Premarin (®) group (5.0 versus 10.1 %, $P = 0.002$, risk ratio 0.64, 95% confidence interval: 0.45–0.86). In addition, both regimens were well-tolerated, with no difference in serious adverse events.
Limitations, reason for caution: The conclusions are limited to the two hormone replacement regimens studied for the patient population examined in the present study.
Wider implications of the findings: Serum E2 levels contribute to the differences of pregnancy rate and miscarriage rate in the two different regimens. From the viewpoint, Estrogel (®) have an advantage as hormone replacement regimen for thawed blastocyst transfer.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Oak Clinic Group.
Trial registration number: UMIN000015488.
Keywords: ART, thawed blastocyst transfer, hormone replacement regimens, a large prospective randomized controlled trial, pregnancy rate

P-407 Prevalence of unrecognized celiac disease in couples with unexplained infertility

Study question: Is there any relation between celiac disease (CD) and unexplained infertile (UEI) couples? What is the prevalence of CD in unexplained infertile couples?
Summary answer: The prevalence of CD in UEI couples is not as high as that some reports. The study findings suggested that investigation of both of the couples with a diagnosis of UEI may be more beneficial in clarifying the etiology.
What is known already: CD is a chronic autoimmune disease characterized by small intestinal malabsorbtion and diarrhea, precipitated by ingestion of food products containing gluten. There are studies reporting that some nutritional deficiencies and some factors related to immunity may cause a decrease in fertility and some problems in sperm paramethers. In former studies, prevalence of CD was investigated in only women with UEI. There is not a knowledge about prevalence of CD in UEI couples.
Study design, size, duration: A total of 68 couples with UEI who had admitted at TDV 29 Mayis Hospital IVF Center between January and June 2014 were included in this prospective pilot study.
Participants/materials, setting, methods: The diagnosis of UEI was reached with basic infertility tests. A history of CD was questioned in the initial evaluation. Anti-gliadin, anti-endomysial, tissue transglutaminase antibodies and total IgA were tested. Gastroscopy was done to patients with positive serologic tests. Histopathological CD diagnosis was reached according to Marsh criteria.
Main results and the role of chance: The mean age of study population were 33.40 ± 4.59 years. Out of 65 couples that were taken into the study group, one of the 5 couples had a positivity in the autoantibidies (7.69%). Out of these 65 couples none of them had a autoantibody positivity at the same time in both partners. Antigliadin antibodies found positive for 2 females out of 5 couples and in 3 male partners for the same group. Out of these 5 couples only one male partner had all the antibodies positive (1.5%). In the histopathological examination of patients with positive autoantibodies, only the patient in whom all autoantibodies were positive had findings compatible with Marsh IIIa gluten enteropathy. Only one couple had a diagnosis of CD (1.5%).
Limitations, reason for caution: Our study is based on a limited sample size. Our data should be confirmed in a larger cohort of subjects.
Wider implications of the findings: CD was shown to affect the reproductive system in women in many studies. CD may also cause a decrease in fertility in men by affecting sperm motility and androgen levels. These results suggest that investigation of both of the couples with a diagnosis of UEI may be more beneficial in clarifying the etiology.

P-408 Association between vitamin D status in serum and follicular fluid and IVF-ET outcomes in Chinese infertile women

J. Guo[1], Q. Zhang[1], W. Wang[1], Y. Li[1], Y. Liu[2], D. Yang[1]
[1]*Sun Yat-Sen memorial hospital of Sun Yat-Sen University, Obstetrics and Gynecology, Guangzhou Guangdong, China*
[2]*Sun Yat-Sen memorial hospital of Sun Yat-Sen University, Pediatric hematology laboratory, Guangzhou Guangdong, China*

Study question: This study aimed to assess the association between 25(OH)D levels in serum and follicular fluid and IVF-ET (*In vitro* fertilization-embryo transfer) outcomes in Chinese infertile women.
Summary answer: Serum vitamin D deficiency significantly reduced pregnancy rates and live birth rates of IVF treatment. Though there was a correlation between follicular fluid vitamin D and serum vitamin D, no significant difference were found between follicular fluid vitamin D and IVF outcomes.
What is known already: Significant controversy has emerged over the last decade concerning the effects of vitamin D on non-skeletal tissues, especially in reproductive field. Data regarding role of vitamin D in female reproduction are sparse and conclusions are conflicting. In particular, a gap on this topic in Asian women needs to be filled.
Study design, size, duration: This was a prospective cohort study. One hundred eighty infertile women undergoing IVF–ET cycles were recruited from March to December, 2012.
Participants/materials, setting, methods: All patients underwent IVF cycles using standardized regimens for pituitary down-regulation and controlled ovarian stimulation. Serum and follicular fluid samples were obtained on oocyte-retrieval day. 25(OH)D levels were quantitatively detected by enzyme-linked immunosorbent assay. Vitamin D deficiency was defined as serum 25(OH)D <50 nmol/L.
Main results and the role of chance: In total population, the number of women with vitamin D deficiency, insufficiency and replete were 51 (28.3%), 101 (56.1%) and 28 (15.6%), respectively. Both pregnancy rates (47.1 vs 67.4%, $p = 0.011$) and live birth rates (40 vs 63.3%, $p = 0.005$) of women with serum 25(OH)D <50 nmol/L were significantly lower than that in women with 25(OH)D ≥50 nmol/L. No significant differences were found in IVF outcomes between groups of 50 nmol/L ≤25(OH)D ≤75 nmol/L and 25(OH)D >75 nmol/L. IVF outcomes of women with different vitamin D status in follicular fluid had no significant differences. After controlling for multiple variables, serum 25(OH)D deficiency significantly associated with reduced pregnancy rates (OR: 2.997, 95% CI: 1.292–6.951) and live birth rates (OR: 3.373, 95% CI: 1.453–7.827).
Limitations, reason for caution: Our results refer only to patients with good ovarian function who have satisfactory responses to ovarian stimulation. For aging women with poor ovarian reserve, differences of pregnancy rates between vitamin D deficiency and those who are not might not be as high as what we have found in this study.
Wider implications of the findings: Serum vitamin D deficiency impairs pregnancy rates and live birth rates in Chinese IVF women. Clinical utility of vitamin D levels in follicular fluid seems to be limit. Future randomized controlled studies which focus on the effectiveness of vitamin D supplement on IVF women who are vitamin D deficient are interesting and meaningful. At the meantime, more studies are needed to confirm the mechanisms undergoing these findings from each aspect of follicular development to embryo implantation.
Study funding/competing interest(s): Funding by national/international organization(s) – This study was supported by the National Natural Science Foundation of China (Grant No. 81070466) and the Science Technology Research Project of Guangdong Province (Grant No. 2012A030400010). The authors have none declared.
Trial registration number: NA.

[4]*Chicago Medical School at Rosalind Franklin University of Medicine and Science, Reproductive Medicine Department of Obstetrics and Gynecology, Vernon Hills IL, U.S.A.*
[5]*National Center for Child Health and Development, Department of Maternal-Fetal Biology, Setagaya Tokyo, Japan*

Study question: We evaluated the clinical efficacy of immunosuppressive treatment with tacrolimus for women with repeated implantation failure (RIF) and an elevated peripheral blood T helper (Th) 1/Th2 cytokine producing cell ratio.
Summary answer: This study indicates tacrolimus treatment significantly increases clinical pregnancy rate and live birth rate in RIF patients with shifted Th1 immune responses without increased maternal fetal complications.
What is known already: Pregnancy is established when an embryo, which is a semi-allograft, is successfully implanted to maternal decidua with an establishment of maternal immune tolerance. Th1 and Th2 cells play important roles in immune responses, such as immune rejection or tolerance. There is a general agreement that pregnancy is associated with Th2 dominance, and Th1 immune response is associated with embryonic rejection. An underling mechanism of embryo rejection is considered to be similar to an allograft rejection.
Study design, size, duration: This was a prospective cohort study of treatment for RIF patients ($n = 66$) with elevated peripheral blood Th1 ($CD4^+/IFN\text{-}\gamma^+$)/Th2 ($CD4^+/IL\text{-}4^+$) cell ratios in our clinic between November 2011 and April 2014.
Participants/materials, setting, methods: Thirty-four patients were treated with tacrolimus (treatment group) and 32 received no treatment (control group). Treatment group received tacrolimus between two days before embryo transfer and the day of the pregnancy test. The daily dose of tacrolimus (1–3 mg) was determined based on the degree of the Th1/Th2 cell ratio.
Main results and the role of chance: The clinical pregnancy rate of the treatment group was 58.8%, which was significantly higher than that of the control group (3.1%) ($P < 0.0001$). In the treatment group, the miscarriage rate was 5.0%, the live birth rate was 55.9% ($P < 0.0001$). There was no significant side effect from tacrolimus in treatment group. No one developed obstetrical complications during pregnancy.

	Treatment group ($n = 34$)	Control group ($n = 32$)
Age (years)[a]	36.2 ± 2.6	36.2 ± 3.9
Number of failed embryo transfer cycle (n)[a]	5.8 ± 2.7	5.9 ± 2.6
Th1/Th2 ratio[a]	16.0 ± 6.9	17.0 ± 4.9
Clinical pregnancy rate per ET (%)[#]	58.8	3.1
Live birth rate (%)[#]	58.8	3.1
Spontaneous miscarriage rate (%)	5.0	0

ET; embryo transfer, [a]mean ± SD, [#]$p < 0.0001$.

Limitations, reason for caution: This study however, has a limitation, since this is not a randomized controlled trial and a sample size is small. Moreover, endometrial changes or peripheral immune responses after tacrolimus treatment were not evaluated thoroughly. Further study is needed for tacrolimus effect on systematic immune responses and endometrial receptivity.
Wider implications of the findings: Tacrolimus has been utilized throughout pregnancy for women who have received an allogeneic organ transplant, and many female recipients have given birth while taking tacrolium. Tacrolimus inhibits T-lymphocyte signal transduction via creating a new complex. Tacrolimus is classified as class C drug by the FDA pregnancy category. The safety of tacrolimus for both mother and fetus/baby during pregnancy has been well established in many reports of female transplant recipients who achieved a post-transplant pregnancy.
Study funding/competing interest(s): Funding by hospital/clinic(s) – The authors have received no funding for this study, and they have no financial interest in any companies. There are no competing interests.
Trial registration number: The authors have received no funding for this study, and they have no financial interest in any companies. There are no competing interests.

P-410 Contraceptive pill and gonadotropin-releasing hormone (GnRH) flare-up agonist versus GnRH antagonist protocol in poor responders: Lessons to a prospective study

F. Scheffler[1], P. Merviel[2], E. Lourdel[2], R. Cabry[1], A. Devaux[1], M. Benkhalifa[1], N. Mansouri[1], N. Celton[1], H. Copin[1]
[1]*CHU Amiens, ART Center, Amiens, France*
[2]*CHU Amiens, Gynecology and Obstetrics, Amiens, France*

Study question: Is a contraceptive pill and gonadotropin-releasing hormone (GnRH) flare-up agonist protocol better than a GnRH-antagonist protocol in poor responders.
Summary answer: The ongoing pregnancy rates per transfer were similar between the two protocols, despite a higher number of transferred embryos in the contraceptive pill and GnRH flare-up agonist protocol.
What is known already: In case of poor responders, several authors have reported advantage of the initial endogenous gonadotropin "flare" induced by GnRH-a, enhancing the effect of exogenous gonadotropins. The introduction of GnRH antagonists (GnRH-ant) have been a hope for the poor responder patients, because of some advantages such as the immediate suppression of LH, absence of flare-up effect, reduction of stimulation duration and the dose of gonadotropins.
Study design, size, duration: In our ART center, before the Bologna criteria, poor responders were defined as having <4 mature oocytes retrieved in the first stimulation IVF cycle with a GnRH agonist (GnRH-a) long protocol and 375 IU/day FSH or hMG stimulation (P1 protocol). The aim of this prospective study between 2004 and 2010 is to compare two other protocols in poor responder patients after failure using long GnRH-a protocol.
Participants/materials, setting, methods: After the P1 protocol and an interval less than 4 months, four hundred forty women were randomized between P2 protocol (with a contraceptive pill then flare-up GnRH-a and 375 IU/d FSH or hMG) and P3 protocol (with a multidose flexible GnRH-ant and 375 IU/day FSH or hMG). Cycle cancellation was recommended when less than three mature follicles were observed.
Main results and the role of chance: Twenty-two women who had an ongoing pregnancy with the P1 protocol (6.6% per transfer) were excluded to the prospective study. There were no significant difference between the two other protocols (demographic data, cancellation rate, total gonadotropin dose, fertilization and cleavage rates, grade A/B embryos), excepted to the estradiol levels on the hCG day ($p < 0.001$), embryos obtained ($p < 0.001$) and transferred ($p < 0.01$), higher in the P2 protocol. Despite these, the ongoing pregnancy rates per transfer were the same between the two groups (14.6 and 14.2%). Prognostic factors of pregnancy (multivariate analysis) were woman age <36 years old, no tobacco use, total FSH/hMG dose <5000 IU and endometrial thickness >10 mm.
Limitations, reason for caution: In 2011, an ESHRE consensus conference had defined the poor ovarian response by "Bologna criteria". In this study, the poor responders were defined before the Bologna criteria by a prior poor response (<4 mature oocytes retrieved after a long GnRH-a protocol with 375 IU/day FSH or hMG).
Wider implications of the findings: Despite the initial dose of gonadotropins was similar in the three protocols (375 IU/day), the number of oocytes retrieved and embryos transferred were significantly higher with the P2 and P3 protocols than with the first protocol. As the Polyzos results in 2013, the increase of the oocytes between P1 and P2/P3 protocols was the most important factor of pregnancy in the poor responders.
Study funding/competing interest(s): Funding by hospital/clinic(s) – CHU Amiens Picardie.
Trial registration number: NA.
Keywords: IVF, poor responder, GnRH agonist, GnRH antagonist, pregnancy rate

P-411 The influence of female overweight and obesity on the outcomes of assisted reproductive technology treatment: the experience of a Portuguese center

T. Simoes[1], C. Julio[1], S. Figueiredo[1], G. Silva[1], S. Pinto[1], M. Rato[1], S. Correia[1], J. Gonçalves[1], G. Pinto[1]
[1]*Maternidade Alfredo Da Costa – CHLC, Reproductive Medicine, Lisboa, Portugal*

Study question: To investigate if female overweight and obesity have negative effects on the probability of achieving a clinical pregnancy after treatments with *in vitro* fertilization (IVF) or intracytoplasmic sperm injection (ICSI).
Summary answer: Compared with women with normal Body Mass Index (BMI) (18.5–24.9 kg/m^2), overweight and obese women required a higher dose of gonadotrophines, more days of stimulation, and had a lower number

of embryos to transfer. However, they had similar rates of clinical pregnancy $p = 0.5$, OR: 1.095 [0.84; 1.43] and miscarriage $p = 0.78$, OR: 1.09 [0.56; 2.06].
What is known already: Studies of outcomes from assisted reproductive technology (ART) treatments have detected negative effects of increased female BMI. The probability of live birth after ART was found to be 9–10% lower among overweight/obese women compared with normal-weight women, with obesity affecting the outcome more than overweight, and with suggestions of a dose response relationship. Otherwise, studies found no conclusive effect of increased female BMI on pregnancy rate after IVF or on deliveries after IVF/ICSI.
Study design, size, duration: Retrospective cohort study. 1110 IVF/ICSI cycles from one Portuguese Center collected throughout 2012–2014. BMI was recorded in the electronic medical chart. Study Group – 384 women with BMI ≥25 kg/m^2; Control Group – 384 women with normal BMI (18.5–24.9 kg/m^2).
Participants/materials, setting, methods: Women going through IVF/ICSI at the Reproductive Medicine Department of Maternity Dr. Alfredo da Costa – CHLC, Lisbon Portugal. BMI was calculated as body weight (kg) divided by height squared (m^2) and categorized according to the World Health Organization. Statistical analyses were performed with the use of SPSS version 22.0.
Main results and the role of chance: Both groups had similar mean age 33.9 versus 34 years ($p = 0.2$). Study Group had greater duration of infertility 5.6 versus 5 years ($p = 0.01$); more cases of polycystic ovary syndrome 16 versus 8% ($p < 0.001$); greater average antral follicle count ($p = 0.007$), needed higher doses of gonadotrophines ($p = 0.02$), more time for stimulation ($p < 0.001$), had low number of embryos 3.7 versus 4.2 ($p = 0.04$) and more cases with less than 4 embryos 57 versus 50% ($p = 0.04$ OR: 1.3 [1.01; 1.67]). However, with regard to clinical pregnancies, miscarriage and multiple pregnancies, we did not find statistically significant differences between both groups. Clinical pregnancies 36 versus 35% ($p = 0.5$; OR: 1.095 [0.84; 1.43]); miscarriage 12.3 versus 11.4% ($p = 0.78$ OR: 1.09 [0.56; 2.06]); multiple pregnancies 22.5 versus 21.3% ($p = 0.77$ OR: 1.07 [0.65; 1.77]). A sub-analysis to obese women alone (88 cycles) showed similar results.
Limitations, reason for caution: The sample size was too limited to draw firm conclusions regarding specific differences in live-birth rates between BMI groups.
Wider implications of the findings: While overweight and obese women have poorer results throughout the cycle, there is no visible difference in terms of final outcome. Therefore, BMI ≥25 kg/m^2 should not be used as a contraindication to IVF treatments. However, couples should be advised that controlling weight will improve chances of success and provide long-term health benefits.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Maternity Dr. Alfredo da Costa – CHLC.
Trial registration number: NA.
Keywords: female, overweight, obesity, ART, pregnancy

P-412 Assessment of uterine, subendometrial blood flows and endometrial gland vascular endothelial growth factor (EG-VEGF) in women with unexplained infertility

A. Elnaggar[1], M. Abdel-Hafeez[2], H. El-Zenneni[2], R. Moustafa[2], H. El-Salally [3], A. Abdel-Kader[2]
[1]*Jersey General Hospital, Obstetrics Gynecology, Jersey, United Kingdom*
[2]*Ain Shams University, Obstetrics Gynecology, Cairo, Egypt*
[3]*Ain Shams University, Pathology, Cairo, Egypt*

Study question: Our study tried to investigate whether there was a defective expression of the EG-VEGF in women with unexplained infertility? And if we could correlate this EG-VEGF expression to non-invasive sonographic variables, namely endometrial thickness as well as subendometrial and uterine blood flows.
Summary answer: Women of the Unexplained Infertility Group had lower VEGF score, thinner endometrial thickness, higher subendometrial flow Resistance index (RI) and lower subendometrial flow Pulsatility Index (PI).
What is known already: It has been noted that a peak stromal VEGF expression occurs in the proliferative phase with a peak glandular VEGF expression occurs during the secretory phase. There is a significant increase in VEGF mRNA throughout the endometrial cycle in the non-pregnant patient with its expression increasing 3–5 times from the early proliferative phase to the late secretory phase.
Study design, size, duration: Cohort prospective study was conducted at Ain Shams University Maternity Hospital during the period between August 2010 and July 2012.The study included two groups of women: The unexplained infertility group, included fifty women and *the* fertile group, included fifty fertile parous women.
Participants/materials, setting, methods: On day 6 after detection of urinary LH surge, transvaginal ultrasound scan (TVS) was done for measuring endometrial thickness, uterine artery and subendometrial Doppler velocimetry indices. On the same day of TVS, endometrial samples were taken using office suction sampler for immunohistochemical detection of the vascular endothelial growth factor.
Main results and the role of chance: When compared to women of Fertile Group, women of the Unexplained Infertility Group had a significantly lower VEGF score [EG-VEGF score 1 (0–2) in infertile group compared to 2 (1–3) in fertile group; $p < 0.001$], significantly thinner endometrial thickness (8 mm compared to 12 mm; $p < 0.001$), significantly higher subendometrial flow RI and significantly lower subendometrial flow PI [1.2 (1–1.33) compared to 1.34 (1.22–1.44); $p = 0.001$]. The difference between both groups regarding the uterine artery RI and PI was statistically insignificant.
There was a significant positive correlation between EG-VEGF score and each of endometrial thickness and subendometrial PI. There was a significant negative correlation between EG-VEGF score and subendometrial RI.
Limitations, reason for caution: The main limitation for this study is the small sample size which affected the confidence interval (CI) of uterine artery Doppler variables, made it a wide interval.
Wider implications of the findings: VEGF may be an important paracrine modulator of the vascular growth, remodelling, and functional vascular permeability in the endometrium. Furthermore, functional studies suggest for the first time a direct role for EG-VEGF and human uterine fluid during initiation of embryo implantation in mid-secretory phase of the cycle.
Study funding/competing interest(s): Funding by University(ies) – Ain Shams university Hospital, Cairo, Egypt.
Trial registration number: NA.
Keywords: unexplained infertility, endometrial gland vascular endothelial growth factor (EG-VEGF)

P-413 Frozen embryo transfer protocols: a comparison of clinical pregnancy and delivery rates

M. Healey[1], T. Osianlis[2], L. Rombauts[3]
[1]*University Melbourne, Department Obstetrics and Gynaecology, Melbourne, Australia*
[2]*Monash IVF, Embryology, Melbourne, Australia*
[3]*Monash University, Department Obstetrics and Gynaecology, Melbourne, Australia*

Study question: Is there a difference in outcome between natural and hormone replacement therapy (HRT) frozen embryo transfer (FET) cycles?
Summary answer: Natural cycle FET results in higher rates of both clinical pregnancies and deliveries than HRT cycles.
What is known already: There is conflicting evidence on the effectiveness of different FET protocols with some studies claiming that HRT protocols are superior and others claiming the opposite.
Study design, size, duration: This is a retrospective observational study of initial FET cycles over 14 years from a prospective IVF database. This included 9,860 single FET cycles and 4,235 double FET cycles.
Participants/materials, setting, methods: The initial FET cycle for each woman was extracted. This included both cleavage and blastocyst embryos. Cycles with incomplete data (3.1%) were excluded. Chi square testing was used to compare proportions (clinical pregnancy and delivery), and multivariate logistic regression was performed to account for potential confounding variables.
Main results and the role of chance: The clinical pregnancy rates were higher for initial cycle single embryo cycles comparing natural and HRT protocols (28.7 vs 23.6% $p < 0.001$) [odds ratio 1.31 (1.17–1.45)]. This was confirmed on multivariate logistic regression with adjusted odds ratio (aOR) 1.79 (1.58–2.03). Comparison of delivery rates provided further support with rates of 23.7 and 17.3% ($p < 0.001$) [OR 1.49 (1.32–1.68)] for natural and HRT protocols, respectively. Again, multivariate logistic regression analysis supported this [aOR 1.91 (1.65–2.21)]. Confounding variables allowed for included patient ages at

time of freeze and thaw, embryo age in days, years of freeze and thaw, patient's previous reproductive history, IVF cycle number, freezing technique, embryo grade, BMI and presence of polycystic ovaries.
Limitations, reason for caution: Although this study limited FET cycles to the initial one for each patient, used single FET cycles and employed logistic regression to allow for known potential confounders, there is still the possibility for bias, which would be better negated by a prospective randomised trial.
Wider implications of the findings: The lower clinical pregnancy and delivery rates with HRT FET cycles indicate that this protocol should be limited in use to women who are unable to cycle naturally.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Monash IVF.
Trial registration number: This study met the criteria for an audit and so was not assigned a registration number.
Keywords: FET protocol, natural FET, HRT FET, delivery rate

P-414 Blastocyst development and pregnancy outcome of the frozen-embryo transfers are similar after GnRH agonist or HCG triggering in patients at risk of OHSS

A. P. Cil[1], S. Selcuk[1], Z. Atayurt[1], H. Yelke[1], Y. Kumtepe[1], S. Kahraman[1]
[1]*Istanbul Memorial Hospital, IVF, Istanbul, Turkey*

Study question: Is there any difference between gonadotropin-releasing hormone agonist (GnRH-a) or human chorionic gonadotropin (HCG) triggering of final oocyte maturation (FOM) in patients at risk of developing ovarian hyperstimulation syndrome (OHSS) regarding blastocyst stage embryo development (BSED) and ongoing pregnancy rates (OPR) of frozen-thawed embryo transfer (FTET) cycles?
Summary answer: Blastocyst stage embryo development and ongoing pregnancy rates of the frozen thawed embryo transfer cycles are similar when final oocyte maturation is triggered with either GnRHa or HCG in patients at risk of OHSS.
What is known already: There are a few studies comparing pregnancy outcomes of FTET cycles after triggering of FOM with either GnRHa or HCG and vitrification of embryos at pronuclear or cleavage stage which reported acceptable chance of live-birth after GnRHa compared to HCG triggering. However, as far as we know comparison of the results of BSET after GnRH versus HCG triggering in combination with OPR has not been reported.
Study design, size, duration: A hundred and twenty-six patients undergoing controlled ovarian stimulation had their embryos frozen after triggering of FOM with either GnRHa or HCG due to OHSS risk. They returned for 150 FTET cycles between August 2011 and September 2014 and the results were analyzed retrospectively from Istanbul Memorial Hospital IVF database.
Participants/materials, setting, methods: Embryos at the blastocyst stage were cryopreserved in 62 and 64 patients after GnRHa and hCG administration, retrospectively. Twenty four patients returned for the second FTET cycle because of a negative result or abortion. BSED after triggering with GnRHa or HCG and OPR of the following FTET cycles were compared.
Main results and the role of chance: There were no differences between age and BMI between the groups. The serum AMH levels were higher in GnRHa compared to hCG group (9.8 ± 6.4 vs. 6.4 ± 3.9; $p \leq 0.001$) which resulted in significantly higher number of retrieved (31.5 ± 10.81 vs 25.5 ± 7.2) and matured oocytes (22.9 ± 8.3 vs 19.6 ± 6.4). However maturation and fertilization, and blastocyst and top quality blastocyst development rates were similar (53 vs 50% and 16 vs 16%) after hCG and GnRHa triggering, respectively. Ongoing pregnancy rate per embryo transfer was similar for hCG and GnRHa groups (53 vs 47%, $p = 0.597$).
Limitations, reason for caution: The major limitation of this study is the retrospective nature which resulted in group differences such as AMH levels. However we believe that this doesn't have any significant effect on our results, because as a known fact live-birth rates do not increase when more than 15 oocytes are retrieved.
Wider implications of the findings: As demonstrated by our study GnRH a triggering of FOM has comparable results regarding BSED and OPR in patients at risk of OHSS. These findings has important clinical implications for future use of GnRHa triggering as an alternative to hCG in patients at risk of OHSS who are patients with polycystic ovarian syndrome as well as patients undergoing COS for fertility preservation or for oocyte donation.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Memorial Sisli Hospital.
Trial registration number: NA.
Keywords: ovarian hyperstimulation syndrome, GnRH analog trigger

P-415 Müllerian malformations in an Assisted Reproductive Technologies Center: clinical implications

T. Lima[1], A. S. Cardoso[1], M. I. Sá[1], A. Pinto[1], C. Leal[1], S. Fraga[1], C. Lourenço[1], M. Barreiro[1], I. Sousa Pereira[1], J. Mesquita Guimarães[1]
[1]*Centro Hospitalar do Porto, Departamento da Mulher e da Reprodução, PORTO, Portugal*

Study question: Are the Müllerian malformations associated with infertility and poor obstetric outcome?
Summary answer: Müllerian malformations can result in poor reproductive outcomes but the most important impact is observed in obstetric outcomes.
What is known already: Müllerian malformations are deviations from normal anatomy resulting from maldevelopment of the Müllerian ducts. Depending on the type and the degree of anatomical distortion they are associated with health and reproductive problems.
Study design, size, duration: We revised all the files of assisted reproductive technologies (ART) cycles in our center from June 2010 to August 2014 ($n = 2100$). The malformations found in this group were divided according to the ESHRE/ ESGE classification (2013) and the study only included the class U3 and the class U4.
Participants/materials, setting, methods: We performed a retrospective study and analysed variables such as women's age, type of infertility, type of malformation (bicorporeal uterus which included dydelphys uterus, and hemi-uterus), type of ART, pregnancy rate and outcomes of pregnancy.
Main results and the role of chance: Of the women submitted to ART cycles, 18 had uterine malformations; 14 had bicorporeal uterus (11 with bicornuate uterus and three with dydelphys uterus) and four had hemi-uterus. 61.1% of women had primary infertility. The main cause of infertility was male factor associated to the uterine malformation; only in two women the cause of infertility was the uterine malformation alone. These 18 women performed 33 cycles of ART: 17 Intracytoplasmic sperm injection (ICSI), 11 *In Vitro* Fertilization (two of them with donor sperm), four frozen embryo transfers and one intrauterine insemination. Pregnancy occurred in 11 cases after ART cycles (success rate of 33%). Seven of these pregnancies resulted in miscarriages (three in the first trimester and four in the second trimester). Two women had preterm labour and two delivered after 37 weeks of gestation.
Limitations, reason for caution: Müllerian malformations as bicorporeal uterus and hemi-uterus have a low incidence, even in women submitted to ART, limiting the power of the present study.
Wider implications of the findings: Bicorporeal uterus and hemi-uterus are major malformations which can result in poor reproductive outcomes but mainly in obstetric complications.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Centro Hospitalar do Porto.
Trial registration number: NA.
Keywords: Müllerian malformations, ART, pregnancy

P-416 Decreased healthcare resource utilization among women undergoing IVF/ICSI treated with GnRH antagonist protocols as compared to GnRH agonist protocols

W. Ledger[1], S. Crespi[2], Hu, H[2], E. M. Kolibianakis[3], G. Griesinger[4]
[1]*University of New South Wales, School of Women's & Children's Health Royal Hospital for Women, Randwick, NSW, Australia*
[2]*Merck & Company Inc, Centre for Observational Research and Real World Evidence, Kenilworth, U.S.A.*
[3]*Aristotle University of Thessaloniki, Medical School 1st Department of Obstetrics and Gynecology, Thessaloniki, Greece*
[4]*University of Lubeck, Department of Gynecological Endocrinology and Reproductive Medicine, Lubeck, Germany*

Study question: Is there is a difference in healthcare resource utilization between women undergoing IVF/ICSI treated with GnRH agonist protocols as compared to those treated with either corifollitropin alfa (CFA) in an antagonist protocol or treated by any antagonist protocol?
Summary answer: Fewer office visits, clinician visits, nurse visits, calls to the clinic, and transvaginal ultrasound scans were recorded in patients treated by CFA in an antagonist protocol or in patients treated with any antagonist protocol as compared to patients treated by agonist protocols.
What is known already: Agonist and antagonist protocols have been demonstrated to be equally efficacious in terms of live birth rate. Since their introduction, antagonist protocols have been generally recognized as patient friendly with fewer injections and days of treatment and hence less burdensome to the patient. The impact of these protocols on the clinic in terms of healthcare resource utilization has been less well investigated.
Study design, size, duration: Prospective observational study in 17 countries in Europe, Asia, Australia, and Israel; analysis includes women who met all inclusion and exclusion criteria, CFA ($N = 1647$), antagonist ($N = 2837$, including CFA patients), and agonist ($N = 465$). Healthcare resource utilization was captured during controlled ovarian stimulation (COS) at each visit.
Participants/materials, setting, methods: Healthcare resource utilization was assessed at each contact with the clinic over the course of COS. Number of office visits, physician and nurse consults, calls to the clinic, and transvaginal ultrasound scans were compared between protocols.
Main results and the role of chance: Both CFA and antagonist patients recorded fewer clinic visits (mean = 3.2 and 3.3, respectively) than agonist patients (mean = 3.7) ($p < 0.001$ for both CFA and antagonist vs agonist). 39.8 and 39.3% of CFA and antagonist patients, respectively, recorded 4+ office visits compared with 56.1% of agonist patients. Similar patterns were observed for physician and nurse consults. Fewer CFA and antagonist patients called the clinic at least once – 18.3 and 18.0%, respectively – compared with 27.7% of agonist patients ($p < 0.001$ for both comparisons). Fewer transvaginal ultrasounds were conducted in CFA and antagonist patients (mean = 2.7 for both) compared with agonist patients (mean = 3.2) ($p < 0.001$ for both comparisons). 28.3 and 28.7% of CFA and antagonist patients, respectively, had 4+ ultrasounds compared with 46.2% of agonist patients.
Limitations, reason for caution: While no clinically meaningful demographic or clinical differences were found at baseline, selection bias cannot be ruled out given that patients were not randomized. Healthcare resource utilization may be underreported as any omitted reports of resource utilization could not be queried or confirmed as reporting was event driven.
Wider implications of the findings: The finding of reduced healthcare resource utilization among women undergoing IVF/ICSI treated with GnRH antagonists compared with a GnRH agonist protocol demonstrates that antagonist protocols are beneficial in not only reducing the burden that ART treatment places on patients but also in optimizing utilization of clinic resources.

P-417 Endometrial thickness after ovarian hyperstimulation in an intrauterine insemination program: a systematic review

van M. N. Vliet[1], N. S. Weiss[1], J. Limpens[2], P. G. A. Hompes[3], C. B. Lambalk[3], M. H. Mochtar[1], F. van der Veen [1], B. W. Mol[4], M. van Wely [1]
[1]*Academisch Medisch Centrum, Center for Reproductive Medicine, Department of Obstetrics and Gynaecology, Amsterdam, The Netherlands*
[2]*Academisch Medisch Centrum, Medical Library, Amsterdam, The Netherlands*
[3]*VU Medisch Centrum, Center for Reproductive Medicine Department of Obstetrics and Gynaecology, Amsterdam, The Netherlands*
[4]*The Robinson Institute, School of Paediatrics and Reproductive Health, Adelaide, Australia*

Study question: Does the stimulating agent used in ovarian hyperstimulation as co intervention in intra uterine insemination (IUI) affect endometrial thickness (EMT)?
Summary answer: Clomiphene citrate (CC) as a stimulating agent in ovarian hyperstimulation results in a thinner endometrium compared to other stimulating agents.
What is known already: EMT has been associated with success rates in medically assisted reproduction. The type of ovarian hyperstimulation might influence the EMT. It has been suggested that CC results in a lower endometrial thickness than gonadotrophins or aromatase inhibitors.
Study design, size, duration: We performed a systematic review and meta-analysis of studies comparing CC, gonadotrophins or aromatase inhibitors in an IUI program reporting on endometrial thickness in couples with unexplained subfertility.
Participants/materials, setting, methods: Medline, EMBASE and CINAHL were searched. Outcome measures were mean pre-ovulatory endometrial thickness and clinical pregnancy. Mean differences with 95% confidence intervals were calculated using a random effect model. Meta-regression was performed to determine if different stimulating agents interacted in the estimated effect of endometrial thickness.
Main results and the role of chance: We included 20 studies in our meta-analysis, of which 12 compared CC and letrozole, four compared gonadotrophins and letrozole and four used a single stimulation agent. There was evidence for a thinner endometrium in women treated with CC compared to letrozole [mean difference -0.36 mm (95% CI -0.72 to -0.01)]. There was no evidence for a difference in EMT in women treated with gonadotrophins compared to letrozole [mean difference 0.06 mm (95% CI -1.46 to 1.14), respectively]. Pre-ovulatory endometrium was thicker in pregnant than in non-pregnant women, although the difference was not statistically significant [6 studies, mean difference 0.55 mm (95% CI -0.11 to 1.21)]. Meta-regression could not rule out interactive effects of the type of stimulating agent used.
Limitations, reason for caution: There was considerable to substantial heterogeneity in the comparisons and the overall quality of the included studies was low, hampering firm conclusions. In addition, a cut-off value for optimal endometrial thickness is lacking.
Wider implications of the findings: Although clomiphene citrate appears to result in a thinner endometrium when compared to other stimulating agents, the influence of endometrial thickness on pregnancy remains unclear. Whether EMT could be used as a biomarker to guide the stimulation in future cycles should be evaluated in RCTs
Study funding/competing interest(s): Funding by hospital/clinic(s) – Academic Medical Center Amsterdam.
Trial registration number: NA.

P-418 Is intra-uterine insemination (IUI) a cost-effective service? Evidence of success and patient satisfaction from a UK clinic specialising in IUI

B. J. Woodward[1], D. Littlehales[1], N. Cotgreave-Keates[1], K. Pooley[1], T. Kohut[1], S. Deb[1], M. J. Tomlinson[1]
[1]*Nottingham University Hospital, Fertility Unit, Nottingham, United Kingdom*

Study question: Does IUI treatment offer a sufficiently high success rate and patient satisfaction for the state to continue funding this treatment? This is particularly relevant question for the UK, where the National Institute for Clinical Excellence (NICE) has recommended that IUI should not be used as first treatment for unexplained infertility.
Summary answer: From 2009 to 2014, a live birth rate of 11.5% was achieved for all IUI patients. The estimated cost per live birth was 7800. 31.2% of patients achieved a pregnancy within three IUI attempts and 90.6% stated they were satisfied to attempt conception via IUI rather than go straight to IVF treatment.
What is known already: IUI is a low complexity therapy recommended by many specialists as first-line treatment for couples with mild or unexplained fertility problems. Pregnancy rates tend to be higher than for natural conception but lower than more complex treatments such as IVF. Advantages of IUI include its low cost, use of less drugs and no surgery. However, recent NICE guidelines recommend that IUI (with ovulation induction) should no longer be used as first treatment for unexplained infertility.
Study design, size, duration: Success rates (clinical pregnancy rate and live birth rate) were calculated from 859 couples having 1875 cycles of IUI combined with mild gonadotrophin stimulation. A questionnaire was then sent to a random sample of treated couples, whether successful or not, to seek their views on the IUI service received.
Participants/materials, setting, methods: Heterosexual couples (median female age 33.8 years, range 21–44 years) with unexplained infertility,

anovulation problems and/or borderline male factor received IUI treatment at a fertility clinic specialising in IUI with partner sperm. The questionnaire was posted to couples who had previously attended the clinic regardless of the outcome.

Main results and the role of chance: The overall clinical pregnancy and live birth rates per IUI were 14.9 and 11.5% respectively, resulting in an approximate cost per live birth of 7800. From the survey, 78.1% couples attended for unexplained infertility, whilst 18.8% had anovulation problems. 44.8% couples were offered IVF as an alternative to IUI at the initial consultation, whilst 51.7% were offered IVF after three IUI attempts. Expectations of success were low for 27.6% couples and moderate to high for 34.5% couples. 90.6% couples considered IUI to have a low level of discomfort and risk and were therefore satisfied with the decision to choose IUI over IVF treatment. 93.8% stated that they would prefer the offer of less invasive treatment via IUI rather than going straight to IVF.

Limitations, reason for caution: Only 32 patients from 50 responded to the survey. A wider survey might reveal different responses, although from the data provided, there was an overwhelming trend for patients supporting access to IUI treatment.

Wider implications of the findings: Despite the relatively low success rate of IUI compared to IVF treatment, the survey showed that couples prefer to be given the chance to conceive without invasive therapy. Moreover, with an 11.5% live birth rate, the cost per take home baby after IUI is significantly less than for IVF (we calculated this at € 7800 for IUI compared to €15400 for IVF, even with allowance for a generous IVF live birth rate of 40% cycle).

Study funding/competing interest(s): Funding by hospital/clinic(s) – Nottingham University Hospital, Nottingham, UK.

Trial registration number: NA.

P-419 Myo-inositol during IVF: possible strategy for poor responders patients?

M. D. D'Eufemia[1], F. Caprio[1], M. R. Campitiello[1], D. Mele[1], C. Trotta[1], N. Colacurci[1]

[1]*Seconda Università di Napoli, Dipartimento della Donna del Bambino di Chirurgia Generale e Specialistica, Napoli, Italy*

Study question: The aim of the present study was to evaluate the effect of Myo-inositol on ovarian function in poor responders patients undergoing ovulation induction for ICSI cycle.

Summary answer: The results suggest that myo-inositol may improve ovarian response to stimulation in poor responder patients

What is known already: The management of poor responders remains a challenge in IVF techniques.

Inositol is a vitamin-factor of B group. The role of inositol in the streamlining of ovulatory process has been widely defined in patients with reduced insulin sensitivity. Recently it has been hypothesized that inositol could have a different way of action on different cell kinds. There is the evidence that inositol may improve ovarian function and optimize oocyte quality in IVF

Study design, size, duration: Prospective controlled observational trial.

Participants/materials, setting, methods: 72 women poor responder scheduled for an ICSI cycle, divided in two groups: group A: 38 patients treated with myo-inositol (4 g) + folic acid (400 µg) for the previous three months before the enrollment day; group B: 38 patients treated with folic acid (400 µg) for the same period.

Main results and the role of chance: The main goal was the definition of the number and the quality of the oocytes retrieved; secondary endpoints were the Ovarian Sensitivity Index (OSI: *n*° oocytes retrieved/total Gn units × 1000), oestradiol levels at the day of hGC administration, fertilization rate, implantation rate, ongoing pregnancy rate. There was no significant difference between the two groups regarding oestradiol level, but total rec-FSH units were significantly lower in group A (1975 ± 298 vs 2212 ± 312, $p = 0.004$). The results show a statistically significant increase in M2 oocytes rate (80.5 vs 66.6%, $p = 0.01$). The ovarian sensitivity index was higher, reaching a statistical significance, in the group A vs group B (1.88 ± 0.81 vs 1.54 ± 0.65, $p < 0.05$), showing an improvement in ovarian sensibility to gonadotropin.

Limitations, reason for caution: Small size of sample.

Wider implications of the findings: Results suggest that myo inositol therapy results in an increase in oocytes number that could be used for ICSI techniques, significantly increasing the number of oocytes recovered in MII in poor responder patients. Besides, the group pre-treated with myo inositol showed a significant increase of the gonadotropin ovarian sensitivity index (OSI), suggesting a myoinositol role in improving ovarian response to gonadotropins. Therefore myoinositol seems to be helpful in 'poor responders' patients undergoing IVF cycles.

Study funding/competing interest(s): Funding by University(ies) – Seconda Università degli studi di Napoli.

Trial registration number: Is not required.

Keywords: IVF, myoinositol, poor-responders

P-420 Effect of endometrial biopsy on intrauterine insemination outcome in controlled ovarian stimulation cycle

L. Wadhwa[1], A. Pritam[1], T. Gupta[1], S. Gupta[1], S. Arora[2], R. Chandoke[3]

[1]*ESI Post Graduate Institute of Medical Science & Research, Obst & Gynae, Delhi, India*

[2]*ESI Post Graduate Institute of Medical Science & Research, Biochemistry, Delhi, India*

[3]*ESI Post Graduate Institute of Medical Science & Research, Pathology, Delhi, India*

Study question: The proposed hypothesis in our study is that endometrial biopsy preceding ovulation induction and intrauterine insemination (IUI) have the same beneficial effect on IUI outcome in patient undergoing controlled ovarian stimulation as demonstrated in IVF.

Summary answer: EB done in early follicular phase in same cycle of stimulation with IUI gives better CPR as compared to EB done in luteal phase of previous cycle.

What is known already: In controlled ovarian stimulation cycle uterine receptivity is diminished due to endometrial alteration and supraphysiological level of steroid hormones. Endometrial injury facilitates embryo implantation and pregnancy rates through local inflammatory and angiogenesis mechanism.

Study design, size, duration: prospective parallel randomized control study in a 1:1 allocation ratio conducted in a tertiary care centre from August 2012 to March 2014.

Assuming the clinical pregnancy rate in intervention and control Group as 32.7 and13.7% in previous study by Narvekar (2010) with alpha = 0.05 and power = 80% minimum 225 cases were to be included, but assuming that few subjects may be lost to follow up, a total of 251 subjects attending infertility clinic were included in the study.

Participants/materials, setting, methods: Subjects undergoing controlled ovarian stimulation with IUI were randomly allocated into 3 Groups. Block randomization with sealed envelope system was used. Group A: EB was taken between D 19-24 of the spontaneous menstrual cycles that precedes the fertility treatment and IUI which was done in next cycle ($n = 86$). Group B: EB was taken before D 6 of the menstrual cycle and fertility treatment and IUI was done in same cycle ($n = 90$). Group C: (Control Group) No EB in previous 3 cycle ($n = 75$).

Main results and the role of chance: Clinical pregnancy rate (CPR) was 19.77, 31.11, and 9.3% for Group A, Group B, and Group C, respectively. The results show a highly significant value for the paired t test of intervention Group B and control Group C of the cases ($p = 0.000957$). Clinical pregnancy rate was maximum after first cycle of OI and IUI following EB scratch in both Groups A and B ($p < 0.001$).

The relative risk (R/R) between Group A and Group C is 2.1179, 95% CI 0.9291–4.8278 ($P = 0.0742$) NNT-9.584. The relative risk (R/R) between Group B and Group C is 3.3333, 95 % CI 1.5442 to 7.1955 ($P = 0.0022$), NNT-4.592. The relative risk (R/R) between Group A and Group B is 1.5739, 95% CI 0.9308 to 2.661 ($P = 0.0905$), NNT 8.815.

Limitations, reason for caution: The study was not blinded and all due care was taken during randomization to prevent selection bias.

Wider implications of the findings: Most of the work related to endometrial scratching has been done in IVF cycles with promising results. In developing countries with lincreasing infertility rates there is requirement of affordable, low cost interventions like endometrial scratching which can be done as an OPD procedure prior to ovulation induction and IUI cycles, thereby improving pregnancy rates before proceeding for high cost alternative ART procedures.

Study funding/competing interest(s): Funding by hospital/clinic(s) – ESI-Postgraduate Institute of Medical Science & Research, Basaidarapur, Delhi.

Trial registration number: CTRI/2013/04/003521, WHO International Clinical Trials Portal

P-421 Association between uterine perfusion and inherited thrombophilia in patients with unexplained infertility

H. Selman[1], C. Valeri[1], G. Antonini[2], M. Sbracia[3], A. Pacchiarotti[4]
[1]*Praxi Provita, IVF, Rome, Italy*
[2]*University of Sapienza, Department of Science, Rome, Italy*
[3]*University of Tor Vergata, Department of Science, Rome, Italy*
[4]*University of Sapienza, IVF, Rome, Italy*

Study question: The aim of this study was to evaluate the possible association between impaired uterine arteries and genetic polymorphism of thrombophilic markers, like Factor V (FV) Leiden gene mutation, prothrombin (PT) mutation and homozygous mutation of methylenetetrahydrofolate reductase (MTHFR), in patients with unexplained infertility.
Summary answer: The polymorphisms taken individually are not sufficient to explain an alteration in blood flow, while combination of these could be the cause of a altered uterine flow, resulting in failure of the system both in a spontaneous pregnancy in a pregnancy induced by PMA.
What is known already: Uterine receptivity is one of the most important factors in determining successful implantation. Several studies showed that failure to conceive might be associated with an increased resistance in the uterine arteries. A reduced pregnancy rate (PR) has been reported in women with impaired uterine perfusion.
Study design, size, duration: This is a prospective study, in which the patients were computerized randomization. Between January 2013 and May 2014, 148 consecutive patients with unexplained infertility underwent basal uterine arteries Doppler velocimetry evaluation.
Participants/materials, setting, methods: Pulsatility index (PI) were automatically calculated and the patients were divided in two groups: Group A ($n = 49$) with PI >3 in at least one of uterine arteries; group B ($n = 99$) with normal uterine arteries. All patient underwent a screening for the three main thrombophilic markers.
Main results and the role of chance: Our results showed a statistically significant association between thrombophilic polymorphism mutations and impaired uterine arteries only with simultaneous presence of two or three mutations: FV Leiden and gene C677T of MTHFR (34.69 vs 1.01% respectively in group A and B, $P = 0.0001$); FV Leiden and mutation G20210A of PT gene (20.4% in Group A vs 2.02% in group B, $P = 0.0003$); gene C677T of MTHFR mutation and FV Leiden and mutation G20210A of PT gene (18.4% in study group vs 3.03% in control group $P = 0.0025$) and FV Leiden mutation, mutation G20210A of PT gene and gene C677T of MTHFR mutation (12.24 vs 1.01% in group A and B respectively).
Limitations, reason for caution: The limit of this study is the small number of the patients.
Wider implications of the findings: This study shows that the increase in resistance of the uterine arteries is positively correlated with the presence of at least two genetic polymorphisms for acquired thrombophilia. Knowing these polymorphisms allows to set the correct treatment immediately and thus avoid treatments that may not work. Also gives us important informations on the possible therapy to be set during the entire pregnancy.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Praxi DS, Praxi Provita.
Trial registration number: This study isn't RCT.
Keywords: uterine receptivity, utery artery perfusion, thrombophilia

P-422 Association between serum folate and vitamin B12 and success of assisted reproductive technologies

A. J. Gaskins[1], Y. Chiu[1], P. L. Williams[2], T. L. Toth[3], R. Hauser[4], J. E. Chavarro[1]
[1]*Harvard School of Public Health, Department of Nutrition, Boston MA, U.S.A.*
[2]*Harvard School of Public Health, Department of Biostatistics, Boston MA, U.S.A.*
[3]*Massachusetts General Hospital and Harvard Medical School, Vincent Obstetrics and Gynecology, Boston MA, U.S.A.*
[4]*Harvard School of Public Health, Department of Environmental Health, Boston MA, U.S.A.*

Study question: Are pre-treatment levels of serum folate and vitamin B12 associated with assisted reproductive technology (ART) outcomes?
Summary answer: Higher serum levels of folate and vitamin B12 prior to ART treatment was associated with higher live birth rates among a population exposed to folate fortification. Moreover, women with higher levels of both serum folate and vitamin B12 had the greatest likelihood of reproductive success.
What is known already: Studies from European infertility cohorts suggest that folate may improve total and mature oocyte counts, embryo quality, and pregnancy rates; however, in studies that investigated live birth rates solely among women undergoing embryo transfer, no associations were observed. Several small studies and case reports have found associations between vitamin B12 deficiency and female subfertility yet a cohort study from the UK found no relation between plasma vitamin B12 and live birth following *in vitro* fertilization.
Study design, size, duration: A random sample of 100 women (contributing 154 ART cycles) participating in a prospective cohort study (EARTH) at the Massachusetts General Hospital Fertility Center (Boston, MA, USA).
Participants/materials, setting, methods: Serum folate and vitamin B12 were measured in blood samples taken between day 3 and 9 of treatment. Outcomes of ART were abstracted from medical records. Generalized estimating equations adjusting for age, BMI, and race were used to evaluate the association of folate and vitamin B12 with ART outcomes.
Main results and the role of chance: Women in the highest quartile of serum folate (>26.3 ng/mL) had 1.62 (95% CI 0.99, 2.65) times the probability of live birth compared to women in the lowest quartile (<16.6 ng/mL) (p-trend = 0.01). Women in the highest quartile of serum vitamin B12 (>701 ρg/mL) had 2.04 (95% CI 1.14, 3.62) times the probability of live birth compared to women in the lowest quartile (<439 ρg/mL) (p-trend = 0.008). Evidence of an additive interaction between serum folate and vitamin B12 was observed; women with serum folate and vitamin B12 levels >median had 1.92 (95% CI 1.12, 3.29) times the probability of live birth compared to women with folate and vitamin B12 levels ≤median. This translated into an adjusted difference in live birth rates of 26% (95% CI 10–48%) (p-value = 0.02).
Limitations, reason for caution: Residual confounding is still possible due to the observational nature of this study. The generalizability of our study to women presenting at infertility clinics worldwide is unclear as our women have much higher serum folate levels than comparable populations in Europe.
Wider implications of the findings: These findings support the importance of preconception folic acid supplementation and suggest the additional intake of vitamin B12. Given that live birth rates per initiated ART cycle have plateaued for approximately a decade, a randomized trial of high dose supplementation with folic acid and vitamin B12 before planned ART warrants serious consideration.
Study funding/competing interest(s): Funding by national/international organization(s) – NIH grants R01-ES009718, P30-DK046200, T32-DK007703-16.
Trial registration number: NA.
Keywords: folate, ART, vitamin B12, IVF

P-423 Gram staining, PCR or PNA FISH analysis for detection and classification of Bacterial Vaginosis – a prospective study in a Danish IVF setting

[5]*Statens Serum Institute, Sexually Transmitted Diseases, Copenhagen, Denmark*

Study question: Should BV be sub-classified with a molecular based tool instead of conventional Gram staining? What is the prevalence of Bacterial

Vaginosis (BV) in infertile Danish women? Finally, should a molecular based abnormal flora be taken into account prior to fertility treatment?
Summary answer: The BV prevalence was 18.9%. BV should be sub-classified using qPCR, enabling to cluster false-positives, constituting *Lactobacillus iners*, which is a lactobacillus species, morphologically indistinguishable from *Gardnerella vaginalis. Gardnerella vaginalis* abundance above a threshold level of 10^9 copies/mL may negatively affect spontaneous as well as assisted conception.
What is known already: BV is a serious reproductive health issue with an incidence of approximately 19% in the fertile population. BV often presents itself sub-clinically with a change of the vaginal microflora from protective and acidic *Lactobacilli* spp. to a more heterogeneous environment dominated by anaerobic bacteria, especially *Gardnerella vaginalis*. Few studies have been conducted in infertile women, and some have suggested a negative impact on fecundity in the presence of BV.
Study design, size, duration: A cohort of 200 asymptomatic infertile patients, primarily Caucasians, attending two Danish fertility clinics from April 2014 to December 2014 were prospectively enrolled in the trial.
Participants/materials, setting, methods: Vaginal swabs from IVF/IUI patients were obtained from the posterior fornix. Gram stained slides were assessed according to Nugents criteria. PCR primers were specific to four common *Lactobacilli* spp., *Gardnerella vaginalis* and *Atopobium vagina*. Threshold levels were established using AUROC analysis. PNA FISH slides were analyzed, using confocal microscopy.
Main results and the role of chance: The prevalence of BV by Nugent score was 18.9% 95% CI (13.7–25.1) versus 21.3% 95% CI (15.6–27.0) by qPCR. The molecular tools revealed that 13.5 % of Nugent positives were false positive due to the abundance of a certain *Lactobacillus* species called *L. iners*. We provide evidence that the non-pathological *L. iners* cluster is morphologically indistinguishable from *Gardnerella vaginalis*. Therefore, a molecular based diagnostic tool should be used when diagnosing an abnormal vaginal flora. Interestingly we observed that none of the patients with *Gardnerella vaginalis abundance* had a successful reproductive outcome. The full data analysis will be presented at the conference.
Limitations, reason for caution: Although a total of 200 patients were included in the study, a larger sample size is needed to draw firm conclusions regarding the reproductive outcome of *Gardnerella vaginalis* infected patients.
Wider implications of the findings: *Gardnerella vaginalis* seems to play a role in infertility, however, when using Gram staining, there is a significant number of false positives due to the presence of non-pathological *L. iners*. This justifies the future use of molecular based diagnostics. If a negative correlation between *Gardnerella vaginalis* and the reproductive outcome is corroborated, we suggest that all patients should be screened for *Gardnerella vaginalis* prior to commencing fertility treatment as this intervention might have significant socioeconomic impacts.

P-424 Does the endometrial secretory immunomodulatory profile differ between women with recurrent implantation failure (RIF) and fertile controls? A case control study

L. Stocker[1], J. C. K. Chan[2], Y. H. Lee[3], Y. C. Cheong[4]
[1]*University of Southampton, Obstetrics and Gynaecology, Southampton, United Kingdom*
[2]*KK Women's and Children's Hospital, Reproductive Medicine, Southampton, Singapore*
[3]*SMART, BioSyM, Singapore, Singapore*
[4]*University of Southampton, Complete Fertility, Southampton, United Kingdom*

Study question: Does the endometrial secretory immunomodulatory profile differ between women with recurrent implantation failure and fertile controls?
Summary answer: This study suggests that the uterine secretome is more tightly associated with RIF patients when compared with unstimulated healthy controls. Analysis demonstrated clear segregation of the two groups of women with eight immunomodulatory molecules, including Leukaemia Inhibitory Factor (LIF), being lower in RIF patients than controls.
What is known already: Human reproduction is tightly governed at the embryo-endometrial interface. Alterations in the constituents of endometrial secretions reflect changes in the underlying endometrial tissue of the peri-implantation environment. Endometrial fluid sampling can be performed accurately and noninvasively. Previous studies have examined general subfertile populations in cycles associated with ovarian stimulation, but the uterine secretion profile of women with RIF is unknown.
Study design, size, duration: A single blind prospective case control study in an *In vitro* fertilisation (IVF) centre, United Kingdom (August 2012 to December 2013). Sixteen women with RIF and twenty healthy fertile controls were recruited.
Participants/materials, setting, methods: Endometrial fluid samples were aspirated from RIF patients (the absence of pregnancy after transfer of ≥3 good quality embryos and over ≥2 IVF cycles) and healthy parous controls in follicular and luteal phases. Samples were investigated for 45 immunomodulatory factors and the data analysed with logistic regression modelling.
Main results and the role of chance: Univariate analysis comparing concentrations of 23 immunomodulatory molecules demonstrated lower βNGF in women with RIF (10.57 pg/µl ± 3.06) than controls (24.96 pg/µl ± 6.21). When five-parameter partial least squares logistic regression modelling was applied, there was a difference in eight immunomodulatory markers, including LIF.
Multivariate analysis demonstrated clear segregation of study patients from controls; principle Component (PC) analysis 1 explaining 55% of the variance and PC2 28%. Magnitude of clustering being tighter between closely clustered patients than controls.
Limitations, reason for caution: Our results may be confounded by a small sample size; a larger scale study in this specific subgroup of women is further needed to confirm our findings.
Wider implications of the findings: Our study demonstrated reduced levels of eight immunomodulatory molecules, including LIF, in RIF compared with controls. This suggests an attenuated inflammatory response in the endometrial peri-conceptual environment, consistent with established data. An understanding of the *in vivo* immunomodulatory milieu in women with RIF, reconfirmed in larger studies, may provide a method to discriminate women with a higher RIF propensity from those who will go on to have successful outcomes whilst serving to delineate plausible underlying mechanisms.
Study funding/competing interest(s): Funding by University(ies) – Funding by hospital/clinic(s). Complete Fertility Centre, Southampton, UK.

P-425 Activator of fatty acid metabolism (AICAR) improves maturation rate, but affects spindle formation and chromosome integrity in *in vitro* maturing denuded mouse oocytes

U. Eichenlaub-Ritter[1], I. Betzendahl[1], T. Trapphoff[1], C. Drechsler[1], M. Heiligentag[1]
[1]*University Bielefeld, Gentechnology/Microbiology, Bielefeld, Germany*

Study question: Does AICAR (5-aminoimidazole-4-carboxamide ribonucleotide), an activator of the 5¢ adenosine monophosphate-activated protein kinase (AMPK), that is assumed to influence fatty acid metabolism, improve quality of *in vitro* matured (IVM) denuded (DO) or cumulus enclosed oocytes (CEO)?
Summary answer: AICAR enhanced dose dependently the rate of polar body (PB) formation of IVM DO and CEO. However, spindle immunofluorescence revealed severe disturbances in metaphase II spindle formation and caused precocious chromatin decondensation in DOs cultured in the presence of AICAR. In contrast, spindle formation was not visibly affected in CEOs.
What is known already: IVM of immature oocytes presents an alternative strategy to obtain fertilizable metaphase II oocytes during ART treatment (e.g., in cases of OHSS). AICAR is an activator of the AMPK that is involved in regulation of fatty acid metabolism. Studies in mammalian oocytes suggest that activation of the fatty acid pathway by AICAR supports meiotic resumption. So far, meiotic progression, spindle, chromosomes and chromosomal constitution of IVM oocytes exposed to AICAR have not been analyzed.

Study design, size, duration: DOs and CEOs from 3- to 6-month-old MF1 mice were matured for 16h i*n vitro* in absence (control), or presence of 0.01, 0.05, 0.1 and 0.2 mM AICAR.
Participants/materials, setting, methods: Spindle, chromosomes and aneuploidy were studied by immunostaining and confocal microscopy, or after spreading. Gap junctional communication was inhibited by 100 mM Carbenoxolone (CBX) in culture with our without AICAR. For pulse chase, IVM was for 7 h in AICAR and 9 h without AICAR (7 h+/9 h-), or with reverse pulse (7 h-/9 h+).
Main results and the role of chance: 0.1 mM AICAR increased the rate of PB oocytes from culture of DOs and CEOs compared to controls. However, there was a significant dose-dependent increase in PB-DOs without spindle or with aberrant spindle and unaligned chromosomes and such with decondensed chromatin, whereas spindles and chromosomes appeared normal in AICAR exposed CEOs. Inhibition of gap junctional communication lead to similar spindle abnormalities and decondensed chromosomes in CEOs as seen in DOs, but were significantly less frequent. First meiosis was only marginally susceptible to 0.1 mM AICAR and there was no induction of first meiotic error. Spindles were also normal in DOs exposed to AICAR for 7 h (up to metaphase I) followed by 9 h without AICAR, whereas the reverse pulse chase interfered with spindle reassembly after anaphase I.
Limitations, reason for caution: Stimulation of fatty acid metabolism via cumulus may increase maturation and possibly quality of oocytes when they are in bi-directional contact with cumulus. In contrast, IVM without cumulus with AICAR appears to critically affect MI/MII transition in mouse DOs, but further studies in other mammals are required.
Wider implications of the findings: IVM is still sub-optimal since oocyte developmental potential appears restricted. Whereas AICAR improves GVBD-rate in experimental studies, it appears to interfere with meiosis I/II progression in DOs, and thereby critically affects spindle formation. Hyperstimulation of AMPK and fatty acid metabolism can possibly contribute to increased ROS in DOs, whereas it may improve supply of metabolites by cumulus in CEOs and thereby increase oocyte maturation. Cumulus appears to protect oocytes from adverse influences of AICAR.
Study funding/competing interest(s): Funding by national/international organization(s) – DFG (German research foundation).
Trial registration number: No number.

P-426 High response to Clomiphen citrate in intrauterine insemination cycles when converted into 'rescue' IVF results in higher implantation rates compared to minimal stimulation IVF cycles

A. N. Chimote[1], B. N. Chimote[2], N. N. Chimote[2], N. M. Nath[3], N. M. Chimote[4]
[1]*Vaunshdhara Clinic and Assisted Conception Centre, Gynecology, Nagpur, India*
[2]*Vaunshdhara Clinic and Assisted Conception Centre, Embryology, Nagpur, India*
[3]*Vaunshdhara Clinic and Assisted Conception Centre, Biochemistry, Nagpur, India*
[4]*Vaunshdhara Clinic and Assisted Conception Centre, Endocrinology, Nagpur, India*

Study question: This study carried out retrospective comparative analysis of clinical pregnancy and implantation rates in young women who were originally slated for IUI but underwent rescue IVF as a result of high response to clomiphen citrate and human menopausal gonadotropin versus women undergoing standard minimal stimulation antagonist protocol with gonadotropin.
Summary answer: Converting IUI cycles of young women giving higher response to clomiphen citrate-human menopausal gonadotropin, to rescue IVF may be a safe, extremely cost effective strategy resulting in higher implantation and ongoing pregnancy rate when compared to age matched high responder women undergoing IVF with standard minimal stimulation protocol using r-FSH.
What is known already: Ovarian stimulation in IUI cycles may improve monthly pregnancy rate by increasing number of oocytes available for fertilization and implantation. However, this treatment modality may also give rise to supernumerary follicles in high responders exposing the women to risks of multiple pregnancy and ovarian hyperstimulation syndrome (OHSS). Although conversion of such IUI cycles to IVF eliminates frustration of cycle cancellation, cost effectiveness of such strategy remains questionable due to use of high dose gonadotropins.
Study design, size, duration: Out of 240 IUI cycles carried out from January to December 2013, 14 cycles in women (age: 23–32 years) with excessive follicular response to CC-stimulation were converted to "rescue" IVF. For the retrospective comparison, case matched women (n = 54) who had undergone mild stimulation protocol IVF were selected from our IVF unit.
Participants/materials, setting, methods: Women slated for IUI were stimulated with clomiphen citrate (100 mg daily, day 3–day 7) and injection hMG (75 IU daily, day8–day of inj.hCG 5000 IU) before they underwent 'rescue IVF' to avoid risk of multiple gestation/ovarian hyperstimulation syndrome. Case-matched control group women had undergone minimal stimulation IVF with 150 IU r-FSH/antagonist
Main results and the role of chance: Age, infertility period, BMI, basal FSH and AMH levels did not differ significantly between test and control groups. Day/hCG Sr. Estradiol levels and the number of eggs retrieved were significantly lower (p = 0.04; p = 0.01 respectively) in rescue IVF group compared with control IVF group. However, blastocyst formation rate and stage / grade of blastocyst transferred (p = 0.58; p = 0.21 respectively) were comparable between both study groups where all cycles involved transfer of d5 blastocyst. Although not statistically significant, clinical pregnancy rate was higher in rescue IVF group (57.1%) compared to control group (44%). Implantation rate was significantly higher in rescue IVF group than in control IVF group (58.3 vs. 25%; p = 0.03). Most significantly, gonadotropin dose used was significantly lower in test group compared to control IVF group.
Limitations, reason for caution: Higher implantation rate in test group is due to more number of twin pregnancies compared to control group despite comparable number of blastocysts transferred. This may be because in test group, supraphysiological levels of estradiol are not as raised as in control group where higher dose of gonadotropins is used.
Wider implications of the findings: We have presented a most cost effective strategy where ovulation induction in IUI with clomiphen citrate-hMG combination was converted to rescue IVF upon obtaining a hyper response. This protocol is cheaper than conventional IVF algorithms and also to IUI protocols where gonadotropins are used from day 3 onwards. If multicenter prospective studies affirm such strategy to give significantly higher clinical pregnancy rates, it may further facilitate transfer of single blastocyst, thus also averting multiple gestation risks.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Self Funded by our IVF clinic. Vaunshdhara Clinic and Assisted Conception Centre.
Trial registration number: NA.

P-427 Adverse obstetrical and neonatal outcomes in pregnancies resulting from oocyte donation

E. Elenis[1], A. Skoog-Svanberg[1], G. Sydsjö[2]
[1]*Womens Clinic Uppsala University Hospital, Department of Women's and Children's Health, Uppsala, Sweden*
[2]*Womens Clinic Linköping University Hospital, Department of Clinical Experimental Medicine, Linköping, Sweden*

Study question: To explore obstetrical and neonatal outcomes among relatively young women with optimal health status conceiving singletons with donated versus autologous oocytes (via IVF and spontaneously).
Summary answer: Oocyte donation is associated with hypertensive disorders of pregnancy, oligohydramnios, preterm delivery, labor induction, delivery by caesarean section, retained placenta, post-partum hemorrhage and longer hospital stay after delivery. However, neonates have similar probability for major congenital malformations and did not differ regarding birth weight and length among term infants.
What is known already: Oocyte donation as an infertility treatment among women with idiopathic, iatrogenic or natural menopause has been associated to gestational diabetes, hypertensive disorders, placental abnormalities, preterm delivery and increased rate of caesarean delivery while simultaneously being characterized by high rates of primiparity, advanced maternal age and multiple gestation constituting the individual risk of mode of conception difficult to assess.

Study design, size, duration: Retrospective cohort case study involving 289 pregnant women with singleton deliveries; 76 women conceiving with donated oocytes, 150 nulliparous women without infertility conceiving spontaneously and 63 women conceiving after non-donor IVF.
Participants/materials, setting, methods: Data on obstetrical and neonatal outcomes were retrieved from the National Birth Medical Register and the medical records of oocyte recipients from the treating University Hospitals of Sweden. Demographic and logistic regression analysis were performed to examine the association of mode of conception and perinatal outcomes.
Main results and the role of chance: OD pregnant women had a higher probability of hypertensive disorders [aOR 2.84, 95% CI (1.04–7.81)], oligohydramnios [aOR 12.74, 95% CI (1.24–130.49)], postpartum hemorrhage [aOR 7.11, 95% CI (2.02–24.97)], retained placenta [aOR 6.71, 95% CI (1.58–28.40)], caesarean delivery [aOR 2.95, 95% CI (1.52–5.71)] and induction of labor [aOR 3.00, 95% CI (1.39–6.44)], when compared to women who conceived spontaneously. Similar trends, though not statistically significant, were noted among OD and non-donor IVF pregnant women. Higher intervention during delivery was observed in women with diminished ovarian reserve but the risk for hypertensive disorders did not differ after adjustment. Despite higher likelihood of prematurity, similar mean birth weight and length among term infants were noted and the presence of congenital malformations did not differ between groups.
Limitations, reason for caution: One of the limitations of our study is the lack of power. Furthermore we did not take into account parameters such as donor age, paternal age, ART method (conventional IVF or ICSI) as well as if the pregnancy resulted from a cryopreserved or fresh embryo.
Wider implications of the findings: The selection process of recipients for medically indicated oocyte donation treatment in Sweden seems to be effective in excluding women with severe comorbidities and beneficial regarding the health status of the infant. Oocyte recipients-despite being relatively young and of optimal health status-need careful counseling preconceptionally and closer monitoring prenatally for the development of hypertensive disorders. Nevertheless neonatal outcomes seem to be favorable.
Study funding/competing interest(s): Funding by national/international organization(s) – Family Planning Fond in Uppsala and Swedish Research Council for Health, Working Life and Welfare.
Trial registration number: NA.

P-428 Three-dimensional assemble of endometrial tissue *in vitro*

G. Kuramoto[1], S. Takagi[2], K. Ishitani[3], T. Shimizu[2], M. Yamato[2], T. Okano[2], H. Matsui[3]
[1]*Tokyo Women's Medical University, Department of Obstetrics and Gynecology/Institute of Advanced Biomedical Engineering and Science, Tokyo, Japan*
[2]*Tokyo Women's Medical University, Institute of Advanced Biomedical Engineering and Science, Tokyo, Japan*
[3]*Tokyo Women's Medical University, Department of Obstetrics and Gynecology, Tokyo, Japan*

Study question: Can regenerative-medicine technique with cell sheets become a new treatment method for endometrial disorder causing female infertility? And can 'functional three-dimensional (3-D) endometrium-like tissues' be produced *in vitro* using cell sheet engineering?
Summary answer: The functional 3-D endometrium-like tissues consisting of epithelium and stroma were assembled *in vitro*. In the future, the tissues might contribute to an endometrial regeneration for severe endometrial adhesions.
What is known already: Endometrial disorder such as endometrial adhesion, Asherman's syndrome, is one of the factors that causes infertility. Severe endometrial adhesions are caused by massive defects of the endometrium including stem cells. Therefore the general therapy such as surgical synechiotomy is not effective.

Recently, a new approach called "cell-sheet engineering", which can harvest confluent-culture-cells as a contiguous cell sheet having intact cell-cell junctions and extracellular matrix without enzymatic treatment, has been developed for tissue regeneration.
Study design, size, duration: Endometrial-epithelial-cell-sheets and endometrial-stromal-cell-sheets were prepared from rat endometrial tissues. The 3-D tissue was assembled using total three cell sheets, which consisted of a single epithelial-cell-sheet on the upper side and two stromal-cell-sheets underneath; they were then layered. After that, the layered-cell-sheets were re-cultured *in vitro*.
Participants/materials, setting, methods: Endometrial tissues resected from SD rats were treated with trypsin/EDTA. The two kinds of cell sheets (endometrial epithelial and stromal cell sheets) were produced from the isolated cells separated by preplate method and harvested from temperature-responsive cell culture dish by reducing the temperature. After re-culture, the layered cell sheets were evaluated histologically.
Main results and the role of chance: Histological examination of the specimens showed two types of cell sheets. By immunostaining, one type of the cell sheets showed a superficial CK18 positive layer, and CK18 negative and vimentin positive layer. Another type of cell sheet showed only vimentin positive layer. And the two types cell sheets could be layered and re-cultured. The 3-D structure assembled by re-cultured cell sheets was similar to normal endometrial tissue constituted of endometrial epithelial and stromal layer.
Limitations, reason for caution: The function of 3-D assembled endometrium-like tissue *in vivo* is still unclear, because the results of this study show only a partial function *in vitro*.
Wider implications of the findings: Transplantation of endometrial-cell-sheets have a high possibility not only to prevent intrauterine re-adhesion after synechiotomy, but also to regenerate endometrium. And the regenerated endometrial tissues might have a normal function such as menstruation and implantation of a fertilized egg.
Study funding/competing interest(s): Funding by national/international organization(s) – This work was partially supported by grant from Formation of Innovation Center for Fusion of Advanced Technologies in the Special Coordination Funds for Promoting Science and Technology "Cell Sheet Tissue Engineering Center (CSTEC)" from the Ministry of Education, Culture, Sports Science, and Technology (MEXST), Japan.
Trial registration number: NA.
Keywords: Asherman's syndrome, intrauterine adhesion, cell sheet, regenerative medicine, tissue engineering

P-429 Molecular biomarkers in cumulus and granulosa cells for oocyte quality estimation and pregnancy outcome prediction

M. Gori[1], A. Luddi[1], L. Crifasi[1], L. Gambera[1], L. Boschi[1], G. Morgante[1], P. Piomboni[1], V. De Leo[1]
[1]*University of Siena, Molecular Medicine and Development, Siena, Italy*

Study question: The aim of the present study is to monitor cumulus and granulosa cells gene expression profile focusing on genes selected as central hubs of networks generated by *in silico* proteomic analyses of follicular fluid.
Summary answer: The preliminary results obtained so far suggest a statistically significant correlation between ART outcome and selected gene expression levels.
What is known already: The granulosa and cumulus cells, contributing to follicular fluid formation, may affect follicle growth, oocyte maturation and competence acquiring. Nevertheless, follicular fluid protein composition remain to be clarified and no oocyte "quality" biomarkers have been still identified. Thus, up to now, oocyte and embryo quality estimation is unsatisfactorily limited to morphological parameters.
Study design, size, duration: In this study, 60 infertile women undergoing to IVF procedure were enrolled and granulosa and cumulus cells were carefully isolated in order to test gene expression level.
Participants/materials, setting, methods: DAVID for functional clusterization and Metacore for pathway analysis were applied to select follicular fluid proteins involved in key process in follicular milieu. In order to validate the specific role of these keys factors, we tested mRNA expression levels of selected genes both in granulosa and cumulus cells in a cohort of 60 women, in comparison with healthy subjects.
Main results and the role of chance: Networks generated by functional pathway analyses essentially converge on key central hubs such as: matrix metalloproteinases (MMPs), thrombin, vitamin D receptor and retinoid X receptor-alpha heterodimer (VDR/RXR-α), whose combined differential presence/functionality may be useful for oocyte quality estimation in IVF programs, in order to improve pregnancy and baby born rates.

Our preliminary results proved that the MMP2 expression in granulosa cells inversely correlates with reproductive outcome, since MMP2 mRNA levels significantly decrease in women with more than 4 oocytes retrieved at the pickup and in women whit ART positive outcome. Also VDR and RAR expression

levels significantly decreased in women with high oocytes retrieval at the pick-up day. These observations clearly highlight a significant impact of granulosa and cumulus gene expression on ART procedure outcome.
Limitations, reason for caution: A larger study needs to be carried out in order to validate these findings.
Wider implications of the findings: This combined *in-silico* approach and gene expression profile allowed us to depict a wide overview on the follicular dynamics and to identify some key factors whose expression levels could be related to positive ART outcome in different category of patients. Therefore our study, if replicated in a larger population, might contribute in improving oocyte selection and ART protocols in infertile women.
Study funding/competing interest(s): Funding by University(ies) – University of Siena.
Trial registration number: NA.

P-430 Lifestyle factors associated with irregular menstrual cycle in Korean women

A. Jung[1], J. Park[2], J. Kim[3], S. Kim[4], B. Jee[5], B. Cha[6], J. Sull[7], J. Jun[8]

[8]*Eulji University, Department of Biomedical Laboratory Science Dept. of Senior Healthcare BK21 Plus Program Graduated School Eulji Medi-Bio Research Institute EMBRI, Gyeonggi do, South Korea*

Study question: Which lifestyle factors are associated with irregular menstrual cycle in Korean women?
Summary answer: Among various lifestyle factors, body mass index (BMI) and smoking habit were significantly associated with irregular menstrual cycle in Korean non-diabetic women.
What is known already: Physiological regulation of menstruation cycle depends on spatiotemporal interactions of signaling between endogenous and ovarian hormones in the hypothalamic-pituitary-ovarian axis. Alteration of these orchestrated interactions by individual lifestyle and unfavorable habits may cause of irregular menstrual cycle.
Study design, size, duration: This cross-sectional study with retrospectively collected data including 3,799 non-diabetic Korean women with 19–49 years old in data from the Fifth Korea National Health and Nutrition Examination Survey (KNHANES) 2010–2012.
Participants/materials, setting, methods: The participants of non-diabetic women did not take any oral contraceptives and female hormones. We examined association of age, body mass index (BMI), drinking and smoking habits with irregular menstrual cycle. Statistical analyses were performed by contingency tables and logistic regression using SPSS program. Estimates are given as adjusted odds ratios with 95% confidence intervals.
Main results and the role of chance: Age, BMI, marriage status, menarche age and smoking habit were significantly associated with the irregular menstrual cycle, respectively ($P < 0.01$). The prevalence of irregular menstrual cycle was 16.9% of 19–29 years, 9.2% of 30–39 years and 9.6% of 40–49 years, respectively. BMIs of Asian obesity criteria were strongly associated with menstrual irregularity. Obese class I group with 25.0–29.9 of BMIs (odd ratio, 1.565; 95% Cl, 1.134–2.161; $P < 0.05$) and obese class II group with ≥30.0 of BMIs (odd ratio, 2.042; 95% Cl, 1.160-3.594; $P < 0.01$) presented significantly higher risk of irregular menstrual cycle compared with normal BMIs of 18.5-22.9. We found significant higher prevalence of irregular menstrual cycle in young women (19–29 years old) with obesity group I and II as 25.4% ($P < 0.001$) and middle-aged women (30–39 years old) with smoking habit group as 16.1% ($P < 0.005$).
Limitations, reason for caution: Possible limitation in our study is the use of retrospective questionnaire information on lifestyles and irregular menstrual cycle. The higher odds of irregular menstrual cycle in severely obese women may reflect other health problems in these women rather than the diabetes on the menstrual cycle.
Wider implications of the findings: This study demonstrates that risk of irregular menstrual cycle was closely associated with BMI and smoking habit in Korean non-diabetic women. Weight control and smoking cessation should be recommended for promotion of women's reproductive health.
Study funding/competing interest(s): Funding by national/international organization(s) – This work was supported by a grant of the Korea Healthcare Technology R&D Project, Ministry of Health and Welfare (A120043).
Trial registration number: (KNHANES) 2010–2012.

P-431 Influence of regional adiposity on assisted reproductive technologies outcome

F. Ferreira[1], M. Moura-Ramos[1], A. P. Sousa[1], T. Almeida-Santos[1]
[1]*Centro Hospitalar e Universitário de Coimbra, Reproductive Medicine Service, Coimbra, Portugal*

Study question: What is the influence of regional adiposity on assisted reproductive technologies (ART)?
Summary answer: Anthropometric measures associated with abdominal obesity were better predictors of ART outcomes than BMI (body mass index). However, neither of them was associated with lower pregnancy and live birth rates.
What is known already: Obesity has a negative effect on female reproductive function, including fertility and pregnancy. The influence on ART is controversial. Most studies have shown that BMI is directly associated with higher gonadotropin requirement, higher cancellation rates and lower number of retrieved oocytes (NRO). However, the effects of obesity on embryo quality, clinical pregnancy and live birth rates are not conclusive. These ART outcomes were based on female and/or male BMI and regional adiposity was not explored.
Study design, size, duration: Prospective cohort study. All the women ($n = 578$) selected in our institution for performing an assisted reproductive technique – *in vitro* fertilization (IVF) or intracytoplasmic sperm injection (ICSI) – were included in the study, which was conducted between October 2012 and August 2014.
Participants/materials, setting, methods: Women's BMI, waist circumference (WC) and waist-to-hip circumference were recorded at the beginning of the stimulated cycle. WC was measured by two different methods: midway between lowest rib and iliac crest (WC_1); just below the lowest rib (WC_2). Women underwent controlled ovarian hyperstimulation with long agonist or short antagonist/agonist protocols.
Main results and the role of chance: Mean BMI (23.9 ± 4.1), WC_1 (83.7 ± 10.8), WC_2 (79.4 ± 8.8) and waist-to-hip ratio (0.83 ± 0.08) were not associated with clinical pregnancy, live birth and cancellation rates. These variables were associated with lower levels of oestradiol at day 5 (E_2) and endometrial thickness. A hierarchical regression examined the additional contribution of regional adiposity. BMI didn´t predict total gonadotropin dose, number of follicles, NRO, number of mature oocytes, fertilization and implantation rates but predicted E_2 ($r = -0.118$, $p = 0.005$) and endometrial thickness ($r = 0.151$, $p < 0.001$). WC_2 increased the explained variance, including E_2 ($b = -0.188$, $p = 0.011$), number of follicles ($b = -0.163$, $p = 0.031$) and NRO ($b = -0.172$, $p = 0.023$). Final models explained <4% of the outcomes. Women with ovulatory dysfunction ($n = 62$) were analyzed separately and outcomes were similar between obese and non-obese. However, fertilization rate was lower in WC_2 >80 cm group when compared with WC_2 ≤80 cm (50.9 vs 71.6%, $p = 0.034$).
Limitations, reason for caution: Visceral adiposity was indirectly evaluated by anthropometric measures, although we measured waist circumference just below the lowest rib, which correlates better with visceral fat. This study has also potential confounding factors, such as woman's age, origin of infertility, duration of infertility, male BMI, smoking habit and number of IVF cycles.
Wider implications of the findings: This study added the importance of fat distribution, especially in women with ovulatory dysfunction, which could translate the clinical effect of oxidative stress on follicular fluid induced by

abdominal obesity, described by some authors. Despite these results, BMI was not a predictor of adverse ART outcomes and adiposity measures had a small relative contribution. Therefore, BMI should not be used to select women for ART treatment.

P-432 The effectiveness of hysteroscopy prior to IVF: a randomized controlled trial (inSIGHT study)

J. Smit[1], J. C. Kasius[1], M. J. C. Eijkemans[2], H. L. Torrance[3], B. W. Mol[4], F. J. M. Broekmans[3], SIGHT Study Group, X.[5]
[1]*University Medical Center Utrecht, Reproductive Medicine and Gynaecology, Utrecht, The Netherlands*
[2]*University Medical Center Utrecht, Julius Center for Health Sciences and Primary care, Utrecht, The Netherlands*
[3]*University Medical Center Utrecht, Reproductive Medicine and Gynaecology, Utrecht, The Netherlands*
[4]*The Robinson Institute, School of Paediatrics and Reproductive Health, Adelaide, Australia*
[5]*Dutch Consortium for Studies in Women's Health, Reproductive Medicine, Utrecht, The Netherlands*

Study question: Does routine hysteroscopy prior to the first IVF treatment cycle improve live birth rates?
Summary answer: Routine hysteroscopy prior to IVF does not increase ongoing pregnancy rates leading to live birth.
What is known already: Hysteroscopy is thought to improve ongoing pregnancy rates in subfertile women entering an IVF program. However, a recent randomized controlled trial did not show any beneficial effect from hysteroscopy performed in women with at least two failed IVF treatment cycles. The effectiveness of routine hysteroscopy prior to the first IVF cycle has never been assessed.
Study design, size, duration: The inSIGHT study was a multicenter, randomized controlled trial in 22 hospitals in the Netherlands, positioned in the Dutch consortium for studies in women's health. Subfertile women with a normal transvaginal ultrasound scheduled for a first IVF treatment were eligible. Women with recurrent miscarriage or intermenstrual blood loss were not included.
Participants/materials, setting, methods: Participants were randomly allocated to hysteroscopy with treatment of detected abnormalities before IVF (intervention group) versus no hysteroscopy before IVF (control group). The follow-up (FU) period was 18 months. Since completed live birth data are not available yet, we report in this abstract ongoing pregnancy rates. Analysis was by intention-to-treat.
Main results and the role of chance: Between 2011 and 2013, we randomized 750 women (intervention group: $N = 373$, control group: $N = 377$). Here, we report on 741 women (99%). Hysteroscopy revealed abnormalities in 17% of the women, which were all instantly treated. Cumulative ongoing pregnancy rates at 18 months of FU were 0.55 in both groups [risk difference (RD): 0.008 (95% CI -0.077, 0.093)]. Cumulative clinical pregnancy rates at 18 months of FU were 0.65 versus 0.62 [RD: 0.028 (95% CI: -0.054, 0.110)] for the intervention and control group, respectively. Miscarriage rates were 0.20 in the hysteroscopy group and 0.16 in the control group (RD: 0.04 [95% CI -0.40, 0.55)]. One complication was reported after the hysteroscopy procedure (endometritis).
Limitations, reason for caution: At the moment of writing the abstract, data on live birth have not been collected completely. Complete follow-up on live births will be available in June 2015.
Wider implications of the findings: In subfertile women with a normal transvaginal ultrasound scheduled for IVF, routine hysteroscopy does not improve outcome.
Study funding/competing interest(s): Funding by national/international organization(s) – ZonMW, the Dutch Organization for Health Research and Development.
Trial registration number: NCT01242852.

P-433 Immunologic and inflammatory markers in prediction models of clinical pregnancy and live birth in association with *in vitro* fertilization (IVF) in women receiving immune-suppressive therapy

M. Vega[1], D. H. Barad[2], K. Seier[2], Y. Yu[2], V. A. Kushnir[2], E. Lazzaroni-Tealdi[2], Y. G. Wu[2], Q. Wang[2], A. Weghofer[3], D. F. Albertini[2], N. Gleicher[2]
[1]*St. Lukes-Roosevelt, Obstetrics & Gynecology, New York City NY, U.S.A.*
[2]*Center for Human Reproduction, N/A, New York City NY, U.S.A.*
[3]*Medical University Vienna, Obstetrics and Gynecology, Vienna, Austria*

Study question: Are baseline titers of immune and/or inflammatory markers in infertile women, receiving immune-suppressive therapy during IVF cycles, predictive of clinical pregnancy and live birth?
Summary answer: Immune-suppressive therapy during IVF cycles appears to negate IVF outcome associations with immune but not with inflammatory markers.
What is known already: When maternal immune systems malfunction, as for example in association with maternal autoimmunity, female immune systems appear to lose the ability to be reprogramed from rejection to tolerance, mounting an allogeneic immune response against the implanting embryo. Such an allogeneic-immune response potentially negatively affects implantation, increases miscarriage risks in early pregnancy and disrupts the inflammatory tissue environment surrounding a normal implantation site.
Study design, size, duration: Immune and inflammatory markers were drawn at first office visits. An initial IVF cycle was completed weeks later at our academically affiliated infertility center, during which patients with positive immune and/or inflammatory markers were treated with immune suppressive treatments (prednisone and, on occasion also IV-Ig).
Participants/materials, setting, methods: We performed a retrospective evaluation of 184 patients undergoing fresh, non-donor IVF cycles between November 2012 and October 2013. All laboratory tests were performed by commercial laboratory assays. Logistic regression models, adjusted for age, were used to estimate the effect of these markers on pregnancy and live birth.
Main results and the role of chance: Testing panels included as inflammatory markers adiponectin, leptin, C-reactive protein (CRP) and interleukin 6 (IL-6). As markers of immune system activation we assessed a panel of thyroid autoantibodies [ant-thyroid peroxidase (TPO), anti-thyroglobulin, anti-thyrotropin receptor antibody], total immunoglobulins (IgA, IgE, IgG and IgM) and a panel of anti-phospholipid antibodies [anti-phosphatidylserine (anti-PS), anti-b2 glycoprotein and anti-cardiolipin (in IgA, IgG and IgM isotypes)]. Increasing CRP ($P = 0.02$) and IL-6 ($P = 0.034$) were associated with decreasing odds of live birth. Increasing total immunoglobulin IgG was associated with increasing chances of live birth ($P = 0.03$). Increasing IgG anti-PS was associated with decreasing ($P = 0.03$), while increasing IgM anti-PS was associated with increasing ($P = 0.04$) chances of pregnancy.
Limitations, reason for caution: Since patients with positive immune and/or inflammatory markers were actively immune-suppressed, here documented associations between primarily inflammatory markers and IVF outcomes apply only to so-treated patients. Untreated patients may demonstrate additional associations.
Wider implications of the findings: In women with activated immune systems, immune-suppression appears to eliminate potential effects of immune markers on IVF cycle outcomes but does not eliminate the effects of inflammatory markers, suggesting a need for better and more aggressive anti-inflammatory treatments in such patients.

P-434 Effect of follicular fluid from infertile women with endometriosis on oocyte maturation, meiotic spindle morphology and markers of DNA damage in mouse oocytes

M. Hamdan[1], S. Lane[2], K. Jones[2], Y. Cheong[1]
[1]*Complete Fertility Centre Princess Anne Hospital, Human Development and Health, Southampton, United Kingdom*
[2]*University of Southampton, Centre of Biological Sciences, Southampton, United Kingdom*

Study question: Does incubation with follicular fluid of women with endometriosis alter oocyte maturation, meiotic spindle morphology or cause DNA damage?
Summary answer: We find that incubation of mouse oocytes in follicular fluid from women with severe, but not mild or no endometriosis, reduced maturation

rates. However, this reduction in maturation is not attributed to defects in spindle morphology or increased DNA damage.
What is known already: Recent meta-analysis showed that women with endometriosis have a lower oocyte yield; it is not known if this is related to impaired oocyte quality attributed to the altered composition of follicular fluid in endometriosis. Quality of an oocyte is closely related to nuclear maturation and this depends on the presence of a normal cell spindle. To date, no study has examined the spindle morphology and level of DNA damage in human oocyte in those with endometriosis.
Study design, size, duration: Samples of follicular fluid were obtained from January 2014 to December 2014 from 20 infertile women during oocyte retrieval at their IVF/ICSI treatment. From August to December 2014 we performed IVM experiments using immature mouse oocytes as described below
Participants/materials, setting, methods: FF containing mature oocytes was obtained from 20 infertile women during oocyte retrieval procedure. Immature mouse oocytes were incubated in the absence of follicular fluid (No-FF) and in the presence of follicular fluid with control (CN-FF), mild (ME-FF) and severe (SE-FF) endometriosis. Five replicates experiments were performed each one using follicular fluid from a control patient and a patient with endometriosis. After 14–16 h of incubation, oocytes were washed, fixed and immunostained for visualization of chromosomes, DNA damage and polar body.
Main results and the role of chance: A total of 555 (SE-FF, n = 167; ME-FF, n = 97; CN-FF, n = 130; No-FF, n = 161) mouse GVs were collected. Following maturation, we found a trend in polar body extrusion percentage: No-FF, 70.8%; MF-FF, 67.7%; ME-FF, 66.0% and SE-FF, 55.1%. We found a statistically lower maturation rate in women with severe endometriosis when compared to either control or no follicular fluid groups ($P < 0.03$ and $P < 0.01$ respectively; CI 95%, Fisher's Exact Test). We found there is no difference in progression from GV to MI stage and there is no difference in MII spindle morphology between all groups. Following image analysis (SE-FF, n = 21; ME-FF, n = 28; CN-FF, n = 36 and No-FF, n = 44) we found no difference in nuclear gH2AX fluorescence between all groups ($P > 0.05$).
Limitations, reason for caution: This study is limited due to its small sample size, and investigations using large cohort of patients is required to verify these results. This study was using animal models and may not necessarily be extrapolated to humans.
Wider implications of the findings: Our result showed that follicular fluid of women with severe endometriosis has detrimental effect on oocyte progression to metaphase II but not from GV to MI stage and may contribute to the pathophysiology of infertility in women with endometriosis.

P-435 Dual trigger of oocyte maturation with gonadotropin-releasing hormone agonist (GnRHa) and human chorionic gonadotropin (hCG) in normal responder patients undergoing IVF/ICSI cycles: a retrospective analysis

L. Luque[1], J. C. Castillo[2], J. Guerrero[2], J. Gomez-Santana[2], J. Llácer[2], R. Bernabeu[2]
[1]*Instituto Bernabeu, Reproductive Medicine, Albacete, Spain*
[2]*Instituto Bernabeu, Reproductive Medicine, Alicante, Spain*

Study question: Does dual trigger significantly improves the laboratory and clinical outcome for normal responders in GnRH-antagonist cycles?
Summary answer: Similar clinical pregnancy rate is achieved when compared dual trigger for oocyte maturation to standard (hCGr) triggering. The number COCs and metaphase II retrieved were reduced with this approach of triggering.
What is known already: Recent data from retrospective studies suggest that the use of gonadotropin-releasing hormone agonist (GnRHa) and human chorionic gonadotropin (hCG) for oocyte maturation is promising and significantly improves the clinical outcome for normal responders in GnRH-antagonist cycles
Study design, size, duration: This single center retrospective case study, including 220 normal responder patients undergoing IVF/ICSI in antagonist cycles, was undertaken during the period January 2013–December 2014.
Participants/materials, setting, methods: Exclusion criteria were: Poor (<4 COCs) or high (>20 COCs) response to ovarian stimulation; >39 years; AMH <1.1 ng/ml; BMI >30 kg/m^2. Dual trigger (6500 IU hCGr + triptorelin 0.2 mg) was employed in 103 patients (January 2014–December 2014) and the results compared to 113 control patients using 6500 IU hCGr-only for triggering (January 2013–December 2013).
Main results and the role of chance: When compared dual trigger vs hCG; the number of COCs retrieved (8.83 ± 4.74 vs 10.39 ± 5.06 $p = 0.019$) and number of metaphase II (ICSI cycles) (6.68 ± 3.23 vs 8.56 ± 4.35 $p = 0.002$) was statistically different. The clinical pregnancy rate per transfer was similar between both groups 29.3% (dual trigger) vs 42% (hCG) $p = 0.07$.
Limitations, reason for caution: This is a retrospective study, moreover case and control cycles were performed in consecutive but different years. Future prospective randomized controlled trials are needed to clarify whether the addition of GnRH agonist to standard hCG is effective in improving the outcomes for normal responders in GnRH antagonists cycles
Wider implications of the findings: Dual trigger for final oocyte maturation in normal responders doesn't appear to improve outcomes. This approach should be validated in properly designed RCT before its application in clinical practice in order to avoid unnecessary extra medication in this population.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Instituto Bernabeu.
Trial registration number: NA.

P-436 Low and high relative number of top quality embryos is associated with decreased cumulative live birth rate – a cohort study of over 20 000 cycles

H. Oksanen[1], S. Mäkinen[2], C. Hydén-Granskog[1], N. Simberg[1], A. M. Suikkari[2], A. Tiitinen[1], H. Martikainen[3], J. S. Tapanainen[1], Z. Veleva[1]
[1]*University of Helsinki and Helsinki University Hospital, Obstetrics and Gynecology, Helsinki, Finland*
[2]*Family Federation of Finland, Helsinki and Oulu Infertility Clinics, Helsinki, Finland*
[3]*University of Oulu and Oulu University Hospital, Obstetrics and Gynecology, Oulu, Finland*

Study question: How does the proportion of top quality embryos (TOPs) affect cumulative live birth rate (cLBR) after IVF/ICSI with frozen-thawed embryo transfer (FET)?
Summary answer: The proportion of TOPs does not change in subsequent stimulations, and low (<25%) but also high (>85%) percentage of TOPs is associated with lower cLBR.
What is known already: The transfer of TOPs is associated with higher chance of live birth after IVF/ICSI and most studies have compared outcomes of different numbers of TOP or TOP vs. non-TOP transfers. However, the impact of the quality of the entire embryo cohort on cLBR has not been studied.
Study design, size, duration: This cohort study analysed data from four infertility clinics. IVF/ICSI cycles with one TOP (n = 6177) or 1–2 non-TOP embryos (n = 5935) transferred on day 2 or 3 were performed during January 2000 – June 2011 (n = 12112). These were followed by 10188 FET cycles during January 2000 – June 2013.
Participants/materials, setting, methods: Regression models for the proportion of TOPs of all cleaved embryos were performed, followed by logistic regression for cLBR/stimulation. Patient and stimulation characteristics and consecutive treatment cycles were used as independent factors. Modeled probabilities were used to determine cutoff points for the probability of cumulative live birth ≥40%.
Main results and the role of chance: The percentage of TOP/all cleaved embryos was 21.1 ± 25.1 % (1.41 ± 1.88 TOP/stimulation). It remained stable with consecutive stimulations of the same patient (ANOVA, $P = 0.7$). Logistic regression showed that the percentage of TOP had a reverse-U-shaped (quadratic) effect on cLBR meaning that chances for live birth were lower with both low and high proportions of TOPs ($P < 0.0001$). The regression model included the number of collected oocytes, which had independent effect ($P < 0.0001$ for all oocyte groups). Modeled cLBR was 25.4% in cases with no TOPs, increased to 40% (at 25% TOPs) and to 46% (55% TOPs), but thereafter a decreasing trend was observed. The probability of live birth at the end of treatment was ≥ 40% if the proportion of TOP was between 25 and 85%.
Limitations, reason for caution: About 8% of women would have needed more time to complete all possible FET cycles. The total duration of the study

was long, but there was no trend in yearly fluctuations of cLBR/stimulation during the study period.
Wider implications of the findings: Present results suggest that a low number of TOPs in the first fresh cycle is associated with low relative number of TOPs in subsequent stimulations regardless of increased gonadotropin dose. cLBR is best at 55% TOPs and good (≥40%) at 25–85% TOPs. The decreasing trend observed thereafter may reflect suboptimal endometrial receptivity. This may be one explanation why some women with high numbers of TOPs do not become pregnant.
Study funding/competing interest(s): Funding by University(ies) – Funding by hospital/clinic(s). Funding by national/international organization(s). University of Helsinki, Helsinki University Hospital, the Sigrid Juselius Foundation, Academy of Finland, University of Oulu, Oulu University Hospital.

[2]*Celmatix Inc., Research & Development, New York, NY, U.S.A.*
[3]*Reproductive Medicine Associates of Texas, Reproductive Endocrinology, San Antonio, TX, U.S.A.*
[4]*Reproductive Medicine Associates of Philadelphia, Reproductive Endocrinology, Philadelphia, PA, U.S.A.*
[5]*Reproductive Medicine Associates of New York, Reproductive Endocrinology, New York, NY, U.S.A.*

Study question: The likelihood of achieving live birth after IVF treatment is often reported on a per-cycle basis using age-based national averages. Our study aimed to assess whether couples' personalized, cumulative likelihoods of success accurately reflect observed events, and could therefore be used to report more precise, journey-wide outlooks.
Summary answer: Provided they did not discontinue treatment, 98.4% of patients predicted to respond well to IVF treatment achieved live birth by the time their cumulative chances of success plateaued. Moreover, on average these patients achieved live birth more than 2 cycles earlier than this plateau point.
What is known already: Estimated success rates for couples beginning IVF treatment are based on average success rates per treatment cycle adjusting for maternal age. Such estimates do not reflect couple-specific chances of having a baby over an entire treatment journey, and do not account for possibilities of treatment discontinuation or the multiple rounds of treatment often required. They could therefore discourage many patients from continuing or even starting treatment altogether.
Study design, size, duration: We performed a retrospective cohort study on 9,750 patients undergoing infertility treatment at three clinics between April 2002 and June 2014. We excluded patients with natural parity ≥1, age ≥45, as well as donor-IVF and RE cycles.
Participants/materials, setting, methods: Diagnostic data of each couple, taken before treatment, was used to calculate cumulative likelihoods of live birth after IVF using a Cox proportional hazards model constructed using retrospective data from more than 14,000 IVF treatment cycles. We compared these likelihoods to observed rates of live birth and patient dropout.
Main results and the role of chance: We ranked patients according to their calculated probabilities of live birth after one IVF cycle. For the 1,950 patients in the top 20% of this ranking, the average probability of success was 53.8% (±3.2). We calculated that, for these patients, cumulative likelihoods for live birth did not increase by more than 5% beyond cycle 4, representing a plateau point of cumulative probabilities of success. In keeping with this, of the 1444 patients (74%) achieving live birth, 98.4% did so by cycle 4. However, the average number of cycles to achieve live birth was 1.37 (±0.75), much earlier than the plateau point. The 506 (26%) of patients discontinuing treatment did so after an average of 1.91 (±1.02) cycles, also preceding their expected plateau point of cumulative probabilities of success.
Limitations, reason for caution: One component of our data model, diagnosis, is subjective across the clinics from which patients were recruited. Out-of-pocket expenses, not biological factors, largely explain dropouts in our IVF cohort.
Wider implications of the findings: Our data suggest that almost all patients achieving success while undergoing IVF treatment do so by the time they reach the point where their predicted cumulative chances of success are at their maximum. Patients who are considering discontinuation of treatment may be encouraged to continue if presented with this information, at least until they reach their own point of maximum cumulative likelihood of success.

P-438 The therapeutic effect of hysterosalpingography (HSG) as a tubal patency test: a multi centre cohort study

P. G. A. Hompes[1], K. Dreyer[1], R. I. Tjon-Kon-Fat[2], J. W. Van der Steeg[3], P. N. Steures[2], F. Van der Veen [2], B. W. J. Mol[4], N. Van Geloven[5]
[1]*VU University Medical Center, Department of Reproductive Medicine, Amsterdam, The Netherlands*
[2]*Academic Medical Center, Department of Reproductive Medicine, Amsterdam, The Netherlands*
[3]*Jeroen Bosch Hospital, Department of Gynaecology and Obstetrics, 's-Hertogenbosch, The Netherlands*
[4]*The Robinson Research Institute, School of Paediatrics and Reproductive Health, Adelaide, Australia*
[5]*Academic Medical Center, Clinical Research Unit, Amsterdam, The Netherlands*

Study question: Does, in women with unexplained subfertility, tubal patency testing with HSG during a basic fertility work-up increase ongoing pregnancy rates compared to no tubal patency testing?
Summary answer: Tubal patency testing with HSG as part of a basic fertility work-up leads to higher ongoing pregnancy rates, compared to no tubal patency testing during the basic fertility work-up.
What is known already: A possible therapeutic effect of diagnostic tubal patency testing has been debated in literature for more than 50 years. Results from both randomized and non-randomized studies are conflicting.
Study design, size, duration: We performed a secondary analysis of a prospective cohort study among 7,860 couples with subfertility. Couples were included in the cohort after the basic fertility work-up had been completed. Couples with ovulation disorders, previous tubal surgery or severe male factor (TMC $<1 \times 10^6$) were not included in our study.
Participants/materials, setting, methods: Couples had been recruited in 38 Dutch clinics between January 2002 and December 2004. Depending on local protocols and patient preferences, some women underwent an HSG, while others did not. Couples were followed until conception, or until start of treatment. We analysed whether HSG had impact on ongoing pregnancy rates.
Main results and the role of chance: From the 7,860 couples included in the cohort we analysed data of 3,164 couples. Mean age of the women was 32 years. Mean duration of subfertility was 22 months. A total of 1,706 women underwent tubal patency testing by HSG during the basic fertility work-up and 1,458 women had no tubal patency test at all. The probability of natural conception after HSG was increased as compared to no tubal patency testing (adjusted Hazard Ratio 1.68, 95% CI 1.38–2.04)
Limitations, reason for caution: This was an observational cohort study in which women had not been randomized, thus bearing the risk of selection bias. We tried to reduce this bias by performing an inverse probability weighting (IPW) analysis.
Wider implications of the findings: Flushing of the tubes during patency testing is likely to have a therapeutic effect in subfertile women.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Not applicable.
Trial registration number: NA.

P-439 A granulosa cell line that acquires cumulus oophorus properties – Early characterization

S. A. Reis[1], A. Ribeiro[2], L. Matos[1], J. L. Silva-Carvalho[3], A. M. Gouveia[1], H. Almeida[1]
[1]*University of Porto Faculty of Medicine, Experimental Biology, Porto, Portugal*
[2]*CETI – Centro de Estudo e Tratamento da Infertilidade and University of Porto Faculty of Medicine, Experimental Biology, Porto, Portugal*
[3]*University of Porto Faculty of Medicine, Obstetrics and Gynecology and CETI, Porto, Portugal*

Study question: Roles of granulosa cells (GCs) and *cumulus oophorus* cells (CCs) in the oogenesis process have been proposed but the underlying mechanisms require elucidation. As the number of primary cells is usually scarce, can a cell line as GC1a be used to enlighten CCs interactions with the oocyte?
Summary answer: Our findings suggest that GC1a cell line is a useful model for the study of follicular development. They show that GC1a cells differentiate in culture with features that mimic CCs, including OFS receptors expression and response to OSFs (oocyte secreted factors) and FSH (follicle stimulating hormone).
What is known already: Oocyte quality, achieved during the development of follicular microenvironment, is crucial for assisted reproductive technologies (ART) success. The microenvironment includes GCs that multiply along the cycle and differentiate into two structurally and functionally distinct types: mural GCs and oocyte surrounding CCs. The oocyte becomes regulator of itself by producing OSFs that modulate follicular cells function and survival that, in turn, modulate oocyte growth. However, the cellular details of such interchange are essentially unknown.
Study design, size, duration: To tackle the study question, granulosa derived GC1a cells were cultured in DMEM supplemented with FBS (fetal bovine serum). Early and late cell passage numbers were elected for experiments performed by adding GDF9 (50 ng/ml), BMP15 (100 ng/ml) and FSH (200 ng/ml) to the culture media and comparing with the controls.
Participants/materials, setting, methods: The presence of OSF and their receptors was evidenced by q-PCR, and the ability of OSFs and FSH to affect proliferation and cell cycle was studied by sulforhodamine-B (SRB) assay and flow cytometry, respectively; their ability to promote the activation of ERK1/2 and SMAD2 signaling was assessed by Western blot.
Main results and the role of chance: We report, for the first time in this cell line, the transcript of the OSF, such as GDF9, and the expression of OSFs receptors, such as BMPRI, BMPRII and TGFbRI. We also demonstrate that OSFs and FSH do not affect GC1a cell proliferation and cell cycle progression, compared with controls. The data indicate that passage number results in cell morphological change and different modulation features. In fact, in early passages, FSH and GDF9 activate ERK1/2 signaling, whereas in late passages GDF9, but not FSH, activates SMAD2 cascade.
Limitations, reason for caution: Despite the relevance to dissect the transduction pathway and the structural features, secretion products assessment is required, at early and late passages, to better support the model.
Wider implications of the findings: The data suggest that in this GC1a model, GCs can differentiated in CCs, which will allow further studies in a reproducible manner. Unveiling details of signaling pathways of oogenesis will evidence specific regulatory points. These are likely to be amenable to useful modulation, aiming at fostering successful oocyte development or, eventually, blocking its progression.
Study funding/competing interest(s): Funding by University(ies) – Funding by commercial/corporate company(ies). Universidade do Porto. GFI – Merck Serono Foundation.
Trial registration number: NA.

P-440 Human embryos from overweight or obese women develop slower from the time to compaction until the start of blastulation

M. Liyanage[1], M. Jansa Perez[1], D. Abdo[1], C. Dearing[2], S. Lavery[1], G. Trew[1]
[1]*IVF Hammersmith, IVF, London, United Kingdom*
[2]*Hammersmith Hospital, Andrology, London, United Kingdom*

Study question: Is there a difference in morphokinetics of embryos from overweight or obese women compared to those from women with a healthy body mass index (BMI)?
Summary answer: Embryos from overweight or obese women show a trend of developing at a faster rate until the 6-cell stage than those from women of a healthy BMI. From the time to compaction until the start of blastulation, embryos from overweight or obese women develop at a significantly slower rate.
What is known already: Women with a higher BMI have been associated with an increased prevalence of infertility, as well as reduced clinical pregnancy rates following assisted reproductive treatment. Female BMI has also been negatively associated with several aspects of fertility, such as ovarian stimulation, uterine receptivity and miscarriage rates. However, there is limited information regarding its effect on embryo morphokinetics. The purpose of this study was to identify possible correlations between female BMI and embryo development.
Study design, size, duration: We performed a retrospective study analysing the developmental timings of 371 embryos from 219 consecutive couples attending IVF Hammersmith for ICSI treatment between April 2012 and November 2014. The Embryoscope™ was used to measure developmental kinetics. The timings to each developmental stage were related to female BMI.
Participants/materials, setting, methods: Women who underwent ICSI treatment between April 2012 and November 2014 whose embryos were cultured in the Embryoscope™ were included. We compared morphokinetics of transferred embryos between healthy (BMI = 19–25, $n = 242$, average age = 36.0), overweight (BMI = 26–29, $n = 76$, average age = 35.2) and obese (BMI ≥ 30, $n = 53$, average age = 34.9) groups, established according to NHS guidelines.
Main results and the role of chance: A trend of faster embryo development was observed in embryos from obese women compared to healthy women in the early stages of development, with a significant difference identified in the time to second polar body extrusion ($P < 0.05$) and to 2-cells ($P < 0.05$). However, embryos from obese women were slower to compact compared to healthy and overweight women ($P < 0.005$ and $P < 0.01$, respectively). Embryo development to the morula stage was also slower in overweight compared to healthy women ($P < 0.05$), and slower in obese compared to overweight women ($P < 0.005$). There was no significant difference in clinical pregnancy rate between the three groups, however a significantly higher implantation rate (47.1 vs 26.9%, $P < 0.01$) was observed in obese women compared to healthy women.
Limitations, reason for caution: This was a retrospective analysis of transferred embryos with different sample sizes between the groups. In order to ascertain the effect of maternal BMI on developmental timings, a prospective cohort study with an evenly distributed population is needed, analysing all embryos created.
Wider implications of the findings: We propose that increased metabolic activity in the embryos could explain the faster early development observed in the obese group, however later epigenetic events which coincide with blastocyst formation may be compromised causing slower development. In spite of slower embryo development in the obese group, the higher implantation rate observed may be explained by the lower average age in this group.
Study funding/competing interest(s): Funding by hospital/clinic(s) – IVF Hammersmith.
Trial registration number: NA.

P-441 Thyroid-stimulating hormone is increased in infertile women with low anti-Müllerian hormone

A. Loft[1], H. W. Hvidman[1], M. van der Klein[2], A. Nyboe Andersen[1], A. K. Rasmussen[2]
[1]*Copenhagen University Hospital Rigshospitalet, The Fertility Clinic, Copenhagen, Denmark*
[2]*Copenhagen University Hospital Rigshospitalet, The Department of Endocrinology, Copenhagen, Denmark*

Study question: What is the prevalence of (i) hypothyroidism assessed by plasma thyroid stimulating hormone (TSH) and (ii) autoimmune thyroid disease assessed by the presence of thyroid peroxidise antibodies (TPOAb); and are these conditions associated with the ovarian reserve estimated by anti-Müllerian hormone (AMH) in infertile women of reproductive age?

Summary answer: In a cohort of 543 infertile women aged 20–40, 10% had autoimmune thyroid disease (with or without hypothyroidism), and another 5% had hypothyroidism without TPOAb. Three-quarters were diagnosed as a result of our screening prior to fertility treatment. TSH was significantly higher in women with an AMH below 5 pmol/l.

What is known already: Female infertility is associated with hypothyroidism and the presence of TPOAb, but the pathophysiology remains uncertain. Whether infertility is caused by a disturbance in the endocrine- and/or the immune system has yet to be established. Infertile women have been shown to have higher levels of TPOAb and TSH compared to fertile women. Studies investigating the correlation between AMH and thyroid function in infertile women are few and have limited sample size.

Study design, size, duration: Baseline data in a prospective cohort study of 543 infertile women. The women were newly referred to fertility treatment with their male partner. All women were aged 20–40 years and recruited between September 2011 and October 2013.

Participants/materials, setting, methods: On Cycle Days (CD) 2–5, prior to start of stimulation, women were examined by transvaginal ultrasonography (antral follicle count (AFC), ovarian volume, pathology) and blood sampling to assess serum-AMH, FSH, LH, TSH, thyroxine (T4), free-T4 and TPOAb. Medical and reproductive history, and lifestyle factors were recorded.

Main results and the role of chance: The mean (SD) age was 32.7 (4.0) years. TPOAb was observed in 56 (10%) women. Another 26 (5%) TPOAb-negative women had a serum-TSH above normal (>4.0×10^{-3} IU/l). Of these 82 women, 19 (23%) had previously been diagnosed with thyroid disease. Twenty-nine (5%) women had a very low AMH-level (<5 pmol/l). TSH was significantly higher in women with an AMH <5 pmol/l ($p = 0.01$), which was also associated with increased levels of FSH ($p < 0.001$), but not associated with LH, T4, free-T4 or TPOAb. Women with an AMH <5 pmol/l were older ($p < 0.001$), had a lower AFC ($p < 0.001$) and a shorter menstrual cycle ($p < 0.001$). In a multiple logistic regression analysis, the following covariates remained significantly associated with very low AMH-levels: TSH (OR: 2.31, 95% CI: 1.17; 4.56), FSH (OR: 1.3, 95% CI: 1.04; 1.49), and AFC (OR: 0.55, 95% CI: 0.44; 0.69).

Limitations, reason for caution: Since the number of TPOAb-positive women with a very low AMH was limited, we could not investigate the correlation between impaired ovarian reserve and autoimmune thyroid disease. Women already diagnosed with thyroid disease may have declined the offer of screening and the prevalence would, thus, be underestimated.

Wider implications of the findings: The prevalence of autoimmune thyroid disease in our cohort is similar to previous findings. A recent study found AMH to be inversely correlated to TSH in infertile women, which corresponds to our results. Untreated hypothyroidism is associated with a decreased fertility and an increased risk of early pregnancy loss. Our results emphasize the importance of screening infertile women prior to fertility treatment, as undiagnosed hypothyroidism and autoimmune thyroid disease may impair their success rate.

Study funding/competing interest(s): Funding by national/international organization(s) – Funding by commercial/corporate company(ies). The study received funding from MSD and through the European Union (EU) Interregional projects "ReproSund" and "ReproHigh". The authors have no conflict of interest.

P-442 Inhibition of sirtuin activity and impaired synthesis of the sirtuin NAD + co-factor disrupts oocyte meiotic maturation

A. Riepsamen[1], D. Listijono[1], W. Ledger[1], L. Wu[2], D. Sinclair[3], H. Homer[1]
[1]*University of New South Wales, School of Women's and Children's Health, Sydney, Australia*
[2]*University of New South Wales, School of Medical Sciences, Sydney, Australia*
[3]*Harvard Medical School, Genetics Department, Boston, U.S.A.*

Study question: Does sirtuin de-regulation brought about by either the sirtuin inhibitor, nicotinamide (NAM), or reduced NAD^+ production induced by inhibiting NAM phosho-ribosyltransferase (NAMPT) in the NAD^+ synthesis pathway impair oocyte maturation?

Summary answer: Sirtuin inhibition severely impaired two key developmental phases during oocyte maturation, entry into meiosis I and establishment of a proper meiosis II-arrested state conducive to fertilisation. Remarkably, the interval between these two extremes of maturation was completely unperturbed pointing to requirements for sirtuins at defined stages of oocyte development.

What is known already: Sirtuins are NAD^+-dependent deacetylases crucial for multiple functions that collectively combat aging in somatic cells. Surprisingly little is known about sirtuins in mammalian oocytes. Highly significantly, the effects of neither NAM nor NAMPT-inhibition have previously been studied during oocyte maturation. Formation of a fertilisable egg requires entry into and progression through meiosis I, transition from meiosis I-to-meiosis II and finally, establishment of a meiosis II-arrest-state characterised by a properly assembled spindle with aligned chromosomes.

Study design, size, duration: Fully-grown germinal vesicle (GV)-stage mouse oocytes ($n > 30$ per group in triplicate) were cultured in media treated with the sirtuin inhibitor, NAM. As an alternative for impairing sirtuin activity we inhibited production of the sirtuin co-factor, NAD^+, using FK866 to specifically inhibit NAMPT, an enzyme required for NAD^+ synthesis.

Participants/materials, setting, methods: Oocytes from hormonally-primed 7- to 9-week-old Swiss mice were cultured in media treated with NAM or FK866. Rates of GV breakdown (GVBD) following release from the GVBD inhibitor, 3-isobutyl-1-methylxanthine (IBMX), and first polar body extrusion (PBE) were assessed. Spindles and chromosomes were analysed using four-colour, high-resolution confocal imaging.

Main results and the role of chance: NAM-treatment significantly reduced GVBD, from 55 to <10% at 1 h ($P < 0.0001$) and from ~80 to 67% at 2 h ($P = 0.0011$) following release from IBMX. In contrast, PBE rates were indistinguishable between treated and untreated groups ($P = 0.22$) at 14 h post-GVBD. Strikingly, although polar bodies appeared morphologically normal, confocal analyses revealed complete failure of spindle assembly in ~35% of NAM-treated oocytes, a defect never observed in untreated controls. Furthermore, chromosomes decondensed and a nucleus formed. Although NAM induced defects at extremes of maturation, there were no defects in spindle assembly and chromosome alignment during the intervening period. Entirely consistent with NAM-induced defects, FK866 treatment markedly reduced GVBD at 1 h ($P < 0.0001$) and 2 h ($P = 0.0002$), providing independent support for the importance of sirtuins during GVBD.

Limitations, reason for caution: Although we corroborated our findings using two independent approaches for disrupting sirtuin function, it is possible that NAM or FK866 could lead to effects on targets other than sirtuins in oocytes.

Wider implications of the findings: This is the first evidence that sirtuins regulate GVBD and the establishment of the meiosis II-arrest state required for fertilisation. Our data are consistent with recent evidence that depletion of Sirtuin-2 induces spindle defects at meiosis II, raising the possibility that at least some NAM-induced defects reflect Sirtuin-2 deregulation. Sirtuin deregulation could underpin cases in which normal-appearing eggs fail to fertilise. Importantly, these data suggest that sirtuin-modulators may constitute novel adjuvants for improving oocyte quality.

P-443 Impact of uterus contraction frequency and elastography assessment on pregnancy rate after intrauterine insemination

N. Swierkowski Blanchard[1], F. Boitrelle[1], T. Quibel[1], J. Selva[1], H. Gronier[1], L. Alter[1], R. Wainer[1], A. Torre[1]
[1]*CHI Poissy-St-Germain-en-Laye, ART Center, Poissy, France*

Study question: Do uterine contraction (UC) frequency and intensity at the time of intrauterine insemination (IUI) modify the fertility outcome of this technique?

Summary answer: Lower frequency and higher intensity of uterine contractions at the day of IUI were associated with a higher pregnancy rate. These two factors, with woman's younger age, thickness and ultrasound aspect of the endometrium were independently predictive of pregnancy rate arisen after IUI.

What is known already: Even without pregnancy, the uterus contracts in a cyclic and painless way. In spontaneous cycle, uterine contractions are common during periovulatory period and rare through the implantation window. In IVF, high contractility at embryo transfer reduces pregnancy rate. However, the impact of uterus contractility in IUI outcomes has never been directly studied. We aimed to assess the impact of uterine contractility, in frequency (contraction count) and intensity (elastography measurement) on the success rate after IUI.
Study design, size, duration: During a 2 years period, we conducted a pilot prospective cohort study including 100 infertile women eligible for IUI. At the time of IUI, we prospectively measured the frequency of UC, and assessed their intensity by elastography. These factors with other parameters entered a predictive model for pregnancy after IUI.
Participants/materials, setting, methods: Patients underwent transvaginal sonography with 5 min sagittal uterus recording, elastography, and 3D endometrial reconstruction, 1 h before IUI. Advanced ultrasound parameters were measured: UC frequency, sub-endometrial elastography, endometrial thickness, volume and aspect. Classical IUI parameters were recorded. With logistic regression stepwise down, we developed a predictive model for pregnancy.
Main results and the role of chance: The median frequency of UC was 2.8/min. Quantitative elastography estimates of sub endometrial area (area of interest) and endometrial area (control) were performed. The ratio of these two respective values was significantly higher (i.e., with a uterine contraction of higher intensity) in women with subsequent pregnancy after IUI. In multivariate analysis, UC number (OR = 0.039; $p = 0.021$; 95% CI 0.002–0.6), patient age (OR = 0.001; $p = 0.004$; 95% CI $1.48.10^{-5}$–0.12), the elastography ratio (OR = 63.26; $p = 0.01$; 95% CI 2.6–1532.0), endometrial thickness on the ovulation triggering day (OR = 28.21; $p = 0.03$; 95% CI 1.3–590.6) were predictive of pregnancy after IUI.
Limitations, reason for caution: The reproducibility of UC profile between several cycles of IUI is uncertain. To draw any conclusion using our predictive model of success after IUI, it should be validated in a new population.
Wider implications of the findings: In women with high uterine contractility and no pregnancy in IUI, fertility outcome after IVF should also be studied in order to state if a quicker appeal to IVF is indicated in this case. There is no consensus to date for the use of utero relaxation treatment during IUI. A randomized study should assess the benefit of this treatment by reducing UC frequency and improving success rates in IUI.

MALE AND FEMALE CONTRACEPTION

P-444 Nano-puerarin: a prospective candidate for emergency contraceptive formulation

G. Saraswat[1], R. Guha[2], A. Konar[2], P. Saha[1], S. N. Kabir[1]
[1]*CSIR-Indian Institute of Chemical Biology, Cell Biology and Physiology, Kolkata, India*
[2]*CSIR-Indian Institute of Chemical Biology, Laboratory Animal Science, Kolkata, India*

Study question: What is the mechanism underlying the post-coital contragestative potential of poly lactic-co-glycolic acid-puerarin nanoparticles (PNP)?
Summary answer: PNP disrupts endometrial receptivity and render it hostile to embryo implantation. Central to this array of events is the attenuated Indian hedgehog (Ihh)–chicken ovalbumin upstream promoter transcription factor (COUP-TFII)–bone morphogenetic protein (BMP2) signaling axis that adversely impacts endometrial expression of estrogen receptor subtypes with consequent repression of progesterone receptor.
What is known already: The currently available post-coital contraceptive formulations are mostly steroid-based. The untoward effects attributed to the proliferative actions of estrogenic component of the pill, or higher failure rate and menstrual abnormalities associated with progestogen-only pills demands the development of non-steroidal EC formulations. Puerarin, a selective estrogen receptor modulator, exerts anti-implantation effects in rats, albeit at unacceptably higher doses. Furthermore, PNP exerts post-coital contragestative effect in rats at 1/4th dose of puerarin.
Study design, size, duration: Pregnant rats were orally administered with PNP ($n = 5$) or void-polymer ($n = 5$) for day 1–2 (D_1–D_2). Human endometrial stromal cell lines (hESCs) was cultured initially for 24 h in presence or absence of PNP and then for a further period of 72 h in the presence of medroxyprogesteroneacetate and db-cAMP.
Participants/materials, setting, methods: The effect of PNP on endometrial receptivity and decidualization was studied in day 5 pregnant rat endometrium (75 mg/kg/day) or cultured ESCs (10–50 nM) by *immunofluorescence*, RT-PCR/western blot analysis, gelatin zymography, and ESC migration assay.
Main results and the role of chance: Oral administration of PNP for day 1–2 of pregnancy led to total failure of implantation ($p < 0.05$). Disruption of endometrial receptivity was evidenced by attenuated endometrial expression of desmin, decidual prolactin, and insulin-like growth factor binding protein-1 ($p < 0.05$). There was down-regulated ($p < 0.05$) uterine expression of Ihh, BMP2, and COUP-TFII, and adversely altered expression of estrogen receptors (ERα, ERβ) and progesterone receptor AB ($p < 0.05$). PNP significantly suppressed the directed migration of hESCs by attenuating ($p < 0.05$) the expression of extracellular signal regulated kinases (ERKs), pERK, and myosin light chain, while the expression of Ras homolog gene family, member A (RhoA), and Rho-associated protein kinase was up-regulated ($p < 0.05$). Gelatin zymography analysis demonstrated attenuated endometrial expression of proMMP-9 ($p < 0.05$).
Limitations, reason for caution: The effective dose of PNP seems considerably high. Also, the *in vivo* effects are based on a rat model.
Wider implications of the findings: PNP exerts its anti-implantation activity by way of prohibitory effect on endometrial bed preparation and decidualization process. PNP is perhaps a prospective candidate molecule that may be further explored for future development of non-steroidal emergency or post-coital contraceptive formulation.
Study funding/competing interest(s): Funding by national/international organization(s) – This study was supported by the Council of Scientific and Industrial research–University Grants Commission, New Delhi, India.

P-445 The effect of hormonal contraceptives and bleeding pattern on migraine headache

M. Vanya[1], I. Devosa[2], M. Szucs[1], F. Bokros[3], D. Szok[3], G. Y. Bartfai[1]
[1]*University of Szeged, Department of Obstetrics and Gynaecology, Szeged, Hungary*
[2]*University of Szeged, Institute of Behavioural Medicine, Szeged, Hungary*
[3]*University of Szeged, Department of Neurology, Szeged, Hungary*

Study question: Preliminary data on headache diaries in migraineurs suggest that the progestin-only pill has a positive effect on the course of both MA and M0, especially reducing the number of days with migraine, the number of analgesics and the intensity of migraine-associated symptoms (including nausea or vomiting).
Summary answer: The Pearson correlation test revealed a relationship between duration of menstrual cycle and the intensity of headache pain ($p = 0.012$). The duration of oral contraceptive use was correlated with the intensity and duration of headpain ($p = 0.001$ and $p = 0.021$).
What is known already: Preliminary data on headache diaries in migraineurs suggest that the progestin-only pill has a positive effect on the course of both MA and M0, especially reducing the number of days with migraine, the number of analgesics and the intensity of migraine-associated symptoms (including nausea or vomiting).
Study design, size, duration: The questionnaire based study have been performed in the Outpatient Unit of Department of Neurology. We invited all women with M0 and MA in the Outpatient Headache Unit of the Department of Neurology to participate in the questionnaire-based study. We collected a data in two time periods: between 2006–2009 and 2013–2014 and we received the answers via 3 ways: personal face-to-face interviews, online and postal way. All participants completed a questionnaire containing 25 items compiled by our research team based on our clinical practice and literature search. The questions referred to socio-demographic data, the menstruation cycle pattern (mean age

at the first menses, duration of menses, characteristic of menstrual cramps and bleeding, the contraception habits, use of reliable and less reliable contraceptive methods) and migraine characteristic (including number of headache days, intensity of headpain, use of acute and prophylactic anti-migraine drugs). The validity process of the questionnaire was performed and internal reliability was also calculated.

Participants/materials, setting, methods: Our study group consisted of 108 women with migraine without aura (58%) and 78 women with migraine with aura (42%).All participants completed a questionnaire containing 25 items compiled by our research team based on our clinical practice and literature search. The validity process of the questionnaire was performed and internal reliability was also calculated. The associations between oral-contraceptive use, bleeding patterns and clinical characteristics migraine were compared by the Pearson correlation tests.

Main results and the role of chance: The average age of the patients at the diagnosis of migraine was 18.79 ± 6.97 years. The mean age at menarche was 12.3 ± 2.1 years. The majority of patients (59.4 %) had regular menstrual cycle (mean duration of the cycle: 28 days, length of bleeding: 3–5 days. Only 27 patients (11.54%) had a large amount of bleeding, 39.31 % of women suffering from menstrual cramps and 44.45% of patients had changes in body mass index in the last year. Regarding the sexual activity, 155 women (83.3 %) had regular sexual life in our study population. Thirty-one women (16.7%) does not have sexual activity during the study period. Regarding contraceptive practice of the migraineurs 54.3% of women used COC, 13.4% of women reported that used levonorgestrel containing intrauterine system and 3 women (1.61%) used vaginal ring. 26.61% of the 186 women have been used not reliable contraceptive methods as condom (22%), withdrawal (2.15%), spermicides (0.53%) and calendar method (1.61%). 3.27 % of women not used any contraceptive methods during the study period. The Pearson correlation test revealed a relationship between duration of menstrual cycle and the intensity of headache pain ($p = 0.012$). The duration of oral contraceptive use was correlated with the intensity and duration of headpain ($p = 0.001$ and $p = 0.021$)

Limitations, reason for caution: Limitations of the present study was the retrospective sample collection. We are going to introduce the prospective follow-up trial to understand better the impact of different type of oral contraceptives and their impact on the headache course.

Wider implications of the findings: NA.

Study funding/competing interest(s): Funding by University(ies) – Albert Szent-Gyorgyi Clinical Centre, University of Szeged.

Trial registration number: NA.

MALE AND FEMALE FERTILITY PRESERVATION

P-446 Controlled ovarian hyperstimulation in cancer patients candidates for fertility preservation is not associated with changes in the Follicular Output RaTe (FORT)

S. Duros[1], C. Sonigo[1], I. Cedrin-Durnerin[1], J. N. Hugues [1], C. Sifer[2], M. Grynberg[1]

[1]*Hôpital Jean Verdier, Department of Reproductive Medicine, Bondy, France*
[2]*Hôpital Jean Verdier, Service d'Histologie-Embryologie-Cytogénétique-CECOS, Bondy, France*

Study question: What is the follicle responsiveness to exogenous FSH, assessed by the Follicular Output RaTe (FORT) in cancer patients, candidates for fertility preservation (FP) by oocyte vitrification following controlled ovarian hyperstimulation (COH)?

Summary answer: The present findings indicate that the follicle responsiveness to exogenous FSH, as far as it is measurable by FORT, is not modified by the cancer status, in young women seeking FP using COH.

What is known already: Oocyte and/or embryo cryopreservation after COH represents an established method of FP before cancer treatment. Whether these patients have a normal ovarian capacity to respond to exogenous FSH is controversial. It is conceivable that the oncologic status may, by itself, be associated with changes in antral follicle sensitivity to FSH. The FORT may be a remarkable tool to evaluate the follicle responsiveness to FSH, independently of the size of pretreatment cohort of small antral follicles.

Study design, size, duration: From July 2013 to December 2014, we prospectively studied 71 cancer patients, aged 20–40 years, candidates for oocyte vitrification following COH (FP group). Ovarian stimulation outcome was compared with that of 86 infertile women (Control group) matched for age, antral follicle count (AFC) at baseline and starting dose of FSH.

Participants/materials, setting, methods: All patients had 2 ovaries, no previous chemotherapy, no endometriosis and underwent COH using GnRH antagonists protocols. Antral follicles were counted before FSH administration and on the day of ovulation triggering (dOT). FORT was determined by the ratio pre-ovulatory follicle count (16–20 mm) on dOT × 100/AFC at baseline.

Main results and the role of chance: By design, mean age and FSH starting dose were similar in FP and Control groups (31.5 ± 0.6 vs. 32.3 ± 0.4 years; 269 ± 9.6 vs. 246 ± 6.0 IU, *NS*, respectively). Whereas antral follicle counts on baseline were comparable in both groups (17.4 ± 1.2 vs. 16.5 ± 0.9 follicles, *NS*, respectively), after a similar total amount of exogenous gonadotropins (2931 ± 141 vs. 2583 ± 120 IU, *NS*), FORT did not differ significantly in cancer patients when compared to controls (35.8 ± 2 vs. 36.9 ± 2%, *NS*). Finally, the total number of oocytes recovered (11.6 ± 1.1 vs. 10.7 ± 0.6 oocytes, *NS*, respectively) and vitrified (8.9 ± 0.8 vs. 8.1 ± 0.4 oocytes, *NS*, respectively) was comparable in FP and Control groups.

Limitations, reason for caution: FORT presents inherent limitations. Indeed, FORT calculation assumes that small antral follicles respond in a coordinated manner to FSH and that only follicles having reached diameters ranging between 16 and 20 mm on dOT effectively responded to FSH. In addition, the sample size may limit the generalization of these findings.

Wider implications of the findings: Further investigation is needed to assess the FORT according to the type of malignant diseases, and their impact on the general condition of patients.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Jean Verdier Hospital.

Trial registration number: NA.

P-447 Oocyte cryopreservation in consecutive Natural Cycles in older women increase their chances of achieving a pregnancy

C. Karamalegos[1], M. Argyrou[1], V. Sisi[1], K. Economou[1], T. Karagianni[1], C. Mentorou[1], S. Davies[1], M. Mastrominas[1]

[1]*c/o Embryogenesis, Ziridi Marousi/Assisted Conception Unit, Maroussi Athens, Greece*

Study question: Does collecting and cryopreserving oocytes with natural cycles (NC) and performing a subsequent thaw cycle help >38 years old women achieve a pregnancy.

Summary answer: Implantation and clinical pregnancy rates recorded in this study demonstrate that storing oocytes and performing a subsequent thaw cycle seems to be beneficial for this group of women.

What is known already: It is estimated that the NC costs 75–80% less than a stimulated cycle and can be safely used to collect and store oocytes for later use with IVF to prevent fertility decline due to age. Using vitrification as a cryopreservation procedure, oocytes can be stored and thawed with high survival rates and good pregnancy results.

Study design, size, duration: This is a retrospective study, from January 2011 until December 2014, including women performing NC and subsequent freezing oocytes, aged more or equal than 38 years old.

Participants/materials, setting, methods: All 174 women participated in this study performed NC and collected oocytes in order to freeze them and plan a subsequent thaw cycle. Vitrification was performed to store one oocyte in separate canes. When thawed, survived oocytes were fertilized using ICSI and embryo transfer (ET) was performed 3–5 days post thaw.

Main results and the role of chance: A total of 516 oocytes were frozen and stored for later use out of 174 patients using NC. Out of these, 34 women (mean age being 41.0) decided to perform an ET, using their vitrified

oocytes, 106 oocytes were thawed and 79 survived giving a survival rate of 74.5%. Following fertilization with ICSI, 69 oocytes were fertilized (87.3%) and 67 of them were transferred, with a mean number of embryos per ET equal to 1.97. Pregnancy was achieved in 11 of them (32.4%) with an implantation rate of 17.9%.

Limitations, reason for caution: Since there are a lot more cases of women with frozen oocytes performing thaw and embryo transfer in the following months, in our Unit, we intent to continue this study in order to increase the number of patients and compare survival rates and success rates to matched stimulated cycles.

Wider implications of the findings: NC can be a reasonable alternative. The benefits are, more friendly approach, significantly less cost, avoidance of anesthesia and oocyte freezing with NC can be suggested in older women with good success rates.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Embryogenesis IVF Unit, Greece.

Trial registration number: NA.

Keywords: natural cycle, oocyte cryopreservation

P-448 The Irinotecan metabolite SN38 is highly cytotoxic to germ cells in the mouse testis but has little ovotoxicity

N. Spears[1], F. Lopes[1], S. Nash[1], R. Smith[1], R. T. Mitchell[2]

[1]*University of Edinburgh, Centre for Integrative Physiology, Edinburgh, United Kingdom*

[2]*University of Edinburgh, Centre for Reproductive Health, Edinburgh, United Kingdom*

Study question: Does SN38, the most potent Irinotecan metabolite, affect germ cells in male and female mouse gonads when exposed to concentrations equivalent to patient plasma range?

Summary answer: Germ cells within the testis are much more sensitive to SN38 than those in the ovary. Male germ cells were present in significantly reduced numbers when exposed to concentrations equivalent to patient plasma range, whilst the ovary was largely unaffected even when exposed to much higher concentrations.

What is known already: Irinotecan is used therapeutically for several tumour types, including paediatric tumours. Irinotecan is metabolised into several compounds, of which 7-ethyl-10-hydroxycamptothecan (SN38) is the most important, displaying stronger cytotoxic action than Irinotecan itself. Plasma concentration of SN38 in patients ranges between 10 and 100 ng/ml within the first 10 h after administration. Long-term side effects on fertility of this drug are not well described.

Study design, size, duration: The study involved culture of neonatal ovarian or testicular tissue for four days, with tissue exposed to varying concentrations of SN38 on Day 2 of culture.

Participants/materials, setting, methods: Whole ovaries from pnd (postnatal day) 4 mice and fragments of testis from pnd 5 mice were placed in serum-free culture media. On Day 2, a range of concentrations of SN38 were added to the media for 24 h (0.002–1 μg ml^{-1} for testes and 0.1–5 μg ml^{-1} for ovaries), with subsequent culture in drug-free medium for a further 2 days. Male germ cells were identified by expression of MVH (mouse vasa homologue), whilst ovarian follicle counts were assessed histologically. SN38-exposed tissues were compared with vehicle- (DMSO-) exposed controls; results are shown as mean ± SEM.

Main results and the role of chance: The pre-spermatogonial population decreased dramatically in SN38-exposed testes, with significantly lower MVH-expression levels than controls. Compared to the control group ($n = 7$), MVH-expression was reduced to: 44 ± 10% of control levels in 0.002μg ml^{-1} ($n = 5$; $p < 0.01$), 25 ± 7% of control levels in 0.01 μg ml^{-1} ($n = 4$; $p < 0.005$), 19 ± 7% of control levels in 0.1 μg ml^{-1} ($n = 7$; $p < 0.001$), and 5 ± 1% of control levels in 1 μg ml^{-1} ($n = 3$; $p < 0.001$). In marked contrast, SN38 exposure did not significantly affect ovarian follicle numbers, even at high concentrations. Follicle numbers were: 1257 ± 215 in 100 ng ml^{-1} ($n = 10$), 627.4 ± 107 in 1 μg ml^{-1} ($n = 8$), 771.9 ± 76 in 2.5 μg ml^{-1} ($n = 12$) and 1051 ± 143 in 5 μg ml^{-1} ($n = 12$), with treated groups not significantly different to the 1134 ± 160 follicles in the control group ($n = 10$).

Limitations, reason for caution: As for any animal *in vitro* model, caution is necessary for extrapolation of the findings to humans.

Wider implications of the findings: Our data demonstrate that male germ cells are particularly sensitive to SN38, even at concentrations lower than those typically found in the plasma of treated patients. This is of particular concern for pre-pubertal male cancer patients, for whom there is currently no option to protect or restore fertility in the case of gonadal damage caused by cancer therapy.

Study funding/competing interest(s): Funding by national/international organization(s) – Medical Research Council UK grant G1002118.

P-449 What is the best protocol to cryopreserve testicular cell suspensions?

J. Onofre Meza[1], K. Faes[1], E. Goossens[1]

[1]*Vrije Universiteit Brussel, Biology of the Testis Research laboratory for Reproduction Geneticts and Regenerative Medecine, Brussel, Belgium*

Study question: Establishing a successful method for testicular cell cryopreservation would be of immense benefit to patients undergoing sterilizing treatments. In view of a clinical application (CA), what would be the best protocol to cryopreserve and store testicular cell suspensions?

Summary answer: Our best protocol to cryopreserve immature mouse testicular cell suspensions (TCS) was found to be a non-controlled freezing procedure performed in an insulated container using vials with a cooling rate of 1°C/min till -80°C. It resulted in an average of 50% recovery of viable cells re-stablishing spermatogenesis in 75% of the transplanted testis.

What is known already: Uncontrolled-slow-freezing is the endorsed method to cryopreserve spermatogonial stem cells (SSCs), reaching 68.3 ± 2.8% post-thaw viability after purification, proliferation and freezing of calf type A SSCs permitting a repopulation efficiency of 43% after transplantation (Izadyar et al., 2002*)*. However, in perspective of a CA, an effective protocol for adult human testicular tissue is already established (Baert et al., 2013)*,* for TCSs, only 55.3 ± 23.8% post-thaw viability has been reported after performing vitrification (Sà et al., 2012), therefore, further improvement is needed.

Study design, size, duration: Three groups of samples ($n = 84$) enclosing five conditions were compared. The first group compared two controlled-slow freezing (CSF) protocols and vitrification. A second evaluated the combination of permeating and non-permeating cryoprotective agents (CPAs) and a third compared two commercial vessels used in cryopreservation. After thawing, TCS were transplanted to recipient mice ($n = 46$) for further functional assay.

Participants/materials, setting, methods: Donor prepubertal SV129xC57BL (GFP+) mice testes were digested to obtain TCSs. These TCSs were frozen under different conditions and thawed in a 37°C water bath. The number and viability of cells was counted immediately after digestion (fresh), after adding CPAs and after thawing. Thawed cells were transplanted to recipient infertile mice for functional assay.

Main results and the role of chance: Our results were compared in terms of the percentage of recovered viable cells and number of positive tubules after transplantation. Both CSF procedures did not differ significantly (41 ± 37% and 38 ± 25%), thus we opted for the best time- and cost-efficient procedure. Adding a non-permeating CPA (sucrose) did not result in a higher viable cell recovery (41 ± 26%), although, post-thaw cell viability presented no differences. When assessing different vessels, cells frozen in vials recovered better than those frozen in straws ($P = 0.046$) permitting to reach 50 ± 25% recovered viable cells. Testes transplanted with cells frozen-thawed in vials presented an average of 67 ± 6 positive tubules per 10^5 cells injected with 75% (6/8) of the transplanted testes having re-stablished spermatogenesis.

Limitations, reason for caution: Since human testicular tissue is scarce, the present protocol was developed in the mouse model. As the paramount perspective of this study is the translation of this protocol to human testicular cell suspensions, supplementary research is required in order to develop xeno-free cryopreservation media.

Wider implications of the findings: An optimal cryopreservation protocol enhances the chances for successful fertility restoration. TCS cryopreservation

is an option to preserve fertility in patients for whom sperm freezing is not an option (e.g., prepublertal boys undergoing gonadotoxic treatments). So far, cryopreservation protocols for TCSs in the human model are still suboptimal, thus, developing an easy, reproducible and cost-effective cryopreservation method is of dire need.

Study question: What are the main reasons for the decision making of individual patients to opt for different fertility preservation techniques? Which patients decide to perform multiple fertility preservation techniques to increase their chance for later conception? Did the tendency to perform individual fertility preservation techniques change over the years?

Summary answer: Fertility preservation has become increasingly important as cancer treatments have improved significantly and the 5-year survival rate for the most common premenopausal cancers are above 85%. Therefore, being able to conceive after survival of cancer treatment has become an important part of quality of live for women.

What is known already: Fertility preservation has become increasingly important as cancer treatments have improved significantly and the 5-year survival rate for the most common premenopausal cancers are above 85%. Therefore, being able to conceive after survival of cancer treatment has become an important part of quality of live for women.

Study design, size, duration: An anonymous retrospective analysis from 2007 to 2013 was performed with 5,159 patients counselled for fertility preservation procedures before chemo- or radiotherapy in 39 (2007) to 85 (2013) university and non-university centers, being part of the network FertiPROTEKT (www.fertiprotekt.com). Of these, 4,060 women received fertility preservation therapies (78.7%).

Participants/materials, setting, methods: The fertility preservation offered included GnRH-antagonists, ovarian stimulation and ovarian cryopreservation. The individually chosen therapy was analysed according to: indication for consultation (cancer/benign disease), setting of consultations, patients' age, marital state, prior children, the number of fertility preservation techniques chosen. Data were analysed with ANOVA followed by SNK post-hoc test.

Main results and the role of chance: Fertility preservation counselling in young women receiving gonadotoxic therapies increased significantly over the years. Most of the counselled patients were childless women under 35 years. The frequency of techniques used changed from GnRH agonist to more invasive treatments like ovarian stimulation and ovarian cryopreservation from 2007 to 2013. The most common reasons for consultation were breast cancer (preferring cell and tissue cryopreservation) and lymphomas (using predominantly GnRH agonist therapy). While women between 20 and 40 years chose all kind of treatment options, younger women (<20 years) predominantly received GnRH agonists and tissue cryopreservation, older women (>40 years) GnRH agonists only. As expected the average number of aspirated oocytes per stimulation cycle decreased with age.

Limitations, reason for caution: Data about pregnancy rates following the individually performed fertility preservation techniques are missing, therefore the efficacy of the chosen therapy cannot be assessed. Only the decision making process could be analysed and correlated to the individual patients characteristics.

Wider implications of the findings: Due to increasing scientific progress more invasive techniques for fertility preservation are chosen by German speaking women, with the hope to further improve their chance of later conception. The fertility preservation options, including usage of GnRH-antagonist, ovarian stimulation and cryopreservation of ovarian tissue however still depend on time available until cancer treatment needs to be initiated, in order not to postpone crucial therapy.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Funding by the participating centers. No competing interests.

Trial registration number: NA.

P-451 Safety assessment of cryopreserved ovarian tissue transplantation in breast cancer patients by molecular techniques and in vivo study

B. Rodriguez-Iglesias[1], E. Novella-Maestre[2], A. Pellicer[3]

[1]*Universidad de Valencia, POG, Valencia, Spain*

[2]*Hospital Universitario y Politécnico la Fe, Unidad de Genética, Valencia, Spain*

[3]*Hospital Universitario y Politécnico la Fe, Obstetricia y Ginecología, Valencia, Spain*

Study question: The aim of this study was to develop an in vivo breast cancer model to validate the sensitivity and specificity of a developed molecular novel panel, for the detection of disseminated cancer cells (DCC), in ovarian cortex (OC) and medulla (OM) from breast cancer (BC) patients, which improve the security of ovarian tissue transplantation (OTT).

Summary answer: These findings confirm the sensitivity and specificity of molecular tools for the detection of DCC in OC and OM from BC patients regarding to histological methods and corroborate that the OTT in BC patients is a safe technique to preserve the fertility.

What is known already: We developed a novel molecular markers panel to increase the sensitivity and specificity of DCC detection in ovarian tissue (OT) from BC patients. After analysed of 60 OC and OM from we were able to confirm the absence of malignant cells in OT from these patients. However, although these methods provided good sensitive and sensible results, it is essential to be validated by an in vivo model.

Study design, size, duration: A total of 500.000 cells were injected in left renal capsule of nude mice divided in 3 experimental groups: A) BC cell-line MDA-MB-468 (n = 1,positive control), B) OC and OM cells from 5 BC patients (stages:I–IIIa; n = 10) and C) healthy ovary from caesarean (n = 1,negative control). Animals were sacrificed at 6 months.

Participants/materials, setting, methods: OT and MDA-MB-468 cells were cultured and transfected with fluorescent protein mCherry. Metastatic development was monitored by In-Vivo Image System (IVIS). Mammaglobin-1(MGB1), Gross Cystic Disease Fluid Protein-15 (GCDFP15) and Small Breast Epithelial Molecule (SBEM), were analysed by immunohistochemistry and RT-PCR in all samples before mice transplantation and in each organ´s mice after sacrificed.

Main results and the role of chance: Mice with OC and OM cells from BC patients and healthy ovary cells did not present any suspicious metastatic signal by IVIS study or tumour development after 6 months. Morphological, histological and molecular analysis of the different organs confirmed the absence of DCC. The GCDFP15, MGB1 and SBEM expression were absent in right/left adrenal gland, liver, kidney, pancreas and spleen. However, the positive control mouse, which received a cancer cell line injection, developed palpable tumour masses

of 2.5 cm. SBEM expression in positive control mouse was detected in tumour masses (ΔCt = 11,92), right adrenal gland (ΔCt = 11.98), spleen (ΔCt = 4.21) and pancreas (ΔCt = 7.5) corroborating the presence of infiltrating malignant cells in these mouse´s organs which had been previously detected by IVIS at day 104 post-injection.

Limitations, reason for caution: In this study we estimated, based on reported cancer models, that the injection of 500.00 cancer cells was enough to developed early metastasis. We do not know if a lower cell dilution could develop an early tumour mass.

Wider implications of the findings: This study validates, by in vivo model, a final panel with the most accurate metastatic markers for using it as diagnostic tool of micrometastases in OC from BC patients and corroborates the safety of OTT from BC patients. This study also shows for the first time that the OM from BC patients is free from malignant cells. The IVIS provides a non-invasive method for malignant cells in situ detection without sacrifice the mouse.

Study funding/competing interest(s): Funding by national/international organization(s) – This work was funded by the Spanish Government, grants FIS-PI13/02353, GV/2014/115, AP-2010-0675 and CD11/00292.

P-452 Ex vivo tumour purging of ovarian cortex fragments to enhance the safety of ovarian tissue autotransplantation

R. Peek[1], C. C. M. Beerendonk[1], D. D. M. Braat[1], J. R. Westphal[1]
[1]*Radboud University Medical Center, Obstetrics and Gynecology, Nijmegen, The Netherlands*

Study question: Ovarian cortex tissue of cancer patients that is cryopreserved for reasons of fertility preservation, may contain metastasized tumor cells that may lead to reintroduction of the malignancy after autotransplantation of the ovarian tissue. Is it possible to purge these metastasized cancer cells from the ovarian cortex tissue fragments?

Summary answer: Using various types of ex vivo chemotherapy, we were able to efficiently eliminate experimentally induced small tumours derived from leukaemia and breast cancer cells from ovarian tissue fragments.

What is known already: Autotransplantation of ovarian tissue fragments that contain metastasized tumour cells may reintroduce the malignancy to the recipient. Tumour cells have been detected in human ovarian tissue fragments, and transmission of the disease via transplantation of these contaminated fragments has actually been demonstrated for ALL (human) and lymphoma (mouse).

Study design, size, duration: Tumours of breast cancer and leukaemia were experimentally induced in ovarian cortex tissue fragments and cultured for 4 days. The inoculated tissue fragments were subsequently treated ex vivo with various regimens of chemotherapy, and the effect on the cancer cells and ovarian tissue was monitored.

Participants/materials, setting, methods: Experiments were performed with ovarian tissue obtained after prophylactic salpingo-oophorectomy in BRCA carriers. Bovine tissue was derived from an abattoir. Human cancer cell lines were purchased from various sources. The efficiency of chemotherapy (doxorubicin, cis-platin or Imatinib) on tumour elimination in ovarian tissue ex vivo was assessed using (immuno) histochemistry.

Main results and the role of chance: Our results show that purging of metastasized leukemia or breast cancer cells in ovarian cortex fragments by *ex vivo* chemotherapy is feasible. Treatment of contaminated fragments with either widely used chemotherapeutics or tumour-specific kinase inhibitors, showed mitotic arrest and large scale necrosis of the tumour cells. Histological examination revealed no deleterious effect of the purging procedure on the ovarian tissue. Our results using the kinase inhibitor Imatinib are especially relevant. As this compound is highly tumour specific, it is likely that the follicles, oocytes and the ovarian stromal will not be negatively affected by the *ex vivo* treatment. In addition, the severe side effects that are observed when Imatinib is administered systemically, will obviously not occur when applying *ex vivo* treatment to tissue fragments.

Limitations, reason for caution: The tumour model we used is based on the growth of human cancer cell lines. It is unknown whether these cells behave differently from malignant cells derived from primary tumours. Furthermore, the condition of the ovarian tissue after *ex vivo* chemotherapy requires further structural and functional investigation.

Wider implications of the findings: Our results indicate that it is possible to efficiently purge contaminating cancer cells from ovarian cortex fragments intended for fertility preservation purposes. Optimizing purging procedures will greatly increase the safety of ovarian cortex cryopreservation for cancer patients. Furthermore, by using these purging procedures ovarian cortex cryopreservation might also become a viable fertility preservation option for cancer patients suffering from types of malignancies for which ovarian cortex autotransplantation is currently considered unsafe.

Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Unconditional funding was received from Ferring pharmaceuticals.

Trial registration number: NA.

P-453 Gonadotoxic chemotherapy agents impact ovarian stroma and vasculature

G. Sahin[1], S. Karahuseyinoglu[2], O. Oktem[3]
[1]*Koc University School of Medicine Graduate School of Health Sciences and The, Obstetrics and Gynecology/Reproductive Biology, Istanbul, Turkey*
[2]*Koc University School of Medicine Graduate School of Health Sciences and The, Histology and Embryology/Reproductive Biology, Istanbul, Turkey*
[3]*Koc University School of Medicine/American Hospital Women's Health Center Graduate School of Health Sciences and The, Obstetrics Gynecology/Reproductive Biology, Istanbul, Turkey*

Study question: Are gonadotoxic chemotherapy agents detrimental to ovarian vascular endothelium and stroma?

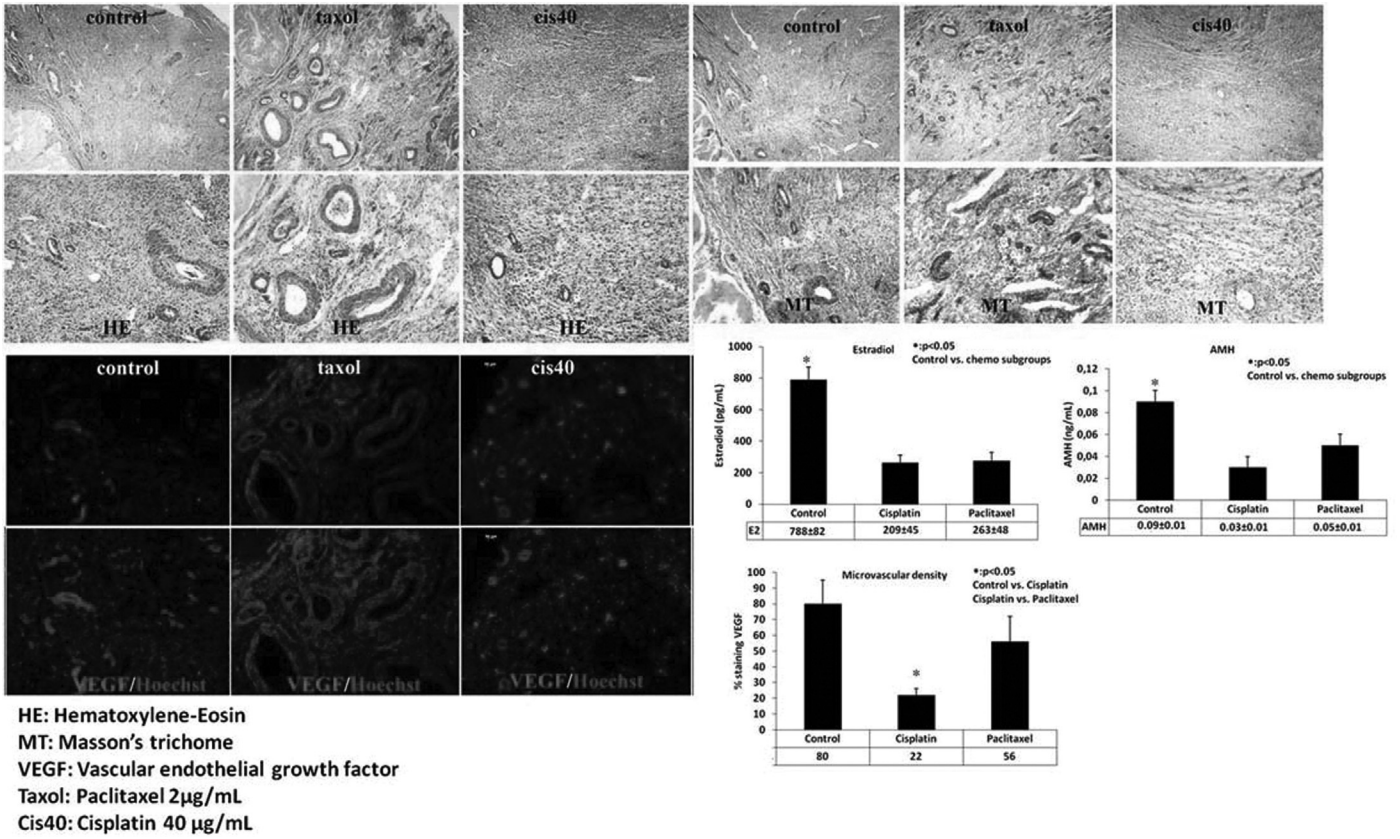
Summary answer: Yes, cisplatin, a chemotherapy agent with a high gonadotoxic potential causes a more extensive destruction in the ovarian stroma and vascular structures compared to control and less gonadotoxic chemotherapy drug paclitaxel.

What is known already: It is well known that massive and accelerated apoptotic death of the follicles is the main pathogenetic mechanism in chemotherapy related premature ovarian failure and ovarian aging in human. There is some evidence albeit not well substaintiated that chemotherapy induced damage in the microvascular endothelium and stroma may contribute to ovarian failure and aging in human. We therefore in this study analyzed the impact of two different chemotherapy agents on the microvascular structures and stroma in human ovary.

Study design, size, duration: An vitro cytotoxicity model of human ovary.

Participants/materials, setting, methods: Ovarian cortical pieces (n = 7, age 24-34) were obtained from patients undergoing laparoscopic ovarian cyst excisions for benign reasons. The samples were cultured for 24 hrs in 24 well plate using DMEM-F12 culture media supplemented with 10%FBS. Cisplatin (40mg/mL) and paclitaxel (2000ng/mL) were used at concentrations corresponding to their therapeutic blood levels. After culture, the ovarian samples were fixed, cryosectioned and stained with H&E, Masson's trichome, VEGF and Hoechst 33342 for examination of ovarian stroma and vasculature. The supernatants of cultured samples were assayed for estradiol and AMH productions by ELISA.

Main results and the role of chance: Ovarian cortical samples treated with cisplatin and paclitaxel produced significantly less E2 and AMH compared to control. The reduction in E2 and AMH productions were more pronounced in the cisplatin treated group compared to paclitaxel. Control ovaries preserved well their structure after 24 hr culture period. Ovarian stroma was stained uniformly HE and MT with many interstitial cells and easily identified microvascular structures. By contrast, the samples treated with cisplatin were characterized by a less cellular, more fibrotic stroma with a marked disarray of the cells and extracellular matrix. Interstitial cells were sparser. The histomorphological changes in ovarian stroma and vasculature in paclitaxel treated samples were



HE: Hematoxylene-Eosin
MT: Masson's trichome
VEGF: Vascular endothelial growth factor
Taxol: Paclitaxel 2µg/mL
Cis40: Cisplatin 40 µg/mL

less remarkable compared to cisplatin. Stroma and vascular structures were preserved to some point. The microvascular density was significantly reduced in the cisplatin group compared to control and paclitaxel (Figure).
Limitations, reason for caution: None
Wider implications of the findings: These results support the view that chemotherapy induced damage in ovarian stroma and vasculature may have additional roles in premature ovarian failure and aging.
Study funding/competing interest(s): Funding by University(ies) – Koc University School of Medicine and the Graduate School of Health Sciences, American Hospital Comprehensive Cancer Care and Fertility Preservation Programs, Istanbul Turkey.

P-454 Nano-porous microtube array membranes loaded with sphingosine-1-phosphate promote ovarian graft survival: a cross-field in vivo transgenic mouse study

S. Tan[1], C. Chen[2], C. Chen[3], C. Tzeng[2]
[1]*Taipei Medical University, Graduate Institute of Clinical Medicine, Taipei, Taiwan R.O.C.*
[2]*Taipei Medical University Hospital, Department of Obstetrics and Gynecology, Taipei, Taiwan R.O.C.*
[3]*Taipei Medical University, Graduate Institute of Biomedical Materials and Tissue Engineering, Taipei, Taiwan R.O.C.*

Study question: Do ovarian grafts survive better with nano-porous microtube array membranes (MTAMs) loaded with sphingosine-1-phosphate (S1P)?
Summary answer: Nano-porous MTAMs loaded with S1P promote ovarian graft survival proved by in vivo bioluminescence imaging (BLI).
What is known already: Ovarian tissue cryopreservation and autotransplantation is a promising option for fertility preservation of female cancer patients. However, the post-transplantation window of ischemia limits the life span of the ovarian grafts. S1P can protect ovarian grafts from ischemic reperfusion injury. The biocompatible scaffolds can be served as connections between the host and grafts and as vehicles for drug delivery to improve the graft survival.
Study design, size, duration: Eight-week-old wild-type mice were transplanted with ovaries from age-matched FVB/N-Tg(*PolII-Luc*)Ltc transgenic mice with or without MTAMs loaded with S1P under the back skin of either side. All animal were sacrificed 5 weeks later.
Participants/materials, setting, methods: Poly-L-lactic acid (PLLA) MTAMs with a nano-porous wall structure were prepared by electrospinning. S1P (2 mM, 5 µL) was loaded into the MTAMs. Ovaries with or with MTAMs were transplanted under the back skin, and the graft survival was tracked in vivo by BLI for 5 weeks.
Main results and the role of chance: Histological examination showed larger size of the ovaries encapsulated by MTAM loaded with S1P with more surrounding vessels compared with those without scaffolds. In vivo BLI also demonstrated stronger intensity of bioluminescence from the ovaries with MTAM loaded with S1P, indicating better survival of the grafts. Nano-porous scaffolds made of biocompatible and biodegradable PLLA biomaterial provided good connection between the graft and host.
Limitations, reason for caution: The effective dosage and the role of S1P should be identified. We used nanotechnology in this study to fabricate delicate scaffolds to promote tissue survival. Although the results are promising, the effect of nanostructure on the tissue still needed to be investigated.
Wider implications of the findings: Scaffolds mimicking the structure and biological function of native extracellular matrix are beneficial for tissue growth. Multi-interdisciplinary approaches bring together chemistry, pharmaceutical science, biology, and medicine to design biodegradable biomaterials for their biological, medical, and pharmaceutical applications. Applying nanotechnology may overcome many limitations in regenerative medicine.
Study funding/competing interest(s): Funding by national/international organization(s) – The Ministry of Science and Technology, Taiwan, R.O.C.
Trial registration number: MOST 103-2321-B-038-008.
Keywords: ovarian transplantation, fertility preservation, scaffolds, tissue engineering, sphingosine-1-phosphate

P-455 Expression of angiogenic factors in cryopreserved mouse ovaries after heterotopic autotransplantation

W. J. Choi[1], J. K. Park[1], J. K. Shin[1], S. A. Lee[1], J. H. Lee[1], W. Y. Paik[1]
[1]*Gyeongsang National University Hospital, Obstetrics and Gynecology, Jinju, South Korea*

Study question: This study was aimed at investigating the effects of cryopreservation techniques (vitrification and slow-freezing) on ovarian expression of angiogenic factors by determining the levels of VEGF and angpt-2 in successful heterotopic ovarian autotransplants of mice.
Summary answer: In ovarian tissue, expression of angiogenic factors is thought to vary by method of cryopreservation. Despite declines in follicular densities due to necrosis, angiogenic factors rose to similar levels after ovarian autotransplantation, regardless of cryopreservation technique.
What is known already: Ovarian tissue banking is a promising option for preserving fecundity in young female cancer patients facing sterilization by chemotherapy and/or radiotherapy. However, the limited functional duration of some nonvascularized ovarian grafts may be due in part to ischemic injury sustained until revascularization is adequate. Revascularization may thus be a critical step in successful ovarian tissue transplantation. Vascular endothelial growth factor (VEGF) and angiopoietin-2 (angpt-2) are the principal mediators of neovascularization.
Study design, size, duration: Design: Prospective study Size: Twenty ICR mice aged 5 or 6 weeks old were sacrificed, and their ovaries were placed in sterile dish. Duration: Autotransplant be done one week after cyropreservation. After two weeks later, autotransplanted ovaries were evaluate for angiogenic factors.
Participants/materials, setting, methods: Ovarian tissues harvested from ICR mice at 5-6 weeks of age were stratified as follows: 1) no cryopreservation (control, group I), 2) vitrification in VFS-40 (vitrification, group II), and 3) gradual freezing in DMSO (slow-freezing, group III). Frozen specimens were thawed at room temperature, assaying VEGF and angpt-2 levels 1 week after cryopreservation and 2 weeks after autotransplantation.
Main results and the role of chance: VEGF and angpt-2 protein levels were significantly lower in cryopreserved ovaries of groups II and III than in controls (group I; $p < 0.05$), whereas groups II and III did not differ significantly in this regard. After autotransplantation, protein levels were similar in all groups, although primary and antral follicular densities of autotransplanted ovaries were again lower in groups II and III than in group I ($p < 0.05$) and did not differ significantly by cryopreservation technique.
Limitations, reason for caution: Since the experimental animal clinical application is limited. The activation of vascular factors do not correlate with the success of the ovary transplant. Although we have optimized freeze/thaw and autotransplantation procedures, not all ovaries so-treated regained their function, and a certain portion became atretic. This suggests that additional improvements in methodology are in order to enhance ovarian tissue survival.
Wider implications of the findings: We hope to improve the success rate of ovarian tissue transplantation after cryopreservation using pretreatment angiogenic factors.
Study funding/competing interest(s): Funding by University(ies) – Gyeongsang National University Hospital.
Trial registration number: NA.

P-456 Metabolites of cyclophosphamide seem to activate dormant human primordial follicles in culture

Y. Lande[1], B. Fisch[2], A. Tsur[1], J. Farhi[2], A. Ben-Haroush[2], G. Kessler-Icekson[3], M. A. Zahalka[3], S. Ludeman[4], R. Abir[2]
[1]*Infertility and IVF Unit Beilinson Women Hospital, Rabin Medical Center, Petach Tikva, Israel*
[2]*Infertility and IVF Unit Beilinson Women Hospital Rabin Medical Center Petach Tikva, and Sackler Faculty of Medicine Tel Aviv University, Tel Aviv, Israel*
[3]*Felsenstein Medical Research Center, Sackler Faculty of Medicine Tel Aviv University, Tel Aviv, Israel*
[4]*Department of Basic and Social Sciences, Albany College of Pharmacy and Health Sciences, Albany NY, U.S.A.*

Study question: How do cyclophosphamide active metabolites [4-hydroxy-cyclophosphamide (4hc) and phosphoramide mustard (PM)], affect dormant human primordial follicles in culture?
Summary answer: Cyclophosphamide metabolites seem to cause enhanced, uninhibited activation of primordial follicles in culture, thus "burning out" the ovarian reserve.
What is known already: The mechanism chemotherapy affects quiescent primordial follicles is unclear. Apoptosis and damage to follicular structure and vascular support are suggested mechanisms, but they have not been consistently proven. The "follicular burnout" theory suggests that chemotherapy targets developing follicles with high mitotic activity. Their removal results in lack of inhibition inducing continuous recruitment of ovarian primordial follicles, thus "burning out" the ovarian reserve. So far, there is no proof of the "burn out" theory in humans.
Study design, size, duration: Frozen-thawed ovarian tissue samples obtained from 10 women, aged 12 ± 5 years, undergoing ovarian cryopreservation were sliced. One slice was fixed immediately [uncultured controls] and other slices were cultured with basic culture medium [cultured controls] or with 4hc/PM (3mM, 10mM) [treated samples] for 24-48 hrs.
Participants/materials, setting, methods: Sliced samples were removed from culture every 24hrs, and spent media were collected at 48hrs. Evaluation of histological slices included follicular counts and classification, Ki67 immunohistochemistry and an apoptosis assay. In addition 17β-estradiol (E2; radioimmunoassay) and antimullerian hormone (AMH; enzyme-linked immunosorbent assay) were measured in spent media samples.
Main results and the role of chance: Samples treated for 48hrs had a significantly lower primordial follicle ratio (20-32%) in parallel with a significantly higher primary/secondary follicle ratio (50-55%) compared with cultured untreated controls (48% and 32%, respectively). At 24hrs these contrasts were less pronounced, and no differences were found between the two concentrations. Most atretic follicles in treated samples were primary/secondary. E2 and AMH levels were more than doubled in treated samples, compared with untreated. There were no traces of apoptosis in cultured follicles including those treated. Most activated follicles (80-100%), including treated samples, were stained positively for ki67 in granulosa cells. Role of chance: as we used organ culture, follow up of the same follicles was impossible, and different follicles were evaluated histologically at various levels of sample.
Limitations, reason for caution: The study included a limited specimen number that was cultured for 48 hrs. We, therefore, could not identify changes occurring beyond this period. Moreover, the organ culture technique does not enable a follow up of the same follicle at all culture time points (uncultured, 24 hrs, 48 hrs).
Wider implications of the findings: It seems that cyclophosphamide metabolites cause enhanced, continuous, uninhibited primordial follicle activation *in vitro*. Our report supports the "burnout theory" as the cause of cyclophosphamide follicular toxicity in humans. Yet, the mechanism by which cyclophosphamide metabolites cause uncontrolled recruitment of primordial follicles was not investigated, and further experiments should be conducted.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Infertility and IVF Unit, Beilinson Women Hospital, Rabin Medical Center.
Trial registration number: 5875, 0100-10-RMC.
Keywords: in vitro culture, cyclophosphamide metabolites, follicular burnout, anti-mullerian hormone, 17ß-estradiol

P-457 A single centre's experience of fertility preservation services: access to care and patient outcome

K. Bambang[1], P. Green[1], A. Drakeley[1]
[1]*Liverpool Women's Hospital, Reproductive Medicine, Liverpool, United Kingdom*

Study question: To assess the fertility preservation service including reasons for referral, access and the corresponding outcomes of these patients following controlled ovarian stimulation (COS) as well as identify the challenges associated with developing a streamlined oncofertility service.
Summary answer: Over a 4 year period, 129 patients were referred for the purpose of fertility preservation and of these 42% were seen within a week of referral. Nearly 80% ($n = 103$) of referrals were for women diagnosed with cancer awaiting treatment and of these 30% did not proceed with treatment.
What is known already: Although national guidance recommends all patients should have access to this service, practice across the UK is variable and recent surveys suggest rate of referral of patients is poor. There is evidence from US models that a structured oncofertility program is successful in not only improving access for patients but also in providing adequate support. Some specific

challenges in COS in these patients include concerns in relation to oestrogen sensitive cancers and minimising OHSS.
Study design, size, duration: Retrospective cohort study reviewing a four year period of data in a large fertility clinic in Mersey UK
Participants/materials, setting, methods: participants were all patients referred for fertility preservation over a four year period. Data collection was retrospective interrogation of patient records.
Main results and the role of chance: There was poor adherence to national guidelines for referral for fertility preservation as evidenced by the small number of referrals in relation to both the population size served and the prevalence of cancer in females of reproductive age in the area. Of the referrals received, 80% (n = 103) were for cancer. The remaining cases related to patients at risk of losing their ovaries or requiring chemotherapy for reasons other than malignancy. Of the referrals received, 42% were seen within a week of referral and treatment was completed within four weeks. The average oocyte yield in the cancer group was 10 which was significantly higher than those requiring fertility preservation for reasons other than malignancy and OHSS rates were low.
Limitations, reason for caution: This is the experience of a single centre so extrapolating to the national or European level is hampered by loco-regional characteristics and population attributes. A multi-centre study is needed to identify problems with accessing care and assessing ovarian response to stimulation in these women. It will also inform on use of currently experimental methods for fertility preservation such as ovarian tissue cryobanking but also help to determine long term risk in hormone sensitive cancers.
Wider implications of the findings: A structured oncofertility program is necessary to provide optimum care for patients as well as regular updates for clinicians looking after patients with regards to available fertility preservation options. The high rate of cancellation may be related to fear of treatment and lack of appropriate counselling. This is a rapidly expanding area which requires robust practice guidelines and further research to optimise current fertility preservation techniques as well as establish experimental techniques into routine practice.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Liverpool Women's Hospital NHS trust.
Trial registration number: NA.

P-458 Sperm banking in male oncological patients over 17 years' experience

I. Pires[1], M. Cabral[1], H. Figueiredo[1], M. Osório[1], S. Pinelo[1], H. Serra[1], A. Barbosa[1], E. Felgueira[1]
[1]*Centro Hospitalar Vila Nova de Gaia/Espinho EPE, Unidade de Medicina da Reprodução Drª Ingeborg Chaves, Vila Nova de Gaia, Portugal*

Study question: To evaluate the role of sperm cryopreservation in the fertility preservation of oncological male patients, regarding characterization of patients and semen parameters, as well as outcomes of thawed samples and intentions of storing after the legal period (3 years).
Summary answer: Sperm cryopreservation is a valid methodology of fertility preservation, besides the low number of patients requering it. Testicular tumor was the main indication for sperm banking and, also, presented the worse semen quality. The majority of men wanted to keep their samples stored for a additional 3 years period.
What is known already: The survival rates in adult oncological males have increased due to the success of multimodal therapies and new diagnostic techniques, reason why sperm banking should be offered to all men before cancer treatment due to gonadal damage risk. Some men may return their normal sperm production after termination of cancer treatment.
Study design, size, duration: From 1997 to 2014 December 93 oncological men were advised preserve their fertility. Cancer indications were grouped as testicular (TT), hematological (HT) and other (OT).
Participants/materials, setting, methods: Routine standard sperm or testicular tissue cryopreservation and thawing tecnniques were realized. Phone contact was established to inquire about the destination of sperm samples stored for more than 3 years.
Main results and the role of chance: 93 oncological men (27,2 ± 6,3 years; range 16-43) were referred to sperm banking. 64,5% had TT, 14% HT and 21,5% OT. Only 3 had prior biological children. 6 had known fertility problems. 89 men had their sperm cryopreserved (3 negative testicular biopsy and 1 desistance). The mean sperm concentration was lowest on TT (19,9 ± 0,5x10^6/ml *vs* 54,8 ± 78,8x10^6/ml on HT and 35,1 ± 36,5x10^6/ml on OT; P < 0,005). Only 5 required thawing to ART techniques (5,6%), had realized 11 FIV/ICSI cycles with one pregnancy. From the 52 men contacted after the initial legal period, 2 died and 7 didn't answer. Among the 43 answers, 3 achieved impregnation without banked sperm (7%). When asked about the future of their samples, 4 required destruction (9,3%) and 39 opted for storing maintenance (90,7%).
Limitations, reason for caution: One limitation is the relative low number of men who answered the questionnaire.
Wider implications of the findings: Although the number of patients with a valid sample for cryopreservation was high, only a minority requested the use of their frozen samples.
Study funding/competing interest(s): Funding by hospital/clinic(s) – none.
Trial registration number: NA.
Keywords: cryopreservation, sperm banking, fertility preservation

P-459 Introduction of social network analysis into the field of fertility preservation

C. C. M. Beerendonk[1], O. Baysal[1], J. Koetsenruijter[2], D. D. M. Braat[1], W. L. D. M. Nelen[1]
[1]*Radboud Universitair Medisch Centrum, Obstetrics and Gynaecology, Nijmegen, The Netherlands*
[2]*Radboud Universitair Medisch Centrum, Scientific Institute for Quality in Healthcare, Nijmegen, The Netherlands*

Study question: Can a social network analysis (SNA) help to get insight into professional networks and clinical referral patterns for fertility preservation counselling (FPC)?
Summary answer: A SNA can be performed among healthcare providers in multidisciplinary oncological care with a good response rate (61%) to the questionnaire. Furthermore, this methodology identifies the 'key figures' in a professional network and professional relationships on which healthcare providers could work on to improve fertility preservation (FP) care.
What is known already: To enable good decision-making about FP, clinical guidelines advise referral of female patients for FPC. However, the adherence to this recommendation is poor. To improve the quality of FP care by improving the FPC referral rates, identification of all barriers is necessary. Since quality of multidisciplinary collaboration in oncological care may play a role in these referral rates. Therefore, we aimed to analyse the patterns in multidisciplinary care and professional networks by a SNA.
Study design, size, duration: A cross-sectional study by questionnaire was conducted among oncological healthcare providers in a demarcated region around a university hospital in the Netherlands, where FPC is performed. Healthcare providers answered questions about baseline characteristics, their FP practices, their attitude towards FP and their collaborations with others in the professional network.
Participants/materials, setting, methods: Doctors and nurses (n = 189) involved in the oncological care of the top three cancers in women aged 18-40 years old (haematological/lymphoid cancers, breast cancer, gynaecological cancers) received our questionnaire by e-mail. By conducting a SNA, the oncological healthcare providers' place within the network was calculated using the software program UCINET.
Main results and the role of chance: Eight hospitals (including a university hospital) and one radiotherapeutic centre were included based on their location within 35 km from our university FP centre. A total of 116 healthcare providers (61%) responded to our questionnaire. Visualization of the total network showed that usually oncologists can be seen as key figures in the network. The density of the professional networks for the individual hospitals ranged from 0.49 to 0.91 (on a 0-1 scale). The average minimum distance for the total network to reach one of the gynaecologists involved in FP, expressed as number of steps needed, was 1.55, ranging from 1.24 to 2.00. The two most 'central' gynaecologists were in direct contact with 23% and 36% of all oncological healthcare providers.
Limitations, reason for caution: The selection of hospitals based on the distance, may have caused selection bias. However, these hospitals were responsible for referring 82% of all our patients in the past. Collaboration with other university hospitals for FPC was not taken into account and may have altered the calculations of the total network.

Wider implications of the findings: SNA was helpful to, not only give us insight in the key figures in our multidisciplinary oncological healthcare network, but also to show us which relationships between FP specialists and others need to be improved to possibly increase FPC referral rates. These key figures can be used to spread knowledge from the FP specialist to the other healthcare providers, or they can function as dedicated healthcare providers who can answer questions and give advice.
Study funding/competing interest(s): Funding by hospital/clinic(s) – This work was supported by the Radboud Institute for Health Sciences (research school affiliated to the Radboud university medical center). The authors have declared no conflicts of interest with respect to this work.

P-460 To freeze or not to freeze: analysis of socio-demographic characteristics between women undergoing social freezing and those only asking for information

R. Vassena[1], D. García[2], O. Coll[1], A. Rodríguez[1], V. Vernaeve[1]
[1]*Clínica EUGIN, Barcelona, Spain*
[2]*Fundació Privada EUGIN, Barcelona, Spain*

Study question: Are there any differences in the socio-demographic characteristics of women who decide to undergo oocyte vitrification to delay motherhood versus those who attend to the clinic for a consultation but do not start the treatment?
Summary answer: We did not find any statistically different socio-demographic characteristic between women who undergo oocyte vitrification and those who only ask for information but do not follow through with treatment.
What is known already: The vitrification of own oocytes in order to delay motherhood (social freezing) is gaining popularity thanks to both technical improvements and an increased awareness among women about this option. Although both individuals and, recently, large corporations express interest in social freezing, the population seeking this option is severely understudied. Limited information is currently available on the decision making factors underlying social freezing versus, for instance, either not freezing or opting to have a child instead.
Study design, size, duration: Cross-sectional study including 120 women who attended a fertility center for a first consultation for oocyte vitrification between July 2012 and May 2014. All women were asked to fill in a 16-item questionnaire at the end of the doctor appointment, and none declined.
Participants/materials, setting, methods: Women were considered 'non-freezers' if they did not start treatment in 6 months from the information appointment. Differences between freezers and non-freezers were analyzed by Chi^2 test and ANOVA. Data were modeled using logistic regression with age, educational level, working status, relationship status and duration, and having children as covariates.
Main results and the role of chance: Women interested in social vitrification were on average 37.4 years old, highly educated (90%), heterosexual (98.3%), and childless (93.3%). The majority either did not have a partner (n = 76, 63%) or were not cohabiting with him at the time of the interview (n = 25, 21%). Sixty-three percent if women indicated the lack of a suitable partner as the main cause of not having children, while 20% reported professional obligations as the main reason. Interestingly, freezers had been consistently longer in their relationship situation than no freezers, whether it was co-habiting with their partner (68.8 vs. 24 months), with a partner but living alone (26.7 vs. 13.4), or being single (21.4 vs. 19.5). None of the characteristics evaluated showed an effect on treatment initiation at multivariate analysis.
Limitations, reason for caution: The main limitation of this study is single center nature; although the women attending the service were from different nationality, caution should be exercised when extending these results to other realities.
Wider implications of the findings: Socio-demographic characteristics of women interested in social freezing does not seem to vary significantly between freezers and non-freezers, although longer permanence in a relationship state might facilitate the decision to freeze. More in depth studies with larger sample base are needed in order to investigate in detail the decision making factors affecting oocyte vitrification for social reasons.
Study funding/competing interest(s): Funding by hospital/clinic(s).
Trial registration number: NA.
Keywords: social freezing, vitrification, oocyte, fertility preservation

P-461 Fertility preservation (fp) and assisted reproductive technology (art) for breast cancer patients (bcp)

K. Kyono[1], K. Sato[1], M. Kuchiki[1], M. Hattori[1], K. Moniwa[1], E. Sakamoto[1], Y. Nakajo[1], H. Hattori[1], M. Doshida[1], M. Toya[1], M. Ono[2], A. Tanaka[2], T. Hashimoto[2], T. Okuda[2], T. Takeuchi[2]
[1]*Kyono ART Clinic, Department of Obstetrics and Gynecology, Sendai, Japan*
[2]*Kyono ART Clinic Takanawa, Department of Obstetrics and Gynecology, Tokyo, Japan*

Study question: What are the best methods of FP pre-chemotherapy and infertility treatment for survivors post-chemotherapy in BCP? How many eggs and embryos can be attained pre-chemotherapy and post-chemotherapy, how many days do we need for FP, and what is the percentages of male factors?
Summary answer: In pre-chemotherapy cycles, we can attain more retrieved oocytes, MII oocytes, and embryos compared with post-chemotherapy cycles. Therefore, FP using letrozole within 2 months before chemotherapy is recommended for BCP. After chemotherapy, survivors should receive ART including intracytoplasmic sperm injection (ICSI) as soon as possible for higher chances of pregnancy.
What is known already: At their first visit to the fertility center, BCP tended to be older than other cancer patients (especially with malignant lymphoma and luekemia). More than half of them were likely to have ovarian factor infertility, especially post-chemotherapy. FP should be performed pre-chemotherapy, and low E2 levels are recommended with estrogen receptor (ER) positive patients during controlled ovarian stimulation (COS).
Study design, size, duration: Subjects were BCP who visited Kyono ART Clinic (KAC) or KAC Takanawa from July 2008 to December 2014. Details of breast cancer, including ER and human epidermal growth factor receptor type 2 (HER2), were received in medical referral letters from oncologists.
Participants/materials, setting, methods: 55 BCP [average age at first visit: 37.8 (25-49); diagnosed with breast cancer; 35.1 (23-47); and 78.2% (43/55) married] were divided into two groups [group A (52 cycles): pre-chemotherapy cycles; group B (47 cycles): post-chemotherapy cycles. Average period to FP pre-chemotherapy was 2.0 ± 2.6 months.
Main results and the role of chance: The 55 patients' receptors were [ER; HER2: positive (18; 3), negative (9; 19), no information (28; 33)]. A total of 99 cycles received ART. Number of retrieved oocytes, MII oocytes, and embryos were 5.6 ± 4.2 vs. 2.4 ± 2.5 ($p = < 0.01$), 4.7 ± 3.3 vs. 2.1 ± 2.2 ($p = < 0.01$), and 3.4 ± 4.6 vs. 1.1 ± 1.2 ($p = < 0.01$), in groups A (52 cycles) and B (47 cycles), respectively.
Seven patients (including one after FP pre-chemotherapy and remission) in group A and four in group B became pregnant. 27.3% (15/55) of the patients' partners had male factor. Peak E2 levels in letrozole and non-letrozole cycles were 705.4 ± 886.8 pg/ml and 885.2 ± 777.2 pg/ml (NS).
Limitations, reason for caution: None.
Wider implications of the findings: We recommend BCP to receive ART for ovarian factor (advanced age and/or reduced ovarian reserve) and male factor (especially severe oligozoospermia) as soon as possible. For ovarian factor, more retrieved oocytes, MII oocytes, and embryos can be achieved pre-chemotherapy compared to those in post-chemotherapy treatment. For severe male factor, ICSI is recommended, especially in patients with advanced age.
Study funding/competing interest(s): Funding by hospital/clinic(s).

P-462 Effect of local basic fibroblast growth factor and vascular endothelial growth factor on subcutaneously allotransplanted ovarian tissue in ovariectomized mice

J. Gao[1], J. Yan[1], Y. Huang[1], M. Li[1], H. Zhao[1], Y. Zhao[1], R. Li[1], Y. Yu[1], J. Qiao[1]
[1]*Peking University Third Hospital, Center of Reproductive Medicine Department of Obstetrics and Gynecology, Beijing, China*

Study question: The role of bFGF and VEGF on ovarian tissue transplantation, especially with regards to the restoration of hormonal function, is not known.
Summary answer: The combination of bFGF and VEGF have beneficial effects on follicle survival, angiogenesis, and resumption of estrous cycles.

What is known already: Strategies to improve and hasten graft vascularization and reduce follicular loss are needed for ovarian tissue transplantation.
Study design, size, duration: Ovarian tissues were isolated from 18-day-old ICR mice. Recipients were adult ICR mice. Female mice underwent bilateral ovariectomy as recipient. Ovarian tissue encapsulated by fibrin hydrogels were transplanted subcutaneously into recipient mice. The fibrinogen solution was mixed with bFGF, VEGF, or a mixture of bFGF and VEGF.
Participants/materials, setting, methods: Follicle morphology and follicle numbers were observed by H&E staining. Angiogenesis were observed tissue by CD31 antibody IHC staining. Daily vaginal cytology was performed to determine estrous cycle and functional restoration of transplanted ovarian tissue. Blood was collected weekly and serum FSH levels were measured.
Main results and the role of chance: The number of primordial follicles and secondary follicles in the bFGF + VEGF group was significantly higher than in the control group. The number of atretic follicles in the bFGF and bFGF + VEGF groups were significantly greater than in the control and VEGF groups. The vascular density in the VEGF group and the bFGF + VEGF groups were significantly higher than in the bFGF group; there was no significant difference between the VEGF and bFGF + VEGF groups. Cyclicity was earlier in the bFGF + VEGF group compared with the control group; all mice in this group restored ovarian function. Serum FSH levels in the bFGF + VEGF group were significantly lower than in the control group by day 14 post-transplantation.
Limitations, reason for caution: However, further investigations are necessary to elucidate the functional mechanism of VEGF and bFGF, in order to ensure the efficacy and safety of exogenous intervention for ovarian tissue transplantation in humans.
Wider implications of the findings: The present study observed the role of bFGF and VEGF in heterotopic transplanted ovarian tissues and showed that combination bFGFand VEGFmight be applied in ovarian tissue transplantation in clinics and might be even benefit for females fertility preservation.

P-463 Short-term hypothermic preservation of human testicular tissue: the effect of storage medium and storage period

K. Faes[1], Y. Baert[1] E. Goossens[1]
[1]*Vrije Universiteit Brussel, Biology of the Testis, Jette, Belgium*

Study question: What is the best condition to preserve human testicular tissue for a short-term period?
Summary answer: Human testicular tissue can be preserved for three days at 4°C in DMEM/F12 without altering tissue morphology, Sertoli cell morphology, number of spermatogonia per tubule or number of apoptotic cells.
What is known already: As of the time that testicular tissue is removed from the patient's body, the tissue has to be kept in optimal conditions until later use. Therefore, the ideal short-term storage conditions until cryopreservation need to be established. Porcine testicular tissue can be preserved up to three days at 4°C in HTS or 20%FBS-Leibovitz medium without tissue morphology deterioration. So far, no studies were done to find the best short-term storage condition for human testicular tissue.
Study design, size, duration: First, human testicular tissue fragments from five patients were kept at refrigerator temperature (RT) for three days in different storage media (DMEM/F12, DMEM/F12 + 20%HSA, DMEM/F12 + 50%HSA and HSA). Secondly, fragments from four patients were kept in the best medium found in the first part for three, five or eight days at RT.
Participants/materials, setting, methods: Viability was measured by TALI® and light microscopy evaluations were performed in order to gain information regarding the general tissue morphology (HE), Sertoli cell morphology (vimentin), number of spermatogonia (MAGE-A4) per tubule and apoptosis (TUNEL). The experimental conditions were compared with fresh control samples.
Main results and the role of chance: DMEM/F12 did not alter any investigated parameter. In all conditions containing HSA, tissue morphology was altered (20% HSA: $P < 0.05$; 50% HSA: $P < 0.0001$; 100% HSA: $P < 0.0001$) as well as Sertoli cell morphology (20% HSA: $P < 0.05$; 50% HSA: $P < 0.0001$; 100% HSA: $P < 0.0001$). The number of spermatogonia was only affected when tissue was stored in 100% HSA ($P < 0.05$). Therefore, DMEM/F12 is suggested as best medium for short-term hypothermic storage. No significant changes were observed in any investigated parameter for the different storage periods apart from tissue morphology as of five days of hypothermic storage (day 5: $P < 0.05$; day 8; $P < 0.0001$). Human testicular tissue should thus not be stored at 4°C for longer than three days.
Limitations, reason for caution: In this study, we have chosen adult human testicular tissue owing to the scarcity of prepubertal material. Functionality tests were not performed because these tests were not yet available for human testicular tissue at the time of this study.
Wider implications of the findings: When human testicular tissue is stored in optimal conditions during transport, the chances of spermatogonial stem cell survival increase which in turn will benefit the patient during future fertility treatment.
Study funding/competing interest(s): Funding by national/international organization(s) – Flemish league against cancer (VLK), Methusalem grant of the Vrije Universiteit Brussel.

P-464 Maturation of human oocytes obtained from small antral follicles during processing of ovarian tissue for cryopreservation

D. A. Gook[1], R. B. Gilchrist[2], J. G. Thompson[3], D. G. Mottershead[3], D. H. Edgar[1]
[1]*The Women's Hospital, Reproductive Services/ Melbourne IVF, Parkville Victoria, Australia*
[2]*University of New South Wales, School of Women's and Children's Health, Sydney, NSW, Australia*
[3]*The Robinson Research Institute University of Adelaide, Research Centre for Reproductive Health, Adelaide, SA, Australia*

Study question: Can oocytes from small antral follicles obtained during processing of human ovarian tissue for cryopreservation (non-stimulated) mature in vitro? Does the medium used for the in vitro maturation (IVM) affect the maturation rate? Does bone morphogenetic protein 15 (BMP-15) improve the maturation rate of oocytes from small follicles?
Summary answer: 47% of oocytes from small antral follicles underwent meiotic maturation in vitro. No difference in the meiotic maturation rate was observed under any of the conditions examined.
What is known already: IVM has been successfully applied to cumulus oocyte complexes (COC's) from PCO patients following FSH stimulation (maturation rate > 70%[1]). Whether oocytes from small antral follicles in the non-stimulated human ovary are capable of maturation is unknown. Different culture media have been used for clinical IVM but few comparisons have been reported. Animal studies have shown that oocytes from small follicles benefit from exogenous BMP-15, which is involved in cumulus- oocyte dialog during maturation.
Study design, size, duration: COC's were recovered during tissue processing in approximately one third of patients undergoing cryopreservation of ovarian cortex for fertility preservation. Two IVM media were compared: G2 plus™ with 100mIU FSH/ml and 500mIU hCG/ml[1] and a bovine IVM medium (Vitromat: containing 100mIU FSH/ml) with/without BMP-15 (100ng/ml).
Participants/materials, setting, methods: Ovarian tissue was processed at 37°C in Quinn's Advantage Hepes buffered medium. Small antral follicles (< 5 mm diameter) were punctured and the COC's transferred to IVM medium for 48 hours. The size and Vanderhyden[2] score for cumulus complex (CC) expansion was recorded at 0, 24 and 48 hours.
Main results and the role of chance: 227 COCs were obtained from 28 patients (mean age 23.6, range 18-36 years). Over half of the oocytes (53.7%, 122/227) were enclosed in a large dense mass of CC (> 15 layers) and 26.4% (60/227) had < 5 layers of CC. Of the 227 oocytes, 22.5% (51) remained at the germinal vesicle (GV) stage, 30.4% (69) had undergone GV breakdown and 47.1% (107) had developed to metaphase II. Of the 107 metaphase II oocytes, 8.4% (9) had matured by 24 hours. No difference was observed for the maturation rate in any of the conditions; G2 -44.8% (26/58); Vitromat - 48.1% (26/54); Vitromat + BMP-15 - 47.8% (55/115). The only difference observed was that fewer of the CC demonstrated a spreading appearance (Vanderhyden score 0) at 48 hours in the presence of BMP-15 (12/115) than in Vitromat (13/54; $p < 0.05$).

Limitations, reason for caution: When possible, similar size CC's from the same patient were allocated to all groups but this was not always feasible. Results may be biased by three patients who had > 20 COC's collected. Although meiotic maturation rates were not different, effects on developmental competence cannot be excluded.
Wider implications of the findings: Small antral follicles contain oocytes capable of meiotic maturation although their developmental competence remains to be established. Although this approach suggests that these oocytes may offer an additional source of reproductive potential when cryopreserving ovarian tissue for fertility preservation patients, their potential for achieving an implantation is unknown.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Melbourne IVF.
Trial registration number: NA.

P-465 Correlates of women's intentions to use fertility preservation to prevent age-related fertility decline

A. ter Keurst[1], J. Boivin[2], S. Gameiro[2]
[1]*Radboud University, Radboud Honours Academy, Nijmegen, The Netherlands*
[2]*University of Cardiff, Cardiff Fertility Studies School of Psychology, Cardiff, United Kingdom*

Study question: Which factors are associated with the intentions of childless women aged between 28 and 35 to use fertility preservation (FP)?
Summary answer: Higher intentions to use FP were associated with feeling susceptible to infertility, considering FP useful to achieve parenthood, perceiving the implications of infertility (i.e., childlessness) as severe, expecting to have children at a later age and having fewer ethical concerns about FP.
What is known already: Many women consider cryopreserving their oocytes but only a minority actually do it. Usually they are already too old (i.e., older than 36). It is unclear why women are not using FP earlier, as this would increase their chances of achieving parenthood. The Theory of Planned Behaviour (TPB) and the Health Belief Model (HBM) are valid models to understand and predict women's intentions to use FP.
Study design, size, duration: Cross-sectional online survey. Childless women without fertility problems, aged 28-35, who desired to have children, were recruited. We recruited from multiple sources (universities, community panel, social media, online communities, fertility websites, online advertisement and experiment websites). The survey ran from the 9th of May 2014 - 15th of June 2014.
Participants/materials, setting, methods: The final sample consisted of 257 childless women. The online survey included questions about parenthood goals, women's intentions to use FP within 2 years, their fertility knowledge and variables from the TPB and HBM. The data were analysed using Structural Equation Modelling.
Main results and the role of chance: On average women were 30.6 years (SD = 2.3), wanted to have 2 children and expected to have their first and last child at 34.4 and 37.6. Desire for children was high (7.4 ± 2.1 [2-10]), intentions to use FP low (2.5 ± 1.5 [1-7]) and fertility knowledge moderate (3.5 ± 1.4, [0-6]). The HBM showed good fit to the data (X^2 (14, N = 257) = 13.63, r = .477; CFI = 1.000: RMSEA = 00, 90%CI [0.00-0.06], showing that women were more likely to use FP when they felt susceptible to infertility, perceived childlessness as severe, considered FP useful and ethically correct and expected to have children at a later age. The TPB lacked explanatory power (X^2 (6, N = 257) = 94.31, r < .001; CFI = .78; RMSEA = .24, 90%CI [0.20-0.28]).
Limitations, reason for caution: 68.1% of the women were employed and 92.6% had university education, which may result in an overestimation of fertility knowledge and an underestimation of access to FP. This study focused on intentions rather than actual behaviour, previous research suggests that women overestimate their intentions to use FP.
Wider implications of the findings: Women have low intentions to use FP. These seem to be related to a lack of perceived susceptibility to infertility and not appraising its consequences as severe. These perceptions seem misaligned with women's desire to have two children at ages when there is already reproductive decline (i.e., 34-38 years) and their strong desire for children. Healthcare professionals should help women by providing accurate and personally relevant information about fertility and FP to delineate feasible parenthood plans.
Study funding/competing interest(s): Funding by University(ies) – Radboud Honours Academy, Nijmegen, The Netherlands.
Trial registration number: NA.

P-466 In vitro maturation: before or after vitrification?

J. Ramalho-Santos[1], A. P. Sousa[2], S. Machado[2], T. Almeida-Santos[2]
[1]*University of Coimbra - Center for Neuroscience and Cell Biology, Department of Life Sciences, Coimbra, Portugal*
[2]*Hospital and University Center of Coimbra, Reproductive Medicine Service, Coimbra, Portugal*

Study question: The aim of this study was to understand whether it is more or less beneficial in terms of structural integrity (presence of a normal meiotic spindle and correct chromosome alignment), to perform *in vitro* maturation (IVM) of immature oocytes before or after vitrification.
Summary answer: IVM of MI oocytes seems to be more efficient when performed before vitrification. No differences were observed for GV oocytes. However, independently of the moment where IVM were performed, mature oocytes obtained from IVM present structural damages in terms of presence of an abnormal meiotic spindle and/or incorrect chromosome alignment.
What is known already: Advances in cancer treatments allow oncology patients to live for extended periods of time and thus issues such as fertility preservation have become increasingly important for survivors. Within the various female fertility preservation options, oocyte vitrification is the one that most effectively ensures the future reproductive autonomy of women. I*n vitro* maturation is a very important technique when there is a need to cryopreserve immature oocytes. However the success of this technique is questionable.
Study design, size, duration: Cross sectional. 170 immature oocytes obtained after controlled ovarian hyperstimulation from 75 patients were used: 50 GV oocytes - germinal vesicles stage; and 120 MI oocytes - metaphase I stage.
Participants/materials, setting, methods: *In vitro* maturation (IVM) was performed in 37 GV (germinal vesicles stage) and 72 MI (metaphase I stage) followed by vitrification; and was performed after vitrification in 13 GV and 48 MI. For both approaches, IVM success was evaluated. Structural integrity (meiotic spindle and chromosomes) were assessed using immunocytochemistry.
Main results and the role of chance: Our results suggest that IVM is more efficient in MI oocytes (61.11%) than GV oocytes (32.43%, $p < 0.001$). Furthermore, IVM of MI oocytes seems to be more efficient when performed before vitrification (61.11% vs 25.00%, $p = 0.009$). No differences were observed for GV oocytes (32.43% vs 8.30%, $p = 0.098$). More importantly, independently of the moment where IVM was performed (before or after vitrification), mature oocytes obtained from IVM present structural damages in terms of presence of an abnormal meiotic spindle and/or incorrect chromosome alignment.
Limitations, reason for caution: Immature oocytes used were obtained from controlled ovarian hyperstimulation cycles triggered by HCG, and that failed the *in vivo* maturation. The same approach should be used with immature oocytes obtained from controlled ovarian hyperstimulation cycles without the triggering of HCG.
Wider implications of the findings: As it is briefly suggested in the literature, our study demonstrates that although it is possible to obtain mature oocytes using IVM, they present structural damage in terms of meiotic spindle structure and/or chromosome alignment. The use of technologies that allows the visualisation of the meiotic spindle in live oocytes should be considered. These approaches can allow the selection of the good oocytes and clarify if IVM is indeed a viable option.
Study funding/competing interest(s): Funding by University(ies) – Funding by hospital/clinic(s) – Funding was from the budget of the University of Coimbra Hospital system, and related to the public oncofertility service provided.

P-467 Oocyte cryopreservation: a retrospective analysis of data from Italian ART register 2007-2012

G. Scaravelli[1], V. Vigiliano[1], R. De Luca[1], R. Spoletini[1], S. Bolli[1], P. D'Aloja[1]
[1]*Istituto Superiore di Sanita, CNESPS - Registro PMA, Rome, Italy*

Study question: To compare the efficacy of mature human oocytes cryopreservation with Slow-Freezing (SF) and Vitrification (VT) in Italy, where these procedures have been most widely used.
Summary answer: VT resulted in a statistically significant higher performance compared with SF based on the higher oocyte survival and pregnancy rates and the lower number of vitrified-warmed oocytes to obtain a live birth.
What is known already: Oocyte cryopreservation is an important option for individuals planning to undergo IVF treatments, because new protocols have greatly improved the applications of this procedure. Two different methods of oocyte cryopreservation are currently performed: Slow-freezing and Vitrification. Vitrification has been shown to be superior, and in some studies its outcomes were similar to those obtained with fresh oocytes. Additional studies are required to confirm these results.
Study design, size, duration: Retrospective analysis of aggregate data collected by the Italian ART Registry (IARTR) from ART centers who have performed at least one frozen cycle in the period from 2007 to 2012. The number of ART centers increased from 93 in 2007 to 116 in 2012.
Participants/materials, setting, methods: Infertile couples who underwent IVF-treatments at Italian ART centers and who have done cryopreservation of supernumerary oocytes. Data were analyzed with IBM SPSS Statistics 21.
Main results and the role of chance: During the 6-year study period ART centers performed 16.517 frozen cycles, of which 57,7% (9.541) with slow-frozen oocytes and 42,3% (6.976) with vitrified oocytes. Following SF and VT, oocyte survival rates were 51,8% vs. 64, 5% and clinical pregnancy rates per cycle and per transfer were 12,2% and 14,9% vs. 14,7% and 18,5%, respectively. On average, 47 oocytes were used to obtain a live birth following SF compared to 36 oocytes utilized with VT.
Limitations, reason for caution: Our data were collected and analyzed in aggregate form only, in compliance with Italian law. This may have limited the variety and depth of our analysis.
Wider implications of the findings: Our findings based on the analysis of a very large number of frozen cycles shows that oocyte cryopreservation is a competitive tool in clinical practice. Because of the good outcomes observed, oocyte cryopreservation represents a viable option for patients declining embryo cryopreservation.
Study funding/competing interest(s): Funding by national/international organization(s) – Minister of Health.
Trial registration number: NA.

P-468 In vitro evaluation of an anti-apoptotic drug, Z-VAD-FMK, for further use in ovarian tissue transplantation

M. Fransolet[1], L. Henry[2], S. Labied[2], A. Noël[1], J. M. Foidart[1], M. Nisolle[2], C. Munaut[1]
[1]*University of Liège, Laboratory of Tumor and Development Biology GIGA-R, Liège, Belgium*
[2]*University of Liège, The Department of Obstetrics and Gynecology, Liège, Belgium*

Study question: In a model reproducing early ischemia after ovarian tissue transplantation, does the pan-caspase inhibitor Z-VAD-FMK could prevent granulosa cells apoptosis?
Summary answer: Results obtained with HGL5 granulosa cell line suggest that Z-VAD-FMK is efficient to protect granulosa cells from etoposide or $CoCl_2$ induced apoptosis.
What is known already: Removal, cryopreservation and subsequent graft of ovarian strips after cancer treatment have been successfully used to re-establish female fertility. However, the pregnancy rate after autografting of cryopreserved tissue is about 30%. Indeed, the major problem after transplantation is follicular loss due to ischemic reperfusion injury.
Study design, size, duration: Three human granulosa cell lines (GC1a, HGL5 and COV434) were cultured during 48h with Z-VAD-FMK with or without etoposide to induce apoptosis. To reproduce the ischemic phase of the graft, cells were cultured without serum under reduced O_2 (1%) or with $CoCl_2$ (chemical hypoxia).
Participants/materials, setting, methods: Granulosa cells were used as a model since they are essential for oocyte survival. Metabolic cell activity was evaluated by the WST-1 assay. Cell apoptosis was analyzed by flow cytometry after annexin V-FITC and propidium iodide double staining. The mRNA levels and protein expression of apoptotic markers were evaluated using RT-qPCR and western blot analysis.
Main results and the role of chance: Flow cytometry showed that cells co-treated with etoposide and Z-VAD-FMK displayed a higher percentage of viable cells as compared to etoposide alone. When *in vivo* ischemic stage was mimicked (1% O_2), no beneficial effect of the Z-VAD-FMK was detected. However, a significant decrease of the number of early apoptotic cells was evidenced by flow cytometry for HGL5 cells treated with Z-VAD-FMK. RT-qPCR and western blot analysis revealed that apoptotic molecules were not modulated. Metabolic activity of the 3 cell lines was reduced by $CoCl_2$. For HGL5 cells, this decrease was partially reversed by Z-VAD-FMK. The number of viable cells was reduced by $CoCl_2$ in HGL5 cells but Z-VAD-FMK allowed to preserve a similar number of viable and apoptotic cells than in control condition.
Limitations, reason for caution: In this study we used 3 different cell lines but granulosa cells represent only a part of the cell types present in ovarian tissue biopsies. Experiences on the effect of Z-VAD-FMK on primary culture of granulosa cells have not yet been realized.
Wider implications of the findings: This study suggests that the use of an antiapoptotic drug could be efficient to improve ovarian tissue transplantation outcomes. Ovarian tissue grafting studies using our xenograft murine model will be performed to test the potential efficacy of this drug to improve tissue viability and primordial follicles preservation after transplantation.
Study funding/competing interest(s): Funding by University(ies) – Funding by national/international organization(s) – This work was supported by the University of Liège and by grants from the Fonds de la Recherche Scientifique Médicale, the Fonds de la Recherche Scientifique - FNRS (F.R.S.-FNRS, Belgium). The authors declare that they have no competing interests.
Trial registration number: NA.

P-469 Vitrification using dimethyl sulfoxide free cryoprotectant is a promising cryopreservation method for fertility preservation of immature mouse testicular tissue

T. Shin[1], M. Fukushima[1], Y. Shimomura[1], K. Suzuki[1], T. Iwahata[1], A. Miyata[2], H. Okada[1]
[1]*Dokkyo Medical University Koshigaya Hospital, Department of Urology, Koshigaya, Japan*
[2]*Dokkyo Medical University Koshigaya Hospital, Reproduction Center, Koshigaya, Japan*

Study question: What is the best cryopreservation protocol of immature testicular tissue for fertility preservation?
Summary answer: Vitrification using dimethyl sulfoxide (DMSO) free cryoprotectant appears to be superior to other methods for cryopreservation of immature testicular tissue and in vitro production of functional spermatozoa.
What is known already: Loss of fertility is a major problem for childhood cancer survivors treated with gonadotoxic therapy, and cryopreservation of testicular tissue is an approach to preserve fertility for prepubertal boys. Slow freezing (SF) and vitrification are cryopreservation techniques that were successfully applied in several animal models but need further exploration.
Study design, size, duration: Fragments of testicular tissue from 10 mice were assigned to one of the following cryopreservation procedures: SF using DMSO as cryoprotectants, SF using DMSO free cryoprotectant (Stem Cell Keep®), vitrification using DMSO, vitrification using Stem Cell Keep®.
Participants/materials, setting, methods: Histological and immunohistochemical analyses were performed to evaluate cell viability, intratubular proliferation (Ki-67), apoptosis (caspase-3) after freezing and thawing. Thawed testicular tissue were cultured for in vitro production of mature sperm using previously described organ culture method. The fertility of induced spermatozoa was tested by intracytoplasmic sperm injection (ICSI).
Main results and the role of chance: Seminiferous tubules showed good integrity after cryopreservation and thawing in all groups. Cell viability and their

ability to proliferate was observed by immunohistochemistry particularlly in SF with DMSO group and vitrification with Stem Cell Keep® group, and mature spermatozoa were induced after 35 days of organ culture in these groups. ICSI showed fertility of induced spermatozoa only in vitrification using Stem Cell Keep® group.

Limitations, reason for caution: Supplementary research is required to confirm this study's findings using human prepubertal testicular tissue.

Wider implications of the findings: An optimal cryopreservation protocol enhances the chances for successful fertility restoration.The findings of the present study have potential implications for cryobanking of immature testicular tissue and fertility preservation. Vitrification using DMSO free cryoprotectant would be a preferable cryopreservation method for later induction of fertile spermatozoa.

Study funding/competing interest(s): Funding by University(ies) – The authors declare that no competing interests exist.

Trial registration number: This study is not an RCT.

Keywords: cryopreservation, testicular tissue, slow freezing, vitrification

P-470 Should letrozole-gonadotropin stimulation be the first choice for young cancer patients desiring oocyte cryopreservation?

T. Almeida-Santos[1], M. Moura-Ramos[2], C. Melo[2], A. P. Sousa[3]

[1]*University of Coimbra Faculty of Medicine, Servico de Medicina da Reproducao Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal*

[2]*University of Coimbra, Faculty of Psychology, Coimbra, Portugal*

[3]*University of Coimbra, Servico de Medicina da Reproducao Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal*

Study question: Could the association of letrozole to gonadotropins be beneficial in terms of oocyte yield in young cancer patients?

Summary answer: Letrozole-gonadotropin stimulation in hormonosensitive breast cancer patients produced more mature oocytes than gonadotropin only stimulation in cancer patients and this was not associated with age or the amount of FSH administered.

What is known already: Short antagonist protocols with the association of aromatase inhibitors to gonadotropins are used for oocyte cryopreservation in the context of fertility preservation in hormonosensitive breast cancer patients to avoid the rise in estradiol levels. A synergistic effect with the release of endogenous FSH may result from the negative feedback of estradiol levels during the initial stimulation allowing the recruitment of a higher number of follicles.

Study design, size, duration: A cross sectional study was developed during the last 18 months including 22 female cancer patients (CP), 25 hormonosensitive breast cancer patients (Let) and 40 women with male factor infertility (IP) who underwent ovarian stimulation with short antagonist protocol and FSHr for oocyte collection.

Participants/materials, setting, methods: Stimulation was started on cycle day 3 in IP, any day of follicular phase or after 3 days of antagonist if on the secretory phase in Let and CP groups. Letrozole was initiated in Let the day before FSH start. Triptorrelin or hCG were used for inducing final oocyte maturation.

Main results and the role of chance: The number of mature oocytes was higher in IP (9.00 ± 5.00, $p = 0.015$) and Let (9.52 ± 6.12, $p = 0.011$) than in CP (5.09 ± 3.79), although the total amount of FSH administered was identical in the 3 groups. The Estradiol levels were significantly lower in day 5 in the Let patients (169.54 ± 136.04) versus CP (555.76 ± 426.66, $p = 0.001$) and IP (638.90 ± 393.27, $p < 0.0001$). On the triggering day estradiol was also significantly lower in Let (395.97 ± 205.41) versus CP (1070.68 ± 676.33, $p = 0.011$) and IP (1852.68 ± 890.08, $p < 0.0001$). Patient age was lower in CP (29.59 ± 4.27) than Let (33.80 ± 3.03, $p < 0.0001$) and IP (32.33 ± 3.42, $p = 0.014$). The difference in the starting day of the stimulation seems not to interfere with the outcome confirming the efficacy of random start protocols in fertility preservation patients.

Limitations, reason for caution: Despite the younger age of the CP group it could have a worse prognosis for oocyte collection than the IP group for unknown reasons, although the ovarian reserve was not evaluated. Cancer patients might have a reduced response to ovarian stimulation. The small number of patients was also a limitation.

Wider implications of the findings: Letrozole associated to gonadotropins in a random start protocol can be more effective than regular gonadotropin stimulation in cancer patients, even when hormonal levels are not detrimental. Induction of final oocyte maturation with triptorelin is effective and accelerates luteolysis, enabling regression of estradiol and progesterone to normal levels and the initiation of chemotherapy. If these findings are confirmed in larger studies this can be the first choice protocol for young cancer patient undergoing oocyte cryopreservation.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Centro Hospitalar e Universitário de Coimbra.

Trial registration number: NA.

Keywords: fertility presevation, letrozole, breast cancer, vitrification, protocol

P-471 Slush nitrogen vitrification of human ovarian tissue reduces stromal cells apoptosis and does not affect the expression of genes involved in stress and toxicity pathways

R. Talevi[1], V. Barbato[1], I. Fiorentino[1], T. Capriglione[1], R. Ronca[1], S. Braun[1], R. Ferraro[2], C. De Stefano[3], G. Mondrone[2], R. Gualtieri[1]

[1]*Università Degli Studi di Napoli Federico II, Dipartimento di Biologia, Napoli, Italy*

[2]*Iatropolis, Centro Genesis, Caserta, Italy*

[3]*Ospedale Moscati, Fisiopatologia Della Riproduzione, Avellino, Italy*

Study question: Does slush nitrogen (SN2) vitrification protect human ovarian tissue from apoptosis and preserve the expression of genes involved in human stress and toxicity pathway compared with liquid nitrogen (LN2) vitrification?

Summary answer: Results demonstrated that compared with LN2 vitrification, SN2 preserves the ultrastructure of follicles and stromal cells, and their DNA integrity. Moreover, the analysis of 84 genes involved in stress and toxicity pathway demonstrated that the expression of 12 genes was altered by LN2 and not SN2 vitrification.

What is known already: The efficiency of vitrification of human ovarian tissue is currently controversial. SN2 vitrification that increases the cooling rate and avoids the Leidenfrost effect has been shown to reduce cryoinjuries and improve human oocyte vitrification. In a preliminary study we recently showed that SN2 better preserves the ultrastructure of ovarian follicles compared to LN2 vitrification.

Study design, size, duration: We performed a control versus treatment study on human ovarian biopsies collected during laparoscopy from eleven consenting patients. Strips (2×4×1mm) were processed for histology, ultrastructure, TUNEL assay and expression of 84 genes involved stress and toxicity pathway through PCR array, either as fresh controls or after LN2 or SN2 vitrification.

Participants/materials, setting, methods: Ovarian strips were treated at RT in 25%, 50% (5min), and in 100 % (1min) vitrification solution (VS: MEM, HSA 20mg/ml, DMSO 10%, EG 26%, PVP 2.5%, sucrose 1M), plunged in LN2 or SN2 and thawed at 37°C in culture medium with 1M (15 seconds), 0.5M and 0.25M sucrose (5min).

Main results and the role of chance: 1043 follicles (control $n = 240$; LN2 $n = 476$; SN2 $n = 327$) were studied. Ultrastructural data on 27 follicles (control $n = 14$; LN2 $n = 6$; SN2 $n = 7$) showed intact oocytes in all samples. Morphometric analysis reported that SN2 better preserved follicular cells (SN2 = 73.3 vs LN2 = 23.1%) and stromal cells (SN2 = 35.4 vs LN2 = 9%), compared to control (follicular cells = 92%; stromal cells = 59.8%). Tunel assay showed an highly significant increase of stromal cells with fragmented DNA in LN2 samples (control = 0.5, LN2 = 2.3, SN2 = 0.4%). Utilizing RT–PCR array we found that LN2 resulted in an up-regulation in the expression of AQP2, CA9, CCL2, CFTR, CRP, DDB2, EPO, RAD51, TNF, and XPC and a down-regulation of ADM, ATG7 and AQP1 ($P < 0.05$). Conversely, only ATG7 was altered being down-regulated in SN2 samples.

Limitations, reason for caution: The RT-PCR data are preliminary and the study should be validated by in vitro culture and xenotransplantation of thawed ovarian strips.

Wider implications of the findings: As SN2 vitrification better preserves the ultrastructure/DNA integrity of follicles and stromal cells, and does not affect the expression of genes involved in human stress and toxicity pathway, it could improve the resumption of endocrine and reproductive functions in post-oncological patients after ovarian slices transplantation**.**

P-472 Female fertility preservation using oocyte vitrification: 7 years experience

S. Geber[1], G. Geber[1], M. M. Capanema[1], M. Sampaio[1]
[1]*ORIGEN, Assisted Reproduction, Belo Horizonte, Brazil*

Study question: Is oocyte vitrification a good alternative for female fertility preservation? Can it be used for all indications, i.e., infertility, social and cancer?
Summary answer: Our study shows that Vitrification is an excellent alternative to preserve female fertility and may be indicated for cases of women who need to delay pregnancy for social reasons and/or for women who will undergo treatment that increase the risk of fertility loss.
What is known already: The evolution of assisted reproduction techniques has allowed the development of vitrification that can be applied for oocyte preservation. Cryopreservation of oocytes is one of the most innovative techniques for fertility preservation against the effects of age and for those who are at risk of premature ovarian failure. As it is a relatively new technique, few authors reported their experience with large numbers of patients.
Study design, size, duration: A retrospective study was performed evaluating 182 patients that were submitted to treatment and had their oocytes cryopreserved, between July 2007 and July 2014. Patients were divided in 3 groups – Infertility (85), Social preservation (69) and Cancer (12); 16 were excluded due to lack of data.
Participants/materials, setting, methods: All women were submitted to COS with GnRH agonist protocol, GnRH antagonist protocol or of emergency protocol. Oocyte retrieval, ICSI, embryo culture, vitrification and desvitrification, were the same for all patients.
Main results and the role of chance: The mean age of the patients was 32.13 ± 5.5, 35.78 ± 5.3 and 31.4 ± 1.3 respectively for group Infertility, Social and cancer ($p < 0{,}0001$). The dose of gonadotropins used in the Social group was higher that in the Infertility group (2833.5 ± 695UI x 2301 ± 573UI - $p < 0.0001$). The number of follicles (22,4 ± 14,5 x 10,5 ± 8,79) and MII oocytes (22 ± 12,3 x 9,2 ± 7) were higher in the Infertility group than in the Social preservation group ($p < 0.0001$). A total of 589 MII oocytes from77 patients of the infertility group (86 cycles) were desvitrified. The mean number of oocytes was 6.84 ± 3.9 per cycle (range:1 to 21). The rate of survival was 87%, fertilization 78.6%, embryo development 93.5% and pregnancy 29.8%.
Limitations, reason for caution: This was a retrospective study and some bias may be present. Prospective studies are needed to confirm these results.
Wider implications of the findings: As it is a relatively new technique, few authors reported their experience with large numbers of patients, therefore our results might reassure that oocyte vitrification is an excellent alternative for female fertility preservation.
Study funding/competing interest(s): Funding by hospital/clinic(s) – ORIGEN.
Trial registration number: NA.

P-473 Oocyte freezing for social indications: how do men and women's views differ? internet based survey of knowledge, attitudes and intentions in Denmark and United Kingdom

C. Lallemant[1], D. Vassard[2], A. Nyboe Andersen[3], L. Schmidt[2], N. Macklon[1]
[1]*Complete Fertility Centre Princess Anne Hospital, Women and Newborn, Southampton, United Kingdom*
[2]*University of Copenhagen, Department of Public Health, Copenhagen, Denmark*
[3]*Copenhagen University Hospital, The Fertility Clinic, Copenhagen, Denmark*

Study question: (1) Assess how knowledge and intentions regarding egg freezing differ between men and women. (2) Describe attitudes differences between men and women regarding circumstances which make it acceptable to freeze eggs. (3) Describe differences between men and women regarding circumstances which would make them more likely to freeze eggs.
Summary answer: 20% of women and 21% of men are interested in social egg freezing. Regarding circumstances making it more acceptable to freeze eggs, men were significantly more likely to find it acceptable to allow (1) women to pursue a career (2) for other care commitments, (3) if not ready.
What is known already: Our previous study showed that 89% of women considered reproductive planning to be an acceptable indication for social egg freezing, and around half would consider it for themselves. There is evidence that men's attitudes influence decisions made by women. However, little is known about men's considerations.
Study design, size, duration: A cross-sectional survey was designed to investigate individuals' knowledge and attitudes in Denmark and UK on oocyte freezing and their potential intentions regarding the procedure. Poster and internet based advertising was used to reach respondents in the general population. The questionnaire was accessible online (www.mycompletefamily.co.uk; www.mycompletefamily.co.dk) and completed anonymously.
Participants/materials, setting, methods: From September 2012 to September 2013, 1000 women and 237 men completed the questionnaire. Univariate analyses were used to identify differences between men and women regarding baseline characteristics, attitudes towards social egg freezing, circumstances which make it acceptable to freeze eggs, and circumstances which make freezing eggs more likely.
Main results and the role of chance: 80% men and women have heard of social egg freezing. 20% women were interested; 21% men were interested in their partner having the procedure. Regarding circumstance making it acceptable to freeze eggs, men and women had similar views with regards to social circumstances. However, men were significantly more likely to find it an acceptable option to allow women to pursue a career ($p = 0.023$), care commitments ($p = 0.005$) or not ready ($p = 0.028$). Regarding general circumstances making them more likely to freeze eggs, men and women had similar views, in particular concerning future fertility, safety, cost and percentage chance of having a baby from a cycle. Regarding personal circumstances however, men were significantly more likely to freeze eggs if stopping work would harm their partner's career ($p = 0.001$).
Limitations, reason for caution: The generalizability of the results may be limited due to the internet-based data collection, and may be subject to response bias.
Wider implications of the findings: This study indicates that men and women have similar attitudes regarding the acceptability of social egg freezing for medical reasons. With regards to social reasons however, men found it much more acceptable for women to freeze eggs to allow them to have a career, than women. Similarly, men are significantly more likely to agree to freeze eggs for this reason. Is this a reflection of a positive step towards gender equality? Of economic awareness?
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Merck Serono.
Trial registration number: Not a trial.
Keywords: social egg freezing, fertility awareness, reproductive life planning, gender equality, men's views

P-474 Preliminary reports of successful pregnancies derived from cryopreserved autologous oocytes of single women for social reasons

G. C. Jou[1], K. H. Chao[1], S. U. Chen[1], H. H. Lai[2], H. H. Chou[2], M. Y. Wu[1], H. F. Chen[1], Y. S. Yang[1]
[1]*National Taiwan University Hospital, Department of Obstetrics and Gynecology, Taipei, Taiwan R.O.C.*
[2]*Stork Ladies Clinic, Fertility Center, Hsin-Chu City, Taiwan R.O.C.*

Study question: With more single women seeking oocyte cryopreservation (OC) for fertility preservation, the value of OC for social reasons remains unclear.
Summary answer: This method would be a viable option of fertility preservation for single women with appropriate ages.
What is known already: The utilization of frozen/thawed oocytes for later IVF/ICSI has been proved to have similar fertilization and pregnancy rates to those with fresh oocytes in young women, and it has been used for fertility preservation of cancer patients, an alternative of embryo cryopreservation, or elective delay of childbearing (so-called social freezing). However, data were limited in women who attempt pregnancy purely from social OC.
Study design, size, duration: This is a two-center retrospective cohort study. A total of 240 single women (326 cycles) using OC for fertility preservation due to social reasons were included from January, 2002 to June, 2014.
Participants/materials, setting, methods: Single women underwent ovum pick-up cycles in National Taiwan University Hospital and Stork Fertility Center. OC was performed either by slow freezing or vitrification. The women returned to thaw their oocytes after marriage for pregnancy. The thawed oocytes

were fertilized with intracytoplasmic sperm injection, and embryo transfer was performed.
Main results and the role of chance: In this study, the mean age of OC was 38.1 ± 3.6 years old (y/o) with a mean of 9.7 ± 6.1 oocytes frozen per cycle. There were 11 women whose oocytes were thawed for pregnancy. In 6 women who froze their oocytes before 40 y/o, the mean oocyte survival and normal fertilization rate were 88.9% and 79.2%, respectively. All of them successfully became pregnant. Four women delivered live-born babies beyond 36 gestational weeks (GWs), one woman now was pregnant at 32 GWs, and one woman had blighted ovum but still had five extra-cryopreserved blastocysts. While in the other five women who froze their oocytes after 40 y/o, lower survival and fertilization rates (72.7% and 57.1%, respectively) were noted, and there was no pregnancy being achieved till now.
Limitations, reason for caution: Our limitation is small case number.
Wider implications of the findings: Although the value of OC in cancer or infertility patients has been documented, this remains unclear in social oocyte freezing for fertility preservation. In our preliminary results, we achieved successful pregnancies from oocytes cryopreserved for social reasons with appearing good success rates in women less than 40 y/o. We hope that more cases will be reported and this method will be a practicable option of fertility preservation for single women.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Funding by National Taiwan University Hospital. All authors declare no conflicts of interests.
Trial registration number: NA.
Keywords: fertility preservation, oocyte cryopreservation, social freezing

P-475 The use of *n*-hexyl-2-cyanoacrylate can facilitate the orthotopic ovarian transplantation

F. Fabregues Gasol[1], J. M. Calafell[1], A. Borras[1], D. Manau[1], O. Herrera[1], F. Carmona[1], J. Balasch[1]
[1]*Institut Clínic of Gynaecology Obstetrics, Department of Gynaecology and Obstetrics, Barcelona, Spain*

Study question: The use of N-hexyl-2-cyanoacrylate can facilitate the fixation of ovarian pieces in the orthotopic transplantation?
Summary answer: The use of N-hexyl-2- cyanoacrylate facilitates the laparoscopic orthotopic ovarian transplantation without affecting the restoration of their functional activity
What is known already: Two techniques has been successfully used to reimplant frozen-thawed ovarian tissue in an orthotopic site: in a specially created window on the peritoneum or on the remaining ovary. In case of small fragments they can be placed on the decorticated medulla but this is particulary difficult when performed laparoscopically. In this study we examined the usefulness of applying a available cyanoacrylate tissue adhesive in orthotopic transplantation**.**
Study design, size, duration: Observational case-series study. Three patients to whom ovarian tissue transplantation was performed between 2013 and 2014 by laparoscopy were studied.
Participants/materials, setting, methods: Ovarian tissue from 3 patients (Patient 1 with nasopharyngeal cancer, Patients 2 and 3 with breast cancer) was cryopreserved with slow freezing protocol prior to chemo-and/or radiotherapy. After cancer remission, the cryopreserved ovarian tissues were retransplanted orthotopicaly in the ovarian medulla laparoscopically, using *n*-hexyl-2-cyanoacrylate as an absorbable adhesion barrier.Endocrine function was assessed by monthly blood tests and ultrasound after transplantation.
Main results and the role of chance: All 3 patients regained ovarian function between 8 and 24 weeks after transplantation, as shown by follicle development and estrogen production. Ovarian function persists 6 months(patient transplanted in july 2014) and one year after transplantation (2 patients). Pregnancy was not obtained in any of the patients still.
Limitations, reason for caution: Preliminary study wich includes few patients
Wider implications of the findings: The use of N-hexyl-2- cyanocryalate can facilitate the placement of ovarian pieces in the orthotopic transplantation by laparoscopy without affecting the restoration and duration of ovarian activity
Study funding/competing interest(s): Funding by hospital/clinic(s) – Hospital Clinic.
Trial registration number: NA.

P-476 The negative influence of sperm cryopreservation on the quality and development of the embryo depends on the morphology of the oocyte

R. C. S. Figueira[1], D. P. A. F. Braga[2], A. S. Setti[2], A. Iaconelli Jr.[3], F. F. Pasqualotto[4], E. Borges Jr.[3]
[1]*Fertility - Centro de Fertilização Assistida, IVF Laboratory, Sao Paulo, Brazil*

[3]*Fertility - Centro de Fertilização Assistida and Instituto Sapientiae - Centro de Estudos e Pesquisa em Reprodução Assistida, Clinical Department, Sao Paulo, SP, Brazil*
[4]*Universidade de Caxias do Sul, Clinical Department, Caxias do Sul RS, Brazil*

Study question: (i) Is there any effect of sperm cryopreservation on embryo quality and chance of blastocyst formation? (ii) Is there any oocyte quality-dependent negative effect of sperm cryopreservation on embryo quality and the chance of blastocyst formation?
Summary answer: There is an oocyte quality-dependent negative effect of sperm cryopreservation on embryo quality and the chance of blastocyst formation.
What is known already: Sperm cryopreservation represents a valuable therapeutic option in the management of infertility. However, during the process of cooling, freezing and thawing, spermatozoa are subjected to a series of changes, which may cause cell damage. Although the ICSI may circumvent some of the problems with sperm quality, whether ICSI can overcome the effect of the cryodamage of sperm and, therefore, avoid detrimental effects on the quality and development of the embryo, has yet to be elucidated.
Study design, size, duration: This study included 22,186 zygotes, obtained from 2802 patients undergoing ICSI cycles with either fresh (n = 2435) or cryopreserved (n = 367) sperm. The effect of sperm cryopreservation on embryo quality and on blastocyst formation chance was evaluated when the oocyte quality was not considered and when at least one oocyte dimorphism was present.
Participants/materials, setting, methods: To elucidate whether the oocyte quality-dependent influence of the injection of cryopreserved sperm was due to an extracytoplasmic or intracytoplasmic oocyte defect, two more groups were formed: Embryos derived from oocytes with at least one intracytoplasmic defect and embryos derived from oocytes with at least one extracytoplasmic defect.
Main results and the role of chance: The binary regression model showed that the embryo quality and the blastocyst formation chance were not influenced by the origin of the sperm when the quality of the oocyte was not considered. However, when at least one oocyte defect was present, a negative influence of the sperm cryopreservation on the embryo quality (OR = 0.90, CI: 0.85-0.96, $p > 0.001$) and blastocyst formation chance (OR = 0.83, CI: 0.76-0.92, $p > 0.001$) was noted. The injection of cryopreserved sperm into oocytes with extracytoplasmic dimorphisms did not affect the embryo quality, but did affect the blastocyst formation chance (OR = 0.79, CI: 0.59-0.95, $p = 0.015$). Conversely, the embryo quality (OR = 0.58, CI: 0.32-0.76, $p > 0.001$) and the blastocyst formation chance (OR = 0.95, CI: 0.92-0.99, $p = 0.046$) were negatively influenced by the injection of cryopreserved sperm in oocytes with intracytoplasmic defects.
Limitations, reason for caution: The main limitation of this study is its retrospective design.
Wider implications of the findings: Apparently, when at least one morphological defect is present, the oocyte is not able to repair a possible negative effect of sperm cryopreservation; therefore, the embryo quality at the cleavage stage and the blastocyst formation are negatively affected. Considering this, for patients undergoing ICSI cycles, in which oocyte defects are detected, the injection of fresh sperm, if possible, would be a better approach.

P-477 A comparison of methylation levels in HPV16, HPV18 and HPV51 genomes in asymptomatic HPV infection and cervical neoplasia

V. Simanaviciene[1], V. Popendikyte[2], Z. Gudleviciene[3], B. Zilaitiene[4], A. Zvirbliene[5]
[1]*Vilnius University, Institute of Biotechnology, Vilnius, Lithuania*
[2]*Thermo Fischer Scientific, Thermo Fischer Scientific Baltic, Vilnius, Lithuania*

[3]*Vilnius University, Institute of Oncology, Vilnius, Lithuania*
[4]*Lithuanian University of Health Sciences, Institute of Endocrinology, Kaunas, Lithuania*
[5]*Vilnius University, Institute of Biotechnology, Kaunas, Lithuania*

Study question: Relationship between methylation status in the L1 gene and the long control region (LCR) of HPV16, HPV18, HPV51 and cervical pathology.
Summary answer: The study revealed that methylation of CpG was more prevalent in the L1 gene as compared to the LCR region of all three HPV types and methylation level correlated with the severity of cervical neoplasia.
What is known already: Human papillomaviruses (HPVs) are common sexually transmitted viruses that can cause cervical cancer and affect female fertility. Epigenetic alterations of HPV genome play an important role in the life cycle of virus and the carcinogenic progression.
Study design, size, duration: A total of 202 cervical specimens were analysed for methylation of HPV DNA: 157 HPV16-positive specimens, 21 HPV18-positive specimens and 24 HPV51-positive specimens.
Participants/materials, setting, methods: The HPV genome was analysed using bisulfite modification, DNA amplification and sequencing.
Main results and the role of chance: The highest methylation frequency of HPV16 was detected at the L1 gene (35.5%) and promoter region (32.3%) in the subgroup of cervical cancer. In other LCR regions it ranged from 0% in asymptomatic HPV16 infection and cervical intraepithelial neoplasia grade 1/2 to 25.7% in cervical cancer. Statistically significant differences after Bonferroni correction were detected between the asymptomatic HPV16 infection and cervical cancer in the L1 region (P = 0.0027). The study also revealed that all HPV18-positive specimens were methylated in the L1 gene in the subgroups of cervical intraepithelial neoplasia grade 3 or carcinoma in situ and cervical cancer. In contrast, the methylation level of the LCR region was very low among all HPV18-positive samples. For the first time, methylation pattern of HPV 51 in cervical cancer has been investigated and compared to that of asymptomatic HPV51 infection and cervical intraepithelial neoplasia grade 1/2. The methylated CpG sites of HPV51 were detected in the L1 gene only in a case of cervical cancer. All other regions of HPV51 were unmethylated in all tested samples.
Limitations, reason for caution: Sample size of the collected speciments of HPV18 and HPV51 was small because of the low prevalence of these genotypes in the population. Most probably this was the reason why there were no significant differences in the methylation frequencies of these genotypes when pathology groups were compared.
Wider implications of the findings: Further investigation of methylation of HPV genome might lead to better understanding and earlier diagnostics of cervical pathology and fertility preservation in women at high risk for cervical cancer.
Study funding/competing interest(s): Funding by University(ies) – Institute of Biotechnology, Vilnius University.
Trial registration number: No trial registration number.
Keywords: human papillomavirus, methylation, cervical pathology

P-478 Prospective study analysing maturation rates of vitrified metaphase 1 stage (M1) oocytes from in vitro maturation and stimulated cycles compared with fresh M1 oocytes

C. Sifer[1], O. Sellam[1], N. Sermondade[1], C. Herbemont[1], C. Sonigo[2], A. Benoit[2], I. Cedrin Durnerin[2], F. Eustache[1], J. N. Hugues[2], R. Levy[1], C. Poncelet[2], M. Grynberg[2]
[1]*Hôpital Universitaire Jean Verdier, Histologie-Embryologie-Cytogénétique-CECOS, Bondy, France*
[2]*Hôpital Universitaire Jean Verdier, Médecine de la Reproduction, Bondy, France*

Study question: Could metaphase 1 (M1) and 2 (M2) stages oocytes from in vitro maturation (IVM) and controlled ovarian hyperstimulation cycles (COH), performed in cancer patients, be frozen in the same time without adverse effect of the vitrification process on further survival (SR) and maturation rates (MR)?
Summary answer: SR of M1 oocytes from IVM or COH are similar with that of M2 oocytes. MR of survived M1 oocytes from COH is similar with that of fresh M1 oocytes. However, MR of M1 oocytes from IVM is significantly decreased compared with that of fresh M1 oocytes.
What is known already: Vitrification of M2 oocytes from COH or IVM may be indicated in the strategy of female fertility preservation. To freeze M1 oocytes at the same time as M2 rather than expecting their eventual further maturation could be a valuable option making the complete procedure easier with only one time of vitrification. To date, nothing is reported concerning this approach.
Study design, size, duration: From November 2013 to October 2014, seventy-two patients suffering from cancer, candidates to oocyte vitrification following IVM (n = 24: 9 studied/15 control IVM group) or after COH (n = 46: 17 studied/31 control COH group) were prospectively included. In addition, 9 egg donors having vitrified M2 oocytes were used as controls.
Participants/materials, setting, methods: Twenty-eight Day-1 and 32 Day-0 M1 oocytes, obtained from studied IVM and COH groups respectively, were frozen using the cryotop device. Warming was immediately performed after freezing and SR were compared with that of 51 M2 oocytes vitrified/warmed from egg donors. MR of survivor oocytes were compared with those of M1 oocytes from control IVM (n = 44) and COH (n = 53) groups, after 24 hours of culture into appropriate media.
Main results and the role of chance: SR of vitrified M1 oocytes after warming were of 87.7 and 76.9%, respectively in the studied IVM and COH groups compared to 89.6% for M2 oocytes, used as controls. No statistical difference of SR was observed between these groups (global p value: p = 0,8). Survived M1 oocytes from the studied COH group reached a 78.9% of MR compared with 81.5% for fresh M1 oocytes from the control COH group ($p > 0.05$). Nevertheless, MR of vitrified/warmed M1 oocytes from the studied IVM group (39.1%) was significantly lower when compared with the control IVM group (74.2%; p = 0.03). Our study showed similar SR of vitrified M1 oocytes following IVM or COH when compared with those of mature oocytes. Furthermore, conversely to the effect observed with M1 oocytes recovered after COH, vitrification procedure may adversely affect the meiotic competence of M1 IVM oocytes having survived thawing.
Limitations, reason for caution: The present findings should be confirmed on a larger series of oocytes in each group.
Wider implications of the findings: In a fertility preservation program, vitrifying M1 and M2 oocytes in the same time could be applied in patients having undergone COH but not IVM.
Study funding/competing interest(s): Funding by University(ies) – Funding by hospital/clinic(s) – Jean Verdier University Hospital.
Trial registration number: Not needed.
Keywords: metaphase 1 oocytes, in vitro maturation, controlled ovarian hyperstimulation cycles, vitrification, maturation rate

P-479 Pressure triggered activation of tolerance (PTAT)-preconditioning of spermatozoa has a positive impact on post-thaw recovery rate of cryopreserved human semen

B. Farago[1], K. Szabo[1], C. Budai[1], N. Pasztor[2], J. Szöllösi[2], S. Matyas[3], J. Cserepes[1]
[1]*Applied Cell Technology Ltd., Administrative Center and Laboratory, Budapest, Hungary*
[2]*University of Szeged, Obstetrics and Gynecology Department, Szeged, Hungary*
[3]*Kaáli Institute, IVF Center, Budapest, Hungary*

Study question: Is it possible to adapt preconditioning by the application of pressure triggered activation of tolerance (PTAT) prior to standard slow freezing procedure, in order to successfully increase human sperm cell recovery rate (characterized by post-thaw motility), as it is already shown in animal species like bovine, porcine, sheep, etc.?
Summary answer: Similarly to previous animal studies, optimizing PTAT-treatment protocol (pressure, duration and equilibration time before freezing) to human spermatozoa could significantly increase the recovery rate of human semen samples, compared to the paired controls frozen without conditioning pretreatment.
What is known already: The application of PTAT-treatment prior to freezing or other in vitro procedures has been shown to successfully decrease the adverse effects of intervention and help cell survival in several species (bovine, porcine, sheep, mouse) and cell types (oocytes, sperm cells, embryos, etc.). To our knowledge, no data have been published on the application of PTAT in human sperm cryopreservation; however, this novel technology might successfully contribute to the improvement of cell survival after freezing.
Study design, size, duration: Semen samples of 21 Caucasian men were included in this proof-of-concept study. Fifteen samples were used to optimize PTAT-parameters (magnitude of pressure, duration of the treatment and the

equilibration time between PTAT and freezing); and 6 semen to validate the optimum settings. Samples were evaluated 60 minutes after thawing.
Participants/materials, setting, methods: All patients met the inclusion criteria. PTAT was performed by the programmable GBOX equipment (AppliedCellTechnology, Budapest, Hungary). Freezing was performed by an IceCube 14S controlled rate freezer (Sy-Lab, Neupurkersdorf, Austria), using a standard slow freezing procedure. After thawing, total, progressive and non-progressive motilities were defined by CASA (Microptic, Barcelona, Spain).
Main results and the role of chance: We have set up several PTAT-parameters from 10 to 50 MPa and 30 to 90 minutes, followed by 10 to 90 minutes of equilibration time before starting the slow freezing protocol of the samples. After thawing the straws, each treatment groups were compared to the matched control and each other, in order to find the optimal treatment conditions. The application of the most effective PTAT-parameters resulted in elevated progressive motilities measured 60 minutes after thawing (20.7 ± 4.84 %), compared to the untreated controls (13.0 ± 2.57 %; mean ± SEM; $p < 0.05$; $n = 6$). All results were reproducible: the findings of each experiment days did not show any significant difference. These observations represent a good basis for further, in-depth examinations on a larger population.
Limitations, reason for caution: Whilst these results suggest that PTAT is able to improve human sperm cell survival after slow freezing, further refining of the treatment parameters is needed. Supplementing our findings by flow cytometry measurements (vitality, DNA-integrity) and morphological evaluations are currently in progress to prove the safety and efficacy of the method.
Wider implications of the findings: Semen cryopreservation as part of IVF procedure and fertility preservation (including sperm banking for donation) means a continuously growing demand. The safety and efficacy of cryopreservation procedures are of major importance, and special attention to any methods improving cell survival should be paid. Incorporating PTAT into conventional sperm freezing procedures has brought promising results, and after refining the protocol by further in-depth studies, it will probably represent an impressive evolution in cryobiology.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Applied Cell Technology Ltd.
Trial registration number: NA.
Keywords: pressure triggered activation of tolerance (PTAT), cryopreservation, human sperm, recovery rate

P-480 Prevention of chemotherapy-induced gonadotoxicity in the mouse model: protective effects of natural bioactive compounds

M. Vitti[1], A. Mancini[1], G. Di Emidio[1], M. Di Carlo[1], P. G. Artini[2], C. Festuccia[3], G. Carta[1], A. M. D'Alessandro[1], C. Tatone[1]
[1]*University of L'Aquila, Department of Health Life and Environmental Science, L'Aquila, Italy*
[2]*University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy*
[3]*University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy*

Study question: This work aims to investigate whether destruction of ovarian reserve by chemotherapy can be attenuated by administration of natural bioactive compounds with antitumoral effects. In particular, we asked whether phytochemicals from *Crocus sativus L*., commonly known as saffron, can prevent gonadotoxic effects of cyclophosphamide (CPM) in the mouse model.
Summary answer: Pre-treatment of mice with saffron phytochemicals (SP) reduces CPM-induced follicle loss and pyknosis. These effects are associated with decreased expression of FOXO3a, a component of the molecular pathway involved in the maintenance of ovarian reserve. Therefore, administration of SPs may be a potential strategy to reduce gonadotoxic effects of chemotherapy.
What is known already: CPM-based chemotherapy severely impacts ovarian reserve. Although mechanisms underlying CPM gonadotoxicity remain poorly understood, CPM was found to cause follicle burnout by activating PI3K/PTEN/AKT pathway involved in suppression/activation of follicle recruitment throughout FOXO3a activation/inhibition. Since FOXO3a activates antioxidant gene expression, oxidative stress (OS) is supposed to be involved in CPM-induced ovarian damage. SPs (mainly represented by carotenoids crocin and crocetin) exhibit their biological activities *in vitro* and *in vivo* as antioxidants and anti-tumour compounds.
Study design, size, duration: Twenty-four CD-1 female mice were divided in four groups and received a single intraperitoneal injection of 100 ml of PBS (CTRL), or an equal volume containing CPM (100 mg/kg) (CPM), saffron extract (300mg/Kg) *per os* for fifteen days (SE), or saffron extract prior to CPM administration (SE + CPM).
Participants/materials, setting, methods: Ovaries were analysed at 24hr post-CPM for FOXO3a expression by Western blotting (WB). At 7 days post-CPM ovaries were monitored for relative abundance of ovarian follicles by hematoxylin-eosin and immunostained for FOXO3a. DNA damage and OS were evaluated by assessing gH2AX-phosphorylation and advanced glycation endproducts (AGEs) accumulation by immunohistochemistry (IHC).
Main results and the role of chance: SE administration prior to CPM-treatment decreased chemo-induced follicles loss, cell pyknosis and molecular damage. The number of primordial and antral follicles was significantly reduced in CPM-mice when compared with control (OneWay ANOVA, Student-Newman-Keuls Multiple Comparison: $p < 0.001$), whereas in the SE + CPM group these follicle classes were similar to control. WB and IHC showed decreased FOXO3a expression in CPM-mice suggesting the activation of CPM-induced follicle recruitment. Consistently, FOXO3a level in the SE + CPM group was similar to control ($p < 0.05$). IHC showed that AGEs increased in CPM and SE + CPM group in comparison to control ($p < 0.05$). Immunostaining revealed increased DNA double strand breaks in CPM, while in SE + CPM they were similar to control ($p < 0.05$). These results indicate that antioxidant compounds may counteract chemo-induced oxidative damage and restore physiological follicle recruitment.
Limitations, reason for caution: Pathways other than antioxidant response could mediate the protective effects of SE. FOXO3a up-and-downstream pathways have not been investigated. Results can be translated to humans with caution.
Wider implications of the findings: Results from this study aims to increase the knowledge of biological and molecular aspects underlying ovarian chemotoxicity and will be helpful to evaluate the possibility to save or rescue fertility in cancer patients. Also, our data may contribute to define new biomolecular markers useful for the evaluation of the level cytotoxicity of innovative pharmacological anticancer treatments and the differential protective potential of molecules in relation to specific anticancer therapies.
Study funding/competing interest(s): Funding by University(ies) – University of L'Aquila.
Trial registration number: Not required.
Keywords: cyclophosphamide, ovarian chemotoxicity, saffron extract, fertility preservation

P-481 Ovarian tissue cryopreservation assisted by computer tomography

R. R. Ramon Risco[1], A. C. Ariadna Corral[2], C. A. Christiani Amorim[3], M. B. Marcin Barczyk[4], M. M. D. Marie-Madeleine Dolmans[3], J. F. Julio de la Fuente[5]

[3]*Universite Catholique de Louvain, Faculté de Médecine et Médecine Dentaire, Louvain, Belgium*
[4]*CNA, CSIC-University of Seville, Seville, Spain*
[5]*INIA, Departamento de Reproduccion Animal, Madrid, Spain*

Study question: Ovarian tissue cryopreservation for transplantation is opening a new field in ART. Conventional Slow Freezing is the most used technique, although is not completely satisfactory. Computer Tomography is able to show a 3D map of the concentration of DMSO as well as the eventual presence of ice. Human and animal ovarian tissue cryopreserved by Slow Freezing has been analysed by a nanoCT (BioScan), offering a power tool for the optimization of the cooling and warming protocols.
Summary answer: We have used a nanoCT to measure the amount of cryoprotectant uptaken by ovarian tissue. The high number of electrons of the sulphur atom in the DMSO molecule, makes it visible. This is a unique property of DMSO, not shared with other cryoprotectants.
What is known already: Computer Tomography is an interesting medical tool. It is based mainly in differences of densities, so in principle it is not useful for cryoprotectants based on alcohol groups. However, DMSO can be easily detected by CT.
Study design, size, duration: A set of four ovarian tissues (human and animal origin) were submitted to a slow freezing protocol based on 10% initial

concentration of DMSO. After ice seeding, the tissues were cooled to -40 deg C and then LN2 vapors till -140 deg C. Finally they were stored. The concentration and distribution of cryoprotectant, the presence of ice and the morphology of the tissue were studied by computer tomography.
Participants/materials, setting, methods: Materials: two samples of cow ovarian tissue, two samples of human ovarian tissue and a microCT (BioScan).
Main results and the role of chance: The pattern of distribution of ice and DMSO in a 3D map was obtained. Very explicit images of how the tissue concentrates the DMSO during the cooling protocol showed up. Also the structure of the dendrites of ice in the extracellular media appeared. This information is CRITICAL for the design of a protocol not based in Slow Freezing but in Equilibrium Vitrification (Liquidus Tracking), that is the ultimate goal of our research.
Limitations, reason for caution: The number of samples and the cooling/warming rates should be studied in a parametrical way.
Wider implications of the findings: This study is critical for the improvent of slow freezing protocols of ovarian tissue, as well as whole ovary. Also is critical for the extension of cryopreservation to Equilibrium Vitrification.
Study funding/competing interest(s): Funding by University(ies) – University of Seville.
Trial registration number: 1.
Keywords: ovarian tissue, cryopreservation, computer tomography

P-482 Recellularization of "ghost" testicular matrix using a gas-liquid interphase method

Y. Baert[1], L. Björk[2], O. Söder[2], J. B. Stukenborg[2], E. Goossens[1]
[1]*Vrije Universiteit Brussel, RGRG, Brussels, Belgium*
[2]*Karolinska Institutet, KBH, Stockholm, Sweden*

Study question: Is it possible to reconstitute the tubular seminiferous epithelium in DTM (decellularized testicular matrix)?
Summary answer: A recellularized testicular scaffold could be obtained after inoculation in DTM and short-term culture (36 h) using a gas-liquid interphase method.
What is known already: Full spermatogenesis using three-dimensional or organ culture systems has been reported only in the rodent so far. Recently, a promising step was made towards a human application with the report on the derivation of cytocompatible DTM from human testis with maintenance of important components and characteristics of the native tissue. Nevertheless, the method of cell inoculation still needed further improvement.
Study design, size, duration: DTM was derived by exposing cadaveric testicular tissue fragments to 1% sodium dodecyl sulphate. Afterwards, total adult human testicular cell suspensions were incubated on DTM discs during short-term culture and analysed microscopically for the presence of germ cells and somatic cells.
Participants/materials, setting, methods: Adult cadaveric testes were harvested by the autopsy department of the UZ Brussel. Fresh testicular tissue was obtained from four patients undergoing bilateral orchiectomy as part of a prostate cancer treatment. Picrosirius red-hematoxylin staining was used to study the testicular cell-DTM interaction.
Main results and the role of chance: DTM discs stained positive for picrosirius red indicating the presence of collagen molecules in this natural scaffold and showed a three-dimensional hollow structure devoid of cells. After inoculation and short-term culture using a gas-liquid phase approach, a good retention of testicular cells was observed in DTM. Cells showing distinct morphology typically for germ or somatic cells filled the tubular and interstitial space.
Limitations, reason for caution: More in-depth analyses on the homing of the cells and their gene and protein expression are warranted and will be performed to confirm the current findings. In addition, it is important to evaluate the function of the cells in the scaffold.
Wider implications of the findings: The ability to reconstitute the seminiferous epithelium in-vitro using DTM as scaffold can ultimately help establishing human in-vitro spermatogenesis which has not yet been achieved. Such a system could be used in fundamental studies unrevealing the mechanisms behind spermatogenesis and has an enormous clinical value as it could treat certain male fertility disorders. Also, it would be an interesting tool in toxicology to screen for reprotoxic compounds.
Study funding/competing interest(s): Funding by University(ies) – Funding by national/international organization(s) – Agency for Innovation by Science and Technology (IWT), Kom Op Tegen Kanker (KOTK), Scientific Research Foundation Flanders (FWO), Vrije Universiteit Brussel (VUB), Swedish Research Council, Finnish Academy, Emil och Wera Cornells Stiftelse.
Trial registration number: NA.

P-483 The effect of vitrification on morphology and apoptosis of human ovarian cortex tissue

X. Wang[1], C. Fang[1], C. G. Di[1], Y. N. Shi[1], X. Y. Liang[1]
[1]*The Sixth Affiliated Hospital of Sun Yat-Sen University, Reproductive Medicine Research Center, GuangzhouGuangdong, China*

Study question: To examine the effect of the operation of vitrification on morphology and apoptosis in human ovarian cortex tissue.
Summary answer: The strategy of vitrification of human ovarian tissue is viable, and still needs more researches.
What is known already: There have been appoximately 26 babies coming from cryopreserved ovarian tissues, most of which were benefiting from the technique of slow freezing, or programmed freezing. In 2005, Silber S.J. has proposed the technique of vitrification could applied in cryopreservation of ovarian tissues, which may also provide a simplified, cheap and reliable method.
Study design, size, duration: Ovarian tissues came from 4 cases of partial ovariectomy, with necessity of diagnosis or treatment, during Nov. 2012 to Feb. 2013. In each case, small pieces of cortex were randomly divided into Fresh Group and Vitrification Group. And then, we conducted vitrification or not according to their groups.
Participants/materials, setting, methods: Inclusion criteria of ovarian tissues were under 40 years old, without any abnormal cells in pathological examination. Morphology of follicles and stromal cells were examined by HE staining, and cell apoptosis in situ was analyzed by TUNEL assay. Furthermore, we quantified the expression of Cleaved Caspase-3 (an indicator of apoptosis).
Main results and the role of chance: The percentage of primordial follicles, primary follicles and secondary follicles in Fresh Group are 53.33%, 35.56% and 11.11% respectively, while the percentage in Vitrification Group are 50.56%, 40.45% and 8.99%. The percentage of primordial follicles, primary follicles and secondary follicles and the apoptosis in situ show no significance between these two groups. Besides, the expression of Cleaved Caspase-3 in ovarian tissue is the same between two groups.
Limitations, reason for caution: Because the eligible ovarian tissues were really rare, the size of study is limited.
Wider implications of the findings: The results are of certain value for providing evidence that vitrification is feasible to preserve fertility of women who suffer from chemotherapy or radiotherapy because of their cancer and desire to have their own babies.
Study funding/competing interest(s): Funding by national/international organization(s) – National Natural Science Foundation of China(Grant no.81070495), and Natural Science Foundation of Guangdong Province(Grant no.S2013010013404).
Trial registration number: NA.

[3]*Federal University Of Ceará, Group of Research in Biology of Reproduction – Department of Animal Science, Fortaleza, Brazil*
[4]*INRA Nouzilly France, PRC, Nouzilly, France*

Study question: To evaluate the importance of the membrane transport proteins, aquaporins (AQPs) 3, 7 and 9 during cryoprotectant perfusion, vitrification and *in vitro* culture of ovine ovarian tissue.
Summary answer: Exposure to cryoprotectants ethylene glycol (EG) and dimethylsulfoxide (DMSO) lead to AQP3 up-regulation.
What is known already: AQPs are involved in the transport of diverse solutes including cryoprotectants such as glycerol, EG and DMSO. We found recently the expression of aquaporins in ovine ovarian follicles.
Study design, size, duration: Ovarian tissue from sheep ($n = 9$) were exposed to cryoprotectants (EG, DMSO or both), vitrified and *in vitro* cultured for 48 hours after thawing.
Participants/materials, setting, methods: All experiments were performed using slaughterhouse material from nine sheep. After exposure to cryoprotectants, vitrification and *in vitro* culture, ovarian tissue w submitted to histological analysis as well as mRNA expression of markers for AQP3, 7 and 9 and immunohistochemistry to assess the expression of these proteins.
Main results and the role of chance: Expression of AQP3 was increased after exposure to EG and DMSO, probably due to hyperosmolarity in the medium. AQP3 proteins were located in the granulosa cells of preantral follicles. Down-regulation of AQP9 was observed after exposure to EG and DMSO.
Limitations, reason for caution: Expression of more transporters involved during cryoprotectant perfusion needs to be assessed.
Wider implications of the findings: This study enhance the knowledge about aolute transport, osmotic stress and aquaporins involved during ovarian tissue vitrification.
Study funding/competing interest(s): Funding by national/international organization(s) – This work was supported by CNPq (UNIVERSAL: grant number 475628/2011-0). Antonia Debora Sales is a recipient of a grant from FUNCAP Brazil. In addition, Ana Paula Ribeiro Rodrigues and José Ricardo de Figueiredo are recipients of a grant from CNPq Brazil.
Trial registration number: 475628/2011-0.

P-485 Planned and unplanned fertility in breast cancer survivors: prospective cohort study in breast cancer patients following cancer treatment

N. Reddy[1], J. Kopeika[1], A. Kugadas[2], Y. Khalaf[3], A. Shewbridge[4], D. Mukerjee[4], I. Sandri[5], J. Mansi[5]
[1]*Guy's and St.Thomas's Hospital, Reproductive Medicine, London, United Kingdom*
[2]*King's College London, Medical School, London, United Kingdom*
[3]*Guy's and St Thomas Hospital, Reproductive Medicine, London, United Kingdom*
[4]*Guy's and St Thomas Hospital, Breast Unit, London, United Kingdom*
[5]*Guy's and St Thomas' NHS Foundation Trust and King's College Biomedical Research Centre, Breast Unit, London, United Kingdom*

Study question: The aim of this study was to establish the incidence of conception in women of reproductive age group following breast cancer treatment, including those who attempted and those who did not plan a pregnancy
Summary answer: Even though significant proportion of women wished to conceive, only a small proportion actively attempted to do so with half of them being successful. Unexpectedly we identified several unplanned pregnancies that were terminated, causing undue distress for these women.
What is known already: There are numerous studies highlighting the importance of offering fertility preservation to women of reproductive age diagnosed with breast cancer, which is one of the most common cancer in this age group. There are also multiple surveys assessing the attitude of cancer patients and medical professionals towards the option of fertility preservation at the time of diagnosis. However, the pregnancy rate after successful cancer treatment has not been sufficiently studied.
Study design, size, duration: A questionnaire survey regarding fertility intent and pregnancies achieved was prospectively conducted between July 2011 and December 2013 in a tertiary breast cancer centre in South-East London, UK.
Participants/materials, setting, methods: Women between 25 and 42 years of age at the time of cancer diagnosis from 2000-2010 who continued to attend for follow up were identified from the local breast cancer registry. A questionnaire was given to 282 women at one of their outpatient appointments.
Main results and the role of chance: The mean age of patients at the time of cancer diagnosis was 37.2 ± 3.9 years. Systemic chemo and hormonal therapies were given to 212 (75%) and 124 (44%) of responders respectively. 136 (48%) women were childless at the time of cancer diagnosis. At the time of the survey 90 (32%) patients wished to have children. Pregnancy was actively attempted by only 28 (10%) women and live birth achieved by 15 (54%). However, there were also 11 pregnancies reported among those who did not plan to conceive: 7 were terminated, 2 miscarried and 2 resulted in live birth. Among patients who did not wish to conceive 146/198 (74%) reported not using any contraception.
Limitations, reason for caution: Even though this cohort is a large representation from the cancer network of breast cancer patients of reproductive age, there is still a possibility of population bias.
Wider implications of the findings: In spite of high rate of childless women diagnosed with breast cancer, only 10% of women subsequently attempted to conceive 6.9 ± 3.1 years since their treatment with 32% still considering pregnancy. Medical professionals must be increasingly aware of the need to provide contraceptive advice and risk of pregnancy following chemotherapy.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Supported by a grant from Guy's and St Thomas's Charity.
Trial registration number: NA.

P-486 Letrozole co-treatment does not jeopardize effectiveness of controlled ovarian hyperstimulation for oocyte vitrification in breast cancer patients

T. Navarro Gonzalez[1], E. Ceballos García[1], V. Moreno Molinero[1], L. Perez Martín[1], S. Guillen[1], M. Ardoy Vilches[1], M. Caballero[1], Y. Gomez Sarabia[1], L. Ortiz Quintana1, F. Pérez Milán[1]
[1]*Hospital General Universitario Gregorio Marañon, Reproductive Medicine Unit, Obstetrics and Gynaecology Department, Madrid, Spain*

Study question: To assess letrozole effect on OCH effectiveness for oocyte vitrification in breast cancer patients in terms of number of retrieved oocytes
Summary answer: Letrozole addition to ovarian estimulation protocol in breast cancer patients treated for oocyte vitrification allows to mantain low estradiol levels and does not reduce total and mature oocyte number compared to healthy IVF controls.
What is known already: Letrozole co-treatment during ovarian hyperestimulation for oocyte cryopreservation is generally applied in breast cancer patients with positive estrogen receptor tumours, in order to diminish serum estradiol increase due to gonadotropin effect. This strategy focuses on safety, but it could have a non desirable effect on effectivity of the procedure, in terms of reduced number of retrieved oocytes.
Study design, size, duration: Retrospective cohort study comparing 96 breast cancer patients undergoing controlled ovarian hyperstimulation for oocyte vitrification and 350 IVF healthy controls. Main results considered were numbers of total and mature oocytes. Study was performed between 2010 and 2014. Follow-up was held from starting of stimulation to oocyte retrieval.
Participants/materials, setting, methods: A cohort of 96 breast cancer patients undergoing oocyte vitrification recieved letrozole, low-medium FSH doses and GnRH-antagonist protocol in a tertiaty university center fertility preservation program. This group was compared with a randomly-selected cohort of 350 IVF patients, matched by age and AFC. Median comparisons and relative risk estimation were used.
Main results and the role of chance: Letrozole-exposed patients and IVF controls were comparable in age, antral follicular count, starting FSH dose and total FSH consumption. In breast cancer patients, ovarian stimulation was significantly longer (medians: 9 vs 8 days; $p = 0,04$), final serum estradiol was predictably lower (medians: 223 vs 1327 pg/mL; $p < 0,001$), and number of total retrieved oocytes was significantly higher (medians: 10 vs 8 oocytes; $p = 0,04$), although medians of mature oocytes were comparable (7 vs 6; $p = 0,097$). Letrozole exposition was not associated with an increase of cancellation rate (9/96 vs 38/350; RR:0,86; 95%CI:0,43-1,72; $p = 0,41$). No significant differences were observed in probability of obtaining less than 5 oocytes (17/87 vs 75/312; RR:0,81; 95% CI: 0,5-1,3; $p = 0,23$) or less than 12 oocytes (55/87 vs 226/312; RR:0,87; 95% CI: 0,73-1,03; $p = 0,064$).
Limitations, reason for caution: Controls were matched by age-stratified randomized selection, to ensure control of potential confounding effects.

We have not considered live-birth rate as main outcome because of necessary delaying of pregnancy in breast cancer patients. Even though observed effect of letrozole was not unfavourable, statistical power to assess hypothesized effect was low.
Wider implications of the findings: Randomized clinical trials focused on letrozole co-treatment effect on effectiveness of ovarian controlled hyperstimulation for fertility preservation are lacking. Most of available studies are retrospective cohort designs of undersized samples, with variable degree of bias control and heterogeneous conclusions. Our data, resulting of analysis of a large sample, doesn't support a deleterious effect of letrozole on oocyte availability for vitrification.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Hospital General Universitario Gregorio Marañón.
Trial registration number: Retrospective cohort study.
Keywords: fertility preservation, letrozole co-treatment, breast cancer, effectiveness

P-487 Spermatogonial quantity during prepubertal life

J. M. Hagen[1], I. Masliukaite[1], M. van Wely[1], A. Meissner[1], A. A. de Melker[1], S. Repping[1], F. van der Veen[1], A. M. van Pelt[1]
[1]*Academic Medical Center, Center for Reproductive Medicine, Amsterdam, The Netherlands*

Study question: Can we determine reference values for spermatogonial quantity in the testis during healthy pre-pubertal life?
Summary answer: Spermatogonial quantity, as defined by the number of spermatogonia per tubular cross section (S/T) and spermatogonial density (S/cm^3), decreases during the first year of life and gradually increases afterwards. The findings can be used as reference for the spermatogonial number in testis biopsies of boys in different age groups.
What is known already: Chemotherapy or radiotherapy can cause damage in spermatogonial stem cells resulting in infertility. Cryopreservation of testicular biopsies to preserve spermatogonial stem cells is offered to prepubertal boys who are at risk of becoming infertile. Studies on S/T and S/cm^3 during prepubertal life only report on a limited number of boys and show contrasting results.
Study design, size, duration: A systematic literature search in MEDLINE and EMBASE through November 2014 focusing on S/T and S/cm^3 in the testes of healthy prepubertal boys. All results from studies using the same method were pooled.
Participants/materials, setting, methods: Literature data on S/T and S/cm^3 from healthy prepubertal boys from 0 to 15 years of age. To estimate S/T and S/cm^3 at different age groups, a polynomial meta-regression analysis was performed combining data described for those age groups.
Main results and the role of chance: From a total of 135 papers, 19 studies were included in our analysis of which four could be used to collect data on S/T and two for S/cm^3. Data revealed a 50% decrease in S/T over the first three years of life. From the age of 3 to 7 years a two-fold increase in cells/T was found with a small decrease at the end of this period. After that, a gradual increase appears, which seemed to accelerate exponential at the age of 10 years to puberty. S/cm^3 showed a similar pattern with a decline during the first three years after birth followed by a gradual increase reaching a maximum at 14-15 years of age.
Limitations, reason for caution: The low number of studies with limited number of boys at different ages. The data in the original papers is reported in age groups spanning 4 to 5 year intervals such that estimates cannot be provided per year of age.
Wider implications of the findings: Our estimates of spermatogonial quantity throughout prepubertal life can be a useful reference in future clinical studies. This is a first step towards determining the required testis volume from a prepubertal testis to obtain sufficient spermatogonia for successful autotransplantation to the adult testis later in life.

P-488 Dynamics of follicular growth after xenotransplantation of cryopreserved/thawed human ovarian tissue in SCID mice

S. Ayuandari[1], K. Winkler-Crepaz[1], S. Hofer[1], M. Paulitsch[1], C. Wagner[1], L. Horling[1], L. Wildt[1], S. C. Ziehr[1]
[1]*Medical University of Innsbruck, Department of Gynecological Endocrinology and Reproductive Medicine, Innsbruck, Austria*

Study question: How does xenotransplantation influence the follicular recruitment and growth in cryopreserved/thawed human ovarian tissue?
Summary answer: The higher proportion of growing follicles compared to resting follicles that was observed after xenotransplantation is most likely not due to apoptosis.
What is known already: Human ovarian tissue xenotransplantation into severe combined immunodeficient (SCID) mice is a good method to assess follicular development after cryopreservation and transplantation in the context of fertility preservation. In animal studies, a rapid decrease of primordial follicles after transplantation was observed. The mechanism behind this phenomenon is still unclear.
Study design, size, duration: A portion of cryopreserved/thawed human ovarian tissue samples donated from female cancer patients (n = 14) was xenotransplanted into 6-week-old SCID mice (n = 46) for 4 and 12 weeks.
Participants/materials, setting, methods: Two 3-mm-pieces of tissue were transplanted into a subcutaneous-neck-pouch of 6-week-old ovariectomized SCID mice for 4 and 12 weeks. By the end of the observation periods, grafts were recovered to be analyzed for follicle number, proliferation (Ki67) and apoptosis (TUNEL). Tissue directly after thawing served as pregraft-control.
Main results and the role of chance: Forty-four out of 46 mice (95.6%) survived through the observation periods. Graft recovery rate was 93.5% as 86 from 92 grafts were found. The recovered grafts were macroscopically comparable to pregraft-controls with some visible vascularization. After 4 weeks, the percentage of primordial follicles was reduced significantly to 43.8% ($P < 0.05$) compared to pregraft-controls (89.7%, $P < 0.05$), while the proportion of growing follicles was significantly increased to 25.2% in 4-week-grafts compared to only 1% in pregraft-controls. The same trend continued within the 12-week-observation period. Antrum formation was observed within 12 weeks. Ki67 immunohistochemistry showed that 75% of the follicles were proliferating after 4 weeks of grafting compared to only 10% in pregraft-controls. No TUNEL-positive follicles were observed in all groups.
Limitations, reason for caution: In this study, the early post-transplantation periods (0-4 weeks) and the molecular mechanisms of the follicular recruitment were not studied. Furthermore, although xenotransplantation is the closest experimental approach, it is also still difficult to translate the results from xenotransplantation to patients' settings.
Wider implications of the findings: The methods used in this study can be applied as a quality control tool for cryopreserved/thawed human ovarian tissue in fertility preservation. This study showed fast follicular growth after xenotransplantation leading to a decrease in primordial follicles and increase in growing follicles. Interestingly, this seems not to be due to apoptosis. Studies on the mechanism of follicular recruitment after grafting are important to improve the grafts quality.

P-489 The role of menstrual cycle phase and AMH levels in young breast cancer patients whose ovarian tissue was cryopreserved for fertility preservation

S. Takae[1], Y. Sugihita[1], N. Yoshioka[1], M. Nakajima[1], C. Nishijima[1], H. Iwahata[1], Y. Horage[1], K. Kawamura[1], N. Suzuki[1]
[1]*St. Marianna University School of Medicine, Obstetrics and Gynecology, Kawasaki Kanagawa, Japan*

Study question: Does the phase of menstrual cycle affect the result of combined procedure that means ovarian tissue cryopreservation and oocyte from an excised one side whole ovary for young breast cancer patients who desire to preserve their fertility ?

Summary answer: The phase of menstrual cycle does not significantly affect for the efficacy of combined procedure either the number of collected oocyte, survival and maturation rate. The number of oocytes extracted from cryopreserved ovarian tissue is well correlated with the anti-Müllerian hormone (AMH) levels and age of patients.
What is known already: The researchers reported that the number of immature oocytes that could be retrieved from a partially excised ovary did not depend upon the menstrual cycle when using the "combined procedure".
Study design, size, duration: Data were retrospectively obtained from the clinical records of breast cancer patients who were referred to the Fertility Preservation Outpatients Clinic at the Center for Reproductive Medicine, Department of Obstetrics and Gynecology of our university hospital between February 2010 and September 2014.
Participants/materials, setting, methods: The patients were 35 of breast cancer patients who received ovarian tissue cryopreservation for preserve their fertility. Mostly participants who received ovary tissue cryopreservation had not enough time for oocyte (or embryo) cryopreservation.
Main results and the role of chance: The patients' mean age was 33.7 (± 3.7) years, mean serum AMH concentration was 3.5 (± 2.4) ng/ml, and mean number of extracted oocytes was 7.7 (± 5.9). The phase of menstruation (follicular or luteal) did not affect either the number of oocytes extracted nor oocyte survival or maturation rates. Likewise, the number of oocytes that could be extracted was not affected by the type of laparoscopic procedure (multiple-port or single-incision laparoscopy) or the molecular subtype of breast cancer (either Luminal A or B). Analysis revealed that the number of extracted oocytes was well-correlated with the patient's AMH serum level and age (coefficient of correlation: 0.60 and -0.48, respectively)
Limitations, reason for caution: It is need to clarify the effect of "combined procedure" including assessment of fertility rate and live birth rate based on more large scale study. And also, it is need to assess about the cryopreserved ovarian tissue after thawing and transplantation to patients.
Wider implications of the findings: According to our study that is the most large size retrospective study about "combined procedure" in the young breast cancer patients at present, we conclude that the outcome of the "combined procedure" primarily depends upon the patient's serum AMH level and age. Importantly, the "combined procedure" may be used during any phase of the menstrual cycle to preserve the fertility of breast cancer patients.
Study funding/competing interest(s): Funding by University(ies) – None.

P-490 Anti mullerian hormone (AMH) co-treatment to prevent chemotherapy-induced follicle activation and loss

H. Roness[1], S. Derekh-Haim[1], Z. Gavish[1], N. Sioni[1], D. Meirow[1]
[1]*Chaim Sheba Medical Center, Center for Fertility Preservation, Ramat Gan, Israel*

Study question: Chemotherapy induces activation and loss of the ovarian follicle reserve, partly due to the destruction of the growing follicles and the removal of their negative regulation. Could replacement of negative regulator, AMH, at the time of treatment prevent chemotherapy-induced follicle activation and loss of the ovarian reserve?
Summary answer: Chemotherapy induces activation and loss of the ovarian follicle reserve, partly due to the destruction of the growing follicles and the removal of their negative regulation. Could replacement of negative regulator, AMH, at the time of treatment prevent chemotherapy-induced follicle activation and loss of the ovarian reserve?
What is known already: A number of chemotherapy classes have been shown to induce follicle loss by triggering activation of the dormant primordial follicles. This occurs via two mechanisms; upregulation of the PI3K-Akt signaling pathway, and death of growing follicles which are responsible for producing AMH, a negative regulator of follicle activation.
Study design, size, duration: *In vivo* treatment of 12 day Balb/C mice with Cyclophosphamide (Cy)/PBS (n = 10 ovaries, 3 repeat experiments), and *ex vivo* culture of whole mouse ovaries with Cy metabolite Phosphoramide mustard (PM)/Media alone, + /- AMH (n = 16). Ovaries were analyzed 1, 4, and 7 days post treatment.
Participants/materials, setting, methods: AMH mRNA expression levels in mouse ovaries were measured (qRTPCR) following *in vivo* Cy treatment (150mg/kg). *Ex vivo*, ovaries were exposed to 20ug/ml PM for 2 hours, + /- 100ng/ml AMH. PI3K proteins AKT, rpS6 were assessed after 24 hours in culture, and differential follicle counts conducted after 4 and 7 days.
Main results and the role of chance: AMH mRNA expression in the ovary decreases after *in vivo* treatment with Cy, reaching their lowest levels at 12 hours (0.5 relative expression), before rebounding at 24 hours and progressively increasing so that by 7 days levels were two times that in controls. Ovaries exposed *ex vivo* to PM showed a significant reduction in primordial follicles per ovary compared to controls (724 ± 50 vs. 1534 ± 176; $p < 0.01$), which was partially rescued in ovaries co-treated with AMH (1081 ± 131, $p < 0.05$). The ratio of growing:dormant follicles in PM treated ovaries was double that in controls (0.65 vs. 0.3, $p < 0.001$), reflecting the activation of the follicle pool, and this was improved in ovaries co-treated with AMH (0.33, $p < 0.05$). There was no change in expression of PI3K pathway proteins at 24 hours.
Limitations, reason for caution: Protein and RNA measurements were conducted on whole ovary lysates, not isolated follicles, so the specific origin of mRNA expression changes cannot be attributed. We chose not to use isolated follicles since it is model that cannot accurately reflect the *in vivo* state.
Wider implications of the findings: The loss of activation-suppressor AMH in the immediate short term after Cy treatment sheds light on the mechanism behind the follicle activation and 'burn-out'. This proof of principle study suggests that replacement of AMH during chemotherapy treatment may prevent/reduce follicle loss. Following testing in primate/human models, such treatment would provide notable advantages over existing techniques, being non-invasive, suitable for patients of all ages, not dependent on ART, and able to prevent the endocrine related side effects of POF.

Trial registration number: NA.

P-491 Safety of cryopreserved ovarian tissue autotransplantation in leukaemia patients

R. Fabbri[1], M. Macciocca[1], R. Vicenti[1], P. P. Piccaluga[2], E. Sabattini[2], A. Gazzola[2], C. Mannu[2], R. Paradisi[1], S. Rossi[1]
[1]*Gynecology and Pathophysiology of Human Reproduction Unit S. Orsola-Malpighi Hospital University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy*
[2]*Hematopathology Section S. Orsola-Malpighi Hospital University of Bologna, Department of Experimental Diagnostic and Specialty Medicine, Bologna, Italy*

Study question: In leukaemia patients ovarian tissue was cryopreserved at remission of disease. May ovarian tissue transplantation be considered safe in this condition?
Summary answer: The risk of finding malignant cells in the ovarian tissue of leukaemia patients cannot be excluded also when the tissue has been cryopreserved at disease remission.
What is known already: An important aspect of cryopreserved ovarian tissue autotransplantation in cured cancer patients is the potential reintroduction of tumour cells with the risk of causing a recurrence of illness. This risk is particularly high in leukaemia patients, for whom the cryopreservation of ovarian tissue might be performed after a few cycles of chemotherapy when testing indicates no evidence of leukaemic cells in the blood.
Study design, size, duration: Cryopreserved ovarian tissue of three patients suffering from different types of leukaemia, Acute Lymphoblastic Leukaemia-ALL, Acute Myeloid Leukaemia-AML, Chronic Myeloid Leukaemia-CML, was checked for the presence of malignant cells by histological and molecular analysis. The presence of specific disease-markers was investigated to allow a highly sensitive analysis of the tissue.
Participants/materials, setting, methods: For AML and CML patients a disease-specific marker (Wilms-Tumor-1 overexpression and chimeric Bcr-Abl gene, respectively) allowed to perform a sensitive evaluation by quantitative Real-Time PCR. In the ALL patient no disease-marker was available at diagnosis so a clonality test for the assessment of T-cell-receptor-rearrangement was evaluated with traditional-capillary-electrophoresis and massive-parallel-sequencing (MPS-Invivoscribe's LymphoTrack).

Main results and the role of chance: At the time of tissue retrieval, the ALL and AML patients were in morphological and molecular disease remission, while the third was only in morphological remission. Histological examination did not reveal malignant cells in ovarian tissues of the patients. As regards molecular investigation, in ALL patient the clonality test (sensitivity10^{-2}) was negative as well as the higher sensitive massive-parallel-sequencing method (sensitivity10^{-5}-10^{-6}). The quantitative Real-Time PCR gave a positive result in both AML and CML patients.
Limitations, reason for caution: Due to the lack of onset material in the ALL patient, only the standard low sensitive clonality test was used although its negativity cannot exclude the presence of malignant cells in cryopreserved samples. Massive-parallel-sequencing, despite a highest sensitivity, is still experimental. This case well embodies how the test-limitations should be amply discussed with patients.
Wider implications of the findings: Only highly sensitive tests allow an accurate monitoring pre-transplantation of cryoprserved ovarian tissue and can minimize the possibility of wrong evaluation (under-estimation) of neoplastic contamination.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Sant'Orsola Malpighi Hospital of Bologna. Competing interest: none.
Trial registration number: Clinical trial 74/2001/O – EM 180/214/O.
Keywords: ovarian tissue cryopreservation, leukaemia, autotransplantation, Real-Time PCR

P-492 The influence of pregnancy on the prognosis of endometrial atypical hyperplasia and adenocarcinoma with assisted reproductive technology after fertility-sparing therapy: a systematic review and meta-analysis

L. P. Yu[1], S. Y. Zhao[1], H. Chao[1], Y. Liu[1]
[1]*Beijing Obstetrics and Gynecology Hospital Capital Medical University, Department of Reproductive Medicine, Beijing, China*

Study question: Does pregnancy has influence on the prognoses of young women (< 40 years old) with early-stage endometrial cancer (EC) and atypical complex hyperplasia (AH) who were treated by conservative management followed by assisted reproductive technology (ART) ?
Summary answer: Live birth rates were encouraging using ART in young women with EC or AH who desired fertility after conservative management.
What is known already: A total of 5% of endometrial carcinoma is diagnosed under the age of 40 years, and over 70% of patients are nulliparous at diagnosis. The dissection approach is unacceptable for these women who wish to maintain their fertility.
Study design, size, duration: A meta-analysis of observational studies with a random or fixed-effects model was carried out. 527 women from 23 studies included 201 women to assess how prognosis might be influenced by pregnancy.
Participants/materials, setting, methods: This systematic review was conducted in accordance with the PRISMA guidelines and was also in accordance with the a priori protocol agreed upon by all authors. The population of interest in this systematic review included women with AH or early clinical stage EC (1988 International Federation of Gynecology and Obstetrics stage IA). The intervention queried was conservative treatment, and the outcomes were evidence of live births or recurrence. The following electronic databases were searched: PubMed (1950 to 2014) and Web of Science conference proceedings (ISI Proceedings, 1990 to 2014).
Main results and the role of chance: Analysis of no pregnancy studies as the reference group pointed to a statistically significant positive association between pregnancy and decreased risk for recurrence (RR) of 0.56, 95% confidence interval (CI): 0.37-0.84]. Eighteen studies including 104 women enabled determination of live birth rates of women with early-stage EC (79 women) and AH (25 women) following treatment with conservative management followed by ART. For patients with AH, 25 women were treated with ART after pathological remission of disease. Thirteen women achieved intrauterine pregnancies, and nine had 10 live births, with a pooled live birth rate of 0.32 with insignificant heterogeneity (P = 0.925). For those with EC, 79 women were treated by ART, 61 by IVF-ET, 12 by IUI, and 6 by ICSI. Fifty-seven women had intrauterine pregnancies, and 45 had 52 live births, with a pooled live birth rate of 0.60 and insignificant heterogeneity (P = 0.923).
Limitations, reason for caution: Our systematic approach included published literature that had only observational evidence, so prospective randomized trials in larger numbers of patients and with longer follow-up times are warranted to evaluate the effects of fertility-sparing treatments.
Wider implications of the findings: Live birth rates were encouraging using ART in young women with EC or AH who desired fertility after conservative management. Resulting pregnancies could reduce recurrent risk of AH and EC. Additionally, minimizing the time interval between treatment termination and pregnancy was important.
Study funding/competing interest(s): Funding by national/international organization(s) – This project was funded by National Natural Science Foundation Project (81471520), State Scholarship Fund (2011911033), Beijing Natural Science Foundation Project (5122015), and Beijing Project of Training High-level Medical Technical Personnel in Health System. The authors declare no conflict of interest.
Trial registration number: No.

PARAMEDICAL - LABORATORY

P-493 Comparison between analytical scale and graduated serological pipette for semen volume analysis: a cross sectional study

C. Pompeu[1], C. M. Feijó[1], S. C. Esteves[2]
[1]*Androfert - Center for Male Reproduction, Andrology Laboratory, Campinas, Brazil*
[2]*Androfert - Center for Male Reproduction, Medical Director, Campinas, Brazil*

Study question: Is there any difference between the measurement of semen volume by weighing the specimen in the container in which it is collected and aspirating the specimen from the container with a serological graduated pipette?
Summary answer: Measuring volume by aspirating the speciment from the container into a pipette underestimate the ejaculate volume. This is due to retention of part of the volume in the container. The magnitude of effect is higher in specimens with high viscosity.
What is known already: Precise measurement of ejaculate volume is essential to determine the total sperm count. Among the semen parameters, total sperm count is one of the most significant as it relates to testicular volume. In addition to the total concentration, viscosity is also a decisive factor when evaluating a semen sample. Highly viscous specimens adheres strongly to the pipette wall and might interfere with final volume determination. In its updated 2010 edition, the World Health Organization manual for the examination and processing of human semen recommends that volume should be measured by weighting the specimen in the vessel in which it is collected, which is more labor-intensive than simply reading the volume from a graduated pipette.
Study design, size, duration: A cross sectional study was performed in an ISO 9001 certified Andrology Laboratory enrolled in external quality control program. Data was obtained from 654 consecutive male patients referred for semen analysis evaluation from September 2013 to December 2014.
Participants/materials, setting, methods: Semen specimens were collected by masturbation after a 2-5 ejaculatory abstinence period into sterile plastic vessels (Fertility, USA) at the collection room adjacent to the Andrology Laboratory. Containers were individually pre-weighed using a calibrated analytical balance (Mettler-Toledo, USA), and weigh was recorded using a label that was attached to the empty container before weighting. Volume was calculated by subtracting the weigh of the container from its weigh with semen in it after liquefaction for 30 minutes at 37°C (v1). Then, volume (v2) was measured by aspirating the specimen into a 10-mL sterile polyestirene graduated pipette (0.1 mL accuracy). Viscosity was determined by assessing the length of any thread, and was considered high when the semen drop formed a thread exceeding 2 cm.
Main results and the role of chance: Semen volume was higher when measurements were carried out by weighting the container with semen in it (3.52 ± 1.68 mL) compared with aspiration of the specimen into a serological pipette (3.24 ± 1.63; $p = 0.002$). Overall, the difference in volume between the two methods was 17%. Of the 654 specimens, 294 (45%) were classified as having high viscosity. The v1 measurements in both hyperviscous and normal viscosity specimens (3.48 ± 1.62 and 3.55 ± 1.72 mL) were higher than v2

(3.17 ± 1.59 and 3.29 ± 1.67 mL; $p = 0.02$). The magnitude of this difference was higher in hyperviscous specimens compared with normal ones (d = 0.20; $p = 0.04$).

Limitations, reason for caution: Results could vary by increasing the liquefaction time. In addition, we have not examined the impact of microscopic semen characteristics, such as sperm count, on the volume determination.

Wider implications of the findings: Measurement of ejaculate volume by weighting the container with semen in it allows the precise determination of total sperm count and the reduction of analytical error in semen analysis. As high viscosity interferes with determination of semen volume, measuring volume by aspirating the specimen container into a pipette is not recommended.

P-494 Relationship between body mass index (BMI) and semen analysis results and effect of World Health Organization criteria for categorization of semen parameters: a cross-sectional study

C. M. Feijó[1], C. Pompeu[1], F. B. Bento[2], S. C. Esteves[3]

[1]*Androfert - Center for Male Reproduction, Andrology Laboratory, Campinas - São Paulo, Brazil*

[2]*Androfert - Center for Male Reproduction, Quality management, Campinas - São Paulo, Brazil*

[3]*Androfert - Center for Male Reproduction, Medical Director, Campinas - São Paulo, Brazil*

Study question: Does body mass index impact on the conventional semen parameters of men referred for infertility evaluation? What is the effect of the new 2010 WHO semen analysis reference values on reclassifcation of previous semen analysis parameters as per WHO 1999 reference values? Does BMI influence the proportion of patients reclassified according to the WHO criteria for semen analyses?

Summary answer: Total sperm count and progressive motility were significantly lower in men with high BMI (> 30 Kg/m2) compared with eutrophic men. The 2010 reference values result in approximately 30% of men with abnormal semen parameters as per the WHO 1999 being reclassified as 'normal', but BMI does not seem to impact on reclassification.

What is known already: Obesity affects about 15-30% of men at reproductive age. It has been suggested that men with high BMI are at risk of subfertility, but studies focusing on semen parameters of such patients are scarce. Semen analysis is still the sole marker for many of the male/couple referrals to infertility clinics, and the World Health Organization criteria is the most used guideline for reference values.

Study design, size, duration: A cross-sectional study was performed in an ISO 9001 certified Andrology Laboratory enrolled in External Quality Control. Data was obtained from 887 men seeking infertility evaluation from 2009 to 2013.

Participants/materials, setting, methods: Men referred for infertility evaluation were included. Patient height and weight were recorded on day of semen collection for BMI calculation. Semen analyses were carried out according to the WHO guidelines, and semen analysis values were compared based on the 2010 versus 1999 reference criteria, both overall and after stratification by BMI, i.e., eutrophic (< 25kg/m^2), overweight (25– < 30kg/m^2) and obese (> 30kg/m^2).

Main results and the role of chance: Median total sperm count and progressive motility were significantly lower in obese men (64.8 M/mL and 54%) compared with eutrophic men (15.7 M/mL and 46.3%; $p = 0.03$). An inverse relationship was observed between BMI and total count (r = -0.11; $p < 0.01$), and BMI and progressive motility (r = -0.09; $p = 0.01$). Overall, 270 patients (30.4%) who had at least one parameter below the reference value according to the WHO 1999 criteria were reclassified to having all parameters at or above the 2010 criteria. Of the men, 9.4%, 6.3%, 22%, 53% and 46% would change classification for volume, count, motility and morphology, respectively. BMI was shown not to play a significant role in these reclassifications.

Limitations, reason for caution: Our findings cannot be extrapolated to the general population because dataset comprised solely men referred for infertility evaluation. Co-founding factors such as age, co-morbidity and other life-style factors such as smoking were not assessed.

Wider implications of the findings: Obesity seems to be associated with decreased semen parameters in men referred for infertility evaluation. The criteria adopted as a reference for semen analysis values impact in the proportion of men classified as normal if status is based on semen analysis alone. However, reclassification as per WHO criteria seems to be independent of BMI. Men facing infertility should be counseled that obesity may pose an additional obstacle for natural fatherhood.

P-495 Improving pregnancy rates in IUI procedure

G. Bahadur[1], A. Illahibuccus[1], A. Al-Habib[1], S. Okolo[1]

[1]*North Middlesex University Hospital, Reproductive Medicine Clinic, London, United Kingdom*

Study question: Which contributing factors will help improve rates for an IUI program using husbands sperm?

Summary answer: Multiple factors associated with a successful pregnancy were: age of woman, having ≥ 5 million TPMS (Total Progressive Motile Sperm), insemination with at least 50% Grade A sperm, a mean of 1.7 follicles as in 45.8% of successful cohort, while.using hMG protocol with IUI at 29 hour hCG trigger.

What is known already: IUI is universally practiced but the pregnancy rates are not well understood, with diverse protocols and practices, sometimes with higher order multiple births. Based on poor outcomes of about 6%/cycle pregnancy rates using clomid stimulation one RCT labelled IUI as ineffective despite the existence of a much larger HFEA database yielding on average 13%/cycle success rates. IUI has also been blamed for higher order multiples births, and to erroneously recommend IVF instead.

Study design, size, duration: The retrospective cohort study from a large teaching hospital charts the increasing pregnancy rates from 2009 to 2014. Improved outcomes were associated with a shift away from clomid to hMG stimulated cycles, and adding a `consecutive ejaculate' to the first ejaculate in the sperm preparation procedure, and this unique approach has not been reported in clinical application before. The IUI outcomes for 2014 relating to 117 IUI cycles and 73 women will be discussed in detail.

Participants/materials, setting, methods: A qualitative analyses from 2009-2014 charted improving pregnancy outcomes, followed by detailed retrospective analyses from January-September 2014 included 117 cycles, 73 women and 24 clinical pregnancies. The unique clinical use of a `consecutive ejaculate' to enhance the TPMS with a realistic hMG protocol made IUI a viable procedure.

Main results and the role of chance: After IUI the pregnancy rates were 20.5%/cycle and 32.9% of the women became pregnant. The result exceeded the UK average of 13%/cycle, which in turn exceeded the the 6%/cycle from the only published RCT to condemn IUI procedure as ineffective. Our result is probably the best available data, robust, maintainable, and follows the improving trend over the years. The unique use of `consecutive ejaculates' has contributed towards allowing 87.5% of the inseminations reach a threshold of ≥ 5 million TMPS, which has been quoted as a threshold for IUI to be realistic, and 54% of the pregnancies were associated with the `consecutive ejaculate.' Insemination after 29 hour post hCG trigger seems to be positively associated with pregnancies.

Limitations, reason for caution: This is a retrospective study needing to be scaled up and preferably entered in a prospective RCT. Patients serve as their own control.

Wider implications of the findings: This is the best available data for IUI pregnancy rates, which if replicated on a large scale would challenge some IVF results, while allowing for a significant reduction of multiple birth rates. The multiple births and OHSS were none existent in our cohort and inseminating with 2-3 follicles may not present a significant risk as transferring 2-3 embryos as in IVF cycles. Consecutive ejaculate application is unique and will prove beneficial globally.

P-496 Oocyte vitrification; case study with fertilization only in vitrified/warmed oocytes and failed fertilization in all un-vitrified oocytes in two consecutive ICSI cycles

A. Nowosad Andershed[1], E. Adolfsson[1]
[1]*University Hospital of Örebro, Fertility Clinic, Örebro, Sweden*

Study question: When validating oocyte vitrification we examined survival rate, fertilization potential and embryo development after vitrification. The aim was to implement standard operation procedures for oocyte vitrification for female fertility preservation, IVF emergency situations and possibility to start donor oocyte bank.
Summary answer: Survival rate were 90 %, fertilization rate 70 % and 42 % of the embryos classified as high quality embryos (HQE). 7 transfers resulted in 4 live births. One participant gave birth to a baby after failed fertilization in all un-vitrified oocytes in two consecutive treatment cycles.
What is known already: Oocyte vitrification technique can be challenging and every clinic needs to validate a protocol for vitrification, warming and fertilization to ensure the outcome. Failed fertilization after ICSI is rare, occurring in 1-3 % of cycles. Failed oocyte activation is the most common cause. Vitrification will induce stress in the oocyte due to mechanical, thermal and chemical stressors. So far, no literature has described failed fertilization counteracted by vitrification.
Study design, size, duration: This was a sibling study performed during autumn 2013. Participants were asked to donate one oocyte if > 8 oocytes were retrieved. One oocyte was randomly selected for vitrification/warming, with the remaining cohort serving as controls. All embryology procedures followed standard operating procedures.
Participants/materials, setting, methods: 29 ICSI patients at the Fertility Clinic at Örebro University Hospital were included in the study. Informed written consent was obtained. Vitrification/warming were done 1 h after OPU using KitaZato media, with ICSI 2 h post-warming. All embryo development culture and analysis was done in EmbryoScope.
Main results and the role of chance: The validation included 30 oocytes from 29 patients. Survival rate was 90 %, fertilization rate 70 %, with 42 % of embryos developing into HQE. For 2013, the control figures for the clinic were 57 % fertilization rate and 44 % HQE. 7 embryos from vitrified oocytes have been transferred, resulting in live births of 4 babies. One female participated twice. First cycle resulted in 16 oocytes, 11 of which were mature. Only the vitrified oocyte fertilized, all control oocytes failed to fertilize. It was transferred as a day 5 morulae, no pregnancy achieved. Second cycle resulted in 11 oocytes, 9 mature. Again, only the vitrified oocyte fertilized. It was transferred as a day 2 four-cell embryo and resulted in the birth of a baby.
Limitations, reason for caution: Study outcome is in line with previous published key performance indicators (KPI) for oocyte vitrification for infertility patients. The high live birth rate indicates good performance and high competency amongst staff members performing oocyte vitrification. Oocyte vitrification KPI will be added for continuous benchmarking.
Wider implications of the findings: The study design is easily adoptable to clinics interested in oocyte vitrification validation. Patient recruitment was easy and participation high. Oocyte vitrification can be applied for fertility preservation, oocyte donor bank, or to resolve IVF emergencies. We found no literature describing failed fertilization after ICSI counteracted by vitrification. The exact same outcome in two consecutive cycles is intriguing and reduces likelihood of chance. A possible mechanism might be artificial oocyte activation by the vitrification procedure.
Study funding/competing interest(s): Funding by national/international organization(s) – This study was supported by the Tissue Establishment of Region Örebro Län, Sweden.
Trial registration number: NA.
Keywords: oocyte vitrification, fertilization only in vitrified/warmed oocytes

P-497 Improved accuracy of embryo scoring using morphokinetic compared with strict morphology

E. Adolfsson[1], A. Nowosad Andershed[1]
[1]*University Hospital of Örebro, Fertility Clinic, Orebro, Sweden*

Study question: Can morphokinetics provide higher objectivity and less reproducibility compared to morphology? Traditional static scoring and selection of embryos using microscopy has reduced reliability and high inter- and intra-observer variability. Morphokinetics might provide a more objective tool. This study compares morphology and morphokinetics on day 5 blastocysts with known implantation data.
Summary answer: Morphokinetic showed improved accuracy compared with morphology. Observers agreed almost perfect on time lapse annotations, whereas for morphology observers showed only fair agreement. Repeated observations by the same observer were more reproducible for morphokinetics. Neither morphokinetics using a previous published model nor morphology correlated with implantation ability for transferred embryos.
What is known already: Morphology suffers from subjectivity and low reproducibility and a reduced potential to predict pregnancy chance. Morphokinetics based on time lapse images takes cleavage patterns into consideration, has been shown to have high objectivity and reproducibility. Changing embryo assessment technique requires validation. In this study, the first to our knowledge, we compare morphology and morphokinetics in terms of intra- and inter-operator variability. Validating morphokinetic parameters is the first step in building prediction models for embryo selection.
Study design, size, duration: This is a retrospective register study from Fertilitetsenheten, Örebro University Hospital, between 2012-2014. 100 transferred blastocysts with known implantation outcome from 100 patients were randomly selected. All embryos were analyzed four times in total, two times each by two experienced embryologist, two months apart, always blinded for previous assessments.
Participants/materials, setting, methods: Blastocysts were scored using Gardner Schoolcraft criteria and examined by detailed time-lapse analysis for pre-selected parameters using EmbryoScope software. ICC for morphokinetics and Cohen´s kappa for morphology was calculated to analyze reproducibility. Morphology and morphokinetics were later correlated with chance of implantation.
Main results and the role of chance: Mean inter-operational variability for morphokinetics were 0.897 (0.753 – 0.996, 95 % CI), which interprets as almost perfect agreement. Highest agreement was found for tPNf, t2, and t5, whereas tPNa and t9 + had slightly lower ICC. ICC for observer A was 0.911 and for observer B 0.901. For morphology, inter-operational agreement had a K value of 0.637, and intra-operational agreement for observer A was 0.477 and for observer B 0.525 (fair agreement). Highest agreement was found for trophodectoderm (0.706), followed by expansion grade (0.669) and inner cell mass (0.541). Ranking the embryos into subcategories using morphology and/or a previous published selection morphokinetic model showed low correlation with implantation.
Limitations, reason for caution: Validation was done on high quality embryos. We repeated the ICC calculations for additional 110 embryos from 20 patients regards of quality. Mean ICC were 0.884 (range 0.701 -0.978) between observer A and B. Therefore, we conclude that ICC for all examined parameters are robust regardless of embryo quality.
Wider implications of the findings: Morphokinetics showed improved accuracy compared with strict morphology. The commonly used morphokinetic parameters were robust and reproducible, therefore suitable in a selection model. However, applying a previously published model to rank embryos did not correlate with chance of implantation. We suggest that each clinic build their own selection model if applying time lapse analysis for embryo selection. The annotation technique per se needs to be validated for each operator to ensure inter- and intra-operational agreement.

P-498 The blastocoele stage in human blastocysts can be improved by position of the trophectoderm biopsy

T. Takano[1], M. Funabiki[1], S. Taguchi[1], N. Amano[1], F. Saji[1], L. Young[1], Y. Nakamura[1]
[1]*Oak Clinic Inc., Infertility Center, Osaka, Japan*

Study question: Although the trophectoderm biopsy within human blastocysts is conducted in preimplantation genetic screening (PGS), can be the blastocoele stage in human blastocysts influenced by position of the trophectoderm biopsy?

Summary answer: The trophectoderm biopsy at near position from inner cell mass (ICM) is the best in order to improve the blastocoele stage in human blastocysts.
What is known already: The best method for the trophectoderm biopsy within human blastocysts in PGS is researched. However, the influence on human blastocysts by position of the trophectoderm biopsy is not yet investigated.
Study design, size, duration: An experimental prospective study was performed from January 2013 to September 2014 on 60 patients (median age 34.3 years) with infertility in our clinic. Furthermore, embryos abrogated with patient's informed consent were cultured to blastocyst stage (Day 5 – Day 7) and were used in the present study.
Participants/materials, setting, methods: Each patient was assigned by position of trophectoderm biopsy as follows. Group A: Near position from ICM ($n = 20$), Group B: Remote position from ICM ($n = 20$), Group C: Position between A and B ($n = 20$). Furthermore, the changes of blastocoele stage between the pre- and post-trophectoderm biopsy were studied.
Main results and the role of chance: The improvement rate of the blastocoele stage in Group A was higher than those in Group B significantly (90% versus 45%, respectively, $p = 0.048$: Fisher's exact test). Furthermore, multivariate analysis showed that the improvement of the blastocoele stage was influenced by position of the trophectoderm biopsy($p = 0.033$) and by the presence or absence of expansion in human blastocysts ($p < 0.001$), regardless of patient's age($p = 0.516$), aspiration pipette's size ($p = 0.781$) and days of human blastocysts in the pre- trophectoderm biopsy($p = 0.051$). Therefore, our findings show that the trophectoderm biopsy at near position from ICM is the best in order to improve the blastocoele stage in human blastocysts.
Limitations, reason for caution: There may be possible biases related to small sample size, although our study is an experimental prospective study.
Wider implications of the findings: This is the first study reporting that the blastocoele stage in human blastocysts can be improved by position of the trophectoderm biopsy. On the other hand, some researches indicate that the improvement of the blastocoele stage in human blastocysts associates with the improvement of clinical pregnancy outcomes. Therefore, a prospective randomized clinical trial is needed to investigate an association between clinical pregnancy outcomes and position of the trophectoderm biopsy in human blastocysts.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Oak Clinic Group.
Trial registration number: NA.
Keywords: human blastocysts, trophectoderm biopsy, blastocoele stage, ICM, preimplantation genetic screening (PGS)

P-499 Benefits of extending routine fresh embryo culture to day 7 on frozen embryo transfer pregnancy rates

E. Ebinger[1], J. Lindstrom[2]
[1]*City Fertility Centre, Embryology, Brisbane, Australia*
[2]*City Fertility Centre, Clinical, Brisbane, Australia*

Study question: What effect does extending the routine culture period to day 7 have on frozen embryo transfer (FET) pregnancy rates?
Summary answer: To date, after 5 months of extending routine culture of fresh embryos to day 7 an additional 80 good quality blastocysts have been vitrified and pregnancies have been achieved from subsequent FET cycles.
What is known already: Studies have shown that a reduction of implantation rate in fresh cycles where day 6 embryos are transferred can be attributed to the asynchrony of the endometrial lining at this stage of the cycle, rather than to a slower embryo development rate (Shapiro *et al* 2008). Based on this data and possibly historical poor outcome from slow freezing of blastocysts, embryos were not routinely cultured past day 6.
Study design, size, duration: In this study across 7 laboratories, 905 IVF cycles were completed and grade A or B blastocysts by day 7 were vitrified over a five month period. The number of blastocysts frozen on day 7, subsequent cryosurvival, biochemical and clinical outcomes were measured from FET cycles.
Participants/materials, setting, methods: All embryos were routinely cultured and assessed using the Gardner's Blastocyst Grading System (Gardener 2000). Grade A or B embryos were classified suitable for vitrification. Embryos that were not vitrified on day 5 were reassessed on day 6 and day 7 for vitrification using the same criteria.
Main results and the role of chance: Total number of embryos assessed on day 7 was 1474 and 80 blastocysts (5.4% of day 7 embryos) were suitable for vitrification for 67 patients. Embryos were vitrified on day 7 in 7.4% of total fresh cycles. For 19 patients 24 embryos were frozen on day 7 only. Day 7 vitrified embryos accounted for 6.7% of total number of embryos vitrified (day 5, 6 and 7) over this time period. To date, 7 day 7 embryos have been warmed, 6 embryos survived (86% cryosurvival) resulting in 5 patients receiving embryo transfer, 3 positive pregnancy (60% per FET) with 2 clinical pregnancies (40% per FET).
Limitations, reason for caution: At this stage of our study, we do not have data on the perinatal outcomes for pregnancies resulting from day 7 vitrified blastocysts.
Wider implications of the findings: The introduction of routinely vitrifying embryos that develop into blastocysts on day 7 may increase the cumulative pregnancy rate per stimulated cycle and embryos should not be discarded on day 5 or day 6 as they still have the potential to achieve an ongoing pregnancy.
Study funding/competing interest(s): Funding by hospital/clinic(s) – City Fertility Centre, Brisbane, Australia.
Trial registration number: NA.
Keywords: day 7, vitrification

P-500 Pregnancy rates and take-home baby rates are not affected by damage of cells vitrified on day 2 when the loss is less than 25%

Y. Tsuji[1], J. Otsuki[1], H. Ogata[1], T. Uozumi[1], T. Iwasaki[1], S. Kokeguchi[2], M. Shiotani[2]
[1]*Hanabusa Women's Clinic, IVF laboratory, Kobe, Japan*
[2]*Hanabusa Women's Clinic, Obstetrics and Gynecology, Kobe, Japan*

Study question: Does the reduced number of blastomeres caused by cryopreservation and thawing procedures of 4-8 stage embryos affect *in vivo* embryo development and take-home baby rates?
Summary answer: There was no difference between intact embryos and embryos with less than 25% of cell damage on pregnancy rates and birth rates.
What is known already: Some reports demonstrated that similar implantation rates were obtained between intact early stage embryos cryopreserved on day 2-3 and those embryos with less than 25% cellular damage after slow freezing and thawing procedure. It is known to have higher survival rates in vitrification procedure than in slow freezing procedure of early cleavage stage embryos. The birth rates of partially damaged embryos have not been reported yet.
Study design, size, duration: A retrospective study has been conducted between the period of January 2010 and December 2013 on the survival rate of 1549 vitrified and thawed embryos which were cryopreserved on day 2.
Participants/materials, setting, methods: Embryos were divided into four groups (intact embryos, embryos with less than 25% cellular damage, 25%-50% damage and more than 50% damage). The relationship between cellular damage and pregnancy rates was analysed in the 1549 single embryo transfers. Birth rates were assessed for 1491 cases through questionnaires.
Main results and the role of chance: The biochemical pregnancy rates in 0%, ≤ 25%, 25-50% and > 50% of cellular damaged groups were 35.1% (460/1309), 34.4% (43/235), 26.2% (16/61) and 28.6% (4/14) respectively. The rates of gestational sac confirmation in each group were 21.1% (277/1309), 19.2% (24/125), 11.5% (7/61) and 7.1% (1/7). The fetal heartbeat rates in each group were 18.3% (239/1309), 19.2% (24/125), 9.8% (6/61) and 7.1% (1/14). The birth rates in each group were 15.1% (196/1299), 13.4% (16/119), 8.5% (5/59) and 7.1% (1/14). There was no difference between 0% and ≤ 25% groups on each parameter. When the cutoff volume of damage was defined as ≤ 25%, the rates of gestational sac confirmation and fetal heartbeat were significantly higher in embryos with ≤ 25% cellular damage than those with > 25% damage ($p = 0.030$ and $p = 0.047$).
Limitations, reason for caution: A limitation of this study is that the number of embryos in the > 50% group was insufficient to provide enough data for accurate study. To improve the accuracy of the data, it is necessary to perform a long-term study in the future.
Wider implications of the findings: The results suggest that embryos with less than 25% damage have the same potential to result in birth as an intact embryo. This study also demonstrated that a baby could be born from an early cleavage embryo with over 50% blastomere damage.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Hanabusa Women's Clinic.

P-501 Times from insemination to three to four cells and to five cells are predictive markers for clinical pregnancy

C. Sumi[1], H. Sato[1], H. Ogata[1], T. Iwasaki[1], Y. Katada[1], Y. Tsutsumi[1], K. Hatano[1], S. Kokeguchi[2], M. Shiotani[2]
[1]*Hanabusa Women's Clinic, Lab, Kobe, Japan*
[2]*Hanabusa Women's Clinic, Doctor, Kobe, Japan*

Study question: This study aimed to evaluate whether a morphokinetic study using time-lapse imaging can predict clinical pregnancy by comparing the time from insemination to cleavage.
Summary answer: Our study shows that the time from insemination to three to four cells (s2) and that to five cells (t5), as observed by the EmbryoScope (Unisense Fertilitech, Denmark), are predictive of clinical pregnancy, but cc2 is not predictive.
What is known already: Several recent publications have shown morphokinetics of embryos by time-lapse imaging as a new method for selecting good quality embryos or clarifying aneuploidy. These findings are based on the time to certain division of embryos. However, each facility used different instruments and cultures in a different manner. We attempted to verify if the criteria that were used by Meseguer (2011) could be used in a more universal situation in the Japanese laboratory.
Study design, size, duration: This study was performed retrospectively. A total of 48 couples (59 embryos) who underwent ICSI and embryo transfer were enrolled in this study from December 2012 to December 2014. The maternal age of participating couples was younger than 38 years, with less than three times of previous unsuccessful IVF.
Participants/materials, setting, methods: Embryos were observed by the EmbryoScope every 15 minutes. We compared the rate of clinical pregnancy between the in-range division group (w/i group) and the out of range division group (w/o group) at each cell division time. This range was based on the definition by Meseguer *et al*.
Main results and the role of chance: The total rate of pregnancy in all of the participants was 40.1% (24/59). There was no difference in cc2 between the w/i and w/o groups. The s2 w/i group (<0.76 h) had a significantly higher rate of pregnancy (56.5%) than the s2 w/o group (³0.76h, 30.6%, $p = 0.048$). The t5 w/i group (44.8–56.6 h after insemination) had a significantly higher ratio of obtaining clinical pregnancy (51.4%) than the t5 w/o group (25.0%, $p = 0.042$).
Limitations, reason for caution: Our results showed a good clinical pregnancy rate using embryos that were selected by time-lapse imaging. This suggests that the criteria of Meseguer using the EmbryoScope are effective for selecting good embryos. However, further clinical studies are required to determine if this method can be used in different environments.
Wider implications of the findings: This study verified the effectiveness of the criteria that were used by Meseguer *et al.* using a similar instrument and culture conditions. Our study shows that selection of embryos for transfer is possible by time-lapse imaging analysis that was defined by them, even in a different environment.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Hanabusa Women's Clinic.
Trial registration number: NA.

P-502 A piezo-micromanipulator in intracytoplasmic sperm injection (ICSI) is effective in older women

M. Matsuura[1], H. Ogata[1], T. Iwasaki[1], Y. Katada[1], T. Sumimoto[1], K. Kishi[1], Y. Goto[1], S. Kokeguchi[2], M. Shiotani[2]
[1]*Hanabusa Women's Clinic, Laboratory, Kobe, Hyogo, Japan*
[2]*Hanabusa Women's Clinic, Doctor, Kobe, Hyogo, Japan*

Study question: This study aimed to determine if age affects the efficacy of piezo-assisted ICSI compared with conventional ICSI.
Summary answer: On day 6 in women older than 42 years old, the rate of blastocyst formation with piezo-assisted ICSI is significantly higher than that with conventional ICSI.
What is known already: Piezo-ICSI can achieve better fertilization and survival rates of fragile eggs compared with conventional ICSI because injury of oocytes is decreased as much as possible in piezo-ICSI. Generally, the fertilization rate of eggs depends on the age of women because eggs in older women are more fragile than those in younger women. However, there are few studies regarding appropriate indications for this method.
Study design, size, duration: A total of 847 mature oocytes from 98 cycles were used for this study from October 2013 to August 2014. At least four oocytes were retrieved from one cycle. Retrieved oocytes were divided into two groups: half of the oocytes underwent piezo-ICSI and the other half underwent conventional ICSI.
Participants/materials, setting, methods: Confirmation of fertilization in eggs was performed the next day, and then eggs were observed and graded on days 2, 5, and 6. Percentages of fertilization, degeneration after ICSI, good embryos, blastocysts, and good blastocysts were evaluated. Results were analyzed by age using the chi-square method.
Main results and the role of chance: Conventional ICSI and piezo-ICSI were used in 428 eggs and 419 eggs, respectively. The age of women ranged from 38 to 45 years old. When we analyzed the total number of embryos, there was no significant difference in percentages of results between the conventional group and the piezo-ICSI group. However, when we analyzed the results by age (38, 39, 40, 41, and older than 42 years old), women who were aged 42 years old or older had a significantly higher rate of blastocyst formation in the piezo-ICSI group compared with the conventional ICSI group (60.9% vs 25.0%, $p = 0.04$). The rate of blastocyst formation was similar between the two groups for the other ages.
Limitations, reason for caution: A limitation of this study was the inability to adopt our results to all women because of the small number of eggs included for each age, despite the considerable total number of eggs. A further, larger study is required to confirm our results.
Wider implications of the findings: This study partially clarified the indication for piezo-ICSI according to age compared with conventional ICSI. Based on our results, piezo-ICSI is recommended for older women (> 42 years old) rather than younger women. Clinical trials, including clinical pregnancy and birth rates, are needed in the future to obtain more clear indications.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Hanabusa Women's Clinic.
Trial registration number: NA.

P-503 Effect of trophectoderm vesicles on blastocyst development in relation to hatching, pregnancy, and spontaneous abortion rates

Y. Matsui[1], A. Iizumi[1], S. Tsuchiya[1], Y. Kaneko[1], K. Sato[1], T. Ozaki[2], K. Nishimura[1], Y. Araki[3], M. Nishimura[4]
[1]*Nishimura Women's Clinic, Laboratory, Hamamatsu, Japan*
[2]*Nishimura Women's Clinic, Obst and Gyne, Hamamatsu, Japan*
[3]*Institute for Assisted Reproductive Medical Technology, Laboratory, Maebashi, Japan*
[4]*Nishimura Women's Clinic, Obst and Gyne, Hamamatsu, Japan*

Study question: Trophectoderm vesicles (TVs) are sometimes observed at the blastocyst stage. In some areas of the trophectoderm, they can penetrate to the cell exterior through the zona pellucida; however, the morphological and physiological mechanisms underlying this phenomenon remain poorly understood.
Summary answer: We observed that intracytoplasmic sperm injection (ICSI) was associated with a higher prevalence of TVs than conventional in vitro fertilization (c-IVF). However, no significant differences were found between TVs positive or negative groups in the pregnancy rate and the spontaneous abortion rate.
What is known already: It is theorized that TVs are a cell component that induce exhaustion of the trophectoderm when hatching occurs from an opening in the zona pellucida of mice. However, no evidence has been found that this mechanism occurs in humans.
Study design, size, duration: In Study 1, a preliminary study, we used time-lapse cinematography to analyze the presence of TVs vitrified–warmed blastocysts. We then categorized the blastocysts into two groups: Group A, in which TVs were observed, and Group B, in which they were not. We also investigated the prevalence of TVs under two treatment protocols, ICSI and c-IVF. In Study 2, a clinical study, a single vitrified–warmed blastocyst was transferred to

patients in our clinic between September 2012 and August 2014. We evaluated the pregnancy rate and spontaneous abortion rate in regard to the presence of TVs (Group C: present; Group D: not present).
Participants/materials, setting, methods: *Study 1*: For the experiment, 112 vitrified–warmed blastocysts were used. These blastocysts were derived from surplus embryos after obtaining informed consent. The embryos were classified by Gardner's criteria 3AA and 4AA and then observed continuously for 4 days using time-lapse cinematography (EmbryoScope™ [ES]; Unisense FertiliTech, Aarhus, Denmark). We retrospectively evaluated the prevalence of TVs under both treatment protocols (ICSI: 56 embryos; c-IVF: 56 embryos). The hatching rate was then compared based on the presence of TVs. *Study 2*: This clinical study comprised 915 embryo transfer cycles in 723 clinic patients who received a single vitrified–warmed blastocyst. The features of embryonic development were recorded by time-lapse cinematography, and vitrification was then conducted at the blastocyst stage on Day 5 or 6. Next, the blastocysts were categorized based on the presence of TVs (Group C: 169 embryos, TVs present; Group D: 746 embryos, no TVs present). All transfers were conducted under a standard hormone replacement protocol. Finally, the pregnancy and spontaneous abortion rates were compared between the two groups.
Main results and the role of chance: *Study 1*: The prevalence of TVs was significantly higher in the ICSI (51/56; 91%) than in the c-IVF group (25/56; 45%) ($P < 0.01$). The hatching rate was significantly lower in the ICSI (11/56; 20%) than in the c-IVF group (29/56; 52%) ($P < 0.01$). In addition, the hatching rate was significantly lower in TV(+)(14/76; 18%) than in TV(-) embryos (26/36; 72%) ($P < 0.01$). *Study 2*: No significant differences were found between Group C and D patients in regard to age, duration of culture, acquired high quality embryo rate, hormone replacement, and endometrial thickness. In addition, no significant differences were found between groups in the pregnancy rate (Group C: 99/169, 58.6%; Group D: 404/746, 54.2%) or the spontaneous abortion rate (Group C: 13/99. 13.1%; Group D: 57/404; 14.1%).
Limitations, reason for caution: We were unable to confirm the reasons behind either TV production before the hatching stage or the differences in treatment (c-IVF or ICSI)-based prevalence. Furthermore, the composition of TVs remains unclear.
Wider implications of the findings: Further studies are needed on the influence of TVs on culture and quality.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Nishimura Women's Clinic.
Trial registration number: NA.

P-504 Is assisted hatching a poisoned gift?

M. Cabral[1], I. Pires[1], M. Osório[1], S. Pinelo[1], H. Serra[1], A. Barbosa[1], H. Figueiredo[1], E. Felgueira[1]
[1]*Centro Hospitalar Vila Nova de Gaia/Espinho EPE, Unidade de Medicina da Reprodução Dra. Ingeborg Chaves, Porto, Portugal*

Study question: What is the most effective technique (Hole *vs*. Thinning)? In which cases should each one be applied? Do these techniques enhance the implantation of abnormal embryos? What about monozygotic twins?
Summary answer: Comparing Hole vs. Thinning, the former had better pregnancy rate, despite the increase in monozygotic twins. Three indications were considered for performing the assisted hatching (AH) technique, and in all of them there was an increased pregnancy rate with the procedure. Fetal malformations occurred more frequently in women with increased age (IA) group, but this happens also in spontaneous pregnancies.
What is known already: Failure of hatching is hypothesized as a cause for repeated implantation failure (RIF). This could be due to intrinsic conditions of the embryo and zona pellucida (ZP), or promoted by cell culture and cryopreservation in assisted reproduction techniques, which could lead to ZP hardening.
Study design, size, duration: The study began in 2011 and is still going (147 couples performed 299 cycles, with and without AH). Selection for performing AH techniques was based on 3 indications: IA (> = 37 years) ($n = 49$), dysmorphic zona pellucida (thick, dense) ($n = 51$) and RIF (2 cycles without implantation) ($n = 47$). The choice between the two AH techniques was randomized.
Participants/materials, setting, methods: AH was performed with infrared non-contact diode laser beam fired about 8-10 times during 0.5 ms (wavelength of 1.48 nm). Techniques were performed either by ZP thinning (approximately 50%-80% of initial ZP thickness – $n = 81$) or by creating a hole in ZP ($n = 86$).
Main results and the role of chance: The pregnancy rate with AH was 32% vs. 12% without AH and the abortion rate was 24% with AH and 30% without AH. Considering the kind of AH technique the pregnancy rate was 44% with thinning technique and 6% with the hole technique. In the IA group pregnancy rate was 36% with AH and17% without AH. In dysmorphic ZP group pregnancy rate was 48% with AH and 21% without AH. In RIF group pregnancy rate was 28% with AH and 6% without AH.
Limitations, reason for caution: AH appears to be associated with multiple pregnancy, specially when thinning technique is performed but the evidence of a correlation with monozygotic twins was insufficient.
Wider implications of the findings: AH appears to be beneficial to the three groups included in the study, by increasing pregnancy rates without increasing fetal malformation or abortion rate.
Study funding/competing interest(s): Funding by hospital/clinic(s) – None.
Trial registration number: NA.
Keywords: assisted hatching, hole, thinning

P-505 Generation of gradients on microfluidic device for high-throughput investigation of spermatozoa chemotaxis

J. Yang[1], Y. Zhang[1], T. L. Yin[1], J. L. Ding[1]
[1]*Renmin Hospital of Wuhan University, Center of Reproductive Medicine, Wuhan, China*

Study question: This study aimed to establish a stable gradient chip allowing for simultaneous detection of sperm chemotaxis in parallel experiments, which was free from influence of shear stress and could improve efficiency of current sperm research.
Summary answer: Firstly, the microfluidic chip used in our study was capable of maintaining a stable concentration gradient for at least 7 hours. Secondly, three parallel experiments of the same sample were carried out on the same chip to investigate sperm chemotaxis to progesterone. Similar phenomena were observed as previous study described.
What is known already: Sperm chemotaxis plays a vital role in fertilization. Historically, various types of assays have been widely used for in vitro detection of sperm chemotaxis which are, however, typically poor in maintenance of gradient stability, not to mention their low throughput. Microfluidic device offers a new experimental tool for a better control of chemical concentration gradient. Its outstanding advantage in miniaturization and potential for high-throughput analysis makes it more economical and efficient over conventional devices.
Study design, size, duration: Microfluidic chip in our study is featured by a central hexagonal pool surrounded by six channels. Channels were connected with the hexagon by 5mm wide microchannels, through which fluid can flow. Sperm loaded in central pool can sense the gradient progesterone solution formed, thus exhibiting chemotactic behavior.
Participants/materials, setting, methods: We firstly used fluorescent dye to characterize concentration gradient formed in the chip. Then sperm response to two different concentrations (100pM and 1mM, respectively) of progesterone was recorded under phase-contrast microscopy. Fluorescence profile and sperm tracks were analyzed in Image J software. Results were processed in Origin 8.0 software.
Main results and the role of chance: Fluid flow within the device was controlled by adjusting heights of solution in loading reservoirs. Concentration gradient profiles in the central hexagon varied when distinct height differences were applied. Gradient was very weak when height difference (DH) was 0.8 mm, but was stable at a higher DH at 1.0 mm or 1.2 mm. In chemotaxis assays, progesterone solution was doped into every other peripheral channel of each chip. Significant differences in chemotactic parameters were recognized between experimental and control groups ($p < 0.05$). There was no great difference between two experimental groups. In terms of kinematic response, values of parameters in 1 mM group were significantly higher than in other two groups ($p < 0.05$). However, no significant difference was found between 100 pM group and control group.
Limitations, reason for caution: This experiment was only carried out using human sperm samples.
Wider implications of the findings: Simultaneous recording of three replications can greatly reduce possible errors caused by repeated assembly of equipment, and saving time in sample processing. Besides, width of interconnecting

microchannels can be adjusted to a greater size so that chemotactic spermatozoa can swim through into peripheral channels. Thereafter, sperm can be collected from the peripheral channels and be used in in vitro fertilization to improve the performance of assisted reproductive technology.

Study funding/competing interest(s): Funding by national/international organization(s) – The National Science Foundation (No.30973196,81370767, 81101971).

Trial registration number: NA.

Keywords: microfluidic chip, human sperm, chemotaxis, progesterone

P-506 Outcomes of systematic blastocyst vitrification during 2 consecutive years before and after its beginning. A significant increase in delivery rate is reached within the first year

A. Force[1], B. Nicollet[2], M. Chomier[2], P. Sergeant[2], M. Lescaille[2], S. Rochigneux[2], F. Robert[2], J. Ginon[2], M. V. Sergeant[2], S. Baucher[2], B. Schubert[1]
[1]*IRH- Centre de FIV de la Clinique du Val d'Ouest, Laboratoire Biomnis, Ecully, France*
[2]*IRH- Centre de FIV de la Clinique du Val d'Ouest, Clinique Val d'Ouest, Ecully, France*

Study question: Systematic blastocysts slow freezing procedure has been established for 8 years with convincing results in our team. Is the introduction of the vitrification will increase our results when it is proposed for all patients and performed by all members of the team?

Summary answer: After a one year-period of training for all the technical team, significant increase in delivery rate can be obtained with blastocysts vitrified, as soon as the first year when it is compared to slow freezing the year before with the same embryo culture systems and transfer policy.

What is known already: Blastocysts vitrification is an established new freezing technique which can give better results than slow freezing. However a learning curve is described for a technique needing skill and practice for all the members of the team. Therefore it is suggested that this technique cannot be proposed for all patients at the beginning of the procedure. The two freezing techniques might coexist during the time necessary for the habilitation of whole laboratory staff.

Study design, size, duration: This is a retrospective study comparing the outcomes of thawed blastocysts transfer between two consecutive years: 2012 (234 couples) vs. 2013 (291 couples). In addition we compared in 2013 the results of thawed blastocysts transfers according to the procedure of freezing used: slow freezing (150 couples) vs. vitrification (141 couples).

Participants/materials, setting, methods: We used a slow freezing protocol with glycerol and sucrose (Origio) in 2012 and start vitrification for all patients in 2013 with ethylene glycol and dimethylsulfoxide (Irvine) in closed system with high-security straws (CryoBio System). The main outcomes measures were thawed blastocysts survival rates and delivery rates.

Main results and the role of chance: In 2012, 100% of the 292 thawing were realized with slow frozen embryos whereas in 2013, there were 51% of the 369 thawing (others were from vitrified embryos). A significant higher delivery rate per thawing was observed in 2013: 13% vs. 23% ($p < 0.01$). Hence in 2013, 190 and 179 thawing of slow frozen or vitrified blastocysts were realized respectively. A higher survival rate (83 vs. 74% respectively; $p < 0.05$) and a higher delivery rate (27 vs. 18%; $p < 0.05$) were observed for the vitrified blastocysts. Mean number of transferred blastocyts (1.1 and 1.2), and miscarriages rate (8% and 4%) were similar for vitrified and slow frozen embryos respectively ($p > 0.05$). Consequently 55 and 37 healthy babies were born after thawing of vitrified or slow frozen embryos respectively.

Limitations, reason for caution: Confounding factors (remaining frozen embryos per couple, rate of thawed embryos the year of freezing, previous pregnancy rate before thawing) showed similar values between both groups. However, it is obvious that vitrified blastocyts had a shorter storage duration than slow frozen embryos.

Wider implications of the findings: After a training of the whole team, a new procedure can be quickly beneficial to all patients with successful results. Although our slow freezing program of blastocysts gave significant results, the vitrification procedure can still increase them, showing its superiority in our team.

Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Biomnis laboratory, Lyon, France.

Trial registration number: Retrospective study.

P-507 Effect of in vitro-supplementation of myoinositol on DNA fragmentation before sperm preparation for assisted reproductive techniques

L. Parmegiani[1], G. E. Cognigni[1], S. Bernardi[1], E. Troilo[1], A. Arnone[1], A. M. Maccarini[1], S. Lanzilotti[1], A. Rastellini[1], W. Ciampaglia[1], M. Filicori[1]
[1]*GynePro Medical, Reproductive Medicine Unit, Bologna, Italy*

Study question: The aim of this study is to test whether myoinositol in-vitro supplementation of semen samples can reduce the DNA damage that may occur before sperm preparation for assisted reproductive (AR) techniques.

Summary answer: Sperm DNA fragmentation significantly increases after a prolonged incubation of 4 hours from semen production. In these conditions, in-vitro myonositol supplementation can significantly decrease the DNA fragmentation process.

What is known already: During gamete handling for assisted reproductive techniques, a prolonged period of incubation before sperm preparation may have detrimental effects on sperm DNA, decrease the integrity of the sperm nuclei and cause dysfunction of mitochondrial membrane potential (MMP). Myoinositol (MI) is a buffer molecule for MMP and it has already been demonstrated that MI medium supplementation increases spermatozoa motility and MMP.

Study design, size, duration: Cross-sectional study of 10 men presenting at an infertility clinic for semen analysis over a period of 6 months. 500 spermatozoa per DNA test (25,000 total) were analysed for DNA fragmentation by Sperm Chromatin Dispersion method; 2mg/ml MI supplementation was performed by Andrositol Lab (Lo.Li.Pharma, Rome, Italy).

Participants/materials, setting, methods: Samples (basal group) were tested for DNA fragmentation after liquefaction, divided as below, and re-tested after 4 hours

1. seminal plasma alone (SP),
2. SP supplemented with myoinositol (SP + MI),
3. SP diluted 1 + 1 with sperm culture medium (CM),
4. SP diluted 1 + 1 with CM and supplemented with myoinositol (CM + MI).

Main results and the role of chance: Sperm DNA fragmentation rate after a 4-hour incubation significantly increased in all the groups except in the CM + MI group. More specifically, DNA fragmentation rate was: 24.0% (1200/5000) in the basal group; 51.6% (2580/5000) in the SP group; 40.9% (2045/5000) in the SP + MI group; 35.8% (1790/5000) in the CM group; 24.5% (1225/5000) in the CM + MI group; P was < 0.001 between all the groups, except in the case of the basal group versus the CM + MI group (0.576) which showed comparable DNA fragmentation rates.

Limitations, reason for caution: This was a small-scale study on forced stress: lab schedule is usually finalized to avoid unnecessary stress for the spermatozoa, but in AR units with a large number of semen samples to be treated simultaneously, a prolonged period of incubation (> 2 hours) may accidentally occur.

Wider implications of the findings: This study confirms that prolonged incubation before sperm preparation is harmful for DNA integrity but also indicates that dilution of seminal plasma with culture medium and supplementation with myoinositol can successfully protect the spermatozoa. Both culture medium and myoinositol alone reduce sperm DNA fragmentation but their combination seems to block the DNA fragmentation process for at least 4 hours. These findings may lead to a re-evaluation and improvement of routine incubation procedures before sperm preparation.

Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Cost of DNA kits and Andrositol Lab funded by Lo.Li.Pharma s.r.l., Rome, Italy.

Trial registration number: Not requested. Basic science study.

Keywords: sperm DNA fragmentation, myoinositol, sperm preparation, sperm handling

P-508 Temperature measurements in different brands of IVF culture dishes

A. H. Jakobsson[1], P. Westrin[2]
[1]*Vitrolife Sweden AB, R&D, Göteborg, Sweden*
[2]*HertArt, R&D, Göteborg, Sweden*

Study question: Do all culture dishes for IVF maintain temperature equally well (or bad) when removed from the incubator or is there a difference between different brands of dishes?

Summary answer: Dishes of all brands fail to maintain the temperature of the culture medium when the lid is removed but the temperature is maintained much better in dishes with direct contact with the heated stage.
What is known already: To maintain temperature in open dishes during laboratory work, heated stage temperature is elevated to 39-40°C and medium is covered with oil. Traditional dishes for handling and culture of oocytes and embryos commonly have an air gap underneath which makes it necessary to increase heated stage temperature above + 37°C to maintain physiological temperature in the medium inside the dish. When the dish lid is removed, temperature drops despite the elevated temperature on the heated stage.
Study design, size, duration: Dishes of three brands (Falcon, Nunc and Vitrolife) were tested. The dishes were Falcon center well dish, Vitrolife center well dish, Nunc 4-well dish and Vitrolife 5-well dish. Falcon and Nunc dishes have an air gap underneath while Vitrolife dishes have a flat bottom without air gap.
Participants/materials, setting, methods: Start temperature was 37°C. Measurements were performed with lids removed and repeated three times. Temperature was measured once per minute for five minutes and heated stage temperature was 39°C. Wells were filled with one ml of medium and moats with 4 ml. Temperature was measured with and without oil cover.
Main results and the role of chance: The temperature of the Falcon center well dish dropped to 31.2°C within 5 minutes after removal from the incubator and continued to go down while the temperature in the Vitrolife center well dish stabilized at 33,2°C. The temperature of the center well dishes covered with oil stayed more stable, the temperature of the Falcon dish went down to 34.5°C and the Vitrolife dish stabilized at 35.8°C. Finally, the temperature of the medium in the Nunc 4-well dish dropped to 31.6°C and the temperature in the Vitrolife 5-well dish stabilized at 34.1°C.
Limitations, reason for caution: The study included a limited number of dish brands and more brands can be studied to give a more complete picture of oocyte and embryo handling temperatures.
Wider implications of the findings: The fact that the temperature in dishes can drop to below 33°C within a few minutes after the lid has been removed during normal IVF laboratory work cause stress to oocytes and embryos resulting in impaired embryo development. All laboratories should check the temperature in open dishes of the brands used in the clinic to minimize a common results reducing factor.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Vitrolife Sweden AB
Trial registration number: NA.
Keywords: IVF culture dishes, temperature, temperature sensitivity, temperature measurement

P-509 Embryo culture in a continuous single medium and selection by morphokinetic analysis: a prospective randomized sibling oocyte trial of the embryo scope and primo vision

L. Nolte[1], N. Silver[1], T. Lundberg[1], F. Hambiliki[1], M. Bungum[1]
[1]*Skanes University Hospital Reproductive Medicine Centre Malmö Sweden, Reproductive Medicine Centre, Malmö, Sweden*

Study question: Is there a difference in the rate of good quality blastocysts per fertilized oocytes, according to the expansion of the blastocoel cavity and the quality of the inner cell mass and trophectoderm, assessed by two different time-lapse systems (EmbryoScope versus Primo Vision) after culture in a continuous single medium.
Summary answer: This ongoing trial showed that culture of embryos using a continuous single medium in the EmbryoScope resulted in a tendency towards an increase in the rate of good quality blastocysts on day 5.
What is known already: It was previously reported that embryos cultured in single medium without renewal during culture, showed an increase in blastocyst development, and that culture and selection of embryos in time lapse monitoring system improves reproductive outcomes. To our knowledge, no randomized controlled trial comparing the two different time-lapse systems, EmbryoScope or Primo Vision has been undertaken.
Study design, size, duration: In this ongoing prospective randomized sibling-split trial, 200 oocytes from 19 women assigned to ICSI were divided randomly to EmbryoScope treatment group (99) or Primo Vision treatment group (101) and cultured to day 5 in a continuous single medium and monitored by time lapse videography.
Participants/materials, setting, methods: Oocytes allocated to EmbryoScope treatment group were cultured singularly in 25 ml (G-TL, Vitrolife, Sweden) in an EmbryoScope culture dish and oocytes allocated to Primo Vision treatment group were cultured in groups in 80 ml (G-TL, Vitrolife, Sweden) in a Primo Vision culture dish. Embryos were cultured and monitored by time lapse videography until day 5.
Main results and the role of chance: Embryo scoring and selection was performed by a time lapse monitoring system (EmbryoScope or Primo Vision) and good quality blastocysts on day 5 were scored according to the degree of expansion > = 2 and Inner Cell Mass (ICM) = {1, 2} and Trophectoderm (TE) = {1, 2}. There was a tendency towards a higher rate of good quality blastocysts in the EmbryoScope treatment group compared to the Primo Vision treatment group (17.2 % versus 14.9 %), however the level did not reach statistical significance.
Limitations, reason for caution: None
Wider implications of the findings: The culture media used (G-TL, Vitrolife, Sweden) achieved good rates of blastocysts development and utilization (embryo transfer and cryopreservation). Thus, embryo culture system that does not require medium renewal during culture provides good condition and greatly reduces external environment stresses on embryos. Time lapse technology combined with a continuous single culture medium may increase the success rate of IVF.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Funded by Skane University Hospital, Malmö,Sweden.
Trial registration number: NA.
Keywords: time lapse, primo vision, embryoscope, blastocyst

PARAMEDICAL - NURSING

P-510 Infertility related communication and coping strategies among women affected by fertilitty problems in Sweden

M. Westerbotn[1], T. Sormunen[1], A. Aanesen[2]
[1]*Sophiahemmet Högskola, Nursing, Stockholm, Sweden*
[2]*Sophiahemmet Hospital, Fertility Clinic, Stockholm, Sweden*

Study question: The aim was to describe infertility related communication and coping strategies among women affected by fertility problems in Sweden.
Summary answer: Thirty percent of participants had difficulties discussing infertility related subjects with their husband or with close other people. To cope their situation 16 percent of participant avoided socialising with pregnant women, and one third of them had difficulties to find other life goals than children.
What is known already: Involuntary childlessness is a reality for many reproductive aged couples and can be psychologically stressful for many of them. The inability to have children affects couples worldwide and causes psychological and emotional distress on them. Both involuntary childlessness and infertility treatment places pressure on those involved. Difficulty in marital communication and high use of active-avoidance coping are significant predictors of high fertility problem stress.
Study design, size, duration: Cross sectional study design involving 156 Swedish women (mean age 36.3). The participants received a letter regarding information of the study including the questionnaire and a postage-paid reply envelope. Data was collected during 2010-2011. Approval from the Ethical Review Board, Stockholm (EPN 2006/1025-31) was obtained.
Participants/materials, setting, methods: The population consists of women with history of primary infertility, minimum of one year, which sought to a fertility clinic voluntarily or were referred from other clinics. A self-administered semi structured questionnaire (COMPI) was used to collect the data. Descriptive statistical methods were used to analyse the data.
Main results and the role of chance: Response rate was 78 %. Seven percent of the population did not discuss the inability to have a child, and nine percent did not discuss about reasons why they were childless at all with their spouse. Seventy-five percent discussed infertility related subjects only to close other people and 20 % did not discuss about the results of examinations and tests with people outside of the family. Thirty-five percent did not ask other childless individuals, friends or relatives for advice and 15 % were not able to discuss about

how tests and treatments affect them emotionally. Twelve percent reported that they leave the room when the subject children or pregnancies are discussed.
Limitations, reason for caution: Participants were recruited from one infertility clinic from great Stockholm area. The population consists of 156 participants and eighty-four percent of them had postgraduate education.
Wider implications of the findings: By highlighting possible problems with infertility relating communication, physicians, midwifes and nurses at fertility clinics may become aware of this problem and therefore dare to address the question. This knowledge may ensure high quality of care, improve patient wellbeing and possibly higher treatment compliance.
Study funding/competing interest(s): Funding by University(ies) – The study was funded by Sophiahemmet Ideel förening, Patientnära forskning, Sweden. The authors declare that they have no competing interests.
Trial registration number: The study is not a Clinical trial.
Keywords: inferility, communication, coping, women

P-511 Managing a fertility practice using set protocols: clinician-focused or patient-focused?

C. Meunier[1]
[1]*Hollywood Fertility Centre, Nursing, Perth, WA, Australia*

Study question: How can set clinical protocols enhance patient experience and practice management in an IVF clinic?
Summary answer: The Set Protocol System provides standardised patient care from all members of staff with benefits to patients, doctors, nurses, laboratory and administration staff. Experience suggests that set protocols do not reduce staff or doctor autonomy, but assures patients of the same level of service across the business.
What is known already: There are multiple ways of managing patient care in IVF clinics. The approach selected is driven by clinical practices designed to suit the practice, its clinicians and staff. In many cases, the practice methodology emerges from the skills and technical experiences of the clinician overlaid by regulatory requirements. It has also been noted that IVF management is influenced by IT systems designed to record practice and patient records. There is no 'one best way'.
Study design, size, duration: The study is based on 14 years of regulated operation of the practice based on the adoption of clinical protocols designed and developed by the senior doctor with assistance from nurses and scientists. The observations have been collected and refined over this time to arrive at set protocols that can be adopted by all doctors in the practice and applied for the benefit of patient outcomes.
Participants/materials, setting, methods: The practice was obliged to establish treatment protocols, whose aim was to standardise treatment regimens and to develop expertise in clinical, nursing and scientific practice. Protocols were matched to international practices through international meetings such as ESHRE and ASPIRE, which remain the source of protocol development. Participants have been doctors, scientists, nurses and administration personnel associated with the practice over 14 years. The research methodology is based on longitudinal observation of set protocols.
Main results and the role of chance: Set protocol start from the moment a patient enters the practice. Patients determine the potential treatment load. All patients have to undertake a set of tests that are obligatory. e.g. rubella, CF, PAP smear for females, semen analysis for males. With additional doctors came standardisation to avoid 'diversity of practice' created by: independent practice habits perhaps because they trained in different years (and universities). Dividing the work to ensure patients received similar treatment was complex, but they could not easily see the same doctor each time they came to the Centre, nor could the same doctor carry out the necessary procedural work. The work had to be divided in fair way that guaranteed appropriate treatment for patients (and agreed remuneration among the doctors).
Limitations, reason for caution: The study relates to one practice that adopted set protocols compared to other practices which did not based on observations collated over 14 years.
Wider implications of the findings: Set protocols create practice standardisation and permit a group of doctors to provide specialised treatment to a diverse and demanding patient group. The protocols assist patients to feel certain about their treatment regimen and the quality of care they are receiving.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Hollywood Fertility Centre.
Trial registration number: NA
Keywords: practice management, protocols

P-512 Elective single embryo transfers (eSET) in Turkey: a need for an educational campaign?

S. Sarikoc[1], C. Pirkevi[1], H. Yelke[1], M. Cetinkaya[1], S. Kahraman[1]
[1]*Memorial Sisli Hospital, ART and Reproductive Genetics Center, Istanbul, Turkey*

Study question: Are Turkish patients aware of risks related to multiple pregnancies?
Summary answer: A survey conducted in a private Turkish ART center enrolling 201 infertile couples showed that only 6% are concerned about having a multiple gestation.
What is known already: To decrease the incidence of multiple pregnancies, a legislation regarding eSET was brought into force by the Turkish Ministry of Health in 2010 and modified in 2014. According to this regulation, for women < 35 years of age, with one or no previous ART cycle(s), the number of embryos which can be transferred is limited to one.
Study design, size, duration: A total of 201 infertile females participated in the survey conducted between August and September 2014, just before the embryo transfer procedure. The survey included 25 questions about satisfaction regarding the center, psychological aspects of the treatment and also concerns about multiple gestation.
Participants/materials, setting, methods: The mean age of the population was 34.1 ± 6.0. The educational level was variable: 64% of the patients were graduated from university, 20% from high school and 16% from elementary school. 44% of patients were referred from the same city as the ART center (Istanbul), 48% from the remainder of Turkey and 8% from abroad.
Main results and the role of chance: For some questions multiple answers were possible and analyzed as such. 77% of patients expressed their main concern as failing their ART attempt. Moreover, in the absence of supportive public ART funding, half of the patients are concerned about financial issues (45%). The quarter of the cohort (26%) was concerned about not being able to share their experience about their ART cycle with their family and close friends. But of the 201 patients surveyed only 6% were anxious about having a multiple gestation.
Limitations, reason for caution: The underlying infertility cause could not be taken into consideration because of the relatively small sample size.
Wider implications of the findings: A very low number of patients were concerned about multiple gestation and the accompanying risks. Therefore, educational campaigns should be organized if we really aim to promote of eSET in the near future in Turkey.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Survey was funded by Memorial Sisli Hospital Administration, Istanbul, Turkey.
Trial registration number: Study design and the survey was approved by the Ethics Committee of the Memorial Sisli Hospital, Istanbul, Turkey.
Keywords: ART, eSET, multiple gestation

P-513 Effects of in vitro fertilization on postpartum depression and stress coping

D. Matsuura[1], S. Hayashi[2], K. Kuroda[2], N. Ichikawa[3], N. Ogawa[3], Y. Nojiri[3], M. Nomura[4], T. Kitagawa[4], K. Furui[4]
[1]*Clinic MAMA, Counseling, Gifu, Japan*
[2]*Clinic MAMA, Nursing, Gifu, Japan*
[3]*Clinic MAMA, Embryology, Gifu, Japan*
[4]*Clinic MAMA, Medical office, Gifu, Japan*

Study question: This study investigated whether patients becoming pregnant as a result of in vitro fertilization are more likely to suffer from postpartum depression than those becoming pregnant spontaneously.
Summary answer: The patients investigated who became pregnant as a result of in vitro fertilization were more likely to suffer from postpartum depression than those becoming pregnant spontaneously at one month postpartum.
What is known already: The coping scale consists of three subscales: problem-focused, emotion-focused, and avoidance-escape (14 items). Prolonged infertility treatment can lead to a more passive stress-coping strategy (avoidance-escape). In addition, patients receiving infertility treatment are likely to

show a higher score of EPDS, which assesses postpartum depression with a cut off of 8/9(assuming a score of 8 points or lower as negative and 9 or higher as positive), at one month after delivery.
Study design, size, duration: We included 24 patients who delivered a child as a result of spontaneous pregnancy (spontaneous pregnancy group) and 19 who did as a result of in vitro fertilization (IVF group) at our outpatient clinic between January 2012 and December 2014 in the study.
Participants/materials, setting, methods: At one month after delivery, we evaluated the 43 patients using the 30-point Edinburgh postpartum depression scale (EPDS) revised by Okano. Furthermore, we examined which strategy the EPDS-negative versus EPDS-positive patients employed among problem-focused (15-point), emotion-focused (9), or avoidance-escape (18), as defined in the stress-coping scale of Ozeki et al.
Main results and the role of chance: Both spontaneous pregnancy and IVF groups indicated "child health/care" as a primary stressor at one month after delivery. The IVF group showed significantly higher EPDS scores and included a significantly higher proportion of EPDS-positive patients (EPDS of 9 or above) compared to the spontaneous pregnancy group. In addition, when comparing the stress-coping strategies for the IVF group, EPDS of 9 points or higher was correlated with a significantly lower scores for the emotion-focused strategy compared to EPDS-passive (8 points or lower), suggesting that the EPDS-positive patients of the IVF group were unlikely to adapt themselves to active coping, i.e., emotion-focused strategy. Some of these EPDS-positive patients underwent treatment for a second child at our clinic after the birth of their first child.
Limitations, reason for caution: Postpartum depression and stress coping strategies are based on the psychological status at one month after delivery in spontaneous pregnancy and IVF patients. In this study, a smaller sample was used, and stress was assessed based on patient's subjective comments.
Wider implications of the findings: It was suggested that the IVF compared to spontaneous pregnancy group was more likely to suffer from postpartum depression, as demonstrated by higher EPDS scores, at one month after delivery. In addition, when comparing the stress-coping strategies for the IVF group, EPDS-positive compared to EPDS-negative patients showed significantly lower scores for the emotion-focused strategy. Furthermore, some of the EPDS-positive patients again visited our clinic to undergo further infertility treatment for a second child.
Study funding/competing interest(s): Funding by hospital/clinic(s) – CLINIC MAMA.
Trial registration number: NA.
Keywords: IVF, postpartum depression, stress coping

P-514 The 'haves' and the 'have-nots': comparing fertility awareness and attitudes towards infertility between parents and non-parents

C. H. Y. Chan[1], T. H. Y. Chan[1], B. Peterson[2], C. Lampic[3]
[1]*The University of Hong Kong, Social Work and Social Adminstration, Hong Kong Island, Hong Kong*
[2]*Chapman University, Crean College of Health and Behavioral Sciences, Orange, CA, U.S.A.*
[3]*Karolinska Institutet, Department Neurobiology Care Sciences and Society, Stockholm, Sweden*

Study question: Is there any difference between parents and non-parents in their fertility-related knowledge and attitudes towards infertility?
Summary answer: Compared to non-parents, parents underestimated to a greater extent the fertility decline, and insisted more strongly on keep trying natural intercourse in the event of infertility.
What is known already: Infertility is a stressful experience and infertile couples often seek social support from their peers, many of whom might be parents. However, it is not known how parents and non-parents perceive fertility issues differently.
Study design, size, duration: An online cross-sectional survey in Hong Kong was conducted in May to August 2013 through a university-wide email invitation.
Participants/materials, setting, methods: A total of 246 participants (parents: $n = 97$, non-parents: $n = 149$) who were aged 30 or above responded to a previously validated questionnaire on fertility knowledge and attitudes towards infertility. The average age was 35.6 (SD = 5.6) for non-parents and 38.8 (SD = 6.3) for parents.
Main results and the role of chance: Although both parents and non-parents overestimated the age at which significant fertility decline occurred (8.2% non-parents and 7.7% parents answered the right age category), parents reported a significantly higher age than non-parents (34.1 and 33.1 respectively, $F = 4.34$, $p < .05$). In the hypothetical event of infertility, parents expressed a stronger wish than non-parents to keep trying natural intercourse ($F = 14.29$, $p < .01$), and less willing to accept childlessness ($F = 20.37$, $p < .01$).
Limitations, reason for caution: Self-selection bias is a limitation of cross-sectional study. This study was conducted in Hong Kong, a Westernized city with an advanced economy where influences of Chinese culture remain strong. Cross-cultural studies should be done in order to generalize the findings.
Wider implications of the findings: This study sheds light for the first time on the discrepancy in perception between parents and non-parents of fertility issues. Since infertile couples are likely to seek social support from peers who are parents, healthcare professionals should make clients more aware of the discrepancy of perception between parents and non-parents and the risk of social pressure in making treatment decisions.
Study funding/competing interest(s): Funding by University(ies) – University of Hong Kong.
Trial registration number: NA.

P-515 Effects of a partnership support program for couples undergoing fertility treatment

K. Asazawa[1]
[1]*Tokyo Healthcare University, Department of Nursing, Tokyo, Japan*

Study question: The study's purpose was to examine the effects of providing a partnership support program. It was designed to improve Japanese couples' partnership, maintain quality of life, decrease psychological distress, and improve marital relationship satisfaction while they underwent infertility treatment that included the possibility of using assisted reproductive technology.
Summary answer: The intervention group showed significant improvement in the couples' partnership and a significant decrease in women's psychological distress using subgroup analysis.
What is known already: Infertile patients had numerous stresses and anxiety, and their quality of life (QOL) was low. One factor compounding women's psychological distress was a deteriorated marital relationship.
Study design, size, duration: This was a quasi-experimental design using a convenience sample and a nonequivalent age-matched control group with non-random group assignment. An estimated 308 participants must be enrolled to achieve the desired 80% power with an alpha level of.05. The data collection period was from April to November 2013.
Participants/materials, setting, methods: Potential participants were couples undergoing fertility treatment visits at a Japanese fertility clinic. The intervention group patients participated in the partnership support program. The comparison group patients received usual care. The program provided information and used a participatory-interactive approach to enhance understanding and cooperation in couples undergoing fertility treatment.
Main results and the role of chance: Agreeing to participate were 152 patients from the intervention group and 166 patients from the comparison group. Completing the study were 108 patients (71.1%) from the intervention group and 120 patients (72.3%) from comparison group. Missing data and participant dropout were managed using 'baseline observation carried forward analysis' (BOCF) for intention to treat analysis.

1. The intervention group's Partnership scale scores after the intervention were significant higher than the comparison group indicating a stronger partnership.
2. The intervention group's FertiQoL scale scores at post-intervention were not significantly higher than the comparison group.
3. The Distress scale scores for the women in the intervention group were significantly lower than the women's scores in the comparison group meaning the women in the intervention group had less distress.

Limitations, reason for caution: Because this study was not a RCT and the location of data collection was only a single clinic; there is limited generalizability and potential bias. The research design was a nonequivalent control

group designs instead of a RCT therefore the internal validity for the intervention effect was weaker.
Wider implications of the findings: The partnership support program was effective in improving the couples' partnership while undergoing infertility treatment, and that in turn was effective in reducing psychological distress among the participating women; however it had less impact for the men. It's possible that there was less distress for men than women undergoing treatment and therefore the men did not require support from their partners. The program was not effective in improving QOL as a whole for the couples.
Study funding/competing interest(s): Funding by national/international organization(s) – The Japan Academy of Midwifery.
Trial registration number: NA.

PSYCHOLOGY AND COUNSELLING

P-516 Considerations and actions towards motherhood in 200 single, childless women aged 35 to 43 years

L. Schmidt[1], K. Birch Petersen[2], H. W. Hvidman[2], R. Sylvest[2], A. Nyboe Andersen[2]
[1]*University of Copenhagen Institute of Public Health, Department of Public Health Section of Social Medicine, Copenhagen, Denmark*
[2]*Copenhagen University Hospital Rigshospitalet, Fertility Clinic, Copenhagen, Denmark*

Study question: Which conditions are of importance and what are the motives for and actions towards motherhood in single, childless women aged 35 and above after fertility assessment and counseling?
Summary answer: The important prerequisites for having children were maturity and the possible combination of work with childbearing. The expected benefits of motherhood were personal development and to give/receive love. The majority feared loss of freedom and less time to job/career. Most expected to have children within two years after the consultation.
What is known already: The reproductive patterns have changed in Europe in recent years. An increasing number of women and men are registered as living alone. In Denmark, 1% of the birth cohort is born by solo-mothers using semen donation and 14% of Danish women never have children. Studies addressing the attitudes towards family formation and fertility awareness have primarily focussed on cohabiting or young women; the knowledge and considerations among older, childless women is limited.
Study design, size, duration: A prospective, population-based, cross-sectional cohort study of 200 single women aged 35-43 years examined at the Fertility Assessment and Counselling (FAC) Clinic at Copenhagen University Hospital from 2011 to 2014. The FAC Clinic was initiated to provide individual fertility assessment and counselling (Hvidman*, et al.*, 2015).
Participants/materials, setting, methods: Eligible participants were heterosexual, single and childless women aged 35 years and above. All completed a web-based questionnaire before and after the consultation including socio-demographic, reproductive, medical, lifestyle and behavioural factors. Consultation by a fertility specialist included transvaginal ultrasound, uptake of a full reproductive history and AMH measurement.
Main results and the role of chance: The 200 single women had a mean (SD) age of 37.5 (2.0) years and 85% had an education length of 3-6 years. The women listed the following aspects as very important/important in relation to childbearing: feeling mature (91%), ability to combine work and children (78%), access to daycare (68%), having a partner (67%) and a stable relationship (67%). The values associated with motherhood were: personal development (90%), to give/receive love (89%), and new perspectives in life (81%). There was a general concern of: loss of freedom (83%), less time to job and career (76%) and an inferior economy (43%). Only half listed children as the meaning of life (55%). Yet, after the consultation, 93% expected to have children within the next two years.
Limitations, reason for caution: Attendance to the FAC Clinic is based on self-referral which could imply a potential selection bias and influence the personal decision-making. The high proportion of women expecting to have children within two years despite their present single status could imply a selected group considering solo-motherhood.
Wider implications of the findings: In contrast to the results of previous studies, having a partner was not the most important prerequisite for having children in our cohort. Personal development, the loving relationship between mother/child, access to day care and the job situation were considered more significant. This may partly explain why an increasing number of heterosexual women of advanced age choose solo-motherhood with donor insemination and emphasizes the importance of social preconditions for family formation among well-educated women.
Study funding/competing interest(s): Funding by national/international organization(s) – The FAC Clinic is a part of the ReproSund and Reprohigh collaboration and was 50% co-financed by EU-regional funding. This study also received funding through the Capital Region Research Fund. The authors have no conflict of interest.
Trial registration number: NA.

P-517 Predictors of pain during oocyte retrieval

Y. Frederiksen[1], M. M. Y. Mehlsen[1], S. M. S. Matthiesen[2], R. Zachariae[3], H. J. Ingerslev[4]
[1]*Business and Social Sciences, Department of Psychology and Behavioral Sciences, Århus, Denmark*
[2]*Family and Youth Aarhus Municipality, Department of Projects and Development Interventions for Children and Family, Århus, Denmark*
[3]*Aarhus University Hospital, Psychooncology and Health Psychology Research Unit Department of Oncology, Århus, Denmark*
[4]*Aarhus University Hospital, Centre for Preimplantation Genetic Diagnosis/ The Fertility Clinicesearch Unit Department of Oncology, Århus, Denmark*

Study question: Can medical, procedural or psychosocial factors predict unacceptably high pain levels in women undergoing oocyte retrieval?
Summary answer: Negative gynecological experience, hormonal side-effects, anxiety levels and lack of control were significantly associated with high pain intensity during oocyte retrieval.
What is known already: The experience of pain during procedures such as oocyte retrieval remains a common challenge to endure, for a number of patients, albeit elaborate pain management protocols have been developed. The present study examined the prevalence of pain, as well as possible medical and psychosocial risk factors for experiencing severe pain levels, for a sample of women going through in vitro fertility or intracytoplasmic sperm injection treatment.
Study design, size, duration: Eight hundred and thirty-seven women in IVF/ICSI treatment completed three questionnaires: at their 21st day of the cycle (t1), before the oocyte retrieval surgery (t2), and after the oocyte retrieval when the effect of sedation and analgesics had subsided (t3). Sixty-nine women were lost to follow-up.
Participants/materials, setting, methods: Participants were in their first treatment cycle. Patients undergoing preimplantation genetic diagnosis or acute change of procedure from insemination to IVF due to too many follicles were excluded.
Main results and the role of chance: The pain level was 1.95 (SD 1.434) for the total sample. High pain intensity was reported in a subgroup of 50 (7%) of the women, with the remaining 690 women (93%) reporting moderate to low-pain. Multiple logistic regression indicated that the significant predictors of high pain intensity, measured before the oocyte retrieval, were negative gynecological experiences [adjusted OR: 1.099 95% CI (1.029, 1.173); $P < 0.001$] and hormonal side effects [adjusted OR: 1.619 95% CI (1.123, 2.128); $P < 0.001$]. Significant independent variables measured after the oocyte retrieval were anxiety [adjusted OR: 1.296 95% CI (1.040, 1.615); $P < 0.001$], perceived control [adjusted OR: 0.621 95% (0.492, 0.784); $P < 0.001$] and the duration of the procedure [adjusted OR: 1.084 95% (1.035, 1.136); $P < 0.001$].
Limitations, reason for caution: We obtained no exact information on non-responders as the registration of those who chose to participate and those who declined was incomplete. Any generalization of the results of this clinical population should be made with proper caution.
Wider implications of the findings: The findings of this study may help prospectively to identify those women who are at risk of experiencing unacceptable pain levels during oocyte retrieval procedures. Targeting and understanding the

role of pain catastrophizing and rumination associated with previous negative gynecological examinations may help improve the individual pain management protocol. Also, factors such as anxiety and feelings of lack of control are commonly associated with higher pain levels, which may also be the case for clinical populations awaiting sub-acute, minor surgery. The medical staff is advised to take psychological factors into account.

Study funding/competing interest(s): Funding by University(ies) – Funding by commercial/corporate company(ies) – This work was supported by research grants from Merck Sharpe Domer and from The Danish Agency for Science Technology and Innovation. The funders had no influence on the data collection, analysis or conclusions of the study. None of the authors have any conflicts of interest to declare.

P-518 Psychosocial effects on reproductive outcomes: examining the impact of infertility-related coping strategies and stress on female and male biological responses and on pregnancy

J. Pedro[1], J. Mesquita-Guimarães[2], C. Leal[2], V. Almeida[3], M. E. Costa[1], M. V. Martins[1]

[1]*University of Porto, Faculty of Psychology and Education Sciencies, Porto, Portugal*

[2]*Porto Hospital Center, Reproductive Medicine Department, Porto, Portugal*

[3]*University of Porto, Faculty of Sciences, Porto, Portugal*

Study question: Do psychosocial variables play a role on biological responses and on achieving pregnancy in couples engaged in IVF/ICSI/TESE treatments?

Summary answer: Female age and women´s use of active confronting and passive avoidance coping strategies were significant predictors of the number of retrieved oocytes. Men´s use of active confronting coping strategies and female age at the beginning of treatments significantly predicted pregnancy.

What is known already: There is previous evidence showing that psychosocial variables can influence the biological response to infertility treatments, but the link between psychosocial adjustment and the successful outcome of infertility treatments remains unclear. Additionally, studies investigating this link on men are lacking because the vast majority of studies considered only female variables. Moreover, further investigation is needed using couple as unit of analysis.

Study design, size, duration: Sociodemographic, lifestyle, and psychosocial data were collected from 613 subjects seeking infertility treatment between February 2010 and March 2011.Of these, 201 couples referenced for fertility treatment for the first time in a Public fertility center were drawn. In December 2013, this database was linked with the center medical records.

Participants/materials, setting, methods: Participants were 79 couples that underwent IVF/ICSI/TESE. Using two separate multiple regressions, we examined the impact of coping and stress on retrieved oocytes and seminal defect controlling for age and lifestyle habits. Effects on clinical pregnancy were controlled with age, infertility duration and type, sperm motility and referral status.

Main results and the role of chance: Participants had on average 33 (women) and 34.9 (men) years. They were living together for 6.7 years and had been trying to conceive for 4.3 years. In December 2013, 41.8 % of couples had achieved a pregnancy. Female age at treatment (b = -.267; P = .021), active confronting (b = -.281; P = .021) and passive avoidance coping (b = -.252; P = .043) significantly predicted the number of oocytes retrieved. None of the variables were significant on the male model. Female age at treatment (B = -.265; P = .009) and male active confronting coping (B = 1.32; P = .005) were significant predictors of pregnancy. The total model can identify correctly 75.4 % of pregnancies.

Limitations, reason for caution: The number of couples included in the analysis is small. Additionally, it is possible that other non-explored variables could add explained variance. Future research should examine the effects of psychosocial variables with both couples' members in larger samples.

Wider implications of the findings: Coping strategies adopted by infertile patients can affect the biological response to infertility treatments, as well its success. Patients can be informed about this result by the clinical staff and if necessary be referred to an infertility counselor. Future research is needed to better understand the role of infertility-related coping strategies and stress on both female and male biological responses and on pregnancy outcomes.

Study funding/competing interest(s): Funding by national/international organization(s) – This work is supported by European Union Funds (FEDER/COMPETE - Operational Competitiveness Programme) and by national funds (FCT - Portuguese Foundation for Science and Technology) under the projects PTDC/MHC-PSC/4195/2012 and SFRH/BPD/85789/2012.

P-519 Satisfaction with fertility care during assisted reproduction treatments and its impact in men and women quality of life

M. Moura-Ramos[1], A. P. Sousa[2], R. Brito[2], R. Silva[2], T. Almeida-Santos[2]

[1]*University of Coimbra, Faculty of Psychology, Coimbra, Portugal*

[2]*Coimbra Hospital and Universitary Centre, Reproductive Medicine Center, Coimbra, Portugal*

Study question: Does satisfaction with fertility care contributes to quality of life of patients undergoing assisted reproduction treatments?

Summary answer: Satisfaction with fertility care, namely with information on treatment procedures and demands contributes to quality of life of patients undergoing assisted reproduction treatment

What is known already: Infertile patients well being is affected by fertility clinic and staff characteristics. It has been documented that patients value positive attributes of fertility clinics (e.g. accessibility, easiness to access, comfort) and fertility staff positive attributes (e.g. courtesy, sensitivity, being available to patients questions). However, it remains unclear which of all these components of care is more likely to affect the quality of life (QoL) of men and women's undergoing assisted reproductive techniques.

Study design, size, duration: In this cross-sectional, 264 infertile patients (132 infertile couples) undergoing an IVF cycle in a public universitary hospital from January to December 2014 were invited to participate. Both partners received the questionnaire and were asked to fill it separately. Participation was voluntary and anonymous.

Participants/materials, setting, methods: Participants were asked to complete a questionnaire on satisfaction with the clinic assessing characteristics (e.g., clinic facilities) and relational aspects of the fertility clinic staff (e.g. sensitivity to the patient needs) and also the FERTIQOL questionnaire on fertility quality of life – treatment module. Patients received the questionnaires at the day of the oocyte retrieval and were asked to return them prior to the pregnancy test.

Main results and the role of chance: Participants were 88 infertile couples (response rate of 66.7%) mostly undergoing their first treatment (68,6%). Women reported worse tolerability and worse treatment QoL than their partners (Both $p < 0.001$). A regression model was conducted to examine the effects of clinic and staff characteristics in patients' treatment QoL. Easiness to access the clinic (b = -6.79, $p = .009$) and clarity of information from clinic staff (b = -15.39, $p = .019$) significantly predicted women Mind and Body Qol. Regarding QoL in treatment, satisfaction with information on treatment procedures and demands significantly predicted women's and men's environmental QoL (b = 1.29, $p = .001$ and b = 1.98, $p = .004$, respectively), mainly for patients undergoing their first IVF cycle ($p = 0.05$). Patients reported they would rather prefer receive the information at the medical appointment (80%) and by the medical staff (42%).

Limitations, reason for caution: As the study is voluntary, it is possible that there is a self selection sample bias and participants less satisfied with fertility clinic or undergoing higher emotional difficulties did not participate in the study.

Wider implications of the findings: Results show that clarity of information and information on treatment procedures and demands are important predictor of patients QoL, namely of treatment related Qol, especially in patients undergoing their first cycle of assisted reproduction techniques. This study highlights the importance of fertility clinics being aware of the importance of providing their patients with full information on their treatment procedures.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Coimbra Hospital and University Centre.

Trial registration number: The study is not a trial.

Keywords: quality of life, quality of care, IVF

P-520 What do parents say to their children when they have been conceived by embryo donation or double donation treatment?

N. Doherty[1], F. MacCallum[1]

[1]*University of Warwick, Department of Psychology, Coventry, United Kingdom*

Study question: When, how and what do parents tell their children when they have been conceived by embryo donation or double donation treatment?

Summary answer: The majority of parents interviewed have already told their young child something about the embryo donation or double donation treatment. Whilst there are some similarities in what information parents give, exactly what they say to their children and how they decide what to tell varies between, and within families.
What is known already: Little is known about parents' thoughts and feelings about disclosure in cases of embryo donation or double donation, and exactly what parents tell their children. Embryo/double donation parents face unique decisions, including whether and how to tell their child that neither parent has a genetic link to them. Previous evidence suggests that being open about donor conception may be beneficial; however, the majority of existing research focuses solely on egg or sperm donation.
Study design, size, duration: Parents were approached via fertility clinics and a support group, and invited to participate in one-to-one interviews. Interviews began in January 2014 and will continue until April 2015. 21 interviews have been completed, with 25 in total anticipated. Data will be analysed using thematic analysis extracting common themes across interviews.
Participants/materials, setting, methods: Parents with a child aged between 3 and 8 years conceived by embryo donation or double donation were recruited. In-depth semi structured interviews were used to explore thoughts and feelings about disclosure, and to ascertain what parents have told their child. In two-parent families, both parents were interviewed where possible.
Main results and the role of chance: Preliminary findings demonstrate that parents who have already started disclosing to their child, generally begin to do so in the first couple of years of their child's life. The perceived benefits are that it allows them to find the terminology that they wish to use before their child can understand their meaning, and so that the foundation is there ready to develop as their child gets older. The language that parents use varies; however emerging themes include disclosure as a story developing over time, concern and anxiety about the future, and that parents tell their children about the 'kindness' of donors. Parents who have disclosed report that they would benefit from additional support on what to tell their children as their understanding matures.
Limitations, reason for caution: The majority of parents interviewed thus far have started to disclose, however a proportion of parents were recruited through a support group, so may not be representative of all parents in similar circumstances. Findings are based on preliminary data, but all data will be available to present at the conference.
Wider implications of the findings: Findings highlight the importance of understanding this relatively unexplored area of parenting. Conclusions will consider parents' thoughts and feelings on disclosure and how parents decide whether to disclose. Suggestions will be made for how counsellors could help to support parents facing these decisions. In particular, consideration will be given as to whether clinics should give more thought to providing post-treatment counselling to support parents with the implications of disclosure as their child's comprehension develops.
Study funding/competing interest(s): Funding by University(ies) – University of Warwick.
Trial registration number: NA.

P-521 Attitudes towards family formation in single and cohabiting childless women in their mid- to late thirties

R. Sylvest[1], K. B. Petersen[1], A. Nyboe Andersen[1], A. Pinborg[2], H. W. Hvidman[1], L. Schmidt[3]
[1]*University Hospital of Copenhagen Rigshospitalet, The Fertility Clinic, Copenhagen Ø, Denmark*
[2]*University Hospital of Copenhagen Hvidovre Hospital, The Fertility Clinic Department of Obstetrics and Gynecology, Hvidovre, Denmark*
[3]*University of Copenhagen, Department of Public Health, Copenhagen, Denmark*

Study question: What are the attitudes and perceptions towards family formation among single and cohabiting women seeking individual fertility counselling?
Summary answer: Well-educated women postpone pregnancy despite their knowledge of the decline in female fecundity with increasing age and their wish of motherhood. We observed an internal conflict of choosing parenthood, as the women described family formation as the meaning of life though they also had considerations related to the negative consequences.
What is known already: During the past 30 years women and men have postponed family formation in Western societies. Several studies have shown that women tend to underestimate the decline in fecundity with age and overestimate the success rate in assisted reproductive technologies. A growing population of women decide to become solo-mothers through assisted reproduction using donor-sperm.
Study design, size, duration: Baseline data from a longitudinal semi-structured qualitative interview study including 20 women aged 34-39 years seeking individual fertility counselling. A total of 25 women were contacted, two were excluded due to pregnancy. In all 10 single and 10 cohabiting women were included. Data was collected between March and September 2014.
Participants/materials, setting, methods: Study participants were single or cohabiting women, residents in the Capital Region of Copenhagen, and seeking individual fertility counselling (Hvidman et al., 2015). Purposeful sampling with maximum variation was used. Data were analysed by qualitative content analysis following the methodology by Graneheim and Lundman.
Main results and the role of chance: The study displayed the conflict towards parenthood both in the single and cohabiting women. The general attitudes and considerations towards family formation were characterised by the fear of negative consequences and lifestyle changes on one hand and the biological clock and the dream of the nuclear family on the other. Finding the right partner was a central point for all of the participants. Despite their advanced age none of the women felt ready to motherhood at the present. Both single and cohabiting women showed an increasing awareness of solo-motherhood as a possible solution to advanced age and the wish for a child.
Limitations, reason for caution: The study participants had all chosen to seek individual fertility counselling. Hence, the results may not be directly transferred to a similar age group in the general population in regards to attitudes towards family formation and concerns of reproductive lifespan.
Wider implications of the findings: Many women postpone childbearing to their late thirties and thereby risk infertility, smaller families than desired, and adverse obstetric outcomes. Our study contributes to the understanding of the personal considerations in relation to childbearing in women (mid- to late thirties). This may be useful in a fertility assessment and counselling setting providing individual guidance to women and men of reproductive age, and it may also be used to enhance pro-fertility initiatives in the general population.
Study funding/competing interest(s): Funding by national/international organization(s) – The study was partly funded through the ReproSund and ReproHigh collaboration receiving EU-regional funding. The authors have no conflicts of interest.
Trial registration number: NA.
Keywords: postponing childbearing, fertility, family formation, women, fertility assessment and counselling

P-522 Family intentions of childless single and cohabiting women aged 35 to 43 years seeking fertility assessment and counselling

K. Birch Petersen[1], H. W. Hvidman[1], A. Pinborg[2], K. T. Macklon[3], E. C. Larsen[3], A. Nyboe Andersen[3], L. Schmidt[4]
[1]*Copenhagen University Hospital Rigshospitalet, Fertility Clinic, Copenhagen, Denmark*
[2]*Copenhagen University Hospital Hvidovre Hospital, Department of Gynecology/Obstetrics, Copenhagen, Denmark*
[3]*Copenhagen University Hospital, Fertility Clinic, Copenhagen, Denmark*
[4]*University of Copenhagen, Department of Public Health, Copenhagen, Denmark*

Study question: What characterizes childless women aged 35 years and above seeking fertility assessment and counselling on their reproductive lifespan and are there significant differences between single and cohabiting women?
Summary answer: The women were aware of age related declining fecundity and wished for 1.8 children on average. More than half would consider sperm donation, 45% oocyte vitrification, but only 15% oocyte donation. Despite advanced age, 78% primarily sought fertility assessment and counselling to gain knowledge on the possibility of postponing pregnancy.
What is known already: Recent studies have indicated an increasing demand for ovarian reserve testing in women without any known fertility problem to obtain knowledge on their reproductive lifespan (Hvidman*, et al.*, 2015, Seifer*, et al.*, 2015). Women postpone their first pregnancy and maternal age at first birth

has increased in Western societies over the past two to four decades. Postponed childbearing implies a higher rate of involuntary childlessness, smaller families than desired and declining fertility rates

Study design, size, duration: Baseline data from a prospective population-based cohort study of 340 women aged 35-43 years examined at the Fertility Assessment and Counselling (FAC) Clinic at Copenhagen University Hospital from 2011 to 2014. The FAC Clinic was initiated to provide individual fertility assessment and counselling.

Participants/materials, setting, methods: Eligible women were childless and at least 35 years of age. All completed a web-based questionnaire before and after the consultation including socio-demographic, reproductive, medical, lifestyle and behavioural factors. Consultation by a fertility specialist included a transvaginal ultrasound, full reproductive history and AMH measurement (Hvidman*, et al.*, 2015)

Main results and the role of chance: The study comprised 140 cohabiting and 200 single women. The majority (82%) was well-educated and in employment. Their mean age was 37.4 years. Nonetheless, the main reasons for attending were to get knowledge on their possibility of postponing pregnancy (78%) and a concern about their fecundity (66%). The women averagely wished for 1.8 children and listed their ideal age of first child and last child as 33 (± 4.7) years and 39 (± 3.5) years, respectively. Of the single women, 70% would accept use of sperm donation compared to 25% of the cohabiting women ($p < 0.001$). In general, 45% considered oocyte vitrification, yet only 15% were positive towards oocyte donation. The two groups were comparable regarding lifestyle factors, number of previous sexual partners, pregnancies, and ovarian reserve parameters.

Limitations, reason for caution: The women in the present study were conscious of the risk of infertility with increasing age and attended the FAC Clinic due to a concern about their remaining reproductive lifespan, which in combination with their high educational level could impair the generalizability to the background population.

Wider implications of the findings: Our results display that despite the women´s chronological age of 37.4 years; their proposed ideal age of 33 years at first child, an awareness of declining female fecundity with age and the wish for two children, only few would consider oocyte donation. This paradox could indicate a general overestimation of the women´s own reproductive ability and an underestimation of the risk of future childlessness with the continuous postponement of pregnancies.

Study funding/competing interest(s): Funding by national/international organization(s) – The FAC Clinic is a part of the ReproSund and Reprohigh collaboration that was 50% co-financed by EU-regional funding. This study also received funding through the Capital Region Research Fund. The authors have no conflict of interest.

Trial registration number: NA.

P-523 The role of infertility concerns in predicting the change in men's quality of life during ART treatment in couples with a male infertility factor

Z. Donarelli[1], G. Lo Coco[2], S. Gullo[3], L. Salerno[1], A. Volpes[4], A. Allegra[4]
[1]*ANDROS Day Surgery Clinic, Psychology Unit, Palermo, Italy*
[2]*University of Palermo, Department of Psychology, Palermo, Italy*
[3]*ANDROS Day Surgery Clinic, Medical Statistic Unit, Palermo, Italy*
[4]*ANDROS Day Surgery Clinic, Reproductive Medicine Unit, Palermo, Italy*

Study question: Does the Quality of Life (QoL) of men, the only cause of a couple's infertility, change during the course of ART treatment, controlling for: duration of infertility, their partners' age, their own and their partners marital satisfaction, need of parenthood and sexual concerns?

Summary answer: Both men and women's QoL increases during the course of ART treatment with men's QoL variation only being influenced by their own marital satisfaction. None of women's variables on commencing ART predict variations in men's QoL.

What is known already: Recent qualitative studies have demonstrated that men's involuntary childlessness constitutes a major life crisis and ART procedures are perceived as burdensome. The psychological profiles of infertile men have a negative impact on their self-image, resulting in relational and psychological distress; there is also evidence that men's psychological distress can predict low levels of QoL. Quantitative data regarding the influence of a couple's relationship (both partners) on men's QoL during ART treatment are scarce.

Study design, size, duration: This longitudinal study comprises two repeated measurements: on commencing treatment (T1) and at the day of Embryo-Transfer (T2). Data were obtained from a restricted group of 56 infertile men and their partners (112 subjects), consecutively referred for ART treatment from February 2013 to December 2014.

Participants/materials, setting, methods: Both members of couples with a male infertility factor were recruited at the ANDROS Clinic in Palermo (Italy). They completed the ENRICH, the Fertility Problem Inventory and the FertiQoL. Structural Equation Modelling was used to analyze the data. Any change in QoL was analyzed by regressing QoL-T1 on QoL-T2.

Main results and the role of chance: Both men's and women's QoL increases during the course of ART procedures ($t = -3.38$, $p < 0.01$ and $t = -4.43$, $p < 0.001$ respectively). The hypothesized model provides an adequate fit to the data ($\chi 2 = 21.54$; $df = 21$; $\chi 2/df = 1.02$; CRI = 0.96; RMSEA = 0.022), showing that a variation in men's QoL is influenced by their own marital satisfaction at T1 ($b = 0.39$; $p < 0.05$). Men with high marital satisfaction on commencing ART treatment, therefore, display an increase in QoL during the course of treatment. Finally, neither men's need for parenthood and sexual concerns nor their partner variables predicts variations in men's QoL.

Limitations, reason for caution: This study has various limitations: firstly, data were obtained from only one clinical site; secondly, the results of the study may be influenced by the small sample size.

Wider implications of the findings: Results of this study show that men's Quality of Life increases during an ART procedure; this could be due to their involvement in how the couples deal with their infertility problem. Due to the influence of men's marital satisfaction on their own change in QoL, couples' relational domains may be identified by health professionals, with a view to providing psychosocial counselling to infertile couples, particularly where men display low marital satisfaction.

Study funding/competing interest(s): Funding by hospital/clinic(s) – ANDROS Day Surgery Clinic, Palermo, Italy. The authors have no conflicts of interests to declare.

Trial registration number: Not necessary.

Keywords: quality of life, marital satisfaction, ART, male factor infertility, longitudinal study

P-524 "A chance to a hope" – opinions of transplanted women of the first uterus transplantation trial

S. Järvholm[1], L. Johannesson[1], M. Brännström[1]
[1]*Department of Obstetrics and Gynaecology. Sahlgrenska University Hospital, Reproductive Medicine, Göteborg, Sweden*

Study question: What are the opinions and experiences during the first year of the women entering the uterus transplantation trial.

Summary answer: The women ($n = 9$) adjusted well to the new life situation and were properly accustomed in everyday life. Both the seven women with ongoing grafts, as well as the two with graft failure, expressed content with the decision to participate in the trial.

What is known already: No data on the psychology of any patients are available in this field with only 11 cases performed worldwide, and with nine of the women participating in the present study. Within our trial the medical results so far are two cases of early (within 4 months after transplantation) removal of grafts and live births in three cases.

Study design, size, duration: A qualitative interview study one year past the first uterus transplantation. All eligible women $n = 9$, were included in the study. Eight of the participants were lacking the uterus from birth (MRKH syndrome) and one after hysterectomy due to cervical cancer. Age; median 33, range 27-38.

Participants/materials, setting, methods: All women (9) who had undergone uterus transplantation in early 2013 in Sweden were interviewed. The interviews were transcribed verbatim. Data was analysed with a thematic approach. The interviews followed a semi-structured guide focusing on four main domains; Psychological well-being, Relationship with the donor, Follow-up and social aspects.

Main results and the role of chance: The analysis lead to the formation of a master theme, labelled: A chance to a hope. In addition four subthemes were emerged: A body like anyone else's, To be in a transition phase, Getting back to

everyday life, A special relationship. All these subthemes contained underlying categories. This first group of women undergoing uterus transplantation already at baseline showed large adherence in how they reported their psychological wellbeing and commitment to the project. In spite of outcome and adverse events the loyalty of the participants continued during the first postoperative year.

Limitations, reason for caution: This study of the first cohort of women undergoing uterus transplantation is a selected population with possibly greater than average of psychological strength. Even so vulnerability and themes of distress are revealed in this study but need to be explored further and probably expanded in upcoming groups.

Wider implications of the findings: In conclusion, the women of the trial adjusted psychological well to their new lifesituation during the first year after transplantation. When uterus transplantation will enter the clinical arena in a wider perspective the participants will naturally reveal a broader psychological diversity. It will then be of uttermost importance to have gained knowledge of psychological strengths and strains also in a qualitative perspective.

Study funding/competing interest(s): Funding by national/international organization(s) – Jane and Dan Olsson Research Foundation

Trial registration number: NCT01844362.

P-525 The mindfulness based program for infertility (MBPI): how does it work in reducing depression?

A. Galhardo[1], M. Moura-Ramos[2], M. Cunha[1], J. Pinto-Gouveia[2]
[1]*Instituto Superior Miguel Torga (ISMT) and Faculty of Psychology and Educational Sciences of the University of Coimbra (FPESUC), Psychology (ISMT) and CINEICC (FPESUC), Coimbra, Portugal*
[2]*Faculty of Psychology and Educational Sciences of the University of Coimbra, CINEICC, Coimbra, Portugal*

Study question: By which mechanism does PBMI help reducing depressive symptoms?

Summary answer: The PBMI contributes to decrease depressive symptoms by increasing self-efficacy in infertile patients through the mindfulness approach.

What is known already: Mindfulness based approaches have been applied and proved efficient to several health problems such as chronic pain, cancer, anxiety disorders, and depression. The MBPI is the first program specifically targeting infertility. This psychological intervention program showed to be effective in reducing depressive symptoms, internal and external shame, entrapment and defeat, in infertile female patients. Inversely it led to a significant improvement in mindfulness skills, self-compassion and in the perception of self-efficacy to deal with infertility.

Study design, size, duration: Longitudinal study. The MBPI is a psychological intervention program that includes 10 weekly sessions, in a group format (10 to 15 participants in each group), with the duration of about two hours each. The MBPI was applied to 5 groups. Data were collect between May 2009 and May 2010.

Participants/materials, setting, methods: Fifty-five women completed the MBPI and 37 women were assigned to a control group. All participants presented a primary infertility diagnosis and were pursuing medical treatment. Standardized measures of depression and infertility self-efficacy were endorsed pre and post MBPI. Participants' recruitment was supported by the Portuguese Fertility Association.

Main results and the role of chance: Significant differences were found on self efficacy ($F_{1,90} = 13.88$, $p < 0.008$) and depressive symptoms ($F_{1,90} = 8.06$, $p = .006$) between intervention and control group from baseline to post intervention. The intervention group reported a significant increase in self efficacy and decrease in depressive symptoms (both $p < 0.001$), while control group reported no significant changes. A mediation analysis was conducted to examine whether changes in self-efficacy mediated the effect of the PBMI intervention in reducing depressive symptoms. Statistical analysis was performed using PROCESS macro in SPSS with bootstrap procedures (5000 samples). Mediation effect was significant (estimate = 1.61, Bootstrap confidence interval:.515; 3.58). Infertile women who received the PBMI intervention increased their perceptions on self efficacy in dealing with infertility, which in turn decreased their depressive symptoms.

Limitations, reason for caution: This was not a blind study given the nature of practical impediments to collecting the sample. Participants' recruitment was conducted through the website of the Portuguese Fertility Association, which means that they have Internet access and may be particularly informed and motivated to some kind of psychological intervention.

Wider implications of the findings: The findings demonstrated the mechanism by which the PBMI is effective in reducing depressive symptoms in infertile patients is by increasing the patients' confidence levels on aspects of cognitive, emotional and behavioral skills related to infertility. The study highlights the importance of promoting self-efficacy, specifically addressing the way infertile patients perceive their abilities to face infertility and the strains of medical treatment when designing psychological intervention programs.

Study funding/competing interest(s): Funding by national/international organization(s) – This research has been supported by the first author Ph.D. Grant (SFRH/BD/68392/2010), sponsored by FCT (Portuguese Foundation for Science and Technology). There is no conflict of interests.

Trial registration number: The study was not a trial.

Keywords: mindfulness based program for infertility (MBPI), infertility self-efficacy, depressive symptoms, mediation analysis

P-526 Patients' educational needs in testicular sperm extraction

E. M. Sparidaens[1], K. W. M. D'Hauwers[2], M. Van den Berg[1], D. D. M. Braat[1], K. Fleischer[1], W. L. D. M. Nelen[1]
[1]*Radboud University Medical Center, Department of Obstetrics and Gynaecology, Nijmegen, The Netherlands*
[2]*Radboud University Medical Center, Department of Urology, Nijmegen, The Netherlands*

Study question: How do men undergoing Testicular Sperm Extraction (TESE) and their partners experience current patient education and how can this patient education be improved, concerning both the content and the different information channels through which the information can be provided?

Summary answer: Patients were positive about the current patient education, although adjustments could be made regarding the content and different information channels. They wanted more information on 'what's TESE', success rates of the procedure and other patients' experiences. They prefer a physical appointment, but also value a leaflet, website or online application.

What is known already: The fertility patient population consists of young, often high educated men and women, who wish to be well informed about their treatment and frequently search the Internet for information. They consider patient education as one of the most important dimensions of patient-centered fertility care. Although TESE is offered to men with non-obstructive azoospermia for many years, yet little is known about patients' educational needs.

Study design, size, duration: A qualitative study consisting of semi-structured in-depth interviews with 11 couples in May 2014, for which the topic guide was based on a literature review and interviews with an expert panel. In addition, after each interview participants composed a priority list of the five most important items of patient education.

Participants/materials, setting, methods: Eligible couples were couples consecutively visiting the Radboud university medical center for TESE treatment. The number of interviews was determined by data saturation. Data were analyzed in accordance with grounded theory. Items on the priority lists received a score based on their ranking, items were ranked by their sum score.

Main results and the role of chance: Although patients were positive about the current patient education, they wanted more information on several topics. They appreciated information on why to choose for a specific fertility clinic, success rates of the TESE-ICSI treatment, the cryopreservation of TESE semen, other patients' experiences, the psychological impact of the treatment and the possibility to get professional support. Supplementing a physical appointment, patients valued various information channels, such as a leaflet, website or a personalized online application, for which various functionalities were suggested. On priority lists, patients considered 'success rates', 'what's TESE' and 'patients' experiences' as the most important topics of patient education. In these rankings women emphasize on treatment results and other patients' experiences, while men also accent the actual TESE treatment, including risks and recovery.

Limitations, reason for caution: Limitations include the single center design of the study, although it's the largest Dutch center performing TESE. Furthermore there's a shortage of quantitative data. We made a start to provide quantitative data through the priority lists patients composed, but given the small sample size statistic measurements could not be performed.

Wider implications of the findings: In-depth insight in the educational needs of both men undergoing TESE and their partners was obtained. The study center size, together with the fact that patients from across Europe have similar views on patient-centered care, defines the generalizability of our results for other European countries. This supports professionals to customize their patient education and to develop instruments that meet the needs of their patients. In this way, patient-centeredness and quality of care can be improved.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Radboud university medical center.
Trial registration number: NA.
Keywords: patient education, male infertility, TESE, patient-centered care, quality of care

P-527 Reconciling childlessness: comparing the experiences of women who are permanently childless after failed fertility treatments versus delayed childbearing

E. Koert[1]
[1]*University of British Columbia, Educational and Counselling Psychology and Special Education, Vancouver, BC, Canada*

Study question: What are the similarities and differences in the psychosocial impact of, and adjustment to, permanent childlessness for women who are childless due to delaying childbearing versus unsuccessful fertility treatments?
Summary answer: Adjustment to childlessness for women who have delayed childbearing is similar in many respects to adjustment to childlessness after unsuccessful fertility treatment. However, there also appear to be important differences that have implications for understanding the psychosocial challenges and support needs of this increasing group of 'unintentionally' childless women.
What is known already: A sizable body of literature has examined the psychosocial consequences of failed infertility treatments and the subsequent transition and adjustment to childlessness for infertile women. However, less is known about the experiences of women who face permanent childlessness, after having delayed childbearing due to the personal, relational, and economic circumstances of their lives.
Study design, size, duration: Results from an interpretive phenomenological qualitative study of the experience of permanent childlessness for women who have delayed childbearing were compared to the existing body of literature on women's adjustment to childlessness after failed fertility treatments.
Participants/materials, setting, methods: Fifteen women who expected to have children but ended up permanently childless after delaying childbearing, took part in two qualitative interviews. Common themes were developed using an interpretive phenomenological analysis (van Manen, 1990). Themes were compared to the existing literature on women's adjustment to childlessness after failed infertility treatments.
Main results and the role of chance: Analysis revealed that women who are childless after delaying childbearing face similar challenges to those who are childless after failed fertility treatments, including: feelings of grief, loss, and isolation; a need to make sense of their childlessness; and a need to rebuild and refocus their lives and identities. In addition, women who are childless after delaying childbearing must also reconcile the reality of their *choice* to delay childbearing based on the personal, social, and economic circumstances of their lives, with feelings of powerlessness to have pursued motherhood when they were likely still fertile. Unlike women who undergo fertility treatments without success, women who expected to become mothers but never actively pursued a pregnancy face more regrets about, and feelings of responsibility for, their childlessness.
Limitations, reason for caution: The findings of this study were based on the experiences of 15 women. More research is needed to increase our understanding of the psychosocial needs and long-term adjustment of the increasing number of women who expect to have children but end up permanently childless after delaying childbearing.
Wider implications of the findings: The findings underscore the importance of educating women about the risks of delayed childbearing, and supporting them in realizing their parenthood goals. They also help to inform mental health practitioners about the psychological support needs of women who end up permanently childless due to delay, and can guide us in our efforts to support this increasing group of women as they reconcile their past choices and construct satisfying and meaningful lives without children.

P-528 Patient decision-making in female fertility preservation prior to gonadotoxic therapy

O. Baysal[1], L. Bastings[1], C. C. M. Beerendonk[1], S. A. E. Postma[1], J. IntHout[2], C. M. Verhaak[3], D. D. M. Braat[1], W. L. D. M. Nelen[1]
[1]*Radboud University Medical Center, Obstetrics and Gynaecology, Nijmegen, The Netherlands*
[2]*Radboud University Medical Center, Department for Health Evidence Section Biostatistics, Nijmegen, The Netherlands*
[3]*Radboud University Medical Center, Medical Psychology, Nijmegen, The Netherlands*

Study question: What do young women indicate as important considerations in their fertility preservation (FP) decision-making at the time of fertility preservation counselling (FPC) and how are these items related to their choices?
Summary answer: The current study revealed that FP decision-making in young women scheduled for gonadotoxic therapy is mainly based on weighing two issues: the intensity of the wish to conceive a child (in the future) and the expected burden of undergoing an FP treatment.
What is known already: Fertility is important for patients whose reproductive function is being threatened by gonadotoxic therapy. To prevent severe psychological effects of infertility and feelings of regret about their FP decision after gonadotoxic treatment, the quality of FPC should be improved. Decisive factors in FP decision-making should be clarified, as they deserve extensive discussion during FPC. These issues have not yet been isolated from the complex interplay of all aspects of FP that women contemplate during decision-making.
Study design, size, duration: By using a mixed methods methodology, a questionnaire developed after qualitative research, was retrospectively sent to eligible patients (n = 143) who had received FPC in the past (1999 - July 2013) and to whom at least one FP option was offered.
Participants/materials, setting, methods: Patients had received FPC at a university hospital in the Netherlands. They were aged ≥ 16 years and were scheduled for gonadotoxic therapy. The relationship between patients' baseline characteristics, their attributed importance to 28 relevant importance items and their FP choices made was investigated.
Main results and the role of chance: After five interviews, 28 importance items for FP decision-making were identified and included in our questionnaire. Of these, 24 items could be clustered into seven importance themes. A total of 87 patients (61%) responded to our questionnaire. After performing a multivariable logistic regression analysis, proceeding with FP was related to higher attributed importance during FP decision-making to the theme 'Wish to conceive (in the future)' (OR 10.8, 95%CI 3.5 – 34.4) and the item 'Having a stable partner relationship' (OR 2.0, 95% CI 1.0 – 4.1), while higher attributed importance to the theme 'Expected burden of FP' during FP decision-making (OR 0.08, 95% CI 0.02 – 0.3) more often resulted in refraining from it.
Limitations, reason for caution: Possible recall, selection bias and the fact that this study was performed in Dutch patients counselled in a single centre possibly limits the representability of our results for a broader European population of patients. Furthermore, we are not able to draw conclusions about the causality of the associations observed.
Wider implications of the findings: The wish to conceive and the expected burden of FP treatment should be discussed carefully with patients during FP decision-making, either by the referring healthcare provider or by reproductive medicine specialist. Prospective research is needed to explore the causality of the associations found. To deliver high quality patient centred care, the development of tools to explore patients' wish to conceive and tools to provide clear information about the burden of FP treatments is needed.
Study funding/competing interest(s): Funding by hospital/clinic(s) – This work was supported by the Radboud Institute for Health Sciences (research school affiliated to the Radboud university medical center). The authors have declared no conflicts of interest with respect to this work.
Trial registration number: NA.
Keywords: fertility preservation, counselling, female, decision-making, gonadotoxic therapy

P-529 Infertile patients' preference for receiving clinical information and participating in decision-making in China

W. Liu[1]
[1]*Reproductive and Stem Cell Engineering Institute Central South University, Outpatient Department, ChangshaHunan, China*

Study question: To assess the Chinese infertile patients' preference for receiving information and participating in decision–making and to evaluate their satisfaction with information provision.
Summary answer: The infertile patients prefer to receive information concerning their diagnosis and treatment options. The female partners were more anxious to receive information while the male partners dominated in clinical decision-making. The desire for information perception and decision-making was positively related to participants' education.
What is known already: Providing enough and clear information to patients, respecting their right to make treatment decisions is significant for high-quality and patient-centered fertility care. Factors as culture, education, age and gender might play roles in patients' desire for information perception and decision-making. The traditional paternalistic physician- patient relationship in some Asian countries including China also affect the patents' attitude towards decision-making. The patients in these countries to some extent rely on physician's involvement in their decision-making.
Study design, size, duration: Prospective survey was performed in cohort of 200 infertile couples (400 individuals) attending the infertility counseling during July, 2013 to Sept. 2014.
Participants/materials, setting, methods: The couples was interviewed by a physician according to a questionnaire contained questions about patients' attitude toward preference for information and participation in decision-making and satisfaction with information provision. A ten-score scale was used to measure the patients' desire. Necessary clarification for each question was given by the interviewer.
Main results and the role of chance: The mean score for desire to receive information was 8.93 (± 2.1) out of 10. The desire to receive information was significantly greater in female partners than in male (9.14 ± 1.7 vs 8.72 ± 1.9, $p < 0.01$). The mean score for satisfaction with information provision was 8.26 ± 2.4. Male partner was more satisfied with information provision than female (8.53 ± 2.8 vs 8.00 ± 2.7, $p = 0.021$). The mean score for preference to participating in clinical decision-making was 8.69 ± 2.9. The desire to participate in decision-making was greater in male than female partners (9.21 ± 1.7 vs 8.16 ± 2.3, $p < 0.01$). The desire to receive information and participate in decision-making was positively related to education (r = 0.33 and 0.45).
Limitations, reason for caution: Though the patients of our Hospital coming all over the country, the sampling limited to our hospital might not be statistically representative of the Chinese population.
Wider implications of the findings: In China, the infertile couples were highly interested in receiving information about their diagnosis and treatment options and participating in clinical decision-making at present. Further investigation would be performed to clarify the gender gap between their desire to information perception and clinical decision-making.
Study funding/competing interest(s): Funding by University(ies) – Central South University.
Trial registration number: NA.
Keywords: decision making, fertility care, information perception, ethics

P-530 Compliance needs across cultures. A multi-cultural study in European and Latin-American countries

G. Baccino[1], E. Ricciarelli[2], E. Hernández de Miguel[3], I. Furman[4], Y. Roa[5], V. Giménez[6], A. L. De Palma[7], P. Morente[7], M. Cassis[7], E. Chardon[8], C. Avelar[9], H. Prado[10], C. Azar[11], L. Urdapilleta[12]

[7]*Clinica PROAR, Psychology, Buenos Aires, Argentina*
[8]*Universidad de Buenos Aires, Psychology, Buenos Aires, Argentina*
[9]*Clinica Pro-Criar, Psychology, Belo Horizonte, Brazil*
[10]*Hospital Moncorvo Filho, Psychology, Rio de Janeiro, Brazil*
[11]*Universidad de Favaloro, Psychology, Buenos Aires, Argentina*
[12]*Clínica Cegyr, Psychology, Buenos Aires, Argentina*

Study question: The main objective was to investigate intention of discontinuation across countries and cultures in patients receiving fertility treatments in Europe (Spain) and Latin-America (Argentina, Chile and Brazil), regarding how do discontinuation rates vary and if it is related to the patient, the treatment or the clinic.
Summary answer: Of 537 participants, most never considered discontinuing treatments (61.6%), but most who did were from Latin America ($P < 0.01$). The most cited reasons, in both continents, in order, are not related to psychological reasons, but to costs of treatment and poor treatment progress.
What is known already: The field of reproduction produced an alarming view of discontinuation rates (high as 65%) and studies demonstrated that discontinuation has an impact on the estimation of success rates (Gameiro, 2014). But reasons for discontinuation are still not clear (Gameiro, 2014, Boivin 2012). There is no knowledge about intention to drop-out in South America, and in comparison with Europe. Cultural differences are necessary to improve specific knowledge of compliance needs across continents.
Study design, size, duration: A multicentre, cross sectional survey was performed during October 2012- May 2014 in four different countries, by 7 private clinics (Argentina 3: Brazil 1, Chile 1; Spain 2).
Participants/materials, setting, methods: 537 participants answered the questionnaire developed by the Scientific-Committee-of Psychosocial-Area-of-ALMER. 348 participants: Latin-America, 189: Europe. Mean- age, type of family, average of fertility treatments, intention to discontinue, perception of being insufficiently informed by the medical staff, lack of emotional support, feeling stressed about results, relationship with partner, and financial reasons were recorded and compared (chi-squared) between continents. $P < 0.05$ was considered significant.
Main results and the role of chance: -61.6% did not intend to discontinue. -38.4% considered discontinuation. Reasons reported, in order of frequency: **cost, negative evolution of treatment, psychological stress**. All reasons evaluated were: costs of treatment, negative evolution of treatment, abortion, psychological stress, not feeling supported by staff, feeling poor informed about the treatment, treatment-related stress in their relationship, adoption, woman's age, others.
-No differences between continents regarding:

- cited reasons for discontinuing
- feeling emotionally supported by medical staff (79% did)
- type of families (92.3% heterosexual couples)
- treatments (47.6 % homologous IVF)

-Comparisons between continents showed patients in Latin-America scored higher ($P < 0.01$) than Europeans on:

- Possibly discontinuing.
- Number of treatments received.
- Poor or incomplete information on their treatment.
- Worries about the progress of their treatment.
- Concerns about treatment cost.
- Treatment-related stress in their relationship.

Limitations, reason for caution: The Study compared date between Europe and Latin-America. Although a larger and more representational sample would give more evidence, these results can be considered to provide further insight into compliance needs across countries and cultures, and indicate that the most common reasons for discontinuation, are not psychological.
Wider implications of the findings: Although most literature cites psychological factors as the main reason for discontinuation (Olivius, 2004, Domar, 2010), this study in European and Latin-American populations agrees with Boivin (2012), and reports reasons other than psychological as the most common cause for drop-out. Different reasons for discontinuation (with no difference between continents), are economic and poor medical response. Further analysis of clinic- and treatment-associated factors should help reduce drop-out. Compliance needs should give special attention to cultural aspects.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Each participant clinic did it funding.
Trial registration number: No trial.
Keywords: discontinuation, fertility treatments, compliance, cultures

P-531 The ART of communication: results from an international needs assessment in assisted reproductive technologies

S. Murray[1], K. Awartani[2], S. Péloquin[1], S. M. Hayes[1]
[1]*AXDEV Group, Performance Improvement Division, Brossard, Canada*
[2]*King Faisal Specialist Hospital and Research Center, Department of Obstetrics and Gynecology Section of Reproductive Medicine, Riyadh, Saudi Arabia*

Study question: Given the importance of providing patient-centered care, what are the challenges reported by reproductive physicians and embryologists in discussing the treatment and management of fertility issues in a patient-centric manner?
Summary answer: Challenges were reported pertaining to provider confidence in communicating with patients with fertility issues regarding: 1) Risks associated with treatment; 2) Patient expectations regarding treatment; and 3) Available resources for support. Challenges were reported communicating these topics across countries.
What is known already: ESHRE guidelines for the psychosocial management of infertile patients outline that the provision of patient-centered care is associated with better quality of life and patient wellbeing during treatment. Positive patient-centered care experiences including optimal patient-provider communication are associated with better compliance to fertility treatment and improved chances of a successful pregnancy. Healthcare professionals should be able to communicate effectively with each patient to ensure their individual informational needs and treatment expectations are properly managed.
Study design, size, duration: An IRB-approved, mixed-methods study combining qualitative telephone interviews and a quantitative survey was conducted in two phases between March 2013 and May 2013 in China, Japan, Turkey, Russia, India, and United States and between January 2014 and April 2014 in Canada, Mexico, France, Italy, Brazil, and South Korea.
Participants/materials, setting, methods: Purposive sampling criteria were used to recruit practicing reproductive physicians and embryologists treating infertile couples across 12 countries. The total sample included 373 healthcare professionals involved in the treatment and management of fertility issues, with the majority represented by Reproductive Endocrinologists (63%). More than half of the sample (54%) had 11-20 years of clinical experience.
Main results and the role of chance: Participants reported the importance of discussing sensitive topics with their patients with a few exceptions, but reported low confidence in their ability to discuss these topics. When asked to rate their confidence (1-low, 3-Good, 5-Optimal), 43% of participants reported their confidence was *low-good*. In relation to the management of patient treatment expectations, more than half of participants (54%) reported that their confidence in discussing the potential psychological impact of ART on the patient and/or the couple was *low -good.* Also, 43% of participants reported that their confidence in discussing the failure of a fertility cycle with their patient was *low-good.* When asked about their confidence in discussing references for external social/financial support, 64% of participants reported their confidence as l*ow-good.*
Limitations, reason for caution: Voluntary participation and self-reports may introduce selection and reporting bias. Large variability in the roles and responsibilities of physicians treating infertile couples across countries render generalization difficult. To further validate the findings, this study should be reproduced with larger samples and include other members of the healthcare teams.
Wider implications of the findings: Addressing challenges in patient-centric communication could contribute to better management of patient's expectations, adherence to treatment and ultimately improved treatment outcomes. Findings from this study could be used to design continuing education initiatives with considerations for social, cultural and gender issues in each region, as in the majority of international training systems, communication competencies may not be integrated systemically into graduate or postgraduate education for healthcare providers with direct patient contact
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – This study was financially supported with education research funds from Merck KGaA, Darmstadt, Germany.
Trial registration number: NA.

P-532 'Because we want a child' - motives and considerations regarding PGD in couples carrying a structural chromosomal abnormality

G. De Krom[1], W. L. Vlieg[2], Y. H. J. M. Arens[3], R. J. T. van Golde[1], C. E. M. de Die-Smulders[3], L. A. D. M. van Osch[2]
[1]*Maastricht University Medical Centre + , Department of Gynaecology and Obstetrics, Maastricht, The Netherlands*
[2]*Maastricht University, Department of Health Promotion/CAPHRI, Maastricht, The Netherlands*
[3]*Maastricht University Medical Centre + , Department of Clinical Genetics, Maastricht, The Netherlands*

Study question: What are motives and considerations of couples carrying a structural chromosomal abnormality deciding on preimplantation genetic diagnosis (PGD)?
Summary answer: Couples carrying a structural chromosomal abnormality consider both PGD and spontaneous conception with or without prenatal diagnosis (PND) as usable reproductive options. Reproductive history is a main motive influencing couples' choice. And couples tend to choose the option, that in their consideration, will lead to a successful pregnancy fastest.
What is known already: PGD can be offered to couples carrying a structural chromosomal abnormality who are at risk of miscarriage or an ongoing pregnancy of an unbalanced fetus resulting in physical or mental disabilities in the child. From our previous study we learned there is no difference in obstetric history between structural chromosomal abnormality couples who opt for or decline PGD. Leading to our question what these couples' motives and considerations are when making a decision on PGD.
Study design, size, duration: A qualitative exploratory study investigating the motives and considerations of couples carrying a structural chromosomal abnormality making a reproductive choice after extensive genetic counselling on PGD. 13 couples were included in 2013 and 2014.
Participants/materials, setting, methods: Semi-structured dyadic interviews were conducted among 13 couples carrying a structural chromosomal abnormality who had an informative consultation in a licensed large PGD centre. Open coding of the data, followed by coding into core themes took place to identify the key aspects of participants motives and considerations regarding PGD.
Main results and the role of chance: A majority of couples indicated that an important reason for them to choose PGD was the wish to increase the chance of a successful pregnancy. All couples considered PGD or natural conception combined with PND in case of an ongoing pregnancy as the only two reproductive options. All couples who opted for PGD had tried to conceive spontaneously at first. They entered the PGD programme because of what they experienced during these attempts (infertility, recurrent miscarriage, termination of pregnancy, affected child). Couples that refrained from PGD express the long trajectory combined with a higher age of the prospective parents as main reasons. However, all couples added that, if conceiving spontaneously does not lead to an ongoing pregnancy, they will eventually try PGD.
Limitations, reason for caution: This is an exploratory study with a qualitative design, results should be confirmed in a quantitative study. Our design excluded couples who do not wish to consider PGD and are therefore not referred to a PGD clinic for genetic counselling.
Wider implications of the findings: This study shows that couples carrying a structural chromosomal abnormality consider both PGD and spontaneous conception with or without PND as usable reproductive options. They are looking for the option that is in their opinion the fastest way to get pregnant. Information on the perceived pros and cons of PGD or spontaneous conception in these couples can help to optimize counselling and psychological support during the decision making process.
Study funding/competing interest(s): Funding by hospital/clinic(s) – G.K. is supported by the 'Fertility Foundation Maastricht' as a junior researcher.
Trial registration number: NA.
Keywords: preimplantation genetic diagnosis, structural chromosomal abnormalities, reproductive decision-making, qualitative analysis

P-533 Measuring quality of life in infertile couples using the Italian version of fertility quality of life -FertiQoL- questionnaire

L. Volpini[1], C. Mazza[1], A. Guglielmino[2], C. Violani[1]
[1]*Sapienza University - Faculty of Medicine and Psychology, Department of Psychology, Roma Rm, Italy*
[2]*U.M.R., Center of Assisted Reproduction Techniques, Catania (CT), Italy*

Study question: The aim of this study was to examine the psychometric properties of the Italian version of the FertiQoL by testing in a national sample the hierarchical factor model previously identified by the authors of the original version and by analyzing the effectof educational level, age, and phase of treatment in which the women are.
Summary answer: CFA confirmed the hierarchical factor model, the internal consistency of the Italian FertiQoL and of its subscales are good or acceplable. The scores are not affected by patients' age and education, while the phase of treatment in which they are has a significant effect on FertiQoL's scores.
What is known already: Infertility and its treatments have significant impact on a individual's Quality of Life (QoL) (Schmidt, 2006; Verhaak et al., 2007; Chachamovich et al., 2010a). The FertiQoL (Boivin et al., 2011) is a fertility specific QoL assessment questionnaires recently developed that has demonstrated good psychometric characteristics (Hsu et al., 2013; Aarts et al., 2011). A recently study (Salerno et al., 2013) tested the Italian version of the questionnaire in a MAP center but the factorial validity was not tested.
Study design, size, duration: Patients in different stages of treatment completed the FertiQoL and other questionnaires within a broader multicenter research on infertile couples attending four centers for assisted reproduction in different Italian cities (Turin, Cattolica, Rome, Catania).
Participants/materials, setting, methods: The sample consisted of 370 infertile women in three different stages of treatment (diagnostic, stimulation, transfer) and with a number of previous treatment cycles ranging from 0 to 9. The FertiQoL raw data were subject to Confirmatory Factor Analysis (CFA), to subscale reliability analysis and the subscales scaled scores to one way ANOVAs.
Main results and the role of chance: The Confirmatory Factor Analysis provided a good fit to the data across the hierarchical model individuated in previous studies with a CFI = .88, RMSEA = .05 and SRMR = .06. All the FertiQoL scales had acceptable internal consistency with values ranging from 0.70 to 0.90. After the deletion of two items, Cronbach's alpha increases from.83 to.87 and from.79 to.81, erasing respectively the item Q4 and T2. Q4, in fact, deal with coping, while the item T2 notice the availability of services. No significant differences among educational level and among age on the FertiQoL scores were found. Interesting effect is observe between the environment subscaled and the previous MAP attempts.
Limitations, reason for caution: The stability of the scores was not investigated.
Wider implications of the findings: The results of this study provide a baseline QoL in infertile couples in Italy and could potentially be used as a reference for future works and clinical QoL counseling.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – This study was funded by Ferring Pharmaceuticals.
Trial registration number: NA.
Keywords: FertiQuol, infertility, validity, assited reproductive technologies

P-534 Treatment anxiety in assisted reproductive technology (ART): how do women differ from their partners?

M. A. Schaller[1], C. Banz-Jansen[1], G. Griesinger[2]
[1]*University Hospital Schleswig-Holstein, Department of Gynaecology and Obstetrics, 23538 Luebeck, Germany*
[2]*University Hospital Schleswig-Holstein, Department of Gynecological Endocrinology and Reproductive Medicine, 23538 Luebeck, Germany*

Study question: The aim of the present study was to determine levels of anxiety during the course of IVF treatment and whether gender differences in treatment anxiety exist.
Summary answer: Women show a higher level of anxiety during IVF treatment and hold different concerns. Neither of the sexes appears to be familiar with the risks associated with multiple pregnancies, a matter that should better be addressed.
What is known already: Several studies have shown that IVF treatment causes high levels of emotional and social distress in patients, causing numerous couples to drop out of the treatment before the goal of pregnancy is reached. Less is known about the gender differences and procedures responsible for the distress.
Study design, size, duration: Patients at first, as well as patients at repeat consultations were asked to fill out an eight page survey on their anxieties and worries in the context of their treatment, which consisted of the STAI (Spielberger state – trait anxiety inventory) and a 25 item questionnaire about specific stress factors and possible triggers of treatment anxiety.
Participants/materials, setting, methods: 119 women and 82 men undergoing IVF treatment in a university affiliated, tertiary care IVF program, from November 2012 to June 2013.
Main results and the role of chance: Women and men undergoing IVF score higher on the STAI than the average population in Germany. Overall, female patients show significantly higher values for state and trait anxiety (Mean = 47.4/40.1, SD = 11.0/9.85) than their male partners (Mean = 41.4/35.3, SD = 9.66/8.57, $p < 0.01$). When asked about specific stress factors on a 4-point scale from "not at all" to "very much so", women report as their main anxiety the failure to achieve a successful pregnancy, scoring significantly higher on questions like "disclosure of infertility" (Mean = 2.99, SD = 1.10, $p < 0.001$). Their male partners, however, are highly significant more concerned about the health risks the women have to take such as "occurrence bleeding or infection after the oocyte aspiration" (Mean = 2.58, SD = 0.84, $p = 0.007$). Both genders indicated to be very little worried about multiple pregnancies by IVF.
Limitations, reason for caution: The questionnaire was completed by the patients on a voluntary basis, leaving the possibility of a selection bias by including only certain couples, that were open minded to participation. Furthermore, the sample might not represent the worldwide population, since the data was acquired in just one reproductive medicine centre in Germany.
Wider implications of the findings: The main findings of this study go in agreement with current literature on this topic, especially showing once more the patients' underestimation of multiple birth risks. The generalizability to other populations remains unclear, but literature suggests that for western countries the results are comparable. New insights have been made in terms of significant gender differences of treatment anxiety and specific stress factors within the treatment, opening new perspectives and possibilities for psychological support.
Study funding/competing interest(s): Funding by hospital/clinic(s) – University Hospital Schleswig-Holstein.
Trial registration number: NA.

P-535 How do we relate to each other? Children's, parents' and donors' perspectives in sister-to-sister oocyte donation families

H. Van Parys[1], V. Provoost[2], E. Wyverkens[1], I. Raes[2], A. Ravelingien[2], S. Somers[3], I. Stuyver[3], P. De Sutter[3], G. Pennings[2], A. Buysse[1]
[1]*Ghent University, Psychology and Educational Sciences, Ghent, Belgium*
[2]*Ghent University, Bioethics Institute Ghent, Ghent, Belgium*
[3]*Ghent University Hospital, Department of Reproductive Medicine, Ghent, Belgium*

Study question: How do family members (parents, children, and the donor) experience family relations in sister-to-sister oocyte donation families?
Summary answer: Family members emphasized the strength of their family relationships both as a given – independently of the oocyte donation – and as a condition for oocyte donation. In two families, the donors' status of 'godmother' seemed to capture the special bond between donor and child and made it manageable for all parties.
What is known already: Although sister-to-sister oocyte donation has been practiced for at least 15 years in several countries, little is known about family relations within these families. Literature points at strong and stable sister relations. However, relations between donor and child and between parents and child are relatively underexplored. The current study aimed to offer an in-depth understanding of multiple family relations within these family constellations, based on the perspectives of both parents, children, and the donor.
Study design, size, duration: As part of a larger qualitative research project on family members' perspectives on social and genetic parenthood, semi-structured interviews were conducted with heterosexual couples, their oocyte donors and one of their children. Participants were recruited via the Department of Reproductive Medicine of the Ghent University Hospital.

Participants/materials, setting, methods: Couples eligible for the study were contacted by their counsellor seven to ten years post treatment. Two couples, one mother, three oocyte donors and three children were interviewed separately. Interviews were analysed using Interpretative Phenomenological Analysis, followed by an analysis within families and a comparison across families.
Main results and the role of chance: Family members stressed that their relationships have always been strong, independently of the oocyte donation. What prevailed was thankfulness towards the donor, and a sense of being able to contribute in the donors themselves. Parents and donors put forward that they did not make initial arrangements apart from the decision to disclose to the child, which in all cases was left to the parents. While overall the role of the mother was clearly distinguished from the role of the aunt/godmother, in two families the donor reported increased feelings of responsibility or even primal mother feelings right after the birth of the child. In these families, being a godmother seemed to have a symbolic function, capturing the increased responsibility that was felt towards the donor child.
Limitations, reason for caution: Our analysis was based on a small sample and does not intend to produce generalizable findings. Moreover, it was based on a specific subset of families in which the donor conception was disclosed to the child and parents felt comfortable with their child being interviewed.
Wider implications of the findings: The current study provides a deeper understanding of family relations underlying and stemming from sister-to-sister oocyte donation. In counselling, the necessity of long-term arrangements regarding the rights and responsibilities of the different parties, is often presupposed. The participants in our study however, pictured the donation as a spontaneous undertaking, based on mutual trust. At the same time, counsellors can play a role in exploring the different meanings of genetic links together with all parties.
Study funding/competing interest(s): Funding by University(ies) – The project is funded by the Special Research Fund of Ghent University. Approval by the appropriate Ethics Committee has been obtained. There are no competing interests.
Trial registration number: NA.
Keywords: qualitative research, oocyte donors, family relations

P-536 Longitudinal assessment of patients' willingness to donate frozen embryos for research

C. Samorinha[1], M. Severo[2], H. Machado[3], B. Figueiredo[4], S. Silva[1]
[1]*Institute of Public Health University of Porto, ISPUP, Porto, Portugal*
[2]*Institute of Public Health University of Porto, Department of Clinical Epidemiology Predictive Medicine and Public Health University of Porto Medical School, Porto, Portugal*
[3]*University of Minho, Department of Sociology, Porto, Portugal*
[4]*University of Minho, School of Psychology, Porto, Portugal*

Study question: Which factors are associated with patients' willingness to donate frozen embryos for research over time?
Summary answer: A significant decrease in patients' willingness to donate frozen embryos for research over time was observed. A higher education level, being non-Catholic and considering research with human embryos not to be very important was predictive of participants being less willing to donate embryos for research over time.
What is known already: Patients' willingness to donate frozen embryos for research is subject to change over time. Qualitative studies show that change results from interrelated dynamic dimensions as cognitive appraisals (e.g. success rate, quality of embryos), emotional responses and moral judgments, shaped by sociocultural and organizational aspects. Few quantitative studies focus on the longitudinal assessment of the factors associated with patients' willingness to donate frozen embryos for research.
Study design, size, duration: Prospective longitudinal study. Patients undergoing infertility treatment were consecutively and systematically recruited in one public reproductive medicine centre, Portugal, between August 2011-August 2012 (313 women and 221 men). Participants were reevaluated 12 months later (114 women and 84 men; participation rate = 37%). This analysis is based on 82 heterosexual couples.
Participants/materials, setting, methods: Data on sociodemographic characteristics, reproductive history, psychosocial variables and willingness to donate frozen embryos for research were collected by a self-report structured questionnaire, in both moments. A mixed-effects model with random effects by couple was fitted for the analysis of the willingness to donate on time.
Main results and the role of chance: There was a significant decrease in patients' willingness to donate frozen embryos for research over time (OR = 0.24;95%CI:0.14-0.41). The effect of time was different according to education, religion and importance attributed to embryo research. Patients with > 12 years of education were less willing to donate embryos for research in the second moment ($Or_{education}$ = 2.64;95%CI:0.82-8.48; OR_{time} = 0.65;95%CI:0.35-1.22; $OR_{interaction}$ = 0.06;95%CI:0.02-0.20). Non-Catholics were less frequently willing to donate over time ($Or_{religion}$ = 14.72;95%CI:7.28-29.77; OR_{time} = 0.36;95%CI:0.60-2.35; $OR_{interaction}$ = 0.24;95%CI:0.15-0.41). Participants who considered research with human embryos not to be very important were less frequently willing to donate embryos for research over time than those who considered research very important ($Or_{importance}$ = 0.51;95%CI:0.15-1.70; OR_{time} = 0.36;95%CI:0.20-0.67; $OR_{interaction}$ = 0.21;95%CI:0.06-0.70). Reproductive history, levels of depression and anxiety and the quality of the partner relationship did not influence change in patients' willingness to donate embryos for research.
Limitations, reason for caution: The sample size and the fact that data derives only from one public reproductive medicine centre, located in a university hospital, implies caution regarding data generalizability.
Wider implications of the findings: This study highlights the need of addressing change in patients' willingness to donate embryos for research in order to obtain fully informed consent. Patients' counseling over time should be provided to improve the patientcentredness of care.
Study funding/competing interest(s): Funding by national/international organization(s) – This study was co-financed through FEDER funding from the Operational Programme Factors of Competitiveness – COMPETE and through national funding from the FCT - Foundation for Science and Technology (Portuguese Ministry of Education and Science) within the project "Health, governance and accountability in embryo research: couples' decisions about the fates of embryos" (FCOMP-01-0124-FEDER-014453), and the Grants IF/00956/2013 (to SS), IF/00829/2013 (to HM) and SFRH/BD/75807/2011 (to CS).
Trial registration number: NA.

P-537 Sister-to-sister oocyte donation: couples' experiences with regard to genetic ties

E. Wyverkens[1], H. Van Parys[1], V. Provoost[2], I. Raes[2], A. Ravelingien[2], S. Somers[3], I. Stuyver[3], G. Pennings[2], P. De Sutter[3], A. Buysse[4]
[1]*Universiteit Gent, Department of Experimental-Clinical and Health Psychology, Gent, Belgium*
[2]*Universiteit Gent, Bioethics Institute, Gent, Belgium*
[3]*University Hospital Ghent, Department of Reproductive Medicine, Gent, Belgium*
[4]*Universiteit Gent, Department of Experimental- Clinical and Health Psychology, Gent, Belgium*

Study question: How do couples experience the difference in genetic ties to their child?
Summary answer: Couples struggled with the prevailing ideal of genetic connectedness. Couples' ways to deal with the imbalance in genetic ties varied: some couples acknowledged each other's different experiences, others tried to convince one another or pushed away the differences.
What is known already: Few research is available on the experiences of sister-to-sister oocyte donation. The available literature suggests that donors and recipients have good and stable relationships or even strengthened sister relationships. Current study aimed to gather in-depth information on couples' experiences with the difference in genetic ties in the case of known intra-familial oocyte donation, which is frequently practiced in the Belgian context.
Study design, size, duration: Semi-structured couple interviews were conducted with five heterosexual couples (10 participants), recruited via the Department of Reproductive Medicine of the Ghent University Hospital. All participants had at least one child conceived via oocyte donation, ranging from 7 to 10 years old.
Participants/materials, setting, methods: An Interpretative Phenomenological Analysis was performed, with a focus on both individual experiences and the couples' experiences with regard to genetic ties. This inductive method entails a phased process from memo writing to the construction of themes. The

validity and trustworthiness of the analysis was guaranteed through auditing by the co-authors.
Main results and the role of chance: Our analysis revealed that the sister-to-sister donation enabled mothers to equal genetic parenthood. Although the gestational and the indirect genetic connection made mothers feel that the child belonged to them, for some the lack of a full genetic tie remained a meaningful absence and led them to question the legitimacy of their motherhood. They questioned their identity and sense of being the 'real mother'. Couples tried to deal with this imbalance in genetic ties by convincing one another, acknowledging the imbalance or trying to erase it. Couples also managed the family positions by negotiating the closeness in their family relationships.
Limitations, reason for caution: We analyzed a small-scale study in order to provide an understanding of people's lived experiences in a specific context. It should be noted that the context of sister-to-sister donation is different from that of known donation, due to the presence of an indirect genetic link between the recipient mother and her offspring.
Wider implications of the findings: Findings of this study plead for offering post-donation care, besides predonation care, as some families struggled with grieving the loss of genetic parenthood. Caregivers should acknowledge the multiple losses experienced by fertility patients and provide space to express the grieving process. In addition, addressing the couples' coping abilities can strengthen the couples' identity and help to increase confidence in their parental position.
Study funding/competing interest(s): Funding by University(ies) – The project is funded by the Special Research Fund of Ghent University. Approval by the appropriate Ethics Committee has been obtained. There are no competing interests.
Trial registration number: NA.

P-538 Sexual function in women with polycystyc ovary syndrome: a systematic review

H. Pastoor[1], C. de Klerk[2], J. S. E. Laven[1]
[1]*Erasmus University Medical Center, Reproductive Medicine, Rotterdam, The Netherlands*
[2]*Erasmus University Medical Center, Psychiatry, Rotterdam, The Netherlands*

Study question: The aim of this systematic review was to present a comprehensive summary of the literature on sexual function in women with Polycystic Ovary Syndrome (PCOS). We also assessed the quality of these studies.
Summary answer: We included 19 studies on PCOS and sexual function. Most of them did not meet quality assessment criteria. Results on sexual function were often contradictory.
What is known already: Data on sexual function in women with PCOS are relatively scarce. Sexual function is influenced by both somatic and psychosocial factors. PCOS and its treatment compromises both. Due to elevated androgen levels and comorbidities such as depression and low self-esteem we expect sexual function to be compromised in women with PCOS. Previous research shows that women with PCOS feel less sexual attractive than healthy women but rate a satisfying sex life equally as important.
Study design, size, duration: A systematic review of literature following PRISMA guidelines was done. Nine electronic databases were searched. No restrictions on date, type of publication or language were applied.
Participants/materials, setting, methods: Selection and quality assessment of studies were independently done by two researchers using an adapted version of the Newcastle-Ottawa Quality Assessment Scale and the Cochrane risk of bias assessment tool. Main keywords for the search: polycystic ovary syndrome, sexuality, sexual dysfunction, coitus, libido, arousal, dyspareunia, vaginismus, lubrication, orgasm, masturbation, satisfaction.
Main results and the role of chance: The search identified 1455 original articles. We included 19 studies based on previously formulated criteria. Most studies did not meet quality assessment criteria. Data were summarized consistent with the domains of the sexual response cycle, complemented with frequency of intercourse, dyspareunia, satisfaction, feeling of attractiveness and distress. Some studies reported treatment effects. Results were often contradictory. For example, our preliminary analysis suggests that lubrication problems are more prevalent in PCOS women than in healthy controls but not dyspareunia. Sexual satisfaction seems to be lower than in healthy control women. Sexual distress seems to be prevalent. Treatment with metformine or oral contraceptives may improve sexual function in women with PCOS.
Limitations, reason for caution: Due to the poor quality of previous studies, no definitive statements can be made about sexual function in PCOS women. For example, several studies did not use a control group, or did not exclude PCOS in the control group or did not use valid outcome measures.
Wider implications of the findings: Assessing the quality of a woman's sex life is important particularly in women with PCOS. Hence it should be addressed in a clinical setting and doctors should try to personalize treatment if possible. More research with sound methodologies and validated questionnaires should be performed. For example, the relationship between androgen levels and sexual function is inconclusive and needs further investigation. We also recommend psychophysiological measurements and intervention studies.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Erasmus MC University Hospital, Rotterdam, The Netherlands.
Trial registration number: NA.
Keywords: PCOS, sexuality

P-539 Corticotropin-releasing hormone and postpartum depression: a longitudinal study

S. I. Iliadis[1], S. Sylvén[1], O. Jocelien[1], C. Hellgren[1], A. K. Hannefors[1], D. Elfström[2], I. Sundström Poromaa[1], E. Comasco[3], A. Skalkidou[1]
[1]*Uppsala University, Department of Women's and Children's Health, Uppsala, Sweden*
[2]*Uppsala University, Department of Information Technology, Uppsala, Sweden*
[3]*Uppsala University, Department of Neuroscience, Uppsala, Sweden*

Study question: To assess possible associations between placental CRH (pCRH) at pregnancy week 18 and postpartum depression.
Summary answer: The findings of this study demonstrate that women with depressive symptoms at postpartum week 6 present significantly higher pCRH levels at pregnancy week 18, compared to healthy controls, after the exclusion of study participants with depressive symptoms during pregnancy.
What is known already: Postpartum depression is a common cause of pregnancy and postpartum related morbidity and may have severe consequences for mothers and infants. Most studies support the role of Hypothalamic Pituitary Adrenal (HPA) axis alteration during pregnancy and the subsequent pCRH withdrawal after delivery of placenta in the development of postpartum depressive symptoms. A few studies have assessed possible associations between pCRH levels in pregnancy and postpartum depression.
Study design, size, duration: In the current study, that was designed as a case-control study, a valid pCRH sample along with a completed Edinburgh Postnatal Depression Scale (EPDS) questionnaire was retrieved by 640 women. Study duration was approximately one year.
Participants/materials, setting, methods: pCRH samples were taken at pregnancy week 18, at the Department of Obstetrics and Gynaecology at Uppsala Hospital. EPDS was filled at pregnancy week 17 and 32 and at six weeks and six months postpartum. At postpartum week six, 87.5% (N = 560) of women had EPDS < 12 and 12.5% (N = 80) had EPDS ≥ 12.
Main results and the role of chance: A logistic regression model with EPDS scores at six weeks postpartum (EPDS ≥ 12 points) as the outcome variable and logarithmized pCRH at pregnancy week 18 as the exposure variable showed a positive association between pCRH levels and depressive symptoms (OR = 3.3; 95% CI 1.32 - 8.25, $p = 0.011$). The association remained significant, even after controlling for stressful life events, history of depression and various medical conditions as possible confounders (aOR = 4.84; 95% CI 1.79 - 13.05, $p = 0.002$). The analysis was performed in women with absence of depressive symptoms during pregnancy (EPDS < 12 at pregnancy week 17 and 32).
Limitations, reason for caution: A limitation is the use of a self-reporting psychometric measure instead of a psychiatric interview. The EPDS is a self-reporting instrument, and thus a degree of misclassification may occur. However, this scale is widely used and validated and has a quite high sensitivity and specificity.
Wider implications of the findings: The results of the few existing studies on the association between levels of pCRH during pregnancy and risk of postpartum depressive symptoms are inconclusive. The biological mechanisms underlying postpartum depression have not yet been clearly elucidated. The novel finding of the present study is the positive association between pCRH levels in

pregnancy and genuine postpartum depressive symptoms, after the exclusion of women with depressive symptoms in pregnancy
Study funding/competing interest(s): Funding by University(ies) – Funding by hospital/clinic(s) – Funding by national/international organization(s) – Uppsala University Hospital, Marianne and Marcus Wallenberg Foundation, The Swedish Research Council.

P-540 Reaching for paternity: a phenomenological study on the desire to build a family among female-to-male transsexuals undergoing fertility preservation

G. Armuand[1], C. Lampic[1], C. Dhejne[2], J. I. Olofsson[3], K. A. Rodriguez-Wallberg[4]
[1]*Karolinska Institutet, Department of Neurobiology Care Sciences and Society, Stockholm, Sweden*
[2]*Karolinska University Hospital and Karolinska Institutet, Gender Team, Stockholm, Sweden*
[3]*Karolinska University Hospital, Reproductive Medicine, Stockholm, Sweden*
[4]*Karolinska University Hospital and Karolinska Institutet, Reproductive Medicine, Stockholm, Sweden*

Study question: How do female-to-male transsexuals experience life regarding their desire to build a family when undergoing fertility preservation (FP)?
Summary answer: Our results show that female-to-male transsexuals that undergo FP by egg freezing experienced their desire to build a family as highly dependent on surrounding boundaries, such as legislative decisions concerning surrogacy and adoption; FP gave them respite while waiting for societal changes that could open additional possibilities to reach paternity.
What is known already: Contemporary assisted reproduction techniques have extended possibilities beyond the normative heterosexual family, and lesbian, gay, bisexual and transsexual's rights to have children have been recognized. However research in the area is still sparse and no studies have investigated transsexual men's lived experience of wanting children and a family, nor the motivations behind the decision to undergo FP.
Study design, size, duration: Prospective pilot project of FP in individuals with transsexualism. Female-to-male transsexuals undergoing FP by egg freezing were invited to participate in individual interviews with a phenomenological approach. The interviews lasted 68-95 minutes and were digitally recorded and transcribed verbatim. The study inclusion started in May 2014 and is still ongoing.
Participants/materials, setting, methods: By January 2015, seven transsexual men (age 19-33) had participated in the study, shortly after having undergone FP. The interviews focused on individual plans of having children and motives behind undergoing FP. Data was analyzed by using a phenomenological hermeneutic approach in order to interpret lived experience.
Main results and the role of chance: The preliminary analysis resulted in one main-theme and three sub-themes. The main-theme 'Being limited by biological and societal boundaries' describes how the desire to build a family was dependent and limited by different boundaries. This caused distress and bitterness, especially when political decisions hindered them to reach life goals. The sub-theme 'Wanting a child of one's own' concerns how the desire to have children had to be adjusted to available possibilities. The sub-theme 'Having gametes in the freezer' shows how the performance of FP had provided them with resources and opened options concerning future possibilities to have children. The sub-theme 'Planning for building a family' describes how different methods were considered to achieve paternity, such as carrying a pregnancy by them-self, surrogacy or adoption.
Limitations, reason for caution: The results are based on an interpretation of text and the authors strived to be reflective about their pre-understanding of the phenomenon. The men were generally well educated and dedicated to transsexuals' rights. So far only seven men have been interviewed and some caution is advised when interpreting the results.
Wider implications of the findings: Our preliminary results indicate that transsexual men who undergo FP experience limited possibilities to achieve paternity even though they have a strong desire to have children. There is a need to offer specifically developed reproductive counseling directed to transsexual men in order to discuss reproductive possibilities and what might be accessible to them.
Study funding/competing interest(s): Funding by University(ies) – Karolinska Institutet, Stockholm, Sweden.
Trial registration number: NA.
Keywords: transsexualism, fertility preservation, qualitative research, family

P-541 Effects of medical causes, role concepts and treatment stages on quality of life in involuntary childless men

M. Schick[1], S. Roesner[2], B. Toth[2], T. Strowitzki[2], A. Jank[3], H. Kentenich[3], C. Thoene[4], T. Wischmann[1]
[1]*Center for Psychosocial Medicine University of Heidelberg, Institute of Medical Psychology, Heidelberg, Germany*
[2]*Women's Hospital University of Heidelberg, Department of Gynaecological Endocrinology and Reproductive Medicine, Heidelberg, Germany*
[3]*Fertility Center, Berlin, Germany*
[4]*Fertility Clinic, Heidelberg, Germany*

Study question: Main goal of this study was to investigate differences in quality of life in men contingent upon various fertility treatment stages, infertility causes and adoption of roles.
Summary answer: Participant's perceptions on quality of life differed in enormity according to the cause of infertility, treatment stage and number of adopted roles, with men reporting higher quality of life when having previously experienced severe medical conditions, haven't started treatment yet and resuming several tasks in the treatment process.
What is known already: Involuntary childlessness is seen as major life crisis for men, with distress in fertility treatment rising over time and treatment procedures sensed as high burden; however perceived quality of life seems not to alter significantly. Mixed findings can be found regarding the suffering due to the causer of infertility, though research concerning infertility as consequence of other medical conditions is missing. A high importance of participation for men in the fertility process is suspected.
Study design, size, duration: A quantitative study was devised in three german fertility centers, approved by the Ethics Committee of the Heidelberg University Hospital. The study took place from July to September 2013 with N = 115 participants.
Participants/materials, setting, methods: Participants completed a standardized, fertility-specific questionnaire devised for men (TLMK) and additional sociodemographic and role items. Recruiting took place by direct approach in the fertility clinic. Care was taken to obtain men from different stages in the treatment process. Data were analyzed using correlation, regression, independent t-test analysis and ANOVA.
Main results and the role of chance: Men having experienced severe medical conditions, e.g. cancer, gene dispositions, showed significant higher quality of life scores compared to men with other infertility reasons ($t(56) = -3.57$, $p = .001$). Furthermore, allocating participants into distinctive groups by means of kind of treatment and duration revealed significant group differences in quality of life ($F(2, 111) = 4.94$, $p = .009$), with distress rising with the use of more invasive fertility methods. A positive relationship had been found in men adopting many tasks in the treatment process in terms of reporting more quality of life and perceiving their contribution to the whole process as high.
Limitations, reason for caution: Generalization of findings is limited due to a response rate of 50%, above-average educational background of participants and the fact that not all involuntary childless couples seek infertility treatment in a fertility clinic.
Wider implications of the findings: The high quality of life displayed by men having experienced severe medical conditions contains valuable and far-reaching information about possible resilience factors that need to be researched more in detail. Confirmation of rising distress in treatment for men, independent of treatment duration, with the use of more invasive methods applies for increased psychosocial services in fertility clinics.
Study funding/competing interest(s): Funding by University(ies) – No competing interests.
Trial registration number: NA.
Keywords: men, involuntary childlessness, fertility treatment, cause, quality of life

P-542 Freezing eggs for transsexual men: a qualitative study of transsexual individuals' experiences of fertility preservation and reproductive healthcare in Sweden

K. A. Rodriguez-Wallberg[1], C. Dhejne[2], J. I. Olofsson[3], C. Lampic[4], G. Armuand[4]
[1]*Karolinska University Hospital and Karolinska Institutet, Reproductive Medicine, Stockholm, Sweden*
[2]*Karolinska University Hospital and Karolinska Institutet, Gender Team, Stockholm, Sweden*
[3]*Karolinska University Hospital, Reproductive Medicine, Stockholm, Sweden*
[4]*Karolinska Institutet, Neurobiology Care Sciences and Society, Stockholm, Sweden*

Study question: How do transsexual men experience the procedures required for fertility preservation (FP) by egg freezing and their reproductive care within a pilot program for FP for transsexual individuals initiated at an university-hospital based assisted reproduction center?
Summary answer: Although the processes involved in FP by egg freezing gave rise to negative emotions and symptoms that challenged the patients' perceived masculinity, the men experienced adequate support from the health care team and they appreciated the team's interest on their feelings and needs during the entire course of treatment.
What is known already: In Sweden, one of the most progressive European countries with regards to lesbian, gay, bisexual and transgender rights (LGBT), the previous requirement of sterilization for legalization of gender reassignment was removed in 2013; hence, transsexuals in Sweden may now undergo FP before sex-reassignment surgery. Transsexuals have previously reported negative experiences of general health care but no earlier research was found in the literature on transsexual men's experiences of FP by egg freezing or reproductive health care.
Study design, size, duration: Prospective study of adult transsexual men undergoing hormonal stimulation and egg retrieval for FP. The study was initiated in May 2014 and recruitment is still ongoing. Patients participated in individual qualitative interviews shortly after their FP treatments. The interviews lasted 68- 95 minutes and were digitally recorded and transcribed verbatim.
Participants/materials, setting, methods: By January 2015, seven transsexual men (age 19-33) that underwent FP by egg freezing have been interviewed. Data were analyzed using qualitative content analysis (Krippendorff, 2012). Patient's psychological perceptions and experiences during the processes involved when undergoing FP were assessed and themes were identified.
Main results and the role of chance: The analysis of this pilot investigation of FP in individuals with transsexualism resulted in three themes identified: [1] Bodily changes, [2] Physical intrusion and [3] Health care encounters. In theme [1] hormonal changes in connection with the hormonal stimulation treatment required were described as causing troublesome effects such as swollen breasts and mood swings, which challenged the patients' perceived masculinity. In theme [2] transvaginal ultrasound examinations gave rise to discomfort, as the men were reminded of their female body. In theme [3] the informants described generally positive experiences of the health care. They acknowledged that even if the FP program for transsexuals was novel and the team's experience of transsexuals limited, efforts to improve patient's compliance and alleviate distress during the process were evident.
Limitations, reason for caution: Only seven individuals have so far participated in the study and some caution is advised when interpreting the results. All men were well-educated and most of them dedicated to transsexuals' rights by working within patient societies. Three men had stopped their previous testosterone treatment to perform FP treatment.
Wider implications of the findings: Our preliminary results suggest that transsexual men's experience of FP by egg freezing is essentially contradictory to their perceived gender identity. This knowledge is important in order to provide adequate professional support during FP to transsexual patients. Although the small sample size, we judge our results as transferable to other transsexual men undergoing FP by egg freezing.
Study funding/competing interest(s): Funding by University(ies) – Supported by grants from the local Research, Education and Development council, Department of Obstetrics and Gynecology, Södersjukhuset, Stockholm, and clinical research and ALF grants from Stockholm County Council (KR-W).
Trial registration number: NA.

P-543 Information on websites of fertility clinics in Europe; a matter of decency

M. Braakhekke[1], S. Feddouli[1], F. van der Veen[1], B.W. Mol[2], F. Mol[1]
[1]*Academic Medical Center, Reproductive Medicine, Amsterdam, The Netherlands*
[2]*School of Paediatrics and Reproductive Health University of Adelaide, Department of Obstetrics and Gynaecology, Adelaide, Australia*

Study question: Are infertile couples well informed on success rates and treatment options on websites of fertility clinics in Europe?
Summary answer: The quality of the websites of fertility clinics in Europe is poor and the recommended success rate 'live births per started treatment cycle' is rarely reported Information on specific treatments such as expectant management, preimplantation genetic screening (PGS) and oocyte vitrification is scarce.
What is known already: Infertile couples have a right to know the proper indications for fertility treatments, and the effectiveness and safety of ART. Accurate reporting of data assists in the building of realistic expectations and promotes patient confidence in the integrity of the ART program. It is unknown whether information provided on expectant management (effective, but not interesting from a commercial perspective), PGS (harmful treatment) and oocyte vitrification (treatment with uncertain efficacy and safety), is accurate.
Study design, size, duration: We performed a sample search from 31 countries by randomly selecting fertility clinics who report to the European IVF Monitoring. We selected the Health on the Net (HON) code to evaluate the quality of the websites. To assess how success rates are presented, adherence to ASRM/SART advertising guideline was measured.
Participants/materials, setting, methods: We assessed the 8 principles of the HON-code, ranging from transparency to financial disclosure. Adherence to the ASRM guideline – recommending reporting success rates as live birth per started cycle – was analysed. Finally we analysed information provided on three strategies: expectant management, PGS and oocyte vitrification to defer childbearing.
Main results and the role of chance: We studied 56 websites. On average, websites adhered to 2,5 HON principles (range 2 - 5,5). None of the websites adhered to all 8 principles of the HON code. Thirty-eight websites reported success rates (68%). Success rates were reported as live birth rate per started treatment cycle on 15 websites (27%). The option of expectant management for unexplained subfertility was described on 8 websites (14%). PGS was not offered. Four websites offered pre implantation genetic diagnosis (PGD) for the indication repeated implantation failure and advanced maternal age, which we interpret as PGS. Oocyte vitrification to defer childbearing was offered on 15 websites (27%).
Limitations, reason for caution: Selection bias might be present since we conducted a sample search. We translated websites that were not available in English with the google toolbar, which may lead to less accurate interpretation.
Wider implications of the findings: The way websites present their information lacks transparency and clarity. In view of the important role of the internet for patients to obtain information, we believe that ESHRE should demand from their members to provide consistent information on their websites. Only then couples are able to make an informed choice and select the clinic which is best suited to them.
Study funding/competing interest(s): Funding by University(ies) – Academic Medical Research Centre.
Trial registration number: NA.
Keywords: websites of fertility clinics, website quality, accuracy of information

P-544 Professionals' knowledge, attitude and referral behaviour regarding preimplantation genetic diagnosis for hereditary breast and ovarian cancer

J. J. G. Habets[1], L. A. D. M. van Osch[1], I. A. P. Derks-Smeets[1], C. E. M. de Die-Smulders[1]
[1]*Maastricht University Medical Center, Department of Clinical Genetics, Maastricht, The Netherlands*

Study question: What are the levels of awareness and knowledge, attitudes and referral behaviour of professionals regarding preimplantation genetic diagnosis (PGD) for hereditary breast and ovarian cancer (HBOC) in the Netherlands?
Summary answer: Less than half of the professionals who are in the position to refer patients with HBOC for PGD are aware of the possibility of PGD for HBOC in the Netherlands, whereas 85% thinks offering PGD for HBOC is acceptable.
What is known already: The only quantitative study that investigated professionals' (clinical geneticists not included) knowledge and attitudes towards PGD for hereditary cancer indicated that their knowledge was limited and acceptability of offering PGD was high. Other, mostly qualitative studies showed that physicians are generally in favour of offering PGD for severe life-threatening diseases, though they are less in favour of offering PGD for adult onset diseases and selection of non-medial traits such as sex.
Study design, size, duration: A cross sectional survey was sent to clinical geneticists, genetic counsellors, gynaecologists, oncologists, radiotherapists and fertility specialists in the Netherlands. In collaboration with professional associations for above stated specializations, eligible professionals received an invitational email to participate in the study. Data was collected between August 2013 and May 2014.
Participants/materials, setting, methods: The survey which assessed demographics, awareness, knowledge, attitude and referral behaviour regarding PGD for HBOC was completed by 170 involved health care providers.
Main results and the role of chance: More than half (51%) of the physicians was not aware of the possibility of PGD for HBOC. Of the physicians who were aware of PGD, 41% had a high level of knowledge about PGD. A majority of 85% considered PGD for HBOC acceptable. 28% agreed that the acceptability of offering PGD depends on the patients personal/ family medical history, whereas 32% indicated that it should be the patients autonomy to assess PGD acceptability. Physicians who worked at a university medical centre (UMC) were more likely to be aware of PGD for HBOC and had more knowledge of PGD than physicians who worked at a peripheral hospital. Male physicians and those who did not consider themselves religious were more likely to find PGD for HBOC acceptable.
Limitations, reason for caution: An equal distribution of specialists in this study was not achieved. Gynaecologists are overrepresented and both genetic counsellors and oncologists are minority groups. Except for the oncologists however, these numbers do comply with the general representation of these specialisms in the Netherlands.
Wider implications of the findings: This study suggests in accordance with previous research that awareness and knowledge of PGD are not optimal among involved health care providers. Moreover, a gap remains between intention to refer patients for PGD and actual referral behaviour. Since the health care providers are gatekeepers and sources of information regarding the use of medical technologies such as PGD, their knowledge should be optimized and further research is required to identify physicians' motives regarding their referral behaviour.
Study funding/competing interest(s): Funding by national/international organization(s) – Dutch Breast Cancer Foundation 'Stichting Pink Ribbon.'
Trial registration number: NA.
Keywords: preimplantation genetic diagnosis (PGD), hereditary breast and ovarian cancer (HBOC), BRCA

P-545 The tell me tool: a tool to help professionals to provide and evaluate personalised fertility care

E. W. Verkerk[1], K. Fleischer[1], E. M. Sparidaens[1], D. D. M. Braat[1], J. A. M. Kremer[2], W. L. D. M. Nelen[1]
[1]*Radboudumc, Obstetrics and Gynaecology, Nijmegen, The Netherlands*
[2]*Radboudumc, IQ-Healthcare, Nijmegen, The Netherlands*

Study question: Is it feasible to develop and use a tool that facilitates both personalised care and personalised evaluation of care in couples that undergo testicular biopsy (PESA/TESE) and intra-cytoplasmic sperm injection (ICSI)?
Summary answer: It is feasible to develop and use a tool that facilitates personalised care delivery and evaluation in couples that undergo PESA/TESE-ICSI. We developed the Tell Me tool, receiving input of patients and professionals in every step.
What is known already: Delivering personalised care is becoming more and more important, but is difficult to achieve as professionals often misdiagnose the patients' care preferences. Therefore, the individual patients' goals and values should be part of the conversation. In addition, care should be evaluated in a personalised way, combining the individual patients' prior preferences with their experiences after care consumption. We aim to develop a tool that facilitates these two goals.
Study design, size, duration: A user-centred design, involving patients and professionals for optimal effectiveness. We performed a literature search, semi-structured interviews, a consensus meeting and 8 improvement rounds to define the content (important aspects of care) and use of the tool. After a pilot test the tool is implemented in daily practice.
Participants/materials, setting, methods: In total 42 couples undergoing PESA/TESE-ICSI from various steps of the treatment cycle were involved in the development of the tool. Furthermore, physicians, embryologists, nurses, and administrative and laboratory staff were involved.
Main results and the role of chance: We achieved consensus on the list of care aspects important to couples undergoing PESA/TESE-ICSI, which includes for example achieving pregnancy, maintaining a healthy relationship, medical expertise of the staff, and information provision. Before the first consult, the tool asks patients to distribute 10 points over the care aspects that they feel require extra attention. After one treatment cycle, the tool asks patients to rate their experiences on every care aspect. The tool is short, easy to complete, and it identifies and evaluates patients' unique values and wishes, which are very usable for professionals to personalise care. There appears to be a large variation in the patients' answers, indicating the potential value of our tool.
Limitations, reason for caution: We had to balance the tool: making it easier to complete, decreased the usefulness for the professional and vice versa. In addition, these preliminary results are based on the experiences of only 42 couples. More data are available this June, when the tool is implemented for 6 months.
Wider implications of the findings: This tool for personalised delivery and evaluation of care is developed for PESA/TESE-ICSI care, but can easily be adjusted to other areas of fertility care by adapting the list of care aspects. For other fields of care, the Tell Me tool has the greatest potential in fields with intensive treatments, chronic illnesses, or difficult treatment decisions.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – This study is supported by Merck, Sharp and Dohme, The Netherlands.
Trial registration number: NA.
Keywords: patient-centeredness, personalised care, user-centred design, patient preferences, TESE

P-546 Relationship between maternal attachment, and oxytocin and cortisol levels during the third trimester

E. Turen[1], H. Toy[1], H. Dulger[2], S. Herguner[3]
[1]*Meram Faculty of Medicine Necmettin Erbakan University, Obstet and Gynecol, Konya, Turkey*
[2]*Meram Faculty of Medicine Necmettin Erbakan University, Biochemistry, Konya, Turkey*
[3]*Meram Faculty of Medicine Necmettin Erbakan University, Child and Adolescent Psychiatry, Konya, Turkey*

Study question: Is there a relationship between oxytosin and cortisol levels, and maternal attachment and maternal attachment during the third trimester?
Summary answer: We found that cortisol but not oxytosin level was predictor of maternal attachment.
What is known already: Previous studies showed that during the prenatal period oxytosin was negatively and cortisol was positively related with depression levels. Oxytosin level was found to be associated with attachment between mother and baby during the postnatal period.
Study design, size, duration: This is a cross - sectional study with a sample of 145 pregnant in their 28-36. weeks. The current study was conducted in the Department of Obstetrics and Gynecology in an university hospital between 2012 December and 2013 September.
Participants/materials, setting, methods: We studied the plasma oxytocin and cortisol levels of 145 pregnant. Inclusion criteria were 1- Being between 18 - 35 years old, 2- Having sufficient reading abilities, 3- Having no history of psychiatric disorder, 4- Having a singleton fetus. All participants filled out Prenatal Maternal Attachment Inventory, Edinburg Postpartum Depression Scale, State and Trait Anxiety Inventory. Relationships between variables was assessed by Pearson's correlation analysis. Predictors of the attachment levels and

depression scores were examined by linear regression analysis. Significance at $p < 0.05$ were considered.
Main results and the role of chance: The group was divided into two groups, according to EPDS, Group I (EPDS ≥ 13) was considered as probable depression and Group II (EPDS < 13) was as without depression. There were 28 cases in Group I and 117 in Group II. Oxytosin level in women with depression (Group I) was significantly lower than women without depression (Group I) (108.9 vs 237.4; $p = 0.08$), however there was no difference in cortisol level between two groups (22.3 vs 21.6). Correlation analysis showed that depression score was correlated with maternal - fetal attachment level (r = -.197) and oxytosin level (r = -.164). Attachment score was correlated with cortisol level (r = -.158). State anxiety was correlated with depression (r = .537), attachment (r = -.160) and oxytosin level (r = -.196). Regression analysis revealed that only cortisol level was predictor of mother-child attachment relationship.
Limitations, reason for caution: Although we had a large sample the main limitation was we relied on self-reports instead of structured interviews. We did not consider the psychological features of fathers.
Wider implications of the findings: This study showed that 12% of the women during their trimester had probable depression. Depression had a negative relation on maternal-fetal attachment. Cortisol levels were the predictor of attachment between mother and the fetus. Identifying depressive symptoms during pregnancy and referring them for psychiatric consultation is essential for an optimum attachment.
Study funding/competing interest(s): Funding by University(ies) – This study was founded by Necmenttin Erbakan University Scientific Research Foundation
Trial registration number: 131518006.

P-547 'He's just like his mom' – understandings of genetics and inheritance by parents of anonymous donor-conceived children

A. Ravelingien[1], V. Provoost[1], H. Van Parys[2], I. Stuyver[3], I. Raes[1], S. Somers[3], E. Wyverkens[2], A. Buysse[2], P. De Sutter[3], G. Pennings[1]
[1]*Ghent University, Bioethics Institute Ghent (BIG) Department of Philosophy and Moral Sciences, Gent, Belgium*
[2]*Ghent University, Department of Experimental-Clinical and Health Psychology, Gent, Belgium*
[3]*Ghent University Hospital, Department of Reproductive Medicine, Gent, Belgium*

Study question: How do parents of anonymous donor-conceived offspring perceive the role of genetics and inheritance in the development of their child, given that only one of them is genetically related to the child?
Summary answer: Parents of anonymous donor-conceived children construe understandings of genetics and inheritance that allow them to deal with the unknown genetic influence of the donor; the sensitivities of the non-genetic parent; difficulties during the upbringing; and deviation from the traditional family norm.
What is known already: Many studies have shown that lay people have individual understandings of the concepts of genetics/inheritance and that these do not necessarily conform with scientific knowledge. Various authors suggest that people acquire situated interpretations of genetics through a dynamic, context-dependent process building on their own experiences and relationships. Little is known about how parents of anonymous donor-conceived children interpret genetics within and through their specific context: one in which only one parent is genetically related.
Study design, size, duration: Semi-structured interviews were conducted with three subgroups of parents who conceived through anonymous donation between 2002-2005: heterosexual (9 couples, 1 individual) and lesbian (10 couples) recipients of sperm donation; heterosexual recipients of oocyte donation (7 couples, 2 individuals). Participants were recruited via Ghent University Hospital's Department of Reproductive Medicine.
Participants/materials, setting, methods: Step-by-step inductive thematic analysis was performed with a focus on the couples' perceptions and understandings of genetics and inheritance. This method included a phased process from memo writing to the construction of themes. The validity and trustworthiness of the analysis was guaranteed through auditing by the co-authors.
Main results and the role of chance: Participants described diverse and variable acknowledgement of a determinative role of genetics in the development of the child, with views ranging from the idea that genes express themselves only at the level of the gamete cell, which is small and negligible, to the assumption that the child is the sum of complex genetic traits of one or both genetic forebears. Participants also commonly relativized the genetic basis of the child's development by focusing on their parental input. One common strategy was to oppose the role of genetics to the timing and duration of their gestational and pedagogical 'labor' or 'imprinting'. A few participants waived the role of genetics aside and emphasized the inherent uniqueness and particularity of the child.
Limitations, reason for caution: This qualitative study aimed at a better understanding of the participants' experiences and interpretations and does not intend to produce generalizable results. Only recipients of anonymous donor gametes were included, as with known donation the situated understanding of genetics may be fundamentally different.
Wider implications of the findings: The findings have implications for counseling before donor treatment. Genetic misconceptions are commonly considered to be problematic as they risk undermining effective and informed personal decision-making in a reproductive context. However, these results lend support to the idea that, when discussing one's understanding of genetic and hereditary processes, one should be aware that it is not only the product of information transfer, but also a result of one's perceptions regarding family relations and narratives.
Study funding/competing interest(s): Funding by University(ies) – Special Research Fund of Ghent University.
Trial registration number: NA.
Keywords: qualitative research, gamete donor recipients, genetics, inheritance

P-548 Preparing for shared treatment decision-making: what information do subfertile couples need?

K. Lankreijer[1], T. D. D'Hooghe[2], F. Mol[1], D. De Neubourg[3], W. Sermeus[4], S. Repping[1], E. Dancet[4]
[1]*Academic Medical Center, Center for Reproductive Medicine, Amsterdam, The Netherlands*
[2]*Catholic University Leuven, Department of Obstetrics and Gynecology, Leuven, Belgium*
[3]*Leuven University Fertility Center, Department of Obstetrics and Gynecology, Leuven, Belgium*
[4]*Catholic University Leuven, Center for Health Services and Nursing Research, Leuven, Belgium*

Study question: Which information do subfertile couples need while being involved in shared treatment decision-making (SDM)?
Summary answer: Couples want information on the options available to them and on the medical reasons justifying the treatments offered. Besides information on effectiveness, safety, burden and costs, information on the following three treatment characteristics is required: 'similarity to natural conception', 'use of advanced technology' and 'patient-empowerment' to deliberate between options.
What is known already: Currently, gynecologists often propose a single treatment and obtain patients' consent after informing them on its effectiveness, safety, cost and burden. Subfertile couples from across Europe have an unmet need for SDM and discussing alternatives for treatment (e.g. adoption). SDM includes team talk (explaining the importance of sharing the decision), option talk (providing evidence based facts on all options) and decision talk (deciding together). Optimal option talk requires identifying the information needed by patients.
Study design, size, duration: In-depth individual or focus group interviews were conducted with fifty-seven subfertile couples between January 2013 and December 2014. Interviews were analyzed with inductive content analysis.
Participants/materials, setting, methods: A convenience sample of subfertile women ($n = 32$) and men ($n = 25$) treated in a Dutch or Belgian fertility clinic participated in individual ($n = 9$) or focus group ($n = 5$) interviews. The interviews were transcribed verbatim and subjected to inductive content analysis with constant comparison by two researchers independently who reached consensus through discussion.
Main results and the role of chance: Subfertile couples want information on all the options available to them. They want to know the medical reasons for offering or not offering each potential treatment. Besides information on effectiveness, safety, burden and costs, information on the following three treatment characteristics is required: 'similarity to natural conception', 'use of advanced technology' and 'patient-empowerment' to deliberate between treatment

options. In general couples want a treatment which is as natural as possible (e.g. with a limited amount of hormonal medication), while at the same time they want treatments to have diagnostic value (e.g. is there fertilization?) and to use the newest and most advanced technology. Treatments empower patients if patients have chosen them and gained expertise (e.g. on subcutaneous injections) and autonomy through them.

Limitations, reason for caution: We are currently continuing data-collection until data saturation is reached. So far, our study mostly included participants who had experience with advanced treatments (e.g. ICSI); efforts are made to develop a more diverse patient sample by additional inclusion of patients with unexplained subfertility.

Wider implications of the findings: A decision aid facilitating SDM should be developed for clinical practice in collaboration with gynecologists and patients. Beside information on efficacy, safety, burden and costs, the decision aid should also provide information on the three newly identified treatment characteristics that were valued by patients. To develop this decision aid, evidence based outcomes for each characteristic and option should be identified by literature review, prognostic models, and patient experience surveys.

Study funding/competing interest(s): Funding by University(ies) – Catholic University Leuven, Belgium

Keywords: medically assisted reproduction, shared decision making, patient-empowerment, patient information

P-549 Childless by circumstance: exploring thoughts and feelings using the rational-emotive cognitive behavioural therapy (RECBT) model

C. Spencer[1], J. Lessiter[1]

[1]*Goldsmiths University of London, Department of Psychology, London, United Kingdom*

Study question: Do single women experiencing 'childlessness' by circumstance (or 'social infertility') (i.e., for reasons other than physical) experience higher levels of RECBT classified unhealthy negative emotions, than women in *relationships* who are experiencing childlessness by circumstance?

Summary answer: A broad range of unhealthy negative emotions were identified amongst the sample of women who were childless by circumstance. In addition to depression and envy reported in the women in couples, single women who would not consider having a baby on their own, also experienced suicidal ideation, anger and shame.

What is known already: Within the UK, our demographics are changing, with more women having never been married now than in the 1970s and 1 in 5 women remaining childless. Research indicates that women in couples undergoing IVF treatment experience emotions such as anxiety, depression and guilt, yet little is known about the emotions and beliefs of women facing social infertility. This is one of the first studies to look at this topic and the first using RECBT.

Study design, size, duration: Face to face interviews were conducted with 17 women aged 35 to 50 allocated to three groups: single women who would, and would not, consider having a baby on their own, and women in couples. Recruitment was via various routes. Data collection was between June 2014 and August 2014.

Participants/materials, setting, methods: The researcher met with 18 women and conducted 17 semi-structured, face to face interviews exploring thoughts and feelings. Mood/belief and demographic questionnaires were also completed. Interviews were fully transcribed and a thematic analysis conducted with data coded according to RECBT emotions. A second experienced RECBT practitioner checked each identified emotion.

Main results and the role of chance: Single, childless women who would not consider having a child on their own experienced the broadest range of RECBT unhealthy negative emotions of depression, anger, envy and shame. Women in couples experienced depression and envy. Single women who would consider having a child on their own spoke less of unhealthy negative emotions but rated stronger desire for a child. Of the 18 women the researcher met with, 33% had a risk score. Of the single women who wouldn't have a child on their own, 75% had experienced thoughts of suicidal ideation at some point. Further work is required to see whether this is reflected amongst a broader sample. Participants articulated the need for better fertility awareness and greater acceptance for professionals to have children younger.

Limitations, reason for caution: As women were primarily recruited via Gateway Women, Donor Conception Network and BICA, it is not possible to know how the thoughts and feelings of these women represent the broader group of women facing social infertility / childlessness by circumstance. Women in couples and lesbian women were underrepresented.

Wider implications of the findings: It is time to acknowledge our changing demographics and the emotional difficulties those who are childless by circumstance may experience. Professional and patient group support may help them to navigate this and redefine their life goals. If these women are experiencing unhealthy negative emotions triggered by specific beliefs, it is possible that RECBT may be a resource that can help. There was a strong message for further education on fertility awareness supporting previous research.

Study funding/competing interest(s): Funding by University(ies) – Goldsmiths, University of London, London, UK, as part of Masters in Rational-Emotive Cognitive Behavioural Therapy. Approval by Ethics Committees from both Goldsmiths University and the Donor Conception Network has been obtained.

Trial registration number: NA.

Keywords: childlessness, social infertility, psychology

P-550 Two mothers and a donor: exploration of children's family concepts in lesbian households

I. Raes[1], H. Van Parys[2], V. Provoost[1], A. Ravelingien[1], S. Somers[3], I. Stuyver[3], E. Wyverkens[2], A. Buysse[2], P. De Sutter[3], G. Pennings[1]

[1]*Universiteit Gent, Bioethics Institute Ghent, Gent, Belgium*

[2]*Universiteit Gent, Department of Experimental-Clinical and Health Psychology, Gent, Belgium*

[3]*Universiteit Gent, Department of Reproductive Medicine, Gent, Belgium*

Study question: How do children from lesbian families define the concepts of the three actors involved in the building of their families: the biological mother, the social mother and the donor?

Summary answer: Children from lesbian families use hetero-normative concepts to define their family-specific concepts of social mother and donor.

What is known already: Although children from lesbian families appear to make a distinction between a residential father and a donor, defining these two concepts seems to be a challenge. They need to appeal to more familiar concepts such as the hetero-normative concept of 'mother' to give a definition of the unfamiliar concepts they are confronted with.

Study design, size, duration: The study is based on qualitative in-depth interviews with 6 children from lesbian families, all of which have been conceived using anonymous sperm donation. Semi-structured interviews were conducted.

Participants/materials, setting, methods: The participants were recruited via their parents, who took part themselves in our study. After each interview, the parents were asked whether their child (aged 7 to 10 years) would also want to participate in the study and whether the parents themselves would agree to this interview. The authors used inductive thematic analysis as the qualitative methodology for this study.

Main results and the role of chance: Two findings stand out. First, in defining the concepts of biological and social mother, both mothers were described as equal parents. No difference was attached by the children to the mothers' position as a parent. Second, the concepts 'social mother' and 'donor' were defined by looking at the hetero-normative concepts of 'mummy' and 'daddy'. To define the social mother, both a 'mummy' and a 'daddy' were used as a reference. To define the donor concept, often references were made to a daddy. This comparison with a 'daddy' turned out to be complex due to the conflict between the role as a progenitor and the lack of a social relationship. The lack of language surrounding this concept turned out to be difficult.

Limitations, reason for caution: This is a qualitative study; the authors present a thematic analysis of the views and experiences of 6 children. The data gathered are not representative for all children from lesbian couples in Belgium.

Wider implications of the findings: This study illustrates the complexity and ambiguity of children's experiences and perceptions when dealing with issues related to genetic and social parenthood.

Study funding/competing interest(s): Funding by University(ies) – Special Research Fund of Ghent University.

Trial registration number: NA.

Keywords: child interviews, gamete donation, lesbian families, family concepts, qualitative

P-551 Emotional state and coping potential of Hungarian infertile couples undergoing *in vitro* fertilization

E. Nagy[1], B. E. Nagy[1], I. Hidegkuti[2], B. Bodnár[3]
[1]*University of Debrecen, Faculty of Public Health, Department of Behavioural Sciences, Debrecen, Hungary*
[2]*University of Debrecen, Faculty of Arts and Humanities, Institute of Psychology, Debrecen, Hungary*
[3]*University of Debrecen, Clinical Centre, Kaali Institute, Debrecen, Hungary*

Study question: What are the Hungarian infertile couples' emotional responses to *in vitro* fertilization (IVF), and how does their emotional state change in the course of the treatment? What coping potential do they have?
Summary answer: Hungarian infertile women experience significantly lower positive affectivity than men. The emotional state of couples does not change significantly in the course of IVF. Getting into a stress situation, women apply seeking social support, seeking emotional balance and withdrawal coping more frequently than men.
What is known already: Previous studies have shown that infertility and infertility treatments are associated with increased levels of anxiety, depression and stress. Most of these studies have examined psychological reactions before and after IVF, and compared them on the basis of IVF outcome; few investigations have focused on these factors during the treatment, especially in Hungary. Besides, most studies have focused exclusively on women, but only a few studies have assessed both partners' psychological reactions.
Study design, size, duration: This preliminary study used a longitudinal design in which fifty-two infertile couples were followed during IVF at the following stages: at the beginning of the treatment (T1), before embryo transfer (T2), and before pregnancy test (T3). Couples were recruited from a Hungarian fertility clinic between September 2013 and September 2014.
Participants/materials, setting, methods: Fifty-two couples (104 participants) completed the following questionnaires: Positive and Negative Affectivity Schedule, the short form of Beck Depression Inventory, the State and Trait Anxiety Inventory, the Hungarian shortened version of the Ways of Coping Inventory, the Psychological Immune Competence Inventory, and a demographic and infertility-specific questionnaire.
Main results and the role of chance: According to the results, we have found no significant differences concerning emotional state between occasions neither among women, nor among men. Besides, we have found no relationship between emotional state and number of previous IVF cycles. Women score significantly lower than men on positive affectivity at T1 and T2 ($p < 0.05$). Compared with a representative sample of the Hungarian adult population, more favourable results have been observed among IVF couples as regards depression, negative and positive affectivity. Getting into a stress situation, women apply seeking social support, seeking emotional balance and withdrawal coping more frequently than men ($p < 0.01$). Men have achieved significantly higher 'Problem-solving capacity,' 'Self-efficacy,' 'Social creating capacity' and 'Emotional control' than their partners ($p < 0.05$). Women have achieved significantly higher 'Social mobilizing capacity' than men ($p < 0.001$).
Limitations, reason for caution: These are preliminary results of an ongoing study, and further longitudinal studies with larger sample sizes are needed for better understanding of the Hungarian infertile couples' emotional reactions to infertility treatment, coping mechanisms and personal resilience resources.
Wider implications of the findings: Our research confirms that consideration and management of psychological factors in treating infertility have an important role to play. Psychological counselling has not been incorporated into the infertile couples' health care yet. Furthermore, most of the studies on this subject are foreign; therefore our study is essential in Hungary. Further studies need to be performed to investigate the effects of psychological factors on IVF outcome and the cultural differences.
Study funding/competing interest(s): Funding by University(ies) – Funded partially by the University of Debrecen.
Trial registration number: Nil.

P-552 Helping beyond skills and ethics: cultivating compassion satisfaction among healthcare professionals working on ART in Hong Kong

Q. S. Wong[1], C. H. Y. Chan[1], M. Y. J. Tam[1], I. P. Y. Lo[1]
[1]*The University of Hong Kong, The Department of Social Work and Social Administration, Hong Kong, Hong Kong*

Study question: How effective is the professional training course on infertility counseling for healthcare professionals working in ART settings in cultivating their professional quality of life in terms of compassion satisfaction and compassion fatigue?
Summary answer: The course could effectively enhance the professional quality of life in terms of Compassion Satisfaction (CS). For healthcare professionals working in ART where patients face much uncertainty and uncontrollability, it is important to cultivate CS in order to guarantee both parties' interest, quality of service and life satisfaction.
What is known already: Professional quality of life incorporates two aspects, the positive (Compassion Satisfaction) and the negative (Compassion Fatigue). While abundance of research focused on the job burnout and compassion fatigue among healthcare professional, less attention has been put about compassion satisfaction. CS refers to the positive feeling of job satisfaction derived from doing helping work effectively. People with higher CS will feel contentment, experience positive thoughts and enjoy the work they do.
Study design, size, duration: This is a quasi-experimental design. Two to three healthcare professionals from 11 licensed ART clinics from public or private hospitals were nominated to attend. The course consisted of nine 3-h weekly sessions spanning two months, with self-reflective exercises like mindfulness training, compassionate meditation, and reflections on meaning of life.
Participants/materials, setting, methods: 25 Healthcare professionals (doctors, nurses, and embryologists) working in ART settings were invited to complete a self-administered questionnaire before and after the course. The questionnaire was comprised of Professional Quality of Life (ProQol) measuring Compassion Satisfaction and Compassion Fatigue (Burnout and Secondary Trauma) and measures related to psychological wellbeing.
Main results and the role of chance: It was found that the participants showed significant improvement in CS after attending the course (Pre-course: 33.94 + 4.4; Post-course: 36.35 + 3.82, $t = -3.29$, $p < 0.005$). However, no significant difference was found in Compassionate Fatigue (Secondary Trauma and Burnout) under ProQol. This showed that regardless of no improvement in Compassionate Fatigue, it is essential to uphold their CS. Healthcare professionals who were younger in age and with lower education level showed greater improvement in CS ($p < 0.05$). Moreover, those who have religious beliefs showed significant improvement in CS as well ($p < 0.05$). Another interesting area is, those who work longer in general medical settings, but shorter in ART field showed significant improvement as well.
Limitations, reason for caution: This is a professional training course with limited number of participants. No random assignment could be performed. In order to evaluate the course in greater details, qualitative analysis such as focus group and interviews should be conducted to obtain better understanding about their compassion satisfaction in working in ART.
Wider implications of the findings: There are a lot of studies focusing on the alleviation of compassion fatigue, while very few on cultivating healthcare professionals' compassion satisfaction. From a positive perspective in enhancing a positive feeling and satisfaction among helping professionals, it is believed that both themselves and service recipients can benefit from better service quality and prevent burnout. This component should thus be taken into consideration in the professional training programme in infertility counseling.
Study funding/competing interest(s): Funding by University(ies).
Trial registration number: Nil.

P-553 Do cultural beliefs play a role in fertility-related quality of life? A study of Chinese women after unsuccessful first IVF cycle

M. Y. J. Tam[1], C. H. Y. Chan[2], T. H. Y. Chan[2], Q. S. Wong[2], I. P. Y. Lo[2]
[1]*Centre on Behavioral Health, University of Hong Kong, Hong Kong, Hong Kong*

[2]*Department of Social Work and Social Administration, University of Hong Kong, Hong Kong, Hong Kong*

Study question: What is the quality of life (QoL) of Chinese women after their unsuccessful first IVF cycle, and do cultural beliefs play a role?
Summary answer: Comparing FertiQoL scores with an existing Western sample of people with fertility issues, Chinese women in Hong Kong who had unsuccessful first IVF cycle reported better fertility-related QoL but similar treatment-related QoL. Traditional cultural beliefs about childbearing were associated with worse QoL scores.
What is known already: Past studies have found IVF and its negative outcome could be stressful and affect QoL among infertile women. Boivin and team (2011) developed a measure of fertility-related quality of life (FertiQoL) and obtained mean scores in a Western sample of people experiencing fertility problems. Little is known about the QoL of Chinese infertile women, especially those after unsuccessful treatment.
Study design, size, duration: A cross-sectional survey consisting of FertiQoL, questions about Chinese cultural beliefs of childbearing, and demographic characteristics was conducted from February to November 2014 in a university-affiliated hospital. Participants were recruited through individual invitation at the assisted reproduction clinic.
Participants/materials, setting, methods: A total of 465 patients were approached after their first IVF cycle was found unsuccessful. Of them, 198 (response rate: 42.58%) have completed the self-administered questionnaires.
Main results and the role of chance: The mean age of participants was 37.0 (SD = 3.5), duration of marriage was 7.4 years (3.7), and duration of infertility was 4.1 years. The majority of them received tertiary education and had full-time job. Mean scores of Total FertiQoL, Core FertiQoL, and Treatment FertiQoL were 63.4 (12.5), 64.1 (14.5), and 61.9 (13.2). Both Total and Core scores were higher than that from a Western sample reported by Boivin et al. (2011) ($t = 8.10$ and 8.36, $p < 0.01$) while no difference was found in Treatment score ($t = 1.41$, *n*.s.). Total and Core FertiQoL were found to be negatively associated with identification with Chinese cultural beliefs about childbearing ($r = -0.446$, $p < 0.05$).
Limitations, reason for caution: Self-selection bias was inevitable in questionnaire survey, and the cross-sectional nature of the study did not permit causal inferences. Only infertile women who failed their IVF cycles were recruited, so the fertility quality of life for those in other stages of IVF is yet to be investigated.
Wider implications of the findings: This study sheds light on the quality of life of Chinese infertile women after unsuccessful IVF treatment. Identification with Chinese beliefs of childbearing, which emphasizes the patrilineal culture, was associated with worse QoL. The findings underline the importance of cultural sensitivity in addressing fertility-related issues in order to better facilitate psychosocial support at the clinic.

P-554 Psychosocial counselling in treatment with donor sperm: exploring expectations of non-anonymous sperm donors

M. Visser[1], M. H. Mochtar[1], A. A. de Melker[1], F. van der Veen[1], S. Repping[1], T. Gerrits[2]
[1]*Academic Medical Center, Center for Reproductive Medicine, Amsterdam, The Netherlands*
[2]*University of Amsterdam, Faculty of Social and Behavioral Sciences Sociology and Anthropology, Amsterdam, The Netherlands*

Study question: What did men expect when they received psychosocial counselling on becoming a non-anonymous sperm donor and how did they experience being a sperm donor?
Summary answer: Sperm donors valued implication counselling before registration and that the counsellor addressed important issues like disclosure and future contact with donor-offspring. They expected that psychosocial counselling would be available to them when donor-offspring would actually seek contact in the future.
What is known already: Most studies on sperm donors focus on medical screening and motivations of sperm donors. Women/couples being treated with donor sperm value psychosocial counseling before treatment commences. There is limited knowledge on the expectations of sperm donors on psychosocial counselling, as well as their experience of being a sperm donor.
Study design, size, duration: We performed a qualitative study from March 2014 until June 2014 in 25 Dutch non-anonymous sperm donors, who had been a donor at the Centre for Reproductive Medicine of the Academic Medical Centre in Amsterdam any time between 1989 and 2014.
Participants/materials, setting, methods: We held semi-structured in-depth interviews based on literature and counselling experience with non-anonymous sperm donors. The interviews were fully transcribed and analysed using the constant comparative method of grounded theory.
Main results and the role of chance: The average age of the 25 sperm donors was 45 years. Sperm donors found it important to talk about issues as disclosure to family and friends, future contact with donor-offspring and rules and regulations and these issues had been addressed during pre-registration counselling. In the years following the donation, most donors just wanted to know how many offspring had been born and had no need for further counseling. Sperm donors frequently mentioned that they were concerned whether the donor-offspring were doing well. In this light they valued the availability of psychosocial counselling at the time when donor-offspring would seek contact in the future.
Limitations, reason for caution: A limitation of the results is the generalizability since only non-anonymous donors at a single center were studied. Potentially, variation in how donors are counselled upon intake affects how donors value psychosocial counselling.
Wider implications of the findings: This study reports the issues donors want to be addressed during pre-registration counselling and at time of actual contact seeking of donor-offspring. These findings can be used to achieve a higher quality of care for sperm donors and may be the starting point for developing guidelines on psychosocial counselling of sperm donors.
Study funding/competing interest(s): Funding by University(ies) – none.
Trial registration number: NA.

P-555 The experience of women undergoing fertility preservation while having breast cancer: a qualitative study

T. Dahhan[1], F. van der Veen[1], A. M. E. Bos[2], M. Goddijn[1], E. A. F. Dancet[1]
[1]*Academic Medical Centre, Obstetrics and Gynaecology, Amsterdam, The Netherlands*
[2]*Utrecht Medical Centre, Obstetrics and Gynaecology, Amsterdam, The Netherlands*

Study question: How do women experience fertility preservation while being newly diagnosed with breast cancer?
Summary answer: The intertwining of cancer and looming infertility was challenging. Fertility preservation was experienced as a welcome way of taking control and focus on survival. It triggered questions about women's own identity as a fertility and cancer patient, and offered them hope for the future.
What is known already: To circumvent the risk of cancer therapy-induced infertility, women can cryopreserve oocytes or embryos. This consists of controlled ovarian stimulation, a treatment known to cause stress. This takes place in the already stressful period of being diagnosed with cancer. How women experience going through fertility preservation whilst being newly diagnosed with breast cancer has not yet been investigated.
Study design, size, duration: We used a descriptive phenomenological approach to study the lived experience of being diagnosed with breast cancer and cryopreserving oocytes or embryos. Twenty-one women were interviewed once between March and July 2014, which was sufficient to reach data-saturation.
Participants/materials, setting, methods: Women with breast cancer who cryopreserved oocytes or embryos between January 2013 and July 2014 in two university based fertility clinics were eligible for inclusion. In-depth, face-to-face interviews were guided by open questions and a topic list. The transcribed interviews were analysed by two researchers.
Main results and the role of chance: It was challenging for women to simultaneously cope with life-threatening cancer, the threat to their fertility and treatments for both. The threats especially collided in case of hormone-sensitive

breast cancer. The two new identities of a cancer patient and of a fertility patient were unpleasant and resulted in shame. Women explained that their cancer survival-mode helped them to experience fertility preservation as a welcome action plan. Whereas breast cancer confronted women with a doom scenario for their future, fertility preservation gave them a new and hopeful perspective. The intertwining cancer and fertility preservation treatment trajectories resulted in time-pressure and confusion, as women did not know whether they should attribute stress and emotions to their hormonal treatment or to emotions about having cancer.

Limitations, reason for caution: The threat of memory bias due to the retrospective nature of the interviews, seemed limited as experiences did not differ depending on how long ago women cryopreserved their oocytes or embryos.

Wider implications of the findings: This study provides an in-depth understanding in how women with breast cancer deal with fertility preservation. This insight in patient's experience can increase health care providers' empathy and ability to support their patients.

Study funding/competing interest(s): Funding by University(ies) – No funding, researchers were allied to Academic Medical Centre (University of Amsterdam) and Utrecht Medical Centre (University of Utrecht).

Trial registration number: NA.

P-556 Do couples' view on disclosure of donor conception change over time? A comparison of disclosure intentions at time of counselling with disclosure decisions during childhood

I. Stuyver[1], V. Provoost[2], H. Van Parys[3], A. Ravelingien[2], S. Somers[1], E. Wyverkens[3], I. Raes[2], A. Buysse[3], G. Pennings[2], P. De Sutter[1]
[1]*Ghent University Hospital, Reproductive Medicine, Ghent, Belgium*
[2]*Ghent University, Bioethics Institute Ghent, Ghent, Belgium*
[3]*Ghent University, Faculty of Psychology and Educational Sciences, Ghent, Belgium*

Study question: Do disclosure intentions at the moment of donor counselling in the fertility centre (Time 1) predict disclosure decisions of mode of conception during childhood (Time 2)? Do parents' view on disclosure change?

Summary answer: In parents of anonymous donor-conceived children an accordance is shown between their disclosure intentions at the moment of pretreatment counselling and their disclosure decisions when their first child is between 7 and 10 years old. If parents change their mind, it is towards secrecy.

What is known already: Literature indicates that intentions to disclose are not interchangeable with the actually assessed disclosure, suggesting that intentions at the time of treatment may differ from what parents actually do later on (Klock, 1997, Daniels et al., 2007, Paul and Berger, 2007). To our best knowledge the presented data is the first comparison of disclosure intentions at the time of donor counselling with disclosure decisions during childhood.

Study design, size, duration: This study is embedded in a research project on genetic and social parenthood. The recruitment of couples treated with anonymous donor sperm or donor oocytes via the Ghent University Hospital was performed between June 2013 and February 2014. Forty-one couples having a child born between 2002 and 2005 were contacted.

Participants/materials, setting, methods: All couples were contacted by phone by the counsellor of the Department. At the time of this contact their disclosure decisions were queried. A comparison with the documented disclosure intentions at counselling was performed. In thirty-five of the forty-one couples all information was available at the two points in time.

Main results and the role of chance: Fourteen couples (40%) had the intention to disclose at the moment of counselling. At time 2, having children between 7 and 10 years old, three of the fourteen families (21%) had informed the child and five (36%) still had the intention to do so. In total a majority (57%) was in accordance with the initial intention. Five out of 14 parents (36%) changed their mind towards secrecy. When the initial intention of couples was not to disclose (40%), the majority of families stayed in accordance with their intention (79%). Seven families were unsure at moment of counselling (20%). At time 2, the majority of them had changed their mind to keeping the mode of conception a secret (57%). Two couples were still unsure and one couple had told the child.

Limitations, reason for caution: The sample size is small and this limits the generalizability of the obtained results.

Wider implications of the findings: The findings have implications for counselling before donor treatment, showing that the moment of counselling is the first moment of reflection on disclosure and an important moment in the further decision-making process of parents.

Study funding/competing interest(s): Funding by University(ies) – The project is funded by the Special Research Fund of Ghent University. Approval by the appropriate Ethics Committee has been obtained. There are no competing interests.

Trial registration number: NA.

QUALITY AND SAFETY OF ART THERAPIES

P-557 Adverse effects in pregnancy after treatment with preimplantation genetic diagnosis – a Danish national multicenter follow-up study

U. S. Kesmodel[1], H. J. Ingerslev[1], J. G. Lemmen[2], I. A. Rasmussen[3], B. Bay[1]
[1]*Fertility Clinic, Department of Obstetrics and Gynaecology, Aarhus N, Denmark*
[2]*Fertility Clinic, Department of Obstetrics and Gynaecology, Copenhagen, Denmark*
[3]*Fertility Clinic, Department of Obstetrics and Gynaecology, Odense, Denmark*

Study question: Do women conceiving by preimplantation genetic diagnosis (PGD) and their children have greater risk of adverse pregnancy and birth outcomes compared to spontaneously conceived children and children born after intrauterine insemination (IUI) or *in vitro* fertilization (IVF) with or without intra-cytoplasmatic sperm injection (ICSI).

Summary answer: Compared to spontaneously conceived pregnancies PGD-pregnancies were at significantly increased risk of placenta praevia, caesarian section, preterm birth, shorter gestation, heavier placenta, and longer neonatal admission. PGD-pregnancies carried systematically higher risks than IVF-pregnancies, although this was significant only for caesarean section and longer neonatal admission.

What is known already: The ESHRE PGD consortium has continuously collected data from a total of 54 PGD centres since 1997. Results from the first 10 years of data collection showed a risk of malformations of 3.9%, and 10% of newborns presented with neonatal complications. Data are generally reassuring, but the validity is difficult to evaluate. Also, it is unknown if any increased risk is directly caused by the invasive procedure or by the underlying known genetic disorder.

Study design, size, duration: The ESHRE PGD consortium has continuously collected data from a total of 54 PGD centres since 1997. Results from the first 10 years of data collection showed a risk of malformations of 3.9%, and 10% of newborns presented with neonatal complications. Data are generally reassuring, but the validity is difficult to evaluate. Also, it is unknown if any increased risk is directly caused by the invasive procedure or by the underlying known genetic disorder.

Participants/materials, setting, methods: We obtained information on type of fertility treatment from the IVF-Registry. PGD cycles were validated against lists of all PGD treatments in relevant clinics. Information on spontaneous conceptions and adverse pregnancy and birth outcomes was obtained from the national Medical Birth Register and linked by the unique personal identification number.

Main results and the role of chance: The indications for PGD-treatments were monogenic diseases (32%), X-linked diseases (21%), and chromosomal translocations (47%). Women undergoing PGD were older, more often nulliparous, and non-smokers compared with women conceiving spontaneously but did not differ from women undergoing IVF/ICSI- or IUI-treatment. Compared to spontaneously conceived pregnancies PGD-pregnancies were at significantly increased risk of placenta praevia (adjusted OR (ORa) = 6.2 (95% CI: 1.5; 25.4)), caesarian section (ORa = 1.7 (1.1; 2.7)), preterm birth (ORa = 1.8 (1.0; 3.1)), shorter gestation (-3.4 days (-6.0; -0.7)), heavier placenta (37 g (7; 68)), and longer neonatal admission (24 days (17; 30)). PGD pregnancies were at significantly increased risk of caesarean section (ORa = 1.6 (1.0; 2.5)) and longer

neonatal admission (23 days (15; 32)) compared with IVF/ICSI-pregnancies, and risks were systematically higher after PGD-treatment compared to IVF/ICSI.
Limitations, reason for caution: The main limitation of the study is the small sample size. However, all PGD-treatments were validated against medical records. Danish national registries have generally been shown to contain valid information.
Wider implications of the findings: There are two immediate implications of our findings. First, the information can be used directly in the communication with couples undergoing PGD-treatment. Second, since we observed systematically higher risk estimates for obstetrical and neonatal outcomes after PGD-treatment compared with IVF/ICSI, where only some suffer chronic diseases, this would suggest that at least part of the observed risks associated with IVF/ICSI-treatment in general may be caused by chronic disease rather than the treatment itself.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Aarhus University Hospital.
Trial registration number: NA.

P-558 No excess risk of preterm birth for singletons following blastocyst transfers compared to cleavage stage embryo transfers in Australia and New Zealand

Y. A. Wang[1], A. A. Chughtai[2], C. Farquhar[3], G. Chambers[4]
[1]*University of Technology Sydney, Faculty of Health, Broadway, Australia*
[2]*University of New South Wales, National Perinatal Epidemiology and Statistics Unit, Sydney, Australia*
[3]*University of Auckland, Department of Obstetrics and Gynaecology and National Women's Health, Auckland, New Zealand*
[4]*University of New South Wales, National Perinatal Epidemiology and Statistics Unit, Sydney, Australia*

Study question: Do singleton and twin pregnancies resulting from blastocyst transfers have higher odds of preterm birth than those resulting from cleavage stage embryo transfers?
Summary answer: During the study period, one in eight births were born preterm. Compared to cleavage stage embryo transfer, blastocyst transfer was not associated with excess risk of preterm birth for singletons, and was associated with 20% lower odds of preterm birth for twins.
What is known already: Some recent studies from Canada, Sweden and the United States using population ART registers found that singletons following blastocyst transfers had higher rate of preterm birth than singletons following cleavage stage embryo transfers. Given the marked differences in ART practices in Australia and New Zealand compared to Canada, Sweden and the United States, the excess risk of preterm birth following blastocyst transfers may not be present in Australia and New Zealand.
Study design, size, duration: A population-based study used Australian and New Zealand Assisted Reproduction Database (ANZARD). The study included 47438 live births following transfers of blastocyst or cleavage stage embryos during 2009–2012 in Australia and New Zealand.
Participants/materials, setting, methods: The rate of preterm birth (<37 weeks gestation) was compared by parental demographics and ART treatment factors. Univariate and multivariate logistic regressions stratified for singletons (43952) and twins (3418) were used to assess the likelihood of preterm birth. Odds ratio and adjusted odds ratio (AOR) were computed.
Main results and the role of chance: The overall rate of preterm birth was 13.1%, with 14.2% for cleavage stage embryo transfers, 12.6% for blastocyst transfers, 9.2% for singletons and 61.5% for twins. Of singletons, there was no significant difference in preterm birth between blastocyst and cleavage stage embryo transfers (AOR 1.00 95% CI 0.94–1.08). Of twins, blastocyst transfer was associated with 20% lower odds of preterm birth compared to cleavage stage embryo transfer (AOR 0.80 95% 0.70–0.93). The number of embryos transferred significantly modified the relationship between preterm birth and blastocyst transfer for twins, with AOR 0.74 (95% CI 0.63–0.88) for double blastocyst transfers compared to double cleavage stage embryo transfers and AOR 1.12 (95% CI 0.76–1.65) for single blastocyst transfers compared to single cleavage stage embryo transfers.
Limitations, reason for caution: The difference in cancellations before transfer between blastocyst and cleavage stage embryo cannot be assessed because the data was not available in ANZARD. Not all potential confounders were adjusted in the study due to availability.
Wider implications of the findings: In contrast with the findings from Canada, Sweden and the United States, blastocyst culture in Australia and New Zealand was not associated with excess risk of preterm birth for singletons, but was associated with a reduction in the risk of preterm birth for twins following double embryo transfers. Further studies assessing infant and child morbidity and mortality are needed to evaluate the risk related to blastocysts and cleavage stage embryos.
Study funding/competing interest(s): Funding by University(ies) – University of Technology Sydney. University of New South Wales.
Trial registration number: NA.
Keywords: preterm birth, blastocyst, cleavage stage embryo

P-559 Maternal age and the risk of major birth defects after *in vitro* fertilisation (IVF) and intracytoplasmic sperm injection (ICSI)

M. J. Davies[1], A. R. Rumbold[1], K. Willson[1], M. J. Whitrow[1], V. M. Moore[1]
[1]*The University of Adelaide, The Robinson Institute, Adelaide, Australia*

Study question: Does older maternal age explain the observed excess risk of major birth defects *in vitro* fertilisation (IVF) and intracytoplasmic sperm injection (ICSI)?
Summary answer: Advanced maternal age did not explain the excess of birth defects in the ART population as it is robustly protective for birth defects compared to young women.
What is known already: It has been claimed that advanced maternal age in the ART population underlies the associations between ART and birth defects. However, this is untested and assumes that the relationship between maternal factors and birth defects observed in the fertile population generalizes to ART conceptions.
Study design, size, duration: This was a whole-of population retrospective cohort study consisting of a census of all births within the State of South Australia for the period January 1986–December 2002 including 2226 IVF and 1395 ICSI births. Over 99.5% of ART births were successfully linked to perinatal outcomes.
Participants/materials, setting, methods: All treatment cycles of assisted reproductive technology (ART) were linked to population registries for births, terminations of pregnancy, birth defects coded to IC9-BPA notified to a child's 5th birthday, and cerebral palsy. Odds ratios (OR) for birth defects were calculated separately for births from IVF and ICSI for exposures of maternal age, parity, pre-pregnancy BMI, smoking, pre-existing diseases and conditions in pregnancy. Analyses controlled for treatment factors, multiplicity and infertility etiology.
Main results and the role of chance: The unadjusted prevalence of any birth defect was 7.1% and 9.9% in the IVF and ICSI groups. For IVF the unadjusted prevalence of birth defects was 9.3% in women ≤29 years compared to 3.4% for women 40+ years. The significant adjusted odds ratios for birth defects after IVF included young age ≤29 years (aOR = 1.59, 95% Confidence Intervals (CI) 1.01–2.49), smoking (aOR = 1.54, 95% CI 1.00–2.36), and being overweight (aOR = 1.63, 95% CI 1.04–2.55) or obese (aOR = 2.16, 95% CI 1.28–3.63). For ICSI, the unadjusted prevalence of birth defects was 10.0% for women aged ≤29 compared to 6.1% for women aged 40+. The significant adjusted odds ratios for birth defects after ICSI were nulliparity (aOR = 2.20, 95% CI 1.32–3.67), pre-existing hypertension (aOR = 3.08, 95% CI 1.00–9.45), anemia (aOR = 1.72, 95% CI 1.06–2.81), and urinary tract infection (aOR = 2.29, 95% CI 1.23–4.26).
Limitations, reason for caution: The relatively sparse data by maternal factors will reduce the capacity to discern types of defect and may reduce statistical power. The study does not preclude the possibility of currently unknown patient factors contributing to the findings.
Wider implications of the findings: Advanced maternal age did not explain the excess of birth defects in the ART population as it is robustly protective for birth defects, which implicates treatment related factors in the etiology of birth defects, particularly in younger women. Variation in risk profiles between IVF and ICSI also require further investigation. The present study should be replicated in other datasets to ensure generalisability to other patient populations.
Study funding/competing interest(s): Funding by national/international organization(s). Supported by grants from the National Health and Medical Research Council (349475, 349548, 453556, and 465455) and the Australian Research Council (FT100101018).
Trial registration number: NA.
Keywords: maternal age, IVF, ICSI, birth defects

P-560 Early embryo cleavage and multiple pregnancies after ICSI

M. Edessy[1], A. E. N. Ali[1], A. Fata[1], W. Hamed[1]
[1]*Al-Azhar University, Obstetrics and Gynecology, Cairo, Egypt*

Study question: Whether Number of early cleavage embryos can be a predictor for multiple pregnancies after ICSI.
Summary answer: Early cleavage could be an additional factor for selecting embryos with a higher potential of implantation and the number of EC embryos could be a useful parameter for the prediction of multiple pregnancies.
What is known already: One of the greatest problems in ART technology today relates to the selection of the optimal embryos for transfer, to achieve high pregnancy rates without increasing multiple pregnancy rates (Tomari et al., 2011). Much effort has been devoted to refining existing embryo scoring systems and finding simple, non-invasive parameters that could improve the embryo selection procedure (Senn et al., 2006; Brezinova et al., 2009). Early cleavage is one of the most promising new selection parameters.
Study design, size, duration: This was cohort prospective study conducted in the period from December 2010 to September 2012. A total of 193 infertile couples were included in this study.
Participants/materials, setting, methods: 193 infertile couples. Controlled ovarian hyperstimulation was performed. Embryos were assessed at 25–27 h after ICSI for early cleavage and classified as Early Cleavage (EC) embryos or Non Early Cleavage (NEC) embryos. The patients were subdivided into two subgroups; one transfer (EC) and the other transfer (NEC).
Main results and the role of chance: Transfer of early cleavage embryos (EC) led to significantly higher pregnancy rates as compared to non early cleavage embryos (NEC) (43.30% versus 21.88%; $P = 0.005$), and also higher implantation rates (25.58% versus 11.35%; $P = 0.000$). Multiple pregnancy rate were significantly increased up to 26% when the number of EC embryos was two or more compared to 15.38% when less than two.
Limitations, reason for caution: No limitation.
Wider implications of the findings: Early cleavage could be an additional factor for selecting embryos with a higher potential of implantation and the number of EC embryos could be a useful parameter for the prediction of multiple pregnancies.
Study funding/competing interest(s): Funding by University(ies) – Al-Azhar University.
Trial registration number: Cohort study.
Keywords: ICSI, multiple pregnancy, early cleavage

P-561 Estimating the risk of monozygotic twins in IVF-ICSI pregnancies using the perspective of a prenatal diagnosis unit

V. Sarais[1], G. M. Baffero[2], A. Paffoni[1], F. Parazzini[2], N. Persico[2], E. Somigliana[1]
[1]*Policlinico-Mangiagalli-Regina U. ElenaO Centro Sterilità, Milano (MI), Italy*
[2]*Policlinico-Mangiagalli-Regina U. ElenaO Ostetricia e Ginecologia, Milano (MI), Italy*

Study question: Is the risk of monozygotic twin (MZT) pregnancies truly increased in IVF-ICSI cycles?
Summary answer: IVF-ICSI pregnancies have a three-four folds increased risk of MZT.
What is known already: MZT is accepted to be increased in IVF pregnancies. However, available evidence is not consistent and estimates of the magnitude of this risk vary widely. These discrepancies may be explained by differences in population studied and methodological pitfalls. In fact, a definitive conclusion on the risk of MZT in IVF-ICSI pregnancies is still lacking. In this study, we suggest to approach the issue from a different perspective, i.e., using data from a tertiary care prenatal diagnosis unit.
Study design, size, duration: Retrospective evaluation of 145 MZT pregnancies. This sample size was calculated based on an expected rate of IVF-ICSI pregnancies in our population of 2.0%, setting type 1 and 2 errors at 0.05 and 0.20 respectively and stating as clinically relevant a three-folds increase in the risk of MZT.
Participants/materials, setting, methods: Data was obtained from outpatient and inpatient charts and phone contact. We included twin pregnancies with a sonographic diagnosis of monochorionic MZT that progressed beyond 12 weeks' gestation. Collected data included baseline clinical characteristics, mode of conception and pregnancy outcome.
Main results and the role of chance: Ten out of the 145 MZT pregnancies were achieved using IVF-ICSI, corresponding to a rate of 6.9% (95% CI: 3.5–11.8%), thus significantly higher than the expected 2.0%. The Odds Ratio (OR) of MZT in IVF-ICSI pregnancies is 3.6 (95% CI: 1.8–6.6). When considering exclusively MZT pregnancies achieving delivery of two vital newborns ($n = 132$), the number of IVF-ICSI pregnancies was nine (6.8%, 95% CI: 3.7–12.5%). The corresponding OR is 3.3 (95% CI: 1.9–7.0). Baseline pre-pregnancy characteristics did not differ between IVF-ICSI and natural pregnancies (data not shown). Moreover, we failed to document significant differences in pregnancy outcome. The rates of delivery of the two alive twins (90% and 91%), twin-to-twin transfusion syndrome (10% and 18%), delivery before 34 weeks' gestation (22% and 25%) and SGA (11% and 23%) were indeed similar ($p = 1.00$, $p = 1.00$, $p = 1.00$ and $p = 0.38$, respectively).
Limitations, reason for caution: Firstly, the antenatal perspective consents to prevent several but not all confounders. Secondly, the small sample size does not allow us to investigate the potentially detrimental independent role of ICSI, assisted hatching or blastocyst transfer. Thirdly, the small sample size exposes our results on pregnancy outcome comparisons to a significant type II error.
Wider implications of the findings: Women undergoing IVF-ICSI should be informed that they have an increased risk of MZT. Largest studies are warranted to assess whether the prognosis of IVF-ICSI and natural MZT pregnancies differs.
Study funding/competing interest(s): Funding by University(ies) – none.

P-562 The comparsion of live-birth defects following luteal phase ovarian stimulation with conventional/mild ovarian stimulation for *in vitro* fertilization and vitrified embryo transfer cycles

H. Chen[1], Y. Wang[1], Q. F. Lyu[1], A. Ai[1], Y. L. Fu[1], H. Tian[1], R. F. Cai[1], Q. Q. Hong[1], Q. J. Chen[1], Z. Shoham[2], Y. P. Kuang[1]
[1]*Shanghai Ninth People's Hospital Shanghai Jiaotong University School of Medicine, Assisted Reproduction, Shanghai, China*
[2]*Kaplan Medical Center, Obstetrics and Gynecology, Rehovot, Israel*

Study question: Our previous study showed that luteal phase ovarian stimulation (LPS) can produce competent oocytes/embryos and optimal pregnancy in women undergoing *in vitro* fertilization/intracytoplasmic sperm injection (IVF/ICSI) treatments. Are there any differences in the live-birth defects following the LPS compared with conventional/mild ovarian stimulation?
Summary answer: Until now, this unique approach has resulted in hundreds of live born infants following frozen-thawed embryo transfer (FET) in our center, while the rates of live-birth defects following LPS were similar to those following conventional/mild ovarian stimulation.
What is known already: So far, there are no reports of this aspect.
Study design, size, duration: A retrospective cohort study was conducted at our center; IVF/ICSI-FET cycles following LPS and conventional/mild ovarian stimulation started between March 1, 2012 and July 1, 2013 are collected.
Participants/materials, setting, methods: Patients who underwent IVF/ICSI-FET treatment leading to births between January 1, 2013 and May 1, 2014 were completed telephone interviews. The final data involved 2060 live-born infants were stratified into groups: LPS ($n = 587$ births), the standard GnRH agonist short protocol ($n = 1257$ births) and mild ovarian stimulation ($n = 216$ births).
Main results and the role of chance: Birth characteristics regarding gestational age, birth weight and length, multiple delivery and early neonatal death were comparable in all groups. The incidence of live birth defects among the LPS group (1.02%) and the short GnRH agonist protocol group (0.64%) were all slightly higher than in the mild ovarian stimulation group (0.46%). However, none of these differences reached statistical significance ($P = 0.624$). For congenital malformations, the risk significantly increased for the infertility-duration factor and multiple births; the adjusted odds ratios (OR) were 1.161 (95% confidence interval [CI]: 1.009–1.335, $P < 0.037$) and 3.899 (95% CI: 1.179–12.896, $P < 0.026$), respectively. No associations were found between congenital birth defects and different ovarian stimulation regimens, maternal age and BMI, parity, insemination method and infant sex.
Limitations, reason for caution: Our data source was limited to extracting neonatal information from parent questionnaires rather than direct access to their medical records. Therefore, it is likely that minor problems may have

escaped detection and birth defect rates may be underestimated, although it is unlikely that this would have altered infant birth characteristics.
Wider implications of the findings: There is no evidence of detrimental effects of LPS on live-born infants at birth, and continuous surveillance will be needed to explore its long-term safety. However, infertility itself poses a risk factor for congenital malformation. A higher likelihood of birth defects in multiple births may influence couples to favor elective single-embryo transfer, and couples undertaking ART should be aware of the known increased birth defects associated with a twin birth.
Study funding/competing interest(s): Funding by national/international organization(s) – National Natural Foundation of China. Natural Science Foundation of Shanghai, China.

P-563 Failure mode and effects analysis of witnessing protocols for ensuring traceability of gametes and embryos during *in vitro* fertilization: a single centre analysis

L. Rienzi[1], F. Bariani[2], M. Dalla Zorza[3], S. Romano[1], C. Scarica[1], A. Nanni Costa[2], F. M. Ubaldi[1]
[1]*GENERA Centre for Reproductive Medicine, Clinica Valle Giulia, Roma, Italy*
[2]*Italian National Transplant Centre (CNT), Istituto Superiore di Sanità, Roma, Italy*
[3]*Centro Trasfusionale, Ulss 9, Treviso, Italy*

Study question: Is failure mode and effects analysis (FMEA) helpful to enhance safety in the IVF laboratory by identifying critical steps where miss-matches may occur and supporting the introduction of new strategies to minimize risks?
Summary answer: FMEA performed by a multidisciplinary team is effective identifying critical procedures during traceability and witnessing of patients and samples. Although double-checking approach and permanent recording of critical data were in place, the analysis allowed to identify weaknesses and redundancy in the protocols and to set-up a more effective system.
What is known already: Traceability of cells during IVF is a fundamental aspect of the treatment that involves witnessing protocols integrated in an effective Quality Management System. Although it is a mandatory requirement according to specific European Directives, miss-matches have been recently reported with dramatic consequences for both patients and health care professionals. FMEA is a method for identifying real or potential breakdowns in processes and to develop strategies to mitigate risks.
Study design, size, duration: To examine the risks associated with traceability and witnessing protocols for patients and cells identification, to identify possible causes of failures and their potential effects, we performed a proactive risk-assessment analysis (FMEA) in a large IVF centre (>1.000 cycles/year), prior and after the implementation of electronic witnessing systems.
Participants/materials, setting, methods: A multidisciplinary team was formed, moderated by a human factors specialist, to calculate a risk-priority-number (RPN) for each element most likely to contribute to failures by multiplying 3 factors: severity-occurrence-detection (graded 1–5). A second analysis was performed after the implementation of electronic witnessing systems (IVF witness, RI).
Main results and the role of chance: The IVF team identified 7 main process phases (oocyte collection, sperm donation, gamete processing, insemination, embryo culture, embryo transfer, cryopreservation), 19 associated process steps and 32 possible failures modes. The highest RPN was 30 (moderate risk) confirming the relative low risk that miss-matches may occur in IVF when a manual witnessing system (based on double-checking approach and permanent recording of critical data) is used. Possible failures modes were mainly associated with: heavy clinical workload and distraction, communication failures between the team, automaticity during witnessing, ambiguous responsibility of the single tasks or redundancy of the protocols. The introduction of the electronic witnessing system allowed reducing the moderate-risk failure mode by 2/3 (highest RPN = 10).
Limitations, reason for caution: The study was performed in a single large centre, with complex protocols for traceability and witnessing. The results are thus only applicable to our setting. FMEA analysis has been shown to be a useful prospective tool however its absolute validity is questionable due to the subjectivity of the judgments.
Wider implications of the findings: The FMEA is effective to support multidisciplinary IVF groups in understanding traceability and witnessing process and identifying critical steps where miss-matches may occur. Due to the irreversible and dramatic consequences of miss-matches in IVF, it is suggested to enhance safety by performing proactive risk-assessment analysis and to consider the implementation of electronic witnessing systems that has been shown in our setting to prevent potential risks.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Funding by national/international organization(s). None.
Trial registration number: NA.
Keywords: FMEA, miss-match, proactive risk-assessment analysis, IVF

P-564 Reduction of multiple pregnancy rate in advanced maternal age population after the introduction of an elective single embryo transfer policy: a pre- and post-intervention study

F. Ubaldi[1], A. Capalbo[2], S. Colamaria[1], R. Maggiulli[1], S. Sapienza[1], S. Romano[1], S. Ferrero[1], C. Scarica[1], M. Giuliani[1], E. Gravotta[1], A. Vaiarelli[1], L. Albricci[1], E. Ievoli[1], D. Cimadomo[1], L. Rienzi[1]
[1]*Reproductive Medicine GENERA, Clinica Valle Giulia, Roma, Italy*
[2]*GENETYX, Molecular Genetic Laboratory, Marostica, Italy*

Study question: Is elective single-embryo transfer (eSET) policy efficient and effective in women aged >35 years?
Summary answer: Elective SET coupled with enhanced embryo selection policy in women older than 35 years reduce the multiple pregnancy rate while maintaining the cumulative success rate of the IVF programme.
What is known already: SET policy is recommended in cases of good prognosis patients. No general consensus has been reached for SET application in the advanced maternal age population (AMA) defined as women older than 35 years. Our objective was to evaluate the results in terms of efficacy, efficiency and safety of eSET policy coupled with routine application of blastocyst culture and pre-implantation genetic screening (PGS) for this population of patients in our IVF program.
Study design, size, duration: In January 2013, a multidisciplinary intervention involving optimization of embryo selection procedure and introduction of an eSET policy in the AMA population was implemented. This is a retrospective 4-year (January 2010–December 2013) pre- and post-intervention analysis.
Participants/materials, setting, methods: Surplus oocytes and/or embryos were vitrified during the entire study period. In the post-intervention period, all couples with good quality embryos were offered eSET. Embryo selection was enhanced by blastocyst culture and PGS (blastocyst stage biopsy and 24-chromosomal screening) was routinely offered. eSET was also applied in cryopreservation cycles.
Main results and the role of chance: Patient and cycle characteristics were similar in the pre- and post-intervention groups (mean age 39,5 + 2,1 and 39,4 + 2,2; range 36–44) as assessed by logistic regression. 1609, 937, 138 and 574, 350 and 27 oocytes retrievals, embryo and oocyte warming cycles were performed, respectively. These resulted in 1854 and 508 total embryo transfers in the pre- and post-intervention period. A mean number of 2,1 + 1,1 and 1,4 + 0,8 embryos were transferred, respectively ($P < 0,01$). Similar cumulative clinical pregnancy rates per transfer and per cycle were obtained: 26,8%, 30,9% and 29,7%, 26,3%. The total efficacy (delivery/oocyte retrieval cycle) was not affected by the intervention (21,1% and 20,4%; OR = 1.17,95% CI: 0.88–1.55;$p = 0.26$) However, significant increased efficiency (life birth/transferred embryo) was observed in the post-intervention group 17,0% vs 10,6% ($P < 0,01$). Multiple pregnancy rate decreased from 20,8% to 6,9% (OR = 0.32 95% CI 0.14–0.71; $P < 0,01$).
Limitations, reason for caution: In this study, the suitability of SET was individually assessed on the basis of both clinical and embryological prognostic factors and was not standardized. For the described eSET strategy coupled with enhanced embryo selection policy an efficient culture system and cryopreservation program is necessary.
Wider implications of the findings: Due to the increased maternal morbidity and mortality and perinatal complications related to multiple pregnancy it is generally recommended to extend the eSET policy also to the AMA population. As shown in this study, in this population of patients enhanced embryo selection procedures allow to reduce the number of embryo transferred at a time without affecting the total efficacy of the treatment but increasing efficiency and safety.
Study funding/competing interest(s): Funding by hospital/clinic(s) – none.

Trial registration number: NA.

P-565 The effect of initiation of strict embryo transfer limits on neonatal complications with in-vitro fertilization (IVF)

T. Shaulov[1], S. Belisle[2], M. H. Dahan[3]
[1]*McGill University, Obstetrics and Gynecology, Montreal, Canada*
[2]*Université de Montreal, Obstetrics and Gynecology, Montreal, Canada*
[3]*McGill University, Reproductive Services, Montreal, Canada*

Study question: What is the effect of the initiation of a government funded in-vitro fertilization (IVF) program with strict limits on numbers of embryos which can be transferred on neonatal complication rates and incidence?
Summary answer: This first North American publicly funded IVF program has decreased the multiple birth rates related to IVF. However, the absolute numbers of IVF babies born prematurely or requiring admission have slightly increased. Also, the average admission cost per IVF baby has seen a substantial increase.
What is known already: Multiple pregnancies carry with them risks to both mothers and fetuses. Several international jurisdictions have demonstrated that publicly funded fertility programs with a single embryo transfer (SET) policy decrease multiple pregnancy rates. Also, IVF pregnancies are generally associated with higher rates of complications than spontaneous pregnancies, attributed partially to multiples. In August 2010, Quebec started funding of IVF with SET, with a goal of decreasing neonatal complications and their costs.
Study design, size, duration: This a retrospective study. Data compares outcomes of all IVF cycles performed in Quebec from the 2009 to 2010 (last complete pre-coverage) to 2012–2013 (first complete post-coverage) fiscal years. This study is based on 168 602 spontaneous and IVF deliveries. In 2009–2010, 906 women conceived with IVF, while in 2012–2013, 1746 conceived.
Participants/materials, setting, methods: Data was extracted from two reports by the Health and Welfare Commissioner as well as the Ministry of Health and Social Services published in June 2014 and October 2013, respectively. This data was collected from all assisted reproduction centers in Quebec providing IVF services. Data was compared using chi-squared tests.
Main results and the role of chance: The number of babies born from IVF increased 63% from 2009–2010 to 2012–2013 (1057–1723). Multiple pregnancy rates decreased from 24.06% in 2009–2010 to 9.45% in 2012–2013 ($p < 0.0001$). The proportions of IVF babies that were the result of multiple births, were premature, or required intensive-care unit (ICU) admission, decreased by 55% ($p < 0.0001$), 35.5% ($p < 0.0001$), and 37% ($p < 0.0001$), respectively, from 2009–2010 to 2012–2013. These changes in absolute numbers were a decrease from 407 to 297, an increase from 313 to 329 and an increase from 199 to 204 babies, respectively. The average ICU admission costs for a baby conceived through IVF and spontaneously was $19,990 and $14,563 in 2009–2010, respectively, and $28,418 and $17,155 in 2011–2012, respectively.
Limitations, reason for caution: Retrospective data concerning IVF cycles and clinical outcomes was gathered from several sources. However this is a robust study on data collected from more than 160,000 women who underwent conceptions either spontaneously or through IVF.
Wider implications of the findings: Publicly funded IVF programs substantially decrease multiple pregnancy rates. However, due to substantially increased usage, neonatal complications increase. Interestingly, the cost per IVF neonatal-ICU admission skyrocketed when the cost of caring for multiples was reduced. This suggests that the singleton IVF pregnancies which require neonatal-ICU care are much sicker than IVF twins which end up in the ICU. Further research should be directed into decreasing the rate of ICU admissions for singleton IVF conceptions.
Study funding/competing interest(s): Funding by hospital/clinic(s) – No funding was provided.
Trial registration number: NA.

[9]*University of Helsinki and Helsinki University Hospital, Department Obstetrics and Gynecology, Helsinki, Finland*
[10]*Institute of Clinical Sciences at University of Gothenburg and Sahlgrenska University Hospital, Department Obstetrics and Gynecology, Gothenburg, Sweden*

Study question: What is the effect of advanced maternal age on maternal and perinatal outcomes after assisted reproductive technology (ART)?
Summary answer: Advanced maternal age seems not to be a further risk factor for adverse maternal and perinatal outcomes in addition to the increased risks associated with ART.
What is known already: Advanced maternal age is associated with increased risk for pregnancy complications and adverse neonatal outcomes in spontaneously conceived (SC) pregnancies. ART compared to spontaneous conception is associated with increased risk for pregnancy complications and adverse neonatal outcomes also in singleton pregnancies.
Study design, size, duration: Population based cohort study performed in three Nordic countries (Denmark, Sweden and Norway) from 1988 to 2007.
Participants/materials, setting, methods: 39922 singletons conceived after ART and 266907 SC singletons. Main outcomes were hypertensive disorders in pregnancy (HDP), placental abruption, placenta praevia, preterm birth (PTB, <37 weeks), low birth weight (LBW, <2500 g), small for gestational age (SGA). Crude and adjusted odds ratios (AOR) with 95% confidence interval were calculated.
Main results and the role of chance: Compared to SC pregnancies in women at age 18–34 years, pregnancies in women ≥40 years had a significantly higher risk of both HDP and placental abruption, regardless of conception method (AOR ART 1.5 and 1.7, SC 1.8 and 1.6, respectively). The risk for placenta praevia was generally increased in ART women (AOR 8–11). The risk for PTB, LBW and SGA were significantly higher in both ART and SC pregnancies for women ≥40 years, compared to SC pregnancies for women 18–34 years. In ART pregnancies, risk was similar across age groups for maternal and neonatal outcomes, while risk increased with increasing age for SC pregnancies.
Limitations, reason for caution: It was only possible to adjust for parity, year of birth, offspring sex and country, thus there may be residual confounders. Women who conceive through ART at an advanced age may represent a selected group.
Wider implications of the findings: The results are reassuring for a large group of women treated with ART at an advanced age.
Study funding/competing interest(s): Funding by University(ies) – Funding by national/international organization(s). The study was supported by grants from the University of Gothenburg/Sahlgrenska University Hospital (LUA/ALF 70940) and the Nordic Federation of Obstetrics and Gynaecology (NFOG).
Trial registration number: Not relevant.
Keywords: advanced maternal age, ART, risk, maternal outcome, neonatal outcome

P-567 Risk of preeclampsia and hypertensive disorders of pregnancy (HDP) in singleton and twin oocyte donation (OD) pregnancies – a systematic review and meta-analysis

M. B. Storgaard[1], S. S. L. Malchau[2], J. Forman[2], A. B. Pinborg[2]
[1]*University of Copenhagen, Faculty of Health and Medical Sciences, Soeborg, Denmark*
[2]*Hvidovre Hospital, Obstetric/Gynecological, Copenhagen, Denmark*

Study question: How much is the risk of HDP and preeclampsia increased in OD singleton and twin pregnancies compared to *in vitro* fertilization (IVF) singleton and twin pregnancies?
Summary answer: The risk of HDP and preeclampsia is almost three-fold increased in OD singleton and twin pregnancies compared to IVF singleton and twin pregnancies.
What is known already: Several mainly smaller studies including multiple pregnancies have shown that the risk of HDP and preeclampsia is increased in OD pregnancies compared to IVF pregnancies. This may be caused by immunological factors as the fetus in OD pregnancies is genetically unknown to the mother. No previous meta-analyses have been performed.
Study design, size, duration: In a systematic review we included 13 studies out of which 6 studies present odds ratios of HDP in OD singleton pregnancies compared to IVF singleton pregnancies and 7 studies present odds ratios of preeclampsia in OD singleton pregnancies compared to IVF singleton pregnancies. Two meta-analyses were conducted on HDP and preeclampsia respectively. Hypertensive disorders of pregnancy include chronic hypertension, pregnancy induced hypertension, preeclampsia/eclampsia and HELLP syndrome.
Participants/materials, setting, methods: We identified 13 original studies presenting data on occurrence of HDP and preeclampsia in OD pregnancies in PubMed and Embase. Only studies in English language and from the last two decades were included. Only studies presenting separate data on singletons or adjusting for plurality were included in the meta-analyses.
Main results and the role of chance: In the meta-analyses the pooled odds ratio of HDP was 2.71 (95% CI 2.10–3.51) and the pooled odds ratio of preeclampsia was 2.92 (95% CI 2.00–4.29) in 869 and 835 OD singleton pregnancies, respectively, compared to IVF singleton pregnancies. In twin pregnancies, 36% (73 out of 200) developed HDP and 21% (27 out of 130) developed preeclampsia. These numbers were too small to perform meta-analyses.
Limitations, reason for caution: Only a limited number of small studies could be included in the meta-analyses as most existing studies pool data on singleton and multiple pregnancies without adjustments. Studies were heterogeneous and up to 20 years old.
Wider implications of the findings: The risk of HDP and preeclampsia in OD pregnancies is noticeably increased and extended antenatal care including extra blood pressure controls and induction of labor at term should be offered. Further women with OD pregnancies may benefit from low dose aspirin treatment.
Study funding/competing interest(s): Funding by University(ies) – no external Funding was obtained for this project.
Trial registration number: No trial registration.
Keywords: oocyte donation pregnancy, preeclampsia

P-568 Systemic oxidative stress could predict assisted reproductive technique outcome

R. Mändar[1], A. Ahelik[1], P. Korrovits[1], P. Karits[2], E. Talving[2], K. Rosenstein[2], M. Jaagura[2], A. Salumets[1], T. Kullisaar[3]
[1]*Competence Centre of Reproductive Medicine and Biology, Tervisetehnoloogiate Arenguskeskus AS, Tartu, Estonia*
[2]*NovaVita Clinic, NovaVita Clinic, Tallinn, Estonia*
[3]*University of Tartu, Department of Biochemistry, Tartu, Estonia*

Study question: Main aim of this research was to detect oxidative stress (OxS) levels in couples attending assisted reproductive technique (ART) procedure.
Summary answer: The study uncovered negative effect of both partners' oxidative stress on maintenance and outcome of pregnancy. A strong positive correlation between the partners' OxS levels was seen.
What is known already: Previous studies have indicated that OxS may appear as a possible reason for poor ART outcome. High seminal ROS (reactive oxygen species) level is associated with impaired sperm fertilizing ability and lower pregnancy rates after IVF. To date, one of the most common marker to assess systemic OxS is measurement 8-isoprostanes (8-EPI), the byproducts of lipid peroxidation.
Study design, size, duration: Prospective laboratory-clinical cohort study of 79 couples attending ART procedure in 2011–2012.
Participants/materials, setting, methods: Altogether 79 couples attending ART procedure (58 IVF and 21 ICSI) were recruited at Nova Vita Clinic (Tallinn, Estonia). Oxidative DNA damage (8-OHdG) and lipid peroxidation (8-EPI) were detected in urine, vaginal fluid and seminal plasma by ELISA method. Clinical background and ART outcome were also recorded in both partners.
Main results and the role of chance: Both OxS markers were significantly associated with clinical conditions of the subjects, the biggest effectors being genital tract infections, endometriosis, uterine myoma and smoking. Furthermore, men whose partners had genital tract infections, showed significantly higher OxS levels compared to men, whose partners were without known diseases (a strong positive correlation among couples $r = 0.42$, $p < 0.001$). The most significant effectors of male OxS were bacterial vaginosis and salpingo-oophoritis. No pregnancies after ART procedures occurred among 63% of patients, 9% of pregnancies were detectable only by pregnancy test and 28% of pregnancies were detectable also by ultrasound. The highest 8-EPI levels were detected in both partners (women 97,8 (±16,7) vs 72.9 (±22,9), $p = 0.007$; men, 89.6 (±20,4) vs 72,1 (±22,6), $p = 0.049$) when biochemically detectable pregnancy did not develop into clinically detectable pregnancy.
Limitations, reason for caution: The weakness of current study was the absence of fertile control group and small study groups. As there are large number of markers and a lot of different technologies available for detecting OxS level in different body fluids, the confirmatory studies with bigger study group are necessary.
Wider implications of the findings: High grade systemix OxS in both partners may negatively affect the maintenance and outcome of pregnancy. Applying detection of OxS in ART patients may select the patients with higher success rate and/or those who need antioxidant therapy. This would lead to improvement of ART outcome as well as natural fertility.
Study funding/competing interest(s): Funding by University(ies) – Funding by commercial/corporate company(ies). The present study was supported by Enterprise Estonia (Grant no. EU 30020), Estonian Ministry of Education and Research (Target Financing SF0180132s08, Institutional Research Fundings IUT 20–42 and IUT 15–19) and University of Tartu (Grant no. SARMBARENG). P-569 Coaching an efficient quality management system for small IVF laboratories

A. C. Herta[1], P. J. Pico[2], M. J. G. Van den Bergh[3], I. Lutescu[1], N. Pavic[2]
[1]*Euromaterna, IVF Laboratory, Constanta, Romania*
[2]*Fertilitas IVF ICSI AG, IVF Laboratory, Basel, Switzerland*
[3]*Quartec GmbH, IVF Laboratory Consulting, Fislisbach, Switzerland*

Study question: Are small fertility units – performing less than 50 oocyte retrievals per year – able to achieve success rates significantly better than the mean success rates published by their national IVF registers?
Summary answer: Coaching based on continuous education, survey mainly via the internet and alternated by quarterly on site visits results in the establishment of small autonomous IVF laboratories having success rates per treatment cycle upto 15% above the national mean.
What is known already: The Swiss National IVF Register data reveal that in 2012, from the 25 centers 20 did less than 1 oocyte puncture a day. The pregnancy rate per initiated cycle ranged from 8.8% to 31.4% in 2012. This large difference remained constant since: 2010 (6%–37%) resp. 2011 (7.7%–42.9%). Such data fuel the believe that smaller units produce less good results because of the availability of an embryologist and/or a discontinuity in their activity, lack of adequate survey and quality management or the difficulty of obtaining adequate technical support.
Study design, size, duration: A laboratory coaching system was setup from the middle of 2013 on in 2 laboratories: one situated in Basel (CH) and one in Constanta (RO) and is still ongoing.
Participants/materials, setting, methods: The coaching consisted in regular on site visits with control of all physical and chemical parameters which are known to influence the outcome of assisted reproductive technologies: temperature logging, infrared thermography, pH logging, magnetic field survey and volatile organic compound analysis by passive chromatographic absorption and active logging. All used instruments for the surveys were calibrated by accredited organizations on a yearly base. All laboratory procedures were reviewed, standardized, skills of all laboratory personal was assessed and continuously monitored via their enrollment in monthly Online Quality Survey Schedules (FERTAID) all personal participates in a continuous education program based on ABB accredited webinars (life interactive internet seminars).

Main results and the role of chance: For the laboratory in Basel the clinical pregnancy rates per oocyte retrieval was: in 2012 13/50 (26%), in 2013 15/54 (28%) and in 2014 19/43 (44%) for the unit in Constanta the results were: in 2012 8/35 (23%), in 2013 10/20 (50%) and 7/20 (35%) in 2014. The Z-test for proportions for dependent groups in 2013 and 2014 was significant at the 95% confidence interval level in the unit located in Basel and significant at the 80% confidence interval level for the unit in Constanta.
Limitations, reason for caution: The median age in both centers for the 3 periods was 35 and ranged between 26 and 42 years.
Wider implications of the findings: Small IVF units are able to provide constant good treatment outcome under continuous external coaching.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Marc Van den Bergh is CEO of Quartec GmbH.
Trial registration number: NA.

P-570 The effect of transferring one or two blastocysts in women 40–42 years of age on pregnancy, clinical pregnancy, live birth and multiple pregnancy rates

M. H. Dahan[1], N. Al-Asmari[1], W. Y. Son[1]
[1]*Royal Victoria Hospital, McGill Reproductive Center, Montreal, QC, Canada*

Study question: Does transferring 2 blastocysts in women at least 40 years old increase the pregnancy, clinical pregnancy, live birth or multiple pregnancy rates as compared to 1 blastocyst transfer?
Summary answer: Transferring two blastocysts does not improve the clinical pregnancy rate or the live birth rate in this age group, but trends to increase the multiple pregnancy rate.
What is known already: In women less than 36-years old transferring two-blastocysts increases the multiple pregnancy rate without necessarily increasing the clinical pregnancy or live birth rates. Few studies have also demonstrated similar findings in women 36–39 years of age. Quebec limits the transfer to a maximum of two blastocysts in women ≥40 years of age. Development to blastocyst does not translate in to euploidy in women of this age. No studies have investigated transferring one or two blastocysts in this population.
Study design, size, duration: A retrospective study was performed on all blastocyst transfers done in women at least 40 years of age ($n = 126$). Data was collected from August 2010 till June 2012. August 2010 was selected as a start date because this is when Quebec limited number of embryos transferred.
Participants/materials, setting, methods: Data was collected at a university center. Research ethics board approval was obtained (13-053-SDR). Data was analyzed using multivariate analysis to control for confounding effects of female age, ovarian reserve, stimulation parameters, and embryo quality. A total of 38 single blastocyst and 88 double blastocyst transfers were performed in women 40–42 years of age.
Main results and the role of chance: When comparing one or two blastocysts transferred, pregnancy rates (45% vs. 38%, $p = 0.54$), clinical pregnancy rates (34% vs. 27%, $p = 0.60$), and live birth rates (21% vs. 19%, $p = 0.82$) did not differ. Best blastocyst transferred grade seemed to trend better among women with a pregnancy ($p = 0.08$), but not those with a clinical pregnancy ($p = 0.43$) or live birth ($p = 0.12$). Best blastocyst grade did not differ for one or two blastocysts transferred ($p = 0.83$). There were no multiple pregnancies among women with single blastocyst transfer. When comparing single vs. double blastocyst transfer, the rate of two intrauterine gestational sacs (0% vs. 20%, $p = 0.06$), two foetal heart beats (0% vs. 25%, $p = 0.05$) and live birth of twins (0% vs. 24%, $p = 0.06$) trended higher in the two embryos transferred group.
Limitations, reason for caution: Retrospective study. Interestingly the pregnancy, clinical pregnancy and live birth rates were higher although not statistically significant in the women with single blastocyst transfer, compared to double blastocyst transfer.
Wider implications of the findings: More data is needed to confirm these findings. However, initially it appears that transferring two blastocysts in women 40–42 years of age does not improve clinical outcomes, only increases the multiples rates, when compared to single blastocyst transfer. Given that the pregnancy rate does have room to increase, it seems likely that transferring 3 or more blastocysts in this age group would improve clinical results. Concurrently, likely further increasing the multiple pregnancy rates.
Study funding/competing interest(s): Funding by University(ies) – none.
Trial registration number: NA.

P-571 The role of cyclin D1 in the development of borderline ovarian tumors after ovarian hyperstimulation

G. Di Luigi[1], A. Castellucci[1], G. Rossi[1], S. Cecconi[1], G. Carta[1]
[1]*University of L'Aquila, Department of Life Health and Environmental Sciences, L'Aquila, Italy*

Study question: Concerns have been raised that ovarian stimulation may increase the risk of ovarian malignancies, especially Borderline Ovarian Tumors (BTOs). To understand if repeated cycles of gonadotropin stimulation could modulate intracellular localization and content of proteins controlling cell cycle progression in mouse ovaries and fallopian tubes (FT).
Summary answer: Repetitive gonadotropin stimulations did not induce changes in a set of proteins directly involved in cell cycle progression and usually altered in ovarian cancer. By contrast, cyclin D1 level increased significantly after the fourth cycle of stimulation in FT of treated mice.
What is known already: Epidemiological data evidenced an increased risk for BTOs in infertile women treated with IVF and about two thirds of serous borderline ovarian tumors are characterized by KRAS mutations that determines a significant increase of cyclin D1 expression.
Study design, size, duration: Ovaries and FT of naturally-ovulating mice and of mice undergoing 2–4 rounds of gonadotropin stimulations were analyzed to detect localization and expression levels of Oct-3/4, Sox-2, p53, β-catenin, pAKT and cyclin D1. Ovulated oocytes were analyzed to detect meiotic spindles and chromosome alignment.
Participants/materials, setting, methods: Two to four rounds of stimulations were performed with intervals of 1 week between each. Repetitive cycles of ovarian stimulation were performer according to the protocol of Van Blerkom and Davis. For each experiment, control (Ctr; $N = 4$) and hyperstimulated ($N = 12$; 4/round) mice were sacrificed. The experiment was replicated four times.
Main results and the role of chance: After round 4, ovaries and FT of control and treatment groups showed no differences in Oct-3/4, Sox-2, p53, b-catenin intracellular localization nor in Oct-3/4, Sox-2, p53, b-catenin and pAKT contents. By contrast, cyclin D1 level increased significantly in FT of treated mice. Number and quality of oocytes decreased meanwhile frequency of abnormal meiotic spindles increased with treatments.
Limitations, reason for caution: The significant increase of cyclin D1 detected in the FT needs to be further investigated.
Wider implications of the findings: We cannot reject the possibility that in a small percentage of susceptible women also a relatively low increase of cyclin D1, as that recorded in mice, could sensitize epithelial cells towards malignant transformation. As a consequence, even if repetitive hormonal stimulation is not "per se" cause of OC, it remains ethically proper to inform women at risk, as those with a family story of solid cancers, about the potential consequences of infertility treatments.
Study funding/competing interest(s): Funding by University(ies) – Funding by national/international organization(s). This work has been funded by the Italian Ministry of Education, University and Research to S.C. and G.C. (ex 60%), and by FARI 2012, "Sapienza" University of Rome to R.C. The study has been performed in the framework of the "Research Centre for Molecular Diagnostics and Advanced Therapies." The authors wish to thank the "Abruzzo earthquake relief fund" (Toronto, Ontario) that supported in part this research with the purchase of confocal microscope Leica TCS SP5 II (Leica, Germany).
Trial registration number: Not needed.

P-572 The effects of regular QC on embryo transfer rates per MD: a 10 year experience

R. Hemmings[1], S. Phillips[1], F. Bissonnette[1], I. J. Kadoch[1]
[1]*Clinique Ovo, Ovo Fertilité, Montreal, QC, Canada*

Study question: At our clinic analysis of pregnancy rate per MD is analysed tri-annually and deviations from the average are assessed. Any MD below 10% from the average is retrained. This study assesses if there is any evidence that the continual QC process causes range between MD results to narrow over time.
Summary answer: There is a clear pattern towards a narrowing in the range of results for the original partners in the clinic but as new partners have joined it takes some time for them to align with the other partners. Fellows demonstrate stable results over their 2 year fellowship.

What is known already: Previous studies have shown differing results in terms of the impact of the physician on the pregnancy rate (van Weering, 2005, Hearns-Stokes, 2000, Desparoir, 2011) however these studies analysed the direct impact of the MD on the pregnancy rate not the ability to narrow the range of pregnancy rates between physicians or the impact of adding new partners with different previous experience to the team.
Study design, size, duration: A retrospective data analysis was conducted for 12649 embryo transfers (ET) between 2004 and 2014. The progress of the original 5 MD partners was analysed along with the changes as 8 new MD partners joined the practise between 2006 and 2010. Furthermore the results of REI fellows was analysed independently.
Participants/materials, setting, methods: The range of pregnancy rates per year for the five original MD was analysed. Additionally 8 MD joined the team; one in 2006, 2007, 2008, 2009 and three in 2010. One was an experienced ET practitioner, one had very little experience and the other five joined from their fellowship.
Main results and the role of chance: The results demonstrate a reduction in the range between the highest and lowest performing original MD for the study period (17, 17, 32, 22, 11, 14, 13, 10, 12, 7, 10) however when the 8 additional MD are added to the analysis the narrowing between practitioners demonstrates more of a plateau suggesting that there is a time element required to reduce the differences. Of special interest is the impact in 2010 of a law change in Quebec forcing the use of eSET: the new, less experienced MD had more difficulty adapting this change and their range increased from 13 (2009) to 25 (2010) returning to 12 (2011), where as the more experienced original MD showed no impact on their range of difference (14, 13, 10).
Limitations, reason for caution: These data involve 12649 cycles over a 10 year period and appear to demonstrate that regular QC can reduce the range in PR between MD however to confirm this it would be necessary to continue analysis and assess how long the additional MD take to reduce their range.
Wider implications of the findings: The ET is an important element of the IVF cycle and it is important to ensure that this element is optimised. By performing regular QC of the results by MD at ET and sharing this data with the entire medical team permits members to optimise their technique and maximise the potential for each cycle. This requires an open-minded non-judgemental mindset from all members of the medical team.
Study funding/competing interest(s): Funding by hospital/clinic(s). No funding was obtained for this study and there is no conflict of interest for any of the authors.
Trial registration number: No Trial registration number.
Keywords: embryo transfer, pregnancy, quality control

P-573 Long-term safety of IVF, ICSI and IVM: a systematic review of animal studies

I. M. van Marrewijk[1], J. G. Thompson[2], T. J. Roseboom[3], M. J. Davies[2], M. Lane[2], R. L. Robker[2], L. J. Moran[2], R. J. Norman[2], B. W. J. Mol[2]
[1]*Erasmus University Rotterdam, Department of Obstetrics and Gynaecology, Rotterdam, The Netherlands*
[2]*The Robinson Research Institute, Department of Obstetrics and Gynaecology, Adelaide, Australia*
[3]*Academic Medical Centre, Department of Obstetrics and Gynaecology, Amsterdam, The Netherlands*

Study question: What is the relationship between assisted reproductive technologies (ART) and long-term effects for the offspring as reported in animal studies?
Summary answer: Based on the small number of studies that we found, it seems that ART has effects in the long-term health of the offspring, but based on all included studies it was not possible to draw a coherent conclusion.
What is known already: Before the birth of the first *in vitro* fertilization (IVF) baby in 1978, aspects of IVF technology were developed in animal models. However, the introduction of human IVF into clinical practice was performed without proper safety assessment of this technology in animal studies. Consequently, the long-term safety of ART is of concern, and subject to debate.
Study design, size, duration: A systematic review based on a search in three different databases from inception until December 2014.
Participants/materials, setting, methods: We systematically searched PubMed, Embase and CAB Abstracts for relevant studies published until December 2014. Studies were eligible if they used an animal model (mammals only) that compared *in vitro* conception to *in vivo* conception, and reported at least one outcome measure focused on the ex-vivo offspring.
Main results and the role of chance: The search identified 2,300 articles, of which 46 primary studies met the inclusion criteria. There were 37 studies that reported on birth weight, and results were assessed as species-specific: studies with a mouse model were heterogeneous, while studies with a bovine model reported similar or higher birth weight after ART. The 3 studies that reported blood pressure had heterogeneous results. Out of 7 studies that reported on glucometabolism, 3 showed impaired glucometabolism after ART. Moreover, two out of five studies showed some difference in animal behaviour after *in vitro* conception. Only one study measured lifespan and this was significantly shorter in mice conceived by IVF and fed a high-fat diet.
Limitations, reason for caution: Our inclusion criteria excluded studies that were interested in the effects of particular steps of *in vitro* production. Instead of looking for any ex-vivo outcome in the offspring, we have used specific outcomes in our search to limit the amount of articles in our database search.
Wider implications of the findings: As long-term follow-up studies in human remain limited, animal studies provide an important avenue to assess the impact of ART on long-term health. Our review shows that a systematic approach to this opportunity has been lacking, as studies are species-specific, use different ART procedures and have not been established specifically to address this question. There is an urgent need for standardized animal studies specifically designed to assess the long-term safety of ART.
Study funding/competing interest(s): Funding by University(ies) – University of Adelaide & Erasmus University Rotterdam.
Trial registration number: NA.

P-574 Pregnant after assisted reproduction: a risk pregnancy is born! 18-years results from a population-based registry in Flanders, Belgium

W. Ombelet[1], G. Martens[2], L. Bruckers[3]
[1]*Genk Institute for Fertility Technology, Obstetrics and Gynaecology, Genk, Belgium*
[2]*Genk Institute for Fertility Technology, SPE (Study Center for Perinatal Epidemiology, Brussels, Belgium*
[3]*The Center for Statistics, University of Hasselt, Diepenbeek, Belgium*

Study question: In this population-based cohort study we examined the perinatal outcome of pregnancies after assisted reproduction (ART) including IVF/ICSI and ovarian stimulation (OS) with or without intrauterine insemination. The outcome results were compared with the results of a reference population of natural conception (NC) pregnancies.
Summary answer: The increased risk for perinatal morbidity and mortality of babies born after ART is largely attributed to a higher rate of multiple gestations but ART singletons are also at increased risk for perinatal problems when compared to NC pregnancies. Therefore all ART-pregnancies should be considered as risk pregnancies.
What is known already: Although the increased risk for perinatal morbidity and mortality of babies born after ART is largely attributed to a higher rate of multiple gestations, a significantly worse perinatal outcome for singleton pregnancies following ART compared to pregnancies after natural conception has been reported. Most studies only include IVF/ICSI pregnancies, studies describing the perinatal outcome of pregnancies after non-IVF assisted reproduction and comparative studies including IVF/ICSI, OS and NC pregnancies are scarce.
Study design, size, duration: By using the data of a population-based registry we studied the perinatal outcome of 1 079 814 births during a 18 years period (1993–2010). We examined and compared the perinatal outcome results of a large cohort of ART, OS and NC pregnancies.
Participants/materials, setting, methods: The Flanders Study Centre for Perinatal Epidemiology collects data on the perinatal outcome of all deliveries of >21 weeks and/or 500 g at birth. The following perinatal outcome parameters were studied: prematurity, low birth weight, perinatal mortality and morbidity including neonatal intracranial bleeding and need for intubation.
Main results and the role of chance: This study describes the perinatal results of a very large cohort of IVF/ICSI and OS births. Our data show that IVF/ICSI singletons had a significantly worse outcome when compared to OS and NC for almost all investigated perinatal parameters. Non-IVF OS singletons were also significantly disadvantaged for birthweight and prematurity when compared to NC singletons. The outcome of twin pregnancies was similar for the three groups unless only unlike-sex twins were studied separately. Among this subgroup, IVF/ICSI carried a higher risk for low birth weight when compared

to NC. OS unlike-sex twins were at increased risk for low birth weight and perinatal mortality when compared to NC unlike-sex twins.
Limitations, reason for caution: Although our logistic regression analysis included co-variables with a potential impact on perinatal outcome such as mode of conception, female age, fetal sex, parity and year of delivery, we couldn't correct for other prominent confounders such as smoking, obesity, insulin resistance, socio-economic status, occupation exposures, pre-existing disease, etc.
Wider implications of the findings: Our results show that all ART-pregnancies have to be considered as risk pregnancies, irrespective of the number of fetuses. ART-singletons are also at increased risk when compared to NC babies. Although IVF/ICSI singletons have the worse prognosis, OS singletons also carry a higher perinatal risk. For unlike-sex twins, results showed that both IVF/ICSI and OS pregnancies carry a higher perinatal risk when compared to NC unlike-sex twins.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Genk Institute for Fertility Technology.
Trial registration number: NA.

P-575 Placental morphology in singleton births following assisted reproductive technology

L. Gooding[1], K. Louie[1], J. Havelock[1], S. Kashyap[1], B. Taylor[1], T. Rowe[1], S. Ma[1]
[1]*University of British Columbia, Obstetrics and Gynecology, Vancouver, Canada*

Study question: Is assisted reproductive technology (ART) treatments associated with abnormal placental morphology in humans?
Summary answer: Our study suggests that term placental weight, placental weight to fetal weight ratio, and placental volume is higher in ART conceptions when compared to natural conception.
What is known already: Some studies have found a significant increase in placenta thickness, weight, and the placental to fetal weight ratio in ART pregnancies compared to natural pregnancies. However, few studies, none with a large sample size, included detailed morphological investigations of the placenta.
Study design, size, duration: Retrospective control versus treatment study using data collected from 2003 to 2015 on 725 singleton pregnancies: 176 *in vitro* fertilization (IVF), 272 intra-cytoplasmic sperm injection (ICSI), and 277 natural conceptions (NC). Growth restricted, gestational diabetes, abnormal karyotype, pre-eclampsia and placenta previa complicated pregnancies were not included.
Participants/materials, setting, methods: We measured placental trimmed weight, diameter, and depth from IVF, ICSI, and NC pregnancies recruited from greater Vancouver. Pregnancy and neonatal details were recorded by hospital staff. We assessed the association between the type of conception and placental morphological variables such as weight, volume, density and placental/fetal weight ratio.
Main results and the role of chance: Placental weights (IVF-NC $P = 0.004$; ICSI-NC $P = 0.4$), the placental to fetal weight ratio (IVF-NC $P = 3.67E-8$; ICSI-NC $P = 0.0001$), and placental volume (IVF-NC $P = 0.06$; ICSI-NC $P = 0.017$) were larger for IVF and ICSI births compared to NC births. However, maximum placental depth and placental density were not significantly different between the three groups.
Limitations, reason for caution: The numbers in the IVF, ICSI and NC groups are not the same. Furthermore, incomplete data on smoking status, BMI, maternal age, gestational age, and ethnicity of patients as well as lack of data on quality of embryo transferred increase the possibility of a bias in our groups.
Wider implications of the findings: Our results support previous findings that placental weight and placental to fetal weight ratios are larger on average in ART births when compared to NC births, which may be indicative of intrauterine stress and predispose ART concepti to long term-health complications. The increase in mean placental volume but not mean density in the ART group compared to NC group has not been observed before and potentially suggests similar placental structural characteristics between the two groups.
Study funding/competing interest(s): Funding by national/international organization(s) – Canadian Institutes of Health Research (CIHR), grant to SM.
Trial registration number: NA.

P-576 GnRH antagonist administered twice the day before hCG trigger, may prevent OHSS in IVF/ICSI antagonist cycles at risk for OHSS without affecting the reproductive outcomes

K. Ravanos[1], Y. Prapas[2], Y. Panagiotidis[1], A. Papatheodorou[1], A. Iuliano[3], G. Gullo[4], S. Petousis[5], N. Prapas[5]

[2]*IAKENTRO Fertility Cente 3rd Department of Obstetrics and Gynaecology Aristotle University, IVF, Thessaloniki, Greece*
[3]*Azienda Ospedaliera "San Carlo", IVF, Potenza, Italy*
[4]*Dipartimento di Ostetricia e Ginecologia Policlinico P.Giaccone-Universita degli studi, IVF, Palermo, Italy*
[5]*IAKENTRO Fertility Centre 3rd Department of Obstetrics and Gynaecology Aristotle University, IVF, Thessaloniki, Greece*

Study question: In GnRH antagonist IVF/ICSI cycles at risk for ovarian hyperstimulation syndrome (OHSS), does a double antagonist dose (0,25 mg/12 h) administered the day before hCG trigger in conjunction to tapering the daily administered follicular-stimulating hormone (rFSH), is effective to prevent OHSS without affecting the reproductive outcomes?
Summary answer: GnRH antagonist dose administered twice (0,25 mg/12 h) for a single day that is the day before hCG trigger in conjunction to tapering the rFSH dose in GnRH antagonist IVF/ICSI cycles at risk for OHSS, may effectively prevent early OHSS without affecting the reproductive outcomes.
What is known already: GnRH antagonist protocol lower but do not eliminate the risk of OHSS in hyper-responding patients in IVF/ICSI cycles. GnRH agonist triggering instead of hCG for final oocyte maturation and freeze all strategy for embryos seems to be for the moment the only safe approaches to eliminate the risk of OHSS. Nevertheless, conflicting data exist regarding whether luteal support is adequate to facilitate a fresh transfer without affecting the reproductive outcomes.
Study design, size, duration: Double blinded RCT from 11/2009 to 2/2013 in a single centre. 194 patients at risk for OHSS undergoing IVF/ICSI antagonist cycle chose to proceed with embryo transfer and avoid cancellation or embryo cryopreservation were allocated into two groups by a sequence generated from a computerized random number table.
Participants/materials, setting, methods: Inclusion criteria: E2 ≥ 3500 pg/ml combined with ≥18 follicles >11 mm in diameter. Intervention group (97 patients) received a double dose of GnRH antagonist (0,25 mg/12 h) the day before hCG while another 97 patients (control group) did not. In both groups rFSH was tapered to 100 IU/24 h the day of the allocation.
Main results and the role of chance: Primary outcomes: incidence of early-onset moderate/severe OHSS was statistically lower in the intervention group compared to control group, (0% vs 12,37%, $P < 0.001$). Neither group developed late-onset moderate/severe OHSS after embryo transfer. Clinical pregnancy rate per cycle (50.52% vs 42.27%, $P = 0.249$), as well as per transfer (50.52% vs 48.24%, $P = 0.759$), were not significantly different between the two groups. Early pregnancy loss between group A and B was not statistically different (16.33% vs 17.07%, $P = 0.925$).
Limitations, reason for caution: Power calculation was based on preliminary data from an earlier pilot study on donation cycles which can introduce bias. Further RCT studies are needed to confirm our results.
Wider implications of the findings: Administration of a double GnRH antagonist dose (0,25 mg/12 h) the day before hCG trigger in conjunction to tapering the rFSH dose in patients at risk for OHSS undergoing an IVF-ICSI antagonist cycle, may represent a safe and effective alternative preventive strategy for early OHSS without compromising the reproductive outcomes.
Study funding/competing interest(s): Funding by hospital/clinic(s) – IAKENTRO Fertility Centre.
Trial registration number: ISRCTN02750360.
Keywords: GnRH antagonists, OHSS, IVF-ICSI

P-577 The incidence of monozygotic twinning in ICSI patients following single cleavage stage or single blastocyst stage transfers

I. De Croo[1], K. Tilleman[1], S. De Gheselle[1], A. Van de Velde[1], B. Heindryckx[1], F. Van de Kerckhove[1], J. Gerris[1], E. Van den Abbeel[1], P. De Sutter[1]
[1]*Ghent University Hospital, Centre for Reproductive Medicine, Ghent, Belgium*

Study question: To determine the incidence of monozygotic twinning (MZT) after single blastocyst stage transfer (SBT) compared with single cleavage stage embryo transfer (SET) in fresh and frozen ICSI cycles.
Summary answer: The incidence of MZT after single blastocyst stage transfer (SBT) is comparable with single cleavage stage embryo transfer (SET) in fresh and cryopreserved ICSI cycles.
What is known already: The primary risk factor for a dizygotic multiple birth outcome is the transfer of more than one embryo. The risk factors for monozygotic twinning are less clear. The division of the embryo at an early stage of development is estimated to occur in 0.6% of all births. Several factors have been suggested to be implicated in the splitting of the embryo with ART, including the use of ICSI, cryopreservation and extended embryo culture.
Study design, size, duration: Retrospective study between July 1st 2010 and October 1st 2014 of 2707 fresh transfers irrespective of patient characteristics (908 SBT and 1799 SET) and 1791 cryopreserved transfers (1581 SBT (vitrification) and 210 SET (freezing)). The incidence of MZT in ICSI patients following fresh or cryopreserved SET or SBT was analyzed.
Participants/materials, setting, methods: Pregnancy was defined as a viable intrauterine pregnancy (fetal heart observed) on transvaginal ultrasound between gestational weeks 6 and 7. Monozygotic twinning was identified when the number of fetal heart beats was more than one. Outcome parameters were compared using c^2 with a 5% significance level.
Main results and the role of chance: A total of 831 fresh transfer cycles (492 SBT and 339 SET) resulting in a pregnancy were identified during the study period. Ongoing pregnancy rate per transfer was significantly lower for SET cycles as compared to SBT cycles ((18.5% (333/1799) versus 23.0% (209/908)) ($p = 0.006$). MZT rate was similar after fresh SBT (0.6% (2/339)) as compared to fresh SET (1.8% (9/492)). A total of 556 frozen transfer cycles (503 SBT and 53 SET) resulting in a pregnancy were identified during the study period. Ongoing pregnancy rate per transfer was significantly lower for frozen SET cycles as compared to vitrified SBT cycles ((13.8% (29/210) versus 19.6% (310/1581)) ($p = 0.0486$). MZT rate was similar after vitrified SBT (0.6% (8/503)) as compared to frozen SET (0% (0/53)).
Limitations, reason for caution: This study is limited by its retrospective design. No correction for confounding factors such as maternal age and embryo quality has been made.
Wider implications of the findings: Our results do not support the published data in which blastocyst transfers are correlated with an increase in the incidence of twinning. Blastocysts transfers continue to offer the advantages of enhanced pregnancy rates without compromising birth outcomes in terms of monozygotic twinning.
Study funding/competing interest(s): Funding by University(ies) – Ghent University Hospital.
Trial registration number: NA.
Keywords: monozygotic, twinning, blastocyst transfer

P-578 Should a single frozen embryo transfer policy be universally applied? A retrospective analysis on 605 frozen blastocyst transfer cycles

A. Vlismas[1], G. Christopoulos[1], G. Ghourab[1], M. Ramos-Luque[1], G. Trew[1], S. Lavery[1]
[1]*IVF Hammersmith, Imperial Colege, London, United Kingdom*

Study question: The aim of this study was to compare the implantation, miscarriage, clinical pregnancy, live birth and multiple pregnancy rates on single frozen embryo transfer (SFET) and double frozen embryo transfer (DFET) cycles after thawing and transferring day 5 embryos.
Summary answer: Although the positive pregnancy rates are statistically significant in favour of the DFET group, the live birth rates are comparable. The patients in the group of DFET are also exposed to significantly higher miscarriage and multiple pregnancy rates. The group of SFET has higher implantation rates.
What is known already: Well-established concerns have been expressed regarding the complications of multiple pregnancy in ART. Consequently a single embryo transfer policy has been applied in UK for patients less than 37 years old. The data on frozen embryo replacement cycles are limited and only few studies have compared SFET with DFET. As a result there is no clear consensus on the number of embryos that should be transferred on frozen cycles.
Study design, size, duration: A retrospective analysis of al frozen embryo replacement cycles between January 2011 and April 2014 was performed. Only cycles with frozen vitrified embryos on day 5 were included. Double and single embryo transfer cycles were compared for patient characteristics and treatment outcomes.
Participants/materials, setting, methods: 511 patients underwent 605 frozen embryo transfer cycles after thawing and transferring vitrified blastocyst(s) at day 5. All blastocysts were 2BB or better at the time of vitrification. All patients with vitrified blastocyst have been included regardless of age, number of previous cycles or type of infertility.
Main results and the role of chance: No difference was observed in age (35.5 ± 4.1 vs 35.8 ± 4.3, $p = 0.437$), number of cycles (2.42 ± 0.9 vs 2.57 ± 1.2, p-value 0.11) or cause of infertility. Pregnancy rates were significantly higher in the DFET group (49.3% vs 60.9% OR: 1.6, 95% CI 1.14–2.24, p-value = 0.006). However, no statistically significant difference was observed in clinical pregnancy (34.6% vs 40.9%, OR: 1.3, 95% CI 0.92–1.85, $p = 0.13$) and live birth rates (30.8% vs 34%, OR: 1.16, 95% CI 0.81–1.66, $p = 0.42$). The implantation rate was significantly higher in the SFET group (35.5% vs 27.1%, OR: 0.67, 95% CI 0.49–0.93, $p = 0.017$). The miscarriage (17.5% vs 26.9%, OR: 1.73, 95% CI 1.14–2.63, $p = 0.01$) and multiple pregnancy rate (1.5% vs 28.4%, OR: 24.68, 95% CI 3.3–184.3, $p < 0.001$) were significantly higher in the DFET group.
Limitations, reason for caution: This is retrospective analysis of embryos frozen at the blastocyst stage. Embryos frozen at cleavage stage have not been included. The selection of the embryos transferred was based on the number of available frozen embryos, preference of the couple, survival of embryos after thawing and number of previous cycles.
Wider implications of the findings: Our study has not identified a difference in live birth rates between SFET and DFET. However, patients with DFET had higher miscarriage and multiple pregnancy rates and lower implantation rates. The single embryo transfer policy has been applied in the UK for fresh IVF cycles. Our results suggest that this policy may justifiably be applied to frozen embryo transfer cycles.
Study funding/competing interest(s): Funding by hospital/clinic(s) – IVF Hammersmith.
Trial registration number: NA.
Keywords: frozen embryo transfer cycle, single embryo transfer, blastocyst, vitrification

P-579 Identifying predictive factors for twin pregnancy after double frozen-thawed blastocysts transfer: analysis of 4000 frozen IVF cycles

S. Suriyakumar[1], T. El-Toukhy[1], B. Springate[1]
[1]*Guy's and St Thomas' NHS Trust, Assisted Conception Unit, London, United Kingdom*

Study question: What are the predictive factors for twin pregnancy after receiving double frozen-thawed blastocysts transfer (DBT)?
Summary answer: The number of previous fresh cycles undergone and number of embryos frozen in the fresh cycle were independent factors affecting the risk of multiple pregnancy after DBT.
What is known already: Maternal age, the transferred embryos' developmental stage and the number of embryos transferred have been identified as key predictors of twin pregnancy in women receiving fresh embryo IVF. However, no such predictive factors have been identified in frozen IVF cycles.
Study design, size, duration: Prospectively, data on all fresh and frozen IVF cycles carried out between January 2006 and June 2014 was included. Data involving 2550 frozen-thawed blastocyst transfers were analysed, of which 1060 cycles involved the transfer of two frozen-thawed blastocysts.
Participants/materials, setting, methods: Data of women who had undergone at least one frozen embryo transfer cycle, since 2006, at a London-based centre were examined. DBT cycles with singleton or twin pregnancy were analysed using a multivariate logistic regression model, to elucidate any predictive factors of twin pregnancies.
Main results and the role of chance: An overall clinical pregnancy rate of 43% and twin pregnancy rate of 26% was observed in the 1060 DBT cycles. The number of previous fresh cycles undergone ($p = 0.03$) and number of embryos frozen during the fresh cycle ($p = 0.03$) were independent factors affecting the risk of multiple pregnancy. For every increase in the order of fresh cycle by 1, there is a reduction in the risk of multiple pregnancy by 36% (adjusted risk ratio = 0.64, 95% CI 0.42–0.97). For every increase in the number of blastocysts frozen at the time of the fresh cycle by 1, the risk of multiple pregnancy increases by 11% (adjusted risk ratio = 1.11, 95% CI 1.01–1.22). Patient age and post-thaw blastocyst re-expansion were not predictive factors of multiple pregnancy.

Limitations, reason for caution: This is a single centre study examining the risk of multiple pregnancy after frozen-thawed double blastocyst transfer. A slow-freezing technique was used for blastocyst cryopreservation.
Wider implications of the findings: This study has identified independent predictors of multiple pregnancies, following DBT in frozen IVF cycles. Future practices could potentially use these predictive factors as tools to recognise women with increased risk of multiple pregnancy, where single embryo transfer may be more suited.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Not applicable.
Trial registration number: NA.

P-580 Does ovarian stimulation affect embryo implantation and perinatal outcomes more in fresh IVF transfer than in frozen embryo transfer cycles?

Y. Khalaf[1], P. Seed[2], S. Sunkara[3]
[1]*Guy's hospital, The Assisted Conception Unit, Centre for Pre-Implantation Genetic Diagnosis, London, United Kingdom*
[2]*King's College London, Division of Women's Health, London, United Kingdom*
[3]*Aberdeen University, Assisted Reproduction Unit Aberdeen Maternity Hospital, London, United Kingdom*

Study question: Does ovarian stimulation in *in vitro* fertilisation (IVF) treatment affect embryo implantation and perinatal outcomes such as preterm birth (PTB) and low birth weight (LBW) following fresh embryo transfer cycles.
Summary answer: There was no significant difference in the implantation rate (IR) and adverse perinatal outcomes of PTB, early PTB, LBW, very LBW with fresh transfer versus frozen embryo transfer cycles following stimulated IVF treatment.
What is known already: Ovarian stimulation is associated with supra physiological steroid levels which subject the endometrium to an altered endocrinological environment. Whether ovarian stimulation is detrimental to embryo implantation and subsequent perinatal outcomes through the effects on the endometrium is debatable with suggestions for avoiding embryo transfer in a fresh IVF cycle in favour of cycle segmentation with freezing of embryos and subsequent replacement either in a natural cycle or following artificial endometrial preparation in order to improve IVF outcomes.
Study design, size, duration: Anonymous data were obtained from the Human Fertilization and Embryology Authority (HFEA), the statutory regulator of assisted reproduction treatment (ART) in the UK. The HFEA has collected data prospectively on all ART performed in the UK since 1991. Data from 1991 to 2012 involving 78,761 singleton live births following stimulated IVF cycles with fresh embryo transfer and 349 singleton live births following frozen embryo transfer which did not have a fresh transfer in the stimulation cycle were analysed.
Participants/materials, setting, methods: Data on all women undergoing either a stimulated fresh IVF transfer cycle or a stimulated cycle with subsequent frozen embryo replacement during the period from 1991 to 2012 were analysed to compare implantation rates (IRs) and adverse perinatal outcomes of PTB, early PTB, LBW and very LBW. IR is defined as the proportion of transferred embryos that resulted in clinical pregnancies. Occurrence of a live birth at <37 weeks gestation is defined as a PTB and <32 weeks gestation as early PTB. Birth weight <2500 g is defined as LBW and <1500 g as very LBW. Perinatal outcomes were analysed for singleton live births only, defined as a singleton live birth event in which the baby is born alive. Logistic regression analysis was performed adjusting for female age, year of treatment, previous IVF cycles, previous live birth, number of oocytes and day of embryo transfer (cleavage or blastocyst stage).
Main results and the role of chance: There was no significant difference in the IR between fresh versus frozen embryo transfer cycles: adjusted odds ratio (a OR) 1.18; 95% confidence interval (CI) 0.97–1.46. There was no significant difference in the risk of PTB: a OR 0.75; 95% CI 0.44, 1.26, early PTB: a OR 0.56; 95% CI 0.27, 1.19, LBW: a OR 0.81; 95% CI 0.47, 1.38 and very LBW: a OR 0.49; 95% CI 0.19–1.23 following fresh versus frozen transfer cycles.
Limitations, reason for caution: In addition to the limitation of being an observational study, other limitations included the relatively smaller number of singleton live births in the frozen embryo transfer cycles and the inability to determine the cryopreservation method (slow freezing versus vitrification).
Wider implications of the findings: Analysis of this extensive dataset showed no detriment to embryo implantation and no increase in adverse perinatal outcomes following fresh versus frozen transfer in stimulated IVF cycles. These findings question the rationale for deferring fresh transfer and advocating frozen embryo transfer for all stimulated IVF cycles which needs addressing in well-designed randomised controlled trials. Furthermore, it would be also be of interest to query whether ovarian stimulation itself through its effects on the oocyte is associated with adverse perinatal outcomes by comparing stimulated versus natural IVF cycles.
Study funding/competing interest(s): Funding by hospital/clinic(s) – No funding was sought/granted.
Trial registration number: NA.

P-581 The effects of two different embryo culture media on the birthweight of singletons: findings after fresh and frozen-thawed embryo transfer

F. Gu[1], J. Gao[1], Y. W. Xu[1], C. Q. Zhou[1]
[1]*The First Affiliated Hospital Sun-Yat sen University, Reproductive Center, Guangzhou, China*

Study question: Does the type of media for embryo culture result in different birthweight of singleton newborns?
Summary answer: No difference was found between the newborn birthweight of the embryos cultured in SAGE and Vitrolife media after fresh or frozen-thawed cleavage embryo transfer.
What is known already: Many studies have shown that embryo culture media used in IVF treatment may affect fetal growth and thus the birthweight of newborns. However, it is still a controversial topic. To further explore this issue, we compared the birthweight of singleton neonates born after the transfer of fresh and frozen-thawed cleavage embryos respectively cultured in the two most widely used culture media: SAGE and Vitrolife.
Study design, size, duration: A retrospective analysis was performed for 2370 singleton neonates born after IVF/ICSI cycles between August 2009 and December 2012. A comparison on the difference of birthweight was made between two different culture media, SAGE and Vitrolife.
Participants/materials, setting, methods: Patients who received blastocyst transfer, preimplantation genetic diagnosis (PGD) and donor oocytes were excluded. Only data from singletons born alive after the 28th week of gestation were included in the data analysis.
Main results and the role of chance: The newborns were divided into two groups, including 1755 cases from fresh cleavage embryo transfer and 615 from frozen-thawed cleavage embryo transfer. No differences were observed in both the absolute birthweight and the birthweight adjusted for gestational age and gender (*z*-score) of the newborns between the two culture media in each group. The sex ratio, rate of small for gestational age (SGA) and large for gestational age (LGA), as well as the rate of low birth weight (LBW) and macrosomia were all comparable between the two media in both fresh and frozen-thawed groups. Multiple linear regression analysis demonstrated that maternal weight, gestational age, frozen-thawed embryo transfer and infant gender were significantly related to neonatal birthweight.
Limitations, reason for caution: The current study is a retrospective study which is not well controlled. Moreover, in addition to gestational age and birthweight of the neonates, more research needs to be performed to evaluate the long-term effects of embryo culture medium on the health of children conceived through ART.
Wider implications of the findings: Our retrospective study demonstrated that embryo culture medium had no influence on neonatal birthweight. Further study will be required to understand its potential epigenetic changes, as well as its variation in fresh and frozen-thawed embryos.
Study funding/competing interest(s): Funding by hospital/clinic(s). The study was funded by the Ministry of Health public welfare scientific research special fund (201402004). The authors have no conflicts of interest to declare.
Trial registration number: NA.
Keywords: neonatal birthweight, culture media, IVF/ICSI

P-582 Patients' attitudes and expectations towards frozen embryo transfer (FET) and a "freeze all"-strategy in assisted reproductive technology (ART)

S. Stormlund[1], L. Schmidt[2], J. Bogstad[1], K. Løssl[1], L. Prætorius[1], A. Pinborg[1]
[1]*Hvidovre Hospital, Department of Obstetrics and Gynecology, Copenhagen, Denmark*
[2]*University of Copenhagen, Section of Social Medicine, Copenhagen, Denmark*

Study question: What are the attitudes towards different aspects of frozen embryo transfer (FET) and a "freeze all"-strategy in assisted reproductive technology (ART) amongst Danish fertility patients before their first cycle of *in vitro* fertilization (IVF) therapy?
Summary answer: Though the patients were concerned about the treatment delay associated with elective FET (eFET) compared with fresh embryo transfer, nearly half of the participants were in favour of eFET assuming that the clinical pregnancy rate was equivalent. The majority also indicated health of mother and child as of primary importance.
What is known already: Vitrification and blastocyst transfer has considerably improved success rates after FET and a meta-analysis has shown similar results after fresh transfer and eFET. Furthermore, the risk of ovarian hyperstimulation syndrome is eliminated in FET cycles, and FET may be beneficial to the foetus. However, the "freeze-all"-strategy is not yet implemented as standard care. One reason is the presumption of negative patient attitudes towards "freeze-all." No published data regarding patients' attitudes on a "freeze-all"-strategy exists.
Study design, size, duration: The study was designed as a cross-sectional survey including 60 fertility patients referred for their first IVF treatment during the period December 2014 to May 2015.
Participants/materials, setting, methods: All newly referred patients participating in the introductory meeting before initiating IVF-treatment at the Fertility clinic, Hvidovre Hospital, Copenhagen, Denmark were requested to fill in an online web-based questionnaire separately for men and women covering attitudes towards FET and a "freeze all" strategy, socio-demographic data, and reproductive history.
Main results and the role of chance: The overall response rate was 62% (n = 60). 69% of the females and 52% of the males responded. Of the respondents, 59% of the women and 30% of the men would choose eFET over fresh embryo transfer assuming that the probability of clinical pregnancy was the same. However, 42% of the women and 23% of the men completely agreed that they would find it difficult to postpone the embryo transfer to the subsequent natural cycle. The primary concern for both male and female participants was minimizing the risks to mother and child, as both men and women strongly agreed that whatever treatment posed the least threat to the health of the mother and the child was preferable.
Limitations, reason for caution: Selection bias cannot be excluded, as the non-response rate was 38%. The hypothetical nature of the items may limit the validity of the results. The participants were from the Capital Region of Denmark and may therefore not be representative for fertility patients in the entire country.
Wider implications of the findings: In a clinical setting with similar pregnancy rates for FET and fresh embryo transfer, these results indicate that patients, when given access to objective information on advantages and disadvantages of both fresh embryo transfer and FET, may be less prone to opt for fresh embryo transfer. This may be ground breaking for a patient-centred paradigm shift in routine IVF with a wider implementation of FET and a "freeze all"-strategy.
Study funding/competing interest(s): Funding by hospital/clinic(s). The study was supported by Hvidovre Hospital. No competing interest exists.
Trial registration number: NA.
Keywords: ART, FET, freeze-all, attitudes

P-583 Increased preeclampsia in pregnancies from double donation of gametes compared to oocyte donation only

A. Blázquez[1], A. Rodríguez[1], O. Coll[1], F. Figueras[2], R. Vassena[1], V. Vernaeve[1]
[1]*Clínica EUGIN, Barcelona, Spain*
[2]*BCNatal. Hospital Clínic. Hospital Sant Joan de Déu. Universitat de Barcelona, Unidad de preeclampsia y retraso de crecimiento, Barcelona, Spain*

Study question: Is there an increased risk of preeclampsia (PE) and/or gestational hypertension (GH) in pregnancies with double donation (both semen and oocytes, DD), compared to those achieved with donation of oocyte only (OD)?
Summary answer: There was a significant increase in incidence of PE when both gametes were donated, in comparison to pregnancies where only the oocyte was donated. The patient cohorts were matched by age, parity and number of fetus in the current pregnancy.
What is known already: PE, characterized by reduced placental perfusion secondary to defective trophoblastic invasion, complicates 2–7% of pregnancies. The trophoblastic invasion is related to uterine natural killer (uNK) activity, in turn regulated by the plug of trophoblastic (fetal) HLA-C and uNK ligands. The HLA alleles expressed by the conceptus are allogenic in DD pregnancies (the mother has never been in contact with sperm or oocyte) or partially allogenic in OD, perhaps leading to higher risk of placenta maldevelopment.
Study design, size, duration: This is a retrospective analysis of 57 pregnancies reaching at least week 23 of gestation, and achieved by either DD (n = 19) or OD (n = 38). Pregnancy outcomes, PE, and GH were recorded by a survey sent to patients between September 2014 and January 2015.
Participants/materials, setting, methods: DD and OD pregnancies were matched (1:2) by age, number of fetus in the current pregnancy, and previous pregnancies in the patients. The incidence of PE and GH was compared in both cohorts. Univariate analysis was employed; differences were compared by Fisher's exact test.
Main results and the role of chance: DD and OD cohorts were similar in demographic variables and cycle characteristics. Mean patient age was 44.6 ± 3.4 and, BMI was 23.2 ± 4.4. Thirty-one percent of patients had previous pregnancies. The average day of embryo transfer was 2.6 ± 0.8 and the number of embryos transferred 2.0 ± 0.3. The majority of embryos transfers (84.2%) were fresh (81.6% of the DD and 89.5% of the OD). The incidence of PE was significantly higher in DD than in OD (21% vs 2.6%, p = 0.038), while no difference was found in GH rate (21.0% vs 13.1%, p = 0.48). Significantly more pregnancies progressed from GH to PE in DD than OD only (100% vs 20%, p = 0.048).
Limitations, reason for caution: The main limitation of this study is the small number of cases reported. Although careful pairing for GH/PE risk factors was performed, some confounding effect may still persist.
Wider implications of the findings: Pregnancies achieved by DD might be at a higher risk of PE than OD pregnancies only. This implicates an additive effect of semen without previous immunological contact with the woman in setting the risk for PE. Physicians should be aware of this possible risk in order to both counsel patients and monitor pregnancies accordingly.
Study funding/competing interest(s): Funding by hospital/clinic(s).
Trial registration number: NA.

P-584 Blastocyst grade does not affect birthweight in ART patients

H. Ohno[1], N. Fukunaga[1], H. Kitasaka[1], T. Yoshimura[2], F. Tamura[1], N. Aoyagi[2], M. Shimomura[2], M. Tokoro[3], Y. Hattori[2], M. Kondo[1], Y. Wakahara[1], K. Kinoshita[2], Y. Yakushi[2], Y. Hashiba[2], Y. Asada[1]
[1]*Asada Ladies Clinic Medical Corporation, Asada Ladies Nagoya Clinic, Nagoya, Japan*
[2]*Asada Ladies Clinic Medical Corporation, Asada Ladies Kachigawa Clinic, Kasugai, Japan*
[3]*Asada Ladies Clinic Medical Corporation, Asada Institute for Reproductive Medicine, Kasugai, Japan*

Study question: Is blastocyst morphology grade associated with birthweight of children born after ART?
Summary answer: There was no difference in the average birthweight and the rate of low birthweight across Inner Cell Mass (ICM) and Trophectoderm (TE) classification grades. However, for TE of grade C, the birthweight compared to TE grade A and B was lower and the rate of low birthweight tended to increase.
What is known already: Previously we have reported that in frozen-thawed embryo transfer cycles, the grade of TE is statistically significantly related to the rate of ongoing pregnancy and miscarriage after adjusting for confounders (Honnma et al., 2012). However, there is still scant information and no consensus on whether blastocyst grade affects fetal growth.
Study design, size, duration: A retrospective analysis of children born after frozen-thawed single blastocyst transfers (n = 800) conceived after treatment in one clinic between January 2010 and January 2013.
Participants/materials, setting, methods: The blastocysts were graded according to the Gardner grading system. ICM and TE grades were compared

with the average birthweight of children as well as the rates of low birthweight (<2500 g) for blastocysts of grades A, B, and C.
Main results and the role of chance: The average birthweight and the rates of low birthweight (%) for ICMs of grades A, B, and C were 3060.0 ± 494.5 g, 3064.7 ± 508.3 g, 2915.0 ± 31.0 g and 8.9%, 12.1%, 0% respectively. The average birthweight and the rates of low birthweight (%) for TE of grades A, B, and C were 3060.8 ± 506.9 g, 3065.2 ± 485.9 g, 2942.9 ± 549.7 g and 9.3%, 10.1%, 14.3% respectively. Overall, there was no significant difference in the average birthweight and the rates of low birthweight across the range of ICM and TE grades. However, for TE grade C, the birthweight was decreased compared to TE grades A and B and the rates of low birthweight tended to increase.
Limitations, reason for caution: Retrospective analysis with a limited sample size.
Wider implications of the findings: These results suggest that, even low grade blastocysts, can result in healthy births of similar birth weights to high grade blastocysts.
Study funding/competing interest(s): Funding by hospital/clinic(s) – none.
Trial registration number: NA.
Keywords: blastocyst, birthweight, ICM, TE

P-585 Neonatal outcomes after IMSI and ICSI at the CPMA of the University of Liège

O. Gaspard[1], D. Danthine[2], S. Ravet[1], F. Wenders[1], C. Jouan[1], F. Thonon[1], S. Labied[1], V. Gridelet[1], M. Dubois[1], S. Perrier d'Hauterive[1], M. Nisolle[2]
[1]*Hôpital de la Citadelle, Dept. of Ob/Gyn Centre de Procréation Médicalement Assistée, Liège, Belgium*
[2]*Hôpital de la Citadelle, Department of Ob/Gyn, Liège, Belgium*

Study question: Data of IMSI (Intracytoplasmic Morphologically Selected sperm Injection) and ICSI (IntraCytoplasmic Sperm Injection) cycles were retrospectively collected in order to compare neonatal outcome, especially the rate of malformation.
Summary answer: A non-statistically significant lower malformation rate has been observed in the IMSI group in comparison to ICSI group, whereas other outcomes were similar (mean weight, height and duration of pregnancy).
What is known already: Since 2001, living spermatozoa can be observed at a high magnification (up to 10,000 times), allowing us to identify a particular sperm head defect called vacuole. They vary in size, position and depth, and large vacuoles (more than 4% of sperm head surface) have been intensely studied by several teams. While these large vacuoles seem to be associated to DNA defects, their effects on male fertility are still discussed.
Study design, size, duration: Data of the CPMA (Centre de Procréation Médicalement Assistée) of the University of Liège were retrospectively collected. Main analyzed data were pregnancy rate, duration of pregnancy, babies height and weight, presence of malformation or not. IMSI and ICSI cycles performed with fresh semen between 2009 and 2013 were included.
Participants/materials, setting, methods: IMSI group includes 266 cycles performed in 162 patients, and ICSI group 2003 cycles in 1211 patients. Data were collected from the CPMA database. In case of data lacking, patients were contacted by post and eventually gynecologist responsible for pregnancy follow up was called by phone.
Main results and the role of chance: Mean ages were similar in IMSI and ICSI groups (34.9 vs 34.5; NS: Not Significant), whereas attempt rank was higher in IMSI cycles (3.31 vs 1.96; $P < 0.0001$). Mean number of transferred embryos was higher in IMSI than in ICSI cycles (1.82 vs 1.54 embryos per transfer; $P < 0.0001$). Pregnancy rates (positive bhCG/embryo transfer) were similar (respectively 30.8% vs 28.9%; NS) as well as neonatal data, excepted major malformation rate which was slightly lower in IMSI babies (1.75% vs 3.38%; NS). In IMSI only one malformation was described (vesico-ureteral reflux). In ICSI we reported 12 malformations (2 cardiac abnormalities, one anencephaly, one anal stenosis …), three of which required medical termination of pregnancy, and one ended in spontaneous in utero death (baby with multiple malformations including club-foot).
Limitations, reason for caution: It is clear that groups are two small to draw conclusions and that prospective randomized studies are needed to confirm these data which are consistent with previously published results (Cassuto et al., 2014). A wider multicentric retrospective study is already ongoing.
Wider implications of the findings: These data encourage us to screen IVF patients for the presence of vacuoles and to propose IMSI to couples presenting high rates of vacuolated spermatozoa. Our aim is to lower the malformation rate observed in ICSI cycles. However, more studies are needed to verify this hypothesis.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Centre de Procréation Médicalement Assistée, University of Liège.
Trial registration number: IMSI babies: retrospective data.
Keywords: IMSI, malformation

P-586 Transuterine oocytes retrieval for IVF: a case-control study

E. Esh-Broder[1], T. Sokal-Arnon[1], J. Ruiter[1], S. Reinblatt[1], T. Tulandi[1]
[1]*McGill University, Obstetrics and Gynecology, Montreal, Canada*

Study question: What is the incidence, risk factors, complications and cycle outcomes of vaginal oocytes retrieval requiring a transuterine approach.
Summary answer: A transuterine approach was required in 2.3% of oocyte retrievals (OCR) in our study. Higher body mass index (BMI) was the most significant risk factor for transuterine puncture. In our cohort, transuterine puncture during OCR did not increase complication rates nor affect cycle outcomes.
What is known already: The reported incidence of transuterine puncture during OCR is 1.7%–4.2%. However, there is a paucity of evidence regarding the relative safety and efficacy of this practice. Potential adverse effects of transuterine puncture during transvaginal oocytes retrieval for IVF are; needle blockage, infection, hematomas, and uterine contractions. Two previous studies have reported no effect on pregnancy rates and a non-significant trend towards higher miscarriage rates among OCRs involving transuterine puncture.
Study design, size, duration: We performed a retrospective, case-control study using an electronic database of all oocytes retrievals performed between December 2008 and October 2014. Cases were identified by documentation of transuterine puncture during OCR. The controls were matched by age and IVF treatment protocol.
Participants/materials, setting, methods: Medical records were analyzed for covariates including demographic characteristics, cause of infertility, treatment cycle and OCR details. Charts were reviewed for complications occurring up to 2 months post OCR. Hyperstimulation-related complications were excluded. Cycle outcomes included number of oocytes retrieved, pregnancy rate, implantation rate and clinical pregnancy rate.
Main results and the role of chance: Of 8023 oocyte retrievals performed, 186 cases involved transuterine puncture (2.3%). Compared to 186 matched controls, we found no significant difference in maternal age, baseline antral follicle count, previous OCR number, nor rates of endometriosis nor tubal factor. BMI was higher in the study group (26.9 ± 6.6 vs 24.7 ± 5.9, $p = 0.01$). The overall complication rate was 4.3% in both groups. Complications included urinary retention in the study group and infection in control group. Mild vaginal bleeding and abdominal pain were reported in both groups. No statistically significant differences were found in pregnancy rate (25.8% vs 28.5%), implantation rate (20.2% vs 27.6%) and clinical pregnancy rate (19.9% vs 22%) for study and control group, respectively. Prophylactic antibiotics during OCR did not reduce complications nor improve pregnancy outcomes.
Limitations, reason for caution: Reporting issues could result in underestimation of incidence and complications related to transuterine puncture. However, in our institution, proper documentation is routine.
Wider implications of the findings: There are no current published guidelines for the management of OCR by transuterine puncture. We found no difference in pregnancy rates and no increase in complication rates associated with transuterine puncture.
Study funding/competing interest(s): Funding by hospital/clinic(s) – none.
Trial registration number: NA.
Keywords: transuterine, oocytes retrieval

P-587 Pregnancy outcomes in women with polycystic ovarian syndrome (PCOS) undergoing *in vitro* fertilization (IVF)

[1]*University of Toronto, Obstetrics and Gynecology, Toronto, Canada*
[2]*University of Toronto, Medical School, Toronto, Canada*
[3]*University of Toronto, LifeQuest Centre for Reproductive Medicine, Toronto, Canada*

[4]*University of Toronto, Division of Maternal-Fetal Medicine, Toronto, Canada*
[5]*University of Toronto, Centre for Fertility and Reproductive Health, Toronto, Canada*

Study question: Is PCOS an independent risk factor for increased pregnancy complications in singleton pregnancies following IVF+/- ICSI?
Summary answer: IVF pregnancies in the PCOS population are at higher risk for the development of specific pregnancy complications than those in women without PCOS, after adjusting for differences in maternal age, parity, body mass index (BMI) and time to conception.
What is known already: Meta-analyses have reported increased rates of specific pregnancy complications in the PCOS population. However, many of the included studies compared women with PCOS undergoing ART with spontaneous pregnancies in the general population. We undertook this study to assess whether PCOS contributes significantly to increased pregnancy complications when groups are matched for type of ART.
Study design, size, duration: Retrospective cohort study identifying all fresh IVF ± ICSI transfers with positive bhCG at a single tertiary reproductive endocrinology unit between December 2006 and 2012. Of the 1084 pregnancies identified, 394 resulted in singleton gestations. The other pregnancies identified had resulted in biochemical or early clinical losses, ectopic, or multiples.
Participants/materials, setting, methods: We compared complication rates among 394 singleton pregnancies (71 women with PCOS and 323 controls without PCOS), adjusting for differences in body mass index (BMI), age, and parity.
Main results and the role of chance: Women with PCOS demonstrated a significantly higher risk of developing the following pregnancy complications, after adjusting for differences in maternal age, parity, and BMI: gestational diabetes (OR 3.15, 95% CI 1.35–7.33), hypertensive disorders of pregnancy (OR 4.25, 95% CI 1.94–9.32), preterm birth <37 weeks (OR 2.30, 95% CI 1.07–4.97), and large for gestational age >90‰ (OR 2.77, 95% CI 1.21–6.35). Time to conception did not differ significantly between groups. There was no significant difference in rates of caesarian section or perinatal mortality. A significantly higher rate of ovarian hyperstimulation syndrome and biochemical pregnancies was seen among PCOS IVF pregnancies than controls.
Limitations, reason for caution: This was a retrospective review limited to a single tertiary centre, which may introduce bias. PCOS is a heterogeneous population. Although our sample size was insufficient to compare pregnancy outcomes across different phenotypes or BMI, we did include a representative variety of patients.
Wider implications of the findings: This study builds upon prior publications which have suggested increased rates of specific pregnancy complications in the PCOS population. Our results suggest that PCOS may be an independent risk factor for pregnancy complications, and this finding warrants further prospective evaluation. Women with PCOS merit close antenatal surveillance, and a better understanding of complication rates in these women is important for risk stratification and patient counseling.
Study funding/competing interest(s): Funding by University(ies) – University of Toronto, Department of Obstetrics and Gynecology.
Trial registration number: NA.

P-588 Elective single embryo transfer (eSET) in United States IVF clinics

A. Mancuso[1], S. Boulet[2], H. Duran[1], E. Munch[1], D. Kissin[2], B. Van Voorhis[1]
[1]*University of Iowa Carver College of Medicine, Obstetrics and Gynecology, Iowa U. S. A. City*
[2]*Centers for Disease Control and Prevention, Division of Reproductive U. Health S. A. Atlanta*

Study question: What is the effect of elective single embryo transfer (eSET) rates on clinic-specific outcomes of *in vitro* fertilization (IVF) including the delivery rate and multiple birth rate?
Summary answer: Increasing rates of eSET to ≥40% of cycles was not associated with a significant decrease in clinic-specific delivery rate in women 37 years and younger and was associated with a linear reduction in the multiple birth rate after IVF for all ages.
What is known already: eSET is an effective means of reducing multiple birth rates after IVF. However, in prospective trials, eSET of cleavage stage embryos results in a reduction in the fresh cycle pregnancy rate. Relative to other countries, United States clinics perform eSET less frequently and utilize extended culture to the blastocyst stage more often. The effect of eSET rates on clinic-specific outcomes in centers performing higher rates of blastocyst transfer is not known.
Study design, size, duration: Retrospective analysis using multivariate linear regression to estimate adjusted means for clinic-level delivery and multiple birth rates according to eSET rates. Separate models estimated for all cycles and fresh cycles only, stratified by patient age and adjusted for clinic size, blastocyst transfer rate, and percent cryopreserved embryo transfer cycles.
Participants/materials, setting, methods: US Clinics performing ≥100 IVF cycles in 2012 using data reported to the Centers for Disease and Control (CDC) National ART Surveillance System. 337 clinics (74% of all US clinics) were included and were classified into 6 categories by eSET rates – <10%, 10–19%, 20–29%, 30–39%, 40–49% and ≥50%.
Main results and the role of chance: eSET rates varied considerably among clinics from 0 to greater than 60% with a mean rate of 10%. Delivery rates in fresh or all cycles did not vary substantially with increasing eSET averaging 38% delivery rate per transfer for all cycles. Women less than 35 and 35–37 years of age had equivalent delivery rates in clinics regardless of the eSET rate. In women 38 years and older, delivery rates decreased in clinics performing 40% eSET or greater. Factors directly associated with higher delivery rates included the rate of blastocyst embryo transfer and the rate of cryopreserved embryo transfer cycles. Multiple birth rates dropped in a linear fashion from 30% to 10% with increasing eSET rates from 0–9% to ≥40%.
Limitations, reason for caution: This is a retrospective cohort study comparing outcomes from individual clinics. The populations of patients treated may vary and could affect the decision to perform eSET and the outcomes of interest.
Wider implications of the findings: We found that clinics are able to perform higher rates of eSET than US national averages with no detrimental effect on delivery rates in fresh cycles or all cycles, especially for women ages 37 years and younger. Increasing utilization of eSET is associated with dramatic and linear reductions in multiple births after IVF. These results should reassure and encourage clinics to utilize eSET more often.
Study funding/competing interest(s): Funding by University(ies) – Funding by national/international organization(s). University of Iowa Carver College of Medicine. United States Centers for Disease and Control (CDC).
Trial registration number: NA.

P-589 Comparison of monozygotic twinning incidence following day 5 blastocyst vs. cleavage-stage single embryo transfer (SET) during IVF/ICSI cycles

R. Shaikh[1], A. Shamsa[2], C. Sjoblom[1]
[1]*Westmead IVF Centre, Sydney University, Westmead, Australia*
[2]*Westmead IVF Centre, Obstertrics and Gynaecology, Westmead, Australia*

Study question: To compare the incidence of monozygotic twinning (MZT) in successful pregnancies following single day 5 blastocyst transfers vs. day 2–3 cleavage stage transfers.
Summary answer: There was no statistically significant difference in the incidence of MZT with blastocyst transfers in single embryo transfer (SET) cycles.
What is known already: The prevalence of MZT in the general population is 0.42%. Numerous studies indicate that MZT rates following ART procedures occur between 2 and 12 times higher than the natural incidence. The biological events responsible for MZT are not well understood, with various factors shown to be associated with the phenomena. These include techniques that include micromanipulation such as intra-cytoplasmic sperm injection (ICSI), as well as frozen embryo transfers (FET) and blastocyst transfers. Extended embryo culture to blastocysts, which has become increasingly popular, has been associated with an increased rate of monozygotic twins compared with cleavage-stage.
Study design, size, duration: This was a retrospective audit over a 5-year period, 2009–2013.
Participants/materials, setting, methods: All IVF/ICSI pregnancies following day 5 blastocyst or day 2/3 transfers, conceived in the study period, at Westmead Fertility Centre, a University IVF centre located in Western Sydney were included. Chi-Square or Fisher Exact tests as appropriate were used to identify associations between categorical variables.

Main results and the role of chance: By the 7 week ultrasound, comparing the incidence of MZT after blastocyst and cleavage stage transfers, there was no significant statistical difference shown. Out of 1504 SET pregnancies resulting from embryos transferred in the blastocyst stage, the total rate of monozygotic twins was found to be 1.33% (20/1504). 668 pregnancies following cleavage stage SET were included in this study; the rate of MZT in these embryos was lower, occurring at a rate of 0.75% (5/668). The incidence of MZT for the combined total (blastocyst and cleavage stage transfers) of pregnancies included in this study was found to be 1.15%. The majority of these pregnancies were derived from fresh embryo cycles (63.8%), the rest from frozen cycles (36.2%). The rate of MZT showed no significant difference between the fresh and frozen single embryo transfers, occurring at 1.08% and 1.27% respectively.
Limitations, reason for caution: as we see there is a small increase in the number of monozygotic twins in the blastocyst group, randomized trials are needed to answer this question. Due to retrospective nature of the study confounding factors like family history of twins could not be taken into account.
Wider implications of the findings: As our study did not show any statistically significant difference in the incidence of monozygotic twinning with blastocyst transfers, it is also noted that blastocyst transfers are understood to increase pregnancy rates; and this has to be taken into account when considering the most appropriate management for IVF patients and counselling women.
Study funding/competing interest(s): Funding by hospital/clinic(s) – westmead fertility centre(no funding required).
Trial registration number: Not required.
Keywords: monozygotic twinning, IVF, single embryo transfer, blastocyst, cleavage stage

P-590 Maternal and perinatal outcomes in oocyte donation pregnancies in Sweden 2003–2012

A. Thurin-Kjellberg[1], S. Nejdet[1], K. Källén[2], U. B. Wennerholm[1]
[1]*Sahlgrenska University Hospital, Department of Ob/Gyn, Göteborg, Sweden*
[2]*Tornblad Institute, Department of Reproductive Epidemiology, Lund, Sweden*

Study question: What are the maternal and perinatal outcomes in singleton pregnancies conceived after oocyte donation (OD), as compared to *in vitro* fertilization (IVF) pregnancies with own oocytes and to pregnancies after spontaneous conception (SC)?
Summary answer: OD is associated with an increased risk for low birth weight (LBW) and preterm birth (PTB) and there is an increased risk for preeclampsia and postpartum haemorrhage (PPH) in singleton pregnancies conceived after OD, as compared to IVF with own oocytes and after SC.
What is known already: IVF as compared to spontaneous conception is associated with increased risk for pregnancy complications and adverse perinatal outcomes also in singleton pregnancies. Singleton pregnancies after OD have an increased risk for preeclampsia, PTB and LBW as compared to both pregnancies conceived after IVF with own oocytes and singletons conceived after SC. However, many studies are small and lack an appropriate control group.
Study design, size, duration: Population based cohort study performed in Sweden from 2003 to 2012 including data from all Swedish IVF-clinics. Comparison between all OD pregnancies and all IVF pregnancies and pregnancies in the general population. Only singleton pregnancies included. OD was not allowed in Sweden until 2003.
Participants/materials, setting, methods: 388 singletons conceived after OD, 27150 singletons conceived after IVF and 1090050 SC singletons. Main outcomes: PTB, LBW, small and large for gestational age (SGA, LGA), perinatal mortality, preeclampsia, placental abruption, placenta praevia, and post partum haemorrhage (PPH). Crude and adjusted odds ratios (AOR) with 95% confidence interval were calculated.
Main results and the role of chance: Singletons conceived after OD had significantly higher risks for PTB (<37, <32 weeks) as compared to IVF (AOR 1.8, 2.8, respectively) and SC (AOR 1.6, 2.1, respectively) and LBW (<2500 g, <1500 g) as compared to IVF (AOR 1.7, 2.9, respectively) and SC (AOR 1.5, 2.2 respectively). Singleton pregnancies after OD had a significantly increased risk for preeclampsia as compared to pregnancies after IVF (AOR 3.1) and SC pregnancies (AOR 2.9). Singleton pregnancies after OD had a significantly increased risk for PPH as compared to pregnancies after IVF (AOR 2.6) and SC pregnancies (AOR 2.9). The rate of LGA was significantly increased in singletons born after OD with frozen cycles as compared with fresh cycles, otherwise outcomes were similar in frozen and fresh OD cycles.
Limitations, reason for caution: In this observational study, it was only possible to adjust for maternal age, parity, year of birth, smoking, body mass index (BMI), years of involuntary childlessness, thus there may be residual confounders. Indications for OD were not available. For rare outcomes larger studies are needed.
Wider implications of the findings: The results were in agreement with the literature. The results are important for the increasing group of women with pregnancies after OD and especially for women of advanced maternal age. In Sweden only public clinics are allowed to perform OD and the maternal age limit is set to a maximum of 40–41 years. Caregivers should be aware of the increased risk of preeclampsia and adverse perinatal outcomes.
Study funding/competing interest(s): Funding by University(ies) – Funding by hospital/clinic(s). The study was supported by grants from the University of Gothenburg/Sahlgrenska University Hospital (LUA/ALF 70940).
Trial registration number: Not relevant.
Keywords: oocyte donation, maternal outcome, perinatal outcome

P-591 Volatile organic compounds (VOCs) that are persistently present inside and outside of the *In Vitro* Fertilization (IVF) laboratories. A 5 years evolution study

V. Vásquez[1], J. L. Romero[1], J. M. De Los Santos[1], F. Insúa[1], S. Pérez[1], C. Albert[1], P. Gámiz[1], T. Viloria[1], A. Galán[1], M. J. De Los Santos[1]
[1]*IVI Valencia, IVF Laboratory, Valencia, Spain*

Study question: Which are the main Volatile Organic Compounds (VOCs) that can be persistently found inside and outside the IVF laboratories and how could they have evolved in a period of 5 years?
Summary answer: Ambient air assessment in the IVF laboratory clean areas has been performed yearly to follow up the VOC concentrations surrounding the embryo environment, and at least 25 substances values have been registered per year, 6 of which exceeded 1% of the Occupational Limit Values (OLV) inside the IVF laboratories.
What is known already: Despite the efforts to clear the IVF laboratory's air through good quality management systems, including contamination preventive strategies and ambient air compounds presence controls, some of these substances may remain in harmful concentrations inside IVF laboratories, surrounding the embryos "*In vitro*" environment and affecting their development and health. The OLV aren't not sufficient because they were only designed to cover daily exposed workers without adverse effects, but not for cultured and largely unprotected cells.
Study design, size, duration: A descriptive retrospective analysis has been performed after the assessment of 54 VOCs inside the IVF laboratories over the past 5 years, since 2010–2014, by a specialized company who evaluated the VOCs concentrations.
Participants/materials, setting, methods: Environmental assessment was performed to determine the VOCs inside the IVF laboratories. Air was evaluated after a cleaning and disinfection protocol. Substances were obtained absorbing 6 L of air with an absorption pump (APEX lite). A total of 54 VOCs were simultaneously identified using the SPME (solid phase microextraction) technique.
Main results and the role of chance: Yearly ambient air assessment inside and outside the IVF laboratory registered 29 of the 54 VOCs evaluated. The most common VOCs found were Acetone, Ethyl Benzene, Limonene, Pinene, m, *p*-Xylene and Styrene. A total of 26 VOCs (89,6%) were inside the IVF in at least 2 years and also showed higher concentrations compared to the outside in at least 1 of the 5 years measured. Years 2012 and 2013 registered the higher amount of VOCs present in higher concentrations in IVF (19–21 respectively). 6 different substances exceeded the OLV 1% limit established; 4 of these (13,79%) were inside the IVF in 2010 (Hexachloro-1,3-butadiene, Tetrachloroethane) and 2012 (Acetic Acid, Tetrachloroethane, Vinyl Acetate). Nevertheless no substances were exceeded in 2011, 2013 or 2014.
Limitations, reason for caution: Specific quality standards and specific threshold levels at which contaminants cause harm to embryos have not been determined yet. For this reason it has been proposed as a quality control parameter the 1% VOCs limit for these IVF laboratories based on the literature as well as the laboratory experience**.**
Wider implications of the findings: Based on VOC measurement reports a new research has been designed in order to determine the accurate limits for some of the most common VOCs inside the IVF laboratory's air, relying upon the results obtained after exposing embryos to specific concentrations. With the

new thresholds, health regulatory bodies could be contacted looking forward to establish official OLV for IVF laboratories that will allow an acceptable embryo development.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Instituto Valenciano de Infertilidad (IVI Valencia).
Trial registration number: NA.
Keywords: IVF, laboratory, VOCs, quality

P-592 A randomized controlled trial of natural versus artificial cycle for frozen thawed embryo transfer

E. R. Groenewoud[1], N. S. Macklon[2], B. J. Cohlen[3]
[1]*Medical Centre Leeuwarden, Obstetrics and Gynaecology, Leeuwarden, The Netherlands*
[2]*University of Southampton. Faculty of Medicine Division of Human Development and Health, Department of Obstetrics and Gynaecology, Southampton, United Kingdom*
[3]*Isala Clinic, Fertility Centre Isala, Zwolle, The Netherlands*

Study question: Is modified natural cycle frozen thawed embryo transfer (FET) non inferior to artificial cycle FET with regard to clinical and ongoing pregnancy?
Summary answer: We found no difference in clinical and ongoing pregnancy rate between modified natural cycle FET and artificial cycle FET. Ongoing analyses considering live birth rates, cancellation rates and cost-efficiency will be presented.
What is known already: FET is of growing importance in assisted reproductive techniques. However the optimal preparation regimen remains unclear. One small RCT has indicated comparable clinical pregnancy rates between natural and artificial cycle FET. Previous systematic reviews have highlighted the need for further well powered randomised controlled trails to elucidate the optimal preparation protocol.
Study design, size, duration: Between February 2009 and April 2014 1032 patients were included in this multicentre, non-inferiority, randomised controlled trial. Patients were randomized between modified natural cycle FET or artificial cycle FET based on a 1:1 allocation using blocks of variable sizes. Stratification for initial treatment (IVF versus ICSI) was performed.
Participants/materials, setting, methods: Ovulatory patients, ages 18–40, undergoing FET after one of the first three IVF or IVF-ICSI treatment cycles were eligible for inclusion in this multicentre study. Patients undergoing FET with embryos derived from donor gametes were excluded.
Main results and the role of chance: Baseline characteristics showed no significant differences between the study groups except a longer duration of cryopreservation in patients undergoing artificial cycle FET. Clinical pregnancy developed in 94 out of the 500 patients undergoing natural cycle FET (18.8%) versus 75 out of the 469 patients undergoing artificial cycle FET (16.0%). Ongoing pregnancy was achieved in respectively 11.6% versus 9.2% of the cycles. Neither clinical pregnancy rate (OR 0.8, 95% CI 0.6–1.2, $p = 0.3$) nor ongoing pregnancy rate (OR 0.8, 95% CI 0.5–1.2, $p = 0.2$) differ significantly between natural cycle FET and artificial cycle FET. Embryo quality was the only significant confounding factor influencing both clinical and ongoing pregnancy rates.
Limitations, reason for caution: Prior to the start of the trial it was estimated that 1150 patients were needed to achieve adequate statistical power. This number was not achieved. Based on the current results a study of least double the size of the current one will be needed to rule out a type 1 error.
Wider implications of the findings: Since clinical and ongoing pregnancy rates don't differ between modified natural cycle FET and artificial cycle FET, other factors, such as cost-efficiency, clinical convenience and patients preference, should determine the choice of protocol. Data on these aspects will be presented.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Schering-Plough.
Trial registration number: NTR1586.
Keywords: frozen thawed embryo transfer, natural cycle FET, artificial cycle FET

P-593 Analysis of day 3 versus day 5 transfer data from the HFEA Database and a survey of eSET and blastocyst transfer policies in the UK

E. D. M. Kritioti[1], J. C. Harper[1]
[1]*Institute for Women's Health, Women's Health, London, United Kingdom*

Study question: What are the comparative outcomes of cleavage-stage transfer (CT) and blastocyst transfer (BT) according to the Human Fertilisation and Embryology Authority's (HFEA) database (2008–2012) and what are the current elective single embryo transfer (eSET) and BT policies of UK clinics?
Summary answer: BT showed a higher pregnancy and live birth rate, more male births and monozygotic twins. The predominant eSET policy of UK clinics was: patient's first cycle, age <37, ≥1 good blastocysts and surplus freezable embryos. For BT policies, the main criteria was ≥3 embryos available on day 3.
What is known already: Advances in assisted reproductive technology have led to a shift in practice from CT to BT with the aim of improving embryo selection and pregnancy rates. Multiple births have been decreasing due to the implementation of eSET policies.
Study design, size, duration: This is a retrospective cohort study using HFEA data of IVF and ICSI cycles performed between January 2008 and June 2012. The study also comprised a survey addressed to 74 IVF UK clinics.
Participants/materials, setting, methods: HFEA data from January 2008 to June 2012 from 78 clinics were analysed. Line, scatter, pie and bar charts and Wilcoxon tests (at 5% significance) were used to compare the outcomes of CT against BT. A survey addressed to UK IVF clinics ($n = 74$) assessed eSET and BT policies.
Main results and the role of chance: The use of BT rose from 12% in 2008 to 37% in 2012, with CT use decreasing from 88% in 2008 to 63% in 2012. Both overall and age-specific pregnancy and live birth rates were significantly higher for BT (p-value: <0.001). Multiple birth rates decreased for both CT and BT; in 2008, BT multiple birth rates were 28% whereas CT were 24%. By 2012 BT were 13% and CT were 17%. BT significantly favours males over females births (52:48). There was no significant difference between CT and BT regarding gestational age (singletons: 38 weeks; multiples: 35 weeks) or birth weight. The response rate of the survey was 53% (39/74). All responding clinics perform CT and BT, freeze embryos and have specific eSET and BT policies.
Limitations, reason for caution: The data requested from the HFEA were not fully provided for anonymity reasons and therefore some variables such as age-specific pregnancy and live birth rates could not be analysed fully.
Wider implications of the findings: BT is now available in all UK IVF clinics and its use has increased since 2008. All clinics have specific eSET and BT policies with the aim to reduce multiple birth rates.
Study funding/competing interest(s): Funding by University(ies) – University College London.
Trial registration number: NA.
Keywords: cleavage-stage transfer, blastocyst transfer, elective single embryo transfer, HFEA

P-594 Assisted reproduction causes placental maldevelopment and dysfunction linked to reduced fetal weight in mice

B. Li[1], S. Chen[1], X. Wang[1]
[1]*Tangdu Hospital the Fourth Military Medical University, Department of Obstetrics and Gynecology, Xi'anShaan'xi, China*

Study question: Is reduced fetal weight associated with assisted reproduction derived from placental maldevelopment and dysfunction?
Summary answer: Yes, assisted reproduction resulted in placental overgrowth at embryonic day 18.5 (E18.5), which is associated with defects in placental layer segregation and perturbation of genomic imprinting in mice.
What is known already: *In vitro* fertilization and preimplantation embryo culture affected fetal and placental development and placental transport of amino acid and glucose during late gestation in mice.
Study design, size, duration: Blastocysts generated by assisted reproduction and *in vivo* were transferred to the uteri of pseudopregnant females. Conceptuses were collected at E14.5 or E18.5. Fetal weight, placental weight, placental structure, the expression of nutrient transporters and imprinted genes, the methylation of *H19* ICR, *KvDMR1* and *SNRPN* ICR were compared.
Participants/materials, setting, methods: Virgin 6- to 8-week-old CD1 female mice, adult CD1 males were used. Histological analyses were analyzed by standard histological and Periodic acid-Schiff staining. Gene expression was analyzed by real-time PCR. The Sequenom MassARRAY platform was used to perform the quantitative methylation analysis.
Main results and the role of chance: Assisted reproduction resulted in reduced fetal weight and placental overgrowth at E18.5, which is associated with aberrant placental morphology, most notably in the spongiotrophoblast

and labyrinth layers. Further, Assisted reproduction resulted in downregulation of most placental nutrient transporters and reduction in placental efficiency. Moreover, IVF and IVC increased the DNA methylation level of the imprinting control regions of *H19*, *KvDMR1* and *SNRPN* and disrupted the expression of imprinted genes in the placenta during mid-to-late gestation.
Limitations, reason for caution: The causal relationship between the aberrant placental maldevelopment and disrupted genomic imprinting is difficult to prove.
Wider implications of the findings: Our results from the mouse model show the first piece of evidence that ART treatment could affect fetal growth by disrupting *placentation* and placental function, suggests that perturbation of genomic imprinting resulted from embryo manipulation may contribute to these problems.
Study funding/competing interest(s): Funding by national/international organization(s). This work was supported by grants from the National Natural Science Foundation of China (81300531). The authors have no conflicts of interest to declare.
Trial registration number: It is a basic research, so have no trial registration number.
Keywords: ART, intrauterine growth restriction, placentation, metabolic syndrome, genomic imprinting

REPRODUCTIVE (EPI)GENETICS

P-595 Homozygous mutation in NTS12 associated with infertility in two brothers with "short tails" syndrome

H. Ghédir[1], S. Ibala-Romdhane[1], O. Okutman[2], A. Saad[1], S. Viville[2]
[1]*Farhat Hached Hospital, Laboratory of Cytogenetics Molecular Genetics and Reproductive Biology, Sousse, Tunisia*
[2]*Institute of Genetics and Molecular and Cellular Biology (IGBMC) University of Strasbourg and Strasbourg University hospitals, Department Functional Genomics and Cancer, Illkirch, France*

Study question: Can we identify a genetic defect in infertile patients with 'short tails' syndrome; a severe form of flagella pathology which causes sperm immobility and shows familial incidence?
Summary answer: We found a missense mutation (*p*.Arg1109Trp) in two infertile brothers issued from a consanguineous marriage in *NTS12* gene. The gene encodes a microtubule associated protein which allowed us to think that this mutation may disrupt the flagella building and may be responsible for infertility in the family studied.
What is known already: 'Short tails' syndrome refers to a condition of absence or severely reduced sperm motility associated to major alterations in the fibrous sheath and dysplastic development of the tail during spermatogenesis. To date the molecular default in this sperm defect is undefined.
Study design, size, duration: This is a case control study carried out on a Tunisian consanguineous family including two brothers described as having 'short tails' sperm defect associated with high percentage of head abnormalities and 13 other infertile patients presenting a similar phenotype. We included as a control group 100 fertile men.
Participants/materials, setting, methods: We used a combination of two methods; homozygosity mapping carried out on 10 patients including two consanguineous brothers and whole exome sequencing carried out on these two brothers. We screened the mutation found and other exonic mutations of the gene in other patients and fertile controls by Sanger sequencing.
Main results and the role of chance: Semen analysis shows akinetozoospermia associated with a total teratozoospermia with a predominance of short tails, microcephalic heads and abnormal acrosomes. Two brothers carried the same homozygous mutation (c.3245C > T, *p*.Arg1109Trp) in *NTS12* which encodes a protein that associates with the microtubule cytoskeleton and localizes at the centrosomes, mitotic spindle and intercellular bridge during cell division. The protein encoded is a potent microtubule-stabilizing protein whose depletion increases microtubule dynamics. Online available tools SIFT and PolyPhen predict that this variation severely affect the protein function. The residue in question (Arginine 1109) is located in a large coiled-coil region. Moreover, this mutation was absent in control group of fertile males and no variation was detected in other patients carried the 'short tails' syndrome.
Limitations, reason for caution: A limitation of this study is the low number of patients presenting with this rare form of male infertility.
Wider implications of the findings: In this study we have identified a first homozygous mutation associated to the 'short tails' syndrome. So far, we could not confirm the pathogenicity of the mutation but we suppose that it could be deleterious and may be responsible for infertility in this family.
Study funding/competing interest(s): Funding by hospital/clinic(s) – none.
Trial registration number: NA.
Keywords: akinetozoospermia, short tails, missense mutation, NTS12

P-596 Digital chromatid counting in polar bodies achieves robust ploidy data of zygotes and improves pregnancy rates in IVF cycles of poor prognosis patients

A. Daser[1], C. Vogt[1], E. Mueller[1], D. Seifert[1], H. Turley[2], H. Wilhelm[2], T. Hahn[3], P. H. Dear[4], M. Schorsch[3]
[1]*SH-Gen Forschungsgesellschaft, SH-Gen, Wiesbaden, Germany*
[2]*Fertility Center, Embryology, Wiesbaden, Germany*
[3]*Fertility Center, Gynecology, Wiesbaden, Germany*
[4]*Laboratory of Molecular Biology, PNAC, Cambridge, United Kingdom*

Study question: Does selection of euploid oocytes and exclusion of aneuploid oocytes improve pregnancy rates in patients of higher age and previous unsuccessful cycles?
Summary answer: Implantation rate in 56 cycles, average maternal age 37.5 years and 2.75 previous cycles was 38% thus demonstrating that polar body diagnosis with direct chromatid counting improves clinical pregnancy rates significantly. Data of ongoing pregnancies will be available.
What is known already: Aneuploidy increases with age.
Study design, size, duration: Method and study design: We have established a simple PCR method to count chromatids directly with DNA at limiting dilution and digital readout. After limiting dilution of polar body DNA into 8 PCR reaction wells (i.e., 0.25 and 0.125 genomes per aliquot in PB1 and PB2 respectively) 16 markers per chromosome for all chromosomes are amplified in a large PCR multiplex. Single marker analysis is then performed in the high throughput format 96.96. Array from Fluidigm, which allows to run 96 markers with 96 DNAs. Marker layout is such that the first round 96 markers are covering around 6 regions (2 markers per region) in the 8 most frequently aneuploid chromosomes 13, 15, 17, 18, 19, 21, 22, X. A significant number of zygotes (at least 50%) can be diagnosed as aneuploid at that stage and are excluded from further analysis. All zygotes, euploid for these 8 chromosomes, undergo a second round of single marker PCR to analyse the 8 next most aneuploid chromosomes. The few remaining zygotes are analysed with the remaining 7 chromosomes and chromosome Y as a control.
Participants/materials, setting, methods: Polar bodies.
Main results and the role of chance: Main results: From 79 cycles (average maternal age 37.5 years and 2.75 previous unsuccessful cycles), 566 zygotes were analysed and results were obtained for 553 (98%): 165 (29%) zygotes were euploid and 388 (69%) were aneuploid. In 15 cycles all zygotes were aneuploid and in 8 cycles blastocysts were cryopreserved. From the remaining 56 cycles with 1–2 transferred embryos implantation rate was 38% (21 pregnancies). Information about ongoing pregnancies will be obtained in the coming month.
Limitations, reason for caution: Copy numbers in single cells can be counted in any cell type such as oocytes, blastomeres, fibroblast and lymphoblast.
Wider implications of the findings: Polar body analysis with digital PCR from DNA at limiting dilution proofs a direct and robust method with beneficial biological outcome in couples with poor prognosis. The method allows a strategy which is fast and reduces costs to the minimum necessary to identify euploid oocytes and exclude aneuploid oocytes.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – SH-Gen Research.
Trial registration number: No register number.
Keywords: polar bodies, aneuploidy screening, digital PCR

P-597 Karyomapping: a novel alternative approach to PGD

S. Seshadri[1], J. Ben-Nagi[1], W. Saab[1], K. Doye[1], A. Doshi[1], D. Wells[2], P. Serhal[1]
[1]*CRGH, Assisted Conception Unit, London, United Kingdom*
[2]*Oxford Reprogenetics UK Institute, Institute of Reproductive Sciences, Oxford, United Kingdom*

Study question: Could Karyomapping be an alternative approach to conventional pre implantation genetic diagnosis (PGD)?
Summary answer: Karyomapping is a novel approach which could be offered to patients with an identified genetic disorder which is less time consuming and cost effective compared to conventional PGD. This is the largest case series of patients in literature undergoing karyomapping to detect monogenic disorders in complement to other chromosomal abnormalities.
What is known already: Conventional PGD is time consuming requiring the development of a specific test for a particular disorder or couple. Karyomapping is a novel technique, whereby chromosomal abnormalities and monogenic disorders can be diagnosed concurrently. Recently, the accuracy of karyomapping has been reported as high as 97.7% when compared to target haplotyping in PGD.
Study design, size, duration: A retrospective case series comprising of 55 patients from February 2014 to date. Patients with an identified genetic disorder were referred to the Centre of Reproductive and Genetic Health (CRGH) clinic by their genetic counsellor. A complete genetic work up was conducted for the couple and the affected family members.
Participants/materials, setting, methods: Patients underwent conventional IVF/ICSI treatment and cleavage/blastocyst biopsies were performed. Biopsied cells were lysed in order to release their genetic material. The DNA was then fragmented and hybridised to a HumanKaryomap-12v2.1 beadarray. After hybridisation and staining the beadarray was scanned and results interpreted using BlueFuse Multi software (Illumina).
Main results and the role of chance: 19 Patients with an autosomal dominant (including retinoblastoma, facioscapulohumeral and muscular dystrophy, huntingtons disease, paragangliomas, Marfans syndrome), 26 patients with an autosomal recessive (e.g: beta thalassemia, sickle cell anemia, cystic fibrosis, spinal muscular atrophy), 4 patients with X linked dominant (e.g: Hypophosphatemic rickets, Incontinentia pigmenti), 6 patients with X linked recessive conditions (Retinoschisis, Norrie disease, Adrenoleukodystrophy, Ectodermal dysplasia) attended the clinic for karyomapping. The average time taken for couples to commence IVF/ICSI treatment following genetic work up was approximately 6–8 weeks. The median age and range for the patients was 32.4 (24.8–40) years. 17 patients completed ovarian stimulation, oocyte retrieval and had their embryos biopsied. Nine patients underwent a transfer of an unaffected embryo. Four patients have an ongoing clinical pregnancy. The remaining patients are awaiting a frozen embryo transfer.
Limitations, reason for caution: Absence of DNA from a family member with the known genetic condition can limit the application of karyomapping. Karyomapping does not detect new mutations and also does not detect post-zygotic chromosome duplication nor copy number variation. Hence larger studies reporting the clinical outcomes following karyomapping are essential.
Wider implications of the findings: Couples referred for PGD treatment have to wait long periods of time for development of an a-priori test before they can proceed for treatment. This wait could impede their fertility potential and also increase anxiety for couples. Conventional PGD only detects a single gene mutation in the embryo without analysing the entire genome component. Couples with multiple coexisting chromosomal abnormalities could be offered Karyomapping with whole genome sequencing rather than conventional PGD.
Study funding/competing interest(s): Funding by hospital/clinic(s) – no external funding.
Trial registration number: NA.
Keywords: karyomapping, PGD, IVF

P-598 The frequency of aneuploidy status of day 5 and day 6 blastocysts assessed by next-generation sequencing technology (NGS) application

J. Liss[1], A. Bruszczynska[1], S. Pukszta[2], K. Lukaszuk[1]
[1]*Invicta, Fertility and Reproductive Center, Gdansk, Poland*
[2]*Invicta, Molecular Biology Laboratory, Gdansk, Poland*

Study question: To assess correlation between day 5 (D5) and day 6 (D6) blastocyst morphology and ploidy status.
Summary answer: Slower developing blastocysts cryopreserved on day 6 but at the same stage of development as those developing to the blastocyst stage on day 5 do not have similar chromosomal status and therefore provide a lower chance of achieving pregnancy.
What is known already: Embryos with the highest morphological scores showed a higher euploidy rate when compared with lower quality embryos. During IVF cycles, the embryonic cohort is asynchronous in development and trophectoderm biopsy can equally be performed on D5 or D6 post-fertilization and on blastocysts of different morphological quality. It is still unknown whether blastocyst morphology and developmental rate relate to the embryo chromosomal constitution.
Study design, size, duration: Retrospective study including the data analysis of 61 blastocysts stage PGS cycles (median age 38 years, range 34–40) performed between August 2013 and November 2014 at INVICTA Fertility Centre, Poland. A total of 168 blastocysts were evaluated with the NGS protocol.
Participants/materials, setting, methods: All embryos were cultured to blastocyst stage. Trophectoderm biopsy was performed on D5 (n = 104) of development or, for slower growing embryos, on D6 (n = 64). The method involved whole genome amplification before NGS protocol. Ion Torrent Suite Software and Invicta Bioinformatics Team Script were used for chromosome copy number variation analysis.
Main results and the role of chance: 49 (47.1%) D5 embryos were euploid, 55 (52.9%) aneuploid. In D6 group, 18 (28.1%) were euploid, 46 (71.9%) aneuploid. Difference in aneuploidy rates between D5 and D6 was statistically significant (p = 0.01). We observed no differences according to blastocyst morphology. There were 69 (80.2%) good quality embryos (>3AA score) on D5, 46 (71.9%) on D6. The euploidy/aneuploidy rates did not vary significantly between good and poor morphology embryos. For D5, the euploidy/aneuploidy rates were 49.3%/50.7% for good and 47.1%/52.9% for poor quality embryos, while for D6 the rates were 28.3%/71.7% (good) and 27.8%/72.2% (poor). Single frozen embryo transfers of 50 euploid blastocysts (D5–39, D6–11) were performed. 18 (46.2%) D5 and 3 (27.3%) D6 clinical pregnancies were confirmed. Implantation rate was 33.3% for D5, 9.1% for D6.
Limitations, reason for caution: The study is limited by sample size. A higher sample size or a prospective randomized design could be used in future studies to corroborate the current findings.
Wider implications of the findings: This study provides insight into determining ploidy status depending on the day of blastocyst biopsy. Slower developing blastocysts cryopreserved on day 6 but at the same stage of development as those developing to the blastocyst stage on day 5 do not have similar chromosomal status. Euploid embryos tend to show faster progression to the most advanced expansion stages when compared with aneuploid embryos.

P-599 Age and ovarian reserve affect the non-coding transcriptome of human oocytes

M. Barragán[1], I. Pons[2], A. Ferrer[1], A. Schweitzer[3], J. Hubbard[3], H. Auer[4], R. Vassena[1]
[1]*Clínica EUGIN, Barcelona, Spain*
[2]*Institute for Research in Biomedicine (IRB Barcelona), Barcelona, Spain*
[3]*Affymetrix, Santa Clara, Canada*
[4]*Functional GenOmics Consulting, Barcelona, Spain*

Study question: What is the non-coding RNA (ncRNA) transcriptome of MII oocytes matured *in vivo* from healthy women, and how is it affected by variations in age and ovarian reserve?
Summary answer: We identify a substantial expression of ncRNA in human MII oocytes; both woman age and ovarian reserve accounts for significant variations in the ncRNA transcriptome.
What is known already: Female age is crucial in determining oocyte developmental competence, as is ovarian reserve. Oocytes store large quantities of mRNA involved in early developmental events. Studies in several animal models indicate that non-coding RNAs (ncRNA), which regulate cellular processes through transcription and translation modulation, have an essential role in maternal to zygote transition, as well as germline specification and maintenance. Despite their central role in development, no characterization of ncRNA in human oocytes is available.
Study design, size, duration: This study included 36 mature (MII) oocytes from 30 oocyte donors; 9 oocytes in each of the following groups: (a) »22 year-old

and >20 AFC; (b) »33 year-old and >20 AFC; (c) »22 year-old and <10 AFC; (d) »33 year-old and <10 AFC. All stimulations were triggered with GnRH agonist.
Participants/materials, setting, methods: Total RNA was purified from individual MII and WTA2 cDNA libraries prepared; 10 mg cDNA was fragmented and biotinylated; 36 Affymetrix GeneChip HTA 2.0 arrays were hybridized, washed, stained, and scanned. Partek Genomics Suite was used to identify differentially expressed transcripts (fold change >1.5 or <-1.5; $p < 0.1$).
Main results and the role of chance: There were 43 differentially expressed NCT (non-coding transcripts) and 3 EST (expressed sequence tag) when comparing age independently of ovarian reserve, and 37 NCT and 7 EST when comparing ovarian reserve independently of age. There were 84 differentially expressed NCT including all classes of ncRNAs: 4 miRNA, 25 piRNA, 46 lncRNA, as well as 22 EST when comparing groups (a) and (d), 27.2% transcripts differences were maintained comparing groups (a) and (b); 27.7% of the differences observed where also maintained when comparing (c) and (d), 10.4% when comparing (a) and (c), and 61.8% when comparing (b) and (d). These results indicate that age is an important determinant of ncRNA abundance and that, in aged oocytes, ovarian reserve is a co-determinant of ncRNA variability.
Limitations, reason for caution: Since the MII included in this study were from young women, and ncRNA populations are understudied in human, no information can be assumed about older women. All donors received the same stimulation protocol, which could impact the array of ncRNA present in MII oocytes.
Wider implications of the findings: This study describes for the first time the ncRNA landscape of MII oocytes in the human species, providing insights into translational regulation of early embryogenesis and how this is affected by age and ovarian reserve. Moreover, we established a platform for the study of ncRNA as putative biomarkers of oocyte quality. As the oocytes analyzed were from fertile women, we can exclude an effect of genetic factor associated with infertility on the ncRNA landscape.

P-600 Medium-based noninvasive preimplantation genetic diagnosis for human a-thalassemias-SEA

H. Wu[1], X. Shen[1], C. Ding[1], J. Xu[1], Y. Xu[1], C. Zhou[1]
[1]*First Affiliated Hospital of Sun Yat-sen University, Reproductive Medicine Center, Guangzhou, China*

Study question: In this study, we tried to establish a novel and noninvasive medium-based testing for screening healthy embryo of patients with a-thalassemias^{-SEA} carriers who undergo *in vitro* fertilization (IVF) and preimplantation genetic diagnosis (PGD).
Summary answer: Medium-based a-thalassemias^{-SEA} detection could be a novel, quick and noninvasive method for patients with carriers who undergo PGD, while there is no significant difference in terms of diagnosis efficiency and allele drop-out (ADO) ratio between single cell based and medium-based a-thalassemias^{-SEA} detection.
What is known already: PGD is introduced for prenatal diagnosis service and blastomere biopsy at cleavage stage is mostly adopted IVF units. However, recently studies on animals suggested that blastomere biopsy may cause aberrant epigenetic modification, neurodegenerative disorders and ovary dysfunction in the offspring so that noninvasive testing method for PGD would be a favorable and urgently needed option.
Study design, size, duration: It is a diagnostic test between March and June 2014. 38 PGD cycles were performed, in which single cells biopsied from blastomeres and according spent culture media and blastocysts were collected. Blastocysts were used to verify. Another 148 media from 6 ICSI cycles were gathered.
Participants/materials, setting, methods: Among 413 Single cells that were subjected to fluorescent gap PCR analysis, 128 embryos that were diagnosed a-thalassemia SEA deletion were abandoned, and their according spent media and blastocysts were subjected to Q-PCR detection. 148 media from ICSI cycles were subjected to Q-PCR detection for quantification of cell-free DNA
Main results and the role of chance: 413 Single cells biopsied from blastomeres were turned out to be 108 normal embryos, 103 heterozygous, 128 a-thalassemia SEA deletion, 74 undetectable. The ratio of this DNA diagnosis efficiency was 82.1% (339/413). Altogether 112 out of 128 medium samples (87.5%) at day 6 was detectable, among which there were 34 heterozygous and 78 homozygous mutant. Blastocysts' verification shows 38 heterozygous and 90 homozygous mutant. 4 samples occurred ADO and its ratio was 10.5%. The *P* value of diagnosis efficiency is 0.175. Detectable ratio of medium collected at day 4 (D3–D4) after fertilization is 19.67% (12/61) with the concentration of 14.24 ± 4.76 pg/ml, which dramatically increased to 90.16% (55/61) with 48.78 ± 20.45 pg/ml at day 5 and 88.46% (23/26) with 54.35 ± 22.78 pg/ml at day 6.
Limitations, reason for caution: First of all, we are not sure to what extent that sample DNA collected from culture medium is representative of the embryo. Contamination may come from cumulus cells, thus washing off cumulus cells thoroughly is required. In addition, to prevent media contamination, individual Pasteur pipettes were used for each embryo.
Wider implications of the findings: First of all, medium-based detection could avoid lost of single cell cause of improper delivery of samples by using biopsy. Secondly, medium-based detection is more flexible and suitable for monitoring different stages of embryo development since cell-free DNA in medium is stable at different stage after D4 in comparison with blastocoelic fluid detection. Thirdly, the detection is simple and efficient. Transplantation of fresh healthy embryo could be achieved after 3 h medium-based detection.
Study funding/competing interest(s): Funding by national/international organization(s). National Natural Science Foundation of China (81370765); Guangdong Provincial Key Laboratory of Reproductive Medicine (2012A06140003) and Natural Science fund of Guangdong (S 2013040014613).

P-601 Ultra-PGD: preimplantation genetic diagnosis by karyomapping. Introduction to clinical genetics and results of first 136 cases

M. Lindeman[1], T. McWilliams[1], E. Czuprenski[1], J. Kitchen[1], M. R. Hughes[1], T. Gordon[2]
[1]*Genesis Genetics, PGD, Plymouth, MI, U.S.A.*
[2]*Genesis Genetics, PGD/PGS, London, United Kingdom*

Study question: Preimplantation Genetic Diagnosis (PGD) has helped thousands of couples avoid passing genetic disorders to their children. Established methods require a lengthy test building period, but new technology promises to revolutionize preimplantation genetics with a more rapid, higher-resolution test. Does Karyomapping provide reliable results in a shorter timeframe?
Summary answer: Karyomapping represents a major advance in preimplantation genetics. PGD tests can now be prepared within 4 weeks of receiving family DNA samples, as compared to many months previously and generate a wealth of data points for tracking the inheritance of parental genes with a high rate of success.
What is known already: Established methods for Preimplantation Genetic Diagnosis (PGD) use Short Tandem Repeats (STRs) to track heritable diseases. Several months are needed to design a custom test for diagnosing embryo biopsies. Using a microarray eliminates the need for a laborious custom test build. The ~300,000 Single Nucleotide Polymorphisms (SNPs) targeted by Illumina's Infinium HumanKaryomap-12 BeadChip can provide a richer dataset in less time than is achievable using the current STR method of PGD.
Study design, size, duration: Since it's introduction into our laboratory 136 couples seeking PGD had 938 embryos tested for 61 different genetic disorders with our "Ultra-PGD" Karyomapping protocol. Family DNAs were analyzed to ensure sufficient informative SNPs surrounded the genes of interest, followed by testing of the biopsies from day-5 frozen embryos.
Participants/materials, setting, methods: Family DNAs and amplified trophectoderm biopsies were analyzed using the Infinium HumanKaryomap-12 DNA Analysis Kit from Illumina. Beadchips were processed and scanned with an iScan array scanner. The data was processed with BlueFuse Multi software to determine inheritance.
Main results and the role of chance: We were able to determine the genetic status of 89% of the embryos tested using our "Ultra-PGD" Karyomapping protocol. This is lower than the 98% success rate for STR PGD tests on trophectoderm biopsies. Genetic status could not be determined for samples which did not amplify or failed quality-control metrics (7.7%). DNA contamination, typically maternal, accounted for an additional 1.7% of samples which could not be genotyped. DNA recombination at the disease locus also prevented genotyping of 1.9% of embryos. In all, 477 embryos (51%) were found to be

genetically unaffected. The likelihood of individual families having unaffected embryos is dependent on the number of embryos biopsied and the inheritance pattern of the disease.
Limitations, reason for caution: Karyomapping is a promising advance in PGD, but is not without limitations. The technology lacks the exceptional sensitivity of STR assays and is consequently more dependent on the quality of embryo biopsies. The poorer SNP calling found with single blastomere samples precluded the possibility of day-3 biopsies.
Wider implications of the findings: All families seeking PGD stand to benefit from a faster, lower cost and more informative test. Particularly, families who have been unable to use PGD due to limited informative STR markers have a greater chance of success with a Karyomapping PGD test. The shorter timeframe especially benefits families who are in need a faster test, such as for HLA matching for transplants.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Genesis Genetics.

P-602 High success rate of preimplantation genetic diagnosis in achieving healthy live-birth for very rare monogenic disorders

H. A. Tac[1], C. Beyazyurek[1], H. Yelke[1], Y. K. Colakoglu[1], C. G. Ekmekci[1], A. P. Cil[1], S. Kahraman[1]
[1]*Istanbul Memorial Hospital, ART and Reproductive Genetics Center, Istanbul, Turkey*

Study question: What are the clinical outcomes of cycles performed for preimplantation genetic diagnosis (PGD) for very rare monogenic disorders and has the method been successful in terms of both diagnostic and clinical efficiency?
Summary answer: In this study we present our experience on clinical and technical aspects of PGD for 9 different very rare monogenetic disorders (prevalence ranging from only 7 cases reported in the literature to 1/10000) demonstrating that this technique is indeed a successful and effective prevention method for couples at risk of transmitting very rarely seen genetic disorders.
What is known already: PGD for monogenic disorders has become an effective alternative to prenatal diagnosis since its first application. Since then, it is estimated that PGD has been performed for over 350 monogenic conditions resulting in births of thousands of healthy children.
Study design, size, duration: This study consists of retrospective analysis of PGD cycles performed for very rare monogenic disorders between years 2003 and 2013. Seventeen cycles were performed for 9 couples referred for PGD with 9 rare monogenic disorders. All patients were counselled by an IVF specialist and a medical geneticist about the process of PGD and the possibilities of misdiagnosis and cancellation of embryo transfer.
Participants/materials, setting, methods: PGD set up procedure was performed initially on the parents' peripheral blood DNA samples in order to establish informative STR markers. PGD was performed on cleavage or blastocyst stage. Biopsied samples were analyzed with single-cell multiplex PCR techniques.
Main results and the role of chance: Seventeen IVF cycles were performed for PGD of 9 rare genetic diseases, which are Ehler-Danlos Syndrome Type VIIC, Co-enzyme Q deficiency, Lafora Disease, Leber's congenital amaurosis, Bartter Syndrome, Glazmann Thrombasthenia, Leukocyte Adhesion Deficiency Syndrome III, Fraser Syndrome, and Renal dysfunction-Cholestasis syndrome. Among them, Leber Congenital Amaurosis has the highest prevalence with 1/10000 and Co-enzyme Q deficiency (COQ2 gene) has the lowest prevalence with only 7 cases reported in the literature up to now. 142 embryos were biopsied and 89% of them were successfully diagnosed by PGD. In 16 cycles (94.7%) 1.6 embryos on average were transferred to the patients. Clinical pregnancy rate per embryo transfer (CPR) was 62.5% with an implantation rate (IR) of 48.1%. Live-birth rate per cycle, transfer and per patient were 41.2%, 43.8%, and 77.7%, respectively. Eleven babies were born from 7 full term pregnancies, while pregnancy is ongoing for one couple.
Limitations, reason for caution: High rate of consanguineous marriages in Turkey creates technical limitations during molecular setup of the PGD cases. It is harder to establish informative markers in consanguineous couples since most of the alleles are shared among the partners. To overcome this problem, high numbers of potential STR markers were screened during the setup procedures that at least 6 informative markers are obtained for each case.
Wider implications of the findings: Although some case reports are published on PGD of rare monogenic disorders, to the best of our knowledge this is the first study evaluating healthy live-birth outcome after PGD for very rare monogenic disorders from one center. The high efficiency of the diagnostic procedures and the high live-birth rate reported in this study indicates that PGD is highly successful when performed for couples with extremely rare monogenic disorders.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Istanbul Memorial Hospital.

[4]*Central Queensland University, Department of Biology, Queensland, Australia*
[5]*Reproductive and Genetic Hospital of CITIC Xiangya, Department of Obstetrics and Gynecology, Changsha, Hunan, China*

Study question: Although SNParray based preimplantation genetic testing (SNP-PGT) and next generation sequencing based preimplantation genetic testing (NGS-PGT) have began widely applied in clinical setting, but few data are available regarding the clinical outcome evaluation.
Summary answer: No significant difference of clinical outcome (including implantation rate, clinical pregnancy rate and miscarriage rate) can be found between SNP-PGT group and NGS-PGT group. However, we found NGS provided higher accuracy in embryonic imbalanced chromosomal segmental rearrangements and even can cover 98.7% ± 3.1% of the mitochondrial DNA (mtDNA).
What is known already: NGS shows great potential of providing more powerful and cost-effective tools for PGD/PGS. Previous studies have proven that aneuploidy and imbalanced rearrangements can be detected accurately by NGS. Here we present the systematic clinical evaluation of NGS based PGD/PGS.
Study design, size, duration: This was a retrospective study of 395 couples with indications to *in vitro* fertilization and preimplantation embryos testing treatment between October 2011 and December 2013, including chromosomal translocations, inversions, advanced maternal age and recurrent pregnancy loss. Couples are randomly divided into NGS and SNParray group.
Participants/materials, setting, methods: The study was performed at the Reproductive and Genetic Hospital of CITIC-Xiangya and BGI-Health, China. In total, 1,512 blastocysts were biopsied, with 1,058 blastocysts for SNParray test and 454 blastocysts for NGS test. The clinical outcomes were calculated and statistically analyzed respectively.
Main results and the role of chance: In NGS cycles, the implantation, clinical pregnancy per ET, ongoing pregnancy rate and miscarriage rates were 52.6% (60/114), 61.3% (49/80), 52.5% (42/80) and 14.3% (7/49). In SNP array cycles, the implantation, clinical pregnancy per ET, ongoing pregnancy rate and miscarriage rates were 47.6% (139/292), 56.7% (115/203), 48.3% (98/203) and 14.8% (17/115), respectively. There were no statistical difference between SNP-PGT and NGS-PGT ($P = 0.362$, $P = 0.480$, $P = 0.522$, $P = 0.934$).
Limitations, reason for caution: This study just technically prove NGS can accurately cover the mtDNA, preliminary we found the copy number of mtDNA have direct correlation between euploidy embryos and aneuploidy embryos but further data validation are required.
Wider implications of the findings: NGS based preimplantation genetic testing can achieve the same clinical outcome as SNParray-PGT, moreover, NGS can not only accurately detect the embryos genome but also be able to cover nearly 95% of the mtDNA. Mitochondria are very crucial for the energy production needed by cell biosynthetic, metabolic and physiologic process. In the near future mtDNA may act as an important factor to assist in selecting the more viable embryos to transfer.

Study funding/competing interest(s): Funding by national/international organization(s). This study was supported by grant from the Major State Basic Research Program of China (No. 2012CB944901), Shenzhen Birth Defect Screening Project Lab (JZF No. [2011] 861).
Trial registration number: NA.

P-604 Embryo genome profiling by single cell sequencing for preimplantation genetic diagnosis in a beta-thalassemia family

Y. Xu[1], X. Yin[2], S. Chen[2], X. Shen[1], G. Vajta[2], F. Wang[2], H. Jiang[2], W. Wang[2], X. Zhang[2], C. Zhou[1], J. Wang[2]
[1]*The First Affiliated Hospital of Sun Yat-sen University, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*
[2]*BGI-Shenzhen, BGI-Shenzhen, Shenzhen, China*

Study question: Is it feasible that embryo genome and haplotype to be analyzed by single-cell next generation sequencing (NGS) with comprehensive pre-implantation genetic diagnosis (PGD) of single-gene disorder, human leukocyte antigen (HLA) matching, sex and aneuploidy?
Summary answer: Full embryonic genome including genotypes and haplotypes can be obtained by single-cell next generation sequencing. Pre-implantation genetic diagnosis of Mendelian disorders, HLA-matching, sex and aneuploidy can be achieved comprehensively and accurately.
What is known already: Embryonic genome, including genotypes and haplotypes, contains important information for PGD. Beta-thalassemia is the most common group of monogenic disorders. PGD of single-gene disorders combining HLA-matching has emerged for couples of beta-thalassemia carriers. At delivery, the umbilical cord blood stem cell can be used to treat the affected sibling. During IVF-PGD, aneuploidy testing for embryos is necessary due to high incidence of embryonic chromosomally abnormalities. Sex information of embryos can be an indication as well.
Study design, size, duration: This is a retrospective study of PGD by NGS in a beta-thalassemia family. A couple with a beta-thalassemia daughter underwent IVF-PGD. Seven blastomeres were biopsied. Amniocentesis was performed for prenatal diagnosis. A normal female baby was born in July 2012. Each participant was provided informed consent with the institutional approval.
Participants/materials, setting, methods: A straightforward strategy to obtain full embryonic genome was developed for a beta-thalassemia carrier couple with a proband daughter. We carried out NGS for single blastomere cells, the family trio and amniotic fluid, and developed the pipeline for embryonic genome and haplotype phasing with comprehensive PGD.
Main results and the role of chance: We obtained embryo genome and haplotype by NGS. The accuracy for homozygous and heterozygous SNPs reached 99.62% and 98.39% according to amniotic fluid genome. Based on embryonic genomes, we performed comprehensive PGD. The proband sister contained a pathogenic mutation at rs7480526 in HBB gene. Genotype at rs7480526 of each embryo agreed with the haplotype. HLA-matching was analyzed according to haplotype. Haplotype of HLA genes for the transferred embryo agreed with the proband sister. Embryonic beta-thalassemia diagnosis and HLA-matching results were validated by Sanger sequencing. Embryonic aneuploidies were detected using the depth ratio of alleles in heterozygous genotypes. The transferred embryo was euploidy. Embryonic sexes were determined from heterozygosity of ChrX. The transferred embryo was female. Embryonic aneuploidies and sexes were validated by SNP-array.
Limitations, reason for caution: Embryo indels can be detected with accuracy about 89%. De novo mutations cannot be confirmed due to false positives in WGA. The cost of NGS for embryo genome would be relatively high currently. Embryo vitrification is needed recently. Ethical questions for PGD toward personal genome need to be discussed.
Wider implications of the findings: This is a retrospective study in a beta-thalassemia family for genetic diagnosis of pre-implantation embryo through whole genome, high-resolution variation detection at single cell level, and clinical models establishing for next generation sequencing application in PGD. It paves the way for PGD towards personal medicine.
Study funding/competing interest(s): Funding by national/international organization(s). This study was funded by the Laboratory of Shenzhen Birth Defect Screening Project (JZF No. [2011] 861 and JZF No. [2011] 862) and was approved by Shenzhen Municipal Commission for Development and Reform and Key Laboratory Project in Shenzhen (CXB201108250096A) and Key Laboratory of Cooperation Project in Guangdong Province (2011A060906007).

P-605 Association between blastocyst morphology and euploidy rates in different age groups analyzed by aCGH and SNP PGD

O. O. Barash[1], K. A. Ivani[1], N. Huen[1], S. C. Lefko[1], C. F. Mackenzie[1], L. N. Weckstein[2]
[1]*Reproductive Science Center of the San Francisco Bay Area, IVF Laboratory, San Ramon, U.S.A.*
[2]*Reproductive Science Center of the San Francisco Bay Area, Preimplantation Genetic Testing, San Ramon, U.S.A.*

Study question: Is it possible to predict the euploidy rate of a blastocyst cohort based on patient age and morphology of the embryos *in vitro*?
Summary answer: There is a strong association between blastocyst morphology and euploidy rates in all age groups. Euploidy rate varies significantly within the same age group depending on morphology of the blastocysts.
What is known already: The vast majority of aneuploidies in preimplantation embryos are of maternal origin (either meiotic or mitotic). The proportion of aneuploid embryos progressively increases with advanced maternal age. Previous studies proved that aCGH- and SNP-based preimplantation genetic testing are the most reliable techniques to determine the genetic status of embryos *in vitro*.
Study design, size, duration: A retrospective comparative study was performed between January 2013 and January 2015. 414 cycles of IVF treatment with PGD were included in the study: in 270 cases blastocysts were analyzed by SNP, and in 144 by aCGH PGD. 2146 embryos were analyzed for euploidy rates and blastocyst morphology.
Participants/materials, setting, methods: Morphology of blastocysts was evaluated using Gardner classification before trophectoderm biopsy. Embryos were divided into three groups based on blastocyst quality: good (AA/AB/BA), fair (BB), and poor (-C or C-) and into five groups based on maternal age (SART age groups).
Main results and the role of chance: Our data demonstrated a statistically significant difference ($p < 0.05$, $\chi^2 = 9.58$) in euploidy rates between good, fair, and poor quality embryos in all age groups. The biggest difference in euploidy rates between embryos with different morphology was identified among young (<38 year-old) patients: euploidy rate for good quality embryos was 71.3% (325/456), for fair quality embryos – 54.2% (352/650), and for poor quality embryos – 30.4% (7/23). The difference in euploidy rates between embryos with different morphology has a tendency to decrease with an increase in patient age. For the patients over 40 years old, the euploidy rate for good quality embryos was 37.2% (48/129), for fair quality embryos – 24.9% (59/237) and for poor quality embryos – 3.6% (1/28), $p < 0.05$, $\chi^2 = 6.12$. The association between euploidy rates and morphology of the embryos was assessed by identifying coefficients of linear regression: for good quality embryos $y = -5.2554x + 89.235$, for fair quality $y = -4.3348 + 69.094$, and for poor quality embryos $y = -2.4784 + 31.021$.
Limitations, reason for caution: Retrospective study and heterogeneity of patients included.
Wider implications of the findings: Reliable data about correlation between morphology and euploidy of the embryos will not only help healthcare providers create the best treatment strategy for the infertile couple but will also help patients make an informed decision about the necessity of PGD based on maternal age, quality and quantity of the embryos.
Study funding/competing interest(s): Funding by hospital/clinic(s) – none.
Trial registration number: NA.
Keywords: PGD, euploidy rate, embryo morphology

P-606 The physiological role of RNA methylation in the oocyte and embryo

L. M. Brayboy[1], G. Wessel[2]
[1]*Warren Alpert Medical School Brown University Women and Infants Hospital of Rhode Island, Obstetrics and Gynecology, Providence Rhode Island, U.S.A.*
[2]*Brown University, Molecular Biology Cell Biology and Biochemistry, Providence Rhode Island, U.S.A.*

Study question: What transcripts are methylated in the oocyte? How does RNA methylation affect oocyte and early embryo development? What is the fate of methylated transcripts in the oocyte?

Summary answer: N6-Methyl-adenosine (M6A) was detected in RNA from mice and knocking down (Kd) METTL3 (RNA methylase) and Alkbh5 (RNA demethylase) with morpholinos in the sea star oocyte did not alter oocyte maturation, fertilization, nor early cleavages. However, blastulation, gastrulation, and embryo motility are delayed compared to controls.
What is known already: Methylation of the N6 position of the adenosine is one of the most prevalent internal posttranscriptional modifications of polyadenylated mRNAs and long non-coding RNAs. Methylation is performed by METTL3, METTL14 and WTAP, while demethylation is accomplished by Alkbh5 and FTO. It has been shown that perturbation of IME4, homolog to METTL3 in *Drosophila*, leads to abnormal oogenesis and Alkbh5 deficiency is implicated in spermatogenic defects in mice.
Study design, size, duration: Experimental laboratory study which is currently ongoing.
Participants/materials, setting, methods: *Patiria miniata* (sea star) oocytes, CL57B6 oocytes, and deidentified discarded human oocytes from ICSI cycles at Women and Infants Hospital of Rhode Island. Morpholinos (MOs) to Alkbh5 and METTL3 were designed based on human sequences.
Main results and the role of chance: Ovaries from mice showed expression of m6A on an RNA dot blot. Sea star oocytes injected with MOs had normal maturation and fertilization. Blastulation, gastrulation, and embryo motility were significantly impaired in the METTL3 Kd as well as with Alkbh5 Kds compared to controls. *In vitro* transcripts made with 100% N6 methylated ATP for GFP and firefly luciferase are being tested following injection in the oocyte to establish the dynamics compared to non-methylated transcripts. In an effort to minimize the possibility of chance these experiments are being performed in triplicate and will be repeated in mouse and human oocytes.
Limitations, reason for caution: One of the limitations of this project is that human oocytes cannot be fertilized due to federal restrictions involving research with human embryos. Additionally, human oocyte donation for the express purpose of research is not yet allowable in our state so the human oocytes were discarded GV or MI.
Wider implications of the findings: RNA methylation may be an important posttranscriptional modification that can report the quality of oocytes and determine embryo progression. Our future work will examine differences in methylation between young and aged oocytes as well as patterns of methylation in the ovary over the reproductive lifespan.

P-607 Influence of GDF9 polymorphisms in follicular dynamics in patients undergoing *in vitro* fertilization

A. J. C. Meireles[1], J. P. Bilibio[2], E. De Conto[1], U. Matte[1], F. Nascimento[2], J. S. L. Cunha-Filho[1]
[1]*Universidade Federal do Rio Grande do Sul, Post Graduate Program, Porto Alegre, Brazil*
[2]*Clínica Pronatus, Reproductive Medicine, Belém, Brazil*

Study question: The objective of this study was to assess the influence of growth differentiation factor-9 (GDF9) polymorphisms in patients undergoing *in vitro* fertilization.
Summary answer: Polymorphisms in the GDF9 gene significantly influence oocyte development. The presence of mutant alleles 447C > T and 398C > G decrease the total number of mature follicles and the total number of oocytes collected from patients undergoing ovulation induction for *in vitro* fertilization (IVF).
What is known already: The role of oocyte-derived growth factors in either up- or down-regulating fertility is an exciting paradigm in reproduction biology. Factors such as GDF9 is known to influence the growth and depletion rates of follicles. Several genetic variants of GDF9 have recently been identified, and their correlations with premature ovarian failure suggest that these variants may contribute to aberrant follicular development and oocyte loss.
Study design, size, duration: A cross sectional prospective study was performed. The setting for this study was a fertility center with Sixty-seven women undergoing IVF treatments using r-FSH and recombinant GnRH antagonist protocol.
Participants/materials, setting, methods: We performed DNA extraction of peripheral blood, followed by polymerase chain reaction (PCR) to amplify the region of interest in the GDF9 gene. We sequenced four polymorphisms of GDF9 and analyzed their influences on patients undergoing IVF.
Main results and the role of chance: Women with the mutant allele 447C > T gene of GDF9 had a smaller number of follicles between 12 and 14 mm on the day of r-hCG administration (1.62 vs. 2.46, $P = 0.007$). In addition, women with the mutant allele 398C > G gene of GDF9 had a smaller number of follicles at least 17 mm on the day of r-hCG administration (4.33 vs. 6.49, $P = 0.001$), a smaller number of follicles between 12 and 14 mm on the day of r-hCG administration (1.42 vs. 2.25, $P = 0.017$), a lower number of follicles on the day of r-hCG administration (7.33 vs. 10.11, $P = 0.007$), and a lower number of total MII oocytes retrieved (5.38 vs. 8.84, $P = 0.017$).
Limitations, reason for caution: The limitation of our results is that we don't realized functional studies to validate the precise genetic mechanism involved in oocyte development.
Wider implications of the findings: This finding shows that in addition to playing a role in the early stages of folliculogenesis, this member of the transforming growth factor-β (TGFB) family also has an important influence on the final stage of oocyte development.
Study funding/competing interest(s): Funding by hospital/clinic(s). We are grateful for the financial support provided by Fundo de Incentivo à Pesquisa (FIPE), Hospital de Clínicas de Porto Alegre, Brazil and Clínica Pronatus – Medicina Reprodutiva, Belém Brazil.
Trial registration number: The study was approved by the Ethics Committee of the Hospital de Clínicas de Porto Alegre *n*: 14/0070.
Keywords: GDF9, polymorphism, oocyte, follicle retrieval, FIV

Abstract withdrawn by the author

P-609 First clinical applications of preimplantation genetic diagnosis for b-thalassemia combined with preimplantation genetic screening on blastocysts from fresh and vitrified oocytes, after next generation sequencing

S. Chamayou[1], M. Sicali[1], A. Guglielmino[1]
[1]*Unità di Medicina della Riproduzione U.M.R. Soc.Coop a.r.l., Laboratory director, Sant'Agata Li Battiati, Italy*

Study question: The present study reports the first clinical applications of preimplantation genetic diagnosis (PGD) for b-thalassemia combined with the diagnosis of aneuploidies (PGS) on blastocysts produced from fresh and vitrified oocytes and using next generation sequencing (NGS).
Summary answer: Applying NGS technology, it is possible to diagnose simultaneously aneuploidies and hemoglobinopathies. The use of fresh oocytes together with vitrified oocytes increases the number of available embryos to transfer.
What is known already: Until now the clinical application of PGD for single cell disease and the PGS on embryos have been applied separately. On the other side, the NGS was applied and previously validated for aneuploidies diagnosis on embryo diagnosis.
Study design, size, duration: The diagnosis of b-globinopathies and aneuploidies were performed from trophectoderm cells of blastocysts produced from fresh and vitrified/warmed oocytes in 7 infertile b-globin mutation carriers. The study was performed on a period of 4 months.
Participants/materials, setting, methods: Few trophectoderm cells were removed on day 5–6 blastocysts produced from fresh and vitrified/warmed oocytes post-ICSI. Whole genome amplification was performed on 39 samples. Sample libraries were prepared with respectively in-home Ion AmpliSeq HBB panel and Ion plus fragment library kit. Enriched barcoded-samples libraries were sequenced on Ion PGM (Life Technology).
Main results and the role of chance: 25 blastocysts from fresh and 14 blastocysts from vitrified/warmed oocytes were produced. 100% of the samples

were amplified after whole genome amplification. B-globin gene analysis and chromosomal status were completed for 37 samples. It was possible to confirm that cells belonged to embryos because of SNP and STR analysis. Respectively 2, 1 o no b-globin mutation were diagnosed in 9, 16 and 12 embryos. Fifteen blastocysts were euploid. After overall analysis, 10 embryos were available for embryo-transfer: 6 from fresh oocytes and 4 from vitrified/warmed oocytes. Seven embryos were transferred after thawing. Four clinical pregnancies were obtained (implantation rate: 57%). PGD and PGS results were confirmed after prenatal diagnosis.

Limitations, reason for caution: The first clinical results after PGD and PGS based on whole genome amplification and NGS and performed on blastocyst produced from fresh and vitrified/warmed oocytes are encouraging. Nevertheless further randomized controlled trial studies are requested specially for PGS efficacy to confirm clinical efficacy.

Wider implications of the findings: The present study shows that the single technology Next Generation Sequencing can be applied to diagnose together chromosomal abnormalities and single cell diseases. In case of limited ovarian response it is possible to combine the diagnosis of embryos from fresh and vitrified embryos. This option allows the couple to limit the cost of genetic analysis and increases the number of available embryos to transfer.

Study funding/competing interest(s): Funding by hospital/clinic(s) – unità di medicina della riproduzione – istituto HERA.

Trial registration number: No rct.

Keywords: preimplantation genetic diagnosis, preimplantation genetic screening, next generation sequencing, oocyte vitrification, clinical outcomes

P-610 Day 3 biopsy and day of transfer?

M. H. Fakih[1], A. Fakih[1], M. Elshmoury[1], M. Chawla[1], J. P. Parkash[1], P. Devroey[1]

[1]*Fakih IVF, Reproductive Medicine, Dubai, United Arab Emirates*

Study question: Is their a difference in ongoing pregnancy rate between a day three transfer and a day five transfer after a day three biopsy and FISH analysis?

Summary answer: So far the ongoing pregnancy rate is 62% after a day three transfer compared to 45% after a day 5 transfer.

What is known already: Clinicians are shying away from day three biopsies with FISH analysis and moving towards trophectoderm biopsy with microarray. Day 3 transfers after day 3 biopsy has never been performed.

Study design, size, duration: Randomized controlled prospective trial. 268 patients. September 1, 2014 and the study is still ongoing. Computer randomized. Blinded to the clinician. All patients with at least four embryos on day of biopsy were included.

Participants/materials, setting, methods: All patients undergoing PGS at Fakih IVF Dubai and Abu Dhabi branches.

Main results and the role of chance: Group sample sizes of 134 in group one and 134 in group two to detect a difference between the group proportions of 0.1700. The proportion in group one (Day three transfer) is assumed to be 0.4500 under the null hypothesis and 0.6200 under the alternative hypothesis. The proportion in group two (Day 5 transfer) is 0.4500. The test statistic used is the two-sided *Z* test with pooled variance. The significance level of the test was targeted at 0.0500. Primary endpoint is ongoing pregnancy rate so far we have 87 patients: Group (day 3 transfer) 43 patients: pregnancy rate per embryo transfer 24/39 or 61.5 percent. (1 patient biochemical pregnancy counted as negative and 4 patients no embryo transfer). Group (day 5 transfer) 45 patients: pregnancy rate per embryo transfer 20/44 or 45.5 percent. (2 patients biochemical pregnancy counted as negative and 1 patient no embryo transfer).

Limitations, reason for caution: The study is still ongoing and we have to wait for the final results.

Wider implications of the findings: Reintroduction of blastomere biopsy with FISH analysis. Apparent higher pregnancy rate than previously reported in the literature with day 3 biopsy and day 5 transfers. It seems that removing one cell from a blastomere does not damage the embryo and decrease pregnancy rate as previously postulated. This finding suggests that it is the prolonged interaction of a biopsied embryo with the culture media that damages the embryo.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Fakih IVF.

Trial registration number: Pending.

Study question: Is there any effect of the *FSHR* polymorphism -29 G > A on ovarian response in females undergoing IVF/ICSI?

Summary answer: No significant association was detected between the *FSHR* polymorphism -29 G > A and ovarian response in females undergoing IVF/ICSI.

What is known already: *FSHR* has a major role in controlling FSH action. Altered *FSHR* expression has been proposed to impact on ovarian response. A single nucleotide polymorphism -29 G > A in the 5' untranslated region of *FSHR* is associated with altered transcriptional activity. Four previous studies have determined a significant correlation between *FSHR* (AA) genotype and poor response to IVF.

Study design, size, duration: In an observational study, we genotyped *FSHR* -29 G > A in 690 women (578 women from a tertiary referral centre for reproductive medicine in Manchester and 112 women from Mansoura fertility centre in Egypt), undergoing their first cycle of controlled ovarian hyper-stimulation for IVF/ICSI between March 2009 and December 2013.

Participants/materials, setting, methods: Blood tests were taken on day 3 of the cycle for assessment of baseline hormones and DNA extraction. Genotypes were determined using Taqman allelic discrimination assay. Correlation analysis was performed to assess effect of *FSHR* genotypes on primary outcome of response (number of oocytes retrieved and gonadotropin dose).

Main results and the role of chance: There is no evidence of any statistically significant difference (p value <0.05) in the number of oocytes retrieved and gonadotropin dose used between individuals with different genotypes.

Limitations, reason for caution: A larger sample size would be required in order to determine if the *FSHR* -29 G > A genotype has a small effect on ovarian response.

Wider implications of the findings: As a result of our finding, the *FSHR* -29 G > A polymorphism should not be used in the individualization of the treatment protocol for women undergoing IVF/ICSI.

P-612 The role of transcript expression levels of nuclear encode (TFAM) and mitochondrial encoded (MT-CO1) genes in single human oocytes maturation from women with pcos

A. Allahveisi[1], M. Ghaffari Novin[2], M. J. Rezaei[1], B. Nikkhoo[1], M. Rezaei[1], F. Farhadifar[1], E. Yousefian[3]

[1]*Kurdistan University of Medical Sciences, Faculty of Medicine, Sanandaj, Iran*

[2]*Shahid Beheshti University of Medical Sciences, Faculty of Medicine, Tehran, Iran*

[3]*Isfahan University of Medical Sciences, Faculty of Medicine, Isfahan, Iran*

Study question: Does nuclear encoded (TFAM) and mitochondrial encoded (MT-CO1) genes in single human oocyte maturation difference from patients with polycystic ovarian (PCOS) compared with normal women?
Summary answer: quantification of the relative transcript abundance indicated that Different expression levels of TFAM, MT-CO1 influence human oocyte maturation in patient women with PCOS.
What is known already: Polycystic ovary syndrome (PCOS) is the most common female endocrinopathy which cause of infertility due to anovulation. Prevalence of PCOS is approximately of 15–20% of reproductive-aged women. Patients with polycystic ovarian syndrome (PCOS) have higher miscarriage rates. It is suggested that this is caused by a lower rate of mature oocytes, and a lower quality of embryos**.** Mitochondria play a critical roles in oocyte maturation. mitochondria have their own genome, which is increased during oocyte maturation. The mitochondrial transcription factor A (TFAM) controls the transcription of mtDNA and regulates the mtDNA-copy number. MT-CO1 is a respiratory chain protein encoded by heavy strand mtDNA. therefore, its transcript level may be an important role for maintaining ATP production.
Study design, size, duration: A cross-section observational study was performed of 64 Oocytes at the metaphase II (MII) stage obtained from women with PCOS as compared to 11 infertile women with male factor who undergoing IVF/ICSI protocol between January 2012 and November 2013.
Participants/materials, setting, methods: Mitochondrial related transcript expression levels of TFAM, MT-CO1 genes were performed by single-cell Taqman real time PCR-based assay.
Main results and the role of chance: For the first time, Taqman RT-qPCR analyses using single oocytes from clinical patients showed that the transcript expression levels of TFAM and MT-CO1 were significantly lower in patient women with PCOS compared with normal women ($p = 0.037$ and $p = 0.001$ respectively).
Limitations, reason for caution: The limitation of this study was small sample size which make it difficult to determine protein by western blotting and proteomics. Therefore, further studies are needed in a large sample size to determine protein levels of these genes in oocytes from women with PCOS.
Wider implications of the findings: Lower transcript expression levels of (TFAM, MT-CO1) genes in metaphase II (MII) stage of oocytes from women with PCOS probably leads to reduction of oocyte quality. These results probably enlighten a new therapeutic approaches for optimizing oocyte quality in treatment of women with PCOS.
Study funding/competing interest(s): Funding by University(ies) – Shahid Beheshti University of medical sciences.
Trial registration number: 1391-1-91-9947.

P-613 Comparison of the live birth rate between preimplantation genetic diagnosis and natural conception in patients with recurrent pregnancy loss associated with translocation

S. Ikuma[1], T. Sato[2], M. Sugiura-Ogasawara[2], M. Nagayoshi[1], A. Tanaka[1], S. Takeda[3]
[1]*Saint Mother Obstetrics and Gynecology Hospital, Fukuoka, Kitakyushu, Japan*
[2]*Department of Obstetrics and Gynecology Nagoya City University Graduate School of Medical Sciences, Aichi, Nagoya, Japan*
[3]*Department of Obstetrics and Gynecology Juntendo University Graduate School of Medicine, Tokyo, Bunkyo, Japan*

Study question: Can preimplantation genetic diagnosis (PGD) improve the live birth rate, as compared to natural conception, in patients with recurrent pregnancy loss (RPL) associated with translocation?
Summary answer: While PGD significantly prevented further miscarriages, there was no difference in the live birth rate.
What is known already: The reported live birth rate in patients undergoing PGD is in the range of 27–54%, and that in patients undergoing natural conception is in the range of 37–66% at first and 68–86% cumulatively. However, no prospective study has been carried out to compare the live birthrates in patients matched for age and number of previous miscarriages undergoing PGD and choosing to have natural conception.
Study design, size, duration: This cohort consisted of 126 Japanese patients with RPL associated with translocation. The 52 patients who desired natural conception and 74 patients who wished to undergo PGD after genetic counseling, between August 2003 and November 2013. The subsequent pregnancies of all the patients were followed up until July 2014.
Participants/materials, setting, methods: The live birth rate, cumulative live birth rate, miscarriage rate were compared between 37 patients undergoing PGD who were matched for age with the natural conception group, and 52 patients who did not undergo PGD and selected natural conception. PGD was performed by fluorescence in situ hybridization (FISH) analysis.
Main results and the role of chance: The live birth rates at the first trial of PGD and the first natural pregnancy after ascertainment of the carrier status were 37.8% and 53.8%, respectively (odds ratio 0.52, 95% confidence interval 0.22–1.23). The cumulative live birth rates were 67.6% and 65.4%, respectively, in the groups undergoing and not undergoing PGD. The time to pregnancy was similar in both groups. The mean number of further miscarriages till a live birth in the PGD (0.22 ± 0.42) group was significantly lower than that in the natural conception group (0.58 ± 0.78, $p = 0.012$). PGD could reduce miscarriage rate significantly. The prevalence of twin pregnancy was significantly higher in the PGD group. The cost of PGD was 6857 € per patient.
Limitations, reason for caution: Comparison was performed between 37 patients aged ≤34 years undergoing PGD and the 52 patients conceiving naturally, because the mean age of the patients undergoing PGD was significantly higher. It remained unclear whether PGD had any effect in elderly patients.
Wider implications of the findings: Information that there was no difference in the live birth rate when PGD and natural conception was compared. Couples should be fully informed of the similar live birth rates, similar time to pregnancy, the advantages of PGD such as the reduction in the miscarriage rate, the disadvantages of PGD such as the higher cost, and the advantages of natural pregnancy, such as avoidance of IVF failure.
Study funding/competing interest(s): Funding by hospital/clinic(s). This study was supported by a Grant-in-aid for Scientific Research from the Ministry of Health, Labour and Welfare, and the Ministry of Education, Culture, Sports, Science and Technology of Japan. All the authors declare that they have no conflict of interests.
Trial registration number: NA.

P-614 A 24-chromosome aneuploidy detection of 100 embryos in PGS by means of NGS

V. Penacho[1], S. Gonzalez-Reig[2], L. A. Alcaraz[3], B. Ramos[4], S. Rogel[5], J. A. Horcajadas[6], J. Aizpurua[7]
[1]*Bioarray, R&D + i Manager, Elche, Spain*
[2]*Bioarray, PGS/PGD Manager, Elche, Spain*
[3]*Bioarray, Founding Partner and Technical Manager, Elche, Spain*
[4]*IVFSPAIN, Embryology Manager, Alicante, Spain*
[5]*IVFSPAIN, Medical Director, Alicante, Spain*
[6]*Pablo de Olavide University, Genetics (Full Associated Professor), Seville, Spain*
[7]*IVFSPAIN, CEO and Managing Director, Alicante, Spain*

Study question: Can the Next-generation sequencing (NGS) platform Ion-Torrent™ along with low-pass whole genome sequencing, be used reliably to evaluate, in terms of Preimplantation Genetic Screening (PGS) for aneuploidy detection, many biopsied trophectoderm cells in order to confirm which euploid embryos were ready-to-transfer in an IVF cycle?
Summary answer: This validation study had provided a 100% consistency for aneuploidy screening in clinical PGS cycles by NGS in contrast to well-established microarray-based comparative genomic hybridization (aCGH), and the subsequent good prognosis for pregnancy from IVF.
What is known already: PGS involves the genetic study of the embryo's genome to determine its chromosomal arrangement, prior to euploid embryos selection and subsequent implantation in IVF. Early fluorescent in-situ hybridization (FISH) showed limitations in genome coverage that were solved by aCGH, a PGS method with demonstrated accuracy. In this way, all the chromosomes can be completely screened in a genome-wide DNA sequencing in terms of NGS data providing an alternative approach for detecting copy number variations (CNV).

Study design, size, duration: This prospective, double-blinded trial involved genetic testing with both NGS and array-CGH techniques of 100 blastocysts from 29 patients (median age 40 ± 5.57 years) recruited in a total of 30 clinical IVF cycles at the fertility clinic IVF-Spain (Alicante) from May 2013 to December 2014.
Participants/materials, setting, methods: After oocyte insemination, 100-blastocyst trophectodermal biopsy was performed on day 5. Whole genome amplified DNA (PicoPlex® technique) followed both NGS and aCGH. CNV analysis was performed with BlueFuse Multi software (aCGH) and Ion Reporter™ Software v4.2. (NGS), which determined the ploidy status with 0.01× read coverage.
Main results and the role of chance: An amount of 42 of 100 embryos were euploid. Thirteen (46.4%) of 28 embryos transferred achieved a successful pregnancy. Four (30.8%) patients have already given birth and 7 (53.8%) pregnancies are still in progress; 2 (15.4%) of them are *dizygotic twin pregnancies.* In respect to aneuploid embryos, 15 of 58 (25.9%) presented trisomies, 20 (34.5%) monosomies, 9 (15.5%) full gain and losses, 3 (5.2%) were chaotic and 6 (10.3%) had partial imbalances. Along the whole process, no technical failures, false positives and negatives were detected. There was a significant concordance (98%; 98/100; 95% confidence interval [95% CI]: 94.75–100) between aCGH and NGS results, including balanced translocations. The two discordant results showed a monosomy on one chromosome by aCGH, while the NGS screening was highly accurate.
Limitations, reason for caution: Although reliability of Next-generation sequencing (NGS) platform Ion-Torrent™ along with low-pass whole genome sequencing for aneuploidy detection and the subsequent higher pregnancy outcomes, further data in a randomized controlled trial are required in order to achieve a broad-based clinical application.
Wider implications of the findings: This supposes an opportunity to model the possible NGS throughput capacity of a single instrument and one chip in both PGS and even PGD (Preimplantational Genetic Diagnosis). In just one biopsy, a combined 24-chromosome aneuploidy and single-gene disorders detection by means of NGS is assumed. Couples could have access to a more affordable PGS/PGD service. Definitively, a higher probability of implantation is achieved and thus drastically improve the IVF success rates.
Study funding/competing interest(s): Funding by national/international organization(s) – Funding by commercial/corporate company(ies). Funding by national/international organization(s): The Torres Quevedo Program from the Spanish Ministry of Economy and Competitiveness, with specific projects PTQ-12-05687 for Penacho, V., PTQ-13-06028 for González-Reig, S., and PTQ-11-04960 for Alcaraz, L. P-615 Warming-biopsy-PGS-revitrification-rewarm-ET: a viable strategy for patients who want to minimize the number of frozen cycles before becoming pregnant

O. Oliana[1], C. F. L. Hickman[1], D. Gwinnett[1], T. Wilkinson[1], A. Carby[2], G. Trew[3], S. Lavery[3]
[1]*Boston Place Clinic, Embryology, London, United Kingdom*
[2]*Boston Place Clinic, Clinical, London, United Kingdom*
[3]*IVF Hammersmith, Clinical, London, United Kingdom*

Study question: Do the benefits outweigh the risks for the strategy of warming, biopsy and re-vitrification to allow for Pre-Genetic Screening (PGS) of embryos currently in storage?
Summary answer: The case studies exemplified how this strategy benefited patients with numerous cryopreserved embryos. Knowing the genetics of cryopreserved embryos may remove the need for patients to undergo multiple unsuccessful cycles, avoiding unnecessary financial and emotional burden. To reduce the risks associated with this strategy, an excellent cryopreservation program is required.
What is known already: PGS of embryos has been demonstrated to be a useful tool for embryo selection. Improvements in cryopreservation survival and implantation rates have demonstrated a reduction in the risk bestowed on an embryo due to vitrification compared to previous cryopreservation techniques. Re-cryopreserving embryos has been demonstrated to not compromise embryo viability by a number of publications (Farhat et al., 2001; Smith et al., 2005, Sheehan et al., 2006, Hashimoto et al., 2007, Kumasako et al., 2009).
Study design, size, duration: Four case reports involving PGS of surplus embryos. Patients A, B, C and D (aged 35, 34, 37 and 29 respectively) had 6, 9, 8 and 10 surplus blastocysts cryopreserved (COOK or Kitazato vitrification protocols). Patients had 1, 3, 13 and 2 previous embryo transfers (respectively) with or without implantation.
Participants/materials, setting, methods: Embryos were warmed using the same warming protocol they were vitrified with and the trophectoderm biopsied after warming. Biopsies were tubed and analysed with array-CGH. Blastocysts were re-vitrified with Kitazato-Cryotop Vitrification system. Normal embryos were transferred in a subsequent Frozen Embryo Replacement Cycle (FERC) where embryos were re-warmed using Kitazato.
Main results and the role of chance: Patient A: All six embryos were euploid. Patient returned for a FERC where a single embryo was warmed and transferred leading to a single foetal heart. Patient B: None of the embryos were diagnosed as euploid. Patient returned for a fresh cycle with PGS analysis instead of having a FERC. Six embryos were euploid and the patient is currently being prepared for a FERC for a single euploid embryo transfer. Patient C: All 8 embryos were diagnosed as aneuploid. Patient was advised to proceed with egg donation. Patient D: After two miscarriages following eSET, surplus embryos were analysed with PGS and 3 embryos were euploid. The patient is currently being prepared for a FERC cycle for a single euploid embryo transfer.
Limitations, reason for caution: These case studies demonstrate how re-vitrification can be used as a strategy for patients who have large numbers of embryos already frozen and did not have the opportunity to perform PGS before freezing to benefit from PGS. Refreezing does carry risks and preference should be to perform biopsy before cryopreservation.
Wider implications of the findings: Case study A demonstrated that embryos re-vitrified in our cryopreservation programme are viable. Case Studies B, C and D demonstrated that this strategy saved the patient having to undergo numerous FERCs with negligible chance of success, protecting the patient from considerable financial and emotional affliction.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Boston Place Clinic.
Trial registration number: NA.

P-616 Carrier testing for twelve common severe recessive pediatric diseases by comprehensive targeted sequencing assay in Chinese population

Y. T. Yi[1], S. M. Zhao[1], T. Liu[1], Y. Song[1], Y. Zh Shan[1], S. A[1], X. Yi[1]
[1]*BGI-Tianjin, Binhai Genomics Institute, Tianjin, China*

Study question: To develop an efficient method for carrier status testing for common severe recessive pediatric diseases.
Summary answer: Carrier screening by next generation sequencing together with other conventional assay made available to the general population could reduce the incidence of severe recessive pediatric diseases even causing by complicated mutations.
What is known already: Carrier screening for a specific disease, for several diseases with high frequency in some region or for several hundreds diseases by next generation sequencing had been reported previously. Identifying carrier persons and couples can provide them with a variety of reproductive options. A comprehensive assay for common severe recessive pediatric disease genes can be useful to assess carrier burden for these diseases in China.
Study design, size, duration: YH genome DNA sample and 100 samples with mutation identified were used for evaluate the power of mutation detection. And then carrier screening was performed for a total of 523 asymptomatic adults including two groups with associated family history or not with.
Participants/materials, setting, methods: All exons and selected intergenic and intronic regions of 15 target genes were enriched by hybrid capture, sequenced by next-generation sequencing (NGS), analyzed with bioinformatics software, and reviewed evidence with stringent rules. Complementary testing also was designed to cover some hot mutations in technical limitation of NGS.
Main results and the role of chance: In the 101 validation samples, the average depth for the targeted regions was more than 200 fold, with 99% coverage.

The mutation detection had ~98% sensitivity and ~100% specificity for substitution, small insertion/deletion, and gross deletion. In 438 individuals with non family history, the average genomic carrier burden for deleterious mutations was 0.19, and about 18% carried at least one deleterious mutations. For the high reproductive risk in this group, we found one carried a deleterious mutation on X-linked recessive genes in 282 females, but none was match in autosomal recessive genes in 100 couples. And in the 85 individuals with family history about the 12 diseases, the average genomic carrier burden was up to 0.66, and about 56% carried at least one deleterious mutations.

Limitations, reason for caution: This screening methods is not able to distinguish two *SMN1* copies on one chromosome (in *cis* configuration) or on two chromosome (in *trans* configuration), and some complicated rearrangement mutations of CYP21A2 can not be detected. For the two diseases, the mutations included in the carrier testing is limited.

Wider implications of the findings: This targeted sequencing assay can used to evaluate the screening program in China for control of common severe recessive pediatric diseases in the population of conception or pre-conception couples.

Study funding/competing interest(s): Funding by national/international organization(s). Tianjin Municipal Science and Technology Special Funds for Enterprise Development.

Trial registration number: NA.

P-617 Human ART culture media influence the epigenetic pattern of Lit1 in mouse preimplantation embryos

K. Schulte[1], J. Ehmcke[2], S. Schlatt[1], M. Boiani[3], V. Nordhoff[1]

[1]*University Hospital of Muenster, Centre of Reproductive Medicine and Andrology, Münster, Germany*

[2]*University of Muenster, Central Animal Facility of the Medical Faculty, Münster, Germany*

[3]*Max-Planck Institute, Max-Planck Institute for Molecular Biomedicine, Münster, Germany*

Study question: Do different human ART culture media have an effect on the methylation status of maternally imprinted genes in murine pre-implantation embryos?

Summary answer: The epigenetic profile of the maternally imprinted gene *Lit1* is changed during in-vitro-culture (IVC) of murine pre-implantation embryos using KSOM(aa) and the human sequential culture media HTF and Multiblast (Irvine Scientific, Bruckberg, Germany), but not ISM1 and Blast Assist (Origio, Berlin, Germany) compared to the *in vivo* control.

What is known already: In ART cycles pre-implantation embryos are cultured at a vulnerable growth phase in an artificial environment. We have shown that different human embryo culture media have an impact on the developmental potential of pre-implantation embryos in mice. During *in vitro* culture epigenetic profiles of imprinted genes change which may result in epigenetic diseases. It has been proposed that ART children carry higher risks of genomic imprinting disorders.

Study design, size, duration: For methylation analysis we used 248 mouse zygotes, cultured until 4.5 days post coitum (dpc) either in two different human sequential media (ISM1/Blast Assist or HTF/MultiBlast) or in KSOM(aa) (*in vitro* control). Blastocysts obtained from the uterus on dpc 3.5 served as *in vivo* control.

Participants/materials, setting, methods: Per group 6 to 10 superovulated female mice (B6C3F1, 6–8 weeks) were mated with C57Bl/6 males. DNA was isolated from *in vivo* and *in vitro* blastocysts and inner cell masses (ICMs), which were obtained via immunosurgery. PCR and pyrosequencing were conducted for two maternally imprinted genes (*Mest*, *Lit1*).

Main results and the role of chance: Methylation levels for *Lit1* did not differ significantly between individual blastocysts of the HTF/MultiBlast group and the *in vitro* control (HTF/MultiBlast: 43.44 ± 11.80% $N = 25$; *in vitro*: 43.01 ± 18.03% $N = 23$). For *Mest* we found lower methylation levels compared to *Lit1*, differences between the treatment groups were not significant (HTF/MultiBlast: 38.44 ± 29.49% $N = 8$; *in vitro*: 31.59 ± 16.20% $N = 44$). However, in individual ICMs the methylation level for *Lit1* in the ISM1/BlastAssist group and *in vivo* control was significantly higher compared to the HTF/MultiBlast and *in vitro* group (ISM1/BlastAssist: 61.67 ± 9.1% $N = 15$; *in vivo*: 56.64 ± 7.99% $N = 12$; HTF/MultiBlast: 42.43 ± 12.21% $N = 18$; *in vitro*: 46.66 ± 13.64% $N = 47$; $p \leq 0.0001$). Again, methylation levels for *Mest* were lower compared to *Lit1*, differences between the treatment groups were not significant (HTF/MultiBlast: 28.32 ± 11.74% $N = 17$; *in vitro*: 33.46 ± 11.84% $N = 26$; *in vivo*: 38.69 ± 16.02% $N = 13$).

Limitations, reason for caution: This was an experimental study using a mouse model. Results cannot be directly transferred to the human situation. Still, our study allows indirect assessment of whether the development of pre-implantation embryos is affected by the use of different culture media.

Wider implications of the findings: Analysis of whole individual blastocysts showed methylation levels of 30–40% for *Mest* and *Lit1*, which is in line with previous findings. However the obtained values show a high heterogeneity. Values obtained for the ICMs are more homogeneous and the epigenetic profile is significantly different between the experimental groups. Therefore analysis of individual ICMs provides a closer insight into epigenetic mechanisms, which could be linked to metabolic changes during pre-implantation development of murine embryos.

Study funding/competing interest(s): Funding by University(ies) – University of Muenster medical school IMF grant No. 11 12 12.

Trial registration number: NA.

P-618 Meiotic segregation analyses of reciprocal translocations in sperm and embryos: no support for predictive value regarding PGD outcome

K. Haapaniemi Kouru[1], H. Malmgren[1], I. White[1], A. Rodriguez Sanchez[1], E. Syk Lundberg[1]

[1]*Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden*

Study question: Is there a correlation between the number of balanced sperm and the number of chromosomally balanced embryos during PGD and could a sperm fluorescence in situ hybridisation (FISH) analysis prior to preimplantation genetic diagnosis (PGD) predict the outcome?

Summary answer: We found that the proportion of balanced sperm was much higher than the number of balanced embryos during PGD, without any linear correlation.

What is known already: Previous studies have suggested that men with more than 60% unbalanced sperm has a poor reproductive prognosis and that there is a linear correlation between the proportion of unbalanced sperm and the proportion of unbalanced embryos.

Study design, size, duration: Prospective cohort study. Ten male reciprocal translocation heterozygotes were included. We analysed 1000 sperm from each patient and between 3 and 29 embryos from the total of PGD cycles that the couples went through. Each couple went through 1–4 PGD cycles for a period of up to 4 years.

Participants/materials, setting, methods: Ten male translocation heterozygotes that went through PGD at the Stockholm PGD centre at Karolinska University Hospital. FISH analysis of sperm and embryos was performed with the same DNA probes.

Main results and the role of chance: The most common segregation mode in the whole sperm count was alternate (51.5%) followed by adjacent 1 (18%), adjacent 2 (13%), 3:1 (13%), 4:0 (0.5%) and other 4%. The total number of embryos was 160 and the segregation modes were as follows; Alternate 21%, Adjacent 1 23%, Adjacent 2 13%, 3:1 20%, 4:0 1% and other 22%. We computed the equation suggested with our data in order to predict the proportion of abnormal embryos in our cohort, and compared the results to the actual outcome. No reliable linear correlation between the levels of unbalanced sperm and unbalanced embryos was found. Four out of ten couples achieved a pregnancy and these translocation heterozygotes had a level of balanced sperm between 28 and 67%.

Limitations, reason for caution: The number of patients included is low and the difference in the number of counted cells between sperms and embryos may be a factor that affected the outcome.

Wider implications of the findings: Our results indicate that a sperm FISH analysis prior to PGD is not a reliable predictor of the PGD outcome. PGD is a valuable reproductive alternative for translocation heterozygotes with reproductive problems and should be offered to these couples.

Study funding/competing interest(s): Funding by national/international organization(s). This work was supported by grants from the Swedish Medical Research Council and the Stockholm County Council.

Trial registration number: NA.

Study question: Is fluorescence in situ hybridization based preimplantation genetic diagnosis (FISH-PGD) more cost-effective than single nucleotide polymorphism (SNP) array based strategy for young translocation carriers undergoing day 5 or 6 trophectoderm biopsy?
Summary answer: For young translocation carriers (age ≤35), D5 FISH-PGD generated higher clinical pregnancy than D3 FISH-PGD, and is equivalent to D5 SNP-PGD.
What is known already: D3 FISH-PGD is gradually replaced by comprehensive chromosome screening (CCS) for translocation carriers. But CCS technique also has some disadvantages, such as more expensive and uncertainty of the minute chromosome segment abnormality, especially the segment abnormality is *de novo*. The incidence of aneuploidy in embryo is increased with the advanced maternal age. Trophectoderm biopsy on D5 decreases risk of embryo damage compared with D3 biopsy.
Study design, size, duration: This was a retrospective study for 1338 chromosome translocation carriers with the female age under 35 years old, who were treated by D5 FISH-PGD between November 2012 and August 2014, D3 FISH-PGD between January 2005 and October 2011, and D5 SNP array-PGD between November 2011 and October 2014.
Participants/materials, setting, methods: The study was set at the Reproductive and Genetic Hospital of CITIC-Xiangya, China. Totally 1338 couples were recruited, including 447 couples treated by D5 FISH-PGD, 427 by D3 FISH-PGD and 464 by D5 SNP array-PGD. 4115 8-cell embryos and 4143 blastocysts were biopsied with balanced embryos being transferred.
Main results and the role of chance: Reliable results obtained in D5 FISH-PGD, D3 FISH-PGD, and D5 SNP-PGD were 97.0% (2092/2156), 90.1% (3707/4115) and 95.87% (1905/1987), respectively. In D5 FISH-PGD group, the proportions of normal/balanced embryos, clinical pregnancy rate and early miscarriage rate were 59.59%, 66.67% and 15% respectively for Robertsonian translocation carriers (ROBs), and 35.41%, 52.45% and 14% respectively for reciprocal translocation carriers (RECs). In D3 FISH-PGD group, 31.86%, 41.60% and 12% respectively were for ROBs, and 16.62%, 41.87% and 15% respectively were for RECs. In D5 SNP-PGD group, were 44.79%, 73.17% and 10% respectively were for ROBs, and 31.12%, 55.0% and 19% respectively were for RECs. D5 FISH-PGD was significantly better than D3 FISH-PGD in clinical pregnancy rate; and no significant difference exists compared with D5 SNP-PGD.
Limitations, reason for caution: There is a chance of selective bias due to not a RCT analysis. The final outcomes of D5 FISH-PGD and D5 SNP-PGD have not been obtained as the late pregnancy loss may occur. We cannot exclude differences between the final data and the data in the present submitted abstract.
Wider implications of the findings: The adoption of FISH-PGD combined with D5 or D6 trophectoderm biopsy and FET is an alternative approach for young translocation carriers. Due to the high cost for SNP-PGD, the couples with relative poor economic conditions may benefit from this strategy.
Study funding/competing interest(s): Funding by national/international organization(s). This work was supported by a grant from the Major State Basic Research Development Program of China (No. 2012CB944901) and National Science Foundation of China (No. 81222007). The authors have no competing interests to declare.

P-620 The origin and significance of additional aneuploidy events in couples undergoing preimplantation genetic diagnosis for translocations by array comparative genomic hybridisation

H. Ghevaria[1], S. SenGupta[1], P. Serhal[2], J. Delhanty[1]
[1]*University College London, Institute for Womens Health UCL Centre for PGD, London, United Kingdom*
[2]*The Centre for Reproductive and Genetic Health, The New Wing Eastman Dental Hospital, London, United Kingdom*

Study question: To what extent do the aneuploidies that occur in addition to the translocation imbalances in embryos from carriers of translocations undergoing PGD by aCGH persist in the embryo? Do these additional abnormalities have a meiotic or mitotic origin?
Summary answer: From a total of 127 aneuploidy events seen on follow up, 106 (83%) were either concordant with the aneuploidy seen on diagnosis or showed a complementary aneuploidy event. Of the 83 embryos, 33 (39%) had meiotic and 37 (44%) had mitotic aneuploidy and 13 (15%) had both types of events.
What is known already: Diagnostic application of aCGH in PGD for reciprocal and Robertsonian translocations has revealed 45–55% embryos with additional aneuploidies with or without translocation related imbalances. The occurrence of these extra abnormalities with the balanced form of the translocation reduces the number of embryos suitable for transfer. The origin and significance of these aneuploidies can only be determined by full follow up studies, of which few have been carried out.
Study design, size, duration: This study targeted whole chromosome and segmental aneuploidies present in addition to the balanced or unbalanced translocations detected on aCGH diagnosis. Whole untransferred embryos collected on day 5/6 of embryo development were spread for FISH or tubed for aCGH analysis. Aneuploidies were classified as meiotic or mitotic after follow up.
Participants/materials, setting, methods: In total, 85 embryos from 23 infertile or sub-fertile translocation carriers (average maternal age, 35 ± 4.2 years) undergoing 31 cycles of PGD by aCGH were included. Sixty-three were followed up by FISH and twenty-two by aCGH with high resolution Agilent oligonucleotide 8 × 60 k and/or BlueGnome 24 Sure BAC microarrays.
Main results and the role of chance: Conclusive follow up results were obtained for 83/85 embryos, 63 by FISH and 20 by aCGH. From a total of 127 aneuploidy events seen on follow up, 106 (83%) were either concordant with the aneuploidy seen on diagnosis or were complementary. Meiotic aneuploidy affected 39% of embryos and 44% had mitotic events; 15% had both types. Meiotic and mitotic events were almost equal (62 versus 65), 97 affected whole chromosomes (59 meiotic, 38 mitotic) and 30 were segmental (3 meiotic, 27 mitotic). With the exception of chromosomes 4 and Y, all were found to be aneuploid, chromosome 22 was most frequently affected by meiotic errors, followed by chromosomes 15, 16 and 19. Chromosomes 2 and 19 had the highest number of mitotic anomalies, then chromosomes 3 and 16.
Limitations, reason for caution: Two methods, aCGH and FISH were used to determine the prevalence of additional aneuploidies at later stages of embryo development. When aCGH is performed on whole embryos mosaicism below the level of 25% is difficult to detect. FISH is better for assessing the exact level of mosaicism.
Wider implications of the findings: Aneuploidies of meiotic origin and the majority of abnormalities of mitotic origin were widespread in the whole embryos followed up. All the embryos diagnosed as abnormal (translocation balanced or unbalanced) after aCGH diagnosis at cleavage stage would have remained unsuitable for transfer if tested at later stages of development and those abnormalities found after diagnosis at the blastocyst stage were confirmed in the rest of the embryo. Additional aneuploidies are thus confirmed as significant findings.
Study funding/competing interest(s): Funding by University(ies) – University College London (UCL).
Trial registration number: NA.

P-621 Polymorphism of CAG and GGN repeats in androgen receptor gene in women with polycystic ovary syndrome

C. Yuan[1], Y. Qian[1], Y. Liu[1], C. Gao[1], Y. G. Cui[1], J. Y. Liu[1]
[1]*Nanjing Medical University, Center of Clinical Reproductive Medicine, Nanjing City, Jiangsu Province, China*

Study question: This study was designed to investigate the polymorphism of CAG and GGN repeats in AR gene, XCI pattern and the expression of AR in Chinese women with polycystic ovary syndrome (PCOS).
Summary answer: In our study, the prolonged GGN repeat in AR gene, and the increased mRNA expression of GGN trinucleotide repeat, was found in PCOS patients, suggesting that the polymorphism of GGN repeat in AR gene was associated with pathophysiology of PCOS.
What is known already: Polycystic ovary syndrome (PCOS) is a common cause of anovulatory infertility, one of characteristics of PCOS is androgen excess, hyperandrogenism or overaction of androgen, which may be related to androgen receptor (AR). The activity of AR is physiologically modulated by its polyglutamine and polyglycine tracts, variable size, in N-terminal transactivation domain. Those polyglutamine and polyglycine tracts are encoded by a highly polymorphic CAG and GGN repeat sequence in exon 1 of *AR* gene located on X chromosome.
Study design, size, duration: A total of 156 women consisting of 80 PCOS cases (aged 21–34 years) and 76 controls (aged 21–34 years) were recruited, in our center from 2012 to 2014. Ovarian tissues from 5 adults women with normal menstrual cycles (during transsexual operation) and 7 PCOS cases (during surgical treatments) were collected.
Participants/materials, setting, methods: The frequency distributions of CAG and GGN repeat alleles, as well as their X-inactivation patterns, were compared between control group and PCOS group. Expression of AR mRNA was tested by qPCR in ovarian tissues of 7 PCOS patients and 5 normal women, while cellular location of AR protein by immunohistochemistry.
Main results and the role of chance: Based on the mean biallelic trinucleotide repeat lengths, we divided the PCOS and control groups into shorter repeat (CAG ≤ 22, GGN ≤ 16) and longer repeat groups (CAG > 22, GGN > 16) to evaluate the effect of the two repeat lengths in PCOS. PCOS cases had significantly higher frequency of longer GGN biallelic mean (29.8%) and X_weighted_biallelic_mean (33.3%) than controls (6.1% and 3.2%, respectively) ($\chi^2 = 9.219$, df = 1, $p = 0.002$; $\chi^2 = 8.717$, df = 1, $p = 0.003$). The *GGN* repeat mRNA levels of ovarian tissue could be measured in both groups, and were approximately 1.8-fold higher in the controls than in the PCOS cases ($p = 0.022$).
Limitations, reason for caution: The size of participants and sample in our study is few, and we did not obtain the clinical data of control group because of ethical issue.
Wider implications of the findings: To our knowledge, this is the first report of an association between the GGN polymorphism and PCOS. Moreover, our study provides evidence of a significant relationship between mRNA expression and trinucleotide repeat length polymorphism, which should be confirmed with further research. Replication of our findings would shed light on the role of androgen metabolism in the development of PCOS and provide useful insights into the possible role of anti-androgen medication for treating this disease.
Study funding/competing interest(s): Funding by national/international organization(s). Major State Basic Research Development Program of China (973 Program) (2012CB944703, 2012CB944902), the Health Commonweal Project of China (201402004), and the Priority Academic Program Development of Jiangsu Higher Education Institutions (PAPD).
Trial registration number: Our study is not RCT.
Keywords: androgen receptor, polycystic ovary syndrome, polymorphism, hyperandrogenism, endocrinology

P-622 An association between thrombophilias and pregnancy loss: should we test?

S. Bristow[1], S. Yarnall[1], A. Bisignano[2], S. Munne[3]
[1]*Recombine, Product, New York, NY, U.S.A.*
[2]*Recombine, CEO, New York, NY, U.S.A.*
[3]*Reprogenetics, Founder, Livingston, NJ, U.S.A.*

Study question: Are genetic variants in thrombophilia-related genes (FV Leiden, FII Prothrombin, FXII, FXIIIAI, and FGB) significantly associated with self-reported recurrent pregnancy loss (RPL) in women seeking treatment at fertility centers as compared to a general population sampled from the 1000 Genomes Project?
Summary answer: We observe a significant association of all studied variants with all women seeking fertility treatment when compared to the control group; further, we find that two variants found in FXII (rs1801020) and FXIIIAI (rs3024477) significantly differ among women with a self-reported history of RPL and the control group.
What is known already: RPL affects 1–5% of individuals diagnosed with infertility. Over 50% of cases are due to aneuploidy, but genetic variants have also been purported to increase RPL risks, such as thrombophilias. Results from studies on thrombophilias are contentious and the role they play in RPL is unclear. Consequently, the benefits of treatment plans guided by thrombophilias, such as low-dose aspirin or low-dose heparin during an at-risk pregnancy, remain a topic of debate for best practices.
Study design, size, duration: We employed a retrospective case-control study to identify significant associations between thrombophilia-related variants and RPL. A total of 2201 females referred for carrier screening and consented to research in a de-identified manner were enrolled into the study. Patients were enrolled between January 2013 and October 2014.
Participants/materials, setting, methods: Illumina's Infinium HD Genotyping Platform identified variants: FV Leiden (rs6025); FII Prothrombin (rs1799963); FXII (rs1801020); FXIIIAI (rs5985; rs3024477); FGB (rs1800790). RPL was defined as ≥2 miscarriages before 20 weeks gestation. The 1000 Genomes Project was used as the control. Fisher's Exact Test calculated significance of genotype frequencies ($p \leq 0.05$).
Main results and the role of chance: We find that all 6 tested thrombophilia variants differ significantly between all female study participants treated at fertility centers and the control group: FV Leiden (rs6025 – $p = 3.56 \times 10^{-5}$); FII Prothrombin (rs1799963 – $p = 1.14 \times 10^{-7}$); FXII (rs1801020 – $p = 2.2 \times 10^{-16}$); FXIIIAI (rs5985 – $p = 6.56 \times 10^{-7}$; rs3024477 $p = 3.43 \times 10^{-6}$); FGB (rs1800790 $p = 4.96 \times 1013$). Only FXII (rs1801020 – $p = 1.82 \times 10^{-6}$) and FXIIIAI (rs3024477 – $p = 0.00496$) significantly differ between study participants with a self-reported history of RPL and the control group. The other variants were not found to be significantly associated with self-reported RPL: FV Leiden (rs6025 – $p = 0.103$); FII Prothrombin (rs1799963 – $p = 0.565$); FXIIIAI (rs5985 – $p = 0.646$); FGB (rs1800790 $p = 0.121$).
Limitations, reason for caution: Participants were categorized for RPL based on self-reported histories taken during genetic counseling sessions for the prescribed carrier screening. Self-reported histories may not be completely accurate and we may have incorrectly categorized participants if they did not accurately report multiple miscarriages.
Wider implications of the findings: Routine thrombophilia-related testing in women diagnosed with infertility or RPL is not performed. However, our findings suggest that women diagnosed with idiopathic infertility may benefit from screening to guide reproductive treatment and pregnancy monitoring. A subset of participants may have unknowingly experienced multiple miscarriages, as 42% report never being pregnant. Women diagnosed with RPL may benefit from FXII and FXIIIAI screening. Interestingly, FXII is a phospholipid-binding protein implicated in antiphospholipid syndrome, another RPL risk.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Recombine.

P-623 Preimplantation genetic diagnosis (PGD) for fragile X (FX) syndrome: direct allele repeat size detection and advantages of blastocyst stage biopsy

R. Prates[1], M. Konstantinidis[2], A. Jordan[3], B. Chu[2], E. Armenti[3], T. Lemma[2], V. Tecson[2], S. Munne[4], S. Jaroudi[4]
[1]*Reprogenetics, Molecular, Miami, U.S.A.*
[2]*Reprogenetics, Molecular, Livingston, U.S.A.*
[3]*Reprogenetics, Genetic Counseling, Livingston, U.S.A.*
[4]*Reprogenetics, Research, Livingston, U.S.A.*

Study question: Is blastocyst biopsy followed by embryo freezing advantageous over cleavage stage biopsy followed by fresh embryo transfer when it comes to PGD for FX with direct allele repeat size detection?

Summary answer: Diagnostic and clinical outcome data showed significant advantages of repeat size detection in trophectoderm samples for FX PGD. Furthermore, higher implantation and pregnancy rates were observed for FX patients who had undergone PGD cycles involving blastocyst biopsy followed by embryo cryopreservation versus cleavage stage biopsy with subsequent fresh transfer.
What is known already: PGD allows the selection of embryos that are unaffected by inherited disorders following *in-vitro* fertilization (IVF). The main difficulty for FX patients is that some carriers have primary ovarian insufficiency, making it difficult to stimulate the ovaries to produce the multiple eggs necessary for PGD. On the technical side, limited amounts of embryonic material available for the diagnosis makes it difficult to detect the alleles' repeat sizes using standard polymerase chain reaction (PCR) methods.
Study design, size, duration: Data were collected from 27 cleavage stage and 22 blastocyst FX PGD cycles (average maternal age of 29.2 and 35.8, respectively) performed between January 2012 and December 2014. A total of 216 cleavage stage and 115 blastocyst embryos were assessed (on average 8 and 5.2 embryos per cycle, respectively).
Participants/materials, setting, methods: Single blastomere or trophectoderm biopsied samples were sent from 25 different IVF clinics in the USA to a single reference PGD laboratory. DNA was processed and analysed via capillary electrophoresis and Karyomapping (Illumina, USA). When requested, comprehensive chromosome screening (CCS) was also performed in parallel to FX testing for blastocysts.
Main results and the role of chance: A diagnosis was obtained for 94.8% (109/115) of blastocysts and 88% (190/216) of cleavage stage embryos ($p = 0.05$). Linkage analysis testing was carried out for all samples. Repeat size assessment and CCS were only possible for blastocyst biopsies. The proportions of embryos found to be available for transfer after linkage analysis alone was 43.7% for cleavage stage and 56.9% for blastocysts. Repeat size assessment indicated 22.9% more blastocysts (having intermediate or premutation allele repeat range results) to be considered for transfer. Despite of the additional CCS, 47.7% of blastocysts were considered for transfer showing similar proportion to the cleavage stage group. Preliminary clinical outcome data showed a significantly higher pregnancy rate for blastocysts compared to cleavage stage embryos ($p = 0.04$); 72.7% (8/11) vs. 33.3% (3/12), respectively.
Limitations, reason for caution: Although knowing repeat size increases the number of embryos available for replacement, transfer of embryos with premutations should be done only after thorough consultation with the patient since individuals with premutations are at increased risk for fragile X-associated symptoms.
Wider implications of the findings: Even though less embryos were available for transfer (52 vs. 83), the blastocyst stage testing strategy followed in this study resulted in significantly higher pregnancy rates compared to cleavage stage. Opting for an IVF/PGD strategy that enables better embryonic selection and more comprehensive diagnosis, leading to achievement of a healthy pregnancy in a shorter period of time is advantageous, especially in cases hindered by poor ovarian response.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Institutional funding. None of the authors have any competing interests.

P-624 Maternal dietary exposure to bisphenol-A (BPA) increases embryo size and alters key epigenetic regulators in the blastocyst

A. E. Batcheller[1], A. Cheong[2], G. L. Christiansen[1], M. A. Thomas[1], S. M. Ho[2], Y. K. Leung[2]
[1]*University of Cincinnati, Obstetrics and Gynecology, West Chester, OH, U.S.A.*
[2]*University of Cincinnati, Environmental Health, Cincinnati, OH, U.S.A.*

Study question: What role does maternal BPA ingestion play in the morphology and epigenetic regulation of preimplantation embryos?
Summary answer: Maternal dietary BPA exposure is associated with increased blastocyst size, as well as upregulation of a pluripotent gene, possibly via DNA methylation.
What is known already: BPA exposure may contribute to increasing infertility rates. BPA negatively impacts embryo transport, development, and implantation in mice. BPA exposure has been reported to alter the murine epigenome in somatic cells and alter imprinting genes in post implantation embryos. Preimplantation embryo development is a time of extensive epigenetic reprogramming. The plasticity of the preimplantation embryo may render it vulnerable to environmental insults, such as BPA exposure.
Study design, size, duration: In this IACUC approved animal study, female Sprague Dawley rats were fed AIN control or 250 mg/kg body weight/day BPA diets during the periconceptional time period. A total of 119 control (10 confocal imaged, 50 PCR analyzed) and 96 BPA (5 confocal imaged, 50 PCR analyzed) embryos were obtained.
Participants/materials, setting, methods: Embryos were retrieved from the uterine horns on gestational day 5 then measured using AxioVision software. Blastocysts were fixed, DAPI stained, and imaged using confocal microscopy. Total RNA was isolated, followed by reverse transcription and quantitative real-time PCR for *18S, Oct4, Dnmt1, Dnmt3a, Dnmt3b, Tet1, Tet2,* and *Tet3*.
Main results and the role of chance: A significant difference in the average area (control 5768.87 $\mu m^2 \pm 1038.60$ vs BPA 6649.37 $\mu m^2 \pm 1386.06$; $p < 0.01$) was noted between groups. There was no difference in the number of cells per embryo (control 23.6 nuclei ± 7.47 vs BPA 23 nuclei ± 8.86; $p = 0.90$). Significant upregulation of pluripotency gene *Oct4* was noted in BPA exposed embryos (fold change 4.32; $p < 0.01$). Epigenetic enzymes involved in *de novo* methylation, *Dnmt3a* (fold change 1.80), *Dnmt3b* (fold change 1.52), *Tet1* (fold change 2.05), *Tet2* (fold change 1.43), and *Tet3* (fold change 52.61), were up regulated in BPA exposed embryos, while methylation maintenance enzyme *Dnmt1* (fold change 0.52) was down regulated, though these changes were not statistically significant.
Limitations, reason for caution: We noted that some epigenetic enzymes may be dysregulated by BPA. However, due to individual variation, significant differences were not detected. Increased sample size will aid in clarifying the role of BPA in modulating the epigenome of preimplantation embryos and the impact of epigenetic dysregulation in advancing embryo morphology.
Wider implications of the findings: Aberrations in *de novo* methylation and methylation maintenance in BPA exposed embryos may be related to increased pluripotency gene expression and embryo size. Given that advanced embryo morphology is often used as a good prognostic feature for embryo selection in the *in vitro* fertilization laboratory, BPA exposure could result in selection for epigenetically dysregulated embryos using this strategy. Additionally, there may be health consequences for the resulting BPA exposed offspring due to the Barker hypothesis.

P-625 A combined day 5/day 6 trophectoderm biopsy strategy followed by frozen embryo transfers can maximize the embryo utilization and clinical outcome in comprehensive chromosomal screening (CCS) cycles

N. Findikli[1], B. Capar[2], B. Musul[2], M. Gultomruk[2], T. Aksoy[1], E. Yagmur[3], M. Bahceci[3]
[1]*Bahceci Fulya IVF Centre, Embryology Laboratory, Istanbul, Turkey*
[2]*Bahceci Fulya IVF Centre, R&D Laboratory, Istanbul, Turkey*
[3]*Bahceci Fulya IVF Centre, Infertility Clinic, Istanbul, Turkey*

Study question: This study questions whether performing a trophectoderm biopsy on embryos that developed into good quality blastocysts on day 6 bring additional benefits in the cycle outcome as compared to day 5 biopsies in CCS cycles.
Summary answer: Day 6 trofectoderm biopsy increases the total number of analyzable as well as chromosomally normal embryos at least by 25%. Also, among the embryos biopsied, the distribution of chromosomal abnormalities as well as clinical pregnancy rates are found to be similar for both day 5- and day 6-blastocysts.
What is known already: Contemporary preimplantation genetic screening (PGS) requires a trophectoderm biopsy on developing good quality blastocysts.

However, not all fertilized embryos develop to blastocyst stage at similar rates. If fresh transfer is planned, only the embryos that are available for biopsy on day 5 are taken into account for analysis. However, some embryos in the same cohort can only reach the blastocyst stage on day 6 hence are not included in the same analysis. The data regarding the chromosomal status as well as clinical performance of day 6 biopsied embryos are scarce and conflicting.

Study design, size, duration: This retrospective comparative study has been performed in Bahceci Fulya Assisted Reproductive Technology Centre between January 2013 and December 2014. It includes 425 consecutive CCS cyles in which 1155 blastocysts were biopsied and analyzed for 24 chromosomes on day 5 and day 6.

Participants/materials, setting, methods: Patients in the study group were CGS candidates having advanced maternal age, recurrent implantation failure and recurrent abortion or combinations. According to the nature of the CCS strategy, whenever the embryos have reached the hatching blastocyst stage, they were biopsied and immediately vitrified after the biopsy. Once a chromosomally normal embryo was found, embryo transfer (ET) was planned for the next suitable time frame with hormone replacement therapy. Within the study period, 743 embryos were biopsied on day 5 and 412 on day 6 and vitrified individually.

Main results and the role of chance: Mean female age in the study group was 36.1, ± 5.1. A total of 146 ETs were performed in these cases. In 102 cycles, utilization of only day-5 biopsied blastocysts gave a 59.8% pregnancy rate while in 44 cycles, transfer of only day-6 biopsied blastocysts resulted in 59.0% pregnancy rate. Results of the CCS analysis as well as the distribution of chromosomal abnormalities for each biopsy day are shown in table.

Day of embryo biopsy	Day 5	Day 6
# of embryos biopsied	743	412
# of embryos analyzed	717 (96.5%)	390 (94.7%)
Normal	180 (25.1%)	100 (24.2%)
Abnormal	537 (74.8%)	290 (70.3%)
Complex abnormalities	115 (21.4%)	59 (20.3%)
Aneuploidies involving a single chromosome	281 (52.3%)	167 (57.8%)
Trisomy	153 (54.4%)	86 (51.5%)
Monosomy	82 (29.2%)	61 (36.5%)
deletion/duplication	46 (16.4%)	20 (12.0%)

Limitations, reason for caution: High risk of embryonic aneuploidies due to the nature of the cases as well as the limited number of the embryos available for ET can be the limitations in this study.

Wider implications of the findings: Our results show that in CCS cycles, biopsy and analysis of day 6 blastocysts should not be ignored since it can bring additional benefit in the clinical outcome by increasing the probability of finding normal embryos as well as successful pregnancies in the routine preimplantation genetic screening programme.

P-626 Comparison of clinic outcomes of preimplantation genetic screening (PGS) in elder patients, repeated miscarriage or those once with fetus of abnormal CGH

K. L. Luo[1], F. Gong[1], Y. Q. Tan[1], Y. F. Gu[1], G. Lin[1], G. X. Lu[1], F. Gong[1], K. Tan[1]

[1]*Citic-Xiangya Reproductive and Genetic Hospital, IVF Centre, Changsha, China*

Study question: To retrospectively compare the differences of miscarriage rate after PGS with whole genome amplification (WGA) and single-nucleotide polymorphisms (SNPs) between advanced maternal age (AMA), repeated miscarriage (RM) and former abortion with abnormal fetal CGH (AC).

Summary answer: PGS show a tendency of more advantages in decreasing miscarriage rate in AMA and AC compared to RSA group.

What is known already: It is supposed that PGS can decrease miscarriage rate by a better selection of euploid embryos. Present indications of PGS include AMA and RM, but which patients group will benefit more from PGS is still in debate.

Study design, size, duration: Patients with unexplained recurrent miscarriage (≥3 repeated spontaneous miscarriage, $n = 38$), ≤2 miscarriage but with abortus of abnormal CGH (AC, $n = 36$) or of advanced maternal age (AMA, $n = 27$) were selected for PGS by SNP. The study was carried out from September 2010 to November 2013. Only those have at least one transferrable blastocysts were selected.

Participants/materials, setting, methods: Laser assisted trophectoderm biopsy was performed on day 5 or 6 post oocytes retrieval. No more than 5 trophoblast cells were biopsized and then vitrified. Less than 2 blastocysts were transferred in the FET cycles. Clinic pregnancy rate (PR), miscarriage rate (MR) and CGH analysis of abortus was measured.

Main results and the role of chance: Of the 101 cycles, PR was relatively lower in AMA (37.04%, 10/27) than in AC (66.67%, 24/36) and RM (68.42%, 26/38) ($p < 0.05$), possibly because of the differences in maternal ages (38–45, 23–42, 30–44, respectively). But all the 10 pregnant women in the AMA group go well through the two trimester, i.e., no one result in miscarriage, while miscarriage rate of AC (12.50%, 3/24) also show a tendency to be lower than that of RM group (26.92%, 7/26) ($P > 0.05$). Of the 10 miscarriage cases, 7 performed CGH and no abnormalities were found with the abortus.

Limitations, reason for caution: The study is limited for its retrospective design. A statistic difference may be reached only after we increase the sample size.

Wider implications of the findings: Our study shows that PGS decrease the miscarriage rate in AMA, mainly by rule out aneuploidy embryos. The miscarriage rate in RM remains high, possibly due to unresolved pathologies causing spontaneous miscarriage. Therefore PGS is a useful tool for AMAs.

Study funding/competing interest(s): Funding by University(ies) – No applicable.

Trial registration number: NA.

P-627 Mosaicism and DNA methylation at imprinted genes varies with severity of oligozoospermia in infertile men

R. Ng[1], K. Louie[1], K. Poon[1], V. Chow[1], S. Ma[1]

[1]*University of British Columbia, Obstetrics and Gynaecology, Vancouver, BC, Canada*

Study question: Does DNA methylation at imprinted genes display increased abnormalities with increasing severity of oligozoospermia in infertile men?

Summary answer: Our data suggests that DNA methylation at imprinted genes does display errors that increases with the severity of oligozoospermia in infertile men, however, the men with the most severe oligozoospermia did not display the greatest number of errors. We also observed a similar pattern for mosaicism in sperm methylation.

What is known already: Previous studies have shown that there may be an upper threshold of sperm concentration, below which DNA methylation errors at imprinted genes become more prevalent in the sperm of infertile men.

Study design, size, duration: Our case control study includes a total of 50 patients, which includes nine fertile control men and 41 oligozoospermic men, subdivided into three categories based on sperm concentration: eight with 5–15 million/ml, 23 with 1–5 million/ml, and 10 with <1 million/ml.

Participants/materials, setting, methods: We examined the methylation status of three imprinted genes (*H19*, *IG-GTL2*, and *MEST*) in the ejaculate sperm of reproductive age men using bisulfite cloning and sequencing. We categorized clones into four groups based on the percentage of abnormal methylation present. DNA fragmentation and *MTHFR* genotype were examined.

Main results and the role of chance: We analyzed DNA methylation at three imprinted regions in 851 clones, in which DNA fragmentation and *MTHFR* genotype were not found to be significant confounding factors. Furthermore, these clones underwent exclusion criteria to reduce amplification bias. Clones with altered DNA methylation in the *H19* gene were found more frequently in men with oligozoospermia, specifically those with a sperm concentration of 1–5 million/ml compared to fertile control men. These men showed significantly fewer clones with normal methylation (51% vs. 75% in controls; $P = 0.006$). Furthermore, these men also showed significantly more clones that were completely abnormally methylated (10% vs. 0% in controls; $P = 0.034$). Inter- and intra-individual mosaicism in sperm methylation was observed consistently throughout the study.

Limitations, reason for caution: The number of patients in each category of oligozoospermia are not the same. There may be potentially significant findings in the other categories if the sample sizes were similar. Additionally, only a few sperm were cloned per patient.
Wider implications of the findings: Our results support other studies showing methylation defects at the *H19* gene in the sperm of oligozoospermic men. Additionally, we show that DNA methylation may not be a contributing factor to male infertility in the most severe cases of oligozoospermia. The aetiology of these cases may not have a significant epigenetic component. We speculate that mosaicism in sperm methylation may also be characteristic of infertility.
Study funding/competing interest(s): Funding by national/international organization(s) – Canadian Institutes of Health Research.

P-628 Carrier screening of 58,000 patients in the IVF setting utilizing next generation DNA sequencing detects common, rare and otherwise undetectable mutations in prevalent, society-recommended diseases

N. Faukner[1], T. Mullen[1], V. Greger[1], R. Rochelle[2], A. Frieden[3], S. Hallam[1]
[1]*Good Start Genetics Inc., Clinical Laboratory, Cambridge, MA, U.S.A.*
[2]*Good Start Genetics Inc., Marketing, Cambridge, MA, U.S.A.*
[3]*Good Start Genetics Inc., Bioinformatics, Cambridge, MA, U.S.A.*

Study question: The objective of this study was to evaluate the clinical effectiveness of NGS in detecting common and rare mutations across a large number of patients in a clinical setting, among 14 diseases recommended for carrier screening.
Summary answer: Due to the more extensive set of pathogenic mutations detectable for the genes assessed, NGS enables more comprehensive examination of carrier status, and is, therefore, able to yield higher detection rates resulting in fewer missed carriers than if traditional carrier tests were used.
What is known already: Carrier screening for specific genetic disorders is recommended by ACOG, ACMG, and societies representing the Ashkenazi Jewish population. Due to cost considerations and limitations of the technologies employed, traditional carrier screening assays are designed to look for only the most common mutations within a gene. This older approach can yield high detection rates in specific populations (e.g., the Ashkenazi Jewish); however, it's suboptimal for other ethnicities or for patients of mixed or unknown ethnic background.
Study design, size, duration: Using NGS, we evaluated carrier status for up to 14 disorders (as ordered by physicians in IVF centers) for 58,338 patients.
Participants/materials, setting, methods: A high-throughput and proprietary methodology (comprised of multiplex gene capture, NGS and computational analysis) has been applied to over 58,000 patient DNA samples across ~400,000 individual tests, as of this writing. Clinical reports were issued on the presence or absence of disease-causing mutations in genes associated with society-recommended, recessive genetic disorders.
Main results and the role of chance: Among the first 58,338 clinical samples evaluated, our NGS-based tests routinely detected common mutations among 14 disorders, as well as numerous rare mutations that would not be detected by traditional screening assays. 2768 (4.7%) of patients were found to be carriers of 403 distinct pathogenic mutations among the 14 diseases. Of the 2768 carriers detected, 13.2%–20.9% would have been missed by traditional carrier tests, putting these reproductive couples at increased risk of conceiving a child with a debilitating or fatal genetic disorder.
Limitations, reason for caution: Not applicable.
Wider implications of the findings: Next generation DNA sequencing (NGS) is able to detect five- to ten-fold the number of pathogenic mutations with potentially higher detection rates in all ethnicities compared to traditional carrier screening tests. Consequently, NGS is expected to provide a more comprehensive determination of carrier status.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Good Start Genetics, Inc., Cambridge, MA. All authors are employees of Good Start Genetics.

P-629 Significant skews in methylation fractions in previously described genotypes and sub-genotypes of the FMR1 gene

D. Barad[1], A. Weghofer[2], G. J. Latham[3], S. Filipovic-Sadic[3], V. A. Kushnir[1], N. Gleicher[1]
[1]*Center for Human Reproduction, N/A, New York, NY, U.S.A.*
[2]*Medical University Vienna, Obstetrics and Gynecology, Vienna, Austria*
[3]*Asuragen Inc, N/A, Austin, TX, U.S.A.*

Study question: Since genotypes and sub-genotypes of the *FMR1* gene have been associated with different ovarian aging patterns, we here investigated whether patterns of methylation skew differ among them, and whether AMH levels, reflective of functional ovarian reserve (FOR, i.e., the small growing follicle pool) are affected by *FMR1* methylation patterns.
Summary answer: Women with normal (*norm*) *FMR1* genotypes ($CGG_{n=26–34}$) differed significantly in mean skew of methylation from women with heterozygous (*het*) genotypes (one allele either $CGG_{n<26}$ or $CGG_{n>34}$). With *norm FMR1* increasing skew was associated with increasing AMH but with *het FMR1* with decreasing AMH.
What is known already: As previously reported [PLoS ONE 2010; 5 (12): e15303], patients can in their *FMR1* gene be classified as *norm* if both alleles are in normal CGG range (n = 26–34), as homozygous (*hom*) if both alleles are outside normal range and as *het* if only one allele is outside normal range. *Hom* and *het* patients can be further divided into sub-genotypes *low* ($CGG_{n<26}$) and *high* ($CGG_{n>34}$). Women with *norm*, *het-low* and *het-high* and *hom FMR1* demonstrate distinctively different declines in FOR, as assessed by AMH and, as we also previously reported, in methylation patterns of the *FMR1* gene.
Study design, size, duration: We here prospectively in a collaborative study between an academically affiliated private fertility center (CHR) and a laboratory corporation with a novel proprietary *FMR1* assay (Asuragen), investigated 74 patients over a 6 month period.
Participants/materials, setting, methods: 52 infertility patients and 12 egg donors were evaluated at their initial consultation for CGG repeat numbers on the *FMR1* gene, methylation and serum AMH, using a high performance *FMR1*PCR (Chen et al., Genet Med 2011; 13: 528–538). This assay allows for determination of CGGn, intermittent AGG genotypes and methylation status of both allele.
Main results and the role of chance: Average age was 34.3 ± 7.2 years (patients 36.6 ± 5.9; donors 24.5 ± 2.4). After adjustments for age and donor/patient status there was a significant difference in mean skew between patients with *norm FMR1* and *het FMR* genotypes (including *het-norm/low* and *het-norm/high* subgenotypes; *norm*, 9.6 ± 7.13; *het*, 15.8 ± 10.2, P = 0.008). Increasing skew was associated with increased baseline AMH among *norm FMR1* patients, while *het* patients demonstrated decreasing AMH with increasing skew (P for interaction = 0.039). No significant differences in methylation percentages or skew were observed between donors and patients.
Limitations, reason for caution: Because of small sizes of study groups, here presented findings should be considered preliminary.
Wider implications of the findings: Neither in reproductive medicine nor in other specialty areas affected by the *FMR1* gene, is the molecular biology of the gene yet well understood. Here presented findings suggest that increasing methylation skew affects AMH values in opposite ways in women with *norm* and *het FMR1* genotypes, thus suggesting a possible role of methylation skew in the gene's function, calling for further exploration.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Center for Human Reproduction; Foundation for Reproductive Medicine; Asuragen, Inc.
Trial registration number: NA.

[2]*IVF Zentren Prof. Zech – Pilsen, IVF Clinic, Plzen, Czech Republic*

[3]IVF Zentren Prof. Zech – Pilsen, IVF Laboratory, Plzen, Czech Republic
[4]IVF Zentren Prof. Zech – Bregenz, IVF Laboratory, Bregenz, Austria
[5]IVF Zentren Prof. Zech – Bregenz, IVF Clinic, Bregenz, Austria

Study question: Does preimplantation genetic screening (PGS) improve pregnancy rates (PRs) in IVF-cycles with embryo transfers (ET) of frozen embryos? Do PGS results and clinical outcome differ in relation to advanced maternal age (AMA)?
Summary answer: Our results demonstrate an overall increase in PRs after PGS. Although the proportion of aneuploid embryos strongly increases with AMA, PRs did not significantly differ from younger patients when PGS was applied. PGS can overcome adverse effect of AMA.
What is known already: The benefit of comprehensive chromosomal screening is still controversially discussed. Recently, a significant increase in PRs in young good-prognosis-patients was reported when performing PGS on trophectoderm (TE) samples by aCGH followed by fresh ET. Further, a benefit of PGS was stated in patients with AMA. Various factors, e.g., effect of post-zygotic mosaic, biopsy procedure, embryo classification prior biopsy, contributing sperm factor, trial bias, number of embryos transferred to mention just a few, influence reported results.
Study design, size, duration: PGS data from a 2 year period (2013–2014) after FETs were retrospectively analyzed in correlation to maternal age. Patients were subdivided into 3 age groups. Clinical outcome (pregnancy rates) was compared with age-matched outcome of FETs without PGS (noPGS). PGS analysis was performed on TE samples by aCGH (BlueGnome 24 sure).
Participants/materials, setting, methods: Group I: ≤32 year: (A) PGS/FET: 27 egg donors; 192 TE-samples; 24 FETs; (B) noPGS/FET: 372 FETs. Group II: ≤38 year: (A) PGS/FET: 30 patients; 162 TE-samples; 19 FETs; (B) noPGS/FET: 200 FETs. Group III: >38 year: (A) PGS/FET: 61 patients; 261 TE-samples; 28 FETs; (B) noPGS/FET: 95 FETs. For statistical analysis Chi-Square test was used.
Main results and the role of chance: Although the proportion of aneuploid embryos was clearly increasing with AMA (group IA: 86/192; 45%; group IIA: 94/162; 58%; group IIIA: 195/261; 75%, $P < 0.00001$), PRs did not significantly differ among the PGS groups (IA: 16/24; 67%; IIA: 13/19; 68%; IIIA: 16/28; 57%, P 0.674). Overall PR after PGS was significantly improved in comparison with FETs without PGS (45/71; 63% vs. 329/666; 49%, P 0.025). Comparing PRs in individual age groups there was improvement seen in all 3 groups. However, only in the PGS group ≤38 year significant difference could be observed in comparison to the non-PGS group (group IA: 16/24; 67% vs. group IB: 219/372; 59%, P 0.451; group IIA 13/19; 68% vs. group IIB: 74/200; 37%, P 0.008; group IIIA: 16/28; 57% vs. group IIIB: 36/95; 38%, P 0.077).
Limitations, reason for caution: It is known that number and probability of euploid embryos decreases with age. Further, a number of embryos are not eligible for TE-biopsy, and PGS-results are sometimes not interpretable. Several stimulated cycles might be necessary to perform one ET, therefore PGS might not be the best therapy for all AMA-patients.
Wider implications of the findings: PGS is a useful method for choosing viable embryos for FET, particularly in patients with AMA since the proportion of aneuploid embryos significantly increases in the older patients groups. According to our results PGS followed by FET improves PR in comparison with FET without PGS. However, further studies of large cohort of patients are needed to confirm these findings.
Study funding/competing interest(s): Funding by hospital/clinic(s) – IVF Zentren Prof. Zech.
Trial registration number: No trial registration number.

P-631 Endogenous retrotransposon expression and de novo retrotransposition events after incorporation of exogenous retroelements in human spermatozoa

L. Lazaros[1], C. Kitsou[2], C. Kostoulas[2], S. Bellou[3], P. Sakaloglou[2], P. Ladias[2], A. Zikopoulos[1], T. Stefos[1], G. Vartholomatos[4], T. Tzavaras[5], I. Georgiou[1]

[2]Ioannina University Medical School, Laboratory of Medical Genetics and Human Reproduction, Ioannina, Greece
[3]Foundation for Research and Technology-Hellas Institute of Molecular Biology and Biotechnology, Department of Biomedical Research, Ioannina, Greece
[4]Ioannina University Hospital, Hematology Laboratory Unit of Molecular Biology, Ioannina, Greece
[5]Ioannina University Medical School, Department of General Biology, Ioannina, Greece

Study question: To investigate the expression of L1, HERV-K10 and SVA retrotransposons in human spermatozoa as well as the potential incorporation of exogenous human and mouse retroelements in human sperm genome favoring new retrotransposition events.
Summary answer: Our results show that (a) L1, HERV-K10 and SVA retrotransposons are transcriptionally active in human spermatozoa and (b) the spontaneous interaction of human spermatozoa with exogenous human and mouse retroelements and their subsequent incorporation into their genome result in *de novo* retrotransposition events.
What is known already: Retrotransposons have played a crucial role in the human genome structure and evolution. Retrotransposition events in human oocytes have been well documented, but their presence in human spermatozoa is still unclear. Mammalian spermatozoa can spontaneously bind exogenous DNA molecules and internalize them into their nucleus. The presence of a functional endogenous reverse transcriptase in murine mature spermatozoa, which has the ability to convert the internalized molecules into cDNA copies, explains the occurrence of retrotransposition events.
Study design, size, duration: Retrotransposon RNA expression was studied in fifty semen samples, 25 from normozoospermic and 25 from oligozoospermic patients. The potential incorporation of exogenous retroelements in human spermatozoa was studied in 108 men, incubating spermatozoa with human LINE-1, HERVK-10 and mouse VL30 retrotransposons, in a period of 2 years.
Participants/materials, setting, methods: RT-PCR analysis was performed in order to confirm the retrotransposon expression in ejaculated human spermatozoa. Exogenous retroelements were tagged with an enhanced green fluorescence (EGFP) gene-based retrotransposition cassette and the *de novo* retrotransposition events were tested using PCR, FACS analysis and confocal microscopy.
Main results and the role of chance: The RT-PCR products detected in human semen samples were specific transcripts of L1, HERV-K10 and SVA elements, providing evidence for retrotransposon expression in spermatozoa. Human sperm cells are capable of internalizing exogenous EGFP-tagged retroelements into their genome, favoring retrotransposition events. The 16.67% of the samples analyzed by FACS and PCR were positive for retrotransposition. The respective retrotransposition frequencies for the L1, HERV-K10 and VL30 retrotransposons were 0.34 ± 0.13%, 0.37 ± 0.17% and 0.3 ± 0.14% per sample containing 10000 spermatozoa. The retrotransposition frequencies were not affected significantly by the duration of incubation, while the increase of plasmid DNA concentration was accompanied by a slight increase of the retrotransposition rates.
Limitations, reason for caution: The possible truncation of retroelements after a retrotransposition event as well as the inadequate fluorescence detection due to very low EGFP expression levels might compromise the retrotransposition rates.
Wider implications of the findings: Controlled retrotransposition events may be beneficial for the quality of human spermatozoa and their contribution to the zygote, whereas the uncontrolled retrotransposon expression and the subsequent genome remodeling could explain the defective development, function and genetic constitution of human spermatozoa and the fairly high rates of *de novo* genomic aberrations in human embryos.
Study funding/competing interest(s): Funding by national/international organization(s). This study has been co-financed by the European Union (European Social Fund – ESF) and Greek national funds through the Operational Program "Education and Lifelong Learning" of the National Strategic Reference Framework (NSRF)-Research Funding Program: Heracleitus II. Investing in knowledge society through the European Social Fund.

Study question: To ascertain if the sex of the carrier influences the rate of aneuploidy for chromosomes not involved in the translocation.
Summary answer: Embryos from couples with a male translocation carrier have a higher chance of having aneuploidy or complex abnormal embryos with abnormalities – unrelated to the chromosomes involved in the translocation compared to embryos from couples with a female translocation carrier.
What is known already: The first studies on sperm for male translocation carriers via FISH mostly supported the theory of ICE. Further FISH studies of ICE on embryos from couples with one translocation carrier were limited because of low number of analyzable chromosomes and small sample size. Due to these limitations, some studies had contradictory results. Currently, Comprehensive Chromosome Screening techniques are able to study all chromosomes making them the most useful tools for ICE studies on embryos.
Study design, size, duration: This is a retrospective study involving 78 reciprocal translocation carrier cycles and 559 embryos. This study extended from cases tested between 6/11/2013 and 4/7/2014.
Participants/materials, setting, methods: This is a retrospective study involving 78 reciprocal translocation carrier cycles and 559 embryos. This study extended from cases tested between 6/11/2013 and 4/7/2014.
Main results and the role of chance: (a) Overall, the chances of having a normal or balanced embryo in reciprocal translocation carrier cycles is 17.9% regardless of the carrier's sex. (b) 50% of the embryos that are balanced or normal for the translocation have abnormalities involving other chromosomes. (c) Female carriers showed a higher proportion of unbalanced embryos (60.3%) than male carriers (55.0%), but with no statistical significant value. Male carriers produce a higher number of abnormal but not unbalanced embryos (20.5%) compared to female carriers (13.2%), and these differences are statistically significant ($p = 0.05$), pointing out an ICE effect on the chromosomal segregation of male translocation carriers. (d) The average maternal age for both groups is about the same: 33.62 for the female carrier group and 33.69 for the male carrier group.
Limitations, reason for caution: This study does not consider male factor effect. Age of male partner is also not considered.
Wider implications of the findings: The ICE effect may explain higher percentages of aneuploidy in embryos in male carriers with other structural abnormalities.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – N/A.
Trial registration number: NA.

P-633 Reverse transcriptase inhibition by lamivudine and nevirapine impairs gametogenesis in mice

C. Kitsou[1], L. Lazaros[1], A. Papoudou-Bai[2], G. Vartholomatos[3], M. Soukia[1], I. Bouba[1], T. Tzavaras[4], K. Zikopoulos[1], A. Batistatou[2], I. Georgiou[1]
[1]*University of Ioannina, Department of Obstetrics and Gynecology, Ioannina, Greece*
[2]*University Hospital of Ioannina, Department of Pathology, Ioannina, Greece*
[3]*University Hospital of Ioannina, Department of Hematology Molecular Biology Unit, Ioannina, Greece*
[4]*University of Ioannina, Department of General Biology, Ioannina, Greece*

Study question: To explore the effect of reverse transcriptase inhibition on gametogenesis in male and female mice with the antiretroviral drugs Lamivudine and Nevirapine and examine testicular and ovarian defects concerning the growth of germ cells, the morphology, the DNA integrity and their capability for fertilization.
Summary answer: Our results show that the reverse transcriptase inhibition by the use of antiretroviral drugs impairs the normal process of gametogenesis. We observed degeneration on the seminiferous tubules structure, increase on sperm cell morphological abnormalities and DNA degradation. In ovaries the inhibition resulted in the formation of multiple cysts and anovulation.
What is known already: Reverse transcriptase (RT) controls RNA virus life cycle and has been the target of many antiretroviral drugs used in HIV and Hepatitis patients. RT expression in cells is related to retroelements and is usually high in gametes, embryos, non-differentiated cells and cancer tissues, thus indicating a role in the process of cell growth and differentiation. Antiretroviral drugs affect semen quality in HIV and Hepatitis patients and impair preimplantation development in mouse embryos.
Study design, size, duration: Immature male and female FVB/N mouse 21 days old, were treated with a nucleoside analog reverse transcriptase inhibitor Lamivudine in a dose of 50 mg/kg and a non-nucleoside reverse transcriptase inhibitor Nevirapine in a dose of 30 mg/kg, for 7 weeks. After treatment, sperm parameters, testicular and ovarian morphology were examined.
Participants/materials, setting, methods: Testes and ovaries were fixed in formalin, embedded in paraffin and stained with haematoxylin-eosin. Histological examination was made under light microscopy. Papanicolaou staining used for sperm morphology analysis and SCSA analysis for DNA sperm integrity. *In vivo* and *in vitro* fertilization of male and female gametes was also checked.
Main results and the role of chance: The inhibition of reverse transcriptase via the use of antiretroviral drugs markedly impairs gametogenesis in male and female reproductive organs in mice. Seminiferous tubules showed signs of apoptotic Sertoli cells and deregulation of sperm cell production and differentiation. Sperm cells DNA integration was adversely affected and sperm morphological abnormalities were increased. *In vivo* and *in vitro* capacity of fertilization was not affected, although prolonged mating period was observed. Ovaries were characterized by the presence of three times higher number of antral and very few corpus luteum. We conclude that the reverse transcriptase inhibition impairs the process of gametogenesis possibly through the disruption of normal cell growth and differentiation. We also examined the side effects of antiretroviral drugs on other molecular targets apart from reverse transcriptase.
Limitations, reason for caution: Non – nucleoside reverse transcriptase inhibitors and especially nucleoside analog reverse transcriptase inhibitors exert a toxic effect on mice testes and ovaries not only through the inhibition of reverse transcriptase but also through other pathways such as mitochondrial activity inhibition on DNA polymerase.
Wider implications of the findings: Our findings show that the use of antiretroviral drugs affects the process of spermatogenesis and oogenesis in mice and potentially the reproductive outcomes of HIV and Hepatitis patients. Men and women, undergoing such treatment should be regarded as a high risk infertility group in need for a specialized approach.
Study funding/competing interest(s): Funding by national/international organization(s). This study has been co-financed by the European Union (European Social Fund – ESF) and Greek national funds through the Operational Program "Education and Lifelong Learning" of the National Strategic Reference Framework (NSRF) – Research Funding Program: Heracleitus II. Investing in knowledge society through the European Social Fund.

P-634 Comparison of egg donation cycle outcome with morphologically high quality blastocyst transfer and genetic embryo selection through PGS

N. Szlärb[1], M. Guijarro[2], B. Ramos[2], M. Fernández[2], L. L. Medrano[2], E. Rocafort[2], I. Herrera[1], S. Rogel[1], J. Aizpurua[1]
[1]*IVFspain, Medicine, Alicante, Spain*
[2]*IVFspain, Embryology, Alicante, Spain*

Study question: Is an egg donation cycle with one transfer of 2 euploid blastocysts after genetic embryo selection through PGS a superior method of treatment when compared to an egg donation cycle outcome with 3 double morphologically high quality blastocyst transfers.
Summary answer: Through the genetic selection of blastocysts using PGS we are giving patients the highest chance of becoming pregnant in one double blastocyst transfer procedure with a pregnancy rate of 95% per transfer. This makes PGS a method of choice in egg donation cycles in the future.

What is known already: For many women today egg donation represents the final step in infertility treatment. They delay family planning due to the cultural revolution not being aware that their best quality eggs are those when they are under 35 years of age. Combining egg donation treatments with genetic screening we may achieve the most efficient treatment option, decreasing the perinatal risks by performing only eSET as PGS showed for IVF cycles.
Study design, size, duration: In 2014 retrospectively we reviewed outcome of 80 egg donation treatments. Exclusive egg Donation (16–20 fresh donor eggs guaranteed) was offered to both groups. First group of 40 patients, six blastocysts were used in three double-embryo transfers. Second group of 40 patients euploid blastocyst selection by PGS took place.
Participants/materials, setting, methods: All 80 donors were under 30 years old, proven fertility, stimulated in the same pattern with rFSH 250 IE. All 80 recipients were enrolled after exclusion of anatomical factors. Male factor was excluded, through enrolment of normozoospermic patients.
Main results and the role of chance: Retrospectively we reviewed outcome of two groups with Exclusive egg donation treatment with genetic selection of blastocysts and without it. In the first group after 3 double blastocyst transfers of morphologically high quality, we achieved a 72.0% pregnancy rate per transfer and a cumulative pregnancy rate of 86.0% per cycle. In the second group with the addition of PGS and identification of euploid embryos, we observed 95% pregnancy rate after just one double-embryo transfer ($p = 0.006$) and mean euploidy rate of 66.3% ± 10.1. Through the genetic selection of blastocysts, patients are given the highest chance of becoming pregnant in one double blastocyst transfer procedure with a pregnancy rate over 95% per transfer. This makes PGS a method of choice in egg donation cycles in the future.
Limitations, reason for caution: Trophectoderm biopsy is an invasive procedure, where few cells are removed and sent for genetic analysis. Blastocyst is then frozen until the results and transfer day. There is a fear that through poor vitrification not all biopsied embryos survive and with fresh blastocyst transfer we could achieve better results.
Wider implications of the findings: Previously reported 32% blastocyst aneuploidy rate obtained from IVF cycles of women under 35 years old cannot be confirmed in our study. Our retrospective analysis shows blastocyst euploidy rate between 10 and 70% per cycle in young egg donors. We cannot rely on donor's age and speculate blastocyst euploidy. Each morphologically good blastocyst must be individually screened through PGS to be sure of its euploid core in order to obtain the highest implantation and pregnancy rates.
Study funding/competing interest(s): Funding by hospital/clinic(s) – University associated Private clinic and its Foundation.
Trial registration number: NA.

P-635 The impact of next-generation sequencing (NGS) preimplantation genetic diagnosis (PGD) on pregnancy rate after frozen blastocyst embryo transfer

S. Pukszta[1], K. Lukaszuk[2], C. Cybulska[1], J. Liss[2], L. Plociennik[2], W. Kuczynski[3], L. Wojcicka[2], P. Kulwikowska[2], J. Zabielska[2]
[1]*Invicta Sp. z o.o., Medical Diagnostics Laboratory, Gdansk, Poland*
[2]*Invicta Sp. z o.o., Invicta Fertility Centre, Gdansk, Poland*
[3]*Kriobank Sp. z o.o., Kriobank Fertility Centre, Gdansk, Poland*

Study question: To assess pregnancy rate after comprehensive chromosome screening using next-generation sequencing-based preimplantation genetic diagnosis (NGS PGD) in trophectoderm after frozen blastocyst embryo transfer.
Summary answer: We confirm that NGS can be applied clinically for the purpose of detecting aneuploidy in human preimplantation embryos. Furthermore, data from this trial indicated that trophectoderm biopsy followed by frozen transfer of euploid embryos was associated with very good implantation and clinical pregnancy rates.
What is known already: Currently used PGD methods of aneuploidy screening have been reported to improve pregnancy rates. However, most of them are based on low-density array comparative genomic hybridisation (aCGH), with results based on less than 2700 probes. New technical possibilities, such as next-generation sequencing (NGS) methods, have shown promise of improved genetic diagnostics.
Study design, size, duration: Prospective case control study included analysis of results from 114 embryos obtained from 32 patients (mean age 37) performed between September 2014 and November 2014 at INVICTA Fertility Centre, Poland.
Participants/materials, setting, methods: Embryos were cultured to blastocyst stage, trophectoderm biopsy was performed. Torrent Suite Software and was used for chromosome copy number variation analysis.
Main results and the role of chance: We transferred 43 (1.3 per transfer) vitrified blastocysts during frozen embryo transfer in the investigated group and 50 (1.5 per transfer) in the control group, resulting in a total of 20 embryos implanted in the PGD group and 12 in the control group. The primary outcome measure of pregnancy rate per transfer was approximately 25% higher in the PGD group compared to the control group (59.4% vs. 35.3%, respectively; $p < 0.04$). The difference in the implantation rate (secondary outcome measure) was greater than 20% (46.5% vs. 24.0%; $p < 0.02$).
Limitations, reason for caution: Limitations of this study are small size of the investigated group and lack of randomization.
Wider implications of the findings: These findings suggest that NGS may be a useful tool for embryo selection that gives normal embryos priority for transfer. NGS technology allows personalisation of the method and therefore could be used for all cases in which PGD is indicated.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Invicta Ltd., Gdansk, Poland. There are not any commercial association of the author of any co-authors that might pose a conflict of interest.

P-636 Mitochondrial DNA copy number assessed using next generation sequencing (NGS), as a selection criteria for viable embryo for transfer

K. Lukaszuk[1], S. Pukszta[2], W. Kuczynski[3], C. Cybulska[1], J. Liss[1], J. Zabielska[1]
[1]*Invicta Sp. z o.o., Invicta Fertility Centre, Gdansk, Poland*
[2]*Invicta Sp. z o.o., Medical Diagnostics Laboratory, Gdansk, Poland*
[3]*Kriobank Sp. z o.o., Kriobank Fertility Centre, Bialystok, Poland*

Study question: Assessment of correlation between mitochondrial DNA (mtDNA) copy number and ploidy status of embryo.
Summary answer: Elevated mitochondrial DNA copy number is observed in abnormal embryos, thus indicating that this parameter assessment could become a viable additional tool for prioritisation of embryos for transfer.
What is known already: The number of mtDNA copies can affect all vital processes which take place in cells but mostly the specialized ones requiring most of the energy for their specialized functions. This could also influence functioning of the gametes and disturb reproductive possibilities It known that number and activity of mitochondrion correlates with embryo quality but the exact relationship has not yet been established.
Study design, size, duration: We set out to retrospectively analyse the amounts of the mtDNA among 359 embryos biopsied either on day 3 or day 5 of development. The study was performed between August 2013 and November 2014 at INVICTA Fertility Centre, Poland.
Participants/materials, setting, methods: Samples analysed during preliminary validation were derived from cytogenetically characterised human cases and their embryos were previously confirmed to be aneuploid during routine preimplantation genetic screening using next generation sequencing. MtDNA relative amount was assessed as number of reads for mtDNA/number of reads for genome DNA ratio × 1000.
Main results and the role of chance: Our results showed a significant difference in mtDNA amount depending on embryo biopsy day. Results from day 3 biopsy showed much higher mtDNA to genome DNA ratio than those from day 5 (5.54 vs. 1.2, $p < 0.001$, respectively). We found a significant difference in mtDNA amount in day 3 biopsy samples between normal and aneuploid embryos (6.3 ± 7.5 vs 7.1 ± 5.8, $p = 0.004$, respectively). In day 3 group no correlation was found between mtDNA copy number and implantation, embryo quality, embryo's sex or patient's age. In day 5 group there was no difference in mtDNA amount between euploid/aneuploid embryos (1.5 ± 1.4 vs 2.1 ± 2.9, $p = 0.72$). We observed a significant difference in mtDNA amount only when comparing transferred embryos that implanted to the ones that did not (1.9 ± 1.3 vs 1.3 ± 1.8, $p = 0.002$, respectively).

Limitations, reason for caution: The findings are contrary to some recently published studies. A future prospective randomized study could potentially support the current findings.
Wider implications of the findings: The findings contribute information on cell physiology and are of important clinical significance supporting PGD performance purposefulness.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Invicta Ltd., Gdansk, Poland. There are not any commercial association of the author of any co-authors that might pose a conflict of interest.
Trial registration number: NA.

P-637 Telomere length: correlation with aneuploidy risk and implantation potential of human oocytes and cleavage stage embryos

S. Jaroudi[1], F. Cariati[1], M. Konstantinidis[2], E. Fragouli[1], D. Wells[2]
[1]*Reprogenetics UK, Institute of Reproductive Sciences, Oxford, United Kingdom*
[2]*University of Oxford, Nuffield Department of Obstetrics and Gynaecology, Oxford, United Kingdom*

Study question: Could the measurement of relative telomere length (RTL) in oocytes and cleavage stage embryos identify aneuploidy and help determine which embryos have the greatest reproductive potential?
Summary answer: Measurement of RTL does not reliably identify aneuploidy in oocytes or embryos, although it is correlated with specific types of chromosomal errors and patient indications. Importantly, RTL showed an association with pregnancy in both oocytes and cleavage stage embryos, suggesting its potential use as an additional biomarker of embryo viability.
What is known already: Telomeres play important roles in ensuring the success of gametogenesis and mitotic divisions in embryos. The regulation of telomere length (TL) in human oocytes and embryos is poorly understood. Previous studies have shown that TL decreases from the oocyte to the cleavage stage, before being reset in blastocysts. An association between TL and reproductive competence has been suggested and TL deficiency has been implicated in aneuploidy. However, the evidence is limited with disagreements between studies.
Study design, size, duration: Human polar bodies and blastomeres were subjected to whole genome amplification (WGA). The amount of telomere DNA was assessed in the WGA products using quantitative real-time PCR. The products were also subjected to comprehensive chromosome screening (CCS), allowing the corresponding oocytes and embryos to be classified as euploid or aneuploid.
Participants/materials, setting, methods: 216 first polar bodies (PB) and 491 blastomeres (from 36 and 71 cycles, respectively) were analyzed. Maternal ages ranged from 28 to 44 years (mean 38.11) for the PBs and 19–47 (mean 37.5) for blastomeres. Real-time PCR was used to assess telomere DNA quantity and RTL was calculated from the results.
Main results and the role of chance: There was no clear correlation between RTL and aneuploidy in oocytes or embryos; however, a trend was observed with shorter telomeres detected in aneuploid samples from patients of advanced reproductive age. Furthermore, RTLs in PBs with chromatid errors only were shorter than in PBs with gains or losses of entire chromosomes ($p = 0.021$). RTL in embryos was associated with indication and clinical outcome. However, in oocytes this relationship was only observed in samples from younger women (<38 years). Patients with previous implantation failure (PIF) or miscarriage (PM) had embryos with shorter telomeres compared to other patients ($p < 0.01$). In oocytes shorter telomeres were observed in PIF versus PM patients ($p < 0.01$). Interestingly, oocytes and embryos from patients who achieved a clinical pregnancy showed longer telomeres ($p < 0.01$).
Limitations, reason for caution: The use of WGA prior to telomere quantification does not distort the results obtained. However, it is possible that this strategy might reduce the capacity to resolve small differences in telomere length. A relative quantification of telomere length is provided, but the actual number of telomere repeats was not calculated.
Wider implications of the findings: Telomere assessment has potential to improve our understanding of preimplantation development and the mechanisms causing aneuploidy. Identification of the embryos having greatest reproductive potential is critical for the success of IVF treatment. Aneuploidy screening and morphological evaluations help to reveal viable embryos, but cannot guarantee implantation. Telomere length measurement may represent a new independent parameter for assessing the viability of chromosomally normal embryos, and may also reveal the embryos that would benefit most from CCS.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Reprogenetics – None of the authors have any competing interests.
Trial registration number: NA.

P-638 Mild oxidative stress is beneficial for increase in telomere length

S. Mishra[1], R. Kumar[2], N. Malhotra[3], R. Dada[1]
[1]*All India Institute of Medical Sciences, Anatomy, Delhi, India*
[2]*All India Institute of Medical Sciences, Urology, Delhi, India*
[3]*All India Institute of Medical Sciences, Obstetrics and Gynaecology, Delhi, India*

Study question: Telomeres are highly conserved hexameric repeats of DNA that confer chromosome stability and maintain genomic integrity. As telomeres are Guanine rich repeats, they are highly prone to oxidative damage. In this study we wanted to know the impact of oxidative stress on telomere length.
Summary answer: Sperm DNA integrity is important for accurate transmission of genetic information to the offspring. Telomere is an essential component of Sperm DNA, if shortened can cause loss of paternal genome integrity, which is important for proper fertilization and healthy embryo. Oxidative stress causes loss of telomere integrity.
What is known already: Telomere shortening results from normal cell division, reactive oxygen species, genotoxic insults, and genetic predisposition. Reactive oxygen species (ROS) shorten telomeres by oxidizing the guanine rich telomeric DNA and triggering a DNA damage response which leads to excision of telomere repeats. In differentiated spermatozoa, telomeres play a fundamental role in the organization of the sperm nucleus. After fertilization, sperm telomeres are the first site in the sperm genome to respond to oocyte signals for pro-nucleus formation.
Study design, size, duration: This is a case control study. The study included 112 cases and 53 controls. Cases and controls were recruited from January, 2013 to July, 2014.
Participants/materials, setting, methods: The study included 112 infertile men and 53 fertile controls. ROS estimation was done by chemiluminescence method. The average telomere length from the sperm DNA was measured by quantitative Real Time PCR. 8-Hydroxy-2-deoxy-Guanosine (8-OHdG) level was assessed by Cayman's ELISA kits. DNA fragmentation Index (DFI) was assessed by Sperm Chromatin Structure Assay (SCSA).
Main results and the role of chance: The mean ROS was significantly elevated in cases (66.61 ± 28.32 RLU/s/million sperm) compared to controls (14.04 ± 10.67 RLU/s/million sperm). The 8-OHdG level in patients were 30.92 ± 3.27 pg/ml and in controls 14.29 ± 2.24 pg/ml. The mean DNA Fragmentation Index (DFI%) in patient was 36.11 ± 13.69 and in controls 24.17 ± 8.7. The mean telomere length was significantly lower in patient group (ROS > 35) as compared to patient group (ROS < 22) but it significantly increased in the patient group (ROS = 22–35) as compared to patient group (ROS < 22).
Limitations, reason for caution: The findings of this study should be validated in more samples.
Wider implications of the findings: In this study we found that in infertile patients oxidative stress leads to sperm DNA damage and telomere shortening. Elevated ROS levels lead to telomere shortening but seminal ROS to a particular level (ROS = 22–35 RLU/s/million sperm) are protective in maintaining telomere length.
Study funding/competing interest(s): Funding by national/international organization(s) – Department of Biotechnology (DBT), INDIA.
Trial registration number: NA.

P-639 Targeted copy number analysis for preimplantation genetic screening

G. Porreca[1], J. Gole[1], A. Gore[1], E. Boyden[1], M. Slevin[1], D. Maganzini[1], P. Saunders[1], M. Umbarger[1]
[1]*Good Start Genetics, Good Start Genetics, Cambridge, U.S.A.*

Study question: Can next-generation DNA sequencing (NGS) be applied in a targeted fashion to measure chromosome copy number in limiting numbers of human cells?
Summary answer: We have developed a targeted, PCR-based approach that determines chromosome copy number with analytical accuracy sufficient for use in preimplantation genetic screening (PGS).
What is known already: PGS is used to assess the chromosome copy number of embryos. Although growing evidence indicates that euploid embryo transfer increases implantation rates and decreases miscarriage rates, PGS adoption has been limited at least in part due to the high cost of traditional PGS approaches. However, increased use of trophectoderm biopsy followed by vitrification and subsequent frozen embryo transfer coupled with streamlined workflows employing next-generation DNA sequencing (NGS) are poised to enable broader PGS adoption.
Study design, size, duration: 12 pg DNA (~2 diploid cells) purified from cell lines, or lysate derived from 1 to 5 cultured fibroblast cells, served as template for the PCR reactions. The products were sequenced to generate count data for each chromosome, and these data were subsequently used to infer karyotypes.
Participants/materials, setting, methods: We have developed and implemented an automated PCR-based method that amplifies regions from each chromosome and simultaneously attaches the sequencing adapters and sample-specific barcodes necessary for multiplexed NGS. Because the PCR primers are human-specific, this method is robust to non-human DNA contamination.
Main results and the role of chance: Using purified gDNA template derived from 19 aneuploid and 16 euploid cell lines, a total of 41 true aneuploid chromosome calls, 3630 true diploid chromosome calls, 1 incorrect aneuploid (false positive) chromosome call, and 0 incorrect diploid (false negative) chromosome calls were made. The incorrect aneuploid call was in a sample that contains additional correctly called aneuploid chromosomes, thus yielding perfect sample-level specificity, and perfect sample- and chromosome-level sensitivity. Aneuploidies detected included trisomies 2, 8, 9, 13, 18, 20, 21, 22, 2 + 21, and 16 + 21, XO, XXXX, XXY, and XYY. The technique also detected trisomy 9, 13, 18, 21, XXY, and XYY when lysate from one, two, or five fibroblasts was used as template.
Limitations, reason for caution:.
Wider implications of the findings: Collectively, our results indicate that this simple, targeted approach for determining chromosome copy number can deliver the level of accuracy required to perform NGS-based PGS.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Good Start Genetics, Inc.
Trial registration number: NA.
Keywords: PGS, next-generation DNA sequencing

P-640 Does the pregnancy rate following transfer of vitrified-warmed embryo biopsied and analyzed by CGH change in different maternal age ranges?

C. P. Gomes[1], M. Nicolielo[2], J. R. Alegretti[2], E. L. A. Motta [3], P. C. Serafini[4]
[1]*Huntington Reproductive Medicine, Clinical, São Paulo, SP, Brazil*
[2]*Huntington Reproductive Medicine, Embryology, São Paulo, SP, Brazil*
[3]*Huntington Reproductive Medicine/Gynecology Department of Federal University of Sao Paulo, Head of Clinical/Gynecology-Endocrinology Discipline, São Paulo, SP, Brazil*
[4]*Huntington Reproductive Medicine/Obstetrics and Gynecology Department of University of Sao Paulo, Head of Clinical/Gynecology Discipline, São Paulo, SP, Brazil*

Study question: Does patients age affect clinical outcome in vitrified-warmed embryos biopsied with comparative-genetic array (CGHa) technique transfer?
Summary answer: In spite of an increase in embryo transfer cancelation rate due to aneuploidies detected in all embryos as patients age is higher, maternal age did not affect IVF clinical outcome in vitrified-warmed embryos transferred cycles since pregnancy rates are similar between groups with at least one euploid embryo transferred.
What is known already: Maternal age is the best predictor of clinical IVF outcomes. In women older than 35 years old, IVF success rates declines progressively and this is more remarkable after forties. Moreover, aneuploidy and abortion rates turns higher as women's age increases. Oocyte aging can cause not only cell cytoplasm alterations, but also nuclear genetic abnormalities due to altered chromosome alignment. Those abnormalities lead to aneuploidies, which can be responsible for implantation failure and abortion.
Study design, size, duration: This retrospective observational study evaluated 299 cycles with 841 embryos biopsied and evaluated with CGHa. Patients underwent standard protocols for ovulation induction and endometrial preparation at a private Assisted Reproduction Center between 2011 and 2014. Participants were split in three groups according with age: <35 year-old (n = 69); 36–39 year-old (n = 90); ≥40 year-old (n = 140).
Participants/materials, setting, methods: Embryos were cultured until D5 and blastocysts biopsied and vitrified using standard protocols. Genetic analysis were done with aCGH. Euploid embryo-transfer were performed on the next menstrual cycle with endometrium preparation. We compared demographic characteristics to evaluate similarity between groups, and primary outcome was ongoing-pregnancy rate in vitrified-warmed transferred cycles.
Main results and the role of chance: Patients age were <35 year-old: 32.8 ± 2.3; 36–39 year-old: 37.8 ± 1.1; ≥40 year-old: 41.7 ± 1.7. The number of embryos biopsied was higher in patients <35 year-old (4.0 ± 2.4) compared to 36–39 year-old (2.9 ± 1.9; $p = 0.001$) and ≥40 year-old (2.6 ± 1.8; $p < 0.001$). The percentage of normal embryos was also higher for younger patients (<35 year-old: 48.2%) compared to 36–39 year-old (24.6%; $p < 0.001$) and ≥40 year-old (15.4%; $p < 0.001$), while the cycle cancelation rate due to non-normal embryos for transfer was higher for older patients ≥40 year-old (67.1%) compared to 36–39 year-old (56.7%; $p < 0.001$) and <35 year-old (18.8%; $p < 0.001$). On the other hand, when we evaluated cycles transferred, older patients had little lower number of transferred embryos (≥40 year-old: 1.3 ± 0.5) related to <35 year-old (1.6 ± 0.5; $p = 0.015$) but no different of 36–39 year-old (1.5 ± 0.6; $p = 0.178$), and ongoing pregnancy rates (<35 year-old: 46.4%; 36–39 year-old: 46.2%; ≥40 year-old: 56.5%; $p = 0.524$) were not affected.
Limitations, reason for caution: This is a retrospective observational study in which we compared clinical outcomes of vitrified-warmed embryo transfer, biopsied with CGHa analysis in according with patients age. Severe male factor, previous recurrent abortion or implantation failures could interfere in genetic results.
Wider implications of the findings: Vitrified-warmed blastocysts biopsied and evaluated by CGHa analysis technique transfers have similar clinical outcomes independently of women age. Genetic abnormalities embryos rate and cycle cancellation progressively increases in older patients, as is expected. However, for an euploid transferred cycles, patients age does not affect clinical outcomes suggesting that negative outcomes are placed exclusively to oocyte chromosome alterations and does not outstanding to other patients characteristic as endometrium.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Huntington Reproductive Medicine.

[2]*University of Ioannina, Medical School Department of Obstetrics and Gynecology Genetics and IVF Unit, Ioannina, Greece*
[3]*University of Ioannina, Medical School Department of General Biology, Ioannina, Greece*

Study question: To investigate the effects of LINE-1 retrotransposition on methylation and DNA damage and also to determine the effects of LINE-1 retrotransposition on stage-specific expression of three major transcriptional factors OCT-4, SOX2, NANOG, during preimplantation stages of human embryo development.
Summary answer: Our data provide novel evidence that LINE-1 retrotransposition in human preimplantation embryos induce double strand breaks and interferes with the expression patterns of pluripotency factors OCT-4, SOX2, NANOG during human preimplantation development. Furthermore, they demonstrate potential changes in methylation reprogramming at the cleavage stage.
What is known already: The epigenetic regulatory mechanism of DNA methylation plays crucial role in cell differentiation, regulation of gene expression, genome reprogramming and silencing of repetitive elements. In mammals, epigenetic reprogramming occurs during early development. OCT-4, SOX2 and

NANOG, are crucial for the establishment and maintenance of pluripotency and self-renewal of ESCs in preimplantation embryo. LINE-1 have been implicated in many human disorders, chromosome rearrangements, gene silencing and are found to be expressed in undifferentiated human ESCs.
Study design, size, duration: *In vitro* preimplantation development of human embryos generated from oocytes and transfected through sperm with active LINE-1 were compared with control embryos. Retrotransposons were tagged with EGFP gene-based retrotransposition cassette in order to demonstrate new retrotransposition events when inserted into the embryonic genome.
Participants/materials, setting, methods: Immature oocytes at GV and MI stages and MII oocytes were donated for research to the IVF center of University Hospital of Ioannina, by infertile couples. Retrotransposition events in oocytes and in embryos were confirmed by fluorescent microscopy. Methylation status, pluripotency and DNA double strand breaks were also examined.
Main results and the role of chance: Embryos infected by retroelements introduced at ICSI in comparison to uninfected, are characterized by accelerated asymmetrical cell division, multiple cellular fragments, cleavage arrest and embryo degeneration. This is also evident from the early expression of the OCT4 and the absence of SOX2 and NANOG which are expressed at the morula stage of controls. In addition, double strand DNA breaks in each particular blastomere at the cleavage stage, coincided with methylation changes and insufficiency of pluripotency factors expression. We conclude that the very early initiation of DNA DSBs as the result of the RE activity, interferes with further preimplantation embryo development to the blastocyst stage and hinders the positive influences of OCT4, SOX2, NANOG on the formation of the morulae, the ICM and the trophectoderm.
Limitations, reason for caution: The injected quantity of LINE-1 cassette may exert a spectrum of damaging effects in the early embryo beyond the designated markers used in this study and confer to the early embryo arrest.
Wider implications of the findings: Our findings show that active retroelements produce DNA breaks as they create new integration sites in the genome, thus may interrupt human embryo development and lead to morphological and genomic abnormalities. The absence of SOX2 and NANOG, apart from the embryo destruction by the active retroelements, may be also influenced by interference of the retroelements with methylation. Uncontrolled human retroelements may cause the high percentages of abnormal embryos in clinical practice.
Study funding/competing interest(s): Funding by national/international organization(s). This study has been co-financed by the European Union (European Regional Development Fund-ERDF) and Greek national funds through the Operational Program "THESSALY-MAINLAND GREECE AND EPIRUS-2007–2013" of the National Strategic Reference Framework (NSRF 2007–2013).

P-642 Chromosomal polymorphic variants increase the embryo aneuploidy rate in IVF cycles

R. Morales Sabater[1], B. Lledo[1], A. J. Ortiz[1], A. Rodriguez-Arnedo[2], H. Blanca[2], J. Llacer[3], R. Bernabeu[3]
[1]*Instituto Bernabeu Biotech, Molecular Biology, Alicante, Spain*
[2]*Instituto Bernabeu, Reproductive Biology, Alicante, Spain*
[3]*Instituto Bernabeu, Reproductive Medicine, Alicante, Spain*

Study question: Could chromosomal polymorphic variations increase the embryo aneuploidy rate in blastocysts obtained after an IVF cycle?
Summary answer: Differences in embryo aneuploidy rates are detected in patients with and without chromosomal polymorphisms. We show that carriers of polymorphisms have a higher risk of embryonic aneuploidy.
What is known already: Chromosomal polymorphic variants are considered as normal but previous studies have reported that they are associated with infertility and recurrent abortions although the way is unknown. On the other hand there is a high incidence of chromosome abnormalities in human gametes and embryos that leads to failure of IVF cycles, including oocyte donation cycles. This could be due to aggressive stimulation, male factor or other issues, but there are causes that are yet to be defined.
Study design, size, duration: A retrospective study was performed. We included the array-CGH results of 524 embryos from 231 comprehensive chromosome screening (CCS) cycles performed between 2013 and 2014 at Instituto Bernabeu, Alicante, Spain. The main outcome measures were embryo aneuploidy rate and implantation rate.
Participants/materials, setting, methods: We included 524 embryos (301 embryos from oocyte donation cycles and 223 from IVF cycles with own oocytes). Whole chromosome imbalances by array-CGH in trophectoderm cells from D5 embryos were detected. Array-CGH analysis was performed using Agilent SurePrint G3 8 × 60 k CGH microarrays previous whole genome amplification (WGA) of genomic DNA.
Main results and the role of chance: Significant differences were reported in the embryo aneuploidy rate between carriers and not carriers of chromosomal polymorphisms (46.8% vs. 34.9%; OR = 1.638, 95% CI = 1.005–2.668). We show that these differences occur in oocyte donation cycles but not in cycles with own oocytes, perhaps because the oocytes donors are a homogeneous group without confusion factors like woman age. The presence of a chromosomal polymorphism in the oocyte donor (and not in the male partner) has a higher risk for embryonic aneuploidy. Moreover, we observed that the implantation rate from euploid embryos transferred were lower in polymorphisms carriers group (42.9% vs. 57.3%) although the difference in this case was not significant.
Limitations, reason for caution: The present work suggests that chromosomal polymorphisms could be responsible for a higher percentage of aneuploidies in embryos from IVF cycles, mainly in young woman. More studies are needed to elucidate how these polymorphisms affect to mechanisms of meiotic segregation.
Wider implications of the findings: This study reveals a higher aneuploidy rate in blastocysts from chromosomal polymorphisms carriers than in embryos from individuals with normal karyotype, showing a relationship between these both phenomena. Karyotyping of individuals, patients and donors, before an IVF cycle is important because the incidence of chromosomal abnormalities, including polymorphic variants, is quite high and application of array-CGH in these cases will improve the IVF results selecting euploid embryos.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Instituto Bernabeu Foundation.
Trial registration number: This study was not registered.

P-643 The inter-chromosomal effect, a reality: an example of a study on paternal meiosis

A. Hajlaoui[1], M. Kammoun[1], I. Zidi-Jrah[1], S. Meddeb[1], M. Fekih[1], M. Ajina[1], S. Ibala-Romdhane[1], A. Saad[1], S. Mougou-Zerelli[1]
[1]*University Hospital Fhached, Department of Cytogenetic and Reproductive Biology, Sousse, Tunisia*

Study question: What's the origin of prenatal aneuploidy in male carriers of translocations: Is there any inter-chromosomal effect???
Summary answer: This cytogenetic evaluation confirmed that the inter-chromosomal-effect (ICE) truly exists and could contribute to higher rates of abnormal prenatal aneuploidy, resulting in a small increase in the risk of miscarriage and birth of children with congenital abnormalities and a potential reduction in fertility.
What is known already: Many researchers have sort to investigate this phenomenon. Some of them did not report any evidence of ICE in several translocation carriers. Some of the analyzed patients had normal semen parameters; therefore the authors suggested that ICE could be restricted to patients with abnormal semen parameters. However, many reports detected an ICE in different translocation carriers.
Study design, size, duration: Five male carriers of translocations (3 reciprocal and two Robertsonian), were included in this study. In addition 7 fertile men with normal 46, XY karyotypes and normal sperm characteristics were recruited as a control group for the analysis of the ICE.
Participants/materials, setting, methods: In all cases, fluorescent in situ hybridization specific for chromosomes X, Y, 18, 21 and 22 was realized. The Mann-Whitney U-test was used to compare the aneuploidy rates between patients and controls.
Main results and the role of chance: In the ICE evaluation, all translocation carriers (both Robertsonian and reciprocal translocation carriers) showed

significantly increased frequencies of disomy of all investigated chromosomes, and diploid gametes compared with the control group ($p < 0.05$). However, disomy XY was not significantly different between controls and patients ($p > 0.05$). We also observed a considerable inter-individual variability in disomy and diploidy rates observed in our group of translocation carriers.
Limitations, reason for caution: The limitations of the available cytogenetic technologies have meant that the existence of an ICE remains a subject of debate. The analysis of additional chromosomes would have been useful in order to draw legitimate conclusions and more elucidate possible mechanism for generating chromosomal imbalances.
Wider implications of the findings: This study demonstrates that besides the direct effect on the chromosomes involved in the rearrangement, there may also be an impact on the segregation of other, structurally normal, chromosomes during meiosis. This might be a consequence of disrupted chromosome alignment on the spindle, or due to interference with other key aspects of the chromosome segregation process, leading to a generalized increase in the risk of producing aneuploid paternal gametes.
Study funding/competing interest(s): Funding by hospital/clinic(s). Departments of Cytogenetic and Reproductive Biology and Gynecology and Obstetrics, Farhat Hached University Teaching Hospital, Sousse, Tunisia.
Trial registration number: NA.

P-644 Increased incidence of partial Y chromosome microdeletions in male newborns conceived by assisted reproductive technologies

P. Stanar[1], R. Ng[1], K. Louie[1], V. Chow[1], S. Ma[1]
[1]*University of British Columbia, Obstetrics and Gynacology, Vancouver, BC, Canada*

Study question: To investigate the incidence of Y chromosome microdeletions in male newborns conceived by intracytoplasmic sperm injection (ICSI), *in vitro* fertilization (IVF), and natural conception (NC).
Summary answer: We found a statistical significance in the proportion of babies with partial Y chromosome microdeletions between the ICSI, IVF, and NC populations.
What is known already: Vertical transmission of Y microdeletions from father to son via ICSI have been widely shown.
Study design, size, duration: A total of 186 male newborns were recruited, including 35 babies conceived by ICSI, 37 babies conceived by IVF, and 114 babies conceived naturally. The Yq genetic status of the newborns was determined according to 18 Y-specific STS markers covering three azoospermia factor (AZF) sub-regions and internal control sequences.
Participants/materials, setting, methods: Genomic DNA was extracted from umbilical cord blood according to the protocol provided with the QIAamp DNA Blood Mini Kit. A two-tailed Fisher's exact test was used to compare the frequency of patients with and without detected Y chromosomal microdeletions in the ICSI, IVF, and NC populations.
Main results and the role of chance: We found that partial AZF microdeletions were identified in 8 (22.9%) of 35 ICSI newborns, 4 (10.8%) of 37 IVF newborns, and 1 (0.9%) of 114 NC newborns. There was a statistically significant difference in the proportion of babies with partial Y chromosome microdeletions between the ICSI, IVF, and NC populations. When analyzed individually, only the SY114 and SY152 STS markers showed a statistically significant difference in incidence between the three cohorts.
Limitations, reason for caution: We did not study the Y chromosome microdeletions in fathers, therefore cannot analyze whether the deletions were inherited or *de novo*.
Wider implications of the findings: Our studies indicate that the population of male children conceived through ARTs, particularly ICSI, are at an increased risk of genetic defect in the form of partial Y chromosome microdeletions. The growing population of ART-conceived children emphasizes the importance of studying genetic repercussions of these procedures in regards to the future fertility of males conceived *in vitro*.
Study funding/competing interest(s): Funding by national/international organization(s) – Canadian Institutes of Health Research.

P-645 The type of chromosomal alteration that is detected in aneuploid embryos is related to maternal age

J. A. Ortiz[1], B. Lledó[1], R. Morales[1], I. Ochando[2], J. Llácer[3], R. Bernabeu[3]
[1]*Instituto Bernabeu Biotech, Biología Molecular y Genética, Alicante, Spain*
[2]*Instituto Bernabeu, FIV, Alicante, Spain*
[3]*Instituto Bernabeu, Medicina Reproductiva, Alicante, Spain*

Study question: Is there any relationship between maternal age and type of chromosome aberrations seen in blastocysts generated by IVF cycles?
Summary answer: Despite embryonic trisomies increase with maternal age, the rate of monosomies in blastocysts is independent of the age. Only significant changes related with advanced maternal age were detected in chromosomes 2, 11, 13, 15, 16, 21 and 22.
What is known already: The aneuploidy is one of the major factors affecting the embryo outcome. The rate of embryonic aneuploidy increases with maternal age. Discarding affected embryos, after a Comprehensive Chromosome Screening (CCS) by array Comparative Genomic Hybridization (aCGH) give us an implantation rate that does not depend on maternal age. Thus, CCS corrects the effect of maternal age in embryo implantation.
Study design, size, duration: This is a retrospective observational study performed between January 2013 and January 2015 at Instituto Bernabeu. Alicante. Spain. The study includes the data analysis of 585 blastocysts with conclusive CCS results obtained from 197 patients.
Participants/materials, setting, methods: We included 518 blastocysts from patients aged ≤40 years old and 67 over 40 years old. Whole chromosome imbalances by array-CGH in trophectoderm cells from D5 embryos were detected. Array-CGH analysis were performed using Agilent SurePrint G3 8 × 60 k. The association between variables was analyzed using Logistic Regression and Chi-square Test.
Main results and the role of chance: 41.4% of the embryos analyzed were aneuploids of which 65.3% had monosomy and 46.2% trisomy. There was no significant difference in the number of monosomies in aneuploid blastocysts between patients ≤40 years old (67.7%) and >40 years old (61.4%) $p = 0.422$. On the other hand, trisomies increase in a statistically significant way between both age groups (42.6% vs 65.9%; $p = 0.005$). After the individual analysis of chromosome, it was observed that most do not modify their levels of alteration with increasing maternal age, only on chromosomes 2, 11, 13, 15, 16, 21 and 22 a statistically significant increase was observed. Surprisingly, on chromosome 3, the opposite effect is observed, this chromosome appears altered less frequently in aneuploid embryos with higher maternal age.
Limitations, reason for caution: The study is limited by its retrospective nature. A higher sample size or a prospective randomized design should be used in future studies to corroborate the current findings.
Wider implications of the findings: This investigation reveals that all types of embryonic aneuploidies are not equiprobables. Trisomies are less frequent than monosomies but trisomies augment with increasing maternal age mainly on chromosomes 2, 11, 13, 15, 16, 21 and 22.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Instituto Bernabeu.
Trial registration number: NA.

P-646 Preimplantation genetic diagnosis (PGD) for inherited disorders using single nucleotide polymorphism (SNP) arrays: clinical outcomes of 100 cycles with transferable embryos

A. Jordan[1], R. Prates[2], N. Goodall[3], E. Armenti[1], V. Tecson[3], S. Munne[3], M. Konstantinidis[3], S. Jaroudi[3], S. Jaroudi[4]
[1]*Reprogenetics, Genetic Counseling, Livingston New Jersey, U.S.A.*
[2]*Reprogenetics, Molecular, Miami Florida, U.S.A.*
[3]*Reprogenetics, Molecular, Livingston New Jersey, U.S.A.*
[4]*Reprogenetics, Molecular, Al Ain, United Arab Emirates*

Study question: Is linkage analysis using a universal SNP array based protocol, known as Karyomapping, a successful PGD treatment strategy for patients requesting embryo testing for inherited disorders?

Summary answer: The high clinical pregnancy rate, including patients from multiple fertility centers throughout the USA, was similar to outcomes achieved by the most successful *in-vitro* fertilization (IVF) programs. Additionally, as lengthy patient-specific test developments were unnecessary, more patients were treated with faster time to embryo diagnosis, transfer, and pregnancy.
What is known already: Karyomapping utilizes a universal protocol, applicable to virtually all patients, for linkage-based PGD. It eliminates the need to develop and optimize patient-specific protocols, drastically reducing the waiting time for initiation of IVF treatment. This technology was previously validated using the gold-standard polymerase chain reaction methodology (with 100% concordance) and has proven to be highly efficient in providing a diagnosis for even the most complex of cases, including those not feasible using conventional PGD methods.
Study design, size, duration: Among the 130 Karyomapping cases performed between December 2013 and September 2014, clinical outcome and follow-up data was collected for 100 PGD cycles that had embryos suitable for transfer. Seventy-two out of the 100 cycles had undergone embryo transfer at the time of data collection.
Participants/materials, setting, methods: Patients were referred from over 50 IVF centers in the USA and Canada. Blastocyst stage embryos were biopsied and frozen for transfer in subsequent cycle(s). Samples were whole genome amplified and analyzed using Karyomapping combined with direct mutation detection as needed and/or independent aneuploidy screening when requested (76% cases).
Main results and the role of chance: The average number of embryos analyzed and eligible for transfer per cycle was 6.15 and 2.5, respectively. The aneuploidy screening, carried out in 76% of cases, likely reduced the number of transferable embryos but improved clinical outcome. The implantation rate was 71.4% (60/84) and the clinical pregnancy rate per cycle started was 72.2% (52/72). Most transfers involved a single thawed blastocyst at a time, except for six patients who had two embryos transferred in one cycle (8%). Two twin pregnancies were identified (resulting from one single and one double embryo transfer). The average maternal age was 32.66 years (range: 25–41). Currently, there are 11 live births and 35 ongoing pregnancies. Prenatal and perinatal testing was performed in four cases confirming PGD in all instances.
Limitations, reason for caution: The collection of clinical outcome and PGD follow-up data can be challenging, particularly when dealing with a large number of referring centers and international patients. Furthermore, few patients elect to undergo prenatal or perinatal testing to confirm the diagnosis, making it more difficult to reliably assess accuracy of PGD.
Wider implications of the findings: With the number of couples undergoing carrier screening steadily increasing, Karyomapping allows IVF groups and PGD laboratories to deal with the rapidly growing demand for embryo testing for inherited disorders. Ongoing follow-up data analyses will help us better determine the clinical accuracy of PGD using this technology. The application of Karyomapping and simultaneous comprehensive chromosome screening of embryos will speed up the testing process and further improve clinical outcomes.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Institutional funding. None of the authors have any competing interests.
Trial registration number: NA.

P-647 Differences in chromosomal abnormalities observed in preimplantation embryos according to male or female meiosis disruption in isolated male factor (MF) and advanced maternal age (AMA)

C. Rubio[1], L. Rodrigo[1], M. Florensa[2], E. Mateu[1], A. Mercader[3], V. Peinado[1], F. Bronet[4], M. Milan[1], S. Garcia-Herrero[1], I. Campos-Galindo[1], C. Simon[5]

[3]*IVI Valencia, PGD, Valencia, Spain*
[4]*IVI Madrid, Embryology and PGD, Madrid, Spain*
[5]*Fundación Instituto Valenciano de Infertilidad (FIVI) Instituto Universitario IVI/INCLIVA Valencia University Department of Obstetrics and Gynecology School of Medicine Stanford University IGENOMIX, Reproductive Medicine, Paterna-Valencia, Spain*

Study question: Are chromosomal abnormalities different in preimplantation embryos from MF and AMA couples?
Summary answer: Significantly higher incidence of chromosomal abnormalities in AMA patients than in MF, mainly due to complex abnormalities. Interestingly, in MF a higher incidence of aneuploidies for chromosome 2 and for sex chromosomes were observed, whereas in AMA patients the significantly higher aneuploidy rate was for chromosomes 15, 16 and 22.
What is known already: Aneuploidy in human embryos increases with advancing maternal age, due to the presence of aneuploid oocytes with a meiotic origin. Preimplantation Genetic Screening (PGS) is commonly indicated for the selection of euploid embryos to improve clinical outcome. Male meiotic impairment can also result in increased risk of aneuploidy offspring. Therefore, PGS could be also applied in couples with severe MF infertility.
Study design, size, duration: Two ongoing RCT studies (2012–2014) in two groups: AMA (75 PGS cycles in women between 38 and 41 years of age), and MF (44 cycles in severe MF, with sperm concentration <2 million sperm/mL, women age <38 years). In both studies, without a history of implantation failure or recurrent miscarriage.
Participants/materials, setting, methods: In both RCTs, patients were randomly allocated into two groups: conventional blastocyst transfer or PGS cycle. For the purpose of this study, only embryos in the PGS groups were considered. Cleavage stage biopsy and array CGH analysis of single blastomere. Statistical comparisons using Fishers 'exact test ($p < 0.05$).
Main results and the role of chance: In AMA group, 376 embryos were informative, 77.9% abnormal, 57.2% with complex abnormalities, 12.7% with chaotic pattern and 6.9% with segmental aneuploidies. In MF group, 277 embryos were informative, 66.4% abnormal, 5.8% with complex abnormalities, 15.9% with chaotic pattern and 6.1% with segmental aneuploidies. AMA group showed a significant increase in chromosomal abnormalities ($p = 0.0013$), mostly due to the significant increased for complex abnormalities ($p < 0.0001$) compared to MF group. Aneuploidy analysis for individual chromosomes in AMA group showed a significant increase in aneuploidy for chromosomes 15 ($p = 0.02$); 16 ($p = 0.03$) and 22 ($p = 0.0033$). In MF a significant increase was observed for chromosome 2 ($p = 0.045$) and sex chromosomes ($p = 0.04$). No statistical differences were observed in embryos with chaotic pattern or segmental aneuploidies and for the other individual chromosomes.
Limitations, reason for caution: This is an Interim analysis and the study needs to be completed to draw stronger evidence. This is not a blinded study. The results are valid for these specific populations.
Wider implications of the findings: These results would help to understand the origin of chromosomal abnormalities observed in preimplantation embryos and products of conception. Additionally, the cytogenetic studies on sperm could be re-oriented to the analysis of different chromosomes that are not commonly considered at high aneuploidy risk, such as chromosome 2.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – BlueGnome (Illumina), IVI, Igenomix.
Trial registration number: ClinicalTrials.gov NCT01571076.

[5]Huntington Reproductive Medicine Gynecology Department of Federal University of Sao Paulo, Head of Clinical Gynecology-endocrinology Discipline, Sao Paulo, Brazil

Study question: Do trophectoderm biopsy performed by array-comparative genomic hybridization (aCGH) at day 5/6, associated with frozen-thawed transfers improve clinical outcomes in all ages compared to elective non-biopsied frozen-thawed transfer in an unselected population?
Summary answer: Trophectoderm biopsy performed at the ideal embryo development (day 5 or 6) associated with vitrification at blastocyst stage possibly enhances pregnancy rates mainly in older patients, where the chromosome alterations are higher. However, in younger patients, assuming lower aneuploidy rates, the CGH selection does not lead to a significant improvement.
What is known already: Failures of IVF cycles may be explained by poor embryo potential, due to aneuploidies. Trophectoderm biopsy, with aCGH, has been shown to produce a better selection. If the embryo does not reach the proper cell expansion on day 5, an aggressive procedure could damage the implantation ability, postponing to an accurate moment and driving to vitrification and transfer in a different cycle. Deferring cycles in unselected patients is also a trend to enhance pregnancy rates.
Study design, size, duration: This is a retrospective observational study including 375 cycles of vitrified-thawed blastocyst transfers from 2013 to 2014 in a private center where we evaluated clinical pregnancy outcomes of frozen-thawed biopsied-euploid embryos (n = 149) compared to unselected frozen-thawed transfers with no chromosomal analyses (n = 226).
Participants/materials, setting, methods: All patients received same endometrium preparation and progesterone supplementation. Frozen-thawed embryo transfers were stratified by age in both groups: with CGH transfers (FET-aCGH group: ≤35 year-old: n = 44; 36–39 year-old: n = 47; ≥40 year-old: n = 58) compared to deferred transfers with no aCGH (FET group: ≤35 year-old: n = 103; 36–39 year-old: n = 72; ≥40 year-old: n = 51).
Main results and the role of chance: In the FET-CGH group, number of biopsied embryos was higher in patients ≤35 year-old (4.1 ± 2.4) compared to 36–39 year-old (2.9 ± 1.9; p = 0.001) and ≥40 year-old (2.4 ± 1.7; p < 0.001). The percentage of normal embryos was also higher for younger patients (≤35 year-old: 54.27%) compared to 36–39 year-old (29.28%) and ≥40 year-old (17.19%), while the cycle cancelation rate due to aneuploidies was higher for older ≥40 year-old (65.52%) against 36–39 year-old (46.81%; p < 0.05) and ≤35 year-old (11.36%; p < 0.05). Combining CGH-FET and FET groups and applying a multiple logistic regression analysis showed a significant chance to become pregnant, per started cycle, only for those who underwent CGHa at ≥40 year-old (OR: 4.7; p = 0.013). The CGH analyses did not influence the pregnancy chance per started cycle in patients ≤35 year-old: (OR: 1.7; p = 0.248) or 36–39 year-old (OR: 1.2; p = 0.683), adjusted for the number of embryos transferred in both groups.
Limitations, reason for caution: This study evaluated unselected patients undergoing frozen-thawed embryos transfer and factors that could imply in pregnancy success, as sperm quality and factor of infertility, were not taking into account.
Wider implications of the findings: Our findings showed a high aneuploidy rate mainly on patients older than 40 year-old, which had beneficial on embryo selection to accomplish better pregnancy rates per started cycle and also a better counseling after CGH. On deferred transfers the low pregnancy rates in olders is probably correlated with chromosomal abnormalities. In younger patients (39 year-old or less), euploid embryos are more expected and other factors may influence the outcomes and questioning the CGH analysis.

[5]Fundación Instituto Valenciano de Infertilidad (FIVI) Instituto Universitario IVI/INCLIVA Valencia University Department of Obstetrics and Gynecology School of Medicine Stanford University, Reproductive Medicine, Valencia, Spain

Study question: Are day-3 blastomere biopsy or day-5 trophectoderm biopsy representative of the whole embryo when analysed by array-Comparative Genomic Hybridization (arrayCGH)?
Summary answer: The results obtained in both types of embryo biopsies showed similar concordance rates when whole blastocysts were re-analysed using the same technique. Therefore, both biopsy strategies can be used for clinical analysis in PGS using arrayCGH.
What is known already: ArrayCGH technique is applied in clinical routine for PGS using either day-3 or blastocyst embryo biopsies. Mosaicism appears during embryo development and it has been described at both cleavage and blastocyst stage. Day-3 embryo biopsies have been discredited as not representative of the whole embryo due to mosaicism. On the contrary, trophectoderm biopsies may provide more accurate diagnosis due to the higher number of cells that can be analysed simultaneously.
Study design, size, duration: Blinded study in which 109 embryos previously diagnosed as chromosomally abnormal by arrayCGH were re-analyzed. All the embryos were re-analysed using arrayCGH on the whole blastocyst. Samples were collected from October 2012 to September 2014.
Participants/materials, setting, methods: Group A: 50 embryos previously diagnosed as aneuploid by arrayCGH on single blastomeres on day-3; Group B: 59 embryos diagnosed as aneuploid by arrayCGH on trophectoderm biopsies on day-5/day-6. Whole chromosome aneuploidies were considered except partial chromosome gains are losses. Re-analysis was performed following the same arrayCGH protocol used for PGS (BlueGnome Ltd, Cambridge, UK).
Main results and the role of chance: High concordance rates were observed in both, day-3 and trophectoderm biopsies when compared with the re-analysis in the whole blastocyst (49/50 (98%) and 57/59 (96.6%) respectively). Specifically, in 39 out of 50 (78%) embryos in group A, and 48 out of 59 (81.4%) of group B, all the aneuploidies reported remained in the re-analysis of the whole blastocysts. At least one aneuploidy observed in the biopsies was confirmed in 6/50 (12%) in group A, and in 7/59 (11.9%) in group B. Complementary aneuploidy for a given chromosome (e.g., monosomy vs. trisomy) was observed in 4/50 (8%) in group A, and 2/59 (3.4%) in group B. The discrepancy in group A showed a mosaic profile in the blastocyst and, in group B the two discrepancies were full euploid blastocysts.
Limitations, reason for caution: Sample size could be increased to confirm the findings. ArrayCGH technology does not allow the detection of mosaicism rates lower than 25–30%.
Wider implications of the findings: Both types of biopsies showed similar false positive rate. Therefore, both approaches are valid for clinical routine in PGS and more patients would be benefited of PGS by choosing a personalized approach based on their clinical background, number and quality of the available embryos.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – IGENOMIX.
Trial registration number: NA.

P-650 Function of TETs in chromatin remodeling during spermiogenesis: a crucial point towards production of potent spermatozoa and in safeguarding of male fertility

U. Schagdarsurengin[1], T. Dansranjavin[1], N. Kai[1], N. Roggenhofer[2], D. Fietz[3], M. Bergmann[3], W. Weidner[4], K. Steger[5]

[5]*Justus-Liebig-University Giessen, Section Molecular Andrology Clinic of Urology Pediatric Urology and Andrology, Giessen, Germany*

Study question: Among all cell types spermatozoa are known to have the lowest genome-wide 5-cytosine-methylation. Ten eleven translocation enzymes (TETs) catalyze in somatic cells the 5C-hydroxymethylation (5hmC) towards DNA-demethylation. Here, we asked the function of TETs in spermatogenesis and their role in production of fertile sperm and maintenance of male fertility.
Summary answer: We found that TET2 and TET3 are expressed in last steps of spermatogenesis and accompany the 5hmC-process. Notably, we could reveal that several conditions typical for male infertility (low sperm concentration, low sperm motility, oligo- and asthenozoospermia, low fertilization and pregnancy rates) are significantly associated with reduced TET expression.
What is known already: Our knowledge about the function of TETs and the impact of 5hmC in human spermatogenesis is still very sparse. Few existing studies are focused on the role of TETs in germ cell cancers (maintenance of active demethylation mechanisms in carcinoma-in-situ and seminomas in order to keep the hypomethylated cancer-genome) and do not deliver a consistent picture about their impact in normal spermatogenesis.
Study design, size, duration: We analyzed TET2- and TET3-expression (mRNA and protein), and 5-hmC, respectively, in normal human spermatogenesis and mature spermatozoa. We compared TET-mRNA-amount in spermatozoa of fertile donors and sub-fertile men, who underwent ART (assisted reproductive technology), and correlated the data to different fertility parameters (spermiogram according to WHO criteria and ART-outcome).
Participants/materials, setting, methods: We examined TET2- and TET3-expression in testis tissue samples exhibiting normal spermatogenesis by in-situ-hybridization (ISH), immunohistochemistry (IHC) and western blot (WB), and 5hmC – by immunofluorescence (IF). Ejaculates from 51 fertile and 44 sub-fertile men (fertility clinic Munich) were utilized for mRNA-studies in spermatozoa by RT-qPCR. Statistics were done using SPSS-20.
Main results and the role of chance: TET2-mRNA and – protein expression could be found in cytoplasm of pachytene-spermatocytes (stage I) up to elongated spermatids (stage II). TET3-mRNA-expression was present in cytoplasm of pachytene-spermatocytes (stage III) up to elongated spermatids (stage II), whereas TET3-protein-expression was examined in nucleus of round spermatids (stage I up to stage IV). 5-hmC was detected in elongated spermatids (stages V and VI). Analyzing mature spermatozoa (note: expressional inactive cells), we could reveal the presence of non-degraded TET2- and TET3-protein as well as a verifiable amount of non-degraded TET2- and TET3-mRNA. Comparing fertile donors with sub-fertile patients we observed that low level of TET-mRNA in spermatozoa is significantly associated with low sperm-concentration and -motility, with oligo- and asthenozoospermia, and moreover, with low fertilization and pregnancy rates.
Limitations, reason for caution: Mature spermatozoa are expressional inactive cells. To be able to quantify TET-mRNA in spermatozoa we tested in spermatozoa (healthy donors and patients) the stability of three standard house keeping genes known from somatic cells (*a-Tubuline*, *β-Actin* and *GAPDH*), and have chosen *GAPDH* as the most stable and suitable.
Wider implications of the findings: Our study shows that the final step of spermatogenesis comprising the huge genome-wide epigenetical modifications like chromatin-hypercondensation by nucleosome-to-protamine exchange and DNA-hydroxymethylation are accompanied and supported by TETs, and are crucial for production of "feature-complete" sperm cells with the ability to fertilize the oocyte. Evaluation of TET-function in spermatozoa of men could be further used for the development of clinical applicable test-systems with prognostic and diagnostic validity.

P-651 Preventing the discard of potentially transferable embryos by next generation sequencing-based preimplantation genetic screening

F. Spinella[1], S. Bono[1], A. Biricik[1], M. Barberi[2], A. Nuccitelli[1], F. Kokocinski[3], C. Michel[3], M. G. Minasi[2], E. Greco[2], F. Fiorentino[1]
[1]*"Genoma", Molecular Genetics Laboratory, Rome, Italy*
[2]*European Hospital, Reproductive Medicine, Rome, Italy*
[3]*Illumina, Inc., Cambridge, United Kingdom*

Study question: Can next generation sequencing (NGS)-protocol be applied for aneuploidy screening of human embryos to improve the detection of potentially transferrable mosaic embryos?
Summary answer: The higher dynamic range of NGS methodology allows an improved discrimination between mosaic and fully aneuploid embryos compared with array comparative genome hybridization (aCGH)-based preimplantation genetic screening (PGS), thus preventing the discard of potentially viable embryos.
What is known already: Aneuploidy screening of embryos at blastocyst stage can be jeopardized by the presence of chromosomal mosaicism, a phenomenon characterized as a mixture of diploid and aneuploid cell lines in the same embryo. Although many of such embryos do not implant, some may undergo through a natural mechanism of aneuploidies rescue during development resulting in euploid embryos. Therefore, an improved discrimination between mosaic and full aneuploid embryos provides a chance to prevent discarding of these embryos, allowing couples to consider the option of their transfer.
Study design, size, duration: This study was organized into two steps. The first involved mixing experiments with different euploid and aneuploid single cell ratios to establish a correspondence curve between aneuploidy percentage and copy number recorded by NGS. In the second step, blastocysts previously diagnosed with aCGH were analyzed by the NGS-based PGS protocol.
Participants/materials, setting, methods: Four hundred thirty-one whole genome amplification (WGA) products of embryos obtained from 196 PGS cycles performed during September 2013/May 2014 were selected for NGS analysis. WGA products included 51 diploid/aneuploid mosaic and 380 aneuploid embryos. NGS analysis was performed using MiSeq instrument. CNV analysis was accomplished by BlueFuse software.
Main results and the role of chance: Results of reconstitution experiments demonstrated that embryos constituted by aneuploid and euploid blastomeres could be consistently identified by NGS. Application of NGS-protocol to clinical samples showed concordant results in all the 51 mosaic embryos detected by aCGH and revealed that 40 out of 380 (10.5%) of aCGH-diagnosed aneuploid embryos were indeed mosaic embryos. After genetic counseling, 19 out of 51 mosaic embryos were transferred in 18 women, 8 of which had positive hCG levels. Two pregnancies resulted biochemical, 6 continued and were confirmed by at least one fetal sac and heart beat. Four pregnancies were ongoing and two went to term resulting in the birth of 2 healthy babies born.
Limitations, reason for caution: The NGS method provides great magnitude results due to the opportunity to avoid discarding of potentially viable embryos. However, this study is limited by the small amount of sample, thus larger studies are needed to confirm the significance of this procedure.
Wider implications of the findings: The possibility to improve the identification of mosaic embryos by NGS could represent a useful tool to increase the chances for infertile patients to achieve a pregnancy following an IVF treatment. This study demonstrates that NGS technique has a substantially increased sensitivity for detection of mosaicism over aCGH. Our results indicate that the transfer of mosaic embryos had the potential to result in healthy live births, thus avoiding discarding of potentially euploid embryos.

P-652 Epigenetic alterations of aromatase coding gene, CYP19A1, in cumulus cells of MII oocytes from infertile endometriosis patients

E. Hosseini[1], M. Shahhoseini[2], F. Mehraein[1], L. Karimian[3], M. Ashrafi[4], P. Afsharian[2], R. Aflatoonian[4]
[1]*Anatomy Department School of Medicine, Iran University of Medical Sciences, Tehran, Iran*

[3]*Department of Embryology at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine ACECR, Tehran, Iran*
[4]*Department of Endocrinology and Female Infertility at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine ACECR, Tehran, Iran*

Study question: Does endometriosis alters expression of *CYP19A1* gene in cumulus cells (CCs) of endometriosis patients and is there any association between altered *CYP19A1* expression with epigenetic changes on its promoter?
Summary answer: Aromatase decreased in CCs of MII oocytes from infertile endometriosis patients compared to control group. There are harmonious patterns between mRNA expression of *CYP19A1* gene and epigenetic alterations of its promoter PII region. Decreased aromatase expression may reduce the competence of the oocyte in endometriosis patients.
What is known already: Aromatase, the key enzyme of estrogen biosynthesis, is encoded by the *CYP19A1* gene. Aromatase plays a pivotal role in ovarian functions, folliculogenesis and acquisition of oocyte competence. Among the various promoters of *CYP19A1*, the promoter PII is the most active ones in ovarian cells. Previous studies showed that changes in gene expression of aromatase are associated with pathogenesis of endometriosis but no epigenetic marks have been reported for aromatase regulation in CCs of endometriosis till date.
Study design, size, duration: Case–control study was conducted on 10 infertile endometriosis patients and 10 patients with tubal factors of infertility who underwent ovarian stimulation with GnRH agonist for Intracytoplasmic Sperm Injection. Cumulus oocyte complexes were obtained from follicles during ovarian puncture. Only the CCs from MII oocytes were selected for this study.
Participants/materials, setting, methods: Total RNA extraction and cDNA synthesis were performed using Micro-RNeasyand QuantiTect Whole-Transcriptome Kits, respectively. Relative expression of *CYP19A1* gene was examined by Quantitative real-time PCR. The DNA binding of MeCP2 and specific histone modifications in PII promoter region of *CYP19A1* gene were examined by Chromatin Immunoprecipitation (ChIP) assay.
Main results and the role of chance: Our data revealed that the mean relative expression of *CYP19A1* gene was significantly lower in CCs from infertile endometriosis patients compared with the control group ($P < 0.05$). In CCs of endometriosis patients, incorporation of MeCP2 in promoter PII of *CYP19A1* is significantly higher than that of control group ($P < 0.05$). Furthermore, a significant hypoacetylation at lysine 9 of histone 3(H3K9ac) of promoter PII was observed in patients affected endometriosis, whereas no significant difference of methylation level atlysine 9 of histone 3 (H3K9me2) was detected between patients and control groups.
Limitations, reason for caution: For getting more complete information, we need to analyze a larger number of endometriosis patients and control groups.
Wider implications of the findings: For the first time our results have shown that decreased *CYP19A1* expression in cumulus cells of endometriosis patients might be the result of epigenetic alterations in regulatory region of*CYP19A1*, either through DNA methylation or histone modifications. Changes in gene expression of aromatase may impair the development of the follicles and follicular steroidogenesis leading to poor oocyte quality and maturity in endometriosis patients. These alterations may have close relationship with endometriosis-associated infertility.
Study funding/competing interest(s): Funding by University(ies), Funding by national/international organization(s) – Iran University of Medical Sciences, Tehran, Iran, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran.
Trial registration number: NA.

[3]*Ospedale Vita-Salute San Raffaele University, Gynaecology and Obstetrics, Milano (Mi), Italy*

Study question: Is first trimester combined screening for major fetal trisomies influenced by assisted reproduction techniques (ART) pregnancies from blastocyst transfer, with or without cryopreservation?
Summary answer: In ART pregnancies from blastocyst transfer, with or without cryopreservation, both the nuchal translucency (NT) measurement and free b-hCG concentration are higher as compared to spontaneous conceptions, whereas PAPP-A does not show any significant difference.
What is known already: Previous studies on ART pregnancies, from fresh and frozen-thawed embryos, showed controversial results concerning differences in NT values, free β-hCG and PAPP-A measurements compared to natural conceptions. Most studies showed no discrepancy of NT measurements, lower levels of PAPP-A and increased levels of free β-hCG. No published data are available analysing differences in the various components of first trimester combined screening between ART pregnancies after blastocyst transfer, with or without cryopreservation, and pregnancy conceived naturally.
Study design, size, duration: Retrospective case-control analysis involving 198 pregnancies recruited between 2012 and 2014. Forty-seven women conceived with fresh blastocysts from in vitro fertilization cycles (fresh-blasto), 51 with frozen-thawed blastocysts (frozen-blasto) and 200 were natural cycles (control group).
Participants/materials, setting, methods: Consecutive singleton pregnancies with euploid fetuses underwent ultrasound assessment at 11^{+0}–13^{+6} weeks with measurements of crown rump length (CRL), NT, free b-hCG and PAPP-A concentrations. Biochemical measurements were converted into multiples of the median (MoM). Sonographic measures were converted into delta values (A = observed-expected). Pregnancy outcomes were recorded.
Main results and the role of chance: The median NT was significantly higher both in frozen-blasto group (median: 0.27 mm; IQR: 0.02–0.44; $p < 0.001$) and in fresh-blasto group (median: 0.17 mm; IQR: 0.04–0.39; $p < 0.05$) as compared to control group (median: 0.00 mm; IQR: -0.19–0.12), whereas it was not different in the frozen-blasto compared to the fresh-blasto group. The median free β-hCG MoM was significantly higher both in frozen-blasto group (median 1.34; IQR 0.84–2.06; $p = 0.001$) and in fresh-blasto group (median 1.06; IQR 0.80–1.74; $p = 0.015$) as compared to control group (median 1.02; IQR 0.77–1.26), and it was also higher in frozen-blasto group compared to fresh-blasto group ($p < 0.001$). The three groups showed no significant differences in the median PAPP-A MoMs.
Limitations, reason for caution: This explorative study is based on a limited number of patients with blastocyst transfer and therefore needs independent confirmation.
Wider implications of the findings: Increased NT measurement and free β-hCG concentrations in pregnancies conceived after blastocyst transfer may lead to a higher false positive rate of the first trimester combined test for trisomy 21, with a consequent increased rate of unnecessary invasive tests and related fetal loss. If our results will be confirmed, first trimester screening algorithms may benefit from adjustments in the reference values of NT and free β-hCG, in pregnancies conceived through fresh and frozen blastocyst transfer.
Study funding/competing interest(s): Funding by hospital/clinic(s) – San Raffaele Hospital.
Trial registration number: NA.

P-654 Preimplantation genetic screening results performed in women aged 40 years old or older

L. Okada[1], R. Azambuja[1], V. Reig[1], A. Tagliani Ribeiro[1], D. Kvitko[1], L. Proença[1], F. Badalotti[1], R. Petracco[1], M. T. Sanseverino[1], J. Michelon[1], M. Badalotti[1], A. Petracco[1]
[1]*Fertilitat-Centro de Medicina Reprodutiva, Center for Medicine Reproductive, Porto Alegre, Brazil*

Study question: Analyze the preimplantation genetic screening (PGS) results performed in women aged 40 years old or older.
Summary answer: Our results confirm the high incidence of aneuploidies in women older than 40 years. When the patient has euplodies embryos to be transferred, the pregnancy rate is similar to the women in the thirties.

What is known already: Preimplantation genetic diagnosis (PGD) was initially developed to conceive healthy children in couples with genetic disorders or with sex chromosome syndromes. In patients with advanced maternal age is not uncommon that more than one-half of oocytes retrieved to be aneuploid. These women produce a high percentage of aneuploid embryos, which may explain the low implantation rate and recurrent miscarriages. Currently, preimplantion genetic screening (PGS) has been offered for many patients around the world.
Study design, size, duration: Retrospective cohort study between June 2012 and November 2014.
Participants/materials, setting, methods: Forty biopsy cycles was performed in women aged 40 years old or older (mean age 41.9 years). All patients had undergone in vitro fertilization (IVF) by intracytoplasmic sperm injection (ICSI). A total of 155 embryos were biopsied and PGS with the use of array comparative genomic hybridization (aCGH) was performed.
Main results and the role of chance: A total of 155 embryos were biopsied on day 3 or day 5 of culture, in 40 cycles of biopsy. These embryos, just 16 were considered euploid (10.3%). The euploid embryos were transferred in 13 cycles, 8 fresh cycles and 5 frozen embryo transfer. One euploid embryo has not been transferred and remains frozen. The pregnancy rate per transfer was 53.8% (7/13), and 17.5% (7/40) when considered the number total of cycles. One miscarriage was observed (14.3%).
Limitations, reason for caution: The study was conducted with a small number of cycles. These patients in the study may have had implantation failure or repeated miscarriages previously, which could explain the high percentage of aneuploidies found.
Wider implications of the findings: PGS does not improve ongoing pregnancy rate but can decrease miscarriages by aneuploidy. Patients with advanced maternal age may benefit with PGS, reaching more healthy babies born.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Fertilitat Centro de Medicina Reproductiva.
Trial registration number: NA.
Keywords: PGS, age, pregnancy rate, implantation rate

P-655 Assessment and validation of a next generation sequencing-based protocol for detection of chromosomal abnormalities in human preimplantation embryos

L. Ribustello[1], S. Tormasi[1], K. Bauckman[1], P. Colls[1], S. Munne[2], M. Konstantinidis[3]
[1]*Reprogenetics, aCGH Team, Livingston, New Jersey, U.S.A.*
[2]*Reprogenetics, CEO, Livingston, New Jersey, U.S.A.*
[3]*Reprogenetics, Research, Livingston, New Jersey, U.S.A.*

Study question: Is the 'VeriSeq PGS' assay (Illumina, USA) as accurate in detecting chromosomal abnormalities in human blastocysts when compared to an established, clinically applied method [array-comparative genomic hybridization (aCGH)]?
Summary answer: The assay was highly accurate in detecting abnormalities affecting whole chromosomes while, it was also found to be able to detect partial gains and losses of chromosomal material arising *de novo* or as a consequence of genetic predisposition (e.g. one of the parents being a translocation carrier).
What is known already: Recent randomized trials have indicated that comprehensive chromosome screening (CCS) of preimplantation embryos enhances *in vitro* fertilization (IVF) success rates. However, although methods currently being used are highly accurate in detecting aneuploidy, mosaicism, smaller deletions and duplications, and even single nucleotide changes may have an impact on reproductive outcome. NGS potentially can offer increased precision and higher analytical depth.
Study design, size, duration: A retrospective assessment of whole genome amplification products (WGA) obtained from 65 clinical PGS cycles involving trophectoderm biopsy of blastocysts was carried out. A translocation cycle involving chromosome segments as small as 9.9 Mb [t(1;21)(p36.23;q22.2)] was also assessed. A total of 378 blastocysts (10 from the translocation cycle) were assessed.
Participants/materials, setting, methods: Aliquots of SurePlex whole genome amplification products previously assessed clinically with 24sure microarrays (Illumina) for aCGH were used to carry out the VeriSeq PGS assay following manufacturer's instructions. A MiSeq desktop sequencer was utilized for next generation sequencing (NGS). The BlueFuse Multi analysis software was used for interpretation of results.
Main results and the role of chance: A total of 9,072 chromosomes were assessed, 365 of which were determined previously by aCGH to carry abnormalities spanning across the entire chromosomal complement. 30/365 were partial aneuploidies affecting only parts of different chromosomes and having a size range of 9.9–139.5 megabases (Mb) (including the translocation cycle samples). Diagnosis reached through the NGS method was in complete concordance (100%) with diagnosis reached through aCGH for all 378 embryos (176 euploid, 202 aneuploid). Furthermore, NGS analysis agreed with aCGH analysis for 9,071/9,072 (99.99%) of chromosomes assessed. NGS analysis detected 1 abnormality (trisomy) in an otherwise abnormal embryo that was not detected by aCGH. All 30 partial aneuploidies were successfully detected by NGS. Results regarding the 10 translocation samples were in complete agreement between the two methods.
Limitations, reason for caution: Only a few samples with partial aneuploidies or inherited chromosomal rearrangements were assessed. Errors caused by the amplification method would affect both aCGH and NGS results and are not measured in this study.
Wider implications of the findings: The VeriSeq PGS assay accurately identifies aneuploidies affecting whole chromosomes and chromosome segments as small as ~10Mb. The results of this study indicate that the method can be used clinically for comprehensive chromosome screening of blastocysts. NGS-based aneuploidy screening is expected to substantially contribute to better care of IVF patients by potentially offering higher precision for diagnosis.

P-656 Development of a rapid low-pass whole genome sequencing technique for the diagnosis of microdelection and microduplication in human embryos prior to implantation

T. Feng[1], K. Tan[2], B. Xiong[3], K. Yang[1], G. Lin[2]
[1]*Peking Jabrehoo Med Tech Co. Ltd, Research and Development, Beijing, China*
[2]*Central South University, Institute of Reproduction and Stem Cell Engineering, Changsha, China*
[3]*Reproductive and Genetic Hospital of CITIC-Xiangya, Genetic Center, Changsha, China*

Study question: Aneuploidy is common in human embryos created using in vitro fertilization (IVF) techniques. Reliable chromosome screening methods are crucial for single cells biopsied from preimplantation embryos to ensure transfer of euploid embryos.
Summary answer: The results demonstrate that next-generation sequencing (NGS) is highly accurate for diagnosis of microdelection and microduplication in cells from human preimplantation embryos.
What is known already: NGS has been shown to be accurate for preimplantation aneuploidy screening at a low cost.
Study design, size, duration: Excess blinded DNA from cells derived from preimplantation genetic diagnosis (PGD) cycles of 25 couples at risk of aneuploidy was evaluated by NGS with the use of the Ion Torrent Personal Genome Machine (PGM) (Life Tech).
Participants/materials, setting, methods: Single Nucleotide Polymorphism (SNP) array and fluorescence in situ hybridization (FISH) were also run on blinded excess DNA from the same samples. Finally, results obtained from NGS, SNP and FISH from the same embryos were unblinded and all three independent methods evaluated for consistency.
Main results and the role of chance: NGS provided 46% (13/25) equivalent PGD diagnoses of compound point mutations and small deletions and insertions compared with SNP–based analyses. In 5 samples (25%), there was complete discrepancy between the two methods. In the other 7 samples, there was partial discrepancy between SNP–based analyses and NGS-base analyses. Further evaluation with FISH indicated that NGS diagnosis was the same as FISH.
Limitations, reason for caution: Wider implications of the findings should be confirmed in large-scale studies.

Wider implications of the findings: NGS can provide more reliable blastocyst PGD results, which would be widely used for preimplantation genetic diagnosis.
Study funding/competing interest(s): Funding by national/international organization(s) – This work was supported by National Science Foundation of China (No. 81222007). The authors have no competing interests to declare.

P-657 Human leukocyte antigen (HLA) matching of preimplantation embryos using a polymerase chain reaction (PCR) based methodology and karyomapping

M. Konstantinidis[1], R. Prates[1], S. Jaroudi[2], N. Goodall[1], K. Milligan[1], D. Goldberg-Strassler[3], R. Cabey[3], S. Munne[2], D. Wells[4]
[1]*Reprogenetics, Molecular Department, Livingston, New Jersey, U.S.A.*
[2]*Reprogenetics, Research and Development, Livingston, New Jersey, U.S.A.*
[3]*Reprogenetics, Genetic Counseling, Livingston, New Jersey, U.S.A.*
[4]*Reprogenetics UK, Research and Development, Oxford, United Kingdom*

Study question: Can universally-applicable methods for preimplantation HLA-matching be established using PCR-based protocols or single nucleotide polymorphism (SNP) arrays (Karyomapping; Illumina, USA)? If so, which of these two methods is most advantageous when it comes to patient care?
Summary answer: Two universally-applicable PGD/HLA-matching methods were successfully established (one based on PCR, the other on Karyomapping) and applied clinically to *in vitro* fertilization (IVF)/PGD cycles. Karyomapping was determined to be highly advantageous as it required a shorter test preparation time and permitted more comprehensive assessment of the region of interest.
What is known already: Linkage analysis through assessment of short tandem repeats (STRs) in the human major histocompatibility complex (MHC) region is the method of choice for many laboratories for PGD/HLA-matching. However, the protocols used frequently demand tailoring to individual patients, a process requiring weeks or months to complete. The development of a universal protocol would be highly beneficial to patients, allowing more rapid treatment and thereby minimising the deterioration of the ill sibling requiring stem cell transplantation.
Study design, size, duration: Tests were prepared using the two developed methods for 19 couples, either seeking preimplantation HLA-matching alone or in combination with PGD for a single gene disorder (SGD). A total of 15 PGD cycles have been carried out to date and 100 embryos assessed (66 cleavage stage and 34 blastocysts).
Participants/materials, setting, methods: A PCR-based method assessing 19 polymorphic STRs was utilized in eight fresh PGD cycles (day-3 biopsy). Karyomapping, a microarray-based method of linkage analysis was used to assess 524 SNPs for seven frozen cycles (day-5 biopsy). Comprehensive chromosome screening (array-comparative genomic hybridization) was carried out in parallel for 5/7 cycles.
Main results and the role of chance: Using the PCR method, the average test development time (in days ± standard error of the mean) was 78 ± 11 for HLA-matching cases and 180.25 ± 13.1 for HLA-matching with SGD; combined average was 146.2 ± 23.3. Karyomapping preparation required a similar amount of time regardless of whether SGD was included (average 40.2 ± 6.1 days). This was significantly shorter ($p < 0.001$) than the time required for development of the PCR-based test. In total, 6/57 cleavage stage embryos and 4/30 blastocysts were found to be HLA-compatible, unaffected/carrier and euploid (when applicable), leading to transfers in 7/15 cycles. Clinical outcome data are currently available for 4 cycles, with two ongoing clinical pregnancies and one healthy live birth followed by successful transplantation to the sibling.
Limitations, reason for caution: Test development times presented in this study reflect the time needed by scientists working in a busy clinical laboratory, with multiple diagnoses and the development of other PGD tests being carried out simultaneously. If tests were prepared by themselves, preparation times using Karyomapping could theoretically be reduced to ~2 days.
Wider implications of the findings: Utilization of a PCR-based universal test still requires extensive test preparation times. Karyomapping offers significantly reduced test development times in addition to more comprehensive assessment of the MHC region. This increases the chances of patients initiating an IVF cycle and achieving pregnancy with a healthy, HLA-compatible embryo in a shorter time period. This is a critical advantage, since any delay to transplantation could have adverse effects on the deteriorating health of the ill child.

P-658 Low responders older than 37 have comparable success rates to normo/high-responders of same age using a novel embryo-banking strategy including PGS at blastocyst stage

B. Ramos[1], M. Fernández[1], E. Rocafort[1], L. Medrano-López[1], M. Guijarro[1], A. Leza[1], N. Szlärb[2], S. Rogel[2], J. Aizpurua[2]
[1]*IVFspain, Embryology, Alicante, Spain*
[2]*IVFspain, Gynecology, Alicante, Spain*

Study question: To evaluate whether an embryo-banking (EB) strategy with Preimplantational Genetic Screening (PGS) can be a reasonable option for low responders in terms of drop out rate, transfer rate, efficiency and satisfaction. We will compare them to normo- and high-responders of same age which needed only one IVF-PGS cycle (IP).
Summary answer: Banking a mean of 2.8 subsequent cycles for low responders equalizes chances for an euploid embryo transfer and pregnancy rate compared to normo/high-responders of same age. Drop out, transfer cancellation rate and satisfaction were similar in both groups, thus low response is not an impediment for a successful outcome.
What is known already: Low response at a certain age (>38) is associated with poor results per cycle and often an indication for egg donation. Usually oocyte quality is not concomitantly decreased, then fertilization and blastocyst rates are proven to be similar. With newest technologies (trophectoderm biopsy, PGS with aCGH and blastocyst vitrification) the accuracy has arisen dramatically. PGS allows eSET contributing to lower twin rates and pregnancy complications. EB of blastocyst is more cost-effective than oocyte banking.
Study design, size, duration: Comparative and retrospective (01/2013–12/2014). 48 patients (mean age 39.3 ± 2.7) were included and divided into two groups: 19 low responder (5.2 ± 2.1 mean follicles) to EB strategy and 29 normo/high-responder patients (9.3 ± 3.1 mean follicles) to single IVF-PGS.
Participants/materials, setting, methods: All patients used the same antagonist protocol with 300 IU of FSH/LH and agonist triggering. Embryos were cultured, biopsied and vitrified on days 5 to 7. aCGH was used for genetic screening. Euploid embryos were transferred in HRT cycle. Severe male and uterine factors were excluded.
Main results and the role of chance: Both groups were comparable in terms of age, male factor and previous cycles. Comparing EB vs. IP groups there were significant differences in average number of oocytes per cycle (7.36 ± 0.74 vs. 12.24 ± 2.08, $p = 0.034$). The average cycle number per patient in EB group was 2.84 ± 0.29. There were no significant differences in biopsied embryos (6.16 ± 1.23 vs. 4.45 ± 0.92; $p = 0.263$) and euploidy rate (35.90% vs. 36.43%; $p = 1.000$). Transfer cancellation rate was 31.58% in EB group, whereas 48.28% in IP group ($p = 0.370$). Pregnancy rate was slightly increased in EB group even though no significant differences were found (69.23% vs 66.67%; $p = 1.0$). Drop out and satisfaction were comparable in both groups. If we assume up to 3 stimulation as a treatment unit for low responders it turns a reasonable option.
Limitations, reason for caution: Previous research suggest that cryopreservation influences embryo quality, but does not increase aneuploidy. In order not to compromise the cycle outcome, an optimized cryopreservation technique must be established at the IVF Laboratory. Further studies are necessary and patient number should be increased to achieve more significant results.
Wider implications of the findings: More than 50% of patients included in the EB group asked primarily for egg donation. With this approach we have contributed to rescue a success using own gametes. PGS on blastocyst and deferred transfers combination eliminates risks of missing endometrial implantation window, associated with premature luteinization that may be observed in this patient group. Another reason for the EB eligibility would be the cost–effectiveness improvement of accumulating all embryos for just one genetic test.
Study funding/competing interest(s): Funding by hospital/clinic(s) – University associated private clinic and its Fundation.

P-659 IVF outcomes for patients that elect to undergo preimplantation genetic screening (PGS)

E. E. Fischer[1], C. R. Givens[2], J. Conaghan[1]
[1]*Pacific Fertility Center, Lab, San Francisco, CA, U.S.A.*
[2]*Pacific Fertility Center, Clinical, San Francisco, CA, U.S.A.*

Study question: For patients of all ages, what is the expected rate of having blastocysts to biopsy, the average number biopsied and the rate of aneuploidy? What is the average number of oocytes needed to result in one euploid embryo and what is the live birth rate following frozen embryo transfer (FET)?
Summary answer: The probabilities of having a sufficient number of embryos to biopsy, the number of biopsied embryos, the likelihood of having ≥ 1 euploid embryo, and a live birth outcome all decrease with increasing maternal age.
What is known already: Older patients produce fewer oocytes and therefore generate fewer blastocysts during IVF. The rate of aneuploidy is higher and the live birth rate is lower in older mothers.
Study design, size, duration: Patients that started an IVF cycle with the intention of performing PGS between June 2010 and July 2013 were reviewed for this study. Outcomes were analyzed for 433 patients that initiated cycles with the intention of having trophectoderm biopsy on Day 5 or 6 post-retrieval.
Participants/materials, setting, methods: Private U.S. IVF clinic with data separated into groups based on patient age at IVF stimulation start. Blastocysts were subjected to trophectoderm biopsy and immediately vitrified. Biopsy samples were analyzed using SNP microarray for all 24 chromosomes. Patients transferred a euploid embryo on progesterone day 6 in an FET cycle.
Main results and the role of chance: The age groups for analysis were: oocyte donor (age 21–29), < 35, 35–37, 38–40, 41–42, and 43–45. Euploidy rates by group were 73.2% (331/452), 62.7% (185/295), 59.5% (154/259), 40.7% (154/378), 23.4% (31/132), and 15.1% (11/73), respectively. The rates at which initiated cycles had a sufficient response to undergo biopsy were 96.7% (58/60), 79.0% (49/62), 73.9% (51/69), 73.7% (87/118), 48.3% (43/89), and 53.3% (24/45), respectively. The average number of blastocysts biopsied were 7.8(452/58), 6.0(295/49), 5.1(259/51), 4.3(378/87), 3.1(132/43), and 3.0(73/24) and the average number of oocytes necessary to result in one euploid embryo were 4.5(1495/331), 6(1114/185), 6.6(1018/154), 10.7(1644/154), 29.1(901/31), and 41.6(458/11) respectively. Live birth rates (LBR) per cycle start were 53.3% (32/60), 58.1% (36/62), 44.9% (31/69), 35.6% (42/118), 7.9% (7/89), and 6.7% (3/45) but the LBR per transfer were 66.7% (32/48), 83.7% (36/43), 79.5% (31/39), 75.0% (42/56), 41.2% (7/17), and 42.9% (3/7), respectively.
Limitations, reason for caution: Criteria for foregoing embryo biopsy may vary by patients' and clinicians' preferences. PGS may not benefit all patients and embryos could be harmed in the biopsy procedure.
Wider implications of the findings: In analyzing a large number of cycles and the resulting embryos, we can confirm that the chances of having euploid embryos decreases with maternal age. However, we can now advise patients on the likelihood of having any euploid embryos and how many eggs it may require to achieve a euploid embryo based on the patient age. This data may help patients in their decision to undergo IVF. Based on these data, patients in the older age groups can expect a reasonable chance of live birth if they can get a euploid embryo from one or more IVF cycle.

P-660 Clinical experience using single nucleotide polymorphism (SNP) arrays for preimplantation genetic diagnosis (PGD) of chromosomal translocations

J. Sarasa[1], K. Wheeler[1], L. Lansdowne[1], A. Raberi[2], D. Babariya[2], D. Wells[2]
[1]*Reprogenetics UK, Institute of Reproductive Sciences, Oxford, United Kingdom*
[2]*Nuffield Department of Obstetrics and Gynaecology, University of Oxford/ Reprogenetics UK, Oxford, United Kingdom*

Study question: Can the use of SNP arrays be used in a clinical setting to perform PGD for couples affected by chromosomal translocations, detecting chromosomally abnormal embryos and also allowing karyotypically normal embryos to be distinguished from those carrying a balanced translocation?
Summary answer: SNP arrays provided a reliable means of detecting the inheritance of rearranged chromosomes, based upon linkage analysis. Normal, balanced and abnormal embryos were revealed. Additionally, this approach permits a simultaneous analysis of the copy number of the structurally normal chromosomes, thus improving the likelihood of transferring a viable euploid embryo.
What is known already: Traditional methods of PGD used for chromosome rearrangements successfully detect unbalanced embryos, but cannot distinguish balanced rearrangement carriers from completely normal embryos. Recently, a new technology known as karyomapping has been developed. The method involves tracking the inheritance of chromosomes from the parents to their embryos, achieved by assessing the transmission of thousands of polymorphisms situated on each chromosome. Although predominantly used for PGD of gene disorders, karyomapping might also be applicable to chromosome rearrangements.
Study design, size, duration: PGD was performed for three patients carrying different balanced translocations between June and September, 2014. A total of 29 embryos were analysed in three cycles: 9 and 10 with biopsy at the cleavage stage; 10 with biopsy at the blastocyst stage.
Participants/materials, setting, methods: The biopsied cells were subjected to whole genome amplification and genotyped with the HumanKaryomap-12 Bead Chip array (Illumina). DNA samples from the parents and from another relative carrying the translocation were genotyped in the same way. Transmission of specific chromosomal regions from parents to embryos was determined using BlueFuse software (Illumina).
Main results and the role of chance: 28 out of the 29 (96.6%) embryos analysed gave analysable results. 8 embryos were found to be euploid of which 3 presented the parental balanced translocation and 5 had an entirely normal karyotype. Out of the 20 chromosomally abnormal embryos, 15 had anomalies related to the translocation, while the other 5 had aneuploidies affecting unrelated, structurally normal chromosomes. Each of the three couples underwent transfer of a single embryo to the uterus, resulting in a positive pregnancy in all the three cases.
Limitations, reason for caution: Due to technical limitations, karyomapping is unable to detect 100% of spontaneously arising aneuploidies. However, we estimate that at least three quarters of chromosome abnormalities present in preimplantation embryos will be detected. Detection of inherited abnormalities (e.g. due to a translocation) are predicted to be detected with higher accuracy >95%.
Wider implications of the findings: Karyomapping is primarily used for PGD of gene disorders, with diagnosis of embryos via linkage analysis. This study confirms that karyomapping can also serve as a widely applicable method for PGD of chromosome rearrangements. Work-up time can be as little as a few days. In many cases, rearrangements that could not be assessed using standard PGD methods due to their complexity, or the small size of the chromosomal regions involved, can be diagnosed using karyomapping.

P-661 Preimplantation genetic screening in combination with cumulus cells gene expression profile: use in assessment of embryo potential

E. Lopez-Bayghen[1], A. Ocampo[2], I. Maldonado[3], F. Camargo[2]
[1]*Ingenes and Cinvestav-IPN, Toxicology, Mexico, DF, Mexico*
[2]*Instituto Ingenes, Investigación, Mexico, DF, Mexico*
[3]*Instituto Ingenes, FIV, Mexico, DF, Mexico*

Study question: The aim of this work was to evaluate the embryo quality and potential for implantation combining two methods: (1) Preimplantation Genetic Screening (PGS) applied with a more reliable biopsy technique (S-biopsy), and (2) egg quality valuation via cumulus cell (CC) qRT-PCR gene expression analysis (GEA).
Summary answer: The simultaneous detection of PTGS2/VCAN index in CC from individual oocytes (expression level generated via qRT-PCR) combined to PGS (24sure array/BlueGnome), became a suitable system that can be added for embryo selection in IVF.
What is known already: PGS is a proven reliable tool to improve clinical outcomes in ART by selecting chromosomally integral embryos for transfer.

Although the day three biopsy required to obtain nucleated cells should not adversely impact embryo viability, this biopsy is technically challenging and requires extensive experience. Egg quality can be assessed by profiling the expression of cumula cells from individual oocytes via qRT-PCR and several potential markers have been described.
Study design, size, duration: Cohort study, one year frame. All 211 embryos assigned to PGS (maternal age or recurrent pregnancy lost), were biopsied with a less invasive, day-three stripper-based method (S-biopsy), using a laser to create a thin funnel in the zona pellucida next to the desired blastomere, then extracted by aspiration and release of the embryo with a 140 micrometer stripper capillary (Maldonado et al 2013).
Participants/materials, setting, methods: PGS was performed with BlueGnome 24sure arrays. CC collection from individual eggs was also performed. To assess egg quality, one step qRT-PCR for PTGS2 (Prostaglandin endo peroxidase synthase) and VCAN (Versican), generating an expression index associated with good embryo quality (cut-off value 57). Clinical pregnancy was recorded after transfer.
Main results and the role of chance: S-biopsy applied prior to PGS considerably reduced invasiveness, performance time, embryo-manipulation and need for extensive technician experience. Biopsied embryos reached blastocyst stage with 80% success rate. Successful chromosome analysis was obtained for all 211 blastomeres. From these, 143 blastomeres were abnormal and not transferred; 68 blastomeres were normal and PTSG2/VCAN index was obtained from their CCs via qRT-PCR. PTSG2/VCAN index (cutoff value 57) accurately predicted pregnancy result in 90% of cases (either negative or positive depending on index). When pregnancy was only assayed by bHCG test, 80% of cases predicted as non-pregnancy were negative while a 100% of cases predicted as positive pregnancy were positive. Of these, 80% of cases were confirmed as clinical pregnancies (week 12, heart beat).
Limitations, reason for caution: Large case number is needed combining normal PGS result and PTSG2/VCAN index to support largely the rutine use of CC analysis. S-biopsy may not be completely risk free as the embryo or the blastomere can be damaged if the technique is not performed properly.
Wider implications of the findings: Particularly in cases when more than 3 normal embryos are available, combination of these techniques can help assess embryo selection, reduce the number of transferred embryos and allow to freeze only valuable embryos. S-biopsy for PGS is cheaper, less time consuming and accessible to a wider array of IVF programs.
Study funding/competing interest(s): Funding by national/international organization(s), Funding by commercial/corporate company(ies) – CONACyT/PROINNOVA, Instituto Ingenes. Biociencias FYA SA de CV.

[6]*Fundación Instituto Valenciano de Infertilidad (FIVI) Instituto Universitario IVI/INCLIVA Valencia University Department of Obstetrics and Gynecology School of Medicine Stanford University., Doctor, Valencia, Spain*

Study question: Is there any difference in the number of aneuploid chromosomes diagnosed per embryo from day-3 (D3b) to trophoectoderm biopsies (D5b)?
Summary answer: There is a significantly higher incidence of abnormal embryos at day-3 compared to blastocyst stage mostly due to the decrease of complex abnormalities and embryos with chaotic pattern at blastocyst stage. There is no selection against segmental aneuploidies from cleavage to blastocyst stage.
What is known already: Preimplantation Genetic Screening (PGS) is commonly indicated for the selection of euploid embryos to improve clinical outcome in specific indications. Different strategies have been applied to analyze the embryos either at day-3 biopsies or blastocyst stage. Aneuploidy impairs embryo development at a different degree, resulting in embryo arrest for certain chromosomal abnormalities. Complex abnormal embryo are defined as having more than 3 aneuploidies and chaotic pattern all chromosomes show abnormal profile.
Study design, size, duration: Retrospective cohort study of 296 embryos analyzed at day-3 and 863 at the blastocyst stage between April to December 2014. Patients' age ranged between 25 and 46 years and were divided into two groups: Group A (25–37 years) and Group B (38–46 years). Welch and Fisher tests were applied for statistical comparisons.
Participants/materials, setting, methods: Patients undergoing PGS for advanced maternal age, repetitive implantation failure, male factor, recurrent miscarriage and mixed causes. Chromosomal analysis for all 24-chromosomes was performed using array Comparative Genomic Hybridization (BlueGnome, Cambridge, UK). A single blastomere was obtained at day-3 or 4–5 cells in trophectoderm biopsies.
Main results and the role of chance: D3b resulted in 81.08% aneuploidies (19.26% chaotic, 22.97% complex abnormalities [CA] and 6.08% segmental aneuploidies [SA]). The mean number of abnormal chromosomes per embryo was 2.6 ± 1.5. In D5b aneuploidy was identified in 62.46% (4.40% chaotic, 8.92% CA and 3.36% SA). The mean number of abnormal chromosomes per embryo was 1.8 ± 1.2. Statistical comparisons showed significant differences for above described parameters except for SA. Regardless of age, there was a significant decrease in the mean number of aneuploid chromosomes per embryo in D5b compare to D3b. In Group A (1.5 ± 0.9 versus 2.2 ± 1.4) ($p < 0.001$) and in Group B (1.9 ± 1.3 versus 2.8 ± 1.6) ($p < 0.0001$).
Limitations, reason for caution: Retrospective study and heterogeneity of patients included.
Wider implications of the findings: These results would help to understand the mechanisms that produce embryo development arrest and the chromosomal abnormalities involved. Also, could help to evaluate what stage of the embryo must be analyzed in each patient.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – None.
Trial registration number: NA.

P-663 Clinical, obstetric and neonatal outcomes of Hungarian preimplantation genetic diagnosis for aneuploidy (PGD-A) cycles of the year 2013

A. Vereczkey[1], G. Y. Téglás[1], E. Margittai[1], M. Csenki[1], L. Nánássy[1]
[1]*Versys Clinics, Human Reproduction Institute, Budapest, Hungary*

Study question: The aim of this study was to determine the success rate and neonatal outcomes of in vitro fertilization (IVF) combined with PGD-A in Hungary in 2013.
Summary answer: Here we present data on clinical, obstetric and neonatal outcomes and success rates of the fresh PGD-A cycles done in Hungary in 2013. A live birth rate of 42,47% was achieved with 31,03% pregnancies showing complications. Neonatal malformation was noted in 6,4% of the cases.
What is known already: Aneuploidy is the leading cause of the failure of IVF cycles. PGD-A is a widely used technique to examine the chromosomal status of early embryos and provide a useful information for embryo selection for transfer. There is a growing body of evidence about the advantages of the technique (e.g. higher pregnancy and implantation rates), but data is lacking about the clinical outcomes – live birth rates and birth data of neonates are only scarcely reported.
Study design, size, duration: Data was retrospectively collected from patients went through IVF combined with PGD-A in the year of 2013. Indication for PGD-A was established by clinical genetisits. One hundred and thirty nine fresh cycles were carried out during this period analysing 431 embryos.
Participants/materials, setting, methods: Patients where aneuploidy screening was indicated and carried out were included in the study. Embryo biopsy was done at cleavage-stage. For aneuploidy screening of embryos array based comparative genetic hybridization was used. Where fetal heart beat was detected, patients were requested to provide data about their pregnancy and birth.
Main results and the role of chance: A total of 155 embryos were diagnosed as euploid (35,96%). Non-diagnostic rate was 4,64% ($N = 20$). Seventy six patients had at least one euploid embryo (54.68%) and 73 fresh embryo transfers were carried out. Chemical pregnancy rate was 56,16% (41/73), clinical pregnancy rate was 42,21% (33/73) and implantation rate was 40,38%

(42/104). Complications were present in 31,03% of pregnancies (e.g. bleeding, gestational diabetes, pre-eclampsia). Live birth rate was 42,47% (31/73). The mean gestational age was 38,31 ± 2.23 weeks with an average birth weight of 2893,5 ± 679.55 g. The sex ratio of newborns was 0,59: 0,41 in favor of males. Neonatal malformations were noted in two cases (6,4%) (aorta vascular ring and hydronephrosis).

Limitations, reason for caution: The number of examined and followed-up cycles are low. Also, caution has to be taken when neonatal malformations are interpreted because of the peculiar patient population where PGD-A is indicated and performed.

Wider implications of the findings: Collection of obstetrical and neonatal data of PGD-A cycles are very important. Only limited data set is available in the literature. The follow-up and analysis of these cycles is very important in order to properly advise patients about their treatment options.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Versys Clinics Human Reproduction Institute.

Trial registration number: NA.

Study question: Does BMI or its change from adolescence to late adulthood associate with the presence of self-reported PCOS symptoms [oligo- or amenorrhea (OA) and/or hirsutism (H)] at age 31 or self-reported diagnosis of PCOS by age 46?

Summary answer: Women with self-reported OA + H at age 31 or diagnosis of PCOS by age 46 had significantly greater BMI in adolescence, early and late adulthood and showed significantly greater weight gain in early, but not in late adulthood, compared to the reference population.

What is known already: Obesity affects more than half of the women with PCOS and is known to affect negatively many aspects of their life. Our previous study showed the importance of obesity in adolescence and in early adulthood, and of weight gain in early adulthood, for reporting PCOS symptoms at age 31. Previous studies, however, have been inconsistent about the association of weight and weight gain with PCOS *per se*.

Study design, size, duration: In the prospective follow-up Northern Finland Birth Cohort 1966 (n = 5889) postal questionnaires were sent at ages 14 (95% answered), 31 (81% answered) and 46 (72% answered), and clinical examination and blood sampling were performed at ages 31 (n = 3115) and 46 (n = 3280).

Participants/materials, setting, methods: At age 31 participants answered to questions on the presence of OA and H (women with both OA + H n = 125, referents n = 2182), and PCOS diagnosis by age 46 (women with PCOS n = 180, referents n = 3466). Pregnant women, users of hormonal preparations, and women with only one symptom were excluded. Odds ratios (ORs) were calculated by logistic regression analysis.

Main results and the role of chance: Women with OA + H at age 31 or self-reported diagnosis of PCOS by age 46 had significantly greater BMI compared to the reference group at ages 14, 31 and 46. Increase of BMI between ages 14 and 31, but not later, was greater in women with isolated OA ($p < 0.05$), isolated H ($p < 0.05$), OA + H ($p < 0.001$) and self-reported PCOS ($p = 0.003$) compared to the reference group. In the univariate logistic regression analysis OA + H (OR = 20.7 [95% CI 11.65–36.80]), isolated OA (OR = 9.32 [95% CI 5.75–15.12], isolated H (OR = 7.80 [95% CI 4.69–12.97]) and WHR (OR = 14.11 [95% CI 2.39–83.34]) and to a lesser degree BMI at age 14, 31 (OR = 1.09 [95% CI 1.06–1.11]) and 46, serum levels of insulin, testosterone, LDL and FAI (OR = 1.11 [95% CI 1.05–1.16] were associated with PCOS by age 46.

Limitations, reason for caution: The symptoms and the diagnosis of PCOS were self-reported. The questionnaire at 46 years did not distinguish between polycystic ovaries on ultrasound and the syndrome. Ovarian ultrasonography was not available to aid the diagnosis of PCOS.

Wider implications of the findings: Isolated OA or H, or both of them screened by a simple questionnaire in early adulthood, are good predictor of PCOS in later adulthood. Weight gain in early adulthood plays a crucial role for the emergence of PCOS, suggesting that, with the dramatic progress of obesity, an increasing prevalence of PCOS can be expected in the future. Therefore, weight gain prevention from early on is crucial in order to prevent the development of PCOS and associated health burdens.

P-665 Investigation of the effect of isotretionine, leuprolid acetate and cetrorelix on ovarian reserve : an experimental study

C. Kart[1], F. Erdemli[1], S. Guven[1], E. S. Guvendag Guven[1]

[1]*Karadeniz Technical University Faculty of Medicine, Obstetrics and Gynecology, Trabzon, Turkey*

Study question: Does GnRH agonist, GnRH antagonist and retinoic acid derivatives have any adverse effect on ovarian reserve (such as follicle number and serum AMH level)? Is there any difference between the effect of three agents on ovarian follicle reserve pool?

Summary answer: Isotretionine, leuprolid acetate and cetrorelix, all have positive effect on ovarian reserve and preserve ovarian follicle number. The best agent on ovarian follicle number preservation may be isotretionin, since it decreased the atretic follicle number.

What is known already: It has been known that GnRH agonists, GnRH antagonists may preserve ovarian reserve especially in patients having ovarian toxicity agents. However the effect of isotretionine on ovarian reserve had not been well known. Also the comparison of such effect of isotretionine with GnRH has not been known.

Study design, size, duration: Prospective randomized placebo controlled experimental study, totally on 32 mature, female rats were used, one month of duration.

Participants/materials, setting, methods: This randomised, placebo–controlled single blind study was carried out on 32 mature, female rats of the Sprague-Dawley weighing between 180 and 220 per gram at the Karadeniz Technical University Surgery Research Laboratory. Rats' serum AMH levels were measured using tail vein blood samples before the treatment in all groups.

I. The control group (8 rats); no-medical care control group
II. Cetrorelix group (8 rats): injected 0.001 mg/day cetrorelix subcutaneous for 30 days.
III. Isotretinoin group (8 rats) : injected orally 10mg/kg/day isotretionin orogastric gavage for 30 days
IV. Leuprolide acetate group (8 rats): injected 0.075 mg/kg/day leuprolide acetate for 30 days.

After ten days of finishing the treatment protochol, both ovaries were excised via laparotomy and histopathologic examination was done for follicle count to assess the ovarion reserve. AMH levels were measured again with the blood taken from abdominal aorta after medical care.
Main results and the role of chance: When compared with the control group, a statistically significant increase was seen in GnRH agonist (leuprolide acetate), GnRH antagonist (retrorelix) and isotretinoin groups in serum AMH levels.(0,59 ± 0,63; 1,04 ± 0,41; 1,19 ± 0,51; and 1,63 ± 1,12 ng/mL; $P < 0.05$, respectively). At the same time, in all three groups, significant increase was seen in primordial and primary follicles number compared to the control group ($P < 0.05$) Unlike other groups, the atretic follicles number was significantly lower in isotretinoin group, compared to control group ($P < 0.05$).
Limitations, reason for caution: The main limitations of the study were the low sample size.
Wider implications of the findings: Isotretionin may have role in preservation of ovarian function especially in poor ovarian responders.
Study funding/competing interest(s): Funding by University(ies) – The authors had no study funding and competing interests to report.
Trial registration number: NA.
Keywords: ovarian reserve tests, isotretionine, GnRH agonist, GnRH antagonist

P-666 FMR6 (a long non coding RNA) may play a role in the pathogenesis of fragile X associated premature ovarian insufficiency (FXPOI)

S. E. Elizur[1], O. Dratviman-Storobinsky[1], S. Derech-Haim[1], O. Lebovitz[1], J. Dor[1], R. Orvieto[1], Y. Cohen[1]
[1]*Sheba Medical Center, IVF unit, Ramat Gan, Israel*

Study question: Does long no coding (lnc) RNA accumulation in granulosa cells of FMR1 premutation carriers play a role in the pathophysiology of fragile X-associated premature ovarian insufficiency (FXPOI).
Summary answer: *FMR6* but not *FMR4* lnc-RNA accumulation in granulosa cells of FMR1 premutation carriers may lead to RNA toxic gain-of-function causing FXPOI.
What is known already: Amplification of CGG triplet number above the normal range (n = 5–44 repeats) towards the premutation status (n = 55–200 repeats) is associated with increased risk for FXPOI in females and fragile X-associated tremor/ataxia syndrome (FXTAS) in males. Both male and female premutation carriers have elevated *FMR1* transcript levels suggesting RNA toxic gain of-function as a possible common mechanism for FXPOI and FXTAS. Recently, *FMR4* and *FMR6* lnc-RNA's were also suggested to play a role in the pathogenesis of FXTAS.
Study design, size, duration: Study population consisted of all 18 consecutive FMR1 premutation carriers referred to our IVF unit for IVF-PGD treatment, during a 12 month period. The control group consists of 12 patients, with less than 55 CGG repeats, undergoing IVF-ICSI for male factor infertility, matched by age, who were treated in the same period.
Participants/materials, setting, methods: After oocyte retrieval granulosa cells from follicular fluid were washed and stored at -80°C until RNA extraction. RNA was transcribed to generate cDNA and the genes RNA levels were measured using RT-PCR.
Main results and the role of chance: In FMR1 premutation carriers there was a trend for a non-linear association between the number of CGG repeats and the *FMR6* RNA levels ($p = 0.07$), but not *FMR4* in granulosa cells. The highest level of *FMR6* was seen in granulosa of women with a mid-size CGG repeats (80–120). In addition, a significant negative linear correlation was observed between the number of oocytes retrieved and the granulosa cells *FMR6* RNA levels ($p < 0.007$) but not *FMR4*.
Limitations, reason for caution: The study sample should be increased in future larger studies are.
Wider implications of the findings: We support previous findings suggesting RNA toxic gain of-function as a possible mechanism underlying FXPOI. As previously shown for *FMR1* mRNA, a non-linear association was observed between the number of CGG repeats and *FMR6* levels in granulosa cells from FMR1 premutation carriers in the mid-range (80–120 CGG repeats). Increased accumulation of both *FMR1* mRNA and *FMR6* lnc-RNA may lead to impaired ovarian function in FMR1 premutation carriers in the mid-range (80–120 CGG repeats).
Study funding/competing interest(s): Funding by University(ies) – Tel Aviv University, Sackler School of Medicine.
Trial registration number: NA.

P-667 MicroRNA-93 promotes ovarian granulosa cells proliferation through targeting CDKN1A in polycystic ovarian syndrome

L. Jiang[1], D. Yang[1], J. Huang[1]
[1]*Sun Yat-sen Memorial Hospital, Department of Obstetrics and Gynecology, Guangzhou, China*

Study question: We want to explore whether different miRNAs expression in polycystic ovarian syndrome (PCOS) ovaries contributes to promoting granulosa cell proliferation in PCOS disease.
Summary answer: MiR-93 was increased in PCOS granulosa cells and through targeting CDKN1A to promote the proliferation and cell cycle progression.
What is known already: Granulosa cells have higher proliferation rates in PCOS ovaries and secreted more AMH to participate in the PCOS ovarian dysfunction.
Study design, size, duration: Experimental study.
Participants/materials, setting, methods: Expression of miRNAs was measured using RT-PCR in cortex of ovaries including 16 PCOS patients and 8 control. KGN granulosa cells were cultured for proliferation assay including MTS, flow cytometric analysis and EdU after overexpreesion or inhibition of miR-93. CDKN1A espression was examined using RT-PCR and Western blot analyses.
Main results and the role of chance: MiR-93 expression was higher in PCOS ovarian cortex and high concentration of insulin induced up-regulation of miR-93 and down-regulation of CDKN1A in granulosa cells. The overexpression of miR-93 dramatically promoted cell proliferation and G1 to S transition. Moreover, we identified CDKN1A gene as a direct target of miR-93. In consistent with the overexpression of miR-93, the down-knocking experiments of CDKN1A promoted cell growth and cell cycle progression in granulosa cells.
Limitations, reason for caution: We used KGN cells but not the granulosa cells from the growing follicles, which might be the best cell model for proliferation research.
Wider implications of the findings: Our finding identified that high concentration of insulin could increase the expression of miR-93 and promote granulosa cells proliferation in PCOS disease. This might offer new insight of why the ovarian production of AMH was excessive in PCOS and influenced the ovarian dysfunction.
Study funding/competing interest(s): Funding by national/international organization(s) – National Natural Science Foundation of China.
Trial registration number: NA.
Keywords: polycystic ovarian syndrome, miR-93, granulosa cell proliferation

P-668 Women with PCOS report decreased health status and present with several BMI-independent comorbidities from reproductive age on – a 15-year population based cohort study

S. Karjula[1], L. Morin-Papunen[1], J. S. Tapanainen[2], T. T. Piltonen[1]
[1]*Oulu University Hospital and University of Oulu and Medical Research Center Oulu, Obstetrics and Gynecology, Oulu, Finland*
[2]*University of Helsinki and Helsinki University Central Hospital, Obstetrics and Gynecology, Helsinki, Finland*

Study question: The aim of the study was to investigate self-estimated health status, comorbidities, smoking and alcohol consumption in women with polycystic ovary syndrome (PCOS) at fertile age (31 years) and perimenopause (46 years), in a population based birth cohort, the Northern Finland Birth Cohort 1966 (NFBC66).
Summary answer: The PCOS women experienced impaired health already at fertile age compared with asymptomatic women and also reported non-metabolic comorbidities (migraine, arthrosis, gastric/duodenal ulcer) by perimenopausal age independently of BMI while the smoking and alcohol consumption was similar between the groups.
What is known already: Women with PCOS have been shown to be in a higher risk for several metabolic (hypertension, dyslipidemia, metabolic

syndrome, T2DM) and non-metabolic comorbidities (infertility, depression and anxiety). Even though we have already previously shown increased risk for mental disorders in women with PCOS in this cohort, a comprehensive analysis of comorbidities in a larger population based analysis with a prospective follow-up, adequate adjustments and reference population is still lacking.

Study design, size, duration: Questions on oligo-amenorrhea (OA), hirsutism (H), self-estimated current health status, self-reported physician diagnosed or treated sicknesses, smoking and alcohol abuse were included in the postal questionnaires at ages 31 and/or 46. At age 31, 4427 (79%) women and at age 46, 3706 (72%) in the NFBC66 answered the questionnaire.

Participants/materials, setting, methods: At age 31 2188 asymptomatic and 125 PCOS women (OA + H) were identified. Of these 1576 asymptomatic and 85 PCOS women participated to the follow-up at age 46. The associations were calculated using logistic regression model and Pearson's Chi-square test. The data were adjusted for BMI, social and marital status.

Main results and the role of chance: Already from age 31 the PCOS women reported considerably impaired health status compared to asymptomatic women (31 years 8.8% vs. 2.60%, $p < 0.001$; 46 years 11.9% vs. 3.40%, $p < 0.001$). After BMI-adjustment PCOS women had increased risks of self-reported hypertension [31 years: OR 1.93, (95% CI 1.23–3.01); 46 years; OR 2.14 (1.29–3.54)] and migraine [31 years: OR 1.71, (1.13–2.59); 46 years: OR 1.60 (0.98–2.62)] already at age 31. At age 31, but not 46, PCOS women reported more gastric/duodenal ulcer [OR 3.85 (1.52–9.76)]. At perimenopause PCOS women reported more T2DM [OR 3.79, (1.62–8.88)] and knee arthrosis [OR 2.55 (1.31–4.94)]. No differences were found as regards genital infections, epilepsy, asthma/allergies, thyroid, gallstone or inflammatory bowel disease. Also the smoking and alcohol consumption was similar between the groups.

Limitations, reason for caution: The health-related diagnosis and the diagnosis of PCOS were based on self-reporting, which may bias the results. However, the self-reported PCOS diagnosis has already been well validated in our previous publications.

Wider implications of the findings: This study provides a unique population based follow-up data and demonstrates that the unfavourable effect of the syndrome on health is complex where also non-metabolic comorbidities developed independently of obesity. Given that PCOS heavily affects women's health from as early as puberty on to older ages it is important to take into consideration all the health risks when treating these women.

Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s), Funding by national/international organization(s) – The North Ostrobothnia Regional Found, the Academy of Finland, the European Commission and Medical Research Council, the National Institute for Health Research, Sigrid Juselius Foundation and Finnish Medical Society Duodecim.

Trial registration number: NA.

P-669 The long-term impact of controlled ovarian hyperstimulation on thyroid function

A. Busnelli[1], S. Ferrari[1], F. Filippi[1], G. Candotti[1], L. Cardellicchio[1], V. Sarais[1], E. Somigliana[1]

[1]*IRCCS Ospedale Maggiore Policlinico Regina Elena, Centro Sterilità Regina Elena, Milano, Italy*

Study question: What is the long-term impact of controlled ovarian hyperstimulation (COH) on serum thyroid stimulating hormone (TSH) levels in euthyroid and hypothyroid women undergoing *in vitro* fertilization (IVF)?

Summary answer: Three months after the end of COH, serum TSH concentration exceeds the recommended threshold of 2.5 mIU/L in one out of two adequately treated hypothyroid women and in one out of six euthyroid women.

What is known already: It has been shown that in approximately one out of three euthyroid women and in two out of three hypothyroid women, TSH concentration exceeds the recommended threshold of 2.5 mIU/L during IVF cycles suggesting a reduced ability of the thyroid to adapt to the increased demand resulting from COH. However, whether thyroid function is restored at the end of the IVF cycle or whether COH results in a long-term impairment has not yet been investigated.

Study design, size, duration: We selected women who underwent IVF and did not become pregnant. Cases were women with treated hypothyroidism and serum TSH <2.5 mIU/L prior to initiate the cycle. Controls were euthyroid women matched to cases by age (±1 year) and basal serum TSH (± 0.1 mIU/L).

Participants/materials, setting, methods: Serum TSH was tested prior to initiate COH (Time 1), at the time of human chorionic gonadotropin (hCG) administration (Time 2), 16 days after hCG administration (Time 3) and three months after the end of the IVF cycle (Time 4). Thirty seven matched case-control pairs were selected.

Main results and the role of chance: Serum TSH at Times 1, 2, 3 and 4 was 1.7 ± 0.6, 3.1 ± 1.4, 3.1 ± 1.3, 2.7 ± 1.7 mIU/L, respectively among cases and 1.7 ± 0.6, 2.9 ± 1.0, 2.7 ± 1.0, 1.9 ± 0.7 mIU/L, respectively among controls. A statistically significant difference emerged at Time 4 ($p < 0.001$). In both groups, serum TSH was higher at time 4 compared to time 1. The rate of cases in which serum TSH exceeded the recommended threshold of 2.5 mIU/L at Time 4 was significantly higher in cases (51%, 95% CI: 35–68%) compared to controls (16%, 95% CI: 4–28%) ($p = 0.003$). In the entire population the only predictive factor of TSH >2.5 mIU/L at Time 4 was a diagnosis of hypothyroidism (adjusted OR = 4.3, 95% CI: 1.1–17.7, $p = 0.04$).

Limitations, reason for caution: Albeit unlikely, we cannot exclude that thyroid function may have deteriorated on its own (thus independently from COH) during the latency period of three months.

Wider implications of the findings: COH seems to have not only a short-term but also a long-term impact on TSH levels. The magnitude of this effect is particularly pronounced among hypothyroid patients. In a clinical perspective, we suggest to systematically retest thyroid function in women who underwent IVF few months after the end of COH, or in any case before a subsequent IVF cycle. Levothyroxine initiation or adjustment should then be considered in women overcoming the threshold of 2.5 mIU/L.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy.

Trial registration number: NA.

P-670 Comparison of the prevalence and characteristics of the metabolic syndrome in Greek women with polycystic ovary syndrome in relation with the general population

G. Kyrkou[1], E. Trakakis[2], C. H. Chrelias[2], E. Alexiou[2], P. Panagopoulos[2], V. Papaevangelou[3], N. Papantoniou[2]

[1]*University hospital of Athens 'Attikon', 3rd Pediatric Department NICU, Athens, Greece*

[2]*University hospital of Athens 'Attikon', 3rd Obstetrics and Gynecological Department, Athens, Greece*

[3]*University hospital of Athens ' Attikon', 3rd Pediatric Department, Athens, Greece*

Study question: Are there differences in the prevalence and characteristics of the metabolic syndrome (MetS) between the Greek women with polycystic ovary syndrome (PCOS) and the general population? Is there association between the body mass index (BMI) and MetS?

Summary answer: The prevalence of the MetS was nearly 7-fold higher in Greek PCOS women compared with the control group. The increased BMI was much more common in Greek PCOS women than in the age-matched healthy controls, and the prevalence of MetS in obese and overweight PCOS women was significantly higher in comparison with the controls.

What is known already: PCOS is the most common endocrinopathy affecting 4–12% of women in the reproductive age group. Multiple studies indicate that women with PCOS are at increased risk for developing of glucose intolerance or type 2 diabetes mellitus (DM2) and therefore at risk of having MetS as well. The prevalence of the MetS is high in women PCOS. The prevalence shows a marked variation between countries and ethnic groups, probably due to differences in diet, lifestyle and genetics factors.

Study design, size, duration: Greek women, during their reproductive age, were participated. The PCOS women were outpatients at the Reproductive Endocrinology Outpatient Clinic of the University General hospital 'Attikon' during the last five years, and they have been diagnosed according to the criteria of Rotterdam. The control group consisted of healthy volunteer females. Both groups were evaluated for MetS based on the International Diabetes Foundation (IDF).

Participants/materials, setting, methods: 385 Greek women; 230 PCOS women and 155 age matched healthy females as controls. All subjects completed a detailed personal and family history, and they underwent to ultrasound scans, clinical examination and biochemical measurements in order to estimate the prevalence, to evaluate the characteristics of the MetS in Greek women with PCOS and to investigate the correlation of MetS with BMI.
Main results and the role of chance: The proportion of participants with MetS was 12.6% in the PCOS group, significantly higher as compared with the correspondence proportion (1.9%) in the control group ($p < 0.001$).. The most frequent MetS component in both study groups was central obesity, followed by low HDL-C and elevated blood pressure. Elevated fasting plasma glucose (7.0% vs. 1.9%) and elevated triglycerides (10.4% vs. 3.2%) were more frequent in the PCOS group as compared with the controls ($p < 0.05$). Of the abnormalities present in affected women with PCOS, BMI occurred significantly higher between two study groups (42.7% vs 21.9%, $p < 0.001$). The proportion of obese and overweight subjects with MetS was greater in the PCOS group in comparison with controls (24.5% vs. 8.8%, $p = 0.050$).
Limitations, reason for caution: The limitation of this study was the relatively small number of women in both study groups, although a ratio of PCOS women and age-matched healthy controls of about 1: 1 was achieved.
Wider implications of the findings: The prevalence of the MetS differs from country to country depending on the habits of diet, lifestyle, and many other factors that increase the risk of incidence of the syndrome. The results of present data indicate that Greek PCOS women have an increased risk of MetS. The lipid abnormalities, the fast plasma glucose abnormality and elevated blood pressure places them an increased risk of long-term cardiovascular disease and DM2. It is important to emphasize that in obese and overweight subjects presented greater prevalence and much more metabolic abnormalities. The results of this study call attention to the need for comprehensive screening and education of women with PCOS regarding appropriate diet and exercise program.
Study funding/competing interest(s): Funding by hospital/clinic(s) – No funding was needed.
Trial registration number: NA.

P-671 The relation between variation in size of the primordial follicle pool and menopause: a cohort comparison for observed and predicted distribution of age at menopause

M. Depmann[1], M. J. Faddy[2], Y. T. van der Schouw[3], S. L. Broer[1], T. W. Kelsey[4], S. M. Nelson[5], F. J. M. Broekmans[1]
[1]*University Medical Center Utrecht, Reproductive Medicine & Gynecology, Utrecht, The Netherlands*
[2]*Queensland University of Technology, Statistics, Brisbane, Australia*
[3]*Julius Center for Health Sciences and Primary Care, Epidemiology, Utrecht, The Netherlands*
[4]*School of Computer Science, Computer Science, St. Andrews, United Kingdom*
[5]*University of Glasgow, Reproductive and Maternal Medicine, Glasgow, United Kingdom*

Study question: This study aims to investigate the hypothesis that the size of the primordial follicle pool is the main determinant for the length of the individual ovarian lifespan.
Summary answer: Predictions of age at menopause based upon the primordial follicle pool show a close conformity with observed ages at menopause.
What is known already: The value of ovarian reserve tests (ORTs), such as anti- Müllerian hormone (AMH) or the antral follicle count (AFC) in the prediction of age at natural menopause has been extensively researched and promising predictions can be made using these ORTs. Interestingly though, there is no research available assessing age at menopause based upon what is generally considered as the true ovarian reserve, i.e. the non- growing (primordial) follicle pool.
Study design, size, duration: Age at menopause (ANM) was modelled based on the declining number of primordial follicles, after identifying a critical threshold for cycle cessation. The distribution of predicted age at menopause based on this model was then compared to an observed distribution of age at menopause.
Participants/materials, setting, methods: 4 papers provided histologically derived non- growing follicle (NGF) counts obtained from single ovaries from women over ≥16 years. ANM data was obtained from the Prospect-EPIC cohort containing women ≥58 years with a natural menopause. Exclusion criteria were hormone use, ovarian abnormalities/surgery and uterus surgery prohibiting a menstrual cycle.
Main results and the role of chance: The decline in NGF numbers was plotted against age and a decline model was constructed. Predicted distribution of ANM was derived from this decline model, assuming menopause occurs when NGF numbers fall below a critical threshold. Derived distribution of ANM was fitted to observed menopausal ages provided by the Prospect-EPIC database. Maximum likelihood was used to estimate models parameters and predicted distributions of ANM were visually compared to observed ANM. Individual predictions of ANM were obtained combining percentile bands for age specific NGF numbers (i.e. low age specific NGF counts place women in the lower 5%, whereas high age specific NGF counts place women in the high 95%). Predictions of ANM based upon the primordial follicle pool showed a close conformity with observed ANM.
Limitations, reason for caution: There was more residual variation present in NGF counts than needed to describe variation in menopausal ages. This most likely stems from slightly different NGF counting methods present in the papers contributing to the NGF database.
Wider implications of the findings: The close conformity observed between NGFs and age at natural menopause supports the hypothesis that that the size of the primordial follicle pool is an important determinant for the length of the individual ovarian lifespan and supports the concept of menopause prediction using ORTs, such as AMH and the AFC, as derivatives of the true ovarian reserve.
Study funding/competing interest(s): Funding by University(ies) – University Medical Center Utrecht.
Trial registration number: NA.
Keywords: non-growing follicles, menopause, prediction, AMH, AFC

P-672 Oscillation expression of circadian gene PER2 and steroidogenesis related gene STAR following human chorionic gonadotropin stimulation in human luteinized granulosa cells

M. Chen[1], Y. Xu[1], B. Miao[1], H. Zhao[2], J. Gao[1], H. Shi[3], C. Zhou[1]
[1]*The First Affiliated Hospital of Sun Yat-Sen University, Reproductive Center, Guangzhou, Guangdong, China*
[2]*The Third Affiliated Hospital of Sun Yat-Sen University, Department of Hepatic Surgery, Guangzhou, Guangdong, China*
[3]*The First Affiliated Hospital of Sun Yat-Sen University, Department of Pathology, Guangzhou, Guangdong, China*

Study question: Are circadian genes expressed in human ovary? Can oscillation expression of circadian genes in human granulosa cells be induced? How are the variation patterns of expression of steroidogenesis related genes in human granulosa cells after hCG stimulation?
Summary answer: Circadian genes were expressed in dominant antral follicles of human ovaries; hCG can induce oscillation expression of PER2 and STAR in cultured human granulosa cells.
What is known already: Expression of circadian genes has been observed in ovary of chicken, quail, rat, mice and ruminants. Both follicle stimulating hormone and luteinizing hormone can induce oscillation expression of circadian genes in cultured granulosa cells.
Study design, size, duration: Paraffin sections of normal ovarian tissue were obtained from five women who had undergone bilateral salpingo-oophorectomy for gynecologic malignancies. Human luteinized granulosa cells were obtained from follicle fluid of ten patients during ovum aspiration undergoing IVF for each experiment.
Participants/materials, setting, methods: Distribution of circadian genes expression in human ovaries was observed by immunohistochemistry. Accumulation patterns of circadian genes mRNAs and steroidogenesis related genes were observed in human luteinized granulosa cells during 48 hours after treatment of hCG.
Main results and the role of chance: Immunostaining of CLOCK and PER2 were observed in in dominant antral follicles in human ovaries. After hCG stimulation, expression of PER2 in human granulosa cells oscillated peaking at 24th and 40th hour; expression of BMAL1 decreased to the bottom at 20th hour; expression of CLOCK increased without statistical significance; expression of STAR displayed a mild oscillation pattern with two peaks at 24th and 40th hour;

expression of HSD3B2, CYP11A1, CYP19A1 increased not displaying oscillation pattern.
Limitations, reason for caution: Present results cannot illuminate the association between expression rhythms of PER2 and STAR.
Wider implications of the findings: Circadian genes expression may be involved in steroidogenesis of human ovary; rhythms of circadian gene expression and steroidogenesis function might exist in granulosa cells of human ovary.
Study funding/competing interest(s): Funding by national/international organization(s) – This work was supported by grants from National Basic Research Program of China (973 program, 2012CB947600), Scientific Project of Health Industry (201002013) and Science and Technology Planning Project of-Guangdong Province, China (2008A030201028).
Trial registration number: Not RCT.
Keywords: circadian, human chorionic gonadotropin, granulosa cell, ovary

P-673 Use of dual trigger with gonadotropin-releasing hormone agonist (GnRH-a) and human chorionic gonadotropin (hCG) to optimize oocyte recovery rates and IVF results

M. J. Iñarra[1], L. Crisol[1], M. A. Guembe[1]
[1]*Hospital Donostia, Unidad de Reproducción Asistida, San Sebastián, Spain*

Study question: Does dual trigger of final oocyte maturation improve the oocyte recovery and pregnancy rates in IVF cycles?
Summary answer: Co-administration of GnRH-a and hCG for final oocyte maturation significantly improves oocyte recovery rate in IVF cycles, however, pregnancy rates are similar in dual trigger and hCG trigger groups.
What is known already: Oocyte maturation for IVF cycles is commonly induced by hCG as a surrogate for the natural LH surge. In the last years, the use of GnRH-a for final follicular maturation has been shown to significantly reduce the occurrence of ovarian hyperstimulation syndrome compared with hCG triggering, however, a poor reproductive outcome was reported after GnRHa triggering. More recently, the so-called "dual trigger" that combines GnRH-a with hCG has been investigated in IVF with promising results.
Study design, size, duration: Prospective randomized study. The population under study consisted of 73 consecutive patients treated by IVF or ICSI at Hospital Donostia Assisted Reproduction Unit, from January to March 2014. Participants were randomly assigned to two groups: (1) hCG trigger group ($n = 39$) and (2) dual trigger (GnRH-a + hCG) group ($n = 34$).
Participants/materials, setting, methods: Final oocyte maturation was triggered by either 250 mg of recombinant hCG (Ovitrelle; Merck Serono) alone, or by 250 µg of recombinant hCG plus 0.2 µg of triptorelin (Decapeptyl; Ipsen Pharma), depending on the assigned group. All oocyte retrievals were performed under transvaginal ultrasound guidance 36 h after triggering. All embryo transfers were performed 48 hours after oocyte retrieval. Statistical analysis was performed using SPSS 21.0.
Main results and the role of chance: Female mean age, corporal mass index, basal FSH levels, number of antral follicles and AMH levels, as well as cycle stimulation characteristics (estradiol, progesterone) were similar in both groups. We found a significantly higher oocyte recovery rate (proportion of the number of oocytes retrieved per number of preovulatory follicles punctioned) in patients who received the double trigger compared to hCG trigger group (82.5% vs 66.9% respectively, $p = 0.013$). However, there were no statistically significant differences in the percentage of MII oocytes retrieved (84% vs 81.1%), fertilization rate (72.5% vs 63.3%) and pregnancy rate per transfer (47.5% vs 41.9%), between the hCG trigger and dual trigger groups respectively.
Limitations, reason for caution: Our results are limited by the small sample size; therefore, it was not possible to analyze the effects of dual triggering in IVF results of different subgroups of patients. A larger data set is needed to provide more information about dual triggering potential use. This is not a blinded study.
Wider implications of the findings: The results from the study indicate that dual trigger of final oocyte maturation with GnRH-a and the standard dosage of hCG significantly improves oocyte recovery rates in IVF. Although we don't find any relation with pregnancy rates, the co-administration of GnRH-a and hCG could be an effective strategy to optimize pregnancy outcome for poor ovarian responders. However, further large prospective studies are needed to elucidate the aforementioned recommendation.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Hospital Donostia.
Trial registration number: NA.

P-674 Serum and follicular hormone levels do not correlate in different age groups, questioning the impact of LH and androgen substitution on the follicular endocrine milieu

N. A. Bersinger[1], P. Stute[1], M. Eisenhut[1], H. U. Marti[2], M. von Wolff[1]
[1]*University of Berne Inselspital, Obstetrics and Gynaecology, Berne, Switzerland*
[2]*MCL, Laboratory, Berne, Switzerland*

Study question: Do serum and follicular fluid endocrine profiles change with age, indicating that endocrine substitution with LH and androgens might improve the follicular endocrine milieu?
Summary answer: As several endocrine parameters such as LH and testosterone decrease with age in serum but not in follicular fluid and as serum and follicular fluid hormone parameters do not correlate, endocrine substitution to improve the endocrine milieu is subject to debate.
What is known already: Serum androgen concentrations decrease with age. The endocrine milieu has been found to be predictive for the implantation potential of oocytes. In "IVF low responders" treatment strategies are based on the administration of LH and androgens to increase the ovarian response and the oocyte quality.
Study design, size, duration: Cross-sectional study involving 97 women undergoing each one Natural Cycle (NC)-IVF cycle without any hormone stimulation apart from ovulation induction with hCG (5,000 IU) and performed between 2011 and 2014.
Participants/materials, setting, methods: Ninety-seven women undergoing NC-IVF were divided into three age groups: 28–35 years ($N = 30$), 35–39 years ($N = 46$), and 39–42 years ($N = 21$). Serum and follicular fluid were collected at the time of follicle aspiration and the concentrations of LH, testosterone (T), estradiol (E_2) and anti-Mullerian hormone (AMH) were determined by immunoassay and their concentrations correlated.
Main results and the role of chance: Serum LH (28–35 years group = 49.2, 39–42 years group = 26.4 mIU/mL, $P = 0.0178$), T (28–35 years group = 1.26, 39–42 years group = 1.01 nM, $P = 0.2394$), and AMH (28–35 years group = 22.3, 39–42 years group = 12.5 pM, $P = 0.1380$) concentrations decreased with increasing age, E_2 did not. However, none of the hormones decreased with age in the follicular fluid. Furthermore, neither serum LH nor testosterone correlated with the follicular fluid concentrations of T, E_2 and AMH. In follicular fluid significant correlations of T vs. LH,, E_2 vs. T, AMH vs. T and AMH vs. E_2 were observed in women aged 35–39 years. The correlation between E_2 and T was found in all three age groups ($P \leq 0.0011$).
Limitations, reason for caution: A direct correlation between the hormone concentrations and the implantation potential of the oocytes could not be investigated as the oocytes were not treated individually in the IVF laboratory.
Wider implications of the findings: As serum concentrations of LH and androgens do not correlate with the concentration of androgens, E_2 and AMH in follicular fluid, it is questionable whether the substitution with LH or androgens would improve the endocrine milieu in follicles. Therefore such substitution in women with advanced age and undergoing IVF therapy should not be encouraged without further clinical studies.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s) – Public university.
Trial registration number: NA.
Keywords: androgens, AMH, LH, follicle, maternal age

P-675 Are AMH type II receptor and AMH gene polymorphisms associated with ovarian reserve, ovarian response or outcomes of ovarian stimulation?

C. Cerra[1], S. Roberts[2], G. Horne[3], W. G. Newman[4], L. Mohiyiddeen[1]
[1]*St Mary's Hospital, Department of Reproductive Medicine, Manchester, United Kingdom*
[2]*University of Manchester, Centre for Biostatistics, Manchester, United Kingdom*
[3]*St Mary's Hospital, Clinical Embriology, Manchester, United Kingdom*
[4]*University of Manchester, Centre for Genomic Medicine, Manchester, United Kingdom*

Study question: Is there any effect of Anti-Mullerian Hormone (AMH) gene and AMH type II receptor polymorphisms on ovarian response/treatment outcomes and/or current markers of ovarian reserve in patients undergoing in vitro fertilization (IVF) treatment?
Summary answer: No significant associations of *AMH* Ile49Serand AMHR2 -482a > g genotypes with ovarian response (number of oocytes retrieved) and/or markers of ovarian reserve (FSH, AFC, and AMH) were detected in our cohort of women undergoing IVF treatment ($p = 0.136$, and $p = 0.208$).
What is known already: Single nucleotide polymorphisms (SNPs) are increasingly being investigated for a possible association with abnormal responses to ovarian stimulation. Serum AMH is used in clinical practice as a biomarker of ovarian reserve and to predict ovarian response. The AMH signalling pathway is thought to regulate FSH sensitivity in the ovary and follicular recruitment and selection. Therefore, polymorphisms of AMH and AMH receptor genes may have a role in influencing ovarian reserve and ovarian response to stimulation.
Study design, size, duration: In this prospective observational study, we genotyped the *AMH* Ile49Ser and AMHR2 -482a > g SNPs in 579 unrelated women undergoing their first cycle of controlled ovarian stimulation for IVF and ICSI (intracytoplasmic sperm injection) using gonadotrophins at a tertiary referral centre for reproductive medicine between March 2009 and August 2010.
Participants/materials, setting, methods: Pelvic ultrasound and blood samples were taken on day 2–3 of the cycle for baseline hormones/DNA extraction. Genotypes were determined using TaqMan allelic discrimination assay. Regression analysis was performed to assess the effect of the two SNPs on the ovarian reserve markers, the primary outcomes of response, and treatment outcomes.
Main results and the role of chance: There was no evidence of any statistically significant ($p < 0.05$) difference in basal FSH, AMH and AFC between individuals with different *AMH* Ile49Ser and AMHR2 -482a > g genotypes. The number of oocytes retrieved and gonadotropin dose used was also comparable between the individuals with different genotypes.
Limitations, reason for caution: A larger sample size would be required in order to determine if the *AMH* Ile49Ser and AMHR2 -482a > g genotypes had a smaller effect on ovarian reserve or response.
Wider implications of the findings: When considering the development of integrative clinical algorithms for individual FSH doses, our analysis suggests that the genotyping of *AMH* Ile49Ser and AMHR2 -482a > g polymorphisms does not provide additional useful information as a predictor of ovarian reserve or response to ovarian stimulation.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s) – The study was funded by the Manchester Biomedical Research Centre.
Trial registration number: South Manchester Research Ethics Committee. REC ref no. 08/81003/212.
Keywords: ovarian response, SNP, AMH, polymorphism, ovarian stimulation

P-676 The effect of isotretinoin on ovarian reserve based on hormonal parameters, ovarian volume, and antral follicle count in women with acne

H. Aksoy[1], L. Cinar[2], G. Acmaz[3], U. Aksoy[4], T. Aydin[5], U. A. Vurdem[6], L. Oz[7], O. I. Karadag[5], D. Kartal[2]

[3]*Kayseri Education and Research Hospital of Medicine, Department of Obstetrics and Gynecology, Kayseri, Turkey*
[4]*Kayseri Memorial Hospital, Department of Obstetrics and Gynecology, Kayseri, Turkey*
[5]*Kayseri Acibadem Hospital, Department of Obstetrics and Gynecology, Kayseri, Turkey*
[6]*Kayseri Education and Research Hospital of Medicine, Department of Radiology, Kayseri, Turkey*
[7]*Kayseri Education and Research Hospital of Medicine, Department of Biochemistry, Kayseri, Turkey*

Study question: Does oral isotretinoin impact on the ovarian reserve as evaluated with hormonal parameters, anti-Mullerian hormone (AMH), ovarian volume (OV), and antral follicle count (AFC) in reproductive aged women with acne?
Summary answer: This prospective study demonstrated that oral isotretinoin had a significant negative effect on ovarian reserve as evaluated by AMH, AFC, and OV in patients with acne.
What is known already: Widely prescribed in routine practice, isotretinoin has several side effects in many organ systems; however, the effect of isotretinoin on female gonads is not clear. Oral isotretinoin significantly affects ovarian reserve evaluated with follicle stimulating hormone (FSH), luteinizing hormone (LH), estradiol (E2) and AMH.
Study design, size, duration: This prospective study was conducted between March 2013 and March 2014 at a tertiary referral center in Turkey. We investigated the impact of oral isotretinoin on ovarian reserve in 82 reproductive aged women with acne who were treated with oral isotretinoin.
Participants/materials, setting, methods: Of the 121 reproductive aged women evaluated for eligibility criteria, 82 were included. Patients were evaluated for ovarian reserve status prior to therapy and reevaluated 6 months after isotretinoin treatment. Their ovarian reserve status was identified according to hormonal parameters, AMH, OV and AFC.
Main results and the role of chance: Significant differences were found between the pretreatment and posttreatment for AMH (2.20 (1.14–4.07) vs. 1.31 (0.32–2.28), $p < 0.001$), AFC (16 (14–18.25) vs 12.5 (10 -15), $p < 0.001$) and OV (23 (18–29) vs 15 (13–18), $p < 0.001$). We found a significant decrease in AFC, OV, AMH, and E2 levels after 6 months of isotretinoin treatment.
Limitations, reason for caution: Data collection from a single clinic is a potential limitation, and the generalizability of our findings is limited. The absence of longitudinal data as well as control data after recovery and treatment is another limitation of this study; hence further prospective, multicenter studies with longer follow-up times are required.
Wider implications of the findings: The findings of our study indicate that oral isotretinoin significantly decreased ovarian reserve evaluated with AMH, AFC and OV. This is the first study which included all these reliable markers of ovarian reserve, such as FSH, LH, E2, AMH, AFC, and OV together. Based on the present findings, widely and commonly prescribed in routine clinical practice, oral isotretinoin treatment should be considered deleterious for ovarian function and reserve.
Study funding/competing interest(s): Funding by hospital/clinic(s) – There were no external funding and financial support for this study and only departmentally available equipment and drugs were used for the study. There are no conflicts of interest to declare.
Trial registration number: Registration number has not been received.
Keywords: acne, anti-mullerian hormone, antral follicle count, isotretinoin, ovarian reserve

P-677 Granulin levels in patients with premature ovarian failure

A. O. Ersoy[1], E. Oztas[1], E. Ersoy[1], S. Ozler[1], M. Ergin[2], N. Yilmaz[1]
[1]*Zekai Tahir Burak Women's Health Care Training and Research Hospital, Obstetrics and Gynecology, Ankara, Turkey*
[2]*Ataturk Education and Research Hospital, Clinical Biochemistry, Ankara, Turkey*

Study question: Are Granulin levels associated with premature ovarian failure (POF)?
Summary answer: Granulin levels in patients diagnosed with POF were significantly lower than ones of fertile women.
What is known already: As a crucial health problem in a woman's life, Premature Ovarian Failure (POF) has gained significance with the prolongation of expected lifetime. Etiology has a diverse spectrum, but no exact etiologic factor was found to-date.
Study design, size, duration: We aimed to investigate the diagnostic value of Granulin which were showed to have oocyte-specific expression in the pathogenesis of POF as a growth factor. 31 women diagnosed with POF and 57 fertile women as a control group were recruited in this cross-sectional study, from August 2014 to December 2014.
Participants/materials, setting, methods: Recruited patients were younger than 40 years and had no systemic disease or drug use. Antecubital venous samples were obtained from each woman in the morning, after 8-h fasting period. Serum samples were separated and Granulin levels were determined with ELISA method.
Main results and the role of chance: Ages of the patients were similar between the POF group (32.06 ± 4.37 years) and the control group (31.89 ± 4.25)

($p = 0.86$). Likewise, body mass indices of the patients were similar between the POF group (23.67 ± 3.05 kg/m^2) and the control group (23.89 ± 3.0 kg/m^2) ($p = 0.747$). Obstetric history characteristics (gravidity, parity, living child and abortus numbers) were significantly different between two groups ($p < 0.001$, for each one). FSH levels were significantly higher in the POF group, as it was expected ($p < 0.001$). Granulin levels in the POF group (2.94 ± 1.91 ng/mL) were significantly lower than ones in the control group (4.76 ± 1.62 ng/mL) ($p < 0.001$). No association found between Granulin levels and FSH levels.

Limitations, reason for caution: A fully evaluation of ovarian reserve (Anti-mullerian hormone, antral follicle count) and its interaction with Granulin levels could not be performed because of insufficient data about it. This was a limitation in our study.

Wider implications of the findings: This is the first study on Granulin levels in POF. Granulin is a candidate biomolecule to shed light on the pathogenesis of POF, but we could not set forth its exact mechanism whether it's a cause or a result. Further large studies are warranted to figure out molecular role of the Granulin about cognitive problems and ovarian reserve in patients with POF and a lifelong follow-up may provide much more reliable results on these inferences.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Zekai Tahir Burak Women's Health Training and Research Hospital.

Trial registration number: NA.

Keywords: growth factor, granulin, marker, ovarian reserve, premature ovarian failure

P-678 Exploring microRNA expression profile in follicular fluid to classify women with polycystic ovary syndrome

A. E. Sørensen[1], M. L. Wissing[2], A. L. M. Englund[2], L. T. Dalgaard[1]
[1]*Roskilde University, Science Systems and Models, Roskilde, Denmark*
[2]*Fertility Clinic Region Sjaelland, Holbaek Hospital, Holbaek, Denmark*

Study question: Can microRNAs (miRNAs) in follicular fluid (FF) from women with polycystic ovary syndrome (PCOS) be used to improve classification of women with PCOS?

Summary answer: The miRNA expression profile in FF between subsets of PCOS women is significantly different ($p < 0.05$) from healthy controls.

What is known already: Few studies have shown that miRNAs can be isolated from FF from women with PCOS and that the expression level of certain miRNAs is altered in PCOS. Furthermore, insulin resistance, a clinical feature of PCOS, has been associated with an altered miRNA profile in type 2 diabetic patients but the involvement of miRNAs in patients with PCOS is unclear.

Study design, size, duration: A case-control study of forty-nine women with PCOS (mean ± SD; age 27.98 ± 3.87, BMI 25.88 ± 5.25) divided into groups based on their PCOS phenotypes, and twenty-one healthy, regularly cycling women (mean ± SD; age 27.76 ± 3.79, BMI 24.24 ± 3.82) undergoing in vitro fertilization from January 2010 to February 2013.

Participants/materials, setting, methods: FF from the first punctured follicle on each ovary was collected at the time of oocyte pick-up. MiRNAs were extracted from the FF and reverse transcribed into cDNA. TaqMan miRNA arrays (748 different miRNAs) on four representative individuals from each phenotypic group were analyzed and individual selected miRNAs were validated using quantitative real-time PCR in the entire study population.

Main results and the role of chance: Several miRNAs showed a significantly and differently expression in subgroups of PCOS patients compared to healthy controls with miR-24, miR-29a and miR-151 being decreased in PCOS patients. Correlation analysis revealed that markers of metabolic syndrome correlated with the expression levels of miR-24, miR-29, miR-132 and miR-320a in PCOS patients. Furthermore, miR-151 was associated with androgen status in PCOS patients. The number of antral follicles correlated with the expression of miR-574 in the controls. Target gene analyses suggest that steroid biosynthesis signaling and metabolic pathways could be over-represented.

Limitations, reason for caution: Only known miRNAs were investigated. The functional targets of the validated miRNAs as well as the consequences of the miRNA expression profile remains to be determined. Since PCOS is a very heterogeneous disorder, it will be relevant to perform sub-phenotype investigations in relation to miRNA expression levels.

Wider implications of the findings: The usage of miRNAs as a minimal non-invasive biomarker holds great potential. This study suggest that women with PCOS have an altered miRNA profile and that miRNAs can be used to further sub-classify women with PCOS. Moreover, miRNAs may be involved in the pathogenic mechanisms underlying decreased fertility among PCOS patients.

Study funding/competing interest(s): Funding by national/international organization(s) – The study was partly funded by grants from The Danish Diabetes Academy supported by the Novo Nordisk Foundation and a Merck Serono Grant for Fertility Innovation (GFI).

Trial registration number: NA.

Keywords: polycystic ovary syndrome, microRNA, insulin resistance, infertility

P-679 Obstetric and neonatal outcome in oocyte donated 46,XY compared to 45,X and 46,XX women: a nationwide controlled cohort study

M. Dreyer Holt[1], J. Fedder[1]
[1]*Odense University Hospital, Fertility Clinic, Odense, Denmark*

Study question: What are the obstetric and neonatal outcomes after oocyte donation (OD) in 46,XY women compared to women with 45,X or 46,XX karyotype?

Summary answer: The obstetric outcomes were reassuring and neonatal outcomes were good for both singleton and twin deliveries in OD women with 46,XY gonadal dysgenesis.

What is known already: There is an increased rate of pre-eclampsia, failed labor induction, and ceasarean section (CS) as delivery method in women with 46,XY gonadal dysgenesis. Numerous reasons have been suggested including deficient uterus receptors for prostaglandin and oxytocin, that causes failure to induce labor and uterus contractions, a weak uterine wall and a small pelvis. Few deliveries are described in literature and they all lack an appropriate control group.

Study design, size, duration: This retrospective controlled cohort study included all OD women nationwide who gave birth between 1994 and 2013 in Denmark. A total of 404 OD women were enrolled in the study with 346 singleton and 92 twin deliveries.

Participants/materials, setting, methods: Women were identified and data collected using the Cytogenetic Central Register, the National Patient Registry, the IVF registry and the Medical Birth Register. Six OD women with 46,XY gonadal dysgenesis were enrolled in the study and delivered eight babies including one set of twins. 29 OD women with 45,X gonadal dysgenesis and 369 OD women with 46,XX karyotype were enrolled in two different control cohorts and delivered 38 babies (including four twin deliveries) and 484 babies (including 87 twin deliveries) respectively.

Main results and the role of chance: The obstetric outcomes were reassuring for both singleton and twin deliveries. There was an increased ceasarean section (CS) rate of 71.4%, similar to previous literature, and an increased elective CS rate of 80% of all CS, the reason for that is still unknown. Additional an increased rate of postpartum haemorrhage of 43%, but the difference was insignificant. The neonatal outcomes were good for both singleton and twin deliveries with Apgar scores = 10, no stillborns, neonatal mortality or serious birth defects.

Limitations, reason for caution: This study was performed over two decades and is the first controlled cohort study of OD 46,XY women, however larger cohorts are needed to assess rare events.

Wider implications of the findings: Obstetric and neonatal data was collected for all OD women nationwide, supporting generalizability to similar populations. Neonatal outcomes were in agreement with the literature, while obstetric outcomes were generally better than previously reported. We suggest evaluation of the uterus and pelvis size before pregnancy and delivery. In addition we recommend cross-matched blood available for delivery. We remind clinicians that OD women with 46,XY gonadal dysgenesis is not in itself an indication for CS.

Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s) – Odense University Hospital.

Trial registration number: Clinical trial registration number was not necessary as it is a register study. Approved by the Danish Data Protection Agency. Journal number: 2014-41-2694.

Keywords: gonadal dysgenesis, oocyte donation, neonatal outcome, 46,XY women, pregnancy outcome

P-680 The kisspeptin-GnRH pathway and the expression of kisspeptin, GnRH and their receptors in human endometrial stromal cells: possible involvement in embryo implantation and early pregnancy

H. M. Wu[1], H. Y. Huang[1], Y. K. Soong[1], H. S. Wang[1]
[1]*Chang Gung Memorial Hospital, Obstetrics and Gynecology, Taoyuan, Taiwan R.O.C.*

Study question: We try to investigate the presence of GnRH, kisspeptin and their receptors in the human endometrial decidual stromal cells, thus establishing an autocrine/paracrine kisspeptin-GnRH pathway in the regulation of embryo implantation and early pregnancy.
Summary answer: These results demonstrate that GnRH, kisspeptin, GnRH receptor, kisspeptin receptor, and kisspeptin-GnRH signaling are present in human endometrial decidual tissues and stromal cells. Our findings represent a new concept regarding the potential modulatory role of kisspeptin and GnRH on embryo implantation and decidual programming of human pregnancy.
What is known already: Endometrial decidualization plays an important role on the implantation of the embryo and human pregnancy. Invasion of the maternal decidua by extravillous trophoblast is an important process for embryo implantation and placentation.
Study design, size, duration: In this in vitro study, we examined the expression of GnRH, kisspeptin, GnRH receptor and kisspeptin receptor in human endometrial decidual stromal cells, indicating the role of GnRH, kisspeptin, and kisspeptin-GnRH pathway in embryo implantation and early pregnancy.
Participants/materials, setting, methods: Endometrial decidual stromal cells were isolated from women undergoing elective pregnancy termination of pregnancy at 6- to 12-week gestation, after informed consent. Immunoblot analysis, immunohistochemistry, kinase array and RT-PCR were performed to investigate the GnRH-kisspeptin signaling following the treatment with steroid hormones and GnRH analoges in human endometrial decidual stromal cellls.
Main results and the role of chance: The mRNA expression of GnRH, kisspeptin, GnRH receptor and kisspeptin receptor was found in human endometrial decidual stromal cells. The protein expression of GnRH, kisspeptin, GnRH receptor and kisspeptin receptor was detected in human endometrial decidual stromal cells. GnRH, kisspeptin, GnRH receptor and kisspeptin receptor immunoreactivity was detected in human endometrial decidual tissue. The expression of kisspeptin and kisspeptin receptor was regulated following treatment with estradiol, progesterone or GnRH analoges in human endometrial decidual stromal cells.
Limitations, reason for caution: Hard to detect the kisspeptin, GnRH and their receptors expression in human endometrial decidual stromal cells by immunoblot analysis.
Wider implications of the findings: Our findings represent a new concept regarding the potential modulatory role of kisspeptin and GnRH on embryo implantation and decidual programming of human pregnancy.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Chang Gung Memorial Hospital.
Trial registration number: NA.
Keywords: kisspeptin, GnRH, endometrium, implantation

P-681 A single-centre evaluation of elecsys roche automated anti-mullerian hormone assay and comparison with the current clinical standard assay

E. Bosch[1], J. L. Zuzuarregui[1], M. Meseguer[1], M. Marí[1], S. M. Nelson[2]
[1]*Instituto Valenciano de Infertilidad, Human Reproduction, Valencia, Spain*
[2]*University of Glasgow, Maternal and Reproductive Medicine, Glasgow, United Kingdom*

Study question: What are the concordance and the repeatability of serum AMH measurements performed by the well established Beckman Coulter Gen II AMH ELISA assay and the novel Roche Elecsys Automated AMH assay?
Summary answer: The Elecsys Roche Automated Assay has different calibration to the Gen II assay, but exhibits greater sensitivity and repeatability consistent with its automated methodology making it superior for clinical use.
What is known already: The Beckman Coulter Gen II assay is the most commonly used AMH assay in routine biochemistry at present, but persistent calibration/interference problems have been reported
Study design, size, duration: Prospective single centre study performed between September and December 2014. Samples from 277 patients submitted for AMH evaluation were determined with both Gen II and Elecys assays. We randomly selected 66 samples for analysis of repeatability
Participants/materials, setting, methods: All serum samples from patients referred for AMH at Instituto Valenciano de Infertilidad during the study period were eligible. Methods were compared using Lin's concordance correlation coefficient (using log transformed data to satisfy assumptions of normal distribution), Passing-Bablok regression and Bland–Altman plots using Pitman's test to assess likelihood of bias.
Main results and the role of chance: Samples which were below the Limit of Detection (n = 35, 5 of which were for both assays) were excluded from the analysis. Median [interquartile range (IQR)] AMH was 13.0 pmol/l in the Gen II (interquartile range 6.8 –29.0) and 10.8 pmol/l (5.4 –22.4) in the Elecsys ($P < 0.0001$). The concordance between log-transformed values was rho = 0.96 (95% CI 0.96 –0.97). The Passing–Bablok regression equation was: y (Roche) = 0.51 + 0.75 x Gen II. Bland–Altman analysis showed evidence of bias in absolute measurements, such that samples with higher AMH had higher estimates on the Gen II assay. The correlation between the difference and the mean was r = 0.51, $P < 0.001$. The R^2 coefficient for repeatability was 0.999 for the Elecsys and 0.993 for the Gen II.
Limitations, reason for caution: The present study is a pragmatic assessment of the new assay under ideal conditions. Lot to lot variation could not be assessed. Demographics and outcomes of patients referred for AMH measurement were not known.
Wider implications of the findings: The new Elecsys Roche Automated assay exhibits different calibration to the Gen II assay such that new reference ranges will be required to be established. That the Elecsys assay exhibits superior sensitivity, precision and repeatability suggests that it would be preferable to the Gen II assay for clinical and epidemiological use.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Roche Diagnostics provided kits for this study free of charge. The manufacturer played no part in conducting assays or data analysis. SM Nelson has received honoraria from Beckman Coulter and Roche Diagnostics. Ernesto Bosch has received honoraria from Roche Diagnostics.
Trial registration number: NA.
Keywords: AMH, diagnostic test

P-682 Serum progesterone elevation in early follicular phase has an adverse effect on cycle cancelation and ongoing pregnancy rates of in vitro fertilization treatment

V. C. Y. Lee[1], R. H. W. Li[1], W. S. B. Yeung[1], P. C. Ho[1], E. H. Y. Ng[1]
[1]*The University of Hong Kong Faculty of Medicine Building, Obstetrics and Gyneacology, Hong Kong Island, Hong Kong*

Study question: It is well known that progesterone elevation (PE) on hCG trigger day has a detrimental effect on the pregnancy rate in IVF cycles. If the progesterone concentration in early follicular phase (EPE) remains elevated, would the pregnancy rate of IVF treatment be also affected?
Summary answer: EPE was associated with a similar number of oocytes and embryos, a higher cycle cancelation rate (CCR) due to no or poor ovarian response and a lower ongoing pregnancy rate (OPR). Women with PE at early and late follicular phases performed worst with the highest CCR and the OPR.
What is known already: PE on hCG trigger day has a detrimental effect on the pregnancy rate in IVF cycles. It may adversely affect the endometrial receptivity, but not the embryos quality, as shown by gene expression study and studies showing comparable pregnancy rate in subsequent frozen-thawed embryo transfer cycles. Only few studies looked into the effect of EPE. A prospective study showed cycles with EPE, even if progesterone concentration normalised within two days, had a significantly lower OPR.
Study design, size, duration: This is a retrospective study. All first IVF cycles carried out between January 2011 and December 2013 at the Centre of Assisted Reproduction and Embryology, The University of Hong Kong were retrieved and 1,122 cycles were included in the final analysis.
Participants/materials, setting, methods: Clinical details of treatment cycles were prospectively entered into a computerized database, which were retrieved for analysis. Cycles with pre-implantation genetic diagnosis, or using donated gametes were excluded. The primary outcome was OPR and

secondary outcomes included the number of oocytes and embryos and CCR due to no ovarian response.

Main results and the role of chance: The cut-off level of EPE was defined as 4.5 nmol/L, above which the OPR dropped abruptly. The incidence of EPE was 4.9% (55/1122, 95% CI 3.9–6.9%). Women with and without EPE had a similar number of oocytes and embryos. The EPE group had a significantly higher CCR than the non-EPE group (9.1% vs 3.7%, RR 0.408 95% C.I.0.171–0.973, $p = 0.043$). The OPR per cycle initiated was significantly lower in the EPE group, when compared with that of the non-PE group (16.4% vs 28.8%, RR 0.971 95% C.I.0.946–0.996, $p = 0.046$). In the subgroup analysis, those women with normal progesterone concentration both at early and late follicular phases performed best with the lowest CCR and the highest OPR, while those with PE on both occasions had the highest CCR and the lowest OPR

Limitations, reason for caution: This is a retrospective analysis but the serum progesterone concentration from the achieved samples did not alter the clinical management of the treatment cycles during the study period. There may be confounding factors that were not controlled during the statistical analysis. There were various stimulation regimen used.

Wider implications of the findings: The findings are important for counselling of women undergoing IVF treatments. Though there were various protocols used and the data look heterogenous, it resembled the real situation in fertility centres. It actually reinforced the generalization and applicability of our data in the real clinical situations. Strategies to deal with the EPE should be studied as it seems that postponing the starting day till progesterone concentration normalised in the same cycle does not help.

Study funding/competing interest(s): Funding by University(ies) – This study was funded by the Department of Obstetric and Gynaecology, the University of Hong Kong.

Trial registration number: This study was registered on the HK clinical trial registry with the register number HKCTR-1820.

Keywords: progesterone elevation, early follicular phase, cycle cancellation, pregnancy rate, IVF

P-683 Effects of Korean red ginseng extracts on endometrium in postmenopausal women

E. Noe[1], B. Yun[1], S. Cho[1], Y. Choi[1], B. Lee[1], S. Seo[1]
[1]*YUHS, Obstetrics and Gynecology, Seoul, South Korea*

Study question: Does Korean red ginseng (RG) extract affect human endometrium of postmenopausal women?

Summary answer: RG extract seems to not influence on serum estradiol and endometrial thickness. Anti-proliferative effect on endometrial stromal and epithelial cells has been shown by our study.

What is known already: Ginseng extract has been a representative tonic, which may exert estrogenic effect. Studies have shown various effects of ginseng in postmenopausal women. Ginseng has been shown positive effect as anti-oxidant, by increasing enzyme activity in postmenopausal women. However, discrepant results have been reported about effect of ginseng on menopausal symptoms. Our previous RCT that evaluated RG effect on menopausal symptoms has shown significant improvement, which may suggest to have favorable effects to postmenopausal women.

Study design, size, duration: A randomized, placebo-controlled, double-blinded clinical trial was conducted for 12 weeks. Total 72 postmenopausal women were enrolled, and analyzed changes in serum estradiol and endometrial thickness on ultrasonography from baseline to 12 weeks. Additional experimental study was conducted to see whether KRG extract affects endometrial cell proliferation/apoptosis.

Participants/materials, setting, methods: Postmenopausal women between ages 45 to 60 years were eligible. Participants were assigned to either RG or placebo group. Experimental study was conducted using isolated endometrial stromal cell from human endometrium, and Ishikawa cell from endometrial cancer cell line. Cell proliferation/apoptosis was assessed after treating RG.

Main results and the role of chance: Serum estradiol level and endometrial thickness were not influenced by KRG supplementations. Moreover, RG extracts were found to inhibit growth of both endometrial stromal cells and Ishikawa cells in a dose-dependent manner, and to induce apoptosis in Ishikawa cells by dose increase as well. Concurrently, western blotting & caspase-3 activity assay revealed that RG extracts lead to activation of caspase-3 and PARP cleavage, indicating caspase-3 mediated PARP cleavage which results in apoptosis. Since RG has shown anti-proliferative, pro-apoptotic effect on endometrium, it may regard as little potential danger of developing endometrial pathology as adverse event associated with taking RG.

Limitations, reason for caution: Limitations for the study are small sample size and lack of detailed adverse events including bleeding pattern.

Wider implications of the findings: Our result may provide a further understanding on ginseng extract as a complementary medication that can be used for postmenopausal women.

Study funding/competing interest(s): Funding by commercial/corporate company(ies) – This work was supported by a grant from the Korean Society of Ginseng, funded by Korea Ginseng Corporation, 2010.

Trial registration number: NA.

P-684 GnRH agonist trigger with intensive luteal phase support versus hCG trigger with standard luteal phase support in a population of high responders

G. Christopoulos[1], A. Vlismas[1], A. Carby[2], S. Lavery[1], G. Trew[1]
[1]*Hammersmith Hospital, IVF Unit, London, United Kingdom*
[2]*Boston Place, IVF Clinic, London, United Kingdom*

Study question: Is there a difference in clinical pregnancy rate, live birth rate and the incidence of ovarian hyperstimulation syndrome when a GnRH agonist (GnRHa) trigger with intensive luteal phase support is compared to hCG trigger with standard luteal phase support in high-risk patients undergoing IVF treatment?

Summary answer: GnRHa trigger is associated with similar pregnancy rates with hCG trigger and a significant reduction in hospitalisation for severe OHSS after an intention-to treat analysis was performed.

What is known already: The GnRHa-induced LH surge has a relatively short duration of 24–36 h. To counteract the resulting luteal phase deficiency, the use of intensive or modified luteal phase support protocols was introduced. The largest study so far comparing GnRHa triggering with intensive luteal phase support to hCG triggering after a GnRH antagonist protocol reported no difference in pregnancy rates and a reduction in OHSS in high responders having a triple embryo transfer on day 2.

Study design, size, duration: A retrospective, cohort study of high-risk patients having a GnRH antagonist protocol with a GnRHa trigger (October 2011–June 2014) was performed. The control group consisted of high-risk patients having a GnRH antagonist protocol with hCG trigger during the transitional period of the introduction of the GnRHa trigger protocol.

Participants/materials, setting, methods: 382 patients had GnRHa triggering and 194 controls had hCG triggering. All patients had ≥18 follicles ≥11 mm and/or serum estradiol >18,000 pmol/l on the day of trigger. Patients had a single or double embryo transfer at cleavage or blastocyst stage. Logistic regression was used to adjust for differences between the groups.

Main results and the role of chance: An intention-to-treat analysis of all started cycles was performed (GnRHa group $n = 382$ vs. hCG group $n = 194$). No statistically significant differences were observed in terms of positive pregnancy test rate (48.9% vs. 48.9%, OR: 0.92, 95% CI: 0.63–1.35, $p = 0.94$), clinical pregnancy rate (35% vs. 41.2%, OR: 0.75, 95% CI: 0.52–1.10, $p = 0.15$), implantation rate (31.2% vs. 36.6%, OR: 0.76, 95% CI: 0.57–1.07) and live birth rate (30% vs. 35.4%, OR: 0.78, 95% CI: 0.51–1.18, $p = 0.24$). Significantly fewer patients had an embryo transfer cancellation in the GnRHa trigger group (3.9% vs. 8.7%, OR: 0.43, 95% CI 0.21–0.87, $p = 0.02$). Only one patient (0.3%) was hospitalised due to severe OHSS in the GnRHa group, compared to 26 patients (13%) in the hCG group (OR: 0.01, 95% CI: 0.00–0.06, $p < 0.001$).

Limitations, reason for caution: No monitoring of serum progesterone or estradiol was performed during the luteal phase. The decision to proceed to a cancellation of the embryo transfer procedure and to an elective cryopreservation of embryos was based on clinical judgment rather than any set clinical or biochemical criteria.

Wider implications of the findings: To our knowledge this is the largest, observational study comparing the outcomes of IVF cycles using a GnRHa or hCG trigger. GnRHa trigger with the use of intensive luteal phase support appears to be as effective and safer than hCG trigger. A large randomised trial comparing the intensive and modified luteal phase support protocols with an

elective embryo cryopreservation protocol is needed to establish the best approach after the use of a GnRHa trigger.
Study funding/competing interest(s): Funding by hospital/clinic(s) – IVF Hammersmith, London, UK.

P-685 Serum levels of 25-hydroxyvitamin D and time to natural pregnancy

A. Paffoni[1], S. Ferrari[1], D. Lattuada[2], B. Colciaghi[2], F. Filippi[1], I. La Vecchia[1], A. Tirelli[3], G. M. Baffero[2], N. Persico[2], E. Somigliana[1]
[1]*Fondazione Ospedale Maggiore Policlinico, Infertility Unit, Milano, Italy*
[2]*Fondazione Ospedale Maggiore Policlinico, Ob and Gyn, Milano, Italy*
[3]*Fondazione Ospedale Maggiore Policlinico, Central Laboratory, Milano, Italy*

Study question: Are serum 25-hydroxyvitamin D (25-OH-D) levels, which is the form of vitamin D reflecting the store of the vitamin, higher in fertile compared to subfertile women?
Summary answer: We did not find differences in serum levels of 25-OH-D between subfertile and fertile patients. Our study does not support a crucial role of 25-OH-D in natural fertility.
What is known already: Studies in animal models support a critical role of Vitamin D in reproductive mechanisms. However, data in human is inconsistent. Some authors reported a detrimental effect of vitamin D deficiency in IVF but others did not. Noteworthy, IVF is a valuable model to investigate several factors affecting fertility in women but it may not properly reveal all the potential effects of vitamin D on natural fertility.
Study design, size, duration: Women referring for 1st-trimester screening for aneuploidies between January 2012 and June 2013 were evaluated to participate to this nested case-control study. The sample size (73 cases and 73 controls) was calculated based on a paired study design and assuming as relevant a 15% reduction in serum 25-OH-D in cases.
Participants/materials, setting, methods: Cases and controls were defined as women conceiving in 12–24 and ≤12 months, respectively. They were matched by age and study period. Exclusion criteria included: known cause of subfertility; BMI > 25 Kg/m^2; pregnancy achieved using ovarian stimulation or ART. 25-OH-D levels were tested using a chemiluminescence kit.
Main results and the role of chance: Baseline characteristics of the studied groups were similar with the exception of men age and parity. Serum 25-OH-D did not differ between cases and controls (21.2 ± 6.8 and 19.7 ± 7.3 ng/ml, respectively; paired *t*-test, $p = 0.16$; unpaired *t*-test $p = 0.20$). The number of women with serum levels <20 ng/ml was 34 (47%) and 37 (51%), respectively (McNemar test, $p = 0.73$; Fisher Exact test, $p = 0.74$). The OR of subfertility in women with 25-OH-D insufficiency (<20 ng/ml) was 0.85 (95% CI: 0.44–1.62). The OR adjusted for men age and parity was 0.84 (95% CI: 0.42–1.66). When considering women with vitamin D deficiency (<10 ng/ml), statistical analyses showed similar results.
Limitations, reason for caution: We could not assess whether appropriate serum 25-OH-D would shorten time to pregnancy since only a minority of studied women had levels >30 ng/ml. Even if time to pregnancy is commonly used to investigate causes of subfertility, we lack results from basic infertility investigations (semen analysis, basal hormones …).
Wider implications of the findings: Our results contrast with the available emerging evidence suggesting a detrimental effect of vitamin D deficiency on woman fertility. However, given that the vast majority of studied women have sub-optimal levels of 25-OH-D, interventional studies are warranted to draw definite conclusion.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Fondazione IRCCS Ca' Granda.

[5]*Huntington – Reproductive Medicine/Gynecology Department of Federal University of Sao Paulo, Head of Clinical/Gynecology-Endocrinology Discipline, São Paulo, Brazil*

Study question: Determine if insulin signaling pathway gene expression in granulosa cells of obese Polycystic Ovarian Syndrome (PCOS) patients is altered compared to eutrophic PCOS patients undergoing *in vitro* fertilization (IVF) cycles.
Summary answer: Among the 84 genes analyzed, 09 genes were statistically significant over-expressed in obese patients compared to eutrophic. The up-regulated genes were BCL2L1, BRAF, CBL, DOK1, FBP1, FRS2, PCK2, RPS6KA1, and SORBS1.
What is known already: Insulin plays a central role on obese PCOS women. It acts through its own receptor or the IGF 1-receptor to enhance ovarian and adrenal steroidogenesis, activating tyrosine kinase phosphorylation intracellular signaling cascades. However the precise mechanism of insulin action on granulosa cells and the consequences to oocyte maturation is not completely elucidated in obese or even in non-obese PCOS patients.
Study design, size, duration: Cross-sectional study to evaluate granulosa gene expression in patients submitted to IVF treatment between January 2013 and October 2014. Fifteen PCOS patients (Rotterdam criteria) were subdivided: 09 eutrophic (Control group) and 06 obese (Obese group). In both groups, a normal insulin resistance were assessed according to *homeostasis model assessment insulin resistance* (HOMA IR).
Participants/materials, setting, methods: PCOS infertile patients were submitted to IVF with standard ovulation induction, oocytes were recovered to IVF and the granulosa cumulus cells were removed to RNA extraction by quantitative PCR array analysis of gene expression profile (RT² Profiler™ PCR Array Human Insulin Signaling Pathway- PAHS-030ZC-Quiagen, USA).
Main results and the role of chance: The results were expressed by fold up (³3) or fold down (≤3) values comparing obese patients gene expression over eutrophic patients. The results were considered statistically significant when $p \leq 0.05$ over gene expression. Among the 84 genes analyzed, 09 genes were statistically significant over expressed in obese patients. The up-regulated genes were BCL2L1 (fold = 4.7; $p = 0.021$), BRAF (fold = 3.8; $p = 0.031$), CBL (fold = 6.2; $p = 0.019$), DOK1 (fold = 4.6; $p = 0.040$), FBP1 (fold = 5.3; $p = 0.011$), FRS2 (fold = 4.1; $p = 0.044$), PCK2 (fold = 4.4; $p = 0.041$), RPS6KA1 (fold 4.2; $p = 0.044$), and SORBS1 (fold = 3.6; $p = 0.014$). These genes are involved in inhibition pathway of follicle development, insulin resistance, glucose uptake, granulosa cell growth and proliferation.
Limitations, reason for caution: The study was developed in a small sample size, as it is a screening for 84 genes. However, the sample power was calculated based on the difference of gene expression between groups and it showed to be higher than 80%. Besides that, the ovulation induction might produce some detrimental effects in the oocyte competence, regardless the insulin action. Hence, the gene profile expression of insulin pathways in the granulosa cells is not well elucidated and can not be generalized for IVF patients.
Wider implications of the findings: PCOS patients submitted to IVF show a large number of immature oocytes, poor embryos, miscarriages and a higher incidence on ovarian hyperstimulation syndrome, mainly in obese if compared to non-obese PCOS infertile patients. Also the pregnancy rate is lower in obese compared to non-obese patients. The knowledge of specific genes that modulate the granulosa-cumulus complex can expand the possibilities of new therapies and individualized approaches to PCOS patients seeking for IVF treatments.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s) – Federal University of Sao Paulo/Huntington Reproductive Medicine.

Trial registration number: NA.

P-688 The performance power of the revised antimullerian hormone Generation II assay and reference range: population based comparison study

J. Y. Lee[1], B. C. Jee[2], S. K. Kim[2], H. J. Lee[3], S. H. Kim[4], J. H. Park[4], J. R. Lee[2]
[1]*Hamchoon Women's Clinic, OBGY, Seoul, South Korea*
[2]*Seoul National University Bundang Hospital, OBGY, Sungnam, South Korea*
[3]*CHA Fertility Center, OBGY, Seoul, South Korea*
[4]*Seoul National University College of Medicine, OBGY, Seoul, South Korea*

Study question: Dose the revised Beckman-Coulter second generation (Gen II) antimullerian hormone (AMH) assay provides more reliable AMH results than the original Gen II assay and what are the age-specific reference AMH ranges for the revised Gen II assay?
Summary answer: Population data suggest a systematic shift between AMH distributions measured by the original and revised Gen II assay. The Immunotech (IOT) and revised Gen II assay are comparable in assay reliability from the point of variability. The quadratic model is fit for describing the decline in AMH measured by all the IOT, original and revised Gen II assay with age.
What is known already: AMH is accepted as a reliable and important predictor of ovarian response in IVF and ovarian reserve in other clinical settings. The original Gen II replaced the Diagnostic Systems Laboratory (DSL) & IOT assays but has higher instability than previous two assays and kit manufacturer revised assay method. There is no study comparing performance power among the IOT, original Gen II and revised Gen II assay in a large cohort.
Study design, size, duration: We recruited AMH data obtained from unselected women aged 25 to 45 years old examined for infertility work-up between November 2008 and June 2014. AMH samples were subject to the same handling procedures and were analyzed by the same laboratory.
Participants/materials, setting, methods: AMH values were measured using IOT assay (from November 2008 to August 2012, Cohort 1: n = 32,824), subsequently using the original Gen II assay (from September 2012 to July 2013, Cohort 2: n = 13,445) and lastly using the revised Gen II assay (from June 2013 to June 2014, Cohort 3: n = 15,801). Three cohorts were comparable in age characteristic. Each cohort was randomly divided into a training and validation cohort to set up and validate optimal age-AMH model.
Main results and the role of chance: AMH values measured with the original Gen II were 40% lower than those with the IOT and 36% lower than with revised Gen II assay in clinical practice. The distribution of AMH values obtained by the revised Gen II is similar with that obtained by the IOT assay. The quadratic model was the most appropriate to describe the decline in AMH obtained using the revised Gen II assay according to age.
Limitations, reason for caution: We can not exclusively rule out the existence of differences among the three cohorts.
Wider implications of the findings: The systematic shift between AMH distributions measured by the original and revised Gen II assay may imply the presence of assay-specific preanalytical instability. The revised Gen II assay may settle a controversy of appreciable variability in the original Gen II assay. Further studies are consistently required to minimize variabilities of AMH measurement.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Hamchoon Women's Clinic.
Trial registration number: NA.

P-689 Cumulus cells DFI as indicator of good response in different protocols of ovulation induction

F. Caprio[1], L. Rocco[2], M. Santonastaso[2], R. Ianniello[1], D. Mele[1], N. Colacurci[1]
[1]*Second University of Naples, Outpatient Fertility Clinic, Napoli, Italy*
[2]*Second University of Naples, Department of Environmental Biological and Pharmaceutical Sciences and Technologies, Napoli, Italy*

Study question: To validate the relationship between cumulus cells (CC) apoptosis rates revealed through the analysis of DNA fragmentation (DFI) and oocyte quality and to determine the effects of different stimulation protocols on apoptosis rate of the cumulus cells.
Summary answer: Cumulus cells DFI correlates with oocyte and embryo quality and fertilization rates. Addition of LH in the early follicular phase in ovulation induction protocols modify the CC apoptotic index; in particular we observed that the LH addition in the early follicular phase reduces DFI rates only in women over 35.
What is known already: A correct oogenesis requires a corresponding development of follicular cell component and an adequate dialogue between cumulus ooforus cells and oocyte is essential for developing oocyte competence. Data from literature have shown that the CC apoptosis rates are inversely correlated with mature oocyte rate, fertilization rates and success rates in IVF cycles. Furthermore it has been observed that different stimulation protocols may affect in different ways on CC apoptosis rates.
Study design, size, duration: Prospective observational study.
Participants/materials, setting, methods: 70 women candidates to an ICSI cycle. Exclusion criteria were age >38 years, BMI >25, smoking status, basal FSH >10 mIU/mL, severe endometriosis and PCOS. At the time of pick-up were isolated CC for laboratory evaluation. The apoptotic index assessment was performed by TUNEL TEST.
Main results and the role of chance: Samples were divided according to the levels of DFI into three groups: A-DFI <25, B-DFI 25–35, C-DFI >35. It is observed that in group C compared to group A (M2 55% vs 85% $p < 0.05$, 2PN 62% vs 93%, $p < 0.05$, embryo 1 45% vs 85%, $p < 0.05$) rate of the analyzed parametres were statistically significantly lower. It was also compared the CC DFI of women treated with LH and FSH together from 2 to 3 of the cycle of stimulation (36 pz) and CC DFI of women treated with FSH alone (29 pz); whereas there is no differences on the CC DFI in women younger than 35, was observed an apoptotic index lower in women of advanced reproductive age treated with LH (31% vs 42%, $p < 0,05$).
Limitations, reason for caution: The number of cases analyzed is still small to draw conclusions; further validation will be required. The small number of patients did not make it possible to rule out other potentially confounding factors.
Wider implications of the findings: Our results can represent a valid support of the already present literature for the use of apoptosis rate of cumulus cells as a possible indicator of oocyte quality and good response to stimulation. Furthermore, our results have suggested that the beneficial effects of the addition of LH from the initial stages of stimulation in women over 35 can be successfully mediated also by the improvement of the apoptotic index of cumulus cells.
Study funding/competing interest(s): Funding by University(ies) – Second University of Naples.
Trial registration number: The study was not registered because it is an observational study and the assignment of the medical intervention is not at the discretion of the investigator.
Keywords: cumulus cells, DFI, Ovulation induction

P-690 Nesfatin-1 level in follicular fluid (FF) is associated with the number of retrieved oocyte in IVF cycle

S. J. Lee[1], J. Y. Jung[1], S. J. An[1], K. Lee[1], J. H. Park[1], H. W. Yang[2]
[1]*Miraewaheemang IVF lab, Department of ob/gyn, Seoul, South Korea*
[2]*Seoul women's University, Department of Biotechnology, Seoul, South Korea*

Study question: Recently, nesfatin-1 is known as a regulator in hypothalamus-pituitary-ovary axis of animal model. What are the roles of nesfatin-1 in human IVF cycles undergoing a GnRH-antagonist protocol?
Summary answer: Nesfatin-1 was expressed in placenta, uterus, ovary, and testis. Furthermore, the expression of nesfatin-1 in ovarian granulosa cells of preantral follicles was higher than those in the other ovarian cells. In addition, higher nesfatin-1 levels in FF were significantly associated with higher number of retrieval oocytes.
What is known already: Nesfatin-1 is an anorexigenic peptide and regulates feeding behavior and energy homeostasis. Also, nesfatin-1 is known to participate in the activation of the hypothalamic-pituitary-adrenal axis in rat and to regulate the hypothalamic-pituitary-ovarian axis of fish.
Study design, size, duration: A total of 104 infertile women without PCOS undergoing IVF were studies from June 1, 2014 to October 31, 2014. The patients were divided to three groups according to the tertile of nesfatin-1 level in FF [Group I (<0.1 ng/ml): 37 cases, Group II (≤0.1–<0.2 ng/ml): 37 cases, Group III (≥0.2 ng/ml); 24 cases)]. The data were analyzed with age, number of retrieved oocyte, maturation rate, fertilization rate, pregnancy rate and BMI.

Participants/materials, setting, methods: Nesfatin-1 mRNA expression was tested by real-time PCR using total RNA of human placenta, uterus, ovary, and testis. Also, the localization of nesfatin-1 protein in human ovarian tissue was performed by immunocytochemistry. Follicular fluid was collected from the first follicle at time of oocyte retrieval. Nesfatin-1 levels were measured by ELISA.

Main results and the role of chance: Real-time PCR results showed that nesfatin-1 mRNA was generally expressed in placenta, uterus, ovary, and testis. In comparison with testis and ovary as reproductive organs, nesfatin-1 in ovary is expressed in about 30 times more than in testis. Nesfatin-1 protein was mainly localized in granulosa cells of primordial follicles and preantral follicles. By analyzing the results of age, maturation rate, fertilization rate, pregnancy rate and BMI, there were not significantly different in comparison of three groups. However, in data analysis of retrieval oocyte number, mean number (18.5 ± 6.8) of retrieved oocyte in group III (> 0.12 ng/ml) were significantly higher than mean number (12.4 ± 7) of retrieved oocyte in group I (< 0.1 ng/ml) ($p < 0.005$). Also we can freeze surplus embryos for cryopreservation cycle in 30 cases (66.7%) of group III,, but only 14 cases (37.8%) of group I are available for cryopreservation cycle.

	Group I ($n = 37$)	Group II ($n = 37$)	Group III ($n = 30$)
Range of nesfatin-1 concentration in FF	<0.1	≤0.1–<0.2	≤0.2
Nesfatin-1 concentration in FF	0.067 ± 0.02	0.133 ± 0.026	0.317 ± 0.139
Age	35.4 ± 4.4	35.8 ± 3.9	36.9 ± 3.8
Number of IVF cycles	1.8 ± 1	2.2 ± 2	2.3 ± 2
BMI	20.3 ± 2.2	20.9 ± 2.4	22.0 ± 3.0
Number of retrieval oocyte	12.4 ± 7.2[a]	16.9 ± 9.0	18.5 ± 6.8[a]
Maturation rate	70.40%	73.30%	73.20%
Fertilization rate	71.90%	81%	81.40%
Chemical pregnancy rate	48.6% (18/37)	45.9% (17/37)	43.3% (12/30)
Ongoing pregnancy rate	40% (15/37)	43% (16/37)	43.3% (12/30)
Percentage of cryopreservation available cycle	37.8% (14/37)[b]	54.1% (20/37)	66.7% (20/30)[b]

Mean ± SD; [a]$p < 0.005$; [b]$p < 0.01$ by *t*-test.

Limitations, reason for caution: There were some limitations in this study, including variable size of follicles that FF was collected from, and possibility of blood contamination during FF collection procedure. Additionally, to consolidate our conclusion, more ART cycles should be studied.

Wider implications of the findings: Finally, our data showed that there are positive correlation between nesfatin-1 and the number of retrieval oocyte, suggesting that nesfatin-1 could play a role in early folliculogenesis in human ovary. Also, it would be another interesting suggestion to study the correlation between nesfatin-1 level in blood and oocyte retrieval number

Study funding/competing interest(s): Funding by hospital/clinic(s) – None.
Trial registration number: NA.

P-691 Ovarian surgery for symptom relief in women with polycystic ovary syndrome: a meta-analysis and systematic review

Y. Obura[1], M. Metwally[2], C. Farquhar[3], B. Jhamb[4], Y. Cheong[5]
[1]*Dorset County Hospital, Obstetrics and Gynaecology, Dorchester, United Kingdom*
[2]*The Jessop Wing and Royal Hallamshire Hospital Sheffield Teaching Hospitals, Obstetrics and Gynaecology, Sheffield, United Kingdom*
[3]*University of Auckland, Obstetrics and Gynaecology, Auckland, New Zealand*
[4]*Poole General Hospital, Obstetrics and Gynaecology, Poole, United Kingdom*
[5]*University of Southampton, Obstetrics and Gynaecology, Southampton, United Kingdom*

Study question: To assess the effectiveness and harms of laparoscopic ovarian drilling (LOD) as a treatment for symptomatic relief of hirsutism, acne and menstrual disturbances in women with polycystic ovary syndrome (PCOS).

Summary answer: Regarding the improvement of menstrual disturbances in women with PCOS, there is no evidence of benefit of LOD over medical or surgical treatment; 4–5 punctures per ovary is more effective than 2 or less. There is insufficient evidence that LOD improves androgenic profiles, BMI or quality of life.

What is known already: PCOS is a common female endocrine condition affecting 1 in 10 women worldwide. Many women with sub-fertility and PCOS also suffer from non-fertility related symptoms such as hirsutism, acne, metabolic derangement and menstrual irregularities. LOD is known to improve fertility in women with PCOS but its impact on the menstrual disturbances, androgenic and metabolic symptoms is yet to be determined.

Study design, size, duration: RCTs on surgery for PCOS were sought using standard search strategy via electronic databases, trials registers and websites. Data was extracted, assessed, synthesised and analysed by two authors (Rev Man 5). The outcome measures were improvement in menstrual and androgenic disturbances, adverse effects, metabolic effects and quality of life.

Participants/materials, setting, methods: 19 RCTs were identified out of 1041 papers extracted. A total of 1811 women were included; 10/19 studies compared LOD vs medical treatment, 6/19 compared LOD vs surgical treatment and 3/19 were head-to-head comparisons between different dosages of diathermy energy or number of punctures per ovary.

Main results and the role of chance: There is no evidence of benefit of LOD over metformin in menstrual regulation of women with PCOS (OR 1.00 95% CI 0.71–1.43, $I^2 = 67\%$, $n = 566$, 4 studies). 4–5 punctures per ovary is more beneficial in regulating the menstrual cycle compared to 2 or fewer (OR 13.77, 95% CI 3.58–52.92, $I^2 = 0$, $n = 70$, 2 studies).There is no evidence that alternative surgical techniques such as unilateral LOD, dosing according to ovarian volume, ultrasound guided LOD, or the use of different energy modalities is superior to traditional LOD. Single studies suggest benefit of ultrasound guided transvaginal LOD and thermally-adjusted dosage LOD on lowering testosterone levels when compared to LOD alone. Metformin was associated with more side effects compared to LOD (OR 20.61, 95% CI 2.67–158.84, $I^2 = 0$, $n = 338$, 2 studies).

Limitations, reason for caution: The results of this review may be influenced by small sample sizes and increased clinical heterogeneity amongst the studies included.

Wider implications of the findings: Whilst there is no evidence that LOD is more beneficial over existing medical and surgical treatments for the improvement of PCOS related symptoms, it should still be considered as a complimentary option for the regulation of the menstrual cycle in women with PCOS. Studies investigating the impact of LOD on symptom relief of PCOS should include economic costings and patient reported outcome measures. The exploration of the biological mechanisms behind LOD is long overdue.

P-692 Association of serum levels of typical organic pollutants with the risk of polycystic ovary syndrome (PCOS)

Y. Zhao[1], Q. Yang[2], X. Qiu[2], J. Qiao[1]
[1]*Peking University Third Hospital, Medical Center for Human Reproduction, Beijing, China*
[2]*Peking University, College of Environmental Sciences and Engineering, Beijing, China*

Study question: What is the relationship between typical organic pollutants exposure and the development of polycystic ovary syndrome (PCOS)?

Summary answer: There is a significant association between the serum levels of pollutants including polychlorinated biphenyls (PCBs), organochlorine pesticides, polycyclic aromatic hydrocarbons (PAHs) and the risk of PCOS in females.

What is known already: Polycystic ovary syndrome (PCOS) is arguably the most common endocrinopathy in females of reproductive age. The etiology of PCOS is thought to be multifactorial.

Study design, size, duration: This was a preliminary case-control study undertaken at the Division of Reproductive Center, Peking University Third Hospital. A total of 50 subjects affected by PCOS and 30 normal controls were recruited between August and October 2012.

Participants/materials, setting, methods: PCOS were diagnosed according to the 2003 Rotterdam criteria. The controls were non-pregnant females unable to conceive due to male azoospermia. Serum levels of a wide range of organic pollutants were analyzed using gas chromatographic mass spectrometry, including PCBs, organochlorine pesticides, PAHs, and more than 20 phenolic pollutants.

Main results and the role of chance: Serum levels of PCBs, pesticides, and PAHs were significantly higher in the PCOS group than the control group. Concentrations of PCBs, *p,p'*-DDE, and PAHs in serum above median levels

were associated with 3.81-fold [95% confidence interval (CI), 1.45–10.0], 4.89-fold (95% CI, 1.81–13.2), and 2.39-fold (95% CI, 0.94–6.05), respectively, increased risks of PCOS. Partial least-squares-discriminant analysis (PLS-DA) confirmed that serum levels of organic pollutants were risk factors of PCOS, especially for *p,p'*-DDE and PCBs.

Limitations, reason for caution: Some other possible covariates (e.g. dietary and income) were missed in this study, although the education and occupation has been considered as an indicator of personal income.

Wider implications of the findings: Our study identified bodily retention of environmental organic pollutants—including PCBs, pesticides (especially *p,p'*-DDE), PAHs—as a risk factor of PCOS.

Study funding/competing interest(s): Funding by national/international organization(s) – This research was supported by the Ministry of Science and Technology of China Grants (973 program; 2014CB943203and 2015CB553401), National Natural Science Foundation of China (21322705, 21190051, 41121004and 81170538), National Key Technology R&D Program in the Twelve Five-Year Plan (2012BAI32B01), and the Collaborative Innovation Center for Regional Environmental Quality.

Study question: What is the most optimal dose of GnRH agonist (GnRHa) used for triggering of final oocyte maturation in oocyte donors who have GnRHa trigger as a standard trigger concept?

Summary answer: The use of either 0.2 mg, 0.3 mg or 0.4 mg of Triptorelin leads to the retrieval of comparable numbers of mature oocytes (MII) and top-quality embryos. Although any of the three doses may be successfully used for trigger in oocyte donors, 0.2 mg sufficiently secures an optimal outcome.

What is known already: GnRH antagonist protocols allow the use of GnRHa to trigger final oocyte maturation. GnRHa displaces the GnRH antagonist from the GnRH receptor in the pituitary, eliciting a surge of LH and FSH, similar to that of the natural mid-cycle surge. Importantly, GnRHa trigger significantly reduces, if not eliminates the risk of OHSS and, thus, GnRHa trigger should be considered the gold standard trigger in oocyte donors. Until now no dose finding study was performed.

Study design, size, duration: A randomized single center study. One-hundred twenty donors (120) were consecutively enrolled and randomized to receive either 0.2 mg, 0.3 mg or 0.4 mg Triptorelin for trigger. Block randomization was performed on cycle day 2, using a computer generated list. The study was performed between August and November 2014.

Participants/materials, setting, methods: A total of 120 oocyte donors, aged 18–35 years, having a BMI < 28kg/m^2, AMH > 1.25ng/ml and AFC ≥ 6 were included. Primary endpoint was the number of MII oocytes. Secondary endpoints were fertilization and cleavage rates, number of embryos and top-quality embryos, steroid levels and ovarian volume.

Main results and the role of chance: No significant difference was found between the 0.2mg, 0.3mg, and 0.4mg trigger groups regarding number of MII oocytes (17.0 ± 8.9, 17.5 ± 7.8, and 14 ± 7.5, respectively). Moreover, no difference was seen regarding cleavage rates (13.5 ± 8.1, 13.0 ± 7.2, 11.3 ± 6.6), and number of top-quality embryos (3.7 ± 2.8, 3.8 ± 2.9, 4.0 ± 2.7), all $p > 0.05$. LH, FSH, and estradiol levels peaked at 39.1IU/L, 42.6IU/L, and 10,985pg/ml, respectively 4 hours after trigger, whereas progesterone peaked at 34.7ng/ml, 36 hours after trigger. LH at 36 hours after trigger was significantly higher in the 0.4mg-group than the 0.2mg-group (4.8 ± 3.4 vs 3.1 ± 2.2IU/L). No difference was found regarding ovarian volume measured on the day of trigger, day of OPU, and day of OPU + 6 between the three groups. A full data analysis will be presented at the conference.

Limitations, reason for caution: This is the first GnRHa trigger dose finding study performed until now. Being performed in Asian oocyte donors, however, the present findings do not necessarily apply to all ethnic groups, as ethnic differences in response to GnRHa trigger might exist.

Wider implications of the findings: Although higher doses may be used, a bolus 0.2 mg GnRHa successfully secures oocyte maturation and the development of competent embryos in oocyte donors. With the increasing number of donor cycles performed worldwide, this finding may have significant economical implications. The knowledge obtained from the early luteal steroid profiles related to the GnRHa trigger dose may be used to further improve the luteal phases of IVF patients who receive GnRHa trigger followed by fresh transfer.

Study funding/competing interest(s): Funding by commercial/corporate company(ies) – MSD.

Trial registration number: ClinicalTrials.gov identifier: NCT02208986.

P-694 Dehydroepiandrosterone (DHEA) treatment for poor responders in IVF patients: a prospective randomised controlled trial

V. Viardot-Foucault[1], B. C. Tai[2], X. W. Ng[1], Z. J. Chen[2], M. S. K. Lau[1], S. Nadarajah[1], H. H. Tan[1], J. K. Y. Chan[1]

[1]*KK Women's and Children's Hospital, Reproductive Medicine, Singapore, Republic of Singapore*

[2]*National University Health System, Investigational Medicine Unit, Singapore, Republic of Singapore*

Study question: Can Dehydroepiandrosterone (DHEA) supplementation improve in vitro fertilisation (IVF) outcomes of ovarian reserve biomarkers, number of oocytes retrieved, embryos generated and clinical pregnancy rates (CPR) in patients with diminished ovarian reserve (DOR) or poor ovarian response (POR)?

Summary answer: No difference was found between the two groups in any of the outcomes. DHEA treatment resulted in an increase in follicular phase serum free-testosterone, DHEA-S and estradiol that did not translate into an improvement in the number of oocytes retrieved and embryos formed.

What is known already: Androgen levels have been suggested to impact upon ovarian response in patients with DOR/POR through enhanced steroidogenic activity in the developing follicle. Besides the use of testosterone or androgen-modulating agents, DHEA treatment has been proposed as a way to increase follicular androgen levels, with reports of improved reproductive outcomes in DOR/POR patients noted in small observational trials.

Study design, size, duration: This is a prospective randomised controlled trial in a tertiary referral academic hospital. It recruited 60 patients with DOR or POR undergoing IVF treatment between February 2012 and October 2014.

Participants/materials, setting, methods: Block randomisation was implemented to allocate 60 women with DOR/POR to DHEA treatment (75mg/day for 4 months) or control, followed by controlled ovarian stimulation (COH) with recFSH 300 IU and hpHMG 150 IU per day and initiation of Antagonist on Day 5 of COH. A Day 2/3 embryo transfer was done.

Main results and the role of chance: 15 patients dropped-out. The baseline characteristics between the groups (25 DHEA and 20 controls) were comparable. DHEA treatment over a median duration of 20 weeks (range 13–30) did not improve AMH or AFC values in the treated group, but increased serum free testosterone (RR = 2.25 [95% CI: 1.74–2.91]), DHEA-S (RR = 3.35 [95% CI: 2.42–4.63]) and estradiol (RR = 1.50 [95% CI: 1.24–1.83]) significantly ($p < 0.001$). There were no difference in IVF outcomes between the groups in terms of number of oocytes retrieved (5.2 ± 2.9 vs. 4.5 ± 3.6), number of embryos generated (2.7 ± 2.4 vs. 2.3 ± 1.8) and CPR (4.0% vs 10.0%, $p = 0.557$). Follicular fluid aspirated from lead follicles showed significantly higher levels of DHEA-S (RR = 4.77 [95% CI: 2.83–8.04]) and free testosterone (RR = 3.44 [95% CI: 2.12–5.59]) in the treatment as compared to the control group, but not in estradiol, AMH or IGF-1 levels.

Limitations, reason for caution: The number recruited was small.

Wider implications of the findings: Enhancement of androgen levels in the follicular compartment may be advantageous in the setting of DOR/POR.

Study funding/competing interest(s): Funding by national/international organization(s) – SingHealth Foundation.

Trial registration number: NCT01535872.

P-695 Human immunodeficiency virus infected women and ovarian reserve: a matched case-control study examining serum anti-mullerian hormone

D. De Montlaur[1], P. Santulli[2], M. C. Lafay Pillet[2], V. Gayet[2], V. Blanchet[2], J. Gonnot[2], D. De Ziegler[2], C. Chapron[2]
[1]*CHU de Poitiers Service de Gynécologie, 86000, Poitiers, France*
[2]*Department "Development Reproduction and Cancer" Institut Cochin INSERM U1016 Université Paris Descartes Sorbonne Paris Cité, 75, Paris, France*

Study question: To evaluate Human Immunodeficiency Virus (HIV) directly or indirectly related altered ovarian function, using serum anti-mullerian hormone (AMH) levels, in a large cohort of HIV infected women and disease free controls. In addition, we looked for correlations between AMH and the characteristics of HIV infection and/or treatment.
Summary answer: Serum AMH levels were lower in the HIV infected group than in the seronegative control group. Age, BMI, CD4 count and viral load were the independent contributors affecting serum AMH levels amongst HIV infected women.
What is known already: Several research groups have reported higher infertility rates and impaired ovarian function in HIV-positive as compared to HIV-negative women. Yet, it is unclear whether it is the virus itself, HIV-related immunodeficiency status, or Highly Active Antiretroviral Treatment (HAART) that primarily hamper(s) the ovarian reserve.
Study design, size, duration: We conducted an age-matched cohort study from January 2008 to December 2013 at our designated viral infection infertility center, in Paris at the Cochin tertiary university center. Two hundred and one HIV infected women and 603 HIV age-matched seronegative women, with male infertility, were enrolled in this study
Participants/materials, setting, methods: All women underwent clinical and laboratory evaluations at the screening visit, using a semistructured questionnaire. All data were collected prospectively. Serum AMH levels in HIV-infected women and age-matched controls were compared. To find out the contributing factors to increased serum AMH levels, a backward multiple linear regression was performed
Main results and the role of chance: Serum AMH levels were significantly lower in HIV infected group as compared to seronegative controls (3.0 ± 2.6 vs 3.3 ± 3.0 ng/ml; respectively, $p = 0.020$). Looking for factors associated with altered AMH in HIV infected women, we show for the first time that tubal disease is associated with a further decrease in serum AMH (2.7 ± 3.4 vs 3.6 ± 3.8 ng/ml; respectively, $p = 0.014$). After multivariate linear regression analysis we showed among HIV infected women that an increase in age, BMI and viral load was associated with a decrease in serum AMH levels whereas in striking contrast higher CD4 count are associated with elevated AMH levels.
Limitations, reason for caution: Our study suffers from the limitations of its design. The nature of the issue studied precludes other approaches however. Aware of these limitations, great care was taken to minimize the possibility of biases. In particular, the most important AMH confounder – women's age– was controlled for.
Wider implications of the findings: The link found between decreased ovarian reserve highlighted by lower serum AMH levels in HIV infected women and CD4 count and viral load stresses that HIV-infected women carefully follow their treatment. If need be that treatment ought to be adjusted prior to attempting ART.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s) – Department 'Development, Reproduction and Cancer', Institut Cochin, INSERM U1016, Université Paris Descartes, Sorbonne Paris Cité, Paris, France.
Trial registration number: NA.

P-696 Polyglycine-containing protein (FMRpolyG) may play a role in the pathogenesis of fragile X associated premature ovarian insufficiency (FXPOI) in FMR1 premutation carriers

Y. Cohen[1], O. Dratviman-Storobinsky[1], A. Aizer[1], J. Dor[1], R. Orvieto[1], S. E. Elizur[1]
[1]*Sheba Medical Center, IVF unit, Ramat-Gan, Israel*

Study question: Does repeat associated non-AUG initiated (RAN) translation of a cryptic polyglycine-containing protein, named FMRpolyG occur in granulosa cells of RMR1 premutation carriers (CGGn = 55–200 repeats)?
Summary answer: Inclusion bodies containing FMRpolyG protein accumulate in granulosa cells of RMR1 premutation carriers but not in granulosa cells from women with less than 55 CGG repeats.
What is known already: Amplification of CGG triplet number is associated with increased risk for FXPOI in women and fragile X-associated tremor/ataxia syndrome (FXTAS) in males. Both male and female premutation carriers have elevated *FMR1* transcript levels suggesting a possible common toxic mechanism for FXPOI and FXTAS. Recently, it has been shown that CGG repeats trigger RAN translation of FMRpolyG. FMRpolyG accumulates in ubiquitin-positive inclusions in neuronal cells from brain tissue of FXTAS patients and may lead to protein-mediated neurodegeneration.
Study design, size, duration: Study population consisted of 5 FMR1 premutation carriers referred to our IVF unit for IVF-PGD treatment. The control group consists of 3 patients, with less than 55 CGG repeats, undergoing IVF-ICSI for male factor infertility, matched by age and treated during the same period.
Participants/materials, setting, methods: After oocyte retrieval, mural granulosa cells were collected from follicular fluid and washed, grown on coverslips and then fixed and permeabilized. Then the cells were immunostained with a primary antibody (mouse anti-polyglycin) and incubated with a secondary fluorescent antibody (labeled goat anti-mouse-IgG antibody).
Main results and the role of chance: Granulosa cells from all 5 FMR1 premutation carriers stained positively to large cytoplasmic inclusion bodies containing FMRpolyG. FMRpolyG was not identified in the granulosa cells from control women.
Limitations, reason for caution: these preliminary results should be validated in larger studies.
Wider implications of the findings: As was previously shown in neuronal cells from brain tissue of FXTAS patients, we observed accumulation of inclusion bodies containing FMRpolyG protein in granulosa cells from FMR1 premutation carriers. These findings support previous findings suggesting a possible common protein-mediated toxic mechanism for both FXPOI and FXTAS.
Study funding/competing interest(s): Funding by University(ies) – Tel Aviv university, Sackler school of medicine.

P-697 Hormonal profile of follicular fluid from mature follicles in mild stimulation and controlled ovarian hyperstimulation IVF cycles in POR patients

X. L. Zhang[1], R. Huang[1], B. Wang[1], X. Yang[1], X. Y. Liang[1]
[1]*Sixth affiliated hospital of Sun Yat-sen University, Reproductive medicine center, Guangzhou Guangdong, China*

Study question: Is there any difference in the hormonal milieu from pre-ovulatory follicles between mild stimulation and controlled ovarian hyperstimulation (COH) in-vitro fertilization (IVF) cycles in poor ovarian response (POR) patients?
Summary answer: Comparing with COH, the intra-follicular LH and testosterone (T) levels were significantly higher, while FSH was lower in mild stimulation group. No significant difference was observed in estradiol (E_2), progesterone (P) and anti-mullerian hormone (AMH) levels between groups. No hormone was found to be correlated with IVF laboratory parameters.
What is known already: Previous studies showed that the follicular hormonal profiles from different ovarian stimulation protocols were varied, while the intra-follicular hormone level was found to be associated with oocyte developmental potential and even can predict embryo development. However, no researches compared the follicular hormonal profiles between mild stimulation and conventional COH in POR patients undergoing IVF treatment and investigate the potential influence of these distinct hormonal characteristics on the yield of oocytes and embryos.
Study design, size, duration: From Jan to Nov. 2014, follicular fluid was prospectively collected at the time of oocyte retrieval from 51 POR patients undergoing IVF treatment stimulated with mild stimulation ($n = 23$) or COH (GnRH

agonist long 'stop' protocol, $n = 28$), and intra-follicular FSH, LH, E_2, P, T and AMH levels were assayed.

Participants/materials, setting, methods: Follicular fluid was collected from one follicle larger than 16mm and analyzed to quantify the concentrations of hormones. The differences in intra-follicular hormonal profile between two groups were compared and the correlation between each hormonal level and the number of oocytes retrieved, transferrable embryos or good-quality embryos was evaluated.

Main results and the role of chance: The differences in basic characteristics, such as age, AFC and AMH levels between two groups had no significant meaning. The dose of Gn consumption was significantly higher in COH group (858.7 ± 223.9 vs.2833.0 ± 580.7, $P < 0.001$), while the number of oocyte retrieved (2.93 ± 2.13 vs. 2.87 ± 2.01), transferrable embryo (1.54 ± 1.48 vs. 1.27 ± .098) and good quality embryo (1.14 ± 1.35 vs. 1.09 ± 0.97) were same in two groups (all $P > 0.05$). The follicular hormonal profiles were listed below.

	Mild stimulation	COH	*P*
FSH (IU/L)	6.77 ± 2,57	10.00 ± 4.96	< 0.01
LH (LH/L)	7.05 ± 4.30	1.81 ± 2.64	< 0.01
Estradiol (ng/ml)	52.29 ± 27.35	54.98 ± 18.79	0.97
Progesterone (μg/ml)	16.36 ± 4.93	15.61 ± 5.01	0.59
Testosterone(ng/ml)	36.70 ± 18.79	5.50 ± 2.93	< 0.01
AMH(ng/ml)	1.41 ± 0.79	1.70 ± 1.24	0.23

None of these hormones was found to be correlated with the number of oocyte retrieved, transferrable embryos, or good quality embryos (all $p > 0.05$).

Limitations, reason for caution: This study was part of an ongoing prospective randomized controlled research on the comparison of mild stimulation and COH in POR patients, therefore, the sample size was limited and conclusion need to be interpreted cautiously. In addition, the impact of the difference in hormonal profiles needs further investigation.

Wider implications of the findings: The distinction of intra-follicular hormone profiles indicated that follicular microenvironment was varied between mild stimulation and COH, which might consequently have impact on the growth and maturation of oocyte. Further study on the comparison of gene expression of granulosa cells between mild stimulation and COH should be continued not only in POR patients but also in normal ovarian reserve patients.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Reproductive medicine center of Sun Yat-Sen University.

Trial registration number: ChiCTR-TRC-13003454.

Keywords: follicular fluid, hormonal profile, mild stimulation, controlled ovarian hyperstimulation, poor ovarian response

P-698 Validation of a new prognostic biomarker to enhance overall implantation rates in an egg donation (ED) program through cancellation of bad prognosis stimulations before triggering

S. Rogel[1], N. Szlärb[1], M. Guijarro[2], M. Fernández[2], J. Aizpurua[1]
[1]*IVF Spain, Gynecology, Alicante, Spain*
[2]*IVF Spain, Embryology, Alicante, Spain*

Study question: To determine whether a progesterone-to-estradiol (P4/E2) ratio at triggering could be a predictor in ED to identify stimulations with good or bad prognosis in terms of blastocyst and implantation rate. Which impact could have cancellation of bad prognosis cases in the overall success rates of an egg donation program?

Summary answer: Using a specific algorithm with P4 and E2 levels/follicle at triggering we defined clearly retrospectively two prognosis groups, which also could get validated prospectively. Cancelling those cycles with bad prognosis before triggering we estimated an increase in overall pregnancy from 63.8 to 72.8% and also the implantation rates.

What is known already: Antagonist protocol with agonist triggering is the golden standard in OD programs, as it eliminates OHSS risk. The premature rise of progesterone in the late folicular phase has been reported to be involved in worsening the clinical outcome, but it still remains unclear if it also applies for egg donation recipients cycles, as it may be affecting separately the embryo viability. Linear cut off limits for hormonal levels may be not strong enough biomarkers.

Study design, size, duration: Retrospective study with 1069 ED cycles studied to determine by multivariate curvilinear regression analysis a new predictive biomarker of outcome. Subsequent prospective validation of the algorithm with 141 fresh ED cycles performed between September and December 2013, generating 2 groups: good prognosis and bad prognosis group.

Participants/materials, setting, methods: Prospective validation study of 298 ED as intent to treat resulting in 141 analyzed cycles, resulting good prognosis group-A ($n = 51$) and bad prognosis group-B ($n = 43$). Donors aged 21–31, stimulated with rFSH 225IU/day in antagonist protocol and agonist triggered. Recipients aged 40.6 + /-2.3 balanced through inclusion/exclusion criteria, in synchronized substituted cycle.

Main results and the role of chance: The algorithm was designed by two curvilinear limits based on our retrospective analysis of more than 1000 cycles; defining an upper limit at: $P4/n^o\ ovo = 0.022*e^{0.013*E2/n^o ovo}$; and a lower limit at : $P4/n^o\ ovo = 0.01*e^{0.006*E2/n^o ovo}$). Patients inside both limits were considered as good prognosis, outside as bad prognosis. No significant differences found between both groups regarding fertilization, number of transferred embryos, transfer quality and abortion rates. Significant differences ($p < 0.05$) found regarding number of mature oocytes (17.1 + /-SD), final Estradiol (2388 + /-SD vs 3400 + /-SD pg/ml) and Progesterone (1.53 + /-SD vs 2.50 + /-SD ng/ml) levels. Overall pregnancy rate was 63.8%, being 72.8% in group-A and 51.6% in group-B, showing statistical significance ($p = 0.001$). We also observed statistically significant differences regarding blastocyst (68.3 ± 10.6 vs. 48.1 ± 18.2; $p < 0.01$) and implantation rates (47.5 ± 7.2 vs. 35.2 ± 10.2; $p < 0.01$).

Limitations, reason for caution: The statistical algorithm described applies for our ED programm. To extrapolate this data to other centers probably an adaptation of the algorithm will be needed. Similarly it is still open if a similar algorithm could also help to predict the outcome in regular IVF patients with own eggs.

Wider implications of the findings: The proposed regression algorithm appears helpful as prognostic indicator to decide when to cancel a donor cycle. Attending to our results we could improve the overall success of our program up to 9–12% just by cancelling those donors with a bad prognosis profile at late folicular phase. There are very few tools available capable of increasing success rates like this, may be PGS, but none of them in a comparable efficient and smooth way.

Study funding/competing interest(s): Funding by hospital/clinic(s) – University-Associated Fertility Private Clinic and its Foundation.

Trial registration number: NA.

P-699 A prospective randomised controlled trial (RCT) on the role of AMH tailored stimulation protocols (Agonist or Antagonist),in improving IVF outcome in previous failed cycles

M. Singh[1], R. Singh[1], A. Jindal[1], P. C. Jindal[1]
[1]*Bhopal Test Tube Baby Centre, Gynaecology and Obstetrics, Bhopal, India*

Study question: Does AMH tailored stimulation protocol (Agonist or Antagonist) improve IVF outcome in previous failed cycles?

Summary answer: Yes, AMH tailored stimulation protocol (Agonist or Antagonist) improves IVF outcome in previous failed IVF cycles.

What is known already: The relative stability and consistency of AMH serum levels indicate that AMH could be used as a predictor of ovarian response in controlled ovarian stimulation. In this application, the predictive power of AMH for ovarian response to FSH appears to be similar to that demonstrated by the Antral follicular count. One main advantage of AMH measurement is that it is a cycle-independent test. The exact role of AMH measurement in the IVF setting should be clarified by a cost-benefit analysis. With high probability, the most useful clinical application of AMH measurement may be in the individualization of treatment strategies for COS-protocols (Agonist or Antagonist).

Study design, size, duration: This study involved 286 infertile patients below 42 years with previous failed IVF cycles, who were treated at our hospital between 2010 to 2014. In the study Group of AMH-tailored COH – the different ovarian stimulation treatments stratified according to the basal AMH level. Patients whose AMH levels fell within the acceptable range were divided into three strata (optimal, satisfactory or low ovarian reserve), which determined their stimulation protocol. Essentially, those with higher levels received lower doses of gonadotrophins and vice versa. Women in the satisfactory ovarian fertility group received an long protocol with a GnRH agonist, whereas those in the optimal or low ovarian fertility groups underwent a GnRH antagonist cycle. In the control group of patients: Conventional stimulation protocol was given (untailored AMH).

Participants/materials, setting, methods:
This is a prospective randomised control study (RCT) of 286 women with failed previous IVF-ICSI cycles. The study group included 143 patients who used AMH Tailored COH prior to entry into another repeat IVF cycle. The control group was composed of 143 women who received Conventional (AMH-Untailored) COH treatment,

- The primary outcome was implantation rate, cumulative pregnancy rate and total cost of cycle.
- The secondary outcomes were cancellation rates and OHSS rates.

Main results and the role of chance: Cumulative pregnancy rates were significantly higher in the AMH tailored study group (39% vs. 23%) with lower cost, less cancellation rates and less OHSS.
Limitations, reason for caution: A more contentious point is whether AMH measurements should be used to deny IVF treatment to couples shown by such a test to have a poor prognosis. This is an issue which may arise with other predictors of ovarian response to the IVF treatment. Although a number of markers, including AMH, may be predictive of ovarian response, none are 100% reliable. Moreover, AMH, as with other markers of ovarian reserve, is a poor predictor of who will achieve a pregnancy after IVF. Indeed, it has been widely demonstrated that many poor responders, in particular young ones, achieve pregnancy and live birth. This indicates that AMH measurement, similarly to the other ovarian reserve markers, should not be offered with the aim of withholding IVF, in particular to women undergoing their first IVF cycle.
Wider implications of the findings: Very good correlation exist between basal AMH and the number of retrieved oocytes, indicating that circulating AMH may definitely be considered a better marker for quantitative aspects of ART.A new interesting field of application is the individualization of treatment strategy on the basis of the AMH-based ovarian reserve assessment, in order to possibly reduce the incidence of cycle cancellation and OHSS. Since low and high AMH values are predictive of poor and high-response to gonadotrophins, respectively, it has been proposed that COC protocol and FSH dose may be adjusted according to the basal AMH levels and independently of the Age, FSH and BMI.
Study funding/competing interest(s): Funding by hospital/clinic(s) – BTTB CENTRE.
Trial registration number: BTTBC/2010/14.

P-700 Ovarian reserve and IVF outcome in different ethnic groups

J. Grace[1], S. Ghosh[1], M. Allan[2], S. Dyson[3], J. Kopeika
[1]*Guy's and St Thomas', Assisted Conception Unit, London, United Kingdom*
[2]*Kingston Hospital, O and G, London, United Kingdom*
[3]*Kings College London, Medical school, London, United Kingdom*

Study question: The aim of the study was to establish if ovarian reserve and IVF outcomes may differ in multi-ethnic populations.
Summary answer: This data demonstrated no difference in ovarian reserve or live birth rate between different ethnic groups of women undergoing IVF, after adjustment to independent variables.
What is known already: Ethnic difference has been previously reported for different reproductive outcomes such as age of menarche, menopause or prevalence of reproductive system pathology. However, the difference of reproductive outcomes within assisted conception in multiethnic-ethnic groups remains uncertain.
Study design, size, duration: Observational Cohort study of 1502 women undergoing cycles of ART between January 2012 and December 2013. Among those patients 983 were white, 213 were black, 173 were Asian and remaining 133 were Chinese, Mixed or Others.
Participants/materials, setting, methods: Data for 1502 women were analysed for AMH, AFC, retrieved oocyte number and IVF outcome. Chi-square tests were performed analysing the relationship between categorical variables. Logistic regression analysis was used to assess the association of ethnicity and other demographic variables with parameters of ovarian reserve and live birth rates.
Main results and the role of chance: The mean age of patients was 35.8 ± 4.5. There was no significant difference in AFC or AMH between different ethnic groups after adjusting for age, smoking, BMI and previous pelvic or ovarian surgeries ($P > 0.05$). The number of oocytes retrieved was significantly different between ethnic groups ($p = 0.005$). On logistic regression analysis, black ethnicity was an independent predictor of low ovarian response (OR 1.7; 95% CI 1.8–2.4) in comparison with white when adjusted to FSH dose, age, BMI and previous surgery. The further analysis demonstrated lower live birth in black people in comparison with white (OR 0.35; 95% CI0.35–0.74). However once adjusted for previous uterine and pelvic surgeries, the odd ration became non significant (OR 1.1; 95% CI 0.2–5.1).
Limitations, reason for caution: This is a retrospective cohort study. In spite of relatively large size of initial cohort, when multiple confounders were taken in consideration, the numbers within individual subgroups were relatively small.
Wider implications of the findings: Analysis of this dataset did not confirm difference in ovarian response or live birth between ethnic groups. Ethnicity does not seem to play as great a role in ART outcome as previously reported when surgical history is taken into account. Larger prospective studies would improve our understanding of effects ethnic factors in ART outcome.

P-701 Androgen synthesis in peripheral adipose tissue: the role of insulin and luteinizing hormone in women with polycystic ovarian syndrome

N. Azanati[1], R. Khan[1], S. Amer[1]
[1]*University of Nottingham, Gynaecology and Obstetric, Nottingham, United Kingdom*

Study question: Is there a role for insulin and/or luteinising hormone (LH) in excess androgen production by peripheral adipose tissue in women with PCOS?
Summary answer: Insulin appears to stimulate adipocyte testosterone secretion, but neither insulin nor LH alone or in combination seems to influence the main steroidegenic enzyme activity.
What is known already: Epidemiological studies in premenopausal women found a positive correlation between circulating androgen, insulin resistance and central obesity. In addition, recent research has provided evidence of androgen synthesis in peripheral adipose tissue, which could be a potential source of hyperandrogenism in PCOS. In-vitro studies provided evidence of increased 17-Beta hydroxysteriod dehydrogenase type 5 (17B-HSD5, AKR1C3) expression and increased testosterone secretion from peripheral adipocytes in PCOS women. The role of insulin ± LH in this excess androgen production remains uncertain.
Study design, size, duration: This laboratory based study involved an in-vitro differentiated serum free monolayer cell culture of adipocytes harvested from subcutaneous adipose tissue obtained during gynaecological surgery from five women with and five without PCOS. All participants were of reproductive age (20–45) with a BMI of 20–35 kg/m^2.
Participants/materials, setting, methods: Pre-adipocytes were isolated from adipose tissue samples and differentiated to mature adipocytes, which were cultured in FCS-free medium. Different concentrations of insulin ± LH ± LY294002 were added to the cell culture. The supernatant was collected to measure testosterone using ELIZA. CYP17A1 and AKR1C3 mRNA expression were determined in cultured cells using qRT-PCR.
Main results and the role of chance: CYP17A1, AKR1C3 and testosterone were significantly higher in PCOS versus the control group in treated and untreated cultures. Insulin increased testosterone concentration in the control, but not the PCOS group, Insulin ± LY294002 reduced testosterone concentrations in both groups. Insulin did not alter CYP17A1 or AKR1C3 mRNA expression in PCOS group. In the control group, AKR1C3 significantly ($p < .05$) increased only with high insulin concentrations (100nm). LH ± insulin did not alter the expression of either of the enzymes. LY294002 + insulin resulted in a significant ($p < 0.0001$) rise in CYP17A1 in the PCOS, but not the control group. LY294002 + insulin resulted in a significant ($p = 0.012$) rise in AKR1C3 mRNA expression in the control, but not the PCOS group.
Limitations, reason for caution: The number of biopsies was relatively small in this study and the results will therefore need to be verified by other larger studies.

Wider implications of the findings: The data in this study revealed a markedly higher CYP17A1, AKR1C3 and testosterone in peripheral adipose tissue of PCOS vs. non-PCOS women. This supports the hypothesis that peripheral adipose tissue plays an important role in the pathogenesis of hyperandrogenaemia and PCOS. The study suggests that insulin, but not LH seems to play a role in excess testosterone secretion by adipocytes in PCOS women as evidenced by reduction of testosterone by inhibition of insulin. However, the effect of insulin on steroidogenic enzymes is less clear. Surprisingly, inhibition of insulin seems to enhance the activity of these enzymes. Further research is therefore required to better understand peripheral adipose tissue dynamics in PCOS and the role of insulin and LH.

Study funding/competing interest(s): Funding by national/international organization(s) – Scholarship from Libyan Government. No conflict of interest to declare.

P-702 The connections between serum anti-mullerian hormone and metabolic parameters in polycystic ovary syndrome patients vary depending on body mass index category

A. Albu[1], D. Albu[2], S. Radian[1], S. Florea[3], S. Fica[1]
[1]*UMF Carol Davila, Endocrinology, Bucharest, Romania*
[2]*UMF Carol Davila, Obstetric Gynecology, Bucharest, Romania*
[3]*Elias Hospital, Laboratory, Bucharest, Romania*

Study question: Is there an influence of body mass index (BMI) on the anti-mullerian hormone (AMH) levels and its relationship with the hormonal and metabolic parameters in polycystic ovary syndrome (PCOS)?

Summary answer: In the PCOS patients the relationship between AMH and hormonal and metabolic parameters vary depending on BMI category and excess body weight is associated with lower serum AMH levels, but this association does not seems to be mediated by adipokines (adiponectin and leptin).

What is known already: It was suggested that obesity could influence the circulating level of AMH. Although in PCOS adiposity play a central pathogenic role, the impact of adiposity on AMH levels and on the connections of AMH with the other pathogenic factors is incompletely understood.

Study design, size, duration: We performed a cross sectional study which included 150 PCOS patients consecutively referred for endocrinological evaluation between January 2011 and January 2014.

Participants/materials, setting, methods: The participants were patients consecutively diagnosed with PCOS (Rotterdam criteria) in an out patients clinic of a public University Hospital. All the patients were evaluated by a clinical exam and hormonal tests. AMH was measured with an ELISA kit (Beckmann Coulter). Analyzed variables were submitted to principal component analysis (PCA).

Main results and the role of chance: AMH serum levels were significantly lower in PCOS patients with overweight and obesity in comparison to those with normal weight ($p < 0,05$). PCA showed that in normal weight PCOS AMH aggregated in the first component (correlation coefficient 0,907) with abdominal circumference, waist-hip ratio, total testosterone and SHBG. In overweight/obese group PCA revealed that AMH correlated with the first component (correlation coefficient 0,829) together with HOMA-IR, insulinemia and free androgen index. In both groups of patients leptin and adiponectin aggregated in a distinct principal component, without any correlation with AMH.

Limitations, reason for caution: Our findings are limited to PCOS patients and probably can not be extended to other populations.

Wider implications of the findings: Our study is the first demonstrating a different relation between AMH and metabolic and hormonal parameters depending on BMI category. Our data suggest that the modality to reduce the increased AMH levels found in some of the patients with PCOS may be different according to adiposity status.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Elias Hospital, Bucharest, Romania, Endocrinology Department.

Trial registration number: NA.

P-703 Identification of altered serum metabolites in women with PCOS using gas chromatography-mass spectrometry (GC-MS)

S. Roy Choudhury[1], T. H. More[2], J. Christie[2], B. P. Mishra[1], R. Chattopadhyay[3], I. Lodh[3], C. DattaRay[4], G. Bose[3], H. S. Sarkar[3], B. N. Chakravarty[3], S. Rapole[2], K. Chaudhury[1]
[1]*Indian Institute of Technology Kharagpur, School of Medical Science and Technology, Kharagpur, India*
[2]*National Centre for Cell Science, Proteomics Lab, Pune, India*
[3]*Institute of Reproductive Medicine, Infertility and ART Clinic, Kolkata, India*
[4]*Institute of Post Graduate Medical Education and Research, Department of Obstetrics and Gynecology, Kolkata, India*

Study question: What are the differently expressed serum metabolites in women with PCOS? Using gas chromatography-mass spectrometry (GC-MS) based metabolomics, is it possible to identify metabolites other than those already known to be altered in PCOS? Whether these altered metabolites hold merit to be considered as supportive diagnostic marker(s) for PCOS?

Summary answer: Using GC-MS based metabolomics, several new metabolites were found to be significantly altered in serum of women with PCOS when compared with controls. Amongst these metabolites, phosphoric acid, oleic acid, β-sitosterol, α-D-glucose and propanoic acid exhibited highest predictive values in discriminating the two groups.

What is known already: PCOS is a metabolic disorder and is known for metabolic dysregulation including dyslipidemia. Few studies arguably suggest differences in expression level of different metabolites. Metabolomic studies involve reliable and reproducible quantification of wide variety of intracellular metabolites. GC-MS based metabolomics has been successfully used in several diseases to assess the alterations in metabolomic profile and has proved to be helpful in the identification of promising diagnostic and predictive biomarkers.

Study design, size, duration: 41 women with PCOS (according to the Rotterdam criteria 2006) and age ≥18 years to ≤40 years diagnosed with hyperandrogenism and ovarian dysfunction were recruited from February 2014 to November 2014. Age and parity matched proven fertile women in good health condition reporting for tubal ligation were considered as the control group ($n = 38$).

Participants/materials, setting, methods: Serum samples were collected from PCOS and controls. Briefly, metabolites were extracted and dried metabolic extract was derivatized. Samples were injected into a GC-MS system with temperature gradient for metabolite separation and helium used as carrier gas. Multivariate and univariate statistical analyses were performed for group-discrimination and marker(s) identification, respectively.

Main results and the role of chance: Principal component analysis, partial least squares discriminant analysis (PLS-DA) and orthogonal-PLS-DA showed strong classification between PCOS and controls based on the differently expressed metabolites. The up-regulated metabolites, phosphoric acid, oleic acid, α-D-glucose along with down-regulated β-sitosterol and propanoic acid were found to contribute most towards the differentiation between PCOS and controls ($p < 0.05$). High levels of phosphoric acid and glucose have been linked to an imbalance in insulin pathway, which is implicated in PCOS. The increase in long-chain fatty acid, such as oleic acid and decrease in propanoic acid suggests increased lipolysis, possibly secondary to impaired insulin action at adipose tissue. Increased rate of visceral fat-cell lipolysis is believed to play a pathophysiological role in PCOS and seems to be associated with lower levels of β-sitosterol.

Limitations, reason for caution: This study needs to be extended to a larger sample size for data reproducibility and accurate predictability. Differences in metabolites expression can also be checked using other analytical platforms. The alterations in expression of these metabolites need further validation in a larger cohort of samples using biochemical tests.

Wider implications of the findings: These metabolites hold merit to be considered as supportive diagnostic marker(s) for PCOS along with the presently existing clinical diagnostic method. This may help in a more precise diagnosis of PCOS along with conventional diagnostic methods.

Study funding/competing interest(s): Funding by national/international organization(s) – Department of Biotechnology, Government of India (BT/PR5063/BRB/10/1058/2012).

Trial registration number: NA.

P-704 Effect of testosterone administration on ovarian morphology, determined by transvaginal (3D) ultrasound in female-to-male transsexuals

M. R. Caanen[1], N. E. Schouten[1], E. A. Kuijper[1], A. Overbeek[1], M. H. van den Berg[2], E. van Dulmen-den Broeder[2], F. E. van Leeuwen[3], M. A. van Trotsenbrug[1], C. B. Lambalk[1]
[1]*VU University Medical Center, Obstetrics and Gynaecology, Amsterdam, The Netherlands*
[2]*VU University Medical Center, Pediatric Oncology-Hematology, Amsterdam, The Netherlands*
[3]*Netherlands Cancer Institute, Epidemiology, Amsterdam, The Netherlands*

Study question: Does exogenous (long-term) testosterone administration result in polycystic ovarian morphology, determined by transvaginal (3D) ultrasound?
Summary answer: Long-term testosterone administration in female-to-male transsexuals does not result in polycystic ovarian morphology determined by transvaginal (3D) ultrasound.
What is known already: The role of androgens in the pathophysiology of polycystic ovary syndrome (PCOS) is still unclear. Small scale uncontrolled ovarian histomorphologic studies indicated that androgens in female-to-male transsexuals can cause PCO-like changes. Ultrasound morphology is an established criterion for PCOS but data on this after prolonged androgen exposure are lacking. The female-to-male transsexual can serve as a model to help clarifying the role of androgens in the development of ultrasound morphology and pathophysiology of PCOS.
Study design, size, duration: Prospective, observational Dutch cohort study, based in an academic setting, performed from 2014 to 2015, included 57 female-to-male transsexuals and 124 controls. The subjects were healthy, native females treated with testosterone for at least 12 months, as part of their cross-sex hormone treatment, scheduled for sex-reassignment surgery (hysterosalpingo-oophorectomy).
Participants/materials, setting, methods: Just before surgery under anaesthesia a transvaginal ovarian ultrasound (3D 3 to 9 MHz probe; Envisor HD, Philips Medical Systems) was performed and stored. Afterwards using 3D analysis-software, antral follicles were counted. Random healthy controls recruited through general practitioners office underwent exactly the same ultrasound evaluation.
Main results and the role of chance: 39 subjects and 77 controls were eligible for 3D-analysis of both ovaries and were under 40 years of age. Polycystic ovarian morphology was defined as: antral follicle count of 12 or more follicles (2–10 mm), in at least one ovary. In the female-to-male transsexuals 35, 9% (14/39) had polycystic ovaries, compared to 27, 3% (21/77) in the control group ($p = 0.34$), OR 0.67 (95% CI 0.294–1.52, $p = 0.34$). After correcting for age: OR 1.46 (95% CI 0.453–4.71), $p = 0.53$). There is no statistical significant difference between the prevalence of polycystic ovarian morphology in long-term testosterone treated females, compared to the control group. The preset power of the study was to substantiate a difference of 28% between the androgen pretreated subjects and controls.
Limitations, reason for caution: Testosterone levels in female-to-male transsexuals are supraphysiological, and may not be comparable to the testosterone levels in women with PCOS. Vaginal ultrasound in the female-to-male transsexuals is usually only allowed under general anaesthesia conditions. Therefore longitudinal data from before throughout androgen treatment are unfortunately not available.
Wider implications of the findings: This study shows that long-term testosterone administration in women does not substantially induce polycystic ovarian morphology, based on transvaginal (3D) ultrasound. To our knowledge this is the first study reporting data on transvaginal ultrasound in female-to-male transsexuals evaluating the effects of long-term androgen treatment on ovaries. Sufficiently powered studies comparing histopathological cross-sections of the ovaries removed from these women compared to ovaries from well defined PCOS patients and controls are justified and underway.
Study funding/competing interest(s): Funding by University(ies) – VU University Medical Center, Amsterdam, The Netherlands.
Trial registration number: Dutch Trial Register, NTR 4784.

[8]*Newham University Hospital, Department of Obstetrics and Gynaecology, London, United Kingdom*
[9]*University College London, Institute for Women's Health, London, United Kingdom*

Study question: Are the neonatal hormone levels of newborns of mothers with PCOS different to newborns of healthy controls?
Summary answer: Neonatal testosterone in girls of mothers with PCOS was raised compared to controls.
What is known already: Polycystic ovary syndrome (PCOS) affects approximately 15% of women of reproductive age. Androgen excess is one of the characteristic features of the syndrome, but the potential effects of this on the developing fetus remain poorly understood. Animal studies have demonstrated that androgen exposure in utero induces insulin resistance, hypertension and changes in behavioural and neurological development in the offspring. There are few studies of elevated prenatal androgens in humans however.
Study design, size, duration: *Design:* Cross-sectional study. *Size:* Four groups were recruited: women with PCOS who delivered a female baby ($n = 17$) or a male baby ($n = 10$); control women (without PCOS) who delivered a female baby ($n = 16$) or a male baby ($n = 17$). *Duration:* 2012–2014.
Participants/materials, setting, methods: *Participants:* Women with singleton pregnancies were recruited. *Setting:* All patients were recruited from four London hospital maternity units. *Methods:* Serum (maternal and umbilical arterial and venous) hormone levels were analysed using Tandem Mass Spectrometry and chemiluminescent microparticle immunoassay. Placental enzymes CYP19 and 3β-HSD were assessed using immunohistochemistry.
Main results and the role of chance: *Results:* Median (range) testosterone levels in the umbilical vein of girls of mothers with PCOS was significantly higher than girls of control mothers: 0.54 nmol/l (0.19–2.12) compared to 0.34 (0.10–0.82) ($P < .04$). Median (range) venous DHEA in girls of mothers with PCOS was significantly higher than girls of control mothers: 7.30 nmol/l (3.31–44.08) compared to 5.86 (1.90–8.10), respectively ($P < .03$). Maternal insulin and testosterone in the umbilical vein were significantly correlated in the PCOS group ($r_s = .640$, $n = 14$, $P < .014$, 2-tailed) but not the controls.
Limitations, reason for caution: Small study size.
Wider implications of the findings: Neonatal testosterone in girls of mothers with PCOS was raised. The correlation between maternal insulin and fetal testosterone could be explained by an inhibitory effect of insulin on placental aromatase expression or activity, as has been found in gestational diabetes. This mechanism could be a potential target for reducing the long term morbidity reported in the offspring of mothers with PCOS.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Royal Free Charitable Trust.
Trial registration number: NA.

P-706 Two-step consecutive controlled ovarian stimulation and oocyte retrieval in the follicular and luteral phase increases chance of obtaining embryos in patients with diminished ovarian reserve

H. Asakura[1], Y. Nakahara[1], M. Nagaike[1], K. Nishio[1]
[1]*Aisei Medical Corporation, Ohgimachi Ladies' Clinic, Osaka, Japan*

Study question: Diminished ovarian reserve is the frequent cause for obtaining low number of embryos in ART. We evaluated efficacy of consecutive oocyte retrievals at the follicular and subsequent luteal phases.
Summary answer: Additional oocyte retrieval during luteal phase increases chance of obtaining embryos in patients with diminished ovarian reserve.
What is known already: The recent wave theory of follicular development is the basis of random start controlled ovarian stimulation for cancer patients with urgent need to cryopreserve embryos for future use. Several reports documented the efficacy of oocyte retrieval during the luteal phase in young population.
Study design, size, duration: A prospective clinical trial of two-step ART in 21 cycles during 12 months period.
Participants/materials, setting, methods: 20 female patients with advance age or diminished ovarian reserve participated in the study. The patients underwent consecutive controlled ovarian stimulation with antagonist and oocyte retrieval (OR) in the follicular and the luteal phase. IVF or ICSI fertilized embryos were vitrified at cleavage stage. The protocol was approved by IRB.
Main results and the role of chance: The average age and serum AMH of the patients were 41.2 ± 2.8 (mean ± SD) year-old and 0.9 ± 0.6 ± ng/mL. After 21 follicular phase OR, 18 underwent luteal phase OR. The average number of oocytes by follicular phase and luteal phase OR were 1.1 ± 0.9, 0.5 ± 0.6, respectively. Fertilization and good morphology rate for IVF and ICSI were 14.3%, 100%, with IVF, and 100%, 33.3% with ICSI in the follicular phase; 100%, 50.0% with IVF and 83.3%, 60.0% with ICSI in the luteal phase. 5 (23.8%) of the follicular OR and 6 (33.3%) of the luteal phase OR resulted in embryo vitrification. Total 9 cycles had vitrified embryos: 3 in the follicular but not in the luteal phase, 4 in the luteal but not in the follicular phase, and 2 in both phases. Therefore, the two-step method increased cycles with embryo vitrification from 5 to 9 (80% increment).
Limitations, reason for caution: Small sample size and non-randomized study without control population.
Wider implications of the findings: Two-step consecutive oocyte retrieval may avert repeating new ART cycle and may shorten time to embryo transfer for patients with diminished ovarian reserve. We observed two clinical pregnancies after transferring luteal phase embryos. Implantation efficacy and pregnancy outcomes of this approach are under investigation.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Aisei Medical Corporation Ohgimachi Ladies' Clinic.
Trial registration number: NA.

P-707 Association of LH, AMH, BMP15, GDF9, FSHR, LHR, and AMHR genetic polymorphisms with poor responses in patients undergoing in vitro fertilization

A. J. C. Meireles[1], J. P. Bilibio[2], U. Matte[1], E. De Conto[1], B. M. Silva[2], A. J. C. Cunha-Filho[1]
[1]*Universidade Federal do Rio Grande do Sul, Gynecology and Obstetrics, Porto Alegre, Brazil*
[2]*Clínica Pronatus, Human Reproduction, Belém, Brazil*

Study question: The objective of this study was to evaluate the associations of the polymorphisms in the LH, AMH, BMP15 and GDF9 genes, and FSH, LH and AMH receptors genes, with poor or normal response in patients undergoing stimulation for in vitro fertilization (IVF).
Summary answer: We conclude that the GDF9 398C > G and 447C > T polymorphisms exert important influences on oocyte development.
What is known already: Approximately 10% of women seeking fertility treatment have diminished ovarian reserve (DOR). Gene association studies have identified several single nucleotide polymorphisms (SNPs) involved in the ovarian response.
Study design, size, duration: The setting for this study was a fertility center with Sixty-seven women undergoing IVF treatments using r- FSH and recombinant GnRH antagonist protocol. A case-control study was performed with normal and poor responders undergoing IVF.
Participants/materials, setting, methods: We extracted DNA from the peripheral blood and assessed polymorphisms in the LH, AMH, BMP15, GDF9, FSHR, LHR and AMHR genes using polymerase chain reaction (PCR). The presence of these polymorphisms were evaluated in poor and normal responder patients undergoing IVF.
Main results and the role of chance: In the present study, we found that the 398C > G polymorphism in the GDF9 gene was present in 68% of poor responders versus 23% of normal responders to ovarian stimulation for IVF (OR: 4.01, 95% CI: 1.52–10.60). In addition, the homozygous mutant genotype for the 447C > T polymorphism of the GDF9 gene was found in 50% and 19%, respectively, of poor and normal responder patients (OR: 2.88, 95% CI: 1.19–6.04), which provides evidence for the strong association between poor ovarian response and ovulation induction. Only the GDF9 398C > G polymorphism was associated with a poor response to treatment, after controlling for any bias related to the other polymorphisms.
Limitations, reason for caution: The limitation of our results is that we don't realized functional studies to validate the precise genetic mechanism involved in oocyte development.
Wider implications of the findings: These findings represent the basis for future functional studies aimed at elucidating the precise genetic mechanism involved in oocyte development and developing potential treatments to improve the number of oocytes retrieved in patients with GDF9 polymorphisms.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s) – We are grateful for the financial support provided by Fundo de Incentivo à Pesquisa (FIPE), Hospital de Clínicas de Porto Alegre, Brazil and Clínica Pronatus – Medicina Reprodutiva, Belém Brazil.
Trial registration number: The study was approved by the Ethics Committee of the Hospital de Clínicas de Porto Alegre *n*: 14/0070.

P-708 Comparison of FMR1 mutations distribution between Indian and other Asian patients

E. Bisplinghoff[1], V. A. Kushnir[2], D. H. Barad[2], A. Weghofer[1], N. Gleicher[2]
[1]*Medical University Vienna, Obstetrics and Gynecology, Vienna, Austria*
[2]*Center for Human Reproduction, N/A, New York, U.S.A.*

Study question: Is the reason why Indian women age their ovaries faster than women of Spanish background (Iglesias et al, Fertil Steril 2014) based on a high prevalence of *low FMR1* alleles ($CGG_{n<26}$) in Indian populations?
Summary answer: Neither age nor distribution of *FMR1* mutations differed between Indian and other Asian patients in a U.S. infertile patient population. Functional ovarian reserve (FOR), assessed by anti-Müllerian hormone (AMH), was however significantly lower than in other Asian women.
What is known already: Women with so-called *low FMR1* alleles ($CGG_{n<26}$) have been reported to prematurely lose FOR. Since women of African descent demonstrate significantly higher distribution prevalence of *low FMR1* alleles than Asian-Chinese and Caucasian women, this finding has been attributed as a possible cause of lower reported in vitro fertilization (IVF) pregnancy chances in African women.
Study design, size, duration: We performed a cross-sectional cohort study of routine infertility patients of Asian descent seen over a 4-year period, comparing Indian women to other Asian women (mostly Han Chinese) for whom *FMR1* results and AMH values were available in our center's anonymized electronic research data base.
Participants/materials, setting, methods: We investigated 99 Indian and 225 patients of other Asian descent for distribution prevalence of *FMR1* mutations at an academically affiliated private IVF center in New York City, U.S., with international patient pool. In addition, their FOR was compared (based on AMH) to women of other Asian backgrounds.
Main results and the role of chance: Mean ages were 35 and 36 years for Indian and other Asian women (N.S.), and they also did not differ in *FMR1* mutation distributions: Among Indian patients 76 (70%) had a normal (*norm*) *FMR1* (both alleles in range $CGG_{n=26–34}$), 29 (17%) were heterozygous (*het*)-normal (*norm*)/high (1 allele in normal range and 1 in abnormal high, $CGG_{n>34}$, range, and 11 (6%) het-norm/low (1 allele in abnormal low range, $CGG_{n<26}$). Other Asian women demonstrated 148 (65%) cases with *norm*, 56 (25%) with *het-norm/high* and 13 (5%) with *het-norm/low FMR1*. Mean AMH values of Indian women were significantly lower than in other Asian women (1.47 vs. 0.83 ng/mL; $P < 0.05$), confirming the report by Iglesias et al.
Limitations, reason for caution: Since only infertility patients were studied, here reported results can not automatically be extrapolated to general populations.
Wider implications of the findings: Though confirming the findings of Iglesias et al, this study failed to establish a cause for the premature decline in FOR in Indian women. By demonstrating a similar *FMR1* mutation distribution with, as previously reported relatively few *het-low* alleles in Indian and

other Asian patients, this study actually eliminates *low FMR1* alleles as a potential cause.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Center for Human Reproduction; Foundation for Reproductive Medicine.
Trial registration number: NA.
Keyword: fragile X mental retardation 1 (FMR1) gene, ovarian reserve, anti-Müllerian hormone (AMH)

P-709 The relationship between serum anti-mullerian hormone and body mass index in a Caucasian population of infertile women is age-dependent

D. Albu[1], R. Tulin[1], A. Albu[2]
[1]*Medlife Hospital UMF Carol Davila, Maternalfetal and Reproductive Medicine, Bucharest, Romania*
[2]*UMF Carol Davila Elias Hospital, Endocrinology, Bucharest, Romania*

Study question: Which is the relationship between serum antimullerian hormone (AMH) levels and body mass index (BMI) in a population of infertile Caucasian women?
Summary answer: The relationship between AMH and BMI in infertile patients mainly of normal weight is influenced by age, the two parameters being positively correlated in women aged 25–40 years, but not in the age categories <25 years and >40 years.
What is known already: Although few studies demonstrated a negative influence of obesity on antimullerian hormone circulating levels, not all reports confirmed these data. These discordant results could be due to a different relationship between BMI and AMH depending on the age or the ovarian reserve and probably the severity of excess body weight of the population analyzed.
Study design, size, duration: We performed a cross sectional study which included 686 caucasian female patients evaluated for infertility over two years.
Participants/materials, setting, methods: The participants were selected from the female patients evaluated in a private outpatient clinic for all causes of infertility between January 2012 and January 2014. Inclusion criteria: age 20–45 years and BMI 18,5–40 kg/m^2. Exclusion criteria: PCOS. Age, weight, height, AMH were measured in all patients.
Main results and the role of chance: Mean age of the study group was 34,97 ± 4,2 years (range 23–45 years), mean BMI 22 ± 3,8 kg/m2 (83,8% normal weight, 12,5% overweight, 3,6% obese) and mean AMH 2,51 ± 2,24 ng/ml (range 0,1–10 ng/ml). In a multivariate liniar regression model with AMH as dependent variable, both age and BMI were independent predictors of AMH serum level (beta = -0,329, $p < 0,0001$ for age, beta = 0,126, $p = 0,001$ for BMI). Dividing the patients in groups according to age we found that: after adjustment for age, AMH and BMI were not correlated in patients <25 years and >40 years, were strongly and positively correlated in patients between 30 and 35 years ($p = 0,002$), and marginally correlated in age groups 25–30 years ($p = 0,023$) and 35–40 years ($p = 0,042$).
Limitations, reason for caution: Due to the fact that our study population was represented mainly by normal weight women we can not extent our findings to other BMI-categories.
Wider implications of the findings: Our study is the first demonstrating a positive association between AMH and BMI in mainly normal weight (83,8% of the patients) infertile female patients 25–40 years old. Our findings are contrasting with previously published data probably due to the small number of obese patients in our group since the negative impact of adiposity on AMH values was reported in obese patients.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Medlife.
Trial registration number: NA.
Keywords: AMH, BMI, ovarian reserve

P-710 Relative progesterone level increases between initiation and end of ovarian stimulation are detrimental for live birth even among cycles with apparently normal late-follicular progesterone levels

S. Santos-Ribeiro[1], N. P. Polyzos[1], M. Camus[1], M. De Vos[1], A. van de Vijver[1], H. Tournaye[1], C. Blockeel[1]
[1]*Universitair Ziekenhuis Brussel, Centre for Reproductive Medicine, Brussels, Belgium*

Study question: Can a relative increase in serum progesterone (P) levels between the initiation of ovarian stimulation (early-P) and the day of ovulation triggering (late-P) impair live birth rates (LBR) following in vitro fertilization (IVF)?
Summary answer: Although it is well established that elevated P levels on the day of ovulation triggering significantly impair LBR, we demonstrate, for the first time, that a relative increase in P > 0.25ng/ml between early-P and late-P is detrimental for LBR, even in cycles with apparently normal late-follicular P levels.
What is known already: Accumulating evidence has shown an association between late-P elevation and a reduction in IVF pregnancy rates. However, it has been challenging until now to define a clinically relevant late-P cut-off, since the previous studies present conflicting results and frequently use different limits. Furthermore, late-P elevations are rather common in both younger and high-responding women and their effect on LBR in these populations are a subject of much debate.
Study design, size, duration: This was a retrospective, single-centre cohort analysis including all patients who underwent ovarian stimulation between February-2009 and March-2013 for IVF followed by a fresh embryo transfer in our centre. All cycles ($n = 2703$) were down-regulated using a GnRH antagonist. Ovulation was triggered with hCG 36 hours before oocyte retrieval.
Participants/materials, setting, methods: We calculated the follicular-phase P variation by subtracting late-P (day of hCG administration) and early-P (stimulation day-1). Using multivariable logistic regression, we compared the LBR of cycles with no significant P variation (absolute variation <0.25 ng/mL) with those in the following follicular-phase P increase intervals: 0.25–0.50, 0.50–0.75, 0.75–1.00 and >1.00 ng/mL.
Main results and the role of chance: Overall, 682 cycles (25.2%) resulted in a live birth. The mean ± SD follicular-phase P variation between stimulation day-1 and the day of hCG administration was 0.28 ± 0.38 ng/mL (early-P 0.63 ± 0.27ng/mL, late-P 0.91 ± 0.41 ng/mL). The effect of the relative increase in P on LBR was evaluated by multivariable logistic regression. After adjusting for female age, basal FSH, the number of oocytes retrieved and day and number of embryos transferred, LBR were significantly higher in cycles with no relative increase in P (28.3%) when compared to cycles with a relative increase in P of 0.25–0.50 ng/ml (23.9%, $p = 0.033$), 0.50–0.75ng/ml (21.8%, $p = 0.018$), 0.75–1.00 ng/ml (18.3%, $p = 0.01$) and >1.00 ng/mL (15.5%, $p = 0.001$). Interestingly, our subgroup analysis including only cycles with late-P < 1.5 ng/mL, demonstrated that cycles with no relative increase in P had significantly higher LBR when compared with all other groups.
Limitations, reason for caution: Our results pertain to cycles in which early-P was ≤1.5 ng/mL, given that it is our centre's policy to not initiate ovarian stimulation otherwise. Therefore, we were unable to evaluate whether a relative increase in P might have had a detrimental effect on LBR among patients with higher early-P levels.
Wider implications of the findings: A relative increase in P between the beginning and end of stimulation significantly impairs LBR, even in cycles with apparently normal P levels on the day of ovulation triggering. The hypothesis that patients have different basal exposures to P and that increased follicular-phase P might impair endometrial receptivity requires further validation. Evaluating the difference between late-P and early-P adds insight into the current limitations of isolated assessments of early-P or late-P in predicting IVF outcome.

P-711 The use of human growth hormone (hGH) in poor prognosis patients increase euploidy rate and improve embryo quality. a patient-controlled trial

J. Aizpurúa Saenz[1], N. Szlarb[1], B. Ramos[1], M. A. Fernandez[1], S. Rogel[1]
[1]*IVF Spain, Reproductive Medicine Unit, Alicante, Spain*

Study question: Use of hGH as co-adjuvant medication prior to and during ovarian stimulation in bad prognosis patients to improve oocyte quality. Impact of hGH treatment in different clinical parameters: fertilization, blastocyst and good quality blastocyst rate as well as embryo euploidy, pregnancy and implantation rate.
Summary answer: The addition of hGH during ovarian stimulation in bad prognosis patients improves the amount of top quality euploid blastocysts and

therefore pregnancy and implantation rate. However, the number of retrieved oocytes, fertilization and blastocyst rate were not different under the influence of hGH during stimulation regimen for in vitro fertilization.

What is known already: We need to increase the chances of poor prognosis patients to deliver a healthy baby. It has been shown that the supplementation of hGH as adjuvant in ovarian stimulation may increase pregnancy and delivery rates, by increasing oocyte quality and subsequent embryo quality. Until now few studies have been published to confirm these findings but none of them has included any genetic data correlated with clinical results, even less with the latest PGS technologies.

Study design, size, duration: Unicentric, comparative, randomized and patient-controlled trial (2013–2014). Twenty-eight poor prognosis patients underwent at least 2 consecutive IVF cycles (same gonadotrophin regimen intra-patient), planed as embryobanking within 6 months, and using hGH supplementation (1 IU/day) in 1 of them selected randomly. Fifty-six cycles were performed with deferred embryo-transfer.

Participants/materials, setting, methods: Poor prognosis patients (age >40 and at least 3 previous IVF attempts) undergoing ovarian stimulation with antagonist protocol and agonist-trigger. hGH (Saizen®) was administered 5 weeks before egg retrieval. Estradiol and Progesterone measured the trigger-day in all cycles. Preimplantational genetic screening (PGS) was performed using trophectoderm biopsy and aCGH.

Main results and the role of chance: Bad prognosis patients were defined according to the criteria of Yovich and colleagues (2010). Serum estradiol was significantly higher in hGH cycles (1780 ± 232 vs. 896 ± 134; $p = 0.01$) although no significant increase in oocytes retrieved was achieved (10.5 ± 4.5 vs 9.4 ± 4.2; $p = 0.5$). Overall blastocyst rate did not differ between groups (31.94 ± 6.3 vs 31.34 ± 8.06; $p = 0.5$), but top quality blastocyst rate was significantly higher in hGH cycles (17.64 ± 4.00 vs 5.92 ± 2.56; $p = 0.04$). Most interestingly, euploid blastocyst rate was significantly higher in hGH cycles (30.75 ± 7.97 vs. 8.75 ± 2.04; $p = 0.02$). Pregnancy rate was significantly higher in the hGH-derived blastocyst (44.5 ± 3.56 vs 23.3 ± 2.23; $p = 0.04$), may be cause to the increased blastocysts quality. Implantation rate was also increased even though with no statistical significant differences observed (36.6 ± 4.56 vs 18.8 ± 3.7; $p = 0.06$).

Limitations, reason for caution: The number of euploid blastocysts obtained is relatively low due to the bad prognosis in this patients group, limiting the application of robust statistics in terms of clinical parameters. Therefore, it would be desirable to increase patient population in order to confirm our results.

Wider implications of the findings: hGH as co-adjuvant in IVF cycles could be an option in patients with bad prognosis. It may improve cytoplasmic maturation by increasing oocyte and blastocyst quality compared to their previous IVF cycles. Moreover, better meiotic competence is suspected as we found an improvement in the euploidy rate. To confirm our findings, we plan a prospective multicenter study across Europe. We would like to present our study design and an invitation to collaborating centers at ESHRE.

Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s) – IVF Spain private fertility clinic, IVF Spain Foundation.

P-712 Bilateral oophorectomy has detrimental effect on intima-media thickness (IMT) in carotid and coronary arteries and augments estrogen receptors in neuronal cells: randomized-controlled-trial in a rat model

S. Ozdemirci[1], T. Kasapoglu[2], B. Dilbaz[3], B. Duran[4], F. Salgur[5], O. Koc[6], H. Unverdi[7], S. Hucumenoglu[7]

[5]*Baskent University, Department of Family Medicine, Ankara, Turkey*

[6]*Memorial Ankara Hospital, Department of Obstetrics and Gynecology, Ankara, Turkey*

[7]*Ankara Teaching and Research Hospital, Department of Pathology, Ankara, Turkey*

Study question: The effects of menopause on the cerebral vasculature and brain function remain controversial. Is there any effect of prior bilateral oophorectomy in terms of estrogen hormone deficiency on intima-media-thickness of carotid and coronary arteries and estrogen receptor status of neuronal cells of oophorectomised to those of non-oophorectomised rats?

Summary answer: Prior bilateral oophorectomy triggers intima-media thicknening in carotid and coronary arteries and augments estrogen receptors in neuronal cells in an experimental rat model. This result may account for the magnified risk of cardiovascular and cerebrovascular diseases in postmenopausal women and lightens the enigmaticpathophysiologic pathway which also introduces new therapeutical insights.

What is known already: The previous studies stated that increased carotid IMT may be observed in postmenopausal women via evaluating by B-mode ultrasound exams, however we assessed it by microscopic immune-histological evaluation in real tissue for the first time in hitherto literature. Effect of estrogen deficiency may cause to increase the IMT, being responsible for atherosclerosis. Alteration of microscopic structures of these arteries may have detrimental effect on the brain with increased estrogen receptors via removing bilateral rats' ovaries.

Study design, size, duration: In this experimental randomised-controlled-trial design study, 10 of 25 *Winter* female rats were randomised to undergo menopause by removing their ovaries surgically. Another ten rats were the control group and hadn't undergone any surgical procedure. The other five rats were sham group. After six-months period, all the rats were euthanised.

Participants/materials, setting, methods: Left descending coronary and carotid arteries including brain of the rats were removed after euthanasia and were investigated under microscopic examination by a pathologist who determined the thickest diameter of these specimens. Neuronal cells were assessed with immune-histological examination to determine the estrogen receptors in the nucleus membrane.

Main results and the role of chance: Mean ± standard deviation of carotid intima-media thicknesses for case, control and sham groups were 268,69 ± 53,67 μm, 195,61 ± 47,60 μm and 193,86 ± 75,01 μm, respectively. Intima-media thickness of coronary arteries were 182,40 ± 30,22 μm for the case, 136,00 ± 35,82 μm for the control and 165,24 ± 40,68 μm for the sham groups, respectively. Both intima-media thickness of carotid and coronary arteries in the case group were significantly higher than those of the other two groups and the difference was statistically significant ($p = 0{,}014$; $p = 0{,}022$, respectively). However, according to the microscopic examination of rats' neuron cells by pathologist, estrogen receptors was more promptly established in the case group by immune-histological investigation subjectively. ANOVA with post-hoc Tukey's tests was performed. *p*-value of less than 0.05 was considered to show a statistically significant result.

Limitations, reason for caution: Our study's advantage is that IMT was evaluated via microscopic measurement in pathologic specimen. However; main limitation is investigating only in one species and not using hormone replacement therapy (HRT) after surgical menopause to compare exact changes and understand the alteration's transiency. This was impossible due to the study's nature.

Wider implications of the findings: Our conclusions are consistent with literature and add new insights in cardiovascular diseases in postmenoposal women. Lack of estrogen may facilitate the process of increased IMT of both coronary and carotid arteries, accounting for the magnified risk of cardiovascular and cerebrovascular diseases. We suggest that the effect of estrogen should further be investigated on IMT of both carotid and coronary arteries by comparing oophorectomized groups with or without HRT in terms of new therapeutic potential.

Study funding/competing interest(s): Funding by hospital/clinic(s) – None.

Study question: In the present study we evaluated whether the systemic chronic inflammatory condition and immune cell activation associated with obesity, dismetabolism, and insulin resistance may affect the endometrial innate immune environment in patients with PCOS (Polycystic Ovary Syndrome)
Summary answer: The endometrium of PCOS patients shows an inflammatory pattern characterized by an increased expression of pro-inflammatory cytokines and of activating NK cell cytotoxic receptor expression. the same alterations, is well Known to be the pheripheral blood of obese women with PCOS, similar to the systemic inflammatory chronic state and the related peripheral immunity imbalance. The endometrial inflammatory state could have detrimental effect on embryo implantation in such patients.
What is known already: Obesity-related inflammation is often considered a disorder of innate immunity. Abdominal obesity is largely prevalent in PCOS women that also have a significantly increased markers of systemic inflammation disease. Also endometrial tissue is characterized by an innate and adaptive immune cells Natural killer cells are a critical component of the innate immunity
Study design, size, duration: A prospective study was performed on 19 PCOS patients and 11 healthy fertile controls with normal menstrual cycles, from January to October 2014. The diagnosis of PCOS was made according to Rotterdam criteria. Controls were selected among women who have undergone surgery for benign disease.
Participants/materials, setting, methods: Endometrial samples were obtained in the proliferative phase from 9 PCOS patients and from 5 controls. Late secretory samples were obtained from 10 PCOS patients a and 6 controls. A fraction of each endometrial sample was prepared for histological examination; a part was stored for PCR.
Main results and the role of chance: A significant increase in the expression of pro-inflammatory cytokine TNF-α (p = 0,04) and of the activating NK cell receptors expression NKG2A, NKG2D, NKp46 was observed in PCOS compared to controls (p = 0,03; p = 0,07;p = 0,02, respectively). A significant increase in the expression of IL-1beta, IL-6, (p = 0,04; p = 0,06, respectively) and of NKG2A, NKG2D and NKp46 (p = 0,006; p = 0,03 and p = 0,01, respectively) was observed in the secretory phase compared with proliferative phase in PCOS group. Approximately 70% of PCOS patients are obese with a central body fat distribution that is associated with insulin resistance, a state of chronic inflammation and a disorder of innate immunity in peripheral blood. Results demonstrated that also endometrial tissue, in PCOS is characterised by an inflammatory status associated with endometrial innate immunity imbalance.
Limitations, reason for caution: Possible biases related to the limited number of cases analysed.
Wider implications of the findings: Our data show for the first time the existence of a chronic inflammatory endometrial disease in PCOS patients, which involves the NK cells and the activating NK cell receptors with interplay between the immune system and abnormal metabolic conditions.

[4]*University of Lübeck, Medizinische Biometrie und Statistik, Lübeck, Germany*
[5]*Klinikk Hausken, Obstetrics and Gynecology, Haugesund, Norway*
[6]*University of Würzburg, Obstetrics and Gynecology, Würzburg, Germany*
[7]*Fertility Center Kiel, Obstetrics and Gynecology, Kiel, Germany*

Study question: Is the type of response associated with the FSH receptor and LH genes polymorphisms as suggested previous studies?
Summary answer: Type of response is not associated with FSH receptor (FSH-R) Asn680Ser or LH gene polymorphism V-betaLH, but is associated with FSH promotor –29A/G gene polymorphism alone or combined with Asn680 Ser polymorphism.
What is known already: Patients with allele Ser (Asn680 Ser) and with allele A (–29A/G) and V-betaLH (Trp8Arg and Ile15Thr) required higher dose of FSH.
Study design, size, duration: The study was prospective including 212 women of reproductive age for controlled ovarian hyperstimulation (COH) between July and December 2012.
Participants/materials, setting, methods: Eumenorhoic women, normal BMI, FSH, LH, progesterone, E2, AMH, AFC measurement, antagonist protocol 6.4 days, stimulation 10.5 days. In Elonva protocol (150 mg) was 19.8% with low, 66.5% intermediate and 13.7% high response, genotyping by TaqMan Assay and RFLP for LH polymorphisms, statistics by χ^2, Kruskall-Wallis and Man-Whitney tests.
Main results and the role of chance: No association in response and AMH/AFC levels was found for Asn/680 Ser and LH Trp8Arg and Ile15Thr. The GG genotype of –29A/G polymorphism was significantly higher – 64.58% in high responders, than in intermediate and high ones – 48.69% and 32.35% (p = 0.0149), difference between low and high responders was higher (p = 0.0068). The genotype A/G was significantly more frequent in high responders -61.76% versus intermediate and low ones – 41.88% and 33.33% (p = 0.0331), difference between low and high responders was significantly higher (p = 0.0138). The integrated genotypes G/G and Ser/Ser were increased in low responders –20.83%, comparing to the intermediate and high ones 8.38% and 8.82% (p = 0.0407), difference between lower and intermediate types is significantly higher (p = 0.0195).
Limitations, reason for caution: Further population studies within COH are necessary to confirm these findings by increasing the number of low and high responders for association studies of genetic and epigenetic impact on the final type of individual response.
Wider implications of the findings: It is important to study also oocytes' biological quality for fertilization success, because FSH influences the further differentiation of oocytes since small antral follicles contrary to AMH. Our study indicates that alleles –29A/G and Ser influence risk of reduced fertility with increased resistance to COH, alleles –29A/G have defining phonotypical effect.
Study funding/competing interest(s): Funding by national/international organization(s) – FNM grant 64203, OPPK and CZ.2.16/3.1.00/24022, IGA NT 13770. There are no competing interests involved.

P-715 Ovarian reserve and response risk categorisation using the new automated AMH assay produced by Roche®

P. Mitchell[1], C. Fairbairn[1], M. Gaudoin[1], D. Lucas[1], R. Fleming[1]
[1]*Glasgow Centre for Reproductive Medicine, Hormone Laboratory, Glasgow, United Kingdom*

Study question: The new automated assay for AMH yields different absolute values from those previously available. Critical values determining risks of sub-optimal and excessive responses to ovarian stimulation have been determined for previously available tests, but they require determination for the new assays.
Summary answer: The regression curve comparison of the new assay compared with the previous assay (Gen II, by Beckman Coulter®) shows highly consistent comparative association (r^2 = 0.95). The antral follicle count profiles confirm the differences between the categories and provide supporting evidence of the validity of these revised concentration cut-off values.
What is known already: AMH is a highly effective biomarker of functional ovarian reserve, but different commercial assays yield different absolute values,

due to different standardisation amongst other factors. Correspondingly, care must be taken when interpreting values obtained from different sources and it is important that guideline cut-off values for the various end-points are ascertained.
Study design, size, duration: Prospective serum samples over a 6-week period from 205 women undergoing ovarian assessment by ultrasound evaluation of antral follicle count were measured using two AMH methods simultaneously – Gen II and the new Roche [E411] automated assay. AMH results between the two assays were compared and regression statistics ascertained.
Participants/materials, setting, methods: The women presented prior to undergoing ovarian stimulation for IVF in a single centre. The previously published cut-off values (Nelson et al, 2007) for response risk prediction in the Gen II assay were transformed for the Roche assay, and the AFC profiles for patients in these categories were determined.
Main results and the role of chance: A strong correlation between the two assays ($r^2 = 0.95$) was found. The response category limits previously described were transformed and the AFC values for these categories showed the expected and significantly different ranges of values (ANOVA: $p < 0.0001$). The 'Negligible response' group upper limit transformed to 1.1 pmol/L and the mean AFC for this group was 4.5, (25^{th}–75^{th} centiles: 3–6). The 'Reduced response' group upper limit transformed to 8.1 pmol/L and mean AFC was 7.7 (5–11). The 'Safe response' group upper limit transformed to 18.3 pmol/L and mean AFC was 12.9 (9–16), and the 'Excessive response' group (AMH > 18.3 pmol/L) showed mean AFC values of 20.9 (13.5–26).
Limitations, reason for caution: The Roche values were 27% lower than the Gen II assay [Roche (pmol/L) = 0.733 × Gen II + 0.6]. Age-related normal data and the response category definitions, currently determined by correlation conversion, will require further confirmation from clinical evaluation and experience, but the extremely close correlation observed is reassuring.
Wider implications of the findings: The new automated assays perform well in all validation tests, and ovarian stimulation risks can now be determined with confidence in a wide variety of settings. These assays will allow greater access for more centres, with guideline values for response risk more generally available.
Study funding/competing interest(s): Funding by hospital/clinic(s), Funding by commercial/corporate company(ies) – GCRM Ltd, Roche®.
Trial registration number: NA.

P-716 Luteal-phase ovarian stimulation strategy for assisted reproduction treatment

N. Wang[1], Y. Wang[1], Y. Kuang[1]
[1]*Ninth People's Hospital of Shanghai Jiaotong University School of Medicine, Department of Assisted Reproduction, Shanghai, China*

Study question: The purpose of this article was to systematically assess this new raised controlled ovarian stimulation strategy by comparing it with conventional follicular-phase ovarian stimulation protocols.
Summary answer: Compared with mild treatment protocol and short-term protocol, the luteal-phase ovarian stimulation (LPS) strategy had good performances in the number of mature oocytes retrieved, pregnancy rate and live birth rate. Neonatal outcomes and congenital malformations of all fetuses and infants conceived after LPS strategy were similar with other two groups.
What is known already: During the past years, we have managed to establish an effective LPS protocol, which mainly includes aromatase inhibitor (letrozole), HMG, and GnRH agonist and this strategy has been proven to be feasible for producing competent oocytes in women for assisted reproduction treatment. However, compared with traditional ovarian stimulation protocols, the efficiency of this new raised LPS strategy has not been determined.
Study design, size, duration: We did a large retrospective cohort study. Strict access standards were set and 2942 ovum pick-up (OPU) cycles (3104 frozen-thawed embryo transfer cycles corresponded) from LPS and the other two ovarian stimulation protocols conducted between April 2012 and September 2013 were enrolled for analysis.
Participants/materials, setting, methods: Primary outcomes were pregnancy rate, live birth rate and neonatal outcomes. Secondary outcomes were number of mature oocytes retrieved, number of top-quality (Grade I + II) embryos and so on. We used the Kruskal-Wallis test to compare continuous variables among the groups of patients or cycles.
Main results and the role of chance: The mean number of mature oocytes retrieved per OPU cycle was 10.9 ± 7.6 in the LPS group, 3.7 ± 3.0 in the mild treatment group, and 9.1 ± 5.5 in the short-term group ($P < 0.001$ for the comparisons of LPS group with the mild treatment group and short-term group). Pregnancy rate in the LPS group did not differ significantly with the mild treatment group ($P > 0.05$), but was higher than the short-term group ($P = 0.038$). Rate of live birth and still in pregnancy per FET cycle was 44.4% in the LPS group, 41.7% in the mild treatment group, and 39.2% in the short-term group ($P > 0.05$ for the LPS group vs. the mild treatment group, $P = 0.012$ for the LPS group vs. the short-term group). Neonatal outcomes and congenital malformations were similar among the groups.
Limitations, reason for caution: Assignment to the treatment groups was arbitrary, and not randomized; thus, there was a possibility for selection bias. Therefore, further large prospective cohort study is still needed to clarify the efficiency and safety of the LPS strategy.
Wider implications of the findings: The LPS strategy owns several advantages: high number of oocytes retrieved, good quality embryos yield and an excellent pregnancy rate; simple, low cost, effective and patient-friendly; also suitable for patients with poor ovarian response. The LPS strategy is not only a quite beneficial complementation to the follicular-phase ovarian stimulation protocols, but also of far-reaching influences on modern assisted reproduction treatment, especially the inherent down-regulation role of progesterone.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Shanghai Ninth People's Hospital, Shanghai.
Trial registration number: NA.

P-717 FSHR genotype is associated with different response to wild type FSH versus recombinant FSH

B. Lledo[1], P. Dapena[1], R. Morales[1], J. A. Ortiz[1], A. Turienzo[1], J. Guerrero[2], J. Llacer[3], R. Bernabeu[3]
[1]*Instituto Bernabeu Biotech, Molecular Biology, Alicante, Spain*
[2]*Instituto Bernabeu, Reproductive Biology, Alicante, Spain*
[3]*Instituto Bernabeu, Reproductive Medicine, Alicante, Spain*

Study question: Does the S680N polymorphism of FSHR gene affect the ovarian response using highly purified FSH or recombinant FSH?
Summary answer: For the first time we show in a population of egg donors 680FSHR gene polymorphism affects the efficacy of wtFSH or rFSH. A possible explanation could be different affinity to the FSH receptor. FSHR genotype is an important factor to determine the doses and the gronadotrophin administration in ovarian stimulation.
What is known already: Previous studies have reported conflicting results for the comparative doses of recombinant FSH (rFSH) and highly purified FSH (wtFSH or FSH-HP) required for an adequate ovarian stimulation. Clinical studies have demonstrated that N680S polymorphism determines ovarian response to FSH stimulation in patients undergoing IVF. Patients with the S680 allele need more FSH during the stimulation. Nothing is known about the clinical efficacy of rFSH or FSH-HP depending on the N680S FSHR polymorphism.
Study design, size, duration: This retrospective study includes 382 cycles performed at Instituto Bernabeu (Alicante. Spain) from 191 oocyte donors genotyped for N680S. All donors carried out two cycles: one with rFSH and the other one with FSH-HP (group1), both with FSH-HP (group2) or both with rFSH (group3). We compare the results in pair from each
Participants/materials, setting, methods: We included 191 egg donors genotyped for N680S polymorphism (63 in group 1, 100 in group 2 and 25 in group 3). The ovarian stimulation protocol was GnRH antagonist with starting doses 150, 225, 300 IU/day according to donor age, body mass index, clinical features and antral follicle count.
Main results and the role of chance: The main outcome measures were oocyte yield, MII, days of stimulation and gonadotrophin dosages. No significant differences were reported when we compared the cycles for each donor in group 1. However, according to FSHR polymorphism statistical differences were shown in oocyte yield and MII. For SS genotype more oocytes (18 vs 17) and MII (16 vs 13; $p < 0,05$) were yielded in a FSH-HP cycle. For NS genotype more oocyte (20 vs 16) and MII (17 vs 14; $p < 0,05$) were yielded in a rFSH cycle. For NN genotype no differences were reported. No significant differences were reported when we compared the cycles for each donor in group 2 and 3 regardless of the FSHR polymorphism.
Limitations, reason for caution: Pharmacogenetics applied to measure ovarian reserve and predicting ovarian response is true. However, an individual is

embedded with the context of that individual's entire genome and environment. In fact, some others genes related to follicular growth could also play an important role in determining the response to gonadotrophins.
Wider implications of the findings: This investigation reveals that in a population of fertile egg donors FSHR gene polymorphism at position 680 is associated with different ovarian response according to gonadotrophin used. Genotyping FSHR N680S could help us to choose not only the doses of gonadotrophin but also the form of administration (rFSH vs FSH-HP) particularly in poor responders where the optimization of protocol is very important to achieve a high number of oocyte retrieval.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Conflicts of interest none declared. This work has been supported by a grant from Rafael Bernabeu Foundation.
Trial registration number: NA.

P-718 GnRH antagonist versus long agonist protocols in IVF. A systematic review and meta-analysis accounting for patient type

C. B. Lambalk[1], F. R. Banga[1], J. A. Huirne[1], R. Homburg[2], F. Van Der Veen[3], M. Van Wely [3]
[1]*VU University Medical Centre, Reproductive Medicine, Amsterdam, The Netherlands*
[2]*Homerton Fertility Centre, Homerton University Hospital, London, United Kingdom*
[3]*Academic Medical Centre, Center for Reproductive Medicine Department of Obstetrics and Gynaecology, Amsterdam, The Netherlands*

Study question: What is the impact of the patient population on GnRH antagonists compared to standard long agonist protocols for prevention of premature luteinization in IVF? The aim of the current study was to compare GnRH antagonist versus standard long agonist protocols in various patient populations using various treatment schedules.
Summary answer: In a general IVF population antagonist use is associated with a lower ongoing pregnancy rate but also with lower OHSS rates. In couples with PCOS and poor responders there is no evidence that ongoing pregnancy rate is compromised with antagonist use.
What is known already: Currently available systematic analysis comparing GnRH agonist with antagonist strategies insufficiently account for various patient populations, such as normal ovulatory women, women with PCOS or poor ovarian response and include studies in which the agonist versus antagonist was not the only variable between the compared study arms.
Study design, size, duration: We searched the Cochrane Menstrual Disorders and Subfertility Review Group specialised register of controlled trials, Pubmed and Embase databases throughout 2014.
Participants/materials, setting, methods: Eligible trials were those that compared GnRH antagonists and standard long GnRH agonist protocols in IVF/ICSI. The primary outcome was ongoing pregnancy rate. Secondary outcomes were: live birth, clinical pregnancy, number of oocytes retrieved and ovarian hyperstimulation syndrome (OHSS) accounting for the general IVF, PCOS and poor responder populations.
Main results and the role of chance: We included 43 studies: 28 studies in general IVF patients, 9 studies in PCOS patients and 6 studies in poor responders (NN antagonist/agonist: 3231/2467, 484/510 and 410/370, respectively). In general IVF patients, ongoing pregnancy rate was significantly lower in the antagonist group (RR 0.87, 95% CI 0.79–0.96). Antagonists resulted in significantly lower OHSS rates (RR 0.63, 95% CI 0.44–0.88). No differences in ongoing pregnancy between antagonist and agonist were observed in women with PCOS (RR 0.97, 95% CI 0.84–1.11) and in women with poor ovarian response (RR 0.87, 95% CI 0.65–1.17). Antagonists resulted in significantly lower OHSS rates in women with PCOS (RR 0.47, 95% CI 0.24–0.93). No data on OHSS was available for trials in poor responders.
Limitations, reason for caution: We focused on ongoing pregnancy as the primary outcome for these analyses as live birth rates were often not available. OHSS was poorly defined by various studies and it was not a primary endpoint in most studies analyzed.
Wider implications of the findings: These findings provide an evidence based underpinning for a tailored decision making in premature LH surge prevention strategies in IVF, dependent on the patient profile.

[5]*University of Milan IRCCS Istituto Auxologico Italiano, Clinical Sciences and Community Health Division of Endocrine and Metabolic Diseases, Milan, Italy*

Study question: The identification of novel molecular mechanisms and genes involved in the pathogenesis of Primary Ovarian Insufficiency (POI) is mandatory to clarify the unknown etiopathogenesis underlying this fertility disorder. For this purpose, we unravelled pathways and molecular events induced by BMP15 treatment in human Granulosa cells (hGCs) by microarray gene-expression analysis.
Summary answer: This is the first comprehensive panel of transcriptomic effects induced by BMP15 on hGCs, indicating BMP15 as a master regulator of many folliculogenesis processes such as proliferation, apoptosis, maturation and hormonal response. These findings would permit a better comprehension of the pathogenic mechanisms underlying POI.
What is known already: POI is an inheritable disease with a strong genetic component but characterized by a highly variable expressivity and penetrance. To date, several mutations in the X-linked gene *BMP15* have been identified in association with POI and this oocyte-derived growth factor plays an essential role as a local regulator of the ovarian folliculogenesis in animal models and in humans, also controlling the ovulation quota. Nevertheless, the already known genetic alterations may explain only few cases.
Study design, size, duration: Each pool of hGCs ($n = 2$) was obtained from 6 normal responders to ovarian stimulation for IVF. hGCs were plated and stimulated with 100 ng/ml of recombinant human BMP15 (rhBMP15) in triplicates. Stimulated and not-stimulated cells were collected at 0, 2 and 6 hours, to evaluate early and late regulated genes.
Participants/materials, setting, methods: RNAs from each condition were processed for hybridization on beadchips and analyzed by the Illumina BeadArray. A differential statistical analysis was performed by applying the Linear Model for Microarray Data: stimulation, timev and pool variables were considered. Gene Ontology pathways were also tested for differential expression.
Main results and the role of chance: After the quantile normalization, 4 groups of samples emerged, pool and time dependents (6 h vs. 0 h/2 h), by applying the Principal Component Analysis (PCA) of the means of technical replicates. The differential analysis of stimulated vs non-stimulated samples over time shows 34 differentially expressed probes after 2 h and 46 probes after 6 h (Benjamini-Hochberg (BH)-adjusted P-value < 0.05). Moreover 21 probes were differentially expressed both after 2 and 6 h. The following GO gene sets enrichment analysis was performed by ROAST test (Rotation gene set tests for complex microarray experiments). The rhBMP15 stimulus modulates the BMP signaling pathway, cell fate commitment, proliferation, apoptosis and estrogen response.
Limitations, reason for caution: The microarray and validation analyses were performed on pools of hGCs obtained after ovarian stimulation, and may not be fully representative of the hGCs at earlier stages of the folliculogenesis.
Wider implications of the findings: Several of the pathways here identified have already been described in previous studies dissecting the mechanisms of folliculogenesis in models of altered fertility, confirming BMP15 as a master regulator of folliculogenesis processes. These findings should prompt future analysis of BMP15-regulated genes as novel candidates in POI cohorts.

P-720 A randomized controlled trial of luteal phase supplementation with vaginal progesterone in women with polycystic ovary syndrome undergoing ovulation induction with letrozole

L. Stadtmauer[1], T. Pakrashi[1], H. Beydoun[1], S. Bocca[1], S. Oehninger[1]
[1]*The Jones Institute for Reproductive Medicine, Obstetrics and Gynecology, Norfolk Virginia, U.S.A.*

Study question: Is there a benefit to the use of vaginal progesterone (8% Crinone gel) in women with Polycystic Ovary Syndrome (PCOS) and ovulatory dysfunction undergoing ovulation induction (OI) with letrozole?
Summary answer: Interim analysis of 85 cycles demonstrates a trend towards higher pregnancy rates (PR) and live birth rates (LBR) in OI cycles supplemented with vaginal progesterone (19.5,17.1%) versus those that were not supplemented during the luteal phase (6.8, 4.5%).
What is known already: PCOS patients can have impaired granulosa cell function in the ability to synthesize progesterone. Letrozole may be superior to clomiphene citrate and improve pregnancy and live birth rates in subfertile women who are anovulatory and have PCOS. Limited data suggests that vaginal progesterone supplementation of PCOS patients undergoing OI with clomiphene citrate in the luteal phase may result in an improvement in pregnancy rates.
Study design, size, duration: RCT of PCOS subjects (n = 44) (November 2012–December 2014) undergoing OI (85 cycles) with letrozole. Those meeting follicle growth criteria on ultrasound underwent randomization (1:1 with computer generated spreadsheet) to 8% Crinone vaginal progesterone gel or no luteal support following intrauterine insemination. Primary outcome measured is PR per cycle.
Participants/materials, setting, methods: PCOS subjects (51 between 20 and 40 years and BMI 18–40 kg/m^2 with patent tubes) were enrolled and underwent OI. 44 women responded and underwent randomization. PR and LBR per cycle and per subject were compared. Statistics included Student's t-test, Chi-square test and multivariate logistic regression analysis with odds ratio.
Main results and the role of chance: A total of 85 cycles with a target of 110 cycles was completed. Each subject participated in a maximum of 3 OI cycles with Letrozole. There were no significant differences in baseline characteristics of age, cycle day 3 labs, total motile sperm count, body mass index, gravidity, parity, dose of letrozole prescribed, number of dominant follicles and endometrial thickness between the treatment (n = 41), and control (n = 44) groups. The PR and LBR per cycle was higher in the treatment (19.5, 17.1%) versus control cycles (6.8, 4.5%) (P = 0.08, P = 0.06) although the results were not statistically significant. The PR and LBR subject was also higher in the treatment (33.3, 29.41%) vs. control (15.38. 10.2%) P = 0.1, but the results were not statistically significant. Logistic regression showed odds of pregnancy in Group 1 vs. 2 (OR = 0.3, 95% CL: 0.04–1.5).
Limitations, reason for caution: Interim analysis of an ongoing randomized controlled trial with small cycle numbers (n = 85).
Wider implications of the findings: An interim analysis of a randomized controlled trial demonstrates a trend towards higher pregnancy rates in PCOS patients supplemented with vaginal progesterone in the luteal phase, undergoing OI cycles with letrozole. This suggests there may be some benefit to exogenous supplementation with progesterone in the luteal phase in PCOS patients with ovulatory dysfunction.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Partial funding by Actavia.
Trial registration number: NA.
Keywords: PCOS, luteal support, ovulation induction, letrozole

P-721 Adjuvant gonadotropin-releasing hormone agonist trigger with human chorionic gonadotropin to enhance ooplasmic maturity

R. T. Elias[1], N. Pereira[1], R. S. Gerber[2], J. P. Lekovich[1], A. P. Melnick[1], G. D. Palermo[1], Z. Rosenwaks[1]
[1]*Weill Cornell Medical College, Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, NY, U.S.A.*
[2]*Weill Cornell Medical College, Department of Obstetrics and Gynecology, New York, NY, U.S.A.*

Study question: Does an adjuvant gonadotropin-releasing hormone agonist (GnRH-a) ovulatory trigger with human chorionic gonadotropin (hCG) improve fresh intracytoplasmic sperm injection (ICSI)-embryo transfer (ET) cycle outcomes in patients with poor fertilization history after standard hCG trigger alone?
Summary answer: Combined ovulatory trigger with 2 mg of GnRH-a and 1500 IU of hCG increases oocyte maturity, as well as fertilization and clinical pregnancy rates in patients with poor fertilization history in prior ICSI-ET cycles after standard hCG trigger.
What is known already: Combined GnRH-a and hCG triggers have previously been used to prevent ovarian hyperstimulation syndrome. More recently, studies have suggested an increase in the percentage of mature oocytes retrieved with combined GnRH-a and hCG trigger compared to a standard hCG trigger. These findings have been attributed to the endogenous luteinizing hormone (LH) surge induced by the GnRH-a component of the combined ovulatory trigger.
Study design, size, duration: Retrospective cohort study of all patients with a fertilization rate of <40% in a prior fresh ICSI-ET cycle with standard hCG trigger who subsequently underwent another ICSI-ET cycle with a combined GnRH-a and hCG trigger between January 2006 and June 2013.
Participants/materials, setting, methods: 18633 cycles occurred during the study period. Of these, 744 (3.99%) cycles utilized combined GnRH-a and hCG triggers. Based on a previous study showing a 16.6% difference in fertilization rate, a sample size of 118 patients was estimated assuming an a error of 5% and a power of 80%.
Main results and the role of chance: 120 patients with <40% fertilization rate in a prior ICSI-ET cycle with standard hCG trigger received a combined GnRH-a and hCG trigger in the subsequent cycle. All patients underwent ovarian stimulation with an antagonist-based protocol. There was no difference in the demographics or baseline cycle characteristics of the two groups. The mean (±standard deviation) oocytes retrieved in the hCG and dual trigger groups were 13.4 (±1.09) and 12.6 (±0.75), respectively. There was an overall increase in the percentage of mature oocytes retrieved, fertilization and clinical pregnancy rate in the combined trigger group compared to the hCG group: 84.2% vs. 70.2% (P = 0.01); 52.2% vs. 35.3% (P = 0.01); 52.5% vs. 40.8% (P = 0.03). These findings remained unchanged even after controlling for age and number of embryos transferred.
Limitations, reason for caution: Although our study reveals increased oocyte maturity, fertilization and clinical pregnancy rates after combined GnRH-a and hCG trigger compared to standard hCG trigger, the molecular mechanisms by which the GnRH-a induced LH surge promotes nuclear and cytoplasmic maturity in oocytes remain to be elucidated.
Wider implications of the findings: Utilization of a combined GnRH-a and hCG ovulatory trigger can be a reasonable approach to increase oocyte maturity and fertilization rates in patients with a history of poor fertilization after standard hCG trigger alone. Prospective data are required to validate the overall generalizability and efficacy of this management strategy.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medical Center.
Trial registration number: NA.

P-722 A review of 100 consecutive new referrals with secondary amenorrhoea: aetiology and presentation

P. Purohit[1], M. Bhaduri[1], T. Bhaduri[1], L. Ganjewar[1], N. Narvekar[1], M. Savvas[1], H. Hamoda[1]
[1]*Kings College Hospital, Reproductive Medicine, London, United Kingdom*

Study question: To assess the causes of secondary amenorrhoea, as well as patient characteristics (age, BMI and ethnic origin), family history and reproductive history in women presenting with secondary amenorrhoea.
Summary answer: The cause for secondary amenorrhoea in this study was PCOS in 34%, POI in 32%, hypogonadotropic hypogonadism in 22%, mixed PCOS/hypogonadotropic hypogonadism [defined as polycystic ovaries with low gonadotropins and low estradiol] in 5%, hyperprolactinemia in 4%, drug induced amenorrhoea in 2% and idiopathic in 1%.

What is known already: Most cases of secondary amenorrhoea have been attributed to polycystic ovary syndrome [PCOS] (WHO Group II), hypothalamic amenorrhoea (WHO Group I), hyperprolactinaemia and Premature Ovarian Insufficiency [POI] (WHO Group III). We carried out this review to assess the causes of secondary amenorrhoea and patient demographics for this condition in our local population.
Study design, size, duration: A retrospective analysis of 100 consecutive new referrals with secondary amenorrhoea to a UK tertiary referral centre during the period 2012–2014. Secondary amenorrhoea was defined as absence of menstrual periods for at least 3months in women with otherwise normal periods.
Participants/materials, setting, methods: 100 new referrals to the Reproductive Medicine clinic where selected. A retrospective analysis was their electronic medical records was done to obtain all the data for this study.
Main results and the role of chance: The cause for secondary amenorrhoea in this study was PCOS in 34%, POI in 32%, hypogonadotropic hypogonadism in 22%, mixed PCOS/hypogonadotropic hypogonadism [defined as polycystic ovaries with low gonadotropins and low estradiol] in 5%, hyperprolactinemia in 4%, drug induced amenorrhoea in 2% and idiopathic in 1%. The mean (+SD) age at presentation was 31 (7.19) years. The mean (+SD) age for PCOS women was 27.8 (5.65) years, 30 (6.78) years for hypogonadotropic hypogonadism, 34 (7.50) years for POI and 29.2 (7.52) years in those with mixed PCOS/hypogonadotropic hypogonadism. The mean (+SD) BMI for the total number of women assessed was 26.15 (6.94). The mean (+SD) BMI for PCOS women was 28.58 (7.03), for hypogonadotropic hypogonadism 22.21 (7.80), for POI 27 (5.60) and for mixed PCOS/hypogonadotropic hypogonadism was 20 (1.38). A total of 59% of women were Caucasian, 31% Afro-Caribbean, 7% Asian and 3% Middle-Eastern. A total of 3% gave a family history of secondary amenorrhoea. The primary reason for referral was secondary amenorrhoea in 75% of women, in 5% was infertility and in 20% both- amenorrhoea and infertility. However, on questioning, a total of 38% of women had a desire for fertility. 29% of the women had previously achieved a pregnancy whereas 9% had livebirths. For women with hypogonadotropic hypogonadism, the mean (+SD) FSH, LH and estradiol levels were 5 IU/L (2.55), LH 2.8 IU/L (2.35) and 101 pmol/L (45.04), respectively. Bone density scans were performed in 14/22 women with hypogonadotropic hypogonadism and of these, 7 (50%) had osteopenia, 4 (29%) had osteoporosis and 3 had normal bone density (21%). The mean (+SD) spine T score was -1.46 (1.31) and the mean (+SD) hip T score was -0.80 (0.88). Bone density scans were performed for 20/32 women with POI and of these, 12 (60%) had normal bone density, 8 (40%) had osteopenia while none had osteoporosis. The mean (+SD) spine T score was -0.44 (1.37) and the mean (+SD) Hip T score was -0.28 (1.29).
Limitations, reason for caution: the number might be considered low. And bone density information was not available for all patients.
Wider implications of the findings: In our study, PCOS was the noted to be the commonest cause of secondary amenorrhoea (34% of cases), while hypogonadotropic hypogonadism was the cause in approximately a fifth of all women assessed. A higher prevalence of reduced bone density was noted in women with hypogonadotropic hypogonadism compared to women with POI (79% and 40%, respectively). Consideration should be given to assessment of bone density in women in the latter two groups to allow detection, treatment and to prevent further loss of bone density. The information could provide useful information for counselling patients and guiding clinicians in their practise.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Kings College Hospital NHS Foundation Trust, London.
Trial registration number: NA.

P-723 Increased prevalence of high normal thyroid stimulating hormone values in intra uterine inseminations and in vitro fertilization

C. C. Repelaer van Driel-Delprat[1], E. W. C. M. van Dam[2], E. Vis[1], L. C. Kooij[1], K. Aissa[1], A. de Roos[1], G. W. C. M. Beelen[1], R. Schats[1], C. B. Lambalk[1]
[1]*VUMC, Department of Obstetrics and Gynaecology/Reproductive Medicine, Amsterdam, The Netherlands*
[2]*VUMC, Department of Internal Medicine/Endocrinology, Amsterdam, The Netherlands*

Study question: The upper reference limits for Thyroid Stimulating Hormone (TSH) are debated. We questioned the prevalence of High Normal (HN) TSH (2,5–4,5 mIU/L) values in an IUI population and a synchronous IVF population in a iodine sufficient area.
Summary answer: The prevalence of HN TSH in the IUI cohort is 21%, and in the IVF cohort 22%, compared with a population prevalence of 5%. The prevalence of HN TSH is comparable in the different groups of causes of infertility.
What is known already: In the overall euthyroid population <5% has HN TSH values. In women undergoing IVF/ICSI HN TSH is ±20%. Karmon et al. and Jatzko showed in their IUI- populations HN TSH prevalences of respectively 26,9% and 15,1% in the euthyroid women. Jatzko's HN TSH women were considered subclinical hypothyroid and therefore treated with Levothyroxine. Evidence lacks until now about beneficial effects of TSH < 2,5 mIU/L on fertility outcomes.
Study design, size, duration: In a retrospective cohort study from January 2008 till March 2012 we analyzed all women starting IUI (n = 1259) and all women starting IVF (n = 2232). We compared the prevalence of LN or HN TSH levels in the different subfertility indications.
Participants/materials, setting, methods: From the women who had (a) IUI or IVF/ICSI treatment(s), we assessed the prevalence of LN/HN TSH if measured within 2 years before treatment and not using thyrotrophic medication (IUI n = 1007, IVF n = 1451), in a single Dutch Academic University Hospital Fertility Centre in a iodine sufficient area
Main results and the role of chance: Both in the IUI- and IVF-population the prevalence of HN TSH values is about four times higher than in the overall population. This might suggest an association with their subfertility. The prevalence's of HN TSH in different indication groups are for IUI/IVF: idiopathic:20/19%, tubal 20/16%, male factor 20%/24%, PCOS 18/15%, endometriosis 20/18%, POF 18/20%.
Limitations, reason for caution: Limitations of this study are its retrospective design, the spread of analysis interval (2 years), the small groups when comparing the indications, and no prolactin nor TPO antibodies known. Finally the value of 2,5 mIU/L as separating LN from HN is debatable.
Wider implications of the findings: Higher prevalence of HN thyroid values in subfertile women than in the overall population might associate thyroid hormones and subfertility. Literature shows until now no differences in treatment or pregnancy outcomes between LN and HN TSH women nor whether this differs in the distinct indication groups. A randomized controlled trial with Levothyroxine when TSH >2,5 mIU/L is needed to know if HN TSH should be considered as subclinical hypothyroidism affecting pregnancy outcomes.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Division of Reproductive Medicine, Department of Obstetrics and Gynaecology, VU University Medical Center (VUmc), Amsterdam.

Keywords: TSH, IVF, IUI, endocrinology, thyroid

P-724 The proliferative phase endometrium in women with PCOS presents with decreased proliferation and density of migratory CD68+ macrophages and CD8+ T-cells

M. Kangasniemi[1], M. Khatun[1], A. Liakka[2], J. Chen[3], J. Irwin[3], L. C. Giudice[3], T. T. Piltonen[1]
[1]*Medical Research Center University of Oulu and Oulu University Hospital, Department of Obstetrics and Gynecology and Center of Clinical Research, Oulu, Finland*
[2]*Medical Research Center University of Oulu and Oulu University Hospital, Department of Pathology (AL), Oulu, Finland*
[3]*University of California (UCSF), Department of Obstetrics Gynecology and Reproductive Sciences, California, U.S.A.*

Study question: Does the endometrium in women with polycystic ovary syndrome (PCOS) present with an altered immune cell profile explaining some of the adverse reproductive outcomes and endometrial pathologies in these women?
Summary answer: PCOS endometrium showed lower proliferation (Ki67) rate with concomitant decrease in the migratory macrophage (CD68+) and T-cell (CD8+) density compared to controls, whereas no difference was observed in the density of CD56+ uterine NK-cells. The expression of estrogen receptor alpha (ERa) and progesterone receptor (PR) were similar between the groups.

What is known already: Immune cells play a crucial role both in implantation and endometrial pathogenesis as they modulate the endometrial immune environment and facilitate embryo invasion. PCOS women present with subfertility and increased risk for endometrial cancer and previous studies have shown several endometrial abnormalities in PCOS endometrium including altered cytokine secretion/response and migratory immune cell (NK-cell) density. To date, no data exists on immune cell density in proliferative phase endometrium in women with PCOS compared to controls.
Study design, size, duration: Prospective, university based, case-control study utilizing endometrium biopsies [20 PCOS (Rotterdam criteria), 18 controls with regular cycles] obtained from fertile age volunteers or patients going through benign gynaecological procedure. The study was designed to compare endometrial immune cell density, proliferation and hormone receptor expression in women with PCOS and controls.
Participants/materials, setting, methods: Study groups were matched for BMI (kg/m^2) (PCOS 27.9, controls 26.4). The proliferative phase histology was confirmed by pathologist and CD68, CD56, CD8, Ki67, ERa and PR expression were assessed by immunohistochemistry. The staining density in stroma was analysed by using computer-assisted cell counting method in ImageJ software.
Main results and the role of chance: According to ANOVA, no difference was observed in the BMI between the study groups. Interestingly, proliferative phase endometrium in women with PCOS presented with lower CD68+ macrophage ($p = 0.014$) and CD8+ lymhocyte ($p = 0.043$) density whereas no difference was found in CD56+ uterine NK cell count. Furthermore, the Ki67 staining showed lower proliferation rate in PCOS endometrium ($p = 0.01$) even though no differences were observed in ERα and PR expression.
Limitations, reason for caution: Due to relatively small sample size the patients were not divided into different BMI-groups. Also even though mean of 7–9 pictures were taken per sample to get representative staining result for ImageJ processing there still may be a chance of estimation bias for the most representative areas in the sample.
Wider implications of the findings: The present data shows low immune cell density of CD68+ macrophages and CD8+ lymphocytes in proliferative phase PCOS endometrium compared to BMI-matched controls. As immune cells play an important role during implantation, the result may relate to adverse reproductive outcomes in women with PCOS especially if the alteration persists towards window of implantation. Furthermore, as the proliferation rate was low in PCOS endometrium it does not suggest hyperplastic endometrium phenotype in these women.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s), Funding by national/international organization(s) – Sigrid Juselius Foundation, Academy of Finland, Finnish Medical Foundation, Orion-Farmos Research Foundation.
Trial registration number: NA.

P-725 Menstrual-cycle-length: a surrogate measure of reproductive health capable of improving the accuracy of biochemical/sonographical ovarian-reserve-test in estimating the reproductive chances of women referred to ART

F. Esposito[1], S. Gizzo[1], A. Vitagliano[1], M. Noventa[1], C. Zicchina[1], M. Quaranta[2], B. Abdulrahim[3], C. J. Aldrich[3], M. Gangemi[1], G. B. Nardelli[1], A. Andrisani[1], C. Saccardi[1]
[1]*Azienda Ospedaliera Padova Università di Padova, Women and Child Health, Padova, Italy*
[2]*University of Verona, OB/GYN Unit, Verona, Italy*
[3]*NHS Trust – Northampton General Hospital, Obstetrics and Gynecology, Northampton, United Kingdom*

Study question: Can the menstrual cycle length (MCL) be considered as a surrogate measure of reproductive health and could it be able to improve the accuracy of biochemical/sonographical ovarian-reserve-test in estimating the reproductive chances of women referred to ART?
Summary answer: In women <35 years, MCL >31 days may be associated with increased risk of OHSS and good Ovarian Sensitivity Index (OSI). In women >35 years, MCL shortening may be associated with poor-ovarian-response, low OSI, reduced fertilization-rate. MCL is a good tool to estimate biological-age and the chances before ART cycles.
What is known already: Recent evidences suggested that long MCLs are associated with a greater number of antral-follicle waves and higher ovarian-response to hormonal stimulation. On the contrary, short MCLs are associated with poor response to ovarian hyperstimulation. So, it seems intuitive that the menstrual-diary should be routinely considered as a useful tool in estimating chances and improving reproductive outcome of ART-cycles, particularly when patient report any previous ART cycle and their biological and chronological age do not match.
Study design, size, duration: Retrospective-observational study on 455 normo-ovulatory infertile women scheduled for their first fresh non-donor IVF/ICSI-treatment owning a personal menstrual-diary of the six months preceding the ART treatment (interval-time 2011–2014). According to pre-treatment ovarian reserve assessment, all patients received the most adequate stimulation protocol.
Participants/materials, setting, methods: We divided the sample according to patients age (AGE_class_1: >40 years, AGE_class_2: 35–40 years, AGE_class_3: 26–34 years, AGE_class_4: <26years) MCL (MCL_class_1: >31 days, MCL_class_2: 30–31 days, MCL_class_3: 28–29 days, MCL_class_4: 26–27 days, MCL_class_5: <26 days), AMH (AMH cohort_1: 0.1–0.4 ng/ml, AMH cohort_2: 0.5–1.1 ng/ml, AMH cohort_3: >1.1 ng/ml).
Main results and the role of chance: With an AMH <1.1 ng/ml the ovarian-response to hyper-stimulation correlates with MCL. Patients with MCL <28 days showed a reduction of ovarian-response in accordance with MCL shortening. In patients with AMH value <0.4 ng/ml (cohort 1) and 30 days MCL an average of 3.5 oocytes per-cycle were collected while only 1.2 oocytes per cycle were retrieved in those with MCL of 26 days. MCL correlates with fertilization-rate of the MII-oocytes, particularly in patients >35 years. Considering patients >40 years, we observed a fertilization-rate of almost 90% with 30–days MCL and of 50% with <26 days MCL. We found that in patients younger than 34 years MCL >31 days was associated with an OSI of about 12.5 compared to an OSI of about 5 when MCL was <30 days.
Limitations, reason for caution: Retrospective study-design, variability in ovarian-stimulation-protocols (choosing the most appropriate for each patients), use of both recombinant and purified gonadotropins, assessment of oocytes fertilization ratio using 6 oocytes as a maximum number to fertilize (according to the Italian law), may represent a reason of caution for data interpretation
Wider implications of the findings: We strongly suggest considering the introduction in routine clinical practice of MCL evaluation, because this parameter may be considered an indicator of ovarian age (better than FSH and chronological age). The large scale applicability and the good accuracy of MCL in estimating ovarian-response, OSI and fertilization-rate allows Clinicians to consider it as an inexpensive good tool capable of improving the accuracy of biochemical/sonographical ovarian-reserve-test and to better estimate the ART success rate.

[2]*Hospital General Universitario Gregorio Marañon., Reproductive Medicine Unit. Obstetrics and Gynaecology Department, Madrid, Spain*
[3]*Hospital General Universitario Gregorio Marañon, Reproductive Medicine Unit. Obstetrics and Gynaecology Department, Madrid, Spain*
[4]*Hospital General Universitario Gregorio Marañon, Obstetrics and Gynaecology Department, Madrid, Spain*

Study question: We analyze the impact of early progesterone elevation (EPE) during IVF ovarian stimulation in different prognostic scenarios, related to patient's age, ovarian reserve, number and quality of available and transferred embryos.

Summary answer: EPE reduces significantly clinical pregnancy and live birth rates, but the effect size depends on prognostic factors of IVF outcomes.
What is known already: Lack of opportunity for embryo implantation due to EPE could be a consequence of progesterone increase grade. It has been hypothesized that classical prognostic factors –woman's age, ovarian reserve, number and quality of obtained embryos– could modulate the dysregulatory effect of EPE; quantification of these potential modifying effects has not been yet accurately estimated. Estimation of negative effect of EPE by prognostic subgroups could help in decisions making about immediate or delayed embryo transfer.
Study design, size, duration: Retrospective cohort study of an opportunity sample of 583 IVF cycles initiated between 2011 and 2014 in a tertiary university ART centre. Exposure was defined as progesterone elevation over an specific cut-off value established by statistical criteria. Clinical pregnancy and birth rate have been considered as main outcomes.
Participants/materials, setting, methods: We analyze 583 IVF cycles with fresh embryo transfer from a tertiary ART program with routinely serum progesterone determination. Frequency of EPP exposure was 4% (23/586). Relative risk for clinical pregnancy and live birth has been estimated globally and for each prognostic stratum.
Main results and the role of chance: EPE was defined for clinical pregnancy as final serum progesterone level >1,7 ng/mL. In EPP exposed patients, clinical pregnancy and live birth rates were significantly lower (3/23 vs 241/560; p = 0,003; RR: 0,3 95% CI: 0,10–0,87) (4/33 vs 122/357; p = 0,006; RR: 0,35; 95% CI: 0,14–0,89). EPE size effect on clinical pregnancy was related to AFC (RR for <5: 0,75 95% CI: 0,11–4,75; RR for ≥5: 0,25; 95% CI: 0,06–0,93) and number of retrieved oocytes (RR for <5: 0,85 95% CI: 0,25–2,80; RR for ≥5: 0,13; 95% CI: 0,02–0,88). Effect of EPE for live birth rate estimation (>1,5 ng/mL) was significantly modified only by number of available oocytes (RR for <5: 1,14 95% CI: 0,3–4,1; RR for ≥5: 0,21; 95% CI: 0,6–0,79).
Limitations, reason for caution: Accuracy of stratified relative risk estimation is probably affected by low frequency of critical EPP, that has been defined towards IVF outcome probabilities distributions. Bivariate analysis of potential confusion or interaction effects of prognostic covariables could be underpowered.
Wider implications of the findings: Our preliminary data support a jeopardizing effect of high levels of EPE on clinical pregnancy and live birth rates. This could be a non-linear effect, probably modulated by main prognostic factors (age, AFC, retrieved oocytes and number and quality of transferred embryos.

Trial registration number: Not applicable (retrospective cohort study).
Keywords: progesterone, IVF, embryo implantation, clinical pregnancy, live birth

P-727 Higher levels of chemerin were detected in the follicular fluids of PCOS than non-PCOS: possibility of involvement of chemerin in the pathogenesis of PCOS

L. Fu[1]
[1]*Peking University Third Hospital, Obstetrics and Gynecology, Beijing, China*

Study question: By checking the levels of chemerin in follicular fluids (FF) and the levels of chemerin in serum in PCOS and non-PCOS, we investigated the presence of chemerin and its possible involvement of chemerin in pathogenesis of PCOS.
Summary answer: The levels of chemerin in the FF of PCOS were significantly higher than those of non-PCOS, but no differences in the serum between PCOS and non-PCOS. And levels of FF were higher than those of serum both in PCOS and non-PCOS. Chemerin may play a role in ovary per se of PCOS.
What is known already: Chemerin, a kind of adipokine presenting in many organs and tissues, modulates immune system functions and glucose metabolism via its own receptor. It also exerts interactions with many inflammtory factors which are related to the reproductive functions and primary incentives of insulin resistance.
Study design, size, duration: Follicular fluids, serum specimens and granulosa cells were collected from 64 PCOS and 58 non-PCOS patients undergoing IVF-ET.
Participants/materials, setting, methods: Follicular fluids and serum specimens were collected from 64 patients undergoing IVF-ET with PCOS and 58 patients without PCOS. ELISA were performed to check the chemerin levels in follicular fluid and serum. Granulosa cells were insolated from follicular fluids. RT-PCR was performed to detect the expression of chemerin in ovary.
Main results and the role of chance: The levels of chemerin in the FF of PCOS were significantly higher than those of non-PCOS, but no differences in the serum between PCOS and non-PCOS. The levels of chemerin in FF were significantly higher than those of serum both in PCOS and non-PCOS. The results of RT-PCR identified the expression of chemerin in granulosa cells.
Limitations, reason for caution: immunohistochemistry or immunocytochemistry is necessary for detecting the location of chemerin in the ovary.
Wider implications of the findings: Based on these results, we proposed that chemerin may involve in the pathogenesis of ovary in PCOS. In further study we aim to investigate the role and effects of chemerin in pathogenesis of insulin resistance in ovary per se.
Study funding/competing interest(s): Funding by national/international organization(s) – Natural science foundation of China.
Trial registration number: NA.

P-728 Do AMH levels predict outcomes for IVF patients doing PGS?

C. R. Givens[1], E. E. Fischer[2]
[1]*Pacific Fertility Center, Clinical, San Francisco, CA, U.S.A.*
[2]*Pacific Fertility Center, Laboratory, San Francisco, CA, U.S.A.*

Study question: Is there a significant difference in cycle and live birth outcomes and numbers of euploid embryos in women undergoing IVF/PGS with their own eggs depending on pre-cycle serum anti-Mullerian hormone (AMH) levels?
Summary answer: There is a significant difference in the numbers of euploid embryos and clinical pregnancy rates (CPR) and live birth rates (LBR) per cycle start for patients undergoing PGS based on AMH levels.
What is known already: Lower AMH levels result in fewer embryos to biopsy as well as lower implantation rates (Gleicher et al, Reprod Biol Endocrinol 2012:10: 48). No association between AMH levels and live births after IVF/PGS has been previously reported.
Study design, size, duration: Retrospective review of 288 IVF/PGS cycles between June 2010 and July 2013 for which AMH levels were available. 122 cycles were done in women with an AMH <1.0 ng/mL (low AMH group) and 166 in women with an AMH >1.0 ng/mL (high AMH group).
Participants/materials, setting, methods: Private U.S. IVF clinic database review. Embryos underwent trophectoderm biopsy and vitrification awaiting SNP microarray results. Data analyzed in 2 groups: AMH <1.0 and >1.0 ng/mL. Data on CPR and LBR are provided for those cycles/patients that have undergone a subsequent frozen ET. Two-tailed Fisher's exact test for statistical analysis.
Main results and the role of chance: Cycle cancellation rates were significantly higher in the low AMH group vs. high AMH group (18% vs. 5.4%, p = 0.004). The number of euploid embryos was significantly lower in the low AMH group (37.9%) vs. the high AMH group (52.6%), p = 0.036. CPR/ET was similar in the low AMH group vs. the high AMH group (55.8% vs. 66.3%, p = 0.74). CPR/retrieval was 19% and 35% in the low and high AMH groups respectively (p = 0.04). CPR/cycle start was also lower (15.6% vs. 30.1%, p = 0.011). LBR/ET were similar in the low AMH group (52.9%) vs. the high AMH group (60.2%), p = 0.74. LBR/retrieval trended lower: 18% in the low group and 32% in the high group, p = 0.066. LBR/Cycle start was significantly lower in the low vs. high AMH groups (14.8% vs. 30.1%, p = 0.019).
Limitations, reason for caution: Retrospective review so AMH levels could have influenced cancellation rates. Not all patients have undergone subsequent FET so some of the data is incomplete. This includes 6 patients in the low AMH group and 9 patients in the high AMH group that have at least one euploid embryo. AMH assays were done in different laboratories.
Wider implications of the findings: As an independent variable, AMH levels lower than 1.0 ng/mL predict higher cycle cancellation rates, more euploid embryos to transfer, and higher CPRs and LBRs and low rates of pregnancy loss. This data confirms earlier data about higher implantation rates but reports on a substantial number of live births as well. AMH levels may be useful for patient counseling.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Pacific Fertility Center, San Francisco, CA.
Trial registration number: Not a registered randomized trial. IRB Expedited review approved by Schulman IRB.
Keywords: AMH, PGS, IVF

P-729 GnRH agonist trigger in PCOS undergoing IVF with GnRH antagonist cycles: single dose vs. double dose – a randomized pilot study

K. Deepika[1], D. Snehal[1], P. Baiju[1], M. S. Navyashri[1], P. Khushbu[1], S. Nivedita[1], R. Suvarna[1], P. Bhagyashree[1], U. Amit[1], G. Anjali[1], P. S. Divyashree[1], K. Anu[1], P. Gautam[1], R. Kamini[1]
[1]*Bangalore Assisted Conception Centre, Reproductive Medicine, Bangalore, India*

Study question: Is a single dose of Gonadotropin-releasing hormone agonist (GnRHa) trigger to induce final oocye maturation in Polycystic Ovarian syndrome (PCOS) undergoing IVF cycles with GnRH antagonist protocol sufficient to provide an optimal outcome in terms of mature oocytes (MIIs)? Is the cycle outcome better with single dose or double dose?
Summary answer: Double dose of GnRHa trigger in PCOS with GnRH antagonist cycles provides a better cycle outcome than a single dose in terms of maturity of oocytes, good quality embryos available on day 3 and day 5 with no OHSS.
What is known already: GnRHa induced LH surge consists of a short ascending phase (~4 h) and a long descending phase (~20 h), total of 24–36 h, different from the physiological LH surge (~48 h). In PCOS with subtle pituitary dysfunction, at times a single dose of GnRHa might not be able to induce LH surge above a threshold level and for a threshold duration (mimicking physiological surge) required for adequate oocyte maturation. It is therefore important to optimize the dosage and frequency of GnRHa for an optimum yield of mature oocytes in PCOS.
Study design, size, duration: This prospective, randomized, double blinded, proof of concept study was from June 2012 to December 2014 on 100 PCOS defined as per the ESHRE/ASRM Rotterdam criteria (2003) undergoing IVF in antagonist protocol. Patients were randomized by computer generated sequence into two groups of 50 each. All participants before allocation signed an informed consent form.
Participants/materials, setting, methods: Group A: single dose, 0.2 mg, 35 h prior to oocyte retrieval. Group B: 0.2 mg, 35 h before oocyte retrieval +0.1 mg 12 h following first dose. GnRHa: Triptorelin acetate (Decapeptyl), administered at least 12 h after the last dose of GnRH antagonist. Post trigger LH and progesterone levels were measured 12 h following first dose. All Embryos were vitrified. Data analysis: SPSS version16.
Main results and the role of chance: The mean age (years) and BMI (kg/m^2) in groups A and B were (29.80 ± 3.71; 28.30 ± 3.24) and (24.64 ± 3.83; 26.05 ± 4.66), respectively. Other variables like cause, duration of infertility and seminal parameters were similar in both groups. Primary Outcome: There was statistically significant odds favoring group B for higher number of MII oocytes (Odds ratio of 0.47; CI: 0.38–0.57; $p < 0.01$). Significantly higher number of MI and GVs were obtained in group A (4.78 vs. 2.76; $p < 0.01$) and (1.84 vs. 0.64; $p = 0.012$), respectively. Secondary Outcomes: Post trigger serum LH (IU/L) and progesterone (ng/ml) levels in group A and B were (42.79 ± 14.17; 41.27 ± 13.42) and (12.36 ± 3.50; 11.68 ± 2.65), respectively. Significantly higher numbers of blastocysts were obtained in group B than group A (4.00 vs. 3.04; $p = 0.023$). Both groups had no OHSS.
Limitations, reason for caution: Sample size was not statistically defined as this was a pilot study. A significant age difference ($p = 0.034$) between the two groups was obtained as the randomization was not stratified. As an extension of the study, we plan to evaluate the clinical pregnancy and live birth rates in frozen thawed embryo transfer cycles.
Wider implications of the findings: GnRH agonist trigger is a good strategy in PCOS and hyper-responders but an appropriate dosage for an optimal cycle outcome needs to be defined. This study clearly shows that a second dose of GnRHa 12hrs following the first dose probably by maintaining a sustained LH level yielded better maturity of oocytes and higher blastocysts than a single dose. Increase in the study population will allow us to confirm the present data.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Bangalore Assisted Conception Center.
Trial registration number: NA.

P-730 Effect of recombinant-LH and hCG on in vitro maturation (IVM), fertilization, and early embryonic development of mouse germinal vesicle (GV)–stage oocytes

V. Dinopoulou[1], S. Kefala[1], E. Kiapekou[1], R. Bletsa[1], E. Anagnostou[1], K. Kallianidis[1], D. Loutradis[1], P. Drakakis[1]
[1]*Division of Human Reproduction IVF Unit, 1st Department of Obstetrics and Gynaecology Alexandra Hospital Athens University Medical School, Athens, Greece*

Study question: Do recombinant-LH and hCG affect the *in vitro* maturation (IVM), fertilization, and early embryonic development of mouse germinal vesicle (GV)–stage oocytes in the absence of FSH?
Summary answer: Our study showed that hCG acts on Lhcgr (LH/hCG receptor) in oocytes of different stages of maturation increasing considerably the nuclear maturation rate. Furthermore the percentages of fertilization and early embryonic development increased when LH was added in hCG cultures of in vitro matured GV-stage oocytes.
What is known already: During IVM, intrinsic and extrinsic f-actors must cooperate properly in order to ensure cytoplasmic and nuclear maturation. LH and hCG are integral components of the HPA axis, which controls sexual maturation and functionality. Comparison of recombinant LH (key regulator of gonadal steroidogenesis and ovulation) and hCG (active in pregnancy and fetal development) for oocyte maturation in clinical IVM offers the possibility of investigating the effects of these gonadotrophins in a well-designed in vitro system.
Study design, size, duration: This prospective observational study was performed on a study population consisted of 100 female mice and 30 male mice (C57BL/6 × CBA) F1 hybrids, which were allocated in 15 sequential experiments of 5–8 female and 2 male mice each. The experiments were performed through an 8-month period.
Participants/materials, setting, methods: Nuclear maturation of GV oocytes was evaluated in the presence of r-LH or hCG. The oocytes were then fertilized to study the role of r-LH and hCG in the fertilization and early embryonic development. The expression of Lhcgr was examined at oocytes of different stages of maturation and early embryos.
Main results and the role of chance: The in vitro maturation percentages of mouse germinal vesicle (GV)–stage oocytes of the group supplemented with hCG were significantly higher compared to the control group. The rate of early embryonic development increased in the hCG and LH cultures of GV oocytes when LH was further added while this wasn't observed when hCG was further added. The LH/hCG receptor was expressed in all different stages of in vitro matured mouse oocytes (prophase I, metaphase I and II) as well as from zygotes and embryos of different stages of development (2-cells, 4-cells, morulae) using reverse transcriptase – polymerase chain reaction (RT-PCR).
Limitations, reason for caution: We used GV oocytes from F1 mouse only. Hormones were added in the culture medium but only an indirect late hormone effect could this study reveal. Recombinant FSH is added constantly to the culture medium in clinical IVM programs, thus a condition with FSH was not included in the study.
Wider implications of the findings: The advantages of oocyte IVM in assisted reproduction as an alternative to hormone stimulation for patients with polycystic ovary syndrome are clear. Cancer patients and patients with hormonally sensitive tumors would also benefit from IVM. Developing a widespread, safe, and effective method to extract oocytes from patients followed by IVM would allow them to produce embryos with their partners that can be frozen for later use and help mitigate their possible loss of fertility
Study funding/competing interest(s): Funding by University(ies) – The study was funded by and conducted at the IVF unit, 1st Department of Obstetrics and Gynecology, Alexandra Hospital, University of Athens Medical School, Athens, Greece.
Trial registration number: No registration number required.

P-731 Low-dose aspirin plus dexamethasone can improve the pregnancy rates of patients undergoing IVF-ET: a prospective clinical study

H. Z. Zhang[1], S. R. Xu[1]
[1]*Shenzhen Zhongshan Urological Hospital, Fertility Center, Shenzhen, China*

Study question: To determine the effects of aspirin and dexamethasone on pregnancy rates in patients undergoing in vitro fertilization (IVF) or intracytoplasmic sperm injection (ICSI) in agonist cycle regimen.
Summary answer: The use of low-dose aspirin and dexamethasone can improve the pregnancy rates in patients undergoing IVF or ICSI in agonist cycle regimen.
What is known already: The effect of aspirin and dexamethasone as adjunvant treatments in the IVF treatment is still controversial.
Study design, size, duration: Prospective clinical study. A total of 1,600 patients underwent the IVF/ICSI treatment in agonist regimen were recruited in this study from December 2012 to June 2013.

Participants/materials, setting, methods: A total of 1600 patients using agonist regimen were recruited. In the treatment group, 1041 patients received a daily dose of 100 mg of Aspirin and 0.75 mg of Dexamethasone from the beginning of the ovarian stimulation. In the control group 559 patients received no adjuvant treatment.
Main results and the role of chance: The mean age, basal FSH levels, antral follicle count, infertility etiology, endometrial thickness, and mean number of embryos replaced were similar between the two groups. However, a significantly higher clinical pregnancy rate (57.61% versus 51.60%, $P = 0.033$) and blastocyst formation rate (33.40% versus 30.82%, $P = 0.019$) were observed in the study group compared with the control group; Furthermore, the number of gonadotropin ampules used was decreased in the study group compared to the control group (32.35% versus 34.40%, $P < 0.001$).
Limitations, reason for caution: This study is a prospective clinical study without strict randomiztion. The sample size of the study group is much larger than the control group. Although the basic clinical characteristics is no different, the results of this study should be cautionly analysed.
Wider implications of the findings: The previous researches were mainly about the efficacy of use of Aspirin or Dexamethasone. The study of the combined use of low-dose Aspirin and Dexamethasone is quite limited. This is the largest study using Aspirin and Dexamethasone as co-treatment in IVF treatment. In this study, it was observed Aspirin and Dexamethasone can improve the clinical pregnancy rate and may augment the ovarian response of the patients.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Shenzhen Zhongshan Urological Hospital.
Trial registration number: NA.
Keywords: IVF, aspirin, dexamethasone, clinical pregnancy rate

P-732 Increased antral follicle count (AFC) does not attenuate the expected age-related decline in IVF-ET outcome and improves live birth rate only in young patients

A. Oppenheimer[1], A. K. Bartmann[1], E. Adda-Herzog[1], N. Achour-Frydman[2], V. Scarabin-Carré[1], R. Fanchin[1]
[1]*Centre Hosp. Antoine Béclère, Department of OB/GYN and Reproductive Medicine, Clamart, France*
[2]*Centre Hosp. Antoine Béclère, Department of Reproductive Biology, Clamart, France*

Study question: To clarify whether AFC differentially influences IVF-ET outcome in elderly and young patients
Summary answer: Increased AFC does not compensate for the expected decline in clinical pregnancy and live birth rates in elderly IVF-ET candidates but it is associated with a noticeable improvement of IVF-ET outcome in youngsters.
What is known already: Whereas, during aging, ovarian follicles become progressively scarce and reproductively incompetent, inter-individual variations exist in the pace of follicle loss. Moreover, follicle distribution over the various stages of growth changes, which leads to an increased antral/non-growing follicles ratio in elderly premenopausal women. Together, these physiologic features concur to explain, at least in part, why some normo-ovulating, no-PCOS women have above-average AFC despite their increasing age. Whether these quantitative variations reflect oocyte competence remains unclear.
Study design, size, duration: We studied selected youngster (26–32 years) and elderly (37–42 years) IVF-ET candidates, regularly-ovulating, devoid of PCOS, and undergoing 863 COH cycles. Prior to COH, all patients had either documented increased (20–24 follicles) or reduced (5–13 follicles) AFC (3–10 mm in diameter in both ovaries) at transvaginal ultrasound scans.
Participants/materials, setting, methods: According to age and AFC, patients were sorted into 4 groups as follows: Youngster-Increased AFC ($n = 167$), Youngster-Reduced AFC ($n = 208$), Elderly-Increased AFC ($n = 122$), and Elderly-Reduced AFC ($n = 366$). Clinical pregnancy and live birth rates were the outcome measures. In addition, serum AMH levels were assessed in all patients. Multivariate analysis was performed.
Main results and the role of chance: Clinical pregnancy and live birth rates were similar in Elderly-Increased (36.1% and 24.6%, respectively) or Elderly-Reduced (34.4% and 23.2%, respectively) AFC groups. Yet, in the Youngster-Increased AFC group, patients showed an improved IVF-ET outcome (55.1% and 46.7%) as compared to the Youngster-Reduced AFC (37.7% and 30.8%) group ($P < 0.001$ and $P < 0.002$, respectively). Similar results were obtained when using AMH instead of AFC to discriminating ovaries with good or defective follicle endowment.
Limitations, reason for caution: Pregnancy and live birth rates are often influenced by a wealth of factors. The present investigation attempted to controlling for most of them.
Wider implications of the findings: The present results indicated that, in IVF-ET candidates, the quantity of antral follicles recorded at ultrasound scans reflect the overall follicle health only in young patients (27–32 years). In elderly patients (37–42 years), even marked variations in AFC failed to influence the likelihood of live birth. These data are contributive for orientating clinical practice and raise unanswered questions on the mechanisms regulating the association between follicle quantity and quality during ovarian aging.
Study funding/competing interest(s): None
Trial registration number: NA.

P-733 The effects of thyroid autoimmunity presence on ovarian reserve in 117 women with euthyroid state

N. Dokuzeylül Güngör[1], A. Ersahin[1], B. Gorgen[1], F. Cengiz[1], S. Ersahin[2], K. Gungor[3]
[1]*Goztepe Medical Park Hospital, IVF and Genetics Center, Istanbul, Turkey*
[2]*Bahçelievler Medical Park Hospital, Perinatology, Istanbul, Turkey*
[3]*Medeniyet University Goztepe EA Hospital, Endocrinology, Istanbul, Turkey*

Study question: The aim of this study was to assess the effects of antithyroid, antibodies (ATA) presence on ovarian reserve
Summary answer: The presence of thyroid antibodies is associated with decreased ovarian reserve (DOR)
What is known already: Thyroid autoimmunity is the most common autoimmune state that affects up to 5–10% of women during the reproductive age. The relationship between thyroid autoimmunity and ovarian reserve has been investigated in some studies. Several studies have denied such an association whereas others have confirmed the presence of a negative relationship between these two parameters.
Study design, size, duration: This is a retrospective cohort study including 117 women positive for (ATA) at 18–38 years of age from November2014 to January2015 at our hospital.
Participants/materials, setting, methods: For ovarian reserve measurement we used AMH levels and antral follicle count. Thyroid function was tested by serum TSH and FT4 levels. Antithyroid peroxidase and antithyroglobulin antibodies (anti-TPO and anti-TG, respectively) were detected as markers for thyroid autoimmunity. Women were classified according to AMH levels. In group A, AMH ≤0.5 ng/ml and in group B AMH >0.5 ng/ml
Main results and the role of chance: No differences were observed between two groups regarding mean female age, mean BMI. There were significant differences observed between two groups regarding AMH levels (respectively; $P < 0.001$), Women with DOR had higher serum levels of anti-TPO in comparison to controls (40.9 ± 59.7 and 17.6 ± 10.7 IU/mL, respectively; $P < 0.05$) and no significant difference was found in serum levels of TSH, or FT4 between the two groups. Patients with DOR had a higher prevalence of positive results for anti-TG and/or anti-TPO in comparison to controls (25.6% and 5.3%, respectively; $P < 0.05$), anti-TPO alone (18.6% and 4.3%, respectively; $P < 0.05$) and anti-TG alone (22.4% and 4.5%, respectively; $P < 0.05$).
Limitations, reason for caution: Our results demonstrate a negative correlation between DOR and thyroid autoimmunity. However, our study does not consent to draw definitive conclusions and further evidence is required prior to show the effects of thyroid autoimmunity on ovarian reserve
Wider implications of the findings: There is a strong association between the presence of thyroid autoantibodies and DOR. High prevalence of thyroid antibodies in euthyroid patients with DOR refers to the importance of investigation for thyroid autoimmunity in those patients. Screening for thyroid disorders in women with DOR is controversial but might be important to detect thyroid autoimmunity to follow-up these parameters in these patients during pregnancy.
Study funding/competing interest(s): Funding by hospital/clinic(s) –There is no conflict of interest. No funding source.

Trial registration number: NA.

P-734 Randomised control trial of low dose gonadotropin in polycystic ovarian syndrome for controlled ovarian stimulation with GnRH agonist long protocol

P. Saini[1], A. Saini[1], A. Saini[2], A. Saini[3]
[1]*Saini IVF and Fertility Research Center, Human reproduction, Dehradun Uttranchal, India*
[2]*Monash University, Gynaecology and Obstetrics, Melbourne, Australia*
[3]*University of Adelaide, Reproductive Health, Adelaide, Australia*

Study question: Low dose (100 IU/day-112.5 IU/day) gonadotropin with Gonadotropin Releasing Hormone (GnRH) agonist long protocol in patients with polycystic ovarian syndrome (PCOS) results in multiple follicle development with minimal iatrogenic side effects.
Summary answer: Gonadotropins with GnRH agonist long protocol for controlled ovarian stimulation, leads to multiple follicle development, reducing risk of ovarian hyperstimulation syndrome (OHSS). Embryo transfer is done in the same cycle; extra embryos are cryopreserved, cost effective, providing flexibility to start ovarian induction at any point after desirable down regulation
What is known already: PCOS patients are difficult to stimulate as higher doses can lead to OHSS, a serious complication. IVM is used as an alternative for these patients, however success rates are limited. GnRH antagoinst is also a good substitute, but discrepancy in follicle size is seen and flexibility to start ovulation induction (OI) is a limiting factor.
Study design, size, duration: 400 cycles of PCOS patients 25–37 years, with duration of infertility 2–14 years, from January 2012 to December 2014 were selected and randomly distributed. PCOS patients with tubal blockage, male-factor infertility and endometriosis were included. Cycles were divided into two groups after down regulation with GnRH agonist long protocol.
Participants/materials, setting, methods: After all investigations, first group received recombinant FSH (100–112.5 IU/day) and second group 150 IU/day for 10–15 days. Oocyte retrieval was performed after 36 h of hCG injection. OI started when estradiol <50 pg/ml, endometrial thickness <5 mm, LH <5 mIU/ml and serum progesterone <1 ng/ml. Statistically analysed by Student's *t-test.*
Main results and the role of chance: Total dose of FSH, in-group one was significantly lower in comparison to group two, $p = 0.0003$. High E2 levels on day of HCG were also observed in both the groups. Symptoms of OHSS, such as abdominal pain, abdominal bloating, nausea and vomiting were noted in an increased number of patients in group two, which was statistically significant, $p < 0.05$. IVF cycles were cancelled in patients who complained about the above symptoms before the hCG injection. There were no cycles cancelled in the low dose group and statistical significance was also achieved when group one was compared to group two $p = 0.0268$.
Limitations, reason for caution: Dose of FSH could not be increased due to risk of severe hyper stimulation.
Wider implications of the findings: COH can safely be done in PCOS patients with low dose of gonadotropins with GnRH agonist long protocol for different indications. This avoids the risk of OHSS and extra embryos are available for cryo-preservation. This method can be a good alternative for *In-Vitro* maturation (IVM) and ovarian stimulation with GnRH antagonist.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Saini IVF and Fertility Research Centre, Dehradun, India.
Trial registration number: Not Applicable in India and consent from patients was taken before the treatment at the centre.
Keywords: gonadotropin releasing hormone (GnRH) agonist, polycystic ovarian syndrome (PCOS), ovarian hyperstimulation syndrome (OHSS), in-vitro maturation (IVM), human chorionic gonadotropin (hCG)

P-735 Follicle stimulating hormone and antral follicle count in combination better predicts live birth rate than anti-Mullerian hormone in women with diminished ovarian reserve

S. K. Goswami[1], P. Chakraborty[2], S. Ghosh[1], R. Chattopadhyay[1], B. N. Chakravarty[1]
[1]*Institute of Reproductive Medicine, ART, Calcutta, India*
[2]*Institute of Reproductive Medicine, Infertility, Calcutta, India*

Study question: This study aims to determine whether endocrine markers (anti-Mullerian hormone (AMH) and follicle stimulating hormone (FSH)) or ultrasound markers (antral follicle count (AFC)) are capable of predicting live birth rate after IVF among women with diminished ovarian reserve (DOR).
Summary answer: FSH in combination with AFC has a greater tendency to predict with live-birth after assisted conception. Although AMH, independently of age and assay used has an association with the same, however, its predictive accuracy in the particular cohort of women is less.
What is known already: Serum levels of FSH and AFC are commonly used as indicators, with high FSH levels and low AFC point to reduced reproductive potential. Since 2005, AMH has emerged as an established marker of ovarian reserve and a good predictor of poor or excessive ovarian response after controlled ovarian hyperstimulation; however, weakly associated with pregnancy following fertility treatment. It is debatable whether it can predict the ultimate outcome of assisted conception, live birth.
Study design, size, duration: A prospective cohort study was conducted from August 2013 to April 2014 including 512 women having irregular menstrual cycle and DOR who were referred to fertility treatment at our centre. The control group included 409 non-PCOS, poor responder infertile females undergoing fresh IVF treatment cycles using standard conventional protocol.
Participants/materials, setting, methods: FSH, LH, E_2 and AMH were measured by chemiluminescence. Serum FSH and AMH levels with AFC were assessed as predictors of clinical pregnancy. Data was compared using multivariate analysis and receiver operator characteristic (ROC) curve. Odds ratio (OR) was estimated as a measure to support ROC findings.
Main results and the role of chance: DOR cohort had lower ($p < 0.001$) AFC (4.42 ± 0.98 vs. 7.11 ± 1.23) and AMH (0.8 ± 0.2 vs. 2.1 ± 0.78) but higher basal FSH levels (9.8 ± 1.9 vs. 5.5 ± 2.1). In multivariate analysis the combination of AFC and basal FSH was superior ($p < 0.001$) to individual entity or AMH alone ($p < 0.007$). Area under curve (AUC) for each parameter according to ROC analysis revealed a combination of FSH and AFC (0.821) performed better in live birth prediction compared with AMH (0.673), basal FSH (0.534) and age (0.497). OR for women with DOR with the combination were 4.63 (95% CI: 2.75–7.81) in comparison to AMH 3.91 (95% CI: 1.85–4.78) and basal FSH alone (2.31 (95% CI: 1.56–3.11)).
Limitations, reason for caution: As conversion of AMH levels from different immunoassays are highly inaccurate, AMH Gen II assay (Beckman Coulter Ltd) was used which is currently the most reliable assay for AMH. Samples were determined by a single experienced laboratory technician and assay result precision was validated using linearity of dilution assessment.
Wider implications of the findings: The combination of AFC and basal FSH in predicting live birth is better than AMH. It recalls and re-establishes the age-old tool to envisage the occurrence of the ultimate outcome of assisted conception, live birth. Though serum AMH levels tend to be cycle independent, however, the diagnostic accuracy of the same in predicting live birth is poor. However, AMH should be considered as an alternative covariate while counseling couples before undergoing fertility treatment.
Study funding/competing interest(s): Funding by hospital/clinic(s) –The study was funded by our own private infertility centre: Institute of Reproductive Medicine.
Trial registration number: NA.

P-736 Age-related normograms of antral follicle count (AFC) – prospective cohort study of 3,677 infertility patients and 3,457 oocyte donors

S. Iliodromiti[1], C. S. Inglesias[2], M. Messow[3], M. Cruz[2], J. A. Garcia Velasco[2], S. M. Nelson[1]
[1]*University of Glasgow, Reproductive and Maternal Medicine, Glasgow, United Kingdom*
[2]*IVI Clinic Madrid, Reproductive Medicine, Madrid, Spain*
[3]*Roberston Institute University of Glasgow, Biostatistics, Glasgow, United Kingdom*

Study question: What is the normal age-related decline in AFC in fertile women and does this differ in subfertile women?
Summary answer: The association of log(AFC) with advancing age is linear. The age related decline in AFC is more pronounced in the subfertile population than in women with normal fertility potential.

What is known already: AFC is widely used to assess the fertility potential of individuals and guide stimulation protocols. The lack of technical and methodological standardisation of AFC measurement has limited the development of large population reference ranges. Small single centre studies have reported a linear negative association between age and AFC, however, models have not been validated and whether the same associations apply to fertile women is unknown.
Study design, size, duration: A large prospective study of 7,134 women undergoing AFC assessment on day 2 or 3 of their cycle across 13 fertility centres by 93 doctors from January to December 2013. 3677 out of them underwent investigations for subfertility and the rest (n = 3457) attended the clinics as potential oocyte donors.
Participants/materials, setting, methods: Identical protocol and machine characteristics were used for AFC assessment across the different centres. The infertility cohort was randomly split into training (1729) and validation (1728) dataset; with similar splitting for donors (1839, 1838). Candidate regression models were fitted on the training set and validated on the validation set.
Main results and the role of chance: Oocyte donors had a mean age of 25.4 years (range 18.0–38.0) and a mean BMI of 22.0 kg × m^{-2} (range 16.4–33.8). Infertility patients were older; (mean 36.6 years, range 22–45) and had a higher BMI (mean 23.1 kg × m^{-2}, range 15.8–49.3). Obstetric characteristics differed between the groups, with more termination of pregnancies and term births in oocyte donors. The linear model provided the most adequate fit in both the training and the validation dataset compared to more complicated nonlinear models (quadratic and piecewise linear). The age related decline in AFC was summarised as log(AFC) = 3.313–0.014*(age) for donors and log(AFC) = 4.551–0.063*(age) for infertility patients.
Limitations, reason for caution: The negative association of AFC with age is based on cross-sectional data so the longitudinal application of the model in predicting the decline of AFC in individuals across their reproductive lifespan requires further investigation. Oocyte donors may have been on hormonal contraception at the time of the AFC measurement.
Wider implications of the findings: This is the first internally validated normogram describing the age related decline in AFC with 95% confidence intervals for both fertile and subfertile women. The normograms can be used in other populations with similar baseline characteristics to infer the normal range of AFC for a given age. External validation of the normograms in populations with different characteristics will grant additional validity on the predicted age specific variation in AFC.

P-737 MicroRNA (miRNA) signature in granulosa cells specific to polycystic ovary syndrome (PCOS)

A. Aydos[1], A. Gurel[2], Y. Oztemur[1], C. Kaya[3], T. Aksu[4], B. Gur Dedeoglu[1]
[1]*Ankara University, Biotechnology Institute, Ankara, Turkey*
[2]*HRS Women Hospital, IVF Department, Ankara, Turkey*
[3]*TOBB-ETU Hospital, Department of Gynecology and Obstetrics, Ankara, Turkey*
[4]*HRS Women Hospital, Department of Gynecology and Obstetrics, Ankara, Turkey*

Study question: The aim of this study is to identify the expression profiles of miRNAs in granulosa cells which is one of the somatic cells of oocyte microenvironment, obtained from PCOS patients compared to normal samples.
Summary answer: As a result of this study 3 miRNAs that have not been previously associated with PCOS were identified.
What is known already: miRNA expression studies in the oocytes and ovaries are still at the very beginning and the roles of miRNAs expressed in oocytes or ovarian somatic cells (theca, granulosa, cumulus), have still not been revealed in reproductive infertility disorders such as PCOS.
Study design, size, duration: In this study, miRNA microarray analysis was conducted with granulosa cells obtained from 14 PCOS patients and 9 healthy controls that are subjected to in vitro fertilization (IVF) procedure.
Participants/materials, setting, methods: Microarray study was performed with Affymetrix miRNA 3.0 array system and data analysis was performed with BRB-ArrayTools to find out differentially expressed (DE) miRNAs. Identification of predicted target genes of DE miRNAs and pathway enrichment analysis was performed by databases. Target genes were validated bioinformatically by an independent microarray study.
Main results and the role of chance: Among the DE miRNAs 2 were found to be upregulated while one of them was found to be downregulated (up to 2.35 fold and -1.9 fold, respectively; $p < 0.05$). 58 of the predicted miRNA target genes like LDLR, TGFB1, PRKACA were validated with an independent microarray study (GSE34526). The validated target genes were found to be enriched significantly in pathways like MAPK, TGF-ß, ovarian steroidogenesis and insulin signaling pathway, which were previously associated with PCOS ($p < 0.019$).
Limitations, reason for caution: The study was performed with human granulosa cells which were isolated from follicular fluid. Follicular fluid was obtained from patients during IVF procedure.
Wider implications of the findings: The validation of the target genes with an independent study increases the reliability of the relationship of these miRNAs with PCOS. The data obtained in this study emphasizes the potential roles of miRNAs in the molecular regulation of oocyte microenvironment in PCOS.

P-738 Impact of vitamin D levels on ovarian reserve and ovarian response to ovarian controlled hyperstimulation in egg donors

C. Iglesias[1], A. Fabris[1], A. Pacheco[1], H. M. Fatemi[2], J. A. Garcia-Velasco[1]
[1]*IVI Madrid, Reproductive Medicine, Madrid, Spain*
[2]*Nova IVI Fertility, Reproductive Medicine, Abu Dhabi, United Arab Emirates*

Study question: Is there any correlation between total and bioavailable serum 25-OH vitamin D, ovarian reserve and ovarian response to controlled stimulation in egg donors. Do they correlate with recipients' pregnancy outcome?
Summary answer: Total and bioavailable vitamin D did not correlate with ovarian reserve and ovarian response to OCH in egg donors. Patients receiving oocytes from vitamin D deficient donors had lower implantation rates, but similar gestational rates. Bioavailable vitamin D did not influence any investigated parameter.
What is known already: There is a global epidemic of vitamin D carency. Studies on its role in human reproduction are controversial. Some demonstrated worse outcome of assisted reproductive technologies in vitamin D non replete patients. A diffuse theory is that vitamin D currency reduces endometrial receptivity. On the contrary we failed to find any correlation of the vitamin and the reproductive outcome in oocytes recipients. Few authors investigated correlations between vitamin D and ovarian function.
Study design, size, duration: Retrospective study on a total of 269 egg donors who were submitted to 310 cycles of ovarian stimulation from June 2013 to April 2014
Participants/materials, setting, methods: 269 egg donors, treated in our University affiliated clinic, we analyzed serum total and bioavailable vitamin D and their relation with antimullerian hormone (AMH), antral follicular count (AFC), number of total and mature oocytes retrieved. We also investigated differences in gestational outcome of their recipients.
Main results and the role of chance: Among all donors, 23 (8.5%) were vitamin D replete (vitamin D >30 ng/ml), 94 (34.9%) had vitamin D insufficiency (20–30 ng/ml) and 152 (56.3%) presented deficiency (<20 ng/ml). AFC and AMH were similar in the three groups. Number of oocytes retrieved, number and rate of mature oocytes and cycle characteristics were comparable in the three groups. Implantation rate was lower in patients receiving oocytes from vitamin D deficient donors compared to replete ones with a difference of -1.843 (P 0.04), while pregnancy rates were independent from donors' total serum vitamin D. Bioavailable vitamin D did not correlate to ovarian reserve and response nor with recipients' reproductive outcome.
Limitations, reason for caution: Being a retrospective study with a limited sample size and the fact that implantation is slightly lower just comparing the group of vitamin D replete and deficient donors with a p value very near to 0.05 ($p = 0.04$), while bioavailable vitamin D has no influence on reproductive outcome
Wider implications of the findings: Donors who are not vitamin D replete nor had a decreased ovarian reserve neither a lower response to COH. Further

studies on patients are necessary to confirm the lack of influence also in a population of infertile women. Lower implantation rate of embryos coming from vitamin D deficient donors could reflect lower oocyte and embryo quality but the etiopathogenetic mechanisms by which they could be affected have still to be investigated. The effect of the supplementation with D vitamin in these patients should be validated in larger trials as well as intervention studies.

P-739 High prevalence of vitamin D deficiency in female patients from an Italian assisted reproduction center

L. Pagliardini[1], L. Privitera[1], M. T. Potenza[1], P. Persico[1], M. Molgora[1], E. Marsiglio[1], P. Giardina[1], E. Papaleo[1]
[1]*IRCCS San Raffaele Scientific Institute, Obstetrics and Gynecology Unit, Milan, Italy*

Study question: What is the baseline vitamin D profile of women attending an infertility center and what are its non-dietary determinants?
Summary answer: Vitamin D serum levels are highly deficient in women seeking medical help for couple's infertility and are significantly associated with body composition, seasonal modifications and specific causes of infertility.
What is known already: Vitamin D is known to be involved in many processes of the human reproductive system in both genders. Assisted Reproduction Technology (ART) represents a valuable model to draw inferences on vitamin D deficiency in specific aspects of human fertility as it allows to evaluate separately the various steps of the reproductive process. Negative effects of vitamin D deficiency on clinical pregnancy outcomes have been reported although the debate in this regard is still open.
Study design, size, duration: This was a cross-sectional analysis of a cohort of 1072 women attending a single Italian academic infertility center between January 2011 and December 2013.
Participants/materials, setting, methods: Serum levels of 25-hydroxy-vitamin D [25(OH)D] was analyzed in relation to demographic characteristics, seasons, causes of infertility and selected general health risk factors. Both unadjusted and adjusted levels of serum 25(OH)D were examined. Data for global solar radiation were also correlated with 25(OH)D levels.
Main results and the role of chance: Serum 25(OH)D circulating levels fluctuated according to a seasonal cycle. Median 25(OH)D concentration was below 30 ng/ml for 89% of the entire year. Over the whole year, 6.5% of patients had 25(OH)D levels ≤10 ng/ml, 40.1% ≤20 ng/ml, and 77.4% ≤30 ng/ml. Relative proportions of patients with serum 25(OH)D concentration below all the three cutoff levels analyzed were always significantly higher in the first year trimester compared to the third and fourth trimesters. Global solar radiation was weakly correlated with vitamin D levels. At multivariable analysis, 25(OH)D levels were inversely associated with weight ($p = 0.0003$); conversely, 25(OH)D levels were positively associated with height ($p < 0.0001$) and a history of endometriosis ($p = 0.033$).
Limitations, reason for caution: The cross-sectional design may limit casual inference on the effects of season and infertility causes on vitamin D status. Moreover, our results were derived from a single center in Northern Italy, therefore we are uncertain that our results are generalizable to other infertility centers across the country and in other countries.
Wider implications of the findings: The high prevalence of vitamin D deficiency in infertile women referring to an ART procedure is likely to be mirrored by a similar prevalence during pregnancy. More in general, the demonstration of an advantage of having adequate levels of vitamin D in ART cycles would be strengthened by the potential subsequent advantage also in terms of prevention of obstetrics complications.

P-740 Altered expression of homeobox (HOX) family genes in cumulus cells of mature MII oocytes from patients with polycystic ovary syndrome

P. Asiabi Kohneh Shahri[1], M. Shahhoseini[2], R. Favaedi[2], F. Hassani[3], B. Movaghar[3], L. Karimian[3], P. EftekhariYazdi[3]
[1]*Faculty of Basic Sciences and Advanced Technologies in Biology at University of Science and Culture, ACECR, Tehran, Iran*
[2]*Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine ACECR, Tehran, Iran*
[3]*Department of Embryology at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine ACECR, Tehran, Iran*

Study question: Is there any correlation between altered expression of *Homeobox (HOX)* family genes in cumulus cells (CCs) of mature MII oocytes and polycystic ovary syndrome (PCOS)?
Summary answer: Several members of *HOX* family genes showed significantly differential expression profile in CCs of PCOS patients *vs.* fertile women with male infertility problems. Present alterations may cause the abnormal folliculogenesis and reduce oocyte competence in PCOS patients.
What is known already: Polycystic ovary syndrome (PCOS) is the most common cause of anovulatory infertility which associated with altered gene expression profiles in oocyte and its enclosing cells. Of essential genes for development of Müllerian tract in the embryonic period and adult function are *HOX* family genes. As the important role of CCs in successful folliculogenesis, oocyte maturation, ovulation and fertilization; evaluation of correlation between expression of *HOX* genes and PCOS can represent better insight into mentioned disorder.
Study design, size, duration: This is a case-control laboratory study involving 20 PCOS patients and 20 fertile women with male infertility problems aged 18–36 year old, referred to the Royan Institute to underwent IVF-ICSI with GnRH antagonist protocol between 15 February 2014 and 20 December 2014. Informed consents were obtained from the participants.
Participants/materials, setting, methods: Thirty six hours after hCG injection, ovaries were punctured and cumulus oocyte complexes were dissected. Cumulus cells were collected from 223 and 191 MII oocytes of PCOS and fertile women, respectively. After RNA extraction and cDNA synthesis qRT-PCR was performed using specific primers for *HOXA1-5, HOXB1-5, HOXC4-5* and *HOXD1-4* genes.
Main results and the role of chance: Expression profile of *HOX* family genes of CCs, revealed significant decrease in mRNA levels of *HOXA1*, *HOXC4* and *HOXD4* ($p \leq 0.05$) and significant increase in *HOXA2*, *HOXA3*, *HOXA5*, *HOXB1*, *HOXB2*, *HOXB4* and *HOXB5* ($p \leq 0.05$) in PCOS patients *vs.* control group. There were no significant changes in expression levels of *HOXA4*, *HOXB3*, *HOXC5*, *HOXD1* and *HOXD3* ($p \leq 0.05$) among two studied groups.
Limitations, reason for caution: Owing to the strict selection criteria (the same stimulating protocol, without chromosomal defects, having no special disease and ovarian cautery), and since total number of oocytes for each participant were between 5 and 20 with more than 93% MII, this study included small sample size. Thus, further investigations using a large cohort of participants are needed to confirm these results.
Wider implications of the findings: These findings imply significant correlation between altered expression of *HOX* family genes and PCOS disorder and provides new insights to understand the pathogenesis of PCOS.
Study funding/competing interest(s): Funding by national/international organization(s) – Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran.
Trial registration number: NA.
Keywords: PCOS, HOX family genes, MII oocyte, cumulus cells

P-741 Exercise training reduces acute physiological severity of menopausal hot flushes

T. Bailey[1], N. T. Cable[2], N. Aziz[3], D. A. Low[4], H. Jones[4]
[1]*Liverpool John Moores University UK and University of the Sunshine Coast Australia, Rises, Liverpool, United Kingdom*
[2]*ASPIRE Qatar, ASPIRE academy, Doha, Qatar*
[3]*Liverpool Women's Hospital UK, Reproductive Medicine, Liverpool, United Kingdom*
[4]*Liverpool John Moores University, Rises, Liverpool, United Kingdom*

Study question: We aimed to determine whether the acute physiological severity of HFs, measured objectively are responsive to intervention, by comparing the thermoregulatory and (cerebro)vascular changes that occur during HFs following exercise training.
Summary answer: This is the first study to demonstrate that objective physiological responses during HFs are responsive to an exercise intervention. Supervised exercise training reduces the frequency, subjective severity and the acute physiological severity of menopausal HFs in symptomatic females.

What is known already: Menopausal hot flushes (HF) occur due to a reduction in oestrogen causing thermoregulatory and vascular dysfunction. A HF consists of a feeling of intense heat, skin reddening, cutaneous vasodilation (CVC), profuse elevations in sweating, heart rate, and reduced blood pressure and brain blood flow, with a combination of these factors defining HF severity. Exercise training enhances thermoregulatory responsiveness of sweating, CVC and improves brain blood flow that may reduce menopausal HF.
Study design, size, duration: Feasibility study; Seventeen symptomatic postmenopausal females were recruited for this via the Liverpool Women's Hospital and local G.P practices and performed either 16 weeks of supervised exercise training (n = 10, 52 ± 4y, 29 ± 6 kg/m^2) or a no-exercise control intervention (n = 7, 52 ± 6y, 30 ± 7 kg/m^2). Intervention was based on patient choice and not randomly assigned.
Participants/materials, setting, methods: A heat stress (48ºC water-perfused suit) was used to induce HF. Sweat rate, CVC, blood pressure, heart rate, middle-cerebral artery velocity (MCAv) were measured during the HF. HF were objectively identified and divided into eight equal segments for analysis. Females also subjectively rated HF's over 7 days.
Main results and the role of chance: Exercise training decreased HF duration by 63s (95% CI: 14, 113) compared to of 17s (95% CI: -43, 66) following control (P = 0.08). During the HFs sweat rate decreased by 0.04 mg·cm^2·min^{-1}(95% CI: 0.02, 0.06) after exercise training compared to no change in control (P < 0.005). This was accompanied by a reduction in chest CVC of 26 AU (95% CI: 21, 30) following exercise training compared to no change in control (P = 0.01). MCAv was attenuated by 3.4 cm/s (95% CI, 0.7, 5.1) during a HF following exercise training compared to control [0.6 cm/s (95% CI, -0.7, 1.8) P = 0.04]. Exercise training reduced HF frequency [39 (47, 31) vs 5 (16, 6) HF·wk] and severity [101 (121, 80) vs 9 (37, 20) AU] compared to control (P < 0.005).
Limitations, reason for caution: Preliminary evidence, to further establish these positive effects, a RCT that assesses the effects of exercise training compared to a no-exercise control is warranted. Importantly, a RCT would allow for a mediation analysis on the data to highlight the causal pathway(s) for the benefits of exercise training on HF.
Wider implications of the findings: This is the first study to show that the physiological changes that occur during HF are responsive to an intervention. Supervised exercise training reduces the frequency, subjective severity and the acute physiological severity of menopausal HFs in symptomatic females. Exercise training could be implemented at low cost by sympomatic females. Once recommendations about exercise prescription are established, this information can be communicated via clinicians and other health professionals.

P-742 The contribution of FSH receptor polymorphism on ovarian response and treatment efficiency following stimulation with FE 999049, a recombinant FSH from a human cell-line

J. C. Arce[1]
[1]*Ferring Pharmaceuticals, Global Clinical R&D (Reproductive Health), Copenhagen, Denmark*

Study question: What is the relation between different FSH receptor (FSH-R) single-nucleotide polymorphisms (SNPs) and ovarian response and gonadotropin use in patients undergoing controlled ovarian stimulation with FE 999049?
Summary answer: The pharmacodynamic parameters of gonadotropin stimulation, including number of oocytes retrieved, were significantly influenced by the daily FE 999049 dose and the patient's anti-Müllerian hormone (AMH). In the AMH range studied, the SNP FSH-R profile did not contribute with additional significant predictive value of ovarian response beyond that already explained by daily FE 999049 dose and AMH. Concerning treatment efficiency, daily FE 999049 dose predicted total dose and duration of stimulation, while neither AMH nor SNP FSH-R profile added significant predictive value.
What is known already: Threonine (Thr) rather than alanine (Ala) at position 307, serine (Ser) rather than asparagine (Asp) at position 680, and an AA genotype in the -29 position in the promotor region have been associated with reduced ovarian response and/or increased exogenous gonadotropin consumption.
Study design, size, duration: Planned analysis of a RCT (Arce et al, Fertil Steril 2014) where 222 IVF/ICSI patients underwent stimulation with FE 999049 at fixed doses of 5.2, 6.9, 8.6, 10.3 or 12.1 mg/day. Randomisation was stratified by serum AMH (low stratum: 5.0–14.9 pmol/L, high stratum: 15.0–44.9 pmol/L; Beckman Coulter Gen2 ELISA).
Participants/materials, setting, methods: Genomic DNA was analysed for SNP at positions -29, 307 and 680 of the FSH-R at the University of Modena and Reggio Emilia, Italy. ANCOVA models were used to determine the predictive value (as expressed by R^2, the proportion of variation explained) on estradiol, inhibin A, inhibin B and follicles at end of stimulation and number of oocytes retrieved as well as total gonadotropin consumption and duration of stimulation. The ANCOVA models for the endocrine parameters included the respective log-transformed baseline values obtained at stimulation day 1. The ANCOVA model for oocytes retrieved included sites. Log(dose) was included as covariate while AMH strata and SNP at positions -29, 307 and 680 were included as factors in these models.
Main results and the role of chance: Distribution of SNP FSH-R combinations: AA 7%, AG 35% and GG 58% for position -29; Thr/Thr 29%, Ala/Thr 54% and Ala/Ala 17% for position 307; and Asn/Asn 30%, Asn/Ser 53% and Ser/Ser 17% for position 680. The distribution for each position and for the overall combinations were not significantly different between the low and high AMH strata.

Frequency of SNP FSH-R (-29,307,680)

A-Thr-Asn/A-Thr-Asn	3%
A-Thr-Asn/A-Ala-Ser	3%
A-Ala-Ser/A-Ala-Ser	1%
A-Thr-Asn/G-Thr-Asn	10%
A-Thr-Asn/G-Ala-Ser	20%
A-Ala-Ser/G-Ala-Ser	5%
G-Thr-Asn/G-Thr-Asn	16%
G-Thr-Asn/G-Ala-Ser	30%
G-Ala-Ser/G-Ala-Ser	11%

Regarding ovarian response, daily FE 999049 dose and AMH were both significant (p < 0.001) predictors of estradiol, inhibin A, inhibin B and follicles at end of stimulation as well as of oocytes retrieved. SNP had no additional significant predictive value on any of these parameters.

ANCOVA for number of oocytes retrieved

	R^2	p
FE 999049 dose	0.208	< 0.001
FE 999049 dose + AMH	0.328	< 0.001
FE 999049 dose + SNP-29	0.217	0.325
FE 999049 dose + SNP307	0.220	0.218
FE 999049 dose + SNP680	0.218	0.286
FE 999049 dose + SNP-29 + SNP307 + SNP680	0.247	0.324

Regarding treatment efficiency, daily FE 999049 dose was a significant predictor of total dose (R^2 = 0.564, p < 0.001) and duration of stimulation (R^2 = 0.215, p < 0.001) with no additional significant predictive value of AMH or SNP on these parameters.
Limitations, reason for caution: The present investigation is applicable for FE 999049, a recombinant FSH derived from a human cell-line. The trial included mainly Caucasians and was limited to patients within a specified AMH range. The analysis was restricted to three positions on the FSH-R.
Wider implications of the findings: In this investigation, FSH-R SNP had no relevance beyond daily gonadotropin dose and AMH in predicting ovarian response and gonadotropin efficiency in patients undergoing controlled ovarian stimulation with FE 999049. As FSH-R SNP as a stand-alone parameter has previously been associated with ovarian response and treatment efficiency, it should be considered to include daily gonadotropin dose and AMH in future analyses as well as to investigate different gonadotropin preparations to provide further clarity on the role of FSH-R SNP.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Ferring Pharmaceuticals.
Trial registration number: NCT01426386.
Keywords: single-nucleotide polymorphism, FSH receptor gene, AMH, FE 999049, ovarian response

P-743 To evaluate which factors determine the incidence of extremely elevated progesterone on the day of HCG administration

Y. R. Tsai[1], K. C. Lan[1]
[1]*Kaohsiung Chang Gung Memorial Hospital, Department of Obstetrics and Gynecology Kaohsiung Chang Gung Memorial Hospital, Kaohsiung City, Taiwan R.O.C.*

Study question: To investigate which factors caused the extreme progesterone (P4) elevation on the day of human chorionic gonadotropin (hCG) administration.
Summary answer: The most strong factor related with the extremely elevated P4 concentration on the day of human chorionic gonadotropin (hCG) administration is the choice of the GnRH agonist protocol(odd ratio:2.786).
What is known already: Extremely high P4 concentrations on the day of hCG administration has an obvious negative impact on pregnancy outcome and the live birth rate. The variable factors which would increase the incidence of extreme progesterone elevation on the day of HCG administration are still not clear.
Study design, size, duration: This is a retrospective observational, single-center cohort study. The data was collected from infertile couples who underwent 2,000 fresh IVF and/or intracytoplasmic sperm injection (ICSI) embryo transfer cycles from January 2000 to December 2014 in our institution
Participants/materials, setting, methods: This retrospective observational, single-center cohort study was based on the medical records of infertile couples undergoing IVF treatment. To further analyze the association between variable factors involved in extreme progesterone elevation on the day of HCG administration, multivariate logistic regression was performed.
Main results and the role of chance: When all cycles were divided into those with P4 < 1.94 ng/ml(*n*:1791) and 1.94 ng/mL(*n*:209) on the day of hCG administration, we found no statistically significant difference between the groups in female age, BMI, body height, primary or secondary infertility, etiology of infertility, LH used or not, and the number of oocytes retrieved. Only five factors: protocol choice (GnRH agonist or GnRH antagonist), the number of dominant follicle, LH values on the day of hCG administration, total FSH dosage, and E2 on day of hCG administration were positively associated with extremely elevated P4 concentration(odd ratio:2.786,1.098,1.085,1.023,1.001, $p < 0.001$ for all). After omitting the antagonist cycles, no factors were statistically significantly associated with extremely elevated P4 concentration in GnRH agonist group.
Limitations, reason for caution: This present study is retrospective cohort study
Wider implications of the findings: The total FSH dosage, luteinizing hormone values on the day of hCG administration, estradiol values on the day of hCG administration, and the number of dominant follicles (>1.6 cm) could only slightly increase the incidence of extremely elevated progesterone on the day of HCG administration in this present study. Clinicians should consider shifting the GnRH agonist protocol to GnRH antagonist protocol in women who had previous cycle associated with extremely elevated P4 concentrations.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Department of Obstetrics and Gynecology, Kaohsiung Chang Gung Memorial Hospital.
Trial registration number: This is not an RCT.
Keywords: extremely elevated progesterone, GnRH agonist

P-744 The effect of LH-activity components contained in HMG on the clinical outcomes during progestin-primed ovarian stimulation in normalovulatory women undergoing IVF/ICSI treatments compared with u-FSH

X. X. Zhu[1], Q. J. Chen[1], A. Ai[1], Y. L. Fu[1], R. F. Cai[1], H. Tian[1], Y. Wang[1], Q. Q. Hong[1], Q. F. Lyu[1], Y. P. Kuang[1]
[1]*Shanghai Ninth People's Hospital, Department of Assisted Reproduction, Shanghai, China*

Study question: To evaluate the effect of LH-activity components(LH and HCG) contained in HMG preparations on the clinical outcomes of normalovulatory women undergoing IVF/ICSI treatments in the progestin-primed ovarian stimulation(PPOS)protocol in terms of the hormone profile, embryo results and pregnant outcomes after frozen embryo transfer(FET)compared with urinary FSH
Summary answer: There were no significant correlations between the concentration of serum LH, serum b-hCG, and urinary b-hCG on the trigger day and embryological characteristics which indicated LH-activity components contained in HMG preparations had no influence on the clinical outcomes during PPOS
What is known already: Premature LH surges can be inhibited by natural progesterone secreted by corpus luteum or medroxyprogesterone acetate(MPA)during ovarian stimulation without down-regulation in normalovulatory women, which were concluded both in the follicular-phase and luteal-phase ovarian stimulation in combination with' freeze-all' strategy. It was still a controversy whether LH-activity components contained in HMG preparations affected the clinical results in down-regulation protocol, while no relevant investigations were reported in PPOS
Study design, size, duration: 180 patients were recruited from September to November in 2014 in this prospective controlled cohort study and allocated into three groups according to the gonadtropin used: group A, u-hMG-A(containing 16.77IU HCG per 75 IU HMG); group B, u-HMG-B(containing 7.86IU HCG per 75 IU HMG);group C, u-FSH(containing only FSH)
Participants/materials, setting, methods: Normalovulatory patients with 25–40 years old were eligible to participate. MPA 10mg/d and Gn 225IU were administered from cycle day 3. When the dominant follicles reached mature, GnRH-a 0.1mg and HCG 1000IU were used for trigger. The clinical results were compared in terms of the types of Gn, levels of β-hCG and LH.
Main results and the role of chance: The number of oocytes retrieved in group A, B, C was 10.72 ± 5.78, 11.33 ± 5.19 and 13.38 ± 8.97, respectively, with no statistic significance ($p > 0.05$). Other indicators such as the number of mature oocyte, fertilization, cleavage and viable embryos were similar ($p > 0.05$). The LH level on the trigger day ranged from 0.1 mIU/ml to 6.44 mIU/ml, with no premature LH surges detected, have no relation with embryo results ($p > 0.05$). The concentration of serum and urinary β-hCG on the trigger day were higher in group A than group B (3.12 ± 1.77 mIU/ml vs 1.9 ± 0.73 mIU/ml, 6.76 ± 5.05 mIU/ml vs 4.43 ± 3.01 mIU/ml, $p < 0.05$), which were not associated with embryo results ($p > 0.05$). There were no significant difference in the clinical pregnancy rate after FET among the three groups (41.46% vs 51.43% vs 41.46%, $p > 0.05$)
Limitations, reason for caution: The sample size is limited as a preliminary trial, therefore, a well designed, adequately powered, randomized, controlled trial should be undertaken to verify these findings
Wider implications of the findings: Our study concluded the clinical characteristics were not affected by the LH-activity components contained in HMG in normalovulatory women undergoing PPOS. The hormone indicators in urine were introduced for the first time in this study to reflect the state of Gn metabolism in different individuals. Further studies will be performed to optimize and individualize the selection of Gn undergoing PPOS in different populations with advanced age, poor responders or polycystic ovarian syndrome (PCOS).
Study funding/competing interest(s): Funding by national/international organization(s) – This study was funded by the Natural Science Foundation of Shanghai (grant number: 14411964300).
Trial registration number: The trial was registered with the Chinese Clinical Trial Registry (ChiCTR-OPN-14005276).
Keywords: urinary HMG, human chorionic gonadotropin, luteinizing hormone, progestin-primed ovarian stimulation, frozen embryo transfer

REPRODUCTIVE EPIDEMIOLOGY, SOCIO-CULTURAL ASPECTS AND HEALTH ECONOMY

P-745 A prospective randomized controlled study (RCT) depicting favourable IVF-ICSI outcomes following anti-tubercular treatment on the sole basis of abnormal hysteroscopic findings

A. Jindal[1], M. Singh[1], R. Singh[1], P. C. Jindal[1]
[1]*Bhopal Test Tube Baby Centre, Infertility, Bhopal, India*

Study question: Does anti-tubercular treatment (ATT) on the sole basis of abnormal hysteroscopic findings yield better IVF-ICSI outcome in developing countries like India with a very high prevalence of Tuberculosis disease?

Summary answer: Yes, infertile women given anti-tubercular treatment (ATT) for abnormal hysteroscopic findings suggestive of tubercular mycobacterial infection had better IVF-ICSI outcome.
What is known already: Genital Tuberculosis is a major cause of infertility in developing countries like India. Prompt anti-tubercular treatment (ATT) can dramatically improve female reproductive function. *The prevalence of the* disease is steadily increasing and has emerged in previously unrecognized populations. The diagnosis is often difficult or unconvincing.
Study design, size, duration: 682 infertile patients below 42 years were evaluated by laparoscopy and hysteroscopy between July 2006 and December 2014. Out of these, 138 patients having abnormal hysteroscopic findings were prospectively randomised into Anti-Tuberculosis treatment and non-treatment groups by a computer generated list, before undergoing IVF-ICSI cycles.
Participants/materials, setting, methods: This was an intervention study done on 138 positive abnormal hysteroscopic women who were randomized into two groups, of 58 patients each, one receiving standard anti-tubercular treatment and the other receiving no treatment before IVF/ICSI cycles. Out of 138 patients, 22 were excluded from the study either because of failure to comply to drug therapy, or other reasons. The primary outcome measured was the implantation rate and cumulative pregnancy rate following IVF-ICSI, and the secondary outcome was the miscarriage rate.
Main results and the role of chance: There was a statistically significant difference between the two groups, the cumulative pregnancy rate being higher following IVF-ICSI in the group who took prior anti tubercular treatment (39% (23/58) versus 21% (12/58)). Although the miscarriage rate was lower in the treatment group, it was not statically significant (15% (3/20) versus 17% (2/12)).
Limitations, reason for caution: The presence of mycobacterial DNA (TB-PCR) is considered as more sensitive for TB than a positive TB smear for diagnosis and treatment TB (Menzies et al., 2011). Further, there are some limitations of the PCR test itself such as the contamination leading to false positive and the presence of inhibitory substance to false-negative tests (Laifer et al., 2004). We also could not include the study of other markers of infertility in the endometrium which would suggest the TB involvement. The group of women in this study had a high clinical probability of TB in our settings after exclusion of other causes of infertility.
Wider implications of the findings: Indication for the treatment of tuberculosis mycobacterial infections is not easy to define due to difficulty in obtaining appropriate tissue samples for mycobacterial smear and culture positivity. In resource poor developing countries where IVF-ICSI cycles are self-funded and difficult to afford, prior treatment of abnormal hysteroscopic findings of tuberculosis mycobacterial infection cases with no other demonstrable cause improves the IVF-ICSI results.
Study funding/competing interest(s): Funding by hospital/clinic(s) –BTTB CENTRE.
Trial registration number: BTTBC/2006/07.
Keywords: genital-tuberculosis, abnormal-positive-hysteroscoy, antitubercular-treatment(ATT), IVF-ICSI, pregnancy-rate

P-746 Frozen-thawed embryo transfer (FET) after elective single embryo transfer is cost-effective for up to two FET cycles

Z. Veleva[1], H. Martikainen[2], S. Mäkinen[3], C. Hydén-Granskog[1], H. Oksanen[1], A. Tiitinen[1], J. S. Tapanainen[1]
[1]*University of Helsinki and Helsinki University Hospital, Obstetrics and Gynecology, Helsinki, Finland*
[2]*University of Oulu and Oulu University Hospital, Obstetrics and Gynecology, Oulu, Finland*
[3]*Family Federation of Finland, Helsinki and Oulu infertility Clinics, Helsinki, Finland*

Study question: What is the impact of consecutive frozen-thawed embryo transfer (FET) cycles on cumulative live birth rate (cLBR) after elective single embryo transfer (eSET) in the fresh cycle?
Summary answer: FET is cost-effective and cLBR increases significantly until the second FET, but if the treatment has resulted in a live birth, all remaining embryos should be transferred.
What is known already: eSET in the fresh IVF or ICSI cycle minimizes the incidence of multiple pregnancies. Usually, one or more supernumerary good quality embryos are frozen and transferred in FET cycles, but the impact of the number of FET following the fresh cycle on cLBR and costs has not been investigated.
Study design, size, duration: This cost-effectiveness analysis examined consecutive treatment cycles performed during January 2000–June 2013 in three infertility clinics. Total number of collected cycles was 23826, from which we analyzed 2771 first eSET cycles (January 2000–June 2011) followed by 4230 FET cycles (January 2000–June 2013).
Participants/materials, setting, methods: In each FET, the best available embryo container was thawed. cLBR/stimulation was calculated after one, two and ≥3 FET. Cycles were analyzed until the second live birth. Incremental cost-effectiveness ratios (ICERs) for change in cost/change in live births used our previously published data on fresh and FET cycle costs.
Main results and the role of chance: cLBR (first birth) increased from 46.8% (1296/2771) after the first FET to 51.0% (1413/2771, $P < 0.0001$) after the second FET and to 53.4% (1480/2771, $P > 0.2$) after ≥3 FETs. After the first birth, 683 couples (46.2%) continued treatment and 30.2% (206/683) had a second birth. 22% of these (46/206) occurred after the third consecutive FET. A live birth cost 8954 in the fresh cycles and 3393 in FET. ICER of a first birth was lowest after the first FET vs. fresh cycles (2646 /birth), gradually increasing to 3217 /birth after ≥3 FETs. The second birth vs. first had higher FET costs (1975 € /birth). However, total costs of the second birth were much lower than those of the first birth with ICER 6975 € /birth.
Limitations, reason for caution: About 8% of women would have needed more time to complete all possible FET cycles. Total duration of the study was long, but there was no trend in yearly fluctuations of cLBR during the study period (42.3–58.2%, linear-by-linear association $P = 0.1$).
Wider implications of the findings: Results are important for health policy makers. Clinicians and patients should be aware that most live births (93.9%) occurred in the fresh and up to two FET cycles. However, 22% of second births occurred after the second FET. Since second births are associated with low costs, the use of FET should not be limited after the first birth. If no live birth has occurred after the second FET, a new stimulation might be considered.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s), Funding by national/international organization(s) – University of Helsinki, Helsinki University Hospital, the Sigrid Juselius Foundation, Academy of Finland, University of Oulu, Oulu University Hospital.
Trial registration number: NA.

P-747 Natural fertility and outcomes of assisted reproductive technologies in different ethnicities

L. Cipriani[1], A. Bazzocchi[1], G. Damiano[1], A. Bianchi[1], I. Orsili[1], F. Fabbri[1], L. Notarangelo[1], E. Porcu[1]
[1]*University of Bologna, IVF Fertilty Center, Bologna, Italy*

Study question: Are natural fertility and in vitro fertilization (IVF) outcomes related to patient's ethnicity?
Summary answer: There is a correlation between reproductive potential and ethnicity, both in spontaneous fertility than in assisted reproductive treatments, in terms of spontaneous pregnancy rate, sterility duration, causes of sterility and IVF outcomes.
What is known already: Ethnicity widely influences reproduction because it is associated with different economic, cultural and genetic characteristics that correlate with reproductive performance and onset of reproductive pathologies. Puberal onset, menopausal age, hormonal levels, prevalence of polycystic ovary syndrome, endometriosis and myomas are related to ethnicity. Some studies underline better in vitro fertilization outcomes in Caucasian women. Unfortunately, in literature there are only a few studies and most of the them include small cohorts of subjects.
Study design, size, duration: This is a cohort study. 4798 patients (86.8% Italian; 1.9% North European, 5.1% East European; 0.1% North American, 1.3% South American, 2.5% African; 2.3% Asian) who underwent in vitro fertilization between 2004 and 2014 were included in the study.
Participants/materials, setting, methods: The different ethnicity groups have been compared in terms of hormonal values, duration and reasons for sterility, in vitro fertilization outcomes (number of oocytes retrieved, ovarian hyperstimulation rate, embryos obtained, implantation rate, pregnancy rate, miscarriages rate).

Main results and the role of chance: The main differences among the ethnicities concern sterility duration, sterility causes, rate of oocyte cryopreservation, embryo quality and pregnancy rate. Endometriosis and polycystic ovarian syndrome are more frequent in Asian women, tubal factor is the main cause of infertility in East European women. Rate of cycles with cryopreservation of supernumerary oocytes is significantly higher in Asian women than in African women (37% vs 16% of all retrievals). Embryo quality resulted better in North European women (68.5% of grade 1–2 embryos), whereas the rate of good quality embryos was low in African women (42.6% of grade 1–2 embryos transferred).
Limitations, reason for caution: The population of the study is not equally divided among the different ethnicities, because the Italian group is much more numerous than the others. Moreover, the groups are very heterogeneous because each one includes several subgroups (for example Chinese, Japanese, Indian in the Asian group).
Wider implications of the findings: The evaluation of fertility in different ethnicities is particularly significant due to the surge in worldwide immigration. The differences in fertility's characteristics and IVF results, observed among the ethnicities, permit to personalize the medical approach in terms of prevention of fertility related diseases, diagnostic path and treatment. Furthermore, these data are helpful in improving personalized patients' counselling about the expected results.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s) –University of Bologna. Sant'Orsola Malpighi University Hospital.
Trial registration number: NA.
Keywords: ethnicity, IVF, fertility counselling

P-748 Knowledge and attitudes regarding fertility and assisted reproductive technology in Portuguese childbearing population

A. Macedo[1], T. Almeida-Santos[2], M. Moura-Ramos[3], C. Melo[3]
[1]*Keypoint Consultora Cientifica, Clinical and Epidemiology Research Unit, ALGÉS, Portugal*
[2]*Faculty of Medicine University of Coimbra Coimbra Center and University Hospitals, Reproductive Medicine Service, Coimbra, Portugal*
[3]*Faculty of Psychology and Educational Sciences of the University of Coimbra, CINEICC, Coimbra, Portugal*

Study question: How good is the fertility knowledge and what are the attitudes regarding Assisted Reproductive Technology (ART) in a Portuguese sample of men and women in reproductive age and without children?
Summary answer: The Portuguese childbearing population had a poor knowledge about fertility and ART. They would like to have two children in the future. The marital and financial stability and the family support are perceived as the most important factors influencing the decision to have children.
What is known already: Human fertility is threatened by several factors, such as the postponing of the first pregnancy. Young adults should be aware of risk factors so they can make high quality reproductive decisions. However, research reveals that young individuals have little knowledge about their fertility and about what to do in face of reproductive problems. There is no study about the knowledge and attitudes regarding fertility and ART in a Portuguese sample.
Study design, size, duration: It was developed a cross-sectional epidemiological study over a 5-month period, between August and December of 2014. It was performed a face-to-face, home-based random-route questionnaire in the 5 regions of Continental Portugal. This was a national representative sample.
Participants/materials, setting, methods: Participants were 2403 individuals (1595 women); median age 33 years old. 28% of the participants were higher educated and 68% were involved in an intimate relationship. The inclusion criteria were the age between 18 and 45 years old and the absence of children. Fertility and ART knowledge and attitudes were assessed.
Main results and the role of chance: Participants revealed poor knowledge about (in)fertility. Artificial insemination was the best-known treatment by this sample and 19% of the women have already heard about fertility preservation techniques. Female participants referred that the ideal age to start having children is 28 years old, to a maximum age of 40 years old. In terms of having children in the future, participants perceived the marital stability, the family support and the financial stability as the most important factors influencing this decision. Most of the individuals (42%) plan to have two children in the future and 27% of the individuals revealed that do not pretend to have any child.
Limitations, reason for caution: It is important to take into account the possible presence of a social desirability bias in this study. This bias means that the sample could have answered in a manner favorably perceived by the researchers.
Wider implications of the findings: Educational interventions to general population should be implemented to improve knowledge about fertility and ART. Moreover, primary care healthcare professionals should discuss fertility and reproductive plans with their young patients. Future studies should try to understand how knowledge and attitudes about ART affect reproductive decisions.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) –Merck Portugal S.A.
Trial registration number: NA.
Keywords: childbearing intentions, attitudes towards assisted reproduction, Portugal

P-749 Effect of ethnicity on live birth rates after IVF/ICSI treatment: analysis of 60,955 treatment cycles from a national database

W. E. Maalouf[1], W. E. Maalouf[2], B. K. C. Campbell[1], K. Jayaprakasan[3]
[1]*University of Nottingham, Division of Child Health Obstetrics and Gynaecology, Nottingham, United Kingdom*
[2]*United Nations Office on Drugs and Crime, Prevention Treatment and Rehabilitation Section, Vienna, Austria*
[3]*Royal Derby Hospital, Derby Fertility Unit, Derby, United Kingdom*

Study question: To evaluate the effect of ethnicity of women on the clinical outcome of In-Vitro Fertilisation (IVF) or intracytoplasmic sperm injection (ICSI) treatment.
Summary answer: Live birth rates following IVF or ICSI treatment were significantly lower in some of the ethnic minority groups (White Irish, Indian, Bangladeshi, Pakistani and Black African) compared with white British women, which suggests that ethnicity is a major determinant of live birth following IVF or ICSI treatment.
What is known already: Despite the rapid advancement in the IVF field, ethnic disparities has attracted limited attention unlike other areas in medicine where ethnicity is a primary prognostic consideration. In the literature, a scarce number of reports were published on the relationship between ethnic background and IVF outcome.
Study design, size, duration: Anonymous data were obtained from the Human Fertilization and Embryology Authority (HFEA), the statutory regulator of IVF and ICSI treatment in the UK. Data from 2000 to 2010 involving 60,955 treatment cycles from 38,709 women were analysed.
Participants/materials, setting, methods: Data on all women undergoing their first stimulated fresh IVF treatment cycle during the period from 2000 to 2010 were analysed for live birth rate per cycle and cumulative live birth rate. Data analysed after adjusting for age, cause and type of infertility and treatment type (IVF or ICSI) to express results as odds ratio and 95% confidence intervals.
Main results and the role of chance: While white Irish (0.73; 0.60–0.90), Indian (0.85; 0.75–0.97), Bangladeshi (0.53: 0.33–0.85), Pakistani (0.68; 0.58–0.80), Black African (0.60; 0.51–0.72), and other non-Caucasian Asian (0.86; 0.73–0.99) had a significantly lower odds of liver birth rates per fresh IVF/ICSI cycle than White British women, ethnic groups of White European (1.04; 0.96–1.13), Chinese (1.12; 0.77–1.64), Black Caribbean (0.76; 0.51–1.13), Middle Eastern (0.73; 0.51–1.04), Mediterranean European (1.18; 0.83–1.70) and Mixed race population (0.94; 0.73–1.19) had equivalent live birth rates. The cumulative live birth rates were also showed similar pattern across different ethnic groups.
Limitations, reason for caution: Controlling for confounders like women's BMI, smoking status, treatment protocol and gonadotrophin dose could not be done because these data were not available.
Wider implications of the findings: Ethnicity should be considered while counseling women and couples about their realistic chances of IVF/ICSI success. Further research is needed to understand the reasons behind the variation in treatment outcome between ethnic groups and towards tailoring the protocol to maximize their IVF/ICSI success.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s) –Nottingham University Hospitals.
Trial registration number: 12/EM/0202.
Keywords: ethnicity, IVF, ICSI, live birth rate, assisted conception

P-750 Relationship between pollutants concentration in ambiance and lunar phases with pregnancy rate during IVF cycles

M. Sánchez Toledo[1], C. Álvarez Lleó[1], J. A. Guijarro Ponce[2], C. García Garrido[1], M. Resta Serra[1], G. González de Merlo[1]
[1]*Hospital General Universitario de Albacete, Unidad de Reproducción, Albacete, Spain*
[2]*Hospital General Virgen de la Luz, Servicio de Ginecología y Obstetricia, Cuenca, Spain*

Study question: Increasing concentrations in pollutants as nitrogen dioxide (NO_2) and ozone (O_3) and changes in percent of the moon illuminated (PMI) from oocyte retrieval (OR) to embryo transfer (ET) day could affect pregnancy rate (PR) in women undergoing an IVF cycle.
Summary answer: Increasing concentrations in NO_2 is associated with a lower chance of pregnancy from oocyte retrieval to embryo transfer. Changes in O_3 concentration and in lunar phases did not affect the outcome of the IVF cycle.
What is known already: Most papers link chemical contaminants and spontaneous pregnancy but there are few bibliography that relate pollutants with IVF outcome; some observed a relationship between a higher level of NO_2 with lower pregnancy and birth rates in all phases of an IVF cycle. Others studies showed that an increase in fine particle matter ($PM_{2.5}$) and particular matters (PM_{10}) were associated with a drop in pregnancy rate.
Study design, size, duration: Retrospective study. *Size:* 363 women undergoing an IVF cycle with ET in day2. *Period:* January 2013–July 2014. Climatological and pollutants factors were collected on a daily basis by the Air Quality Network of Castilla-LaMancha. We compared data relating to lunar phases and contaminants in order to ascertain how they affect pregnancy rate.
Participants/materials, setting, methods: Mean concentration of pollutants(MCP)was calculated during the culture period (NO_2 = 12.16mg/m^3 and O_3 = 78.46mg/m^3). Full moon was considered as PMI >75%. Chance of pregnancy was analyzed depending on MCP and PMI since OR to ET. Chi square Fisher's test and multivariable binary logistic regression analysis was performed to determinate the variables related to pregnancy rate
Main results and the role of chance: We found a statistically significant increase of pregnancy rate when NO_2 concentration in the environment during the embryo culture period was lower than the mean concentration (n = 90) (OR: 2.02, CI 95%: 1.21–3.38. p = 0.048). No significant differences were found in pregnancy rate when O_3 was below the mean concentration (n = 100) (OR: 0.75 CI 95%: 0.46–1.24 p = 0.265). On the other hand, if PMI was above 75% (n = 99) a marginally significant effect on pregnancy rate was observed (OR: 0.65, CI 95%: 0.41–1.03 p = 0.068). Consequently, we could say that NO_2concentration has a deleterious effect on pregnancy rates in women undergoing IVF. These results also suggest a possible link between lunar phases and pregnancy rate.
Limitations, reason for caution: We are measuring the only period in which embryos and mother are separated, so we could hypothesize that the toxic effect would be lower. However, not all laboratories are equipped with good air filtration system. Other limitation is the limited period of time. We could extend the study to stimulation and implantation period
Wider implications of the findings: The impact of exposure to environmental contaminants on human fertility remains controversial. Some studies show a relationship between $PM_{10}$and a drop in spontaneous fertility. In agreement with Legro et al. (2010), we found a persistent negative association between pregnancy and NO_2 concentration. The most prominent sources of NO_2 are internal combustion engines like those used in motor vehicles. Further studies are necessary but these results highlight the fact that pollution is in someway affecting human fertility.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Universitary General Hospital from Albacete.
Trial registration number: NA.
Keywords: pollution, IVF, contamination, lunar phases, pregnancy rate

P-751 Publication bias in the field of subfertility

S. Lensen[1], V. Jordon[1], M. Showell[1], E. Showell[1], V. Shen[1], C. Venetis[2], C. Farquhar[1]
[1]*University of Auckland, Obstetrics and Gynaecology, Auckland, New Zealand*
[2]*University of New South Wales, School of Women's and Children's Health, Sydney, Australia*

Study question: Is the statistical significance of the results from subfertility randomised controlled trials (RCTs) that have been presented at conferences associated with the probability of publication of these RCTs as full-text articles? A preliminary report.
Summary answer: This study found no evidence to suggest that subfertility RCTs of conference abstracts that reported statistically significant (SS) results were more or less likely to be published than studies that did not report SS results.
What is known already: Publication bias due to the failure to publish study results based on the direction or strength of study findings can lead to a misleading interpretation about the effectiveness of an intervention and ultimately impact patient care. Publication bias has been detected in many clinical areas including subfertility. This study aimed to investigate

- whether publication bias exists in a recent cohort of conference abstracts, and
- associations of other factors with the probability of full-text publication.

Study design, size, duration: Eligible abstracts were subfertility RCTs reporting ≥1 reproductive outcome. The Cochrane Menstrual Disorders and Subfertility Group specialised register (MDSGSR) was searched for abstracts presented between 01/01/2007 and 31/12/2010. A search was performed to identify full-text publications in MDSGSR, Pubmed, Medline, Embase, and Cinahl December 2014 to February 2015 (ongoing).
Participants/materials, setting, methods: Two authors independently screened abstracts for eligibility and extracted data. One author searched for full-text publications not found by the other author. Odds ratios (OR) and 95% confidence intervals (CI) will be calculated with the use of multiple regression to identify additional factors independently associated with probability of publication.
Main results and the role of chance: As at January 2015, 229 articles were eligible from a total of 337 retrieved. Preliminary analysis indicates that: 37% of abstracts were oral presentations, <1% were stated as registered, 3% were stated as interim or preliminary analyses, 11% acknowledged industry funding, while the source of funding was not reported in 68% of studies. Overall, 50% of the abstracts were found to be published as full-text articles. There was no SS difference between likelihood of publication of abstracts reporting SS results compared to abstracts reporting non-SS results (OR = 1.16 95% CI 0.66–2.02). Of studies not reporting SS results, 13% made a positive statement about the findings, for example describing a trend towards improved outcomes.
Limitations, reason for caution: The included RCTs were only those captured by the MDSGSR and which investigated interventions for subfertility. To assess the true extent of publication bias a more comprehensive survey might be conducted using a cohort of RCTs from trial registers. Further, these results are interim analyses only.
Wider implications of the findings: Publication bias is a problem for evidence based health care, and the presence of this bias has been detected across many clinical areas. The absence of significant publication bias in subfertility, if confirmed, will enhance our confidence in the results of published systematic reviews of evidence in this field.
Study funding/competing interest(s): Funding by University(ies) – University of Auckland.
Trial registration number: NA.
Keywords: publication bias, publication deficit, subfertility, abstract publication

P-752 Retrospective six year analysis of ART directory of India

J. Malhotra[1], N. Malhotra[1], H. D. Pai[2], D. Goswami[1]
[1]*Global Rainbow Hospitals, IVF, Agra, India*
[2]*Bloom IVF, IVF, Mumbai, India*

Study question: How have ART practices and outcomes changed in India over the last six years.
Summary answer: Over the last six years there has been a progressive increase in the number of ART clinics offering ART services including surrogacy. Most common indication for ICSI being male factor infertility. Long protocol still remains most preferred but increase in antagonist cycles is noted.
What is known already: World data on the availability, safety and effectiveness of ART have been published since 1989. The number of embryos transferred is a major determinant of the increase in multiple pregnancies.

Study design, size, duration: : Retrospective analysis of data over last 6 years (2007–12) from all IVF centres in India registered with ISAR (Indian Society of Assisted Reproduction)
Participants/materials, setting, methods: Data from total of 139 registered centres regarding number of ART clinics, types of cycles and procedures, pregnancy, delivery and multiple birth rates.
Main results and the role of chance: The number of reporting centres increased from 113 in 2007 to 139 in 2012. Total 30,270 IVF and ICSI cycles were performed in 2012. Maximum number of centres 69% performed <50 cycles in a year with 3.5% performing >500 cycles a year. Long luteal was the preferred protocol in all years with increase in the number of antagonist cycles. Number of single embryo transfer cycles remains constant around 11–13% but still around 14% cycles had 4 embryos transferred. The overall pregnancy rate was 38.5% and multiple pregnancy rate 21% for 2010 and 41.6% with 22 % multiples in 2012. The overall pregnancy rate for FET cycles egg donation and embryo donation cycles was around 35.6%, 43.5%, and 47.6%, respectively.
Limitations, reason for caution: Still many centres in India are not registered with any body and not reporting their results. There is need for a central regulatory body to monitor the working and practices of the various IVF centres.
Wider implications of the findings: To compare the ART practice and outcomes with international Data. To assess need for guidelines regarding embryo transfer policy and encourage more transparency amongst centres.
Study funding/competing interest(s): Funding by national/international organization(s) – Indian society of assisted reproduction
Trial registration number: NA.

P-753 Pre-treatment serum vitamin D levels and fertilization rates among women undergoing assisted reproduction

L. Abadia[1], A. J. Gaskins[2], Y. H. Chiu[1], D. L. Wright[3], R. Hauser[4], J. E. Chavarro[2], I. Souter[3], J. Vanegas[1]
[1]*Harvard School of Public Health, Nutrition, Boston, MA, U.S.A.*
[2]*Harvard School of Public Health, Nutrition and Epidemiology, Boston, MA, U.S.A.*
[3]*Massachusetts General Hospital, Obstetrics and Gynecology, Boston, MA, U.S.A.*
[4]*Harvard School of Public Health, Epidemiology, Boston, MA, U.S.A.*

Study question: Is there an association between levels of 25-hydroxyvitamin D (25OH-D) and fertilization rate among women undergoing assisted reproduction (ART)?
Summary answer: Serum 25OH-D levels were positively related to fertilization rate and this relation was stronger in conventional insemination cycles than in intracytoplasmic sperm injection (ICSI) cycles.
What is known already: In female rats, vitamin D deficiency results in decreased litter size and impaired neonatal growth. Human data is inconclusive; some studies have found that women undergoing ART with higher serum levels of vitamin D significantly more likely to achieve implantation and clinical pregnancy while other studies have failed to document a benefit.
Study design, size, duration: 100 women (contributing 158 ART cycles) randomly sampled from participants of an ongoing prospective cohort study (EARTH study) of couples recruited from a Fertility Center in a university hospital between 2007 and 2013.
Participants/materials, setting, methods: Pre ART treatment serum levels of 25OH-D were measured by immunoassay. Generalized linear mixed models with random intercepts were used to evaluate the association of serum 25OH-D with fertilization rate accounting for repeated treatment cycles and adjusting for age, BMI, infertility diagnosis, protocol, race and dietary factors.
Main results and the role of chance: The median serum 25OH-D levels were 87.5[58.3–119.3] ng/mL. Vitamin D levels were positively related to fertilization rate. The adjusted fertilization rates (95% CI) for women with increased quartiles of serum 25OH-D were 0.68 (0.58–0.76), 0.60 (0.50–0.69), 0.71 (0.62–0.79) and 0.78 (0.70–0.84) (p, linear trend = 0.01). This relation was stronger in conventional insemination cycles than in ICSI cycles. Specifically, the adjusted fertilization rates (95% CI) in increasing quartiles of 25OH-D were 0.65 (0.52–0.78), 0.51 (0.37–0.64), 0.74 (0.66–0.81) and 0.83 (0.72–0.90) among women undergoing conventional insemination cycles (p, linear trend = 0.005), and 0.74 (0.61–0.83), 0.64 (0.47–0.78), 0.62 (0.42–0.79) and 0.79 (0.66–0.88) among women undergoing ICSI cycles (p, linear trend = 0.22).
Limitations, reason for caution: None of the women included in this analysis were vitamin D deficient. In addition, residual confounding cannot be ruled out.
Wider implications of the findings: If these findings are replicated in randomized control trials, vitamin D supplementation could be offered as an inexpensive adjuvant to infertility treatment.
Study funding/competing interest(s): Funding by national/international organization(s) – National Institutes of Health (NIH) grants and the Early Life Nutrition Fund from Danone Nutricia US.
Trial registration number: NA.
Keywords: vitamin D, reproductive techniques, assisted

P-754 Patients experience of viewing time-lapse sequences, a prospective survey study

A. Bladh Blomquist[1], I. Liljeqvist Soltic[1], R. Samir[2], A. B. Engström[2], S. Nilsson[2], A. K. Lindh[3], G. Westlander[3], S. Larsson[3], T. Hardarson[3], J. Hreinsson[2]
[1]*IVF-Sweden, IVF-Kliniken CuraÖresund, Malmö, Sweden*
[2]*IVF-Sweden, IVF-Kliniken Falun, Falun, Sweden*
[3]*IVF-Sweden, Fertilitetscentrum Göteborg, Göteborg, Sweden*

Study question: How do patients value the chance to view time-lapse sequences of their own embryos during treatment?
Summary answer: Patients found viewing the sequences to be a relevant and important aspect of their treatments. There was a clear interest in obtaining a copy of the time-lapse sequence but only if the treatment resulted in a pregnancy.
What is known already: Studies are lacking on patients experience of using time-lapse monitoring in ART. We consider it to be highly important to study the patient-oriented aspects of this new technology which currently is spreading rapidly and is already considered an important aspect of treatment in many centers internationally.
Study design, size, duration: This prospective, observational questionnaire study was carried out at three of IVF Sweden`s centers in Sweden. We report the results from the first 163 self evaluated scores on patient´s experience reported anonymously.
Participants/materials, setting, methods: Participants in the study are patients who are offered to view time-lapse sequences of embryos selected for transfer at privately funded ART clinics. After the embryo transfer, patients were asked to fill in a questionnaire where a 5-grade Likert-scale instrument was used for assessing patient's experience.
Main results and the role of chance: Patients found the offer to view the time-lapse sequences to give important and relevant information regarding their treatment (average score 4.5) and felt that this gave them increased participation in the treatment (4.7). Extremely few patients preferred not to know the details of the development of their own embryos (1.1). A modestly positive attitude towards extra payment for time-lapse monitoring was expressed in the study (3.2) but viewing the sequences increased satisfaction with the treatment (3.6). Patients wish to obtain a copy of the time-lapse sequence, but only if a pregnancy is achieved (2.3). The results from the study are collected from a large number of patients and in three different private ART clinics and do not vary between clinics.
Limitations, reason for caution: This may be considered a pilot study as it is the first to assess patients experience of viewing time lapse sequences. Further studies are required to analyze for example how closely patients identify with the embryos before implantation.
Wider implications of the findings: Embryologists and clinicians may consider whether the positive expectations of an ART treatment may lead to feelings of regret and sorrow if the treatment is unsuccessful. The results do not indicate that viewing time-lapse-sequences specifically adds extra stress in this aspect. Although time-lapse technology is a useful innovation in the field of ART, it is important not to forget the individuals behind the gametes and embryos being cultured in the ART laboratories.
Study funding/competing interest(s): Funding by hospital/clinic(s) – IVF Sweden – The authors have no financial interests to declare.
Trial registration number: The regional ethics committee at Lund University considered the study to lie outside the boundaries of ethical vetting because of the non-invasive and anonymous nature of the study.
Keywords: time-lapse, patient experience

P-755 Sequential awareness surveys on clinical application of uterine transplantation among Japanese general public

A. Hayashi[1], Y. Tsutsumishita[1], I. Kisu[2], M. Mihara[3], N. Suganuma[1]
[1]*Kyoto University Graduate School of Medicine, Human Health Sciences, Kyoto, Japan*
[2]*Keio University School of Medicine, Obstetrics and Gynecology, Tokyo, Japan*
[3]*Saiseikai Kawaguchi General Hospital, Vascular Surgery, Kawaguchi, Japan*

Study question: Uterine transplantation (UTx) has been applied clinically in some countries recently, and the first childbirth was obtained in Sweden in 2014. However, evaluation of social consensus is not enough yet. To address this point, sequential awareness surveys were performed among Japanese citizen by gathering public comments for the new technology.
Summary answer: Although UTx seems to be acceptable for Japanese general peoples, the awareness for the reproductive technology has not markedly changed even after successful childbirths with UTx has been reported. These results may indicate that more information concerning UTx procedure should be opened and spread to public.
What is known already: It has been proven that even the patients with absolute uterine factor infertility are able to be pregnant and give birth by themselves, and many studies related to experimental and clinical UTx technologies have been reported recently. However, no analyses of public awareness on clinical application of UTx have been available. Moreover, no sequential surveys were performed though the social intensions for third party reproduction are always changing.
Study design, size, duration: Cross-sectional surveys were conducted on Japanese general population aged from 20 to 39 years. The infertile persons were excluded. The first and second surveys were performed on June 2012 and December 2014, respectively. Answers were obtained from 300 females and 300 males at each survey.
Participants/materials, setting, methods: The age of the participants (mean ± SD) was 30.1 ± 5.6 years old. In them, 33.5% in the females and 22.0% in the males had children. Self-reported questionnaire consisting of ethical, social and clinical aspects on UTx and gestational surrogacy was used through the Internet.
Main results and the role of chance: More than 3/4 (79.3% of the females and 76.3% of the males) of the peoples permitted the clinical UTx application morally, and about 40% of peoples (44.7% in females and 36.0% in males) showed interest in the UTx. Both 22.7% of the females and 19.9% of the males hoped for UT treatment if she or his partner has lost uterus. These rates were greater than those of surrogacy, however, the answer 'unknown' was occupied more than 50%. As uterine donor candidates, physical woman with gender identity disorder who would receive sex reassignment surgery was selected equally to cadaver and her or his partner's mother/sister. No significant differences in these ratios were observed between the first and second surveys.
Limitations, reason for caution: Because these surveys were carried out through the Internet, the participants were restricted to the Internet users who could access the website and answer the questionnaire. Opinions were collected only from reproductive aged people, which mean that the data may not reflect overall social mood.
Wider implications of the findings: To progress UTx clinically, not only agreement between patients and medical staffs but also social consensus should be established. Because ethical, legal, ethnic, religious situations for third party reproduction including both UTx and gestational surrogacy are different in each country, an independent national direction has to be assessed. For this purpose, continuous awareness survey for clinical application of UTx has to be performed among general public in each regions of the world.
Study funding/competing interest(s): Funding by University(ies) – Kyoto University.
Trial registration number: NA.

P-756 Pregnancy planning and among women attending antenatal care in Sweden and Denmark

T. Tyden[1], H. Hegaard[2], M. Hedegaard[2], P. Kristiansson[1], J. Stern[1], C. Aarts[1], M. Ekstrand[1], M. Larsson[3], A. Berglund[4], A. Rosenblad[5]
[1]*Uppsala University Public Health and Caring Sciences, Public Health and Caring Sciences, Uppsala, Sweden*
[2]*Rigshospitalet Copenhagen, Rigshospitalet Copenhagen, Copenhagen, Denmark*
[3]*Uppsala University Womens´ and Children's Health, Womens´ and Children's Health, Uppsala, Sweden*
[4]*The National Centre for Knowledge on Men´s Violence Against Women, The National Center for Knowledge on Men´s Violence Against Women, Uppsala, Sweden*
[5]*Uppsala University, Centre for Clinical Research, Västerås, Sweden*

Study question: To what level have pregnant women entering antenatal care in Sweden and Denmark planned their pregnancies and is pregnancy planning associated with folic acid supplement intake?
Summary answer: In both Sweden and Denmark three out of four women considered their pregnancy to be highly or quite planned. Women with planned pregnancies were more likely to have taken folic acid, but in total only 29% of Swedish and 48% of Danish women took folic acid prior to the pregnancy.
What is known already: Unplanned pregnancy is associated with unfavorable outcomes for mother and infant. Pregnancy planning is often measured in an imprecise and dichotomous manner and consequently the prevalence of planned and unplanned pregnancies varies between countries. Since the most critical period for organ development occurs before many women even know they are pregnant; the first contact with antenatal care is often too late for advice about health promoting changes such as intake of folic acid supplement.
Study design, size, duration: Cross sectional studies among women attending antenatal care in Sweden and Denmark in 2013–2014. In Sweden 5494 women were asked to participate at the first visit to the antenatal clinic. In Denmark 4616 women received a link to a clinical questionnaire before the first visit to the antenatal clinic.
Participants/materials, setting, methods: In Sweden the participation rate was 68% and in Denmark 87%. Women answered a multiple-choice questionnaire and pregnancy planning was measured with one single question with five alternatives; highly planned/quite planned/neither planned nor unplanned/quite unplanned/highly unplanned. A dichotomous question measured intake of folic acid supplements.
Main results and the role of chance: Of the Swedish women (n = 3343) answering the question about pregnancy planning 47% (n = 1557) had a highly planned pregnancy, 27% (n = 915) had a quite planned pregnancy, 14% (n = 468) had a pregnancy that was neither planned nor unplanned pregnancy, 4% (n = 145) had a quite unplanned pregnancy and 8% (n = 458) had a highly unplanned pregnancy. Of the Danish women (n = 3805), 46% (n = 1750) had a highly planned pregnancy, 29% (n = 1087) had a quite planned pregnancy, 17% (n = 646) had a pregnancy that was neither planned nor unplanned pregnancy, 4% (n = 154) had a quite unplanned pregnancy and also 4.4% (n = 168) had a highly unplanned pregnancy. The level of pregnancy planning was associated to intake of folic acid ($p < 0.001$) in both countries.
Limitations, reason for caution: Conclusions should only be drawn on women who aim to pursue their pregnancies. Women with immigrant background were underrepresented.
Wider implications of the findings: The level of pregnancy planning is not but should be inquired routinely at registration to antenatal clinics to enable individualized counselling and support, and improved data on outcomes of planned and unplanned pregnancies.
Study funding/competing interest(s): Funding by University(ies) – Funding by national/international organization(s) – The Family Planning Foundation in Uppsala, The Faculty of Medicine, Uppsala University, Sweden, The Uppsala-Örebro Regional Research Council, Sweden.
Trial registration number: NA.

P-757 Knowledge, attitudes, and intentions toward fertility awareness and oocyte cryopreservation among United States obstetrics and gynecology (OB/GYN) residents

L. Yu[1], B. Peterson[2], M. C. Inhorn[3], J. K. Boehm[4], P. Patrizio[5]
[1]*Yale University School of Medicine, Obstetrics Gynecology and Reproductive Sciences, New Haven, CT, U.S.A.*
[2]*Chapman University, Department of Psychology Marriage and Family Therapy Program Crean College of Health and Behavioral Sciences, Orange, CA, U.S.A.*
[3]*Yale University, Department of Anthropology and International Affairs, New Haven, CT, U.S.A.*

[4]*Chapman University, Department of Psychology Crean College of Health and Behavioral Sciences, Orange, CA, U.S.A.*
[5]*Yale University, Fertility Center, New Haven, CT, U.S.A.*

Study question: What knowledge, attitudes, and intentions do US OB/GYN residents have toward discussing age-related fertility decline and oocyte cryopreservation with their patients, and at what ages and with what types of patients would they have such discussions? Do opinions differ toward medically indicated versus elective oocyte banking?
Summary answer: US OB/GYN residents are likely to initiate discussions regarding age-related fertility decline and oocyte cryopreservation in patients with cancer, but are less likely to initiate discussions of elective oocyte banking. Most residents believe that age-related fertility decline should be discussed during well-woman annual exams, but not oocyte cryopreservation.
What is known already: Currently, no studies of US OB/GYN residents exist that question their knowledge, attitudes, and intentions toward discussing age-related fertility decline and oocyte cryopreservation with patients. Oocyte cryopreservation is no longer an experimental technique, as current literature suggests that fertilization and pregnancy rates using vitrified oocytes are similar to fresh in vitro fertilization or intracytoplasmic sperm injection cycles. However, not all practitioners are familiar with this technique or are comfortable counseling patients about these options.
Study design, size, duration: A cross-sectional online survey was conducted during the fall of 2014 to evaluate residents in American Council for Graduate (ACOG) Medical Education-approved OB/GYN resident programs. Program directors were emailed via the ACOG Council on Resident Education in Obstetrics and Gynecology server listing and asked to solicit resident participation.
Participants/materials, setting, methods: Participants included 238 residents evenly distributed between post-graduate years 1–4 with varied post-residency plans. 90% of residents were women, and 75% were 26–30 years old. The survey was divided into three sections: demographics, fertility awareness, and attitudes toward discussing fertility options with patients. Descriptive and inferential statistics were conducted.
Main results and the role of chance: Residents (83%) believed an OB/GYN should initiate discussions about age-related fertility decline with patients (mean age 31.8), and 73% believed these discussions should be part of an annual exam. However, 93% of residents overestimated the age at which female fertility slightly declines and 47% overestimated the age it markedly declines. Residents were likely to support oocyte cryopreservation in cancer patients no matter the age, but much less likely to support elective oocyte banking. For elective oocyte cryopreservation, 40% believed OB/GYNs should initiate discussions with patients (mean age 31.1), while only 20% believed this topic should be part of an annual exam. Interestingly, only 25% of residents were 'familiar' or 'very familiar' with oocyte cryopreservation, although 63% worked in training settings that offered it.
Limitations, reason for caution: Because the study invitation was sent through US OB/GYN resident program directors rather than directly to residents, it is possible that some residents did not receive the invitation to participate. This limits the generalizability of the findings.
Wider implications of the findings: This study highlights a critical need for improved education and curricular offerings among OB/GYN residencies related to issues of age-related fertility decline and oocyte cryopreservation. To promote informed reproductive decision-making among patients, efforts should be made to help OB/GYNs provide comprehensive fertility education, while also respecting patient choices. Differences in attitudes towards egg banking with and without medical indication warrant further study.
Study funding/competing interest(s): Funding by University(ies) – Yale University.
Trial registration number: NA.
Keywords: oocyte cryopreservation, oocyte banking, age-related fertility decline, fertility preservation, OB/GYN residents

P-758 IVF – follow up study; cumualtive pregnancy rate in a new series of IVF attempts following 3 or more failed attempts

J. Hausken[1], A. Schwennicke[1], S. Sayed[1], J. Severeide[1], E. Amundsen[1], S. N. Eikeland[1]
[1]*Klinikk Hausken, Haugesund, Haugesund, Norway*

Study question: What is the cumulative pregnancy rate in a new series of IVF-treatment cycles following three or more previous IVF-treatment cycles without live birth?
Summary answer: 46.3% of subjects starting treatment achieved an ongoing pregnancy within one year, and of those that went through the intended three cycles, almost 70% achieved an ongoing pregnancy.
What is known already: It is known that the accumulated pregnancy rate in a series of IVF-treatments is high; however, there is insufficient information about couples that change clinics and start a new series of IVF treatments following three failed cycles. Some studies suggest that success rates are still high even after a series of negative attempts.
Study design, size, duration: This was a prospective, observational cohort trial. 149 subjects were included in the trial and were followed for three cycles in one year from their first treatment, between June 2009 and May 2014. Approximately 33% of the subjects did not complete the intended three cycles within 1 year.
Participants/materials, setting, methods: Subjects having had three or more previous IVF-treatment cycles without live birth were recruited to this study. The treatment cycle commenced with a routine agonist or antagonist treatment with GONAL-f®. Subjects were assessed and treated according to routine clinical practice at the study site.
Main results and the role of chance: Of the 149 subjects included in the study, 69 achieved an ongoing pregnancy within one year (46.3%). 99 subjects completed the intended three cycles, with an accumulated ongoing pregnancy rate of 69.7%. Some of the remaining subjects had planned new attempts but did not complete them within the study period of one year. A longer study period might have given a more accurate result on a per subject basis.
Limitations, reason for caution: Approximately one third of the subjects did not complete the intended three cycles within the allotted time-frame. This could reduce the results since some subject might become pregnant on a second or third attempt occurring after the study period.
Wider implications of the findings: Most subjects benefit from undertaking a new series of IVF-treatments even if they have had three or more failed treatments. While most subjects get pregnant within their first three treatments, hope is not lost for the remaining population. The study suggests that completing a new series of three IVF attempts can give an accumulated ongoing pregnancy rate approaching 70%.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Merck Serono.
Trial registration number: 2008-002840-41.
Keywords: IVF, previous failed attempts, cumultative pregnancy rate

P-759 Comparison of reproductive parameters in European and middle eastern minority patients

W. Feichtinger[1], M. Feichtinger[2]
[1]*Wunschbaby Institut Feichtinger, Wunschbaby Institut Feichtinger, Vienna, Austria*
[2]*Medical University of Vienna, Obstetrics and Gynecology, Vienna, Austria*

Study question: Is there a difference in reproductive parameters and outcome between middle eastern minorities and Europeans?
Summary answer: Couples of middle eastern origin did not show any difference in pregnancy and implantation rates but some reproductive parameters differed significantly.
What is known already: US studies revealed that racial minorities show differences in reproductive outcome parameters. Little is known about European populations.
Study design, size, duration: Observational cohort study of patients being treated between 2000 and 2011.
Participants/materials, setting, methods: 2993 European- and 288 middle eastern women undergoing their first IVF treatment in a private IVF institute.
Main results and the role of chance: Middle eastern patients were significantly younger at treatment (30.84 vs. 34.35 years, $P < 0.001$ for women and 34.98 vs. 37.82 years, $P < 0.001$ for their male partners) and first wish for a child (23.75 vs. 28.99 years, $P < 0.001$). Still, duration of infertility was significantly longer in women of middle eastern origin (6.39 vs. 4.63 years, $P < 0.001$). Middle eastern women showed significantly less tubal and more male and PCO indications for fertility treatment ($P = 0.005$). When corrected for age, middle eastern women had a significantly lower number of oocytes ($P = 0.003$, OR 0.96). There was no difference in pregnancy outcome, even when corrected for

age (34.9% vs. 41.2%, in the middle eastern vs. the European group, $P = 0.689$, OR 1.07) and implantation rates ($P = 0.834$).
Limitations, reason for caution: retrospective study; these results do not point out solely racial differences. Differences between the two groups can be explained by multifactorial cultural and ethnical differences as well as life-style factors.
Wider implications of the findings: Clinicians should be aware of the medical impact of patient's origin to support ideal medical care
Study funding/competing interest(s): Funding by hospital/clinic(s) – None.
Trial registration number: NA.

P-760 Seasons in the sun: the impact on IVF results

H. Van der Veken[1], F. Vandekerckhove[1], K. Tilleman[1], I. De Croo[1], E. Van den Abbeel[1], J. Gerris[1], P. De Sutter[1]
[1]*University Hospital Ghent, Centre for Reproductive Medicine, Gent, Belgium*

Study question: We evaluated if weather conditions determined by temperature, rain and sunshine at the start of ovarian stimulation or one month before had an effect on the outcome of IVF in terms of number of mature and fertilized oocytes, pregnancy and live birth rates.
Summary answer: The live birth rate per cycle was statistically different between cohorts of patients that were stratified into quartiles of sunshine hours during the month before the start of ovarian stimulation.
What is known already: Several retrospective studies have evaluated seasonal variations in the outcome of IVF treatment. Some also included weather conditions, mostly temperature and hours of daylight. The results were conflicting. We focused on individual variables provided as monthly results by our national meteorological institute. We shifted the results in IVF outcome to the weather results of one month earlier, as we supposed that the selection of good quality oocytes may start in the weeks before.
Study design, size, duration: Retrospective cohort study. Between January 2007 and December 2013, the IVF outcome of all Belgian patients treated in our university center was compared to the quarter of the year and monthly mean values of temperature, rain fall, rainy days and sunshine hours during the month when gonadotropins were started or the month before.
Participants/materials, setting, methods: 11494 patients started an IVF cycle and were included. Firstly bivariate correlation was performed by linear modelling between monthly weather conditions and IVF results. Secondly the same IVF outcome variables were plotted against the weather results stratified per quartile for each individual meteorological variable (Kruskal-Wallis Test).
Main results and the role of chance: There was no relationship between IVF outcome and the quarter of the year. When looking for a linear correlation between IVF results and the mean monthly values for the weather, the results were inconsistent. However, when the same analysis was repeated with the weather results of 1 month earlier, there was a clear trend towards better IVF outcome with higher temperature, less rain and more sunshine hours. This was most striking, although not statistically significant, for live birth rate and sunshine hours (Pearson Correlation Coefficient 0.230, p 0.052). The live birth rate per cycle was significantly different (p 0.019) between different groups (Q = quartile) of mean number of sunshine hours (Q1 = 60.75, Q2 = 136.00, Q3 = 174.50).
Limitations, reason for caution: Because of the retrospective design of the study, further adjusting for possible confounding factors such as age of the woman, type of infertility and indication for IVF is mandatory. The weather conditions seem to have their strongest impact on live birth rates.
Wider implications of the findings: The impact of sunlight on the early selection of good quality oocytes is an important finding for future research. Maybe we should focus further on environmental factors during the early phases of oocyte recruitment during the period just before ovarian stimulation for IVF. A strong impact of light, as illustrated by the importance of sunny weather, brings melatonin again in the picture for further research and treatment options.
Study funding/competing interest(s): Funding by hospital/clinic(s) – UZ Gent.
Trial registration number: NA.
Keywords: seasonal variations, fertilization rate, live birth rate

REPRODUCTIVE SURGERY

P-761 Antral follicle count: a new marker predicting ovarian response in women with ovarian endometriomas

L. Benaglia[1], G. Candotti[1], A. Busnelli[1], V. Sarais[1], A. Paffoni[1], E. Somigliana[1]
[1]*Fondazione Ospedale Maggiore Policlinico U.O. Centro Sterilita, Centro Sterilità, Milano, Italy*

Study question: Ovarian responsiveness to hyper-stimulation is actually considered the best non-invasive surrogate measurement of ovarian reserve. The aim of this study is to evaluate the accuracy of Antral Follicular Count (AFC) in estimating ovarian reserve and responsiveness in ovaries with endometriomas or with a past history of surgical excision of endometriomas.
Summary answer: AFC performs similarly in unaffected ovaries, in ovaries with endometriomas and in ovaries with a history of surgery for endometriomas. AFC is a reliable mean to estimate ovarian reserve in gonads with endometriomas or with a past history of surgical excision of endometriomas.
What is known already: The evaluation of the ovarian reserve in women with current or past ovarian endometriomas is challenging. In most cases, these cysts are unilateral, thus hampering the validity of hormonal assessments. As a matter of fact, sonographic assessment of AFC is the unique mean to obtain independent data on the ovarian reserve of an ovary. However, to the best of our knowledge, AFC in ovaries with current or past endometriomas has never been validated.
Study design, size, duration: Retrospective review of 84 women with present or operated endometriomas and/or with a history of surgery for endometriomas who underwent IVF.
Participants/materials, setting, methods: The outcome was the total number of developing follicles. A linear regression model that included age, BMI and the mean daily dose of gonadotropin was used to calculate the adjusted B coefficients. The capacity of AFC to predict low (≤2 follicles) or hyper-response (³7 follicles) was evaluated using ROC curves.
Main results and the role of chance: The adjusted B coefficients in non-operated gonads without endometriomas ($n = 45$), in gonads with endometriomas ($n = 68$) and in operated gonads ($n = 76$) were 0.55 (95% CI: 0.10–1.10, $p = 0.013$), 0.76 (95% CI: 0.54–0.98, $p < 0.001$) and 0.50 (95% CI: 0.25–0.75, $p < 0.001$), respectively. The Areas Under the Curve-AUC for prediction of low response were 0.84 (95% CI: 0.69–0.99, $p = 0.001$), 0.82 (95% CI: 0.72–0.92, $p < 0.001$) and 0.73 (95% CI: 0.62–0.85, $p = 0.001$), respectively. The AUCs for prediction of hyper response were 0.85 (95% CI: 0.72–0.98, $p < 0.001$), 0.78 (95% CI: 0.67–0.90, $p < 0.001$) and 0.77 (0.60–0.94, $p = 0.003$), respectively. Data were insufficient to draw a reliable estimate for the prediction of hyper-response in the group of previously operated gonads with recurrences. Statistically significant AUCs emerged for all groups for the prediction of poor response.
Limitations, reason for caution: The study is retrospective and we used the number of developing follicles as a marker of ovarian reserve. However, we deemed more appropriate to refer to the number of follicles rather than the number of oocytes retrieved because this outcome is not influence by technical difficulties in oocytes retrieval.
Wider implications of the findings: AFC is a reliable mean to estimate ovarian reserve in gonads with endometriomas or with a past history of surgical excision of endometriomas. In particular, the presence of an endometrioma does not affect the diagnostic performance of AFC.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Not funding. Retrospective study in hospital.
Trial registration number: NA.

P-762 Comparison of vaginal misoprostol and dinoprostone for cervical ripening before diagnostic hysteroscopy in nulliparous women

H. Inal[1], Z. Inal[1], E. Tonguc[2], T. Var[2]
[1]*Konya Education and Research Hospital, Reproductive Medicine, Konya, Turkey*
[2]*ZTB Women's Health Education and Research Hospital, Reproductive Medicine, Ankara, Turkey*

Study question: To compare the effectiveness of vaginal misoprostol and dinoprostone for cervical ripening before diagnostic hysteroscopy in nulliparous women.
Summary answer: In a prospective, randomized study, vaginally administered dinoprostone before diagnostic hysteroscopy is more effective than misoprostol for inducing cervical ripening.
What is known already: One of the most significant problems during diagnostic hysteroscopy is the difficulty of the instrument to go along the cervical canal and to pass the internal os and the related complications such as cervical injury or tear, bleeding, a false track or uterine perforation. In order for this passing to be easier there needs to be cervical ripening and widening of the cervical canal at a specific diameter.
Study design, size, duration: A total of 90 women with suspected intrauterine lesions (such as uterin polyps, filling defects in the uterine cavity) on the basis of abnormal findings from hysterosalpingo-graphy, ultrasonography or saline-infusion-graphy were admitted to the study between July 2012 and December 2013.
Participants/materials, setting, methods: Ninety women in reproductive age eligible for diagnostic hysteroscopy were recruited. Patients were randomly assigned to receive 400 mcg misoprostol (n = 30), 10 mg dinoprostone (n = 30) vaginally before diagnostic hysteroscopy; the control group (n = 30) did not receive any cervical priming agent.
Main results and the role of chance: Primary outcome; the number of women requiring cervical dilatation. In the control group, 23 (76.7%) patients needed cervical dilatation before hysteroscopy; in the misoprostol group, 17 (56.7%) patients needed it, whereas only 9 (30%) patients in the dinoprostone group did. There was significant difference between misoprostol and dinoprostone group (p = .037) and placebo and dinoprostone group (p < .001), but there was not difference between placebo and misoprostol group (p = .100).
Limitations, reason for caution: A potential weakness of the present study is the subjective measurement of cervical width. To overcome this situation, it is recommended to use a tensinometer but most of the previous studies the cervical width was achieved by Hegar's bougies.
Wider implications of the findings: To date, only one study has evaluated the effects of vaginal misoprostol and dinoprostone for cervical ripening in nulliparous women before operative hysteroscopy. Preutthiron and colleagues found that vaginal misoprostol was more effective than dinoprostone for cervical priming in nulliparous women before hysteroscopic surgery. The discripency of results between our study and Preutthipan's study might be that we have employed different procedures, we performed diagnostic hysteroscopy.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Konya Education and Research Hospital.
Trial registration number: NCT01620814.
Keywords: misoprostol, dinoprostone, cervical ripening, hysteroscopy

P-763 Congenital adrenal hyperplasia: outcomes surgical correction of ambiguous genitalia

Z. Uzhegova[1], E. Andreeva[1]
[1]*National Scientific Center of Endocrinology, Reproduction, Moscow, Russia C.I.S.*

Study question: Outcomes of surgical treatment of congenital adrenal hyperplasia (CAH).
Summary answer: Considering the results of surgical treatment of adolescent girls with CAH simple virilizing form female plastic of external genitals must be conducted at the age of 2–3 years in one-stage operation. For the patients with CAH salt-wasting form two-stage operation of external genitals female plastic is recommended.
What is known already: -
Study design, size, duration: 103 subjects 15–26 year old (middle age 19,4) participated in this study. All subjects were divided into 2 treatment groups: 67 subjects with CAH simple virilizing form entered into the first treatment group, 36 subjects with CAH salt-wasting form entered into the second treatment group. Feminizing genitoplasty was conducted for all subjects. For the patients of the 1 group it was performed when they were 3–6 years old including clitoris plastic and section of urogenital sinus in one-stage operation. For the patients of the second group two-stage operation was conducted: female plastic of external genitals was performed at the age of 2–6 years and introit plastic was conducted at the age of 14–16 years. Of these 35 subjects 8 subjects underwent operation with subsequent vaginal dilatation in the postoperative period.
Participants/materials, setting, methods: Several postoperative complications were registered: vaginal vestibule cicatricial deformity, formation of vaginal stricture, coarse fibrosis, stenosis. Most of the complications were registered in the second group. All first group girls with CAH simple form were sexually adapted. 4 second group girls could not be sexually active due to postoperative complications
Main results and the role of chance: -
Limitations, reason for caution: -
Wider implications of the findings: -
Study funding/competing interest(s): Funding by national/international organization(s) – National Scientific Center of Endocrinology.
Trial registration number: L28.
Keywords: feminizing genitoplasty, congenital adrenal hyperplasia, ambiguous genitalia

P-764 Immunohystochemical features of IL-6 in pelvic peritoneal adhesions of various etiologies at reproductive age women

G. Sulima[1], O. Davydova[2], V. Litvinov[3]
[1]*Crimean State Medical University Named after S. I. Georgievskiy, Obstetrics Gynaecology and Perinatology, Simferopol, Ukraine*
[2]*Crimean State Medical University Named after S. I. Georgievskiy, Pathological Anatomy with Autopsy Course, Simferopol, Ukraine*
[3]*AltraVita IVF, IVF, Moscow, Russia C.I.S.*

Study question: To examine the morphological structure and expression of IL-6 in the tissues of the pelvic peritoneal adhesions at reproductive age women and forecast scientifically the future behavior of formed adhesions after adhesiolysis.
Summary answer: Regardless of the genesis of morphological features and adhesions in women of the reproductive age, the immunohistochemical study of IL-6 observed tissue staining of varying intensity, the highest level of IL-6 marker's expression was detected in adhesions at patients with external genital endometriosis.
What is known already: Increased production of IL-1 and TNF-a in traumatic inflammation or infection correlates with an increase in the number and severity of adhesions. Unlike IL-1 and TNF-a, the role of IL-6 in the adhesion process is characterized by conflicting data reports. Some authors have suggested that IL-6 is involved in the formation of adhesions, possessing the properties of proinflammatory cytokines. According to other researchers, its concentration doesn't correlate with the presence and severity of peritoneal adhesions.
Study design, size, duration: The materials of this study were fragments of the surgical specimens (adhesions and their parts) n = 100, obtained from reproductive age women during operative laparoscopy. The morphological and immunohistochemical study of adhesions were carried out by standard procedures using paraffin blocks of Dako reagents and monoclonal antibodies to IL-6.
Participants/materials, setting, methods: The adhesions of 38 patients with a history of chronic inflammatory diseases, pelvic adhesions of 32 patients with endometrial disease (12 patients with ovarian endometriosis and 20 patients with peritoneal endometriosis outside) and 30 patients who previously underwent surgeries of pelvic and abdominal cavity.
Main results and the role of chance: During the immunohistochemical study of adhesions obtained from women undergoing surgery of pelvic organs, the expression of IL-6 was extremely low and was equal to 33 ± 0,2 points, only a few positively stained cells were found in the walls of arteries. Tissue adhesions in women with a history of inflammatory diseases of the pelvic organs, characterized by moderate expression of IL-6, was 65 ± 0,3 points. Positive staining was detected mainly in the mesothelial cells covering the walls of the spike and the arteries. The material of adhesions in case of external genital endometriosis, was characterized by a pronounced expression of IL-6. The most commonly observed diffuse was the one of the moderate severity staining of fibroblasts and arterial walls and mesothelial cells. It reached 154 ± 0,6 points.
Limitations, reason for caution: Age limitation, only women aged 19–49 years took part in this study. Exclusion criteria the following for the groups: acute gynecological diseases, malignant diseases of female genitalia and ovarian tumors.
Wider implications of the findings: Regardless of the genesis of morphological features and adhesions in women of the reproductive age, the immunohistochemical study of IL-6 observed tissue staining of varying intensity. The highest

level of IL-6 marker's expression was detected in adhesions at patients with external genital endometriosis. Such characteristics of IL-6 as a system device indicate the need for more active management of patients with external genital endometriosis, using anti-inflammatory and immunomodulatory therapy.
Study funding/competing interest(s): Funding by University(ies) – Crimean State Medical University named after S. I. Georgievsky.
Trial registration number: This study isn't an RCT.
Keywords: pelvic peritoneal adhesion, morphology, interleukin 6, reproductive age women

P-765 Unidirectional knotless barbed suture for laparoscopic myomectomy (bsLM): fertility, pregnancy and delivery outcomes

A. Racca[1], F. Alessandri[2], U. Leone Roberti Maggiore[1], F. Sozzi[1], P. L. Venturini[1], S. Ferrero[1]
[1]*IRCCS San Martino Hospital and National Institute for Cancer Research University of Genoa, Obstetrics and Gynecology Unit, Genoa, Italy*
[2]*IRCCS San Martino Hospital and National Institute for Cancer Research, Obstetrics and Gynecology Unit, Genoa, Italy*

Study question: Which are the fertility, pregnancy and delivery outcomes in women undergoing bsLM?
Summary answer: Fertility and pregnancy outcomes are similar to those reported in the literature for laparoscopic myomectomy with standard suture.
What is known already: During laparoscopic myomectomy, the use of barbed suture aids surgeons by reducing operative time, difficulty of suturing, suturing time, and blood loss. No information is available on fertility and pregnancy outcomes in patients treated with bsLM.
Study design, size, duration: This prospective single-centre cohort study included 61 women who tried to conceive after bsLM that was performed between January 2010 and August 2013.
Participants/materials, setting, methods: The study included patients with at least one myoma with diameter ≥4 cm and at least one FIGO type 3, 4 or 5 myoma who tried to conceive for at least 12 months during follow-up. Patients with infertility factors (i.e. endometriosis, hydrosalpinx) were excluded from the study.
Main results and the role of chance: The mean (± SD) age at bsLM was 35.9 (±3.8) years. The median number of myomas removed was 2 (range, 1–5) with a mean diameter of the larger myoma of 6.7 (±1.9) cm. The mean length of follow-up was 2.9 (±1.0) years. 34 patients (55.7%) spontaneously conceived; the mean time to conception was 5.7 (±3.9) months. 11 patients (18.0%) conceived by assisted reproductive technologies. There were 17 cesarean sections (13 because of previous myomectomy); labor was successful in 12 women (73.3% of all vaginal delivery trials). There were 5 miscarriages and 1 voluntary termination of pregnancy (because of Down Syndrome); 10 pregnancies are on-going. There was no uterine rupture or placental complication.
Limitations, reason for caution: The small sample size is the major limitation of the study which is unpowered to draw definitive conclusions on the risk of uterine rupture during vaginal delivery in patients treated by bsLM.
Wider implications of the findings: The use of barbed suture during laparoscopic myomectomy does not decrease spontaneous fertility and does not affect pregnancy outcome. Further investigations are required before bsLM can be routinely performed in women wishing to undergo vaginal delivery.
Study funding/competing interest(s): Funding by University(ies) – University of Genoa.
Trial registration number: NA.
Keywords: laparoscopic myomectomy, barbed suture, fertility, pregnancy outcome, vaginal delivery

P-766 Salpingostomy in the treatment of hydrosalpinx: a systematic review and meta-analysis

J. Chu[1], H. M. Harb[1], I. D. Gallos[1], R. K. Dhillon[1], F. M. Al-Rshoud[1], L. Robinson[1], A. Coomarasamy[1]
[1]*Birmingham Womens Hospital NHS Foundation Trust, Assisted Conception Unit, Birmingham, United Kingdom*

Study question: What is the chance of natural conception when salpingostomy is used to treat hydrosalpinx?
Summary answer: The rate of natural clinical pregnancy after salpingostomy is performed for hydrosalpinx is 26% (95% CI 24–29%).
What is known already: Tubal surgery is now not commonly offered for women with hydrosalpinges. Surgical correction of hydrosalpinges has declined simulateously with the increasing utilisation of in vitro fertilisation. This is the first systematic review to investigate natural conception rates following salpingostomy in the treatment of hydrosalpinx.
Study design, size, duration: We conducted a systematic review of 21 observational studies. These studies encompassed 2376 patients that underwent salpingostomy and then attempted natural conception. Follow up was over a variety of time periods.
Participants/materials, setting, methods: Literature searches were conducted to retrieve observational studies which reported salpingostomy for hydrosalpinx. Databases searched included MEDLINE, EMBASE, Cochrane Register and CINAHL. Only studies that focused on salpingostomy (rather than other tubal conserving surgeries) for the treatment of hydrosalpinx were included. 21 studies matched the inclusion criteria.
Main results and the role of chance: The pooled natural clinical pregnancy rate from the 21 observational studies (including 2376 patients) was 26% (95% CI 24–29%) after salpingostomy was performed for hydrosalpinx. The cumulative clinical pregnancy rates were 6.4% (95% CI 3.2–12.8%) at 6 months, 21.9% (95% CI 19.0–26.0%) at 12 months, 22.1% (95% CI 18.8–26.0%) at 18 months and 28.2% (95% CI 22.9–34.7%) at 24 months. The pooled live birth rate (eight studies, 954 patients) was 24% (95% CI 21–28%) after salpingostomy was performed for hydrosalpinx. The pooled ectopic pregnancy rate (18 studies, 2228 patients) was 10% (95% CI 8–11%). The pooled miscarriage rate (seven studies, 924 patients) was 7% (95% CI 6–9%). The included studies scored well on the Newcastle Ottawa quality assessment scale.
Limitations, reason for caution: Strict inclusion criteria were used in the conduct of the systematic review. However, the studies included are clinically heterogeneous in many aspects including patient characteristics, surgical technique and duration of follow up after salpingostomy.
Wider implications of the findings: The findings of this systematic review suggest that there may be an alternative treatment strategy in patients presenting to fertility services with hydrosalpinx. Further prospective, large and high quality studies are needed to identify the sub-population that would most benefit from tube conserving surgery.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Birmingham Womens NHS Foundation Trust.
Trial registration number: No trial registration number is available as this is a systematic review.

P-767 Uterine allotransplantation in a rabbit model using aorto-caval anastomosis: a long-term viability study

J. R. Smith[1], S. Saso[1], T. Bracewell-Milnes[2], M. Y. Thum[3]
[1]*Imperial College London, Surgery and Cancer, London, United Kingdom*
[2]*King's College London, Gynaecology, London, United Kingdom*
[3]*The Lister Hospital, Fertility, London, United Kingdom*

Study question: Can a large vessel aortic-caval vascular patch technique, whereby the recipient and donor aortae and vena cavae are anastomosed together, bring about long-term graft functionability and animal survival following an allogeneic uterine transplant in a rabbit model.
Summary answer: Our method used a macrovascular patch technique to ensure adequate blood supply to the donor uterine graft. We have demonstrated the feasibility of uterine allotransplantation using this technique in the rabbit, demonsatrted by a resulting pregnancy, but were unable to demonstrate a higher long-term survival percentage.
What is known already: Women with absolute uterine factor infertility are considered as being 'unconditionally infertile'. Currently, the only two fertility management options are surrogacy or adoption. These women may also benefit from a possible third option: uterine transplantation. Allogeneic uterine transplantation has been attempted in a number of animal models, but achieving an adequate blood supply for the transplanted uterus still presents the biggest challenge. Microvascular re-anastomosis was unsuccessful in a number of animal models.
Study design, size, duration: This was a longitudinal study involving a small-animal model. The study was performed at the Royal Veterinary College and Imperial College London, United Kingdom between May 2011 and December 2012. Nine donor and nine recipient allogeneic New Zealand White rabbits of proven fertility were chosen for the cross-transplantations.

Participants/materials, setting, methods: An aortic-caval macrovascular patch was harvested as part of the uterine allograft. Tacrolimus was administered for immunosuppression. If long-term survival was ensured, embryos were transferred into each cornua via mini-midline laparotomy. The pregnancy was monitored with regular reproductive profiles and trans-abdominal ultrasound. The recipients were monitored until death or euthanasia.
Main results and the role of chance: In this case series, long-term rabbit survival was 11% ($n = 1$). Surgical survival was 56% ($n = 5$). Three rabbits (UTx #3, #4, #8) died intra-operatively as a result of blood aspiration, ventricular hematoma, and massive hemorrhage. Three does (#1, #2, #7 and #9) died within the first 24h as a result of the veno-vena and anastomosis breakdown. Does #6 and #9 died secondary to pre-operative pneumonia and a pulmonary embolus, respectively. Only one rabbit survived longer than a month. In this doe, a gestation sac was visualised on ultrasound from day 9 post-embryo transfer but by D18 the gestation sac had reduced in size, suggesting fetal resorption had occurred. Scheduled necropsy on D27 and histopathology confirmed evidence of a gravid uterus and presence of a gestational sac.
Limitations, reason for caution: The biggest limitation of the study is the paucity of data and therefore we recognize that it is difficult to make any conclusions regarding our immunosuppression regimen. The combination of a CNI and a steroid can clearly slow down the rejection process, if not completely inhibit it. If UTx were available in humans, one can envisage the addition of a monoclonal antibody for the induction the end. Disappointingly our sole pregnancy did not result in the birth of healthy term offspring. Also, tissue typing between the donor and the recipient does was not performed.
Wider implications of the findings: Despite the end-result i.e. failed pregnancy, the study represents only the third example of conception and pregnancy following an allogeneic animal uterine transplant. The surgical anatomical macrovascular model was successful. The cause of fetal demise is most likely secondary to inadequate prevention of the immunological rejection response.
Study funding/competing interest(s): Funding by national/international organization(s) – Funded by a registered UK charity – Womb Transplantation UK.
Trial registration number: NA.
Keywords: uterus, transplantation, fertility, rabbit, Allogeneic

P-768 Uterine auto-transplantation in a sheep model using iliac vessel anastomosis

S. Saso[1], M. Y. Thum[2], T. Bracewell-Milnes[3], J. R. Smith[1]
[1]*Imperial College London, Surgery and Cancer, London, United Kingdom*
[2]*The Lister Hospital, Fertility, London, United Kingdom*
[3]*King's College London, Gynaecology, London, United Kingdom*

Study question: To investigate, develop and evaluate anatomical, surgical and anastomotic aspects necessary for a successful uterine transplant in a large-animal (sheep) model, whereby uterine autotransplantation will be carried out in an orthotopic position in the pelvis and with vascular anastomosis to the external iliac vessels.
Summary answer: Internal to external iliac vessel anastomosis, whereby the external iliac vessles may be used as recipients of the graft vessels in order to allow for a secure blood flow, is an acceptable surgical technique that should be applied in a human uterine transplantation model to ensure adequate subsequent uterine perfusion.
What is known already: Women with absolute uterine factor infertility are considered as being 'unconditionally infertile'. Currently, the only two fertility management options are surrogacy or adoption. These women may also benefit from a possible third option: uterine transplantation. There is a need to further develop the large animal uterine transplantation model in order to study anastomotic and other surgical techniques. The large animal model resembles the human pelvis much more closely than small animals.
Study design, size, duration: This was a longitudinal study involving a large-animal model. The model itself was a sheep model. The study was performed at the Royal Veterinary College and Imperial College London, United Kingdom between January and June 2013. Five ewes of proven fertility were chosen for the auto-transplants.
Participants/materials, setting, methods: The uterine allograft along with the internal iliacs, and uterine arterial and venous tree all intact were harvested en bloc. An end-to-side anastomosis was performed between the external iliac and the internal iliac vessels. Successful reperfusion of the graft was judged by the color shift of the uterus during reperfusion.
Main results and the role of chance: The main outcome measures were as follows: operative details (retrieval, ischaemic, clamping, reperfusion and recipient hysterectomy duration); physiological profiles; gross morphology and histopathology. Five autotransplants were performed in the sheep model. One procedure was abandoned because of the inappropriate size of sheep model. Another procedure was halted because the animal suffered from respiratory failure in the immediate intra-operative period. Three transplants were completed. In those, at least two of four possible anastomoses were finished and the grafted uteri demonstrated immediate perfusion and appropriate viability 45 min post-operatively.
Limitations, reason for caution: Five cases were attempted, with only three completed. The reasons for the non-completion of autotransplants #1 and #4 were non-surgical. The next study should assess long-term uterine function by attempting conception, with analysis of fetal weight/well-being. Fluid balance must be recorded to prevent future occurrences of renal failure.
Wider implications of the findings: The present study was the first time that the UK team attempted a macrovascular uterine transplant large-animal model. The surgical technique was very similar to what would be used in a human model. The external iliac vessels may be used as recipients of the graft vessels in order to allow for a secure blood flow. A future experiment should attempt to achieve normal pregnancies after removal and subsequent auto-/allo-transplantation of the sheep uterus.
Study funding/competing interest(s): Funding by national/international organization(s) – Funded by a registered UK charity – Womb Transplantation UK.
Trial registration number: NA.
Keywords: uterus, transplantation, fertility, sheep, anastomosis

P-769 IVF treatment should not be postponed for patients after exeresis of ovarian endometrioma with normal basal FSH concentration: a retrospective study

L. Yue[1], H. Xuefeng[1], L. Jinju[1], W. Peiyu[1], Z. Junzhao[1]
[1]*The First Affiliated Hospital of Wenzhou Medical University, Reproductive Medicine Center, Wen Zhou, China*

Study question: Whether IVF treatment should be delayed in patients after exeresis of ovarian endometrioma with normal basal FSH concentrations.
Summary answer: IVF treatment should not be delayed in patients after exeresis of ovarian endometrioma with normal basal FSH concentrations.
What is known already: Infertile patients with endometriosis have a similar concentration of Follicular-fluid anti-Müllerian hormone (AMH) as compared with non-endometriotic patients, and basal concentrations of serum FSH are routinely used as a marker for predicting ovarian reserve and as a screening test for patients undergoing IVF. However, there are few studies to investigate basal FSH fluctuations in women after exeresis of ovarian endometrioma.
Study design, size, duration: A total of 146 controlled ovarian hyperstimulation (COH) cycles were registered; 3 of these cycles had ovarian hyperstimulation syndrome, which had been excluded. So we retrospectively evaluated 76 cycles after previous exeresis of ovarian endometrioma and 67 cycles with male factor infertility from January 2008 to January 2013.
Participants/materials, setting, methods: (1) All patients' basal FSH level was lower than 10 IU/l, infertility associated with ovarian endometrioma diagnosed by laparoscopy, (2) age ≤40 years old, (3) body mass index (BMI) <30 kg/m, (4) absence of polycystic ovarian syndrome and other endocrine disease. The treatment protocols were long agonist protocol.
Main results and the role of chance: The patients' characteristics and mostly the IVF treatment outcome parameters between the two groups had no significant differences. However, the number of retrieved oocytes was significantly higher in group II than that in group I ($P = 0.02$) and the number of retrieved oocytes significantly decreased in patients less than 1 year and 2–3 year after exeresis of ovarian endometrioma ($P = 0.028$, $P = 0.005$, $P = 0.04$). The post-operative period independently contributed to the FSH units used in a COH cycle ($P = 0.018$) and the FSH units used significantly increased in more than 4 years after exeresis of ovarian endometrioma ($P = 0.000$, $P = 0.001$, $P = 0.012$, $P = 0.001$, $P = 0.004$).
Limitations, reason for caution: our study did not take into account the impact of frozen–thawed cycles on the cumulative pregnant rates (due to data currently

not being available as some patients still have some frozen embryos which are not transferred in).
Wider implications of the findings: This study shows that basal FSH concentration is not useful for the clinician deciding on whether to delay treatment in a patient after exeresis of ovarian endometrioma with a normal FSH concentration. It would therefore be appropriate to treat infertile patients if they are normally cycling with the full knowledge of the smaller number of retrieved oocytes.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Reproductive Medicine Center of the First Affiliated Hospital of Wenzhou Medical University.
Trial registration number: NA.

P-770 The effect of laparoscopic myomectomy on fertility of infertility patients

R. Tsutsumi[1], M. Hirano[1], M. Tanaka[1], H. Tsuchiya[1], R. Kondo[1], Y. Takemura[1], S. Tsuchiya[1], O. Nishi[1]
[1]*Teikyo University School of Medicine University Hospital Mizonokuchi, Obstetrics and Gynecology, Kawasaki, Kanagawa, Japan*

Study question: What is the effect of laparoscopic myomectomy for infertility patients?
Summary answer: This study confirmed that laparoscopic myomectomy may be effective for infertility patients with intramural uterine myoma.
What is known already: Submucous myomas led to decreased fertility. Hysteroscopic myomectomy for submucous myomas is likely to improve pregnancy rate.
Study design, size, duration: A retrospective study was performed from January 2008 through December 2012 on 96 infertility patients with intramural myomas. They had undergone laparoscopic myomectomy.
Participants/materials, setting, methods: Out of 96 patients analyzed, 40 were laparoscopic myomectomy cases and 56 were laparoscopic assisted myomectomy cases. Sixty-seven cases were analyzed for their fertility improvement. During the same period, patients who had submucous myoma and undergone hysteroscopic myomectomy were studied for the pregnancy after the surgery for comparison.
Main results and the role of chance: Forty out of 67 (61.2%) patients become pregnant within one year with or without infertility treatment. Twenty-seven pregnancies followed an IVF/ICSI procedure. There were 6 IUI cases and 8 natural conception cases. Twenty cases were conceived within 1–3 months, 11 cases were within 4–6 months, 8 cases were within 7–9 months and 2 cases were within 10–12 months Conception tends to occur in early months after surgery. The cumulative pregnancy rate of group which had distortion of uterine cavity were 59.3% (32/54) and that of group which had no distortion of uterine cavity were 64.3% (9/14). The cumulative pregnancy rate of the patients who had undergone hysteroscopic myomectomy were 55.6%. Laparoscopic myomectomy for infertility patients was not inferior to hysteroscopic myomectomy for submucous myomas.
Limitations, reason for caution: Possible biases related to retrospective studies and limited number of cases.
Wider implications of the findings: A prospective randomized clinical trial is needed to confirm our findings.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Teikyo University School of medicine University Hospital, Mizonokuchi.

P-771 Almost half of unilateral hydrosalpinx need additional contralateral fallopian tubal surgery

H. G. Sun[1], K. H. Lee[1], I. H. Park[1], H. J. Chi[1], S. G. Kim[1], K. H. Maeng[1], S. J. Kwak[1], J. Y. Park[1]
[1]*Mamapapa&baby Obstetrics Gynecology Clinic, OB&GY, Ulsan City, South Korea*

Study question: When we perform unilateral salpingectomy due to unilateral hydrosalpinx on HSG, is really contralateral fallopian tube normal?
Summary answer: With a unilateral hydrosalpinx on HSG, abnormalities in contralateral fallopian tube were found in 45.6% and performed additional surgeries salpingectomy or fimbrioplasty.
What is known already: Tubal factor is about one third causes of infertility. For tubal factor evaluation, the most commonly used tests are hysterosalpingography (HSG) and laparoscopy. HSG has high specificity for diagnosis of tubal occlusion and low sensitivity in cases with peritubal adhesions. Tubal patency on HSG does not necessarily indicate normal tubal function. Among women with patent tubes on HSG, 18% were found to have tubal obstruction or peritubal adhesions on laparoscopy.
Study design, size, duration: This retrospective study included 178 salpingectomy cases due to hydrosalpinx on HSG between January 2010 and December 2014.
Participants/materials, setting, methods: Total 178 cases salpingectomy were performed. 99 cases were excluded (69 cases - bilateral salpingectomy due to bilateral hydrosalpinx, 30 cases – unilateral salpingectomy due to unilateral hydrosalpinx with contralateral tubal obstruction on HSG/previous salpingectomy).
Main results and the role of chance: We analyzed 79 cases with unilateral hydrosalpinx and contralateral normal patency on HSG. Among 79 cases, 43 cases were performed only unilateral salpingectomy (US). 14 cases were performed US and contralateral salpingectomy due to unexpected hydrosalpinx. 22 cases were performed US and contralateral fimbrioplasty or adhesiolysis due to peritubal adhesion or abnormal result on dye test. Therefore in case of unilateral hydrosalpinx on HSG, 45.6% (36/79) were found abnormality of contralateral tube and needed additional surgery.
Limitations, reason for caution: The subjectivity of radiologists may be involved in interpretation of HSG. Also during operation, the subjectivity of surgeon may be involved in decision making of contralateral tubal surgery.
Wider implications of the findings: An abnormal tubal condition affects negatively natural pregnancy or IVF outcomes, therefore proper surgery is needed. Among women with normal tubes on HSG, 18% were found abnormalities on laparoscopy. But with unilateral hydrosalpinx, proportion of requiring opposite fallopian tubal surgery is increased by 45.6%. Therefore, in case of elective unilateral salpingectomy due to unilateral hydrosalpinx on HSG, operators must examine opposite tube carefully and make full explanation about incidental bilateral salpingectomy and possibility of IVF.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Mamapapa & baby OB&GY clinic.
Trial registration number: NA.

P-772 The outcome of "conservative debulking surgery" in infertile women with uterine adenomyosis

S. H. Yoon[1], J. W. Roh[1]
[1]*Dongguk University Ilsan Hospital, Obstetrics and Gynecology, Goyang city Gyeong Gi Do, South Korea*

Study question: Does conservative debulking surgery of adenomyosis have clinical efficacy in infertile women?
Summary answer: Conservative debulking surgery could be an effective method for increasing pregnancy rate and conservation of fertility potential in infertile women with adenomyosis.
What is known already: Adenomyosis appears to affect endometrial receptivity and increase abortion rate. In infertility where uterine conservation is paramount, the treatment of adenomyosis is often complicated. that is to say, hysterectomy has been a standard surgical treatment for eradication. Until now, there is no agreement on the most appropriate therapeutic methods. There have been several reports that surgical procedures, including endometrial resection, myometrial reduction and excision by electrocautery, reduced the need for hysterectomy in patients with adenomyosis
Study design, size, duration: Prospective clinical trial was conducted. The subjects consisted of 39 infertile patients with adenomyosis undergoing In Vitro Fertilization-Embryo Transfer (IVF-ET) and were enrolled from December 2007 to June 2014.
Participants/materials, setting, methods: 39 patients having unexplained infertility, adenomyosis were enrolled after the failure of IVF. This newly designed operation included transverse H-incision on the adenomyotic wall, excision of adenomyosis tissue using argon laser under the monitoring of intraoperative ultrasonography. After debulking surgery, patients underwent follow up for checking symptom relief and pregnancy.

Main results and the role of chance: The mean age of the patients was 35.15 ± 3.05 years and the volume of excised specimens of adenomyosis was 88.00 ± 71.45g. The relief of dysmenorrhea was observed clearly in all patients at 6 months after operation (NRS; 7.88 ± 2.50 vs. 1.76 ± 1.86, $p < 0.001$). The CA 125 level was significantly decreased at the time of 6 months after operation (187.55 ± 221.13 vs. 26.78 ± 19.29, $p < 0.016$). Post-operational complication occurred in three patients (ureter fistula, uterus necrosis and POF). Of 31 patients who attempted pregnancy, 10 patients conceived by IVF-ET or Thawing-ET after the operation (10 of 31; 32.3%). Miscarriage occurred in three patients, ectopic pregnancy in one patient and six patients delivered by cesarean section at term.
Limitations, reason for caution: The sample size was small, so further study with larger number of patients will be helpful to investigate the possibility of this result.
Wider implications of the findings: This conservative debulking surgery was related to the symptom relief of dysmenorrhea and increasing pregnancy rate, implying that this surgical approach could be considered as a useful method for infertile women with adenomyosis who need conservation of uterus. This is the first report on the pregnancy status of surgical approach in infertile women with uterine adenomyosis.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Dongguk University Ilsan Hospital.
Trial registration number: NA.

P-773 Does laparoscopy still have a role in patients with unexplained infertility?

A. Mahran[1], A. Abdelrahem[1], M. Gadelrab[1], A. Eissa[1]
[1]*Faculty of Medicine, Obstetrics and Gynaecology Department, Minia, Egypt*

Study question: Do patients with unexplained infertility benefit from undergoing laparoscopy?
Summary answer: Laparoscopy still has an important role in diagnosis and management of cases of unexplained infertility.
What is known already: Unexplained infertility remains a challenge in diagnosis and management even after the introduction of IVF technology. It is well known that patency of the fallopian tubes by hyterosalpingogram does not rule out pelvic adhesions that can only be diagnosed by laparoscopy. Laparoscopy can diagnose cases with mild endometriosis that are not diagnose clinically of with ultrasound. It is debatable whether laparoscopy should be a mandatory step in sub-fertility workup.
Study design, size, duration: Case control study included 229 patients with unexplained infertility that underwent laparoscopy during the period from January 2012 to December 2012 (study group). The control group included 300 patients with unexplained infertility treated expectantly or with ovulation induction during the same period.
Participants/materials, setting, methods: We reviewed the files and operative reports of 229 patients with unexplained infertility that underwent laparoscopy at the endoscopy unit in Minia University Hospital, Minia, Egypt within one year. We traced these patients to know whether pregnancy was achieved or not within one year after laparoscopy. We traced patients in the control group during the same duration of time.
Main results and the role of chance: Among the 229 patients that underwent laparoscopy, pelvic adhesions were found in 20 patients, tubal problems not revealed by hysteroslpingram were found in four patients and mild endometriosis was found in 9 patients. Laparoscopic adhesolysis, tuboplasty and diathermy of endometriotic spots were done respectively. Eighty four patients achieved pregnancy within one year after undergoing laparoscopy. In the control group ($n = 300$), fifty one patients achieved pregnancy during the same period either spontaneously or on top of ovulation induction. Odds ratio for achieving pregnancy after laparoscopy in patients with unexplained infertility was 2.83 which was statistically significant ($P < 0.01$).
Limitations, reason for caution: Laparoscopic procedures in this study were done in a tertiary hospital by experts in laparoscopic surgery. That allowed proper managements of cases with pelvic adhesions and endometriosis with subsequent high pregnancy rate after laparoscopy. Laparoscopic surgeons with equal expertise are not available for all laparoscopic procedures done for patients with unexplained infertility.
Wider implications of the findings: Patients with unexplained infertility constitute a large proportion of infertile patients. Laparoscopy can diagnose and treat problems like pelvic adhesions and mild endometriosis in these patients. Laparoscopy is recommeneded to be done as a part of sub-fertility workup in patients with unexplained infertility.
Study funding/competing interest(s): Funding by University(ies) – Minia University, Minia, Egypt.
Trial registration number: The study is not a clinical trial.
Keywords: laparoscopy, unexplained infertility

P-774 Effectiveness of bilateral uterine artery chemoembolization with methotrexate and gelatine foam in the treatment of caesarean scar pregnancy

S. Wozniak[1], P. Czuczwar[1], P. Szkodziak[1], K. Pyra[2], T. Paszkowski[1]
[1]*University School of Medicine, 3rd Chair and Department of Gynecology, Lublin, Poland*
[2]*University School of Medicine, Interventional Radiology Department, Lublin, Poland*

Study question: The aim of this study was to investigate the efficacy and safety of uterine artery embolization (UAE) with intra-arterial methotrexate (MTX) and gelatine foam combined with dilation and curettage (D&C) for the treatment of caesarean scar pregnancy (CSP).
Summary answer: Bilateral Uterine Artery Chemoembolization with the use of absorbable embolizing material combined with D&C seems to be an effective and safe method, and may be beneficial for women wishing to preserve fertility.
What is known already: Caesarean scar pregnancy (CSP) is the rarest type of ectopic pregnancy. It is a life-threatening abnormal form of implantation of a gestational sac in the myometrium at the site of a previous Caesarean scar. The incidence of this pathology ranges from 1/1800 to 1/2200 pregnancies and its rate is 0.15% in women with previous Caesarean sections. CSP can lead to massive haemorrhages, uterine rupture, and disseminated intravascular coagulation or death. Early diagnosis is essential for effective treatment to avoid life-threatening complications. Despite increasing incidence rates of Caesarean scar pregnancy, no universal guidelines for its management and treatment have been suggested.
Study design, size, duration: In this retrospective observational study the studied group consisted of 10 patients between 6 and 9 weeks of pregnancy.
Participants/materials, setting, methods: Caesarean scar pregnancy was confirmed by transvaginal ultrasound, using the following criteria: an empty uterine cavity, empty cervical canal, development of the gestational sac in the anterior part of the uterine isthmus and blood flow around the gestational sac. The therapeutic procedures were performed under local anaesthesia by puncturing the right femoral artery using the Seldinger technique. The 5F vascular sheath was inserted; the Pigtail catheter was placed in the abdominal aorta. Digital subtraction angiography of both internal iliac arteries was performed. Using the cross-over method, the 5Fr Robert catheter was moved to the opposite side. The uterine artery was selectively cannulated using the Progreate microcatheter; 25 mg of methotrexate was infused bilaterally (total 50 mg) administered in a slow bolus and the vessel was embolized using the gelatine foam (technical pearls: two screw syringes, three way stopcock, gelatin sponge cut into small pieces, add contrast, mix it between the syringes through a stopcock) until stasis was achieved. After 48 h, all patients were treated with D&C.
Main results and the role of chance: A total of 10 women diagnosed with caesarean scar pregnancy were successfully treated with Bilateral Uterine Artery Chemoembolization (UTACE) with local MTX and Gelatine Foam combined with uterine curettage. None of the treated patients required a hysterectomy. The mean blood loss was estimated at 125 ml.The mean duration of hospital stay was 5 days. The average time for beta-hCG to decline to normal values was 24 days. The mean time to recovery of normal menstruation was 32 days.
Limitations, reason for caution: Limitation of the study is a small group of patients studied.
Wider implications of the findings: UTACE with the use of absorbable embolizing material combined with D & C is a new, safe and effective treatment method of caesarean scar pregnancy allows to preserve the uterus.
Study funding/competing interest(s): Funding by University(ies) – Medical University of Lublin.

Trial registration number: KE-0254/120/2012.

P-775 How often can FloSeal®, a gelantine-thrombin matrix sealant, effectively achieve haemostasis after laparoscopic stripping of ovarian endometriomas?

J. P. W. Chung[1], W. S. Kong[1], H. S. Chung[1], L. P. Cheung[1], T. C. Li[1]
[1]*The Chinese University of Hong Kong, Department of Obstetrics and Gynaecology, Hong Kong, Hong Kong*

Study question: To assess how effective FloSeal®, a gelantine-thrombin matrix sealant, is in achieving haemostasis after laparoscopic stripping of ovarian endometriomas.
Summary answer: FloSeal® is an effective method in achieving haemostasis after laparoscopic stripping of ovarian endometriomas and should be considered as an alternative to traditional electrocoagulation for haemostasis, especially in those women with fertility wish or low ovarian reserve.
What is known already: Laparoscopic ovarian cystectomy by the stripping method is the most common operative technique to treat endometriomas. Traditional methods for controlling haemostasis are by electrocoagulation and by laparoscopic suturing. FloSeal® consists of a bovine-derived Gelatin Matrix and a human derived Thrombin component and has been an effective alternative method of haemostasis in various operations. There is limited data on its use in gynaecological reproductive surgery.
Study design, size, duration: This is an observational study which is a part of a randomized controlled study in assessing ovarian function after laparoscopic stripping of ovarian endometriomas conducted at the Department of Obstetrics and Gynaecology of Prince of Wales University Hospital in Hong Kong between July 2013 and December 2014.
Participants/materials, setting, methods: All women aged 18–40 years old with clinical and ultrasound diagnosis of unilateral or bilateral endometriomas was enrolled. Patients were consented to use FloSeal® for haemostasis after laparoscopic stripping of ovarian endometriomas.
Main results and the role of chance: A total of 20 patients aged 34 ± +4.44 years old underwent laparoscopic ovarian cystectomy for ovarian endometriomas during the study period. Forty-eight percent of the participants have unilateral ovarian endometrioma over the left side, 36% over the right side and 16% of them had bilateral endometriomas. The average diameter of the endometrioma examination was 4.82 ± +1.93 cm. The average AFS score for endometriosis was 46.5. The average duration for the operation was 69.2 minutes and postoperative haemoglobin drop was 0.7 ± +1.1g/dL. All but one case (95%) was able to achieve haemostasis with FloSeal® within 5 minutes with no additional haemostatic procedure required. No case required intraoperative blood transfusion and there were no intraoperative or postoperative complications noted.
Limitations, reason for caution: Our study was limited by the small sample size.
Wider implications of the findings: Controlling haemostasis with FloSeal® after laparoscopic stripping of ovarian endometriomas is an effective alternative haemostatic method and it avoids further ovarian tissue damage. It should be considered in those who want to preserve the ovarian reproductive function especially in women with fertility wish.
Study funding/competing interest(s): Funding by national/international organization(s) – The study was supported by the Hong Kong Obstetrical and Gynaecological Trust fund.
Trial registration number: Joint CUHK- NTEC Clinical Research Ethics Committee of the Chinese University of Hong Kong (CRE-2011.296).

P-776 Laparoscopic resection of deeply infiltrating endometriosis of the lower urinary tract

A. Bokor[1], P. Lukovich[2], P. Nyirady[3], J. Rigo[1]
[1]*Semmelweis University, 1st Department OB/GYN, Budapest, Hungary*
[2]*Semmelweis University, 1st Department Surgery, Budapest, Hungary*
[3]*Semmelweis University, Department Urology, Budapest, Hungary*

Study question: Our study aimed to assess the outcome of different laparoscopic surgical approaches in the treatment of deeply infiltrating endometriosis of the lower urinary tract.
Summary answer: There was no difference regarding the intra-and postoperative complications in patients who underwent mucosal skinning when compared to partial cystectomy.
What is known already: Involvement of the urinary tract by deeply infiltrating endometriosis (DIE) is estimated in 1–2% of all cases, most frequently affecting the bladder. Extrinsic ureteral DIE is more common than the intrinsic form [1]. The treatment's goal is the alleviation of the patient's symptoms and prevention of renal insufficiency.
Study design, size, duration: Between 10/07/2009 and 31/12/2014 at the 1st Dept. of OB/GYN, Semmelweis University, Budapest a series of 21 laparoscopic partial (Group A) CO2-laser bladder resection and 26 extramucosal resection (Group B) was performed for bladder DIE. Ureterolysis was performed in 190, segmental ureteral resection in 3 cases.
Participants/materials, setting, methods: A prospective database was established for all elective patients undergoing laparoscopic bladder/ureteral surgery by the same surgical team. The main outcome measures assessed were operative duration, conversion rate, incidence of early complications, length of hospital stay, morbidity and mortality.
Main results and the role of chance: There was no difference regarding the intra-and postoperative complications in patients who underwent mucosal skinning when compared to the partial cystectomy. In our series of 190 laparoscopic ureterolysis ureteral injury occured in one case (0.5%). In case of segmental ureteral resections we observed no intra-and/or postoperative complication.
Limitations, reason for caution: The major limitation of our cohort study was the low number of patients intrinsic ureteral DIE. For this reason we were not able to make a meaningful comparison between the surgical outcome of laparoscopic ureterolysis and segmental ureteral resection.
Wider implications of the findings: According to our results both mucosal skinning and partial cystectomy are safe and reproducible surgical methods for the treatment of bladder DIE.
Study funding/competing interest(s): Funding by University(ies) – Semmelweis University 1st Department of OB/GYN.
Trial registration number: NA.

P-777 Reliability of the ESHRE/ESGE and ASRM classification systems of uterine congenital malformations

A. Ludwin[1], I. Ludwin[1], M. Kudla[2], J. Kottner[3]
[1]*Jagiellonian University Medical College, Department of Gynecology and Oncology, Kraków, Poland*
[2]*Medical University of Silesia, Department of Oncological Gynecology Gynecology and Obstetrics, Katowice, Poland*
[3]*Charité -Universitätsmedizin Berlin, Department of Dermatology and Allergy, Berlin, Germany*

Study question: What is the reliability of diagnosis of congenital uterine anomalies, especially in differentiation between septate uterus/others and between anomaly/norm using the European Society of Human Reproduction and Embryology-European Society for Gynaecological Endoscopy (ESHRE-ESGE) classification in comparison to the American Society for Reproductive Medicine (ASRM) classification supplemented with absolute morphometric criteria?
Summary answer: Standardized interpretation indicate that the ESHRE-ESGE system has substantial/good or almost perfect/very good reliability ($\kappa > 0.60$, and >0.80, respectively), but other interpretation way showed insufficient reliability for clinical use ($\kappa < 0.90$), especially in diagnoses of septate uterus, and poorer reliability than ASRM, which was sufficient ($\kappa > 0.95$).
What is known already: The ESHRE-ESGE classification, its criteria and results are different than ASRM, however both are based on anatomy and use the same terms as 'congenital anomaly' and 'septate uterus'. Surgical treatment of septate uterus by ASRM has improved reproductive outcomes, unlike most of the other malformations and normal uterus. One of the conditions to ensure the appropriate management of uterine malformations is the reliability in diagnoses using the same classification system. Three-dimensional ultrasound is the recommended method to diagnose uterine anomalies by ESHRE-ESGE, which was an accurate and reproducible method of diagnosis using ASRM classification supplemented by morphometric criteria.
Study design, size, duration: A reliability study based on 112 prospective acquired 3D ultrasound single volumes of uterus, selected from women in

reproductive age, who were enrolled between June and September 2013, and these stored volumes re-evaluated in June 2014 during the three-day rounds.
Participants/materials, setting, methods: The same 3D volumes of uterine malformations (n = 50; consecutively included) and normal uterus (n = 62; randomly selected) by ESHRE-ESGE were independently offline evaluated by two experienced blinded raters (A and B), using the same ultrasound machine, both classifications criteria and methodology of evaluation and measurements, in a private medical centre. Rater A once again evaluated these volumes after two weeks. Inter- and intrarater repeatability of measurments of main benchmarks for malformation diagnosis (ASRM; internal fundal identation, external cleft, ESHRE-ESGE; added myometrial thickness) was estimated. The reliability/agreement for both systems in diagnosis of specific uterine congenital anomalies, recognition of septate uterus and differentiation between anomaly/norm was calculated and compared.
Main results and the role of chance: Intraclass correlation coefficient for measurments of internal fundal identation was >0.99 (interpreted as very good included lower limit of CIs), and for external cleft and uterine wall thickness was 0.95–0.99 (interpreted as good). Reliability / agreement of the ESHRE-ESGE classification in diagnoses of uterine malformations was lower (interrater p_o = 0.92, κ = 0.86, 95% CI 0.71–1.00; intrarater p_o = 0.88, κ = 0.80, 95% CI 0.65–0.95) than using ASRM system (interrater p_o = 0.99, κ = 0.98, 95% CI 0.87–1.00; interrater p_o = 0.98, k = 0.96, 95% CI 0.85–1.00). The greatest difference between these systems concerned the interrater reliability/agreement in diagnosis of septate uterus (ESHRE-ESGE, p_o = 0.88, k = 0.76, 95% CI 0.57–0.94; ASRM, p_o = 0.99, κ = 0.96, 95% CI 0.78–1.0). The relative risk of disagreement in recognition of septate uterus in different time of evaluation by the same rater and between two raters using ESHRE-ESGE classification relative to ASRM classification was significantly higher (RR intrarater disagreement; 9.0; 95% confidence interval 1.2–70; P = 0.04, RR interrater disagreement; 13; 95% CI 1.8–98; P = 0.04).
Limitations, reason for caution: Estimates of reliability/agreement may be greater, than those to be expected in clinical practice, where are additional sources of variation in comparison to offline analysis of the same stored 3D volumes.
Wider implications of the findings: Consequence of lower reliability of diagnosis by ESHRE-ESGE may be lack of agreement in uterine malformations management and biased research interpretation. Improvement of ESHRE-ESGE system is needed. The use of the simple morphometric criteria supplemented ASRM classification may be temporary better.
Study funding/competing interest(s): Funding by University(ies) – This work was supported by Jagiellonian University.
Trial registration number: NA.
Keywords: congenital uterine anomalies, septate uterus, reliability, interobserver intraobserver agreement, three-dimensional ultrasonography

P-778 Reproductive outcome and recurrence rate of surgically treated endometrioma patients and its relation to endometriosis fertility index

E. Dogan[1], U. Atlihan[2], B. S. Dogan[3], C. Posaci[1]
[1]*Dokuz Eylul Universtiy Ivf Unit, Obstetrics and Gynecology, Izmir, Turkey*
[2]*Dokuz Eylul Universtiy, Obstetrics and Gynecology, Izmir, Turkey*
[3]*Gaziemir State Hospital, Obstetrics and Gynecology, Izmir, Turkey*

Study question: What is the cumulative pregnancy and recurrence rate in advanced stage endometriosis patients treated laparoscopically for endometrioma with the stripping technique and its relation with the novel endometriosis fertility index (EFI).
Summary answer: Age of the patient and EFI score are two independent factors affecting pregnancy rate after laparoscopic surgery. Endometriosis patients with very low EFI scores (<4) should be directed to assisted reproduction without expected management since the have very poor pregnancy outcomes after surgery.
What is known already: Surgery for endometriosis improves spontaneous conception rates in infertile patients, however pregnancy rates after endometrioma excision for advanced stage endometriosis is limited. EFI is a newly formulated staging system and it is validated to be clinically useful for surgically confirmed endometriosis patients who desire pregnancy.
Study design, size, duration: This was a retrospective study in 71 patients managed for ovarian endometriomas with the laparoscopic stripping technique who were desiring pregnancy. The same surgeon performed all the operations. EFI score was calculated for each patient (range 1–10). Patients were fallowed expectantly with a mean follow up of 46,7 ± 20,2 months.
Participants/materials, setting, methods: Patients had standard conservative laparoscopic surgery for endometriosis at a university hospital. At operation all the visible endometriotic foci were destructed or excised, tubo ovarian anatomy was restored and ovarian endometriomas were excised. Bilateral tubal occlusion at the end of the surgery or severe male factor infertility patients were excluded
Main results and the role of chance: The mean age of the patients was 31.9 ± 5.0 and the mean duration of infertility was 36.9 ± 30.9 (12–204) months. Forty-six (64.8%) patients had primary infertility, while the remaining 25 (35.2%) had secondary infertility. Forty-two (59.2%) patients had monolateral and 29 (40.8%) had bilateral endometrioma. The cumulative pregnancy and delivery rates were 54.9% and 47.9%, respectively. The mean time to pregnancy was 16.8 ± 13.2 months. The mean EFI score was 6.49 ± 1.90. EFI score was significantly higher in pregnant patients compared to non-pregnant patients (7.33 ± 1.43 vs 5.47 ± 1.91, $p < 0.001$). Pregnancy rate was significantly higher in high EFI score patients (8–10) compared to moderate (4–7) and low (0–3) EFI score patients (78.3%, 48.8%, and 0%, respectively p < 0,001). Twelve patients had endometrioma recurrence (16.9%). Mean recurrence time was 27.5 ± 16.3 months.
Limitations, reason for caution: The retrospective nature of the study may limit to make firm conclusions. Preoperative and postoperative ovarian reserve of the patients was not available which may have impact on the pregnancy results.
Wider implications of the findings: Conservative laparoscopic surgery for advanced stage endometriosis patients has a cumulative pregnancy rate of over 50%. Endometriosis fertility index which includes both historical and surgical factors of the patient has a strong association with the probability of pregnancy after surgery. Therefore, it may guide the clinicians in deciding the treatment option for endometriosis patients after surgery
Study funding/competing interest(s): Funding by University(ies) – No funding.
Trial registration number: NA.
Keywords: endometrioma, laparoscopy, reproductive outcome

P-779 The septate uterus: a systematic review on the features of the septum

J. F. W. Rikken[1], S. Letteboer[1], M. van der Wely[1], M. H. Emanuel[2], C. E. J. M. Limpens[3], F. van der Veen[1], M. Goddijn[1]
[1]*Academic Medical Center, Center for Reproductive Medicine, Amsterdam, The Netherlands*
[2]*Spaarne Hospital, Gynaecology, Hoofddorp, The Netherlands*
[3]*Academic Medical Center, Medical Library, Amsterdam, The Netherlands*

Study question: What is known about the histology and pathophysiology of the septate uterus?
Summary answer: The precise histological aspects of the intrauterine septum remain unclear since different studies report contradictory findings, but it seems to be more comparable to normal uterine tissue then currently assumed. The pathophysiology of the risk for subfertility, miscarriages or preterm delivery of women with a septate uterus remains unknown.
What is known already: Women with a septate uterus are at risk for subfertility, recurrent miscarriages and preterm birth. Aiming to improve the fecundity of these women, resection of the septum is standard procedure in many countries, although evidence regarding its effectiveness is lacking. The exact pathophysiological processes underlying the poor reproductive outcome remain unclear. Hypotheses include differences in vascularization, contractility or vascular endothelial growth factor receptors, but a thorough overview is missing.
Study design, size, duration: Systematic review of the literature.
Participants/materials, setting, methods: Relevant studies were identified by searching Medline, Pubmed, EMBASE and the Cochrane Controlled Trials Register from 1900 until December 2014.
Main results and the role of chance: We found 7 observational and prospective studies, who report contradictory findings on the histology of a intrauterine septum. No reports were found about vascularization. Six studies who compared biopsies of the septum with normal uterine tissue, all found a difference in one of the following histological aspects: more myometrial tissue, more

muscular fibers, less connective tissue, a decrease in VEGF receptor expression or a decrease in sensitivity to preovulatory hormonal changes. One prospective study revealed no statistically significant differences in septate and myometrial tissue and concluded that the histology of the septum corresponds almost completely to normal uterine tissue.
Limitations, reason for caution: Evidence is limited, studies are small and mostly published before 2000.
Wider implications of the findings: This review, although based on a limited number of studies, questions the assumption that a intrauterine septum exists of mainly abnormal uterine tissue. This finding may imply that the higher risk to subfertility, miscarriages and preterm birth in women with a septate uterus could be due to other, to be investigated, factors.
Study funding/competing interest(s): Funding by University(ies) – Academic Medical Center Amsterdam.
Trial registration number: NA.
Keywords: septate uterus, histology

P-780 Diagnosis, management, and outcome of obstructed hemivagina and ipsilateral renal agenesis (OHVIRA syndrome) in 16 cases

F. Gungor Ugurlucan[1], O. Dural[1], C. Yasa[1], E. Bastu[1], B. Keyif[1], S. E. Akhan[1]
[1]*Istanbul University Istanbul Faculty of Medicine, Obstetrics and Gynecology, Istanbul, Turkey*

Study question: To discuss the management options, need for laparotomy, and outcome in patients with OHVIRA syndrome.
Summary answer: Most patients with OHVIRA syndrome, with indentation of the vaginal wall with hematocolpos and short distance between the hematocolpos and the vagina may be operated vaginally with vaginal septum resection with no complications and no recurrences.
What is known already: Early diagnosis of the syndrome is essential to preserve fertility. Conservative treatment is effective and has a good prognosis for the patients' reproductive function.
Study design, size, duration: Retrospective study.
Participants/materials, setting, methods: Retrospective evaluation of patients operated between 2001 and 2014.
Main results and the role of chance: The number of patients diagnosed with OHVIRA syndrome and operated in our clinic between 2001 and 2014 was 16. The mean age of the patients was 16.9 ± 6.0 (12–33). The presenting complaint was pain after menarche in 11 of the patients. One patient presented with acute abdomen. Three patients presented over 20 years of age (25, 27, 33), two of them with the complaint of infertility, and one presented with a pelvic mass. Two of the patients over 20 years of age had not undergone any diagnostic method or operations before. One patient presenting with the complaint of infertility had a history of diagnostic laparoscopy, but vaginal septum resection was not performed. Among the patients presenting before 20 years of age, one presented with pyocolpos, the rest presented with cryptomenorrhea. One had undergone diagnostic laparotomy and hysteroscopy, but vaginal septum resection was not performed. All of the 16 patients were diagnosed with OHVIRA syndrome before the operation by ultrasonography and MRI findings. 12 patients underwent vaginal septum resection only with no complications. In four patients laparotomy had to be performed in order to complete the procedure. One of the patients was the one who had previously undergone diagnostic laparotomy and hysteroscopy. Access to the hematocolpos was impossible in this patient due to lack of indentation in the normal vagina and access to the pelvic cavity was needed for safe resection of the vaginal septum. In the other 3 patients, it was impossible to perform vaginal septum resection without laparotomy because there was over 8 cm distance between the hematometrocolpos and the normal vagina in the MRI. In one of these, anastomosis was impossible and hysterectomy was performed. No complications developed in any of the procedures. And none of the patients suffered from vaginal septum reclosure after the procedure.
Limitations, reason for caution: Main limitation of this study is the retrospective nature of the study.
Wider implications of the findings: OHVIRA syndrome should be considered among the differential diagnoses in young females with renal anomalies presenting with pelvic mass, dysmenorrhea, symptoms of acute abdomen, and infertility. It may be impossible to perform vaginal septum resection in some cases where there is no indentation in the vagina and the distance between the hematocolpos and normal vagina is long. Hysterectomy may be needed in these cases.
Study funding/competing interest(s): Funding by University(ies) – Istanbul University Istanbul Medical Faculty.
Trial registration number: NA.

P-781 Diagnostic accuracy of ultrasonography for diagnosing endometrial pathologies in postmenopausal women with bleeding or asymptomatic thickened endometrium

B. Seckin[1], M. N. Cicek[1], A. Ugras Dikmen[2], E. Isci Bostanci[1], K. H. Muftuoglu[3]
[1]*Zekai Tahir Burak Women's Health Research and Education Hospital, Reproductive Endocrinology, Ankara, Turkey*
[2]*Gazi University, Public Health, Ankara, Turkey*
[3]*Zekai Tahir Burak Women's Health Research and Education Hospital, Pathology, Ankara, Turkey*

Study question: How accurate is the transvaginal ultrasound measurement of endometrial thickness for predicting endometrial carcinoma in postmenopausal women with vaginal bleeding or asymptomatic thickened endometrium?
Summary answer: Sonographic endometrial thickness measurement have a high diagnostic accuracy for detection of endometrial carcinoma in postmenopausal women with bleeding, but it does not have sufficient accuracy in women with asymptomatic thickened endometrium.
What is known already: Endometrial assessment is indicated in all postmenopausal women with vaginal bleeding. Ultrasonography is preferred as the initial test for the investigation of postmenopausal bleeding and has a high negative predictive value for ruling out malignancy. Different guidelines use different cut-off levels of endometrial thickness that should warrant endometrial sampling, varying from 3 to 5 mm. The significance of asymptomatic postmenopausal thickened endometrium remains unclear. Routine endometrial sampling for these women is not recommended.
Study design, size, duration: Study design: Cross sectional study. Study size: Six hundred and two women. Study duration: Between June 2012 and December 2014.
Participants/materials, setting, methods: Participants/materials: A total of 602 postmenopausal women. Setting: Tertiary education and research hospital. Methods: Two hundred and seventy-four women with vaginal bleeding and 328 asymptomatic women with increased endometrial thickness (³5 mm) were underwent endometrial sampling by the Pipelle® instrument. The histopathological findings were investigated.
Main results and the role of chance: In women with vaginal bleeding, 8 (2.9%) were found to have endometrial carcinoma. Three (0.9%) cases of endometrial carcinoma were diagnosed in asymptomatic women. The best cut-off point for endometrial thickness in predicting endometrial carcinoma established by the Receiver Operating Characteristics (ROC) was 8.2 mm with diagnostic accuracy of 88.3%, a sensitivity of 75% and a specifity of 74% in women with bleeding (p = 0.0001). In asymptomatic women, endometrial thickness of 7.2 mm was an optimal cut-off point, with diagnostic accuracy of 76.5%, a sensitivity of 66.7% and a specifity of 65.8%, but the area under ROC was not statistically significant (p = 0.114). The diagnostic accuracy of endometrial thickness for prediction of polyp was 77.5% for symptomatic women and 61.0% for asmptomatic women.
Limitations, reason for caution: The detailed evaluation of the effects of clinical variables that can improve the diagnostic performance of ultrasonography such as age, parity, body mass index, hormone replacement therapy usage, presence of hipertension and diabetes is needed. Larger prospective studies including patient characteristics could provide better results.
Wider implications of the findings: Endometrial thickness measurement has a high diagnostic accuracy for detection of endometrial carcinoma in postmenopausal women with bleeding, but it does not have sufficient accuracy in women with asymptomatic thickened endometrium. Endometrial thickness has a moderate diagnostic accuracy for polyp detection in symptomatic women, but its predictive accuracy is low in asymptomatic women. In clinical practice, endometrial thickness assessment along with clinical variables could provide better results for predicting endometrial pathologies in asymptomatic patients.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Zekai Tahir Burak Women's Health Education and Research Hospital, Ankara, Turkey.

Trial registration number: This study is not an RCT.
Keywords: endometrial thickness, endometrial biopsy, postmenopause, ultrasound, vaginal bleeding

P-782 Why myomas grow during ulipristal acetate treatment?

C. Pascual[1], F. Raga[1], S. Cholvi[1], C. Llinares[1], V. Puglia[2], C. Sanchez[2], A. Cano[1]
[1]*Hospital Clínico Universitario, OB/GIN, Valencia, Spain*
[2]*Hospital Clínico Universitario, Pathology, Valencia, Spain*

Study question: Contrary to previously reports, uterine fibroids increase their volume during the initial phases of ulipristal acetate (UPA) treatment. Additionally, some myomas may increase their volume at the end of preoperative treatment with UPA. Which pathophysiologic mechanism is behind this phenomenon?
Summary answer: Using preoperative 3D-ultrasound and Doppler technology and its correlation to postoperative pathological examination, we describe the adaptive mechanism that generates considerable hydropic and cystic degenerative changes in leiomyomas under UPA treatment leading to a transitory increase in their volume.
What is known already: Uterine leiomyoma is the most common benign uterine tumor in women of reproductive age. Symptomatic women usually experience pelvic pain, anemia, and infertility. Contemporary therapeutic approaches principally comprise surgical interventions. Recently, UPA, a selective progesterone receptor modulator (SPRM), has become an effective and well-tolerated option for the preoperative treatment of leiomyomas. According to clinical data, UPA improves haemoglobin levels in anaemic patients, and it grants a significant reduction in the size of fibroids.
Study design, size, duration: A prospective, longitudinal study conducted at our Department of Obstetrics, Gynaecology and Reproductive Medicine from September 2013 to January 2015, comparing the effect of UPA and triptorelin on leiomyoma volume. The study was approved by the institutional review Board and all participants gave informed consent for the trial.
Participants/materials, setting, methods: 50 premenopausal women with symptomatic myomas were treated with UPA (5 mg/d) during 12 weeks preoperatively. VOCAL software for 3D ultrasound was used to measure leiomyoma volume and blood flow indices before treatment and weekly until surgery. As a control group 25 women received triptorelin (3.75 mg/mo) before surgery.
Main results and the role of chance: No differences were observed in either volume or vascularization between both groups at baseline. Moreover, reduction in myoma volume and vascularization indices at the end of the treatment protocol was similar in both groups ($P > 0.05$). However, myomas treated with UPA experience an increase in its volume during the initial 6 weeks of treatment, followed by a rapid decrease in the next 6 weeks. Nevertheless, up to 15% of the myomas in the UPA group presented an increased volume at the end of the preoperative treatment. Pathological examination revealed a significant increase in hydropic and cystic degenerations among myomas treated with UPA. On the other hand, myomas treated with triptorelin presented increased areas with necrosis and thrombotic vessels.
Limitations, reason for caution: We cannot exclude potential selection bias due to pretreatment histopathological differences between our groups.
Wider implications of the findings: An overall decrease in the volume of uterine leiomyomas treated with UPA is generated by an apoptotic phenomenon. However, the intercellular compartment seems to undergo more often degenerative hydropic degenerations, which may contribute to a transitory increase in the volume of myomas or even a complete cystic degeneration with a considerable increase in its size. Therefore, clinicians have to be aware of this circumstance in order not to misdiagnose it with malignant pathology.

P-783 Safeguarding fertility with whole ovary cryopreservation in ewe: slow freezing compared to vitrification

A. Torre[1], D. Vertu-Ciolino[2], C. Mazoyer[3], J. Selva[4], J. Lornage[3], B. Salle[3]
[1]*Centre Hospitalier Poissy – St. Germain, Département de Médecine de la Reproduction Service de Gynécologie Obstétrique Centre Hospitalier Intercommunal de Poissy Saint Germain en Laye, Poissy, France*
[2]*Hopital Edouard Herriot, Service d'ORL Chirurgie Cervico Facial, Lyon, France*
[3]*Hopital Femme Mère Enfant, Médecine de la Reproduction, Lyon, France*
[4]*Centre Hospitalier Poissy – St. Germain, Service de Biologie de la Reproduction, Poissy, France*

Study question: Should slow freezing or vitrification be used on whole ovaries, as cryopreservation method, before micro-vascular transplantation, for efficiently safeguarding fertility?
Summary answer: In a ewe model, both methods led to poor fertility outcomes. A gestation was obtained in the slow freezing group, but fertility outcomes weren't significantly different between groups.
What is known already: Numerous live births have been obtained after non vascular grafting of cryopreserved fragments of ovarian cortex. However, fragments suffer ischemia during revascularization, which could limit the lifespan of these grafts. Micro-vascular transplantation of cryopreserved whole ovaries could allow immediate revascularization and improve fertility outcomes. To date, this method allowed gestations only in a ewe model, and remains in the research field. The most appropriate method for whole ovary cryopreservation -slow freezing or vitrification- is unknown.
Study design, size, duration: In this animal study, 12 ewes were randomized for micro-vascular auto-transplantation, with either slow-frozen or vitrified ovary. The remaining ovary was removed. Fertility and ovarian function were assessed for the 3 subsequent years. Ovarian follicular count of native ovaries (control) and transplants was performed at the end of the study.
Participants/materials, setting, methods: Ovaries from 6 ewes were slow-frozen using DMSO as cryoprotector. The ovary of 6 other ewes were exposed to increasing concentration of the vitrificant solution "VM3", while gradually lowering the temperature to reduce toxicity, and vitrified. After thawing/warming, cryoprotector(s) was(were) gradually removed, and vessels were anastomosed to the systemic circulation.
Main results and the role of chance: Warming phase crystallization occurred in each ovary vitrified with "VM3". All anastomoses from the slow frozen group were permeable, whereas 2 primary failures of blood flow reestablishment occurred in the vitrification group. Two ewes from the slow frozen and vitrification group died 4 week and 7 months after transplantation, respectively, death cause being independent from the present protocol. Hormonal resumption occurred in 4/5 ewes from the slow frozen group and 6/6 ewes from the vitrified group. A ewe from the slow frozen group delivered healthy twines, 1 year 9 months and 12 days after transplantation. Estimated whole follicle survival was dramatically low in each group, although significantly higher in the vitrification group ($0.3\% \pm 0.5\%$), than in the slow-frozen group ($0.017\% \pm 0.019\%$, $p < 0.05$).
Limitations, reason for caution: The limited number of animals used, didn't allow drawing any evidence-based conclusion for fertility outcomes. The extrapolation from ewe model to human is not established.
Wider implications of the findings: Micro-vascular transplantation of slow frozen ovaries was confirmed to allow fertility in a ewe model. However, poor follicular survival and fertility outcomes observed after transplantation of cryopreserved whole ovary call in question the ability of this technique to efficiently safeguard fertility, whatever the cryopreservation method used.
Study funding/competing interest(s): Funding by national/international organization(s) – Research grants from "Agence de la Biomédecine", and "Fondation de l'Avenir."
Trial registration number: This study was approved by the Ethics Committee of the Veterinary School of Lyon (ENVL no: 0804).
Keywords: fertility preservation, vitrification, slow freezing, whole ovary, ewe model

P-784 The role of diagnostic and therapeutic mini invasive surgery in couples with unexplained infertility: a restrospective observational study

V. Immediata[1], D. Romualdi[1], S. De Cicco[1], V. Tagliaferri[1], C. Di Florio[1], A. Lanzone[1], M. Guido[1]
[1]*Obstetrics and Gynecology, Obstetrics and Gynecology, Roma, Italy*

Study question: In the era of ART (assisted reproductive techniques), does the mini invasive surgery still play a role in the diagnostic work-up and therapeutic management of the infertile couple?
Summary answer: Combined laparoscopy and hysteroscopy, associated with chromopertubation with methyleneblue, allow to identify and contextually treat

pelvic and uterine abnormalities that may impair fertility, with a resulting reliable rate of spontaneous pregnancies.
What is known already: Laparoscopy, with the direct visualization of the pelvis, is the only method able to identify specific peritoneal factors, such as minimal endometriosis and pelvic adhesions, which may impair fertility. ESHRE-ASRM guidelines indicate surgery for women with symptoms, or risk factors, or abnormal hysterosonography/ultrasonography, with no other reasons to undergo ART. However, the role of laparoscopy in asymptomatic women with normal imaging is debated, as few studies previously evaluated the pregnancy rate following the procedure.
Study design, size, duration: The operative findings, interventions and the subsequent pregnancy rate were retrospectively analyzed in 70 women undergoing surgery for unexplained infertility from January 2010 to December 2012 in our tertiary care academic medical center.
Participants/materials, setting, methods: 358 infertile women underwent combined hysteroscopy-laparoscopy during the observation period. We excluded from the analysis subjects presenting at least one of the following: age >38 years, infertility duration <3 years, proven or suspected pelvic organs abnormalities before surgery, anovulation, secondary infertility, male factors. 70 women resulted eligible for the evaluation.
Main results and the role of chance: On hysteroscopy, intrauterine lesions were detected and contextually treated in 12 women (17%). On laparoscopy, endometriosis was found in 16 women (23%): 13 minimal or mild, 2 ovarian and 1 deep endometriosis. Pelvic adhesions were observed in 23 patients (33%). All cases of pelvic abnormality were surgically treated. The bilateral tubal patency, documented prior to surgery in all selected patients by imaging, was confirmed on the chromopertubation in 60 women. 9 subjects exhibited unilateral tubal patency, and one case of bilateral obstruction, without macroscopic alterations, was observed. The cultural examination of the peritoneal fluid resulted negative in all cases. A spontaneous pregnancies occurred in 20 women (28%), independently of age, in the following 18 months. This percentage achieved 50% in the subgroup treated for endometriosis.
Limitations, reason for caution: It is a retrospective study done in a single unit. Even if we found an high percentage of spontaneous pregnancy, it cannot be ruled out that factors other than surgery may play a role. In this context, the lack of a control group does not allow to draw definitive conclusions.
Wider implications of the findings: The considerable rate of success in terms of spontaneous pregnancies makes the surgical management of unexplained infertility an intriguing option, in particular for its diagnostic potential. Even if it implies general anesthesia and hospital stay, the cumulative economical cost, psychological burden and complications rate is comparable to those of II-III level ART.
Study funding/competing interest(s): Funding by University(ies) – Catholic University, Rome.

STEM CELLS

P-785 B:Role of HECTD1 in cell movement during embryogenesis

S. Xiaoli[1], C. De Geyter[2], H. Zhang[2]
[1]*University of Basel, Department of Biomedicine, Basel, Switzerland*

[2]*University of Basel, University Hospital Basel, Department of Biomedicine, Basel, Switzerland*

Study question: HECTD1 was first identified as E3 ubiquitin ligase for inhibin B receptor which mutant phenotype was characterized by impaired placental development, severe neural tube defects (spina bifida) and growth retardation. We are interested in the HECTD1 functional molecular networks in cell spreading and migration during embryogenesis.
Summary answer: Together, our findings indicate that IQGAP1 and Hax1 serve as important downstream factors controlled by ubquitination of HECTD1, impacting on formation of focal adhesions and cytoskeleton, and further regulating cell spreading and migration in embryogenesis.
What is known already: Three models about HECTD1 molecular signaling were proposed, one was about increased secretion of Hsp90 in the cranial mesenchyme of HECTD1 mutants may be responsible for the altered behavior of these cells. Another model suggested that HECTD1 promotes the adenomatous polyposis coli (APC) protein-Axin interaction to negatively regulate Wnt signaling. The latest theory proposed that ubiquitination of PIPKIγ90 by HECTD1 and consequent degradation of PIP2 controls focal adhesion dynamics and cell migration.
Study design, size, duration: Using the secretory-trap approach, we generated HECTD1 mutant mice by insertion of β-geo expression cassette between intron 26 and 27. The wild type mouse embryos are taken as control. Whenever we do DNA/siRNA transfection, there are always non-targeting control groups.
Participants/materials, setting, methods: Mouse embryonic fibroblasts were cultured from E12.5 embryos. General approach: cell culture/transfection, gene knockout, mass spectrometry, yeast two hybrid, immunohistochemistry, immunoprecipitation, Western blots, FACS, ubiquitination assay, half-life assay, protein phosphatase activity assay.
Main results and the role of chance: Loss of HECTD1 exerts shorter spreading time and irregular cell shapes in cell spreading, enhanced velocity with decreased directionality in directional cell migration. The formation of focal adhesions, adherens junctions and cytoskeleton are also impaired in HECTD1 knockout MEFs. We confirmed IQGAP1 and Hax1 are two binding partners of HECTD1. Over-expression of IQGAP1 and Hax1 together with high activity of GTPases in HECTD1 knockout MEFs reminiscent of IQGAP1 and Hax1 may act as substrates of HECTD1. Comparing with wild type cells, ubiquitination of IQGAP1 and Hax1 in HECTD1 knockout cells was decreased but the half-life of the two proteins were increased. siRNA knockdown of IQGAP1 and Hax1 in HECTD1 knockout cells significantly rescued the expression of focal adhesions, cell spreading time and migration velocity.
Limitations, reason for caution: As having more generations, it is getting harder for Heterozygotes to be pregnant, which makes it difficult for us to compare the role of HECTD1 in different stages of embryos.
Wider implications of the findings: Our results provide new mechanisms of HECTD1 in regulating cell spreading and migration during embryogenesis. IQGAP1 and Hax1 serve as essential downstream factors of HECTD1 which might be the potential therapeutic targets for growth retardation and neural tube defects.
Study funding/competing interest(s): Funding by national/international organization(s) – The Repronatal Fundation, Basel, Switzerland.
Trial registration number: NA.

P-786 The effect of BMP-4 and RA on histone modifications in human amniotic epithelial cells expressing DAZL and VASA

H. Kreizman Shefer[1], S. Goldman[2], E. Shalev[1]
[1]*Technion- Israel Institute of Technology, The Ruth and Bruce Rappaport Faculty of Medicine, Haifa, Israel*
[2]*Emek Medical Center, Laboratory for Research in Reproductive Sciences and Department of Obstetrics and Gynecology, Afula, Israel*

Study question: The effects of introducing human amniotic epithelial cells (hAECs) to a microenvironment consistent of necessary cues for primordial germ cells (PGCs) differentiation was tested to induce histone modification in hAECs expressing germ cells markers (DAZL and VASA).
Summary answer: The extrinsic inducers bone morphogenic protein (BMP)4 and retinoic acid (RA) may regulate intrinsic factors such as DAZL and VASA, thus affecting cell fate. BMP4 and RA were also found to affect epigenetic state in hAECs already committed to the germline differentiation, via specific histone modification which characterizes pre-colonized PGCs.
What is known already: Previous reports describing germ like cells differentiation from various cell types have shown that exogenous addition of BMP4 and RA improves recruitment of PGCs and enhances their maintenance in vitro. The crucial role of epigenetic patterning via histone modifications, which establish a unique PGCs pluripotent state, was also found in these studies. hAECs model was recently found to be an in vitro culture system that allows us to study germline differentiation pathway.
Study design, size, duration: hAECs isolated from term placentas and passaged every 8 days. Three differentiation protocols used: spontaneous protocol; hAECs cultured in SSM. BMP4 protocol; 50 ng/ml BMP4 added to freshly

isolated hAECs cultured in SSM for 10 days. RA protocol; BMP4 protocol followed by addition of 1 μM RA for 30 hours.
Participants/materials, setting, methods: Characterization of freshly isolated-, passage 3 and 5 hAECs was conducted by the examination of DAZL and VASA germ cell markers, Dnmt3a expression and H3K9me2, H3K27me3, H3K9ac, H3K4me3 and H3S10phosph. expression in OCT-3/4 expressing cells. Methods used included qPCR, immunofluorescence and Flow cytometry.
Main results and the role of chance: Extrinsic inducers BMP4 and RA advance hAECs differentiation to large 30–50 mm cells with rounded morphology and zona-pellucida-like structures cells expressing germ cell markers by regulating intrinsic factors such as DAZL and VASA. RA was found to induce PGCs differentiation more efficiently than BMP4 alone, as the expression of VASA was found to be more elevated. However, BMP4 induce epigenetic state that may imply pre-colonized cells expressing germ cell markers, including elevated expression of H3K27me3, H3K4me3 and H3S10phosph in OCT-4 expressing cells. Role of chance: Freshly isolated and spontaneously differentiating hAECs are referred to as control group for differentiating cell and BMP4 and RA treated cells, respectively. Experimental methods include examination of unstained cells or DNA free samples. $P < 0.05$ was considered significant.
Limitations, reason for caution: Placentas were obtained only after uncomplicated vaginal deliveries from healthy mothers with written informed consent.
Wider implications of the findings: Epigenetic patterning is believed to be crucial for prevention, at least in part, of some heritable diseases and reproductive failure. hAECs has unique features that make this model attractive for potential stem cell based therapies such as lack of teratomas formation *in vivo*, low antigenicity and anti-inflammatory. A better understanding of epigenome reprogramming may potentially allow us to manipulate *in vitro* endogenous cells of diseased tissues as well as stem cells to properly differentiate into germ cells.
Study funding/competing interest(s): Funding by University(ies) – Technion-Israel Institute of Technology.
Trial registration number: 0045-09-EMC.

P-787 Cultured cells from the human oocyte cumulus niche are efficient feeders to propagate pluripotent stem cells

S. Assou[1], M. Péquignot[2], E. Pourret[3], V. Rigau[4], V. Kalatzis[2], O. Aït-Ahmed[3], S. Hamamah[5]
[1]*Institute for Regenerative Medecine and Biotherapy-CHRU Montpellier, University of Montpellier-UFR de Médecine, Montpellier Cédex 5, France*
[2]*Institut des Neurosciences de Montpellier, Inserm U1051, Montpellier Cédex 5, France*
[3]*Institute for Regenerative Medecine and Biotherapy, Inserm U1203, Montpellier Cédex 5, France*
[4]*CHRU Montpellier, Pathology Department, Montpellier Cédex 5, France*
[5]*Institute for Regenerative Medecine and Biotherapy-Inserm U1203-CHRU Montpellier, ART-PGD Department, Montpellier Cédex 5, France*

Study question: Do cells cultured from the human oocyte CCs niche (hCC) support the human induced pluripotent stem (hiPS) cells propagation and pluripotency?
Summary answer: The hiPS cells cultured on hCC (hCC-iPS) maintained their pluripotency potential and exhibited much better self-renewal performance in terms of proliferation rate compared with the classically used fibroblast (hFF) feeders (hFF-iPS).
What is known already: It is known that the maintenance of undifferentiated state requires culturing human pluripotent stem cells (PSC) on a variety of human feeder cells including fetal and adult fibroblast, endometrial cells, adult marrow cells, and placental fibroblast. However, despite the development of diverse culture systems, no standardized method of co-culture has emerged.
Study design, size, duration: Human cumulus cells were collected from patients referred to our centre for intra-cytoplasmic sperm injection (ICSI) for male infertility. The hiPS cells were obtained by reprogramming the human fibroblast foreskin hFF cell line using lentiviral vectors to express human *OCT4, SOX2, NANOG* and *LIN28*. The propagation of hiPS cells was compared between hiPS cultured on hCC and hFF feeders respectively.
Participants/materials, setting, methods: Cumulus cells were dissociated mechanically from the MII oocyte on collection day and adapted to growth on a human collagen substrate for a long period in a xeno-free defined medium. Affymetrix Human Genome U133 Plus 2.0 DNA chips were performed to analyze the transcriptome of hCC and hiPS cells. Levels of expression of pluripotency and differentiation markers were examined by RT-qPCR, immunofluoresence and flow cytometry. Chromosomal abnormalities were analyzed using array comparative genomic hybridization (aCGH).
Main results and the role of chance: We have optimized isolation and culture protocols for long-term maintenance of hCC in xeno-free conditions. This new feeder, characterized at molecular and cellular levels, able to support growth of hiPS cells during long term passaging. Flow cytometric analysis showed that hiPS-hCC retained expression of surface markers (CD24, SSEA4, TRA-1-81 and TRA-1-60), demonstrating successful preservation of stemness. Moreover, hiPS-hCC also improved the competence to differentiate into the three germ layers *in vitro* (embryoid bodies) as well as *in vivo* (teratoma formation). The self-renewal rate of hiPS-hCC was higher than of hiPS-hFF determined by measurement of colonial diameters and cell cycle analysis, suggesting that hCC has a growth-promoting effect. Additionally, hiPS-hCC did not exhibit detectable sub-chromosomal aberrations, confirming their genetic stability. A comparative gene expression study of hCC and hFF feeders revealed significant differences ($p < 0.05$) in expression of cellular matrix components and an up regulation in hCC of genes known to be important players in cell proliferation such as interleukin 6 gene (IL6).
Limitations, reason for caution: More investigations are required to study the role of the cytokines secreted by hCC that are potentially responsible for successful maintenance and higher proliferation of the hiPS cells.
Wider implications of the findings: This culture system can be suggested for autologous hCC as co-culture of human early embryos to boost embryonic development. Moreover, hCC can be used as a model to identify secreted and adhesion molecules that are required for the self-renewal of PSC.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Ferring pharmaceutical company supported the study but had no influence on the study design and was not involved in the analysis of the results. There were no competing interests.
Trial registration number: NA.

Study question: can albumin phosphate calcium 3D scaffold be replaced with seminiferous extra cellular matrix as a suitable culture device for reconstitution of an artificial testis?
Summary answer: Human testicular derived mesenchymal stromal cells (ht-MSCs) were cultured on a homemade albumin phosphate calcium 3D scaffold. The sections of the scaffolds have shown the successful growth of htMSCs within the spaces inside the scaffold resemble to seminiferous tubes. However, the function of the device needs to be improved.
What is known already: Several reports have shown the generation of stem cells from animal and human testis in 2D culture system. Recent data in human studies have shown that these cells are from stromal origin and have a multipotent capacity instead of pluripotency. One of the reasons of this difference might be due to lack of specific factors to induce pluripotency in human spermatogonial stem cells niche*in vitro*.
Study design, size, duration: A novel scaffold has been designed to improve the 3D culture of the htMSCs *in vitro*. First, htMSCs been cultured in different 2D culture conditions and then monolayer cultures and embryoid bodies (EBs) were passaged onto the scaffolds and cultured for another week. Scaffolds been sectioned, stained.

Participants/materials, setting, methods: Two TESE samples were used after fully concern by patients and minced mechanically and treated by three steps enzymatic digestion to isolate single cells. Single cells have been cultured with HES-KOSR medium with/without feeder layer for week and then passaged and cultured onto a 3D scaffold for 7, 14 days.
Main results and the role of chance: From both TESE samples htMSCs were derived and cultured using HES-KOSR medium onto the mitotically inactivated mouse embryonic fibroblast (MEFs) feeder layer and without MEF feeder layer. Without MEFs cells formed embryoid bodies (EBs), but those onto feeder layer have formed clusters after almost a week. Both clusters and EBs have been passaged onto a new albumin phosphate calcium 3D scaffold with HES-KOSR medium. For each TESE sample, three scaffolds have been used. Scaffolds have been sectioned and stained with hematoxolin and eosin (H & E) and compared with human testis sections. Not lot but some cells have been cultured and growth within the free spaces of the scaffold, comparable to seminiferous tubules sections.
Limitations, reason for caution: It was not feasible to localize the cells within the scaffold similar to their arrangement inside the testis. It might be possible to resolve by using specific antibodies within the scaffold.
Wider implications of the findings: Our findings prepared a 3D culture of htMSCs which would lead itself to design an artificial testis for the future male infertility treatment.
Study funding/competing interest(s): Funding by University(ies) – yazd shahid sadoughi university for medical sciences.

P-789 Derivation conditions affect pluripotency and differentiation propensity of mouse embryonic stem cells

S. Ghimire[1], M. Van der Jeught[1], J. Neupane[1], F. Van Nieuwerburgh[2], D. Deforce[2], S. Chuva de Sousa Lopes[3], P. De Sutter[1], B. Heindryckx[1]
[1]*Ghent University Hospital, Reproductive Medicine, Gent, Belgium*
[2]*Ghent University, Pharmaceutical Biotechnology, Gent, Belgium*
[3]*Lieden University, Anatomy and Embryology, Leiden, The Netherlands*

Study question: Do the state of pluripotency and differentiation propensity of mouse embryonic stem cells (mESCs) vary when they are derived in different culture conditions?
Summary answer: mESCs derived in '2i' or in '3i' show higher pluripotency markers and lower lineage-specific markers expression compared to those derived in LIF-serum. LIF-serum cells tend to differentiate more easily into endoderm whereas '2i' and '3i' cells into the ectoderm and mesoderm respectively than into other lineages during EBs formation.
What is known already: Naive mESCs derived in LIF-serum condition show heterogeneous expression of pluripotency markers, whereas ground-state mESCs derived in '2i' (PD0325901 and Chir99021, FGF and GSK3b signaling inhibitors respectively) are more homogeneous. Nanog is heterogeneous even in 2i-derived mESCs. Inhibiting TGFb signaling with SB431542 during mESCs-derivation promotes the ground-state pluripotency of stem cells. Previous studies have compared different conditions/strains during mESCs derivation. However, it is not clear yet whether all these cells are functionally similar.
Study design, size, duration: mESCs were derived from embryos of '129Ola/Hsd' mice in the following three conditions, using 1000 units/ml LIF in all conditions.

i DMEM based medium with 20% serum + LIF (LIF-serum line)
ii N2B27 medium with '2i' + LIF ('2i' line)
iii N2B27 medium with '3i' ('2i' + SB431542) + LIF ('3i' line)

Participants/materials, setting, methods: Pluripotency markers (Oct4/Sox2/Nanog) expression was examined in undifferentiated mESCs by RT-qPCR. Cells were differentiated spontaneously into embryoid-bodies (EBs) in their respective basal medium after removing LIF and/or inhibitors. Ectodermal-FGF5, mesodermal-T and endodermal-Sox17 markers were examined on control cells collected on D0 and EBs collected on D4, D7 and D10.
Main results and the role of chance: '2i'- and '3i'-derived undifferentiated mESCs showed significantly higher expression of pluripotency-markers and significantly lower expression of lineage-specific-markers compared to LIF-serum-derived pluripotent mESCs ($p < 0.05$). D4-EBs demonstrated more biased differentiation of LIF-serum cells towards the endoderm, whereas '2i' cells towards ectoderm. However, '3i' cells showed differentiation into both ectoderm and mesoderm. On D7, '2i'-EBs exhibited significant up-regulation of all three germ-layer-markers but LIF-serum EBs showed increased expression of endo- and ectodermal markers only. In contrast, '3i' EBs displayed significantly higher expression of meso- and ectodermal markers. On D10, EBs in all three conditions demonstrated the expression of all three lineage-specific-markers. Interestingly, overall comparison of EBs revealed superior degree of differentiation of LIF-serum cells towards endoderm, of '2i' cells towards ectoderm and of '3i' cells towards mesoderm.
Limitations, reason for caution: LIF-serum derived lines were differentiated in serum-containing medium without LIF, whereas '2i' and '3i' lines were differentiated in N2B27 medium without small molecules and cytokines. It will be interesting to examine if these cells still behave similarly when exactly identical differentiation conditions are used.
Wider implications of the findings: Our results show that derivation conditions affect pluripotency and differentiation propensity of mESCs. The ultimate application of pluripotent stem cells in the field of regenerative medicine is to differentiate them towards a particular lineage of interest. Therefore, these findings display a significant role in selecting the appropriate derivation conditions depending upon the final use of cells.

Study question: This study examined whether pluripotent and germ cell marker expression and differentiation potential of ovarian surface epithelium (OSE)-derived ovarian stem cells (OSCs) differ with female age in mice
Summary answer: Aged female mice have OSCs in OSE, but their differentiation potential including oocyte regeneration, expression of germ cell marker and number of OSCs were significantly decreased compared to those of young mice
What is known already: Many studies have proposed that OSCs derived from OSE layer of adult mammalian ovaries can produce oocytes. Few studies have reported that ovaries of aged mammalian females including mice and women possess rare premeiotic germ cells that can generate oocytes
Study design, size, duration: Controlled experimental study. Twenty female mice for each age group.
Participants/materials, setting, methods: C57BL/6 female mice of 2 age groups (6–8 and 28–31 weeks) were super ovulated by injection with 5 IU equine chorionic gonadotropin (eCG). Both ovaries were removed after 48 hours and scrapped to obtain OSE. Gene expressions of pluripotent (Oct-4, Sox-2, Nanog) and germ cell markers (c-Kit, GDF-9, and VASA) were evaluated in the intact ovary, scraped OSE, and three weeks postcultured OSE by RT-PCR. After 3 weeks culture of OSE, the number of positively stained Oct-4 by immunohistochemistry and oocyte production were examined
Main results and the role of chance: Expressions of germ cell markers in the intact ovary were significantly decreased in aged females, whereas expressions of pluripotent markers were not detected, regardless of age. Scraped OSE expression of all pluripotent and germ cell markers, except for c-Kit, was similar between both age groups. Three week post-cultured OSE had significantly decreased expression of GDF-9 and VASA, but not c-Kit, in old mice, as compared to young mice; however there was no difference in the expression of other genes. The number of positively stained Oct-4 by immunohistochemistry in postcultured OSE was 2.5 times higher in young mice than aged mice. Oocyte-like structure was spontaneously produced in postcultured OSE. However, while that of young mice revealed a prominent nucleus, zona pellucida-like structure and cytoplasmic organelles, these features were not observed in old mice.

Limitations, reason for caution: This study was for mice. Therefore, further study should be processed for women to prove a clinical effectiveness of the result of the present study.
Wider implications of the findings: These results implicated that advancing female age resulted in decreased potential of differentiation into oocytes or stemness activity of germ cells in OSEs, but they also can produce oocyte-like structure from OSE-derived OSCs. Therefore, if an appropriate milieu for inducing regeneration of oocytes from OSCs in aged female is elucidated, it is expected that this study may contribute to the development of a new strategy for the production of oocytes in the treatment of female age-related infertility and POF.
Study funding/competing interest(s): Funding by national/international organization(s) – This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education (NRF-2013R1A1A2013063).

P-791 Ovarian stem cells in perspective treatment of infertility: a preliminary isolation approach

E. Silvestris[1], M. D'Avenia[2], S. D'Oronzo[2], G. D'Amato[3], E. Caroppo[3], G. Loverro[2]
[1]*University of Bari "Aldo Moro" IMO, Biomedical Sciences and Human Oncology, Molfetta, Italy*
[2]*University of Bari "Aldo Moro" IMO, Biomedical Sciences and Human Oncology, Bari, Italy*
[3]*ASL Ba, Reproductive and IVF Unit, Conversano, Italy*

Study question: Ovarian stem cells (OSC) have been detected in mice and postulated in human ovaries[1]. They typically expose Ddx-4 (*DEAD box polypeptide 4*), a stemness marker uniquely expressed by germ line cells as both OSCs and spermatogones. Thus, we tried to isolate OSCs from woman ovaries by immunoselection using anti-Ddx-4 antidodies.
Summary answer: Although at low percentage, OSCs are located within the cortex of the human ovary and their isolation is possible by sorting with appropriate combined separation methodology. Once isolated, OSCs appear viable and can be further characterized and/or cultured for additional studies.
What is known already: Despite the general opinion that postnatal mammalian ovaries of most species do not contain renewable germinal OSCs[2], previous work by Tilly and co-workers showed the existence of OSCs in human ovaries since these cells were separated by Ddx-4 positive selection[3]. However, these finding were confuted for the major cytoplasmic expression of Ddx-4. The antigen, indeed, is expressed both on cell membrane and cytoplasm by OSCs, whereas mature oocytes contain only its cytoplasmic tale.
Study design, size, duration: The study was aimed to verify the occurrence and tentatively separate the OSCs from a small number of human ovaries by using magnetic immunoselection and sorting with anti-Ddx-4 reagents and subsequent typing by flowcytometry with specific monoclonal antibodies (MoAb) to specific cell lineage markers.
Participants/materials, setting, methods: Ovarian cortex fragments from three women undergoing ovariectomy in premenopausal age, were digested by collagenase, filtered, suspended in presence of rabbit anti-Ddx-4 antibody and then passed through a column including anti-rabbit IgG conjugated magnetic microbeads. The eluted cells were typed by flowcytometry and confocal microscopy to assess the Ddx-4 localization.
Main results and the role of chance: Within the full cell suspension, we gated the putative OSC population in relation to the cell size and found that the double positive population including $OCT4A^+$/$Ddx\text{-}4^+$ cells, was poorly expressed, whereas a definite enrichment was observed after the immunomagnetic sorting. In fact, the enriched $Ddx\text{-}4^+$ cell population was increased up to 24% from the original 2% value in the initial cortical suspension, with remarkable fluorescence intensity suggesting the high molecular expression of Ddx-4 molecule. By immunofluorescence under confocal microscopy, these cells appeared of small size with a large nucleus, few cytoplasm and highly FITC-fluorescent deposits on the cell membrane reflecting the consistent expression of Ddx-4 molecules. This result supports the suitability of the separation of OSCs by this simple methodology using the immunomagnetic cell sorting.
Limitations, reason for caution: Major skepticism derives from using Ddx-4 as cell surface marker for the OSC sorting since its location in cytoplasm is still detectable in mature oocytes. However, only OSCs express the membrane associated Ddx-4 and further work investigating other membrane markers as OCT-4A and SSEA-4 may improve the OSC separation methods.
Wider implications of the findings: The future applications of these findings to the infertility field will cover different and unrelated conditions ranging from the endocrine defective ovarian reserve to the iatrogenic infertility associated to chemotherapy in cancer patients. On the other hand, besides the infertility treatment, OSCs can be further investigated in parallel studies aimed at restoring the woman endocrine physiology in postmeno-pausal age. However, this approach primarily requires animal experimental models to prove their efficacy in treating endocrine dysfunctions.

P-792 Comparison of attachment layers for the priming human embryonic stem cells towards epiblast-like cells

Study question: How can we adjust the conditions described in the protocol for primordial germ cell formation of mouse embryonic stem cells (mESCs), in order to achieve an equivalent priming of human embryonic stem cells (hESCs) towards epiblast-like cells?
Summary answer: Naïve hESCs did not survive seeding on ornithine and laminin (O/L) as a coating layer, regardless whether the seeding occurred in their nascent naïve medium or in epiblast-like cell (Epi-LC) medium. In contrast, normal colony growth was observed on matrigel and fibronectin.
What is known already: Mouse primordial germ cell like cells (PGC-LC) can be successfully generated *in vitro* from naïve mESC. For this, mESC are first primed towards PGC formation by culture in N2B27 medium with bFGF, Activin A and 1% KSR. This priming step ideally takes 2 days and is done on a coating of O/L. Human PGC-LC have been generated from hESC only at low frequency by spontaneous differentiation.
Study design, size, duration: Three independent naïve hESC lines were seeded onto the following attachment layers: O/L, matrigel, fibronectin and mouse embryonic fibroblasts (MEFs). One group was directly seeded in Epi-LC-medium, another was first seeded in their nascent naïve medium and cultured for one day (habituation), before the medium was changed to Epi-LC-medium.
Participants/materials, setting, methods: All cells were seeded on wells of a 24-well plate, and experiments were performed in three biological replicates. Morphology and cell survival was compared between the different attachment layers after two days of priming in Epi-LC-medium, with and without initial habituation for one day in the nascent naïve medium.
Main results and the role of chance: We observed that seeding of naïve hESCs on an O/L coating and in Epi-LC priming medium, as described for mESC, did not result in viable hESC or Epi-LC colonies. Next we added a habituation period to the protocol in which naïve hESCs are seeded and cultured for one day in their nascent naïve medium, before addition of Epi-LC medium. This approach showed no improvement in colony growth or survival. Both approaches were then tested on matrigel and fibronectin coatings, which allowed good colony growth up to three days in Epi-LC medium. Although signs of differentiation were noticeable after two days, no apparent morphological differences were seen between the approach with or without habituation on both matrigel and fibronectin.
Limitations, reason for caution: It remains to be investigated how well the expression profile of the hESCs after priming in Epi-LC medium, corresponds to that of mouse Epi-LCs, either in matrigel or in fibronectin.
Wider implications of the findings: Good colony growth and survival of naïve hESCs on matrigel and fibronectin, as opposed to O/L, could be the first

requirement to successfully convert the PGC differentiation protocol, described for mouse, to human PGC formation *in vitro*. Future generation of human stem cell-derived gametes will lead to major advances in human germ cell biology and fertility.

Study funding/competing interest(s): Funding by national/international organization(s) – Jasin Taelman is holder of a research fund supported by agency for Innovation through Science and Technology (IWT) (Project number: 131673). The authors declare they have no conflict of interest.

Study question: To develop a rapid, reliable and reproducible method for human spermatogonial stem cell (SSC) culture and cryopreservation.

Summary answer: Findings indicate that the technique of establishing a niche-like environment *in vitro* is successful in maintaining long-term cultures of human SSCs, and by combining immunofluorescence (IF) labeling and confocal imaging I have shown that vitrification of human spermatogonial stem cell is successful in maintaining viability.

What is known already: With advances in paediatric oncology, survival rates are high. Following chemo-radiation treatment sperm production is compromised by depletion of SSCs, leading to sub- or infertility. Pre-pubertal boys with cancer do not have a means of preserving their fertility. Human SSC culture remains in its infancy although testicular biopsies are being cryopreserved from pre-pubescent boys in some centres. Independent of time stored, SSC cryopreservation experiments demonstrate a post-thaw SSC viability of 40–60%.

Study design, size, duration: Human SSCs were cultured on 0.2% gelatin-coated plates and in co-culture with testicular somatic cells, incubated at 37°C and 5% CO_2. Images were captured at intervals whilst in culture. Colonies were vitrified and control SSC colonies remained in culture prior to fixation. All experiments were performed in triplicate.

Participants/materials, setting, methods: SSCs isolated from testicular biopsies, taken from azoospermic men were co-cultured with testicular somatic cells. Colonies were fixed in 4% PFA and IF labeled using antibodies against GFRa1 and PLZF. SSCs were cryopreserved using vitrification. Proliferation and cell death was assessed using Ki67 and TUNEL IF labeling and confocal-microscopy.

Main results and the role of chance: The co-culture method was superior, giving rise to SSC chains, clusters and colonies. To date, I have maintained these cultures for a period of 20 weeks. Vitrified human SSC colonies were viable and continued to proliferate upon warming. SSC colonies were fixed, and IF labeling combined with confocal imaging demonstrated comparable viability to the non-vitrified SSC colonies.

Limitations, reason for caution: Future work will concentrate on ensuring genetic integrity is maintained in cultured and vitrified SSC colonies.

Wider implications of the findings: This finding is significant because cryostorage is an essential component of the treatment pathway. Undoubtedly a clinically acceptable cryopreservation method is essential in germ cell cryopreservation; therefore I do feel this is an important practical step forward in the male germline stem cell field. The progress made in harvesting, propagating and vitrifying human SSCs *in vitro* is an important step towards the future development of a fertility preservation service for male childhood cancer survivors.

P-794 Is skewed X chromosome inactivation in human embryonic stem cells driven by a culture advantage?

[4]*Center for Regenerative Medicine, Barcelona, Spain*

Study question: What are the dynamics of X chromosome inactivation (XCI) in a large cohort of female human embryonic stem cell (hESC) lines during long-term culture and differentiation?

Summary answer: We found a stable, though aberrant XCI pattern during long-term undifferentiated culture and after differentiation to somatic and trophoblast lineages: all lines displayed stage III XCI, with major loss of XCI marks, and a completely non-random XCI pattern in lines informative for the microsatellite markers under study.

What is known already: Female hESC cultures have previously been shown to display variable XCI patterns. Unlike mouse embryonic stem cells, most hESC already display XCI at the undifferentiated state. Moreover, a predominant occurrence of non-random XCI patterns has been reported; but the extent and origin of this non-random pattern in hESC remains unresolved.

Study design, size, duration: XCI patterns of 22 female hESC lines were analyzed at different passages during long-term culture, and after differentiation into somatic osteoprogenitor-like cells and the trophoblast lineage. The parental origin of the inactivated X chromosome was identified if DNA from the embryo donors was available.

Participants/materials, setting, methods: We used methylation-sensitive DNA restriction and PCR, and massive parallel bisulphite sequencing for microsatellite markers to study DNA methylation. Histone modifications were analysed by immunostaining. Expression of *XIST* was investigated using real time PCR, while cDNA mini sequencing was used to determine mono- or biallelic gene expression.

Main results and the role of chance: Methylation analysis revealed XCI in all investigated lines. One line was non-informative for the studied markers; all other lines displayed a completely skewed, non-random inactivation pattern, from early passage on and in undifferentiated cells as well as after differentiation. We observed a transition from a random to a non-random pattern in only one line. From ten lines for which donor DNA was available, six lines displayed inactivation of the male donor allele; four of the female donor allele. Massive parallel bisulphite sequencing revealed partially methylated profiles, suggesting erosion of methylation. While in some early passage lines we could still observe repressing histone marks and *XIST* expression, these were very rapidly lost after limited culture time. Strikingly, loss of histone marks occurred in a colony-specific manner.

Limitations, reason for caution: We investigated the methylation status of the X chromosome using three microsatellite markers. Further refinement of the analysis at multiple loci spread over the whole chromosome could offer a more in-depth view of the XCI patterns in hESC.

Wider implications of the findings: The extent of the observed non-random XCI patterns is striking. We excluded a parent-of-origin-related mechanism and also its occurrence as passenger aberration is unlikely because of the number of cell lines involved and the presence at early passages. The transition found in one line rules out an embryonic origin of the skewed XCI, therefore we hypothesize that this XCI skewing originates from a culture advantage conferred by a specific XCI pattern.

P-795 Human embryonic stem cells derived from embryos donated by male infertility couples showed abnormal germ cells differentiation

Q. J. Zhang[1], Y. M. Zhang[2], S. Ning[1], A. Q. Chen[1], Y. G. Cui[1], J. Y. Liu[1], L. J. Qin[1]

[1]*Nanjing Medical University, First Affiliated Hospital, Nanjing, China*

[2]China Pharmaceutical University, School of Life Science and Technology, Nanjing, China

Study question: Whether spermatogenic abnormality will transmit to next generation through IVF.
Summary answer: Our results suggest that male infertility brought out by oligozoospermia may be inherited by IVF.
What is known already: Although many couples suffered oligozoospermia have benefited from IVF, possible defects in germ-specific gene in IVF babies are not yet repaired, thus there are risks of transmitting abnormal genes to offsprings. However, to date there has no clear evidence to testify the risks.
Study design, size, duration: Three normal human embryonic stem cells (hESCs) and two abnormal hESCs with male parents attacking by oligozoospermia were employed. All hESCs were differentiated into post-meiotic spematids by direct induction. The differentiation behaviors of germ cells were observed, analyzed and compared during the 14-day induction course.
Participants/materials, setting, methods: Normal CCRM15, abnormal CCRM16 and CCRM27 were established in our own laboratory. Normal H1 (46, XY) and H9 (46, XX) come from WiCell. The morphology of hESCs and hESCs-derived embryoid bodies (EBs) was compared. The expression pattern of germ cell specific genes was valuated by quantiative-PCR and immustaining.
Main results and the role of chance: The morphology of hES lines, and growth of EBs derived from different hES lines did not showed obvious difference. SOX2 (pluripotency and primordial germ cell (PGC) marker) expression level was high in hESCs and then declined gradually except for CCRM27. The peak expression of SCP3 (pluripotency and PGC marker) appeared later in H9.The expression of PRMM1 and PRDM1 (post-mmeiotic markers) in CCRM27 and CCRM16 were downregulated throughout differentiation stages. TNP1 and TNP2 (post-meiotic markers) showed increased expression in CCRM27 during the whole differentiation course, but expressed critically low in CCRM16 in later differentiation period. Further immustaining results were in accordance with the mRNA expression pattern. Our study indicated that hESCs with male parents suffered from oligozoospermia showed abnormal germ cell differentiation.
Limitations, reason for caution: Our sample size isn't big enough to make an incontrovertible conclusion, thus more normal (>3) and abnormal (>3) male hES lines should be employed to give a more reliable verdict in future studies. Also, besides hESCs derived from oligozoospermia parents, hESCs derived from asthenozoospermia and oligozoospermia parents also should be included in further investigation.
Wider implications of the findings: Our results implicated that a man suffered male infertility caused by oligozoospermia can has babies through IVF, but his boy babies may still be infertility. To completely recover the reproductive function, of IVF generation, the gene mutantion must be repaired at the blastomere stage.
Study funding/competing interest(s): Funding by University(ies) – Funding by hospital/clinic(s) – First affiliated Hospital of Nanjing Medical University.
Trial registration number: NA.

P-796 Establishment of embryonic stem cells from parthenogenetic haploid embryos and generation of cloned oocytes in mice

M. Kobayashi[1], A. Yoshida[1]
[1]Kiba Park Clinic, Tokyo, Japan

Study question: The aim of this study was to establish parthenogenetic haploid embryonic stem cells (PHESCs) from mouse parthenogenetic haploid embryos. In addition, we attempted to reconstitute unfertilized mouse oocytes by nuclear transfer with PHESCs.
Summary answer: ES cell-like cells with a maternal haploid chromosome set derived from PH embryos were able to establish and maintain them for a long-term period. Further, cloned oocytes reconstituted with nucleus of PHESCs were able to fertilize and developed to blastocyst stage.
What is known already: The embryonic stem (ES) cells with one set of maternal genome derived from parthenogenetic haploid (PH) embryos are amenable for the genetic analysis and the generation of genetically modified animals. Further, these cells could provide the valuable cell source for the reproductive and the regenerative medicine. However, available information about the haploid ES cells is very limited.
Study design, size, duration: BDF1 mice were used for production of PH embryos. ES-like cells with a haploid genome were established from the inner cell mass (ICM) of the PH blastocyst and determined their biological characteristics. Further, PHESCs in G0/G1 phase were injected into enucleated M-II oocytes to generate cloned oocytes.
Participants/materials, setting, methods: PH embryos were produced by removal of male pronucleus from fertilized oocytes, and were cultured until to blastocyst stage. Expression of ES cell markers in mouse PHESCs was examined immunohistochemically. The DNA content of PHESCs was measured by flow cytometry, and karyotype analysis was also performed. For generation of cloned oocytes, PHESC at G0/G1 phase was injected into enucleated mouse M-II oocyte. The cloned oocytes were fertilized by ICSI and cultured in KSOM.
Main results and the role of chance: After the culture for 4 days, 18.9% of PH embryos were reached to blastocyst stage, and ICM outgrowth was observed in approximately 60% of these. The ICM cells were dispersed, seeded over feeder cells, and spherical colonies were observed. In these cells, colony formation and proliferation were maintained up to 4 months. By immunohistchemical staining, these cells were positive for ES cell markers, such as Oct4, Nanog, Sox2, and Rex1. Further, flow cytometric analysis and karyotyping revealed that these cells had a haploid set of 20 chromosomes (19 autosomes and the X chromosome). After ICSI to cloned oocytes reconstituted by nuclear transfer with PHESCs, 58.6% of these cleaved to 2-cells and 6.2% formed blastocyst.
Limitations, reason for caution: This study was conducted using a mouse model. This finding does not directly represent human reproductive and regenerative medicine.
Wider implications of the findings: Our results may provide novel insights into the haploid embryonic stem cell biology and ES-like cells derived from PH embryos will be a powerful tool for reproductive and regenerative medicine, and genetic analysis.
Study funding/competing interest(s): Funding by hospital/clinic(s) – There are no conflicts of interest to declare.
Trial registration number: NA.
