Abstracts of the 31st Annual Meeting of the European Society of Human Reproduction and Embryology

Lisbon

Portugal

14 to 17 June 2015

Abstracts

31st Annual Meeting of the
European Society of
Human Reproduction and Embryology
Lisbon, Portugal
14 to 17 June 2015

Print copies of the meeting abstracts are provided for Conference Delegates only. However, the abstracts are available on-line to all Human Reproduction/Update/Molecular Human Reproduction subscribers and are also freely available to all visitors to the following website www.humrep.oxfordjournals.org, and on the ESHRE website: www.eshre.eu

Note to the media: all abstracts are strictly embargoed until the time and date of presentation at the conference.

The opinions or views expressed in this abstracts supplement are those of the authors and do not necessarily reflect the opinions or recommendations of ESHRE. The abstracts have been reviewed by the Congress Scientific Committee and revised accordingly by the authors. The selection of abstracts is based on the scores given by an international panel of peer reviewers.

Dosages, indications and methods of use for products that are referred to in the abstracts by the authors are not necessarily appropriate for clinical use and may reflect the clinical experience of the authors or may be derived from the professional literature of other clinical sources. Because of differences between in-vitro and in-vivo systems and between laboratory animal models and clinical data in humans, in-vitro and animal data may not necessarily correlate with clinical results.

The investigators of these abstracts have stated in their submission letter that prospective studies where patients are involved have institutional Ethics Committee approval and informed patient consent, and that the studies using experimental animals have institutional approval. The Publishers have endeavoured to reproduce faithfully all of the abstracts as accepted by the Conference Organisers, but can accept no responsibility for inaccuracies or omissions caused by the late receipt of abstracts.

The cover of *Human Reproduction* shows histone acetylation in two human germinal vesicle (GV) stage oocytes. The upper panels show an early-stage GV oocyte with a non-surrounding nucleolus stained for (A) chromatin (DAPI; blue) and (B) histone acetylation (anti-H4K12ac; red). Note the regions of intense chromatin staining in some areas, whereas others show no acetylation (C; overlay). The lower panels, of a more developed oocyte with a surrounding nucleus stained for chromatin (D) and histone acetylation (E), show more condensed chromatin than in the early-stage oocyte (above), although the oocyte still has some acetylated chromatin as shown in E and overlay (F). For more details see van den Berg *et al.*, pp. 1181–1190.

INVITED SESSION

SESSION 01: ROBERT G. EDWARDS' MEMORIAL KEYNOTE SESSION

Monday 15 June 2015 **08:30–09:30**

O-001 Human reproduction keynote lecture – preconception stress increases the risk of infertility: results from a couple-based prospective cohort study, the LIFE study

C. D. Lynch[1], R. Sundaram[2], J. M. Maisog[2], A. M. Sweeney[3], G. M. Buck Louis[2]
[1]*The Ohio State University College of Medicine, Department of Obstetrics and Gynecology, Columbus, U.S.A.*
[2]*Eunice Kennedy Shriver National Institute of Child Health and Human Development, Division of Intramural Population Health Research, Rockville, U.S.A.*
[3]*Texas A&M Health Science Center, Department of Epidemiology and Biostatistics, College Station, U.S.A.*

Study question: Are women's stress levels prospectively associated with fecundity and infertility?
Summary answer: Higher levels of stress as measured by salivary alpha-amylase are associated with a longer time-to-pregnancy (TTP) and an increased risk of infertility.
What is known already: Data suggest that stress and reproduction are interrelated; however, the directionality of that association is unclear.
Study design, size, duration: In 2005–2009, we enrolled 501 couples preconceptionally in a prospective cohort study in Michigan and Texas, USA. Couples were followed for up to 12 months and through pregnancy if it occurred. A total of 401 (80%) couples completed the study and 373 (93%) had complete data available for this analysis.
Participants/materials, setting, methods: Enrolled women collected saliva the morning following enrollment and then the morning following their first observed study menses for the measurement of cortisol and alpha-amylase, which are biomarkers of stress. TTP was measured in cycles. Covariate data were captured on both a baseline questionnaire and daily journals.
Main results and the role of chance: Among the 401 (80%) women who completed the protocol, 347 (87%) became pregnant and 54 (13%) did not. After adjustment for female age, race, income, and use of alcohol, caffeine, and cigarettes while trying to conceive, women in the highest tertile of alpha-amylase exhibited a 29% reduction in fecundity (longer TTP) compared with women in the lowest tertile [fecundability odds ratio = 0.71; 95% confidence interval (CI) = (0.51, 1.00); $p < 0.05$]. This reduction in fecundity translated into a more than twofold increased risk of infertility among women these women [Relative Risk = 2.07; 95% CI = (1.04, 4.11)]. In contrast, we found no association between salivary cortisol and fecundability.
Limitations, reasons for caution: Due to fiscal and logistical concerns, we were unable to collect repeated saliva samples and perceived stress questionnaire data throughout the duration of follow-up. Therefore, we were unable to examine whether stress levels increased as women continued to fail to get pregnant.
Wider implications of the findings: This is the first US study to demonstrate a prospective association between salivary stress biomarkers and TTP, and the first in the world to observe an association with infertility.
Study funding/competing interest(s): This study was supported by the Intramural Research Program of the Eunice Kennedy Shriver National Institute of Child Health and Human Development (contracts #N01-HD-3-3355, N01-HD-3-3356, N01-HD-3358). There are no conflicts of interest to declare.
Trial registration number: NA.

O-002 How a dead duck can be fertile

Moeliker Kees[1]
[1]*Natural History Museum Rotterdam, Rotterdam, The Netherlands*

For witnessing and publishing 'The first case of homosexual necrophilia in the mallard duck (*Anas platyrhynchos*)' the speaker was awarded the 2003 Ig Nobel Prize in the field of Biology. Thanks to this much coveted award he became known as ´The Duck Guy´ and people from all over the globe send him their own observations of and/or publications on non-reproductive sexual behavior in animals. Here he presents highlights from his ever growing 'Necrophilia Files', including some severe cases that were overlooked for decades.
To address the topic of human reproduction too, the speaker will also share his insights in possibly the most dramatic example of current habitat destruction and loss of biodiversity – the disappearance of the once-ubiquitous crab louse (*Pthirus pubis*) due to excessive removal of pubic hair among sexually active people.
Keywords: ducks, animal behaviour, non-reproductive sexual behaviour, necrophilia, pubic louse

SELECTED ORAL COMMUNICATIONS

SESSION 02: NEW PERSPECTIVES ON EMBRYO SCORING

Monday 15 June 2015 **10:00–11:30**

O-003 Embryo quality scoring: a correlation between trophectoderm development and aneuploidy rate in developing blastocysts

J. Blazek[1], M. Large[1], V. Pham[2], M. Hughes[3], T. Gordon[4]
[1]*Genesis Genetics, R&D/PGS, Houston, TX, U.S.A.*
[2]*Fertility Specialists of Houston, Embryology, Houston, TX, U.S.A.*
[3]*Genesis Genetics, PGS/PGD, Plymouth, MI, U.S.A.*
[4]*Genesis Genetics, PGS/PGD, London, United Kingdom*

Study question: Blastocysts cultured for IVF are graded based on stage of hatching and organization of the inner cell mass and trophectoderm. Common practice is to implant embryos based on quality score in cases where preimplantation genetic screening (PGS) is not used. Is blastocyst embryo quality score correlated with chromosomal ploidy?
Summary answer: PGS is critical to improving success rates in implantation and live birth during IVF. In cases where PGS is not used prior to implantation, embryo quality score can be used to determine the likelihood of embryo aneuploidy based on strong correlations between embryo aneuploidy and *in vitro* trophectoderm development.
What is known already: It is common to select embryos for transfer based on morphology during IVF. A retrospective study assessing ploidy and general blastocyst morphology suggests that blastocysts graded "excellent" have a higher euploid rate than embryos graded "good," "average," and "poor," but the value of this information is limited to the general definitions of morphology used. A better understanding of how ploidy effects blastocyst morphology and organization may help improve efficacy in non-PGS related IVF transfers.
Study design, size, duration: Embryo quality scores have been obtained for 528 blastocysts from 112 patients all using the same IVF center. Trophectoderm biopsies from 528 blastocysts underwent PGS for chromosomal abnormalities using array CGH or Next Generation Sequencing and the results were compared to embryo quality score to determine any existent correlations.
Participants/materials, setting, methods: Blastocyst stage embryos were scored according to the standard Gardner blastocyst grading system by a single embryologist. Amplified trophectoderm biopsies were analyzed using either Illumina's 24-sure array CGH or VeriSeq NGS protocols and chromosomal profiles were compared to embryo score to determine correlates.

Main results and the role of chance: We received blastocyst morphology scores for 528 embryos (112 patients) from a single IVF clinic. All 528 embryos were subjected to PGS using aCGH or NGS platforms and chromosome ploidy was determined for all but 4 embryos (all had poor quality or no DNA post biopsy). Embryos were grouped based on their Gardner scale embryo score (3–6 for stage of hatching, A–C, for inner cell mass and trophectoderm score with A being optimal) and genotypes were compared. Embryos with the optimal A trophectoderm score exhibited a significantly higher euploid rate (79.31%) compared to those with a B (60.51%) or a C (38.66%) trophectoderm. No correlation was found between stage of hatching or inner cell mass organization and embryo ploidy at this time.
Limitations, reason for caution: Identifying a correlation between blastocyst morphology and ploidy provides an additional resource for optimal embryo transfer but does have limitations. The process is dependent on consistent scoring and grading of the blastocyst and on the judgment of the individual embryologist, which undoubtedly varies across all clinics.
Wider implications of the findings: All subjects seeking IVF treatments stand to benefit from a more accurate system of identifying suitable embryos for transfer. In cases where PGS is not used, a comprehensive analysis of embryo morphology is the most efficient method in obtaining the successful transfer of an embryo. The findings of this study may transform the assessment of embryo morphology and establish a more universal methodology in the morphological determination of embryos that are suitable for transfer.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Genesis Genetics.
Trial registration number: NA.
Keywords: PGS, IVF, embryo morphology, blastocyst

O-004 An investigation into the developmental potential of mosaic embryos

E. Fragouli[1], S. Alfarawati[1], K. Spath[2], N. Tarozzi[3], A. Borini[3], D. Wells[2]
[1]*Reprogenetics UK, Institute of Reproductive Sciences, Oxford, United Kingdom*
[2]*University of Oxford, Nuffield Department of Obstetrics and Gynaecology, Oxford, United Kingdom*
[3]*Tecnobios, Bologna, Italy*

Study question: The existence of preimplantation embryos composed of a mixture of diploid and aneuploid cells has been recognised for more than two decades, but the developmental fate of such embryos has been impossible to determine. Can mosaic diploid-aneuploid blastocysts implant and lead to ongoing pregnancies and chromosomally normal births?
Summary answer: Most mosaic diploid-aneuploid blastocysts either fail to implant or miscarry after transfer, although a minority do succeed in producing chromosomally normal pregnancies. These findings confirm that diploid-aneuploid embryos have reduced developmental capacity in comparison with uniformly euploid embryos, but that some are potentially viable.
What is known already: Mosaicism – the presence of chromosomally distinct cell lines within the same embryo – is common during preimplantation development, affecting ~30% of blastocysts. Mosaicism is caused by incorrect segregation of chromosomes, most often arising during the first three cleavage divisions following fertilisation. Technical limitations have precluded detection of mosaicism in preimplantation embryos transferred to the uterus, preventing determination of its impact on clinical outcome and causing uncertainty over the clinical utility of such embryos.
Study design, size, duration: The study involved next-generation sequencing (NGS), a method capable of detecting aneuploidy in trophectoderm biopsies, even when only a minority of cells are affected. Genetic material from transferred embryos, surplus after aneuploidy screening using microarray-CGH, was reassessed using NGS, revealing mosaicism. Outcomes for mosaic and non-mosaic embryos were compared.
Participants/materials, setting, methods: 42 mosaic blastocysts were identified following reanalysis of biopsied material using NGS. All embryos had been transferred and had a known clinical outcome (i.e., implantation, miscarriage, birth). Outcomes for these embryos were compared to those for 51 blastocysts, predicted to be uniformly euploid, derived from a well-matched contemporary control group.
Main results and the role of chance: Of the blastocysts with mosaicism detected, 62% did not implant, 12% miscarried and only 26% produced ongoing pregnancies. A total of 109 mosaic abnormalities were detected, affecting almost all chromosomes, 63% of which affected whole chromosomes, the remainder involving chromosomal fragments (segmental). 30% of the mosaic embryos contained a mixture of segmental and whole chromosome abnormalities, 40% had whole chromosome errors only and 30% had segmental errors alone. Blastocysts with mosaic whole chromosome aneuploidy failed to implant significantly more often than those with mosaic segmental abnormalities (P = 0.0038). Embryos with mosaic errors affecting three or more chromosomes never produced an ongoing pregnancy. Control group outcome comparison showed that both implantation and ongoing pregnancy rates were reduced by a third when mosaic embryos were transferred.
Limitations, reason for caution: Analysis of entire mosaic blastocysts should be undertaken in order to determine the extent of euploidy and aneuploidy within them.
Wider implications of the findings: NGS succeeded in detecting mosaic abnormalities difficult to identify using previous methods. Most mosaic blastocysts failed to implant or miscarried, although a minority produced viable, euploid pregnancies. It can be concluded that mosaic embryos are usually compromised by the presence of aneuploid cells and have reduced developmental potential. However, if no entirely normal embryos are found, those with only 1–2 aneuploidies or segmental abnormalities could be considered for transfer (with appropriate patient counselling and prenatal follow-up).
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Reprogenetics UK.
Trial registration number: NA.
Keywords: embryo, mosaicism, next generation sequencing, implantation potential

O-005 Does disappearance of multinucleation from the 2-cell to 4-cell stage observed by time time-lapse correlate chromosomal normality detected by PGS microarray?

A. Bayram[1], M. Fakih[2], A. Shunnar[3], J. Divakaran[1], N. Poukaram[1]
[1]*Fakih Fertility Center, IVF Laboratory, Abu Dhabi, United Arab Emirates*
[2]*Fakih Fertility Center, IVF Clinic, Abu Dhabi, United Arab Emirates*
[3]*Fakih Fertility Center, IVF Clinic, Dubai, United Arab Emirates*

Study question: Is multinucleation at the 2 cell and 4 cell stage of embryonic development associated with increased aneuploidy rate and reduced blastocyst formation rate?
Summary answer: Multinucleation in the 2 cell stage embryos is relatively frequent during embryonic development, even in euploid embryos. Early multinucleation could later disappear when embryos progress to 4 cell stage. This transitory event can be monitored using Time-lapse imaging system.
What is known already: Time lapse technology allows embryo development to be monitored continuously. Embryos that have multinucleated blastomeres have a greater chance of being chromosomally abnormal. Detection of multinucleated blastomeres either on day 2 or 3 is associated with poor prognosis to blastocyst formation and chromosomal status of day 3 embryos.
Study design, size, duration: This is a retrospective study including 261 embryos from 50 patients (mean age = 34.9). Embryos were monitored in a special tri-gas incubator with built-in time-lapse monitoring system (EmbryoScope™, Unisense, Danmark). Data was collected from cycles carried out between January 2014 and December 2014.
Participants/materials, setting, methods: After standard microinjection, oocytes were placed in the EmbryoScope and cultured in Global Total Medium (LifeGlobal, IVF Online) under mineral Oil (Sage). Images were acquired every 20 min from 7 different focal planes. On day 3 of embryonic development, 236 embryos were biopsied and analyzed by array-CGH technique. Multinucleation (MN) was annotated at 2-cell and 4 cell-stage. Blastocyst formation was scored by according to Gardner's grading system (Gardner, 1990). For statistical analysis Chi-square contingency test was performed using Prism (GraphPad).
Main results and the role of chance: Among 236 embryos analyzed that had multinucleation at 2-cell and 4-cell stage, 70 (29.6%) were detected as euploid. In Table 1 shows parameters and number of embryos with multinucleation at 2-cell and 4-cell stage; and also embryos that did not have multinucleation at both states.

Table 1

	Group 1 MN at only 2-cell stage	Group 2 MN at 2 and 4-cell stage	Group 3 No MN
No of embryos	87	33	116
Age	35.6 ± 6.02	36.3 ± 5.65	33.8 ± 5.84
Blastocyst Formation rate	57.4% (50/87)	51.5% (17/33)	63.7% (74/116)
Euploidy Rate	31.0% (27/87)	15.1% (5/33)	32.7% (38/116)

P-value > 0.05.

Limitations, reason for caution: Number of embryos and cycles included in the study.

Wider implications of the findings: Although not significant, embryos with multinucleation both 2-cell stage and 4-cell stage, have higher aneuploidy rate compared to those with multinucleation at only at the 2-cell stage (31.0% vs. 15.1%). Blastocyst formation rate was similar in both groups (57.4% vs. 51.5%, $p > 0.05$). These findings suggest that time lapse observation of multinucleation at both 2-cell and 4-cell stages coincides with higher aneuploidy. A larger study including higher number of embryos are needed to investigate this association.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Fakih Fertility Center, Abu Dhabi, UAE.

Trial registration number: 0

Keywords: A-CGH, multinucleation, time lapse, ICSI, blastocyst

O-006 Embryos with cell division aberrations monitored by time-lapse imaging in a PGS program: are they able to develop into euploid blastocysts?

C. Lagalla[1], N. Tarozzi[1], R. Sciajno[1], M. Nadalini[1], M. Di Santo[1], V. Distratis[1], D. Wells[2], A. Borini[3]

[1]*Tecnobios Procreazione, Reproductive Medicine IVF Laboratory Unit, Bologna, Italy*

[2]*Reprogenetics UK, Institute of Reproductive Sciences, Oxford, United Kingdom*

[3]*Tecnobios Procreazione, Reproductive Medicine Clinical Unit, Bologna, Italy*

Study question: What is the ultimate fate of embryos with cell division abnormalities (e.g., direct cleavage, reverse cleavage and asymmetric cleavage) observed using time-lapse technology? How do affected embryos evolve throughout preimplantation development and is there evidence of aneuploidy rescue?

Summary answer: The majority of embryos with cleavage aberrations arrested. Those which developed into euploid blastocysts excluded some cells during morula compaction. Analysis of the excluded cells revealed a higher incidence of aneuploidies with respect to corresponding trophectoderm cells, providing evidence for a potential self-correction mechanism for mosaic embryos.

What is known already: Erroneous cleavage divisions (such as 1–3 cells and 2–5 cells) are considered negative morphological indicators of embryo viability and are associated with a significant reduction in implantation potential. While most anomalous cleavage divisions are expected to produce aneuploid cells, it is unknown whether this occurs in all cases. Additionally, the existence of systems for the elimination of aneuploid cells has been proposed, although thus far no mechanisms that could achieve such 'self-correction' have been described.

Study design, size, duration: 130 patients underwent PGS and 730 embryos were retrospectively morphokinetically analyzed. Cleavage aberrations were observed affecting 89 embryos and only 19 of these formed blastocysts. Chromosomal analysis was carried out to determine embryo ploidy status. Additionally, excluded cells of 11 euploid blastocysts, which developed from partially compacted morulae, were analyzed.

Participants/materials, setting, methods: Embryo development was retrospectively analyzed using a time-lapse imaging system (Embryoscope, Unisense Fertilitech). Multiple cell divisions were measured and evaluated. Embryo biopsy was undertaken on Day 5–6 and comprehensive chromosome screening performed through Array-CGH on trophectoderm and excluded cells.

Main results and the role of chance: Out of 730 embryos obtained from 130 patients (mean age 39.8 ± 4.4), 89 (60 patients, mean age 39.1 ± 4.1) showed cell division aberrations. Of those, 70 arrested or were discharged (78.7%): 47 arrested at <8/9 cell stage (67.1%), 13 at morula stage (18.6%) and 10 developed into not transferrable blastocysts (14.3%). Only 19 blastocysts out of 89 were suitable for TE biopsy (21.3%): 14 were found to be euploid (73.7%) and 5 aneuploid (26.3%). All the euploid blastocysts were derived from partially compacted morulae, whereas all the fully compacted morulae produced aneuploid blastocysts. Analysis of cells excluded by 11 chromosomally normal blastocysts while at the partially compacted morula stage revealed aneuploidy in 5 samples, apoptosis in 4 samples and euploidy only in 2 samples.

Limitations, reason for caution: Limited number of cases of the study group. Further studies are recommended.

Wider implications of the findings: This study revealed the fate of embryos displaying morphokinetic aberrations, confirming high rates of aneuploidy and developmental arrest. Furthermore, a potential mechanism of aneuploidy 'rescue' was identified. The results suggest that mosaic embryos may form partially compacted morulae in order to exclude aneuploid cells, which subsequently undergo apoptosis. Not only is this finding of great biological interest, but there are also significant clinical ramifications, especially in terms of cells chosen for biopsy during PGS.

Study funding/competing interest(s): Funding by hospital/clinic(s) none.

Trial registration number: None.

Keywords: cell division aberrations, time lapse, aneuploidy rescue, ArrayCGH, morula compaction

O-007 Immunohistochemical study of abnormal mitosis in development of human embryos

J. D. De Pinho[1], G. Chia[2], D. Georgieva[3], D. Kort[1], R. A. Lobo[1], M. V. Sauer[1], D. Egli[4]

[1]*Columbia University College of Physicians and Surgeons, Department of Obstetrics and Gynecology Division of Reproductive Endocrinology and Infertility, New York, U.S.A.*

[2]*Columbia University College, Department of Pediatrics, New York, U.S.A.*

[3]*Columbia University College, Department of Molecular and Biophysical Studies, New York, U.S.A.*

[4]*The New York Stem Cell Foundation Research Institute, Department of Obstetrics and Gynecology Division of Reproductive Endocrinology and Infertility, New York, U.S.A.*

Study question: What is the consequence of abnormal mitosis on preimplantation development? And what are the mechanisms of formation for supernumerary nuclei?

Summary answer: We demonstrate that nuclear abnormalities are frequent in early human embryos, associated with DNA damage, the presence of centromere-less chromosomal fragments, poor developmental potential, and chromosomal mosaicism. These results show that a significant portion of the genomic abnormalities in embryo development arise from post-fertilization mitosis.

What is known already: The focus in genomic abnormalities in embryo-development research has been on oocyte meiosis, although reports assert that mosaicism may frequently arise post-fertilization. It is also known that blastomeres can contain extra-nuclear DNA (i.e., micro and macro-nuclei) in pre-implantation human embryos (cleavage and blastocyst stage). Mosaicism is challenging to clinically diagnose, as multiple cells are required, and the mechanisms of their formation are still poorly defined.

Study design, size, duration: An internal review board approved, academic laboratory in-vitro research study, on consented, donated cryopreserved (2000–2010) human embryos, from an university-affiliated infertility clinic. A total of 163 cryopreserved cleavage stage embryos containing 731 blastomeres were analyzed. Mitotic abnormalities, including multiple nuclei, abnormal spindles, abnormal cytokinesis were quantified.

Participants/materials, setting, methods: Vitrified stage embryos of good or poor quality were thawed, stained for markers to study chromosome segregation (anti-centromere, pericentrin, and β-tubulin), and DNA damage (phospho-γH2ax). Confocal microscopy was used to analyze abnormal DNA segregation, cytokinesis anomalies, and distinguish spindle attachment from DNA packaging errors (nuclear, mitotic spindle, ±centromere).

Main results and the role of chance: Cleavage stage blastomeres contained multinucleation in 15.7% (115/731 blastomeres), higher in low quality arrested embryos (66%), comparing to successful developing blastocyst (5%), suggesting it adversely affects preimplantation development ($p < .0001$). Mechanistically, multinucleation arises if abnormal chromosome segregation

[pre-mitotic (chromosome breaks preventing centrosome-microtubule-spindle attachment), and mitotic errors (abnormal chromosome attachment due to intrinsic microtubule-spindle defects)], and cytokinesis, defined for embryos containing a supernumerary centrosomes and larger size blastomeres within the embryo. Moreover, cells with a high number of multinucleation exhibited failed cytokinesis, and suggest that is the consequence of abnormal chromosome segregation. We found that cells with micronuclei frequently lack centromeres (49%), and in all their DNA content analysis showed mosaicism, indicating DNA damage as the cause for micronucleation that directly correlates with chromosomal aneuploidy.

Limitations, reason for caution: The data on cytokinesis are preliminary and are further investigated. Additional molecular studies regarding the mechanism of abnormal cytokinesis will be performed.

Wider implications of the findings: This study reinforces the relevance of mitotic errors in human embryo development and demonstrates that abnormal mitosis significantly contributes to their developmental arrest. The presence of abnormally segregating mitotic chromosomes, and nucleoplasmic bridges suggest abnormalities in chromosome cohesion/segregation as the cause for abnormal nucleation. We also report that defective cytokinesis as an abnormal blastomeric development mechanism, secondary of abnormal chromosome segregation, and that centromere absence suggest pre-mitotic DNA damage as the cause for multinucleation.

Study funding/competing interest(s): Funding by hospital/clinic(s) – The study was funded by the Naomi Berrie Diabetes Research Center.

Trial registration number: NA.

Keywords: mitosis, cytokinesis, human embryo, developmental arrest, multinucleation

O-008 Multi-nucleation in human embryos should not be used as a marker for their elimination from candidates for transfer

S. Hashimoto[1], T. Nakano[1], M. Inoue[1], K. Yamagata[2], K. Ito[1], Y. Morimoto[3], Y. Nakaoka[1]

[1]*Sunkaky medical corporation, IVF Namba Clinic, Osaka, Japan*
[2]*Osaka University, Research Institute for Microbial Diseases, Osaka, Japan*
[3]*Sunkaky medical corporation, HORAC Grand Front Osaka Clinic, Osaka, Japan*

Study question: Is the appearance of multinucleated blastomeres (MNBs) at 2-cell stage a marker for developmental failure of human embryos?

Summary answer: Appearance of MNBs is not always a predictor of chromosomal aneuploidy. The blastulation rate of embryos with MNBs is similar to that of embryos without MNBs. Blastocysts developed from embryos with MNBs have a full term developmental competence to healthy babies.

What is known already: MNBs are frequently observed in human embryos with poor morphology. Its appearance would be associated with low pregnancy rates following transfer probably due to chromosomal aberration or chromosome mosaicism. Although such morphological abnormalities implicate developmental failure of embryos, it remains unknown whether these properties lead to aneuploidy and implantation failure.

Study design, size, duration: This study was approved by the ethical committee of the Japan Society of Ob/Gy. We assessed relationships between the appearance of MN in human embryos and their development *in vitro* using 139 donated embryos and *in vivo* by retrospective analysis of time-lapse images of 46 embryos which were singly transferred.

Participants/materials, setting, methods: Donated pronuclear ova were injected with a mixture of mRNAs encoding EGFP-α-tubulin and mRFP1-histone-H2B. Dynamic changes of their chromosomes were monitored continuously using a confocal microscope inside an incubator for 120 h. Chromosome analysis was performed using microarray-CGH. Time-lapse images of embryos in clinical study were captured using PrimoVision.

Main results and the role of chance: Fluorescent imaging study revealed that 74% of embryos (80/108) showed MNBs at 2-cell stage after RNA injection. Nevertheless, embryos with MNBs developed to the blastocyst stage (45%, 36/80) and morphologically good blastocysts (15%, 12/80). These values were similar to those obtained from embryos without MNBs (blastulation rate 50%, good blastocyst rate 18%). The duration between first and second cleavage was 8.5–12.0 h for embryos with MNBs that developed to the blastocyst stage. Seventy percent of blastocysts developed from embryos with MNB were found to be euploid (14/20). This value was also similar to that of embryos without MNBs (75%). In clinical study, sixteen embryos (35%) with MNBs transplanted following transfer and four healthy babies were born at the present time (January 5, 2015).

Limitations, reason for caution: Multi-nucleation of embryos at 2-cell stage which had normal developmental competence appeared late at night. Thus, it is difficult to observe multi-nucleation of normal embryos based on conventional observation without time-lapse system. Further studies are required to make critical evaluation of normal and abnormal embryos showing multi-nucleation.

Wider implications of the findings: This study suggests that the appearance of MNB at first mitosis does not directly correlate with chromosomal aneuploidy and subsequent embryo development. It would be of negligible significance to assess the presence of MNBs compared with the observation of timing of mitosis.

Study funding/competing interest(s): Funding by national/international organization(s) – Japan Society for the Promotion of Science. No other competing interests are declared.

[10]*AstraZeneca Pharmaceuticals, Innovative Medicines and Early Development, Manchester, United Kingdom*

Study question: To test the hypothesis that Neurokinin B (NKB) receptor antagonism will reduce LH secretion and thereby decrease testosterone in women with Polycystic Ovary Syndrome (PCOS).

Summary answer: The selective NKB receptor antagonist AZD4901 reduced LH secretion and pulse frequency in women with PCOS, with a significant and sustained fall in serum testosterone.

What is known already: PCOS is characterized by elevated serum testosterone (T) concentrations, and associated with increased luteinizing hormone (LH) secretion and accelerated pulse frequency. Recent discoveries have led to the emergence of the kisspeptin-NKB-dynorphin system as the pivotal modulator of GnRH and gonadotropin secretion: manipulation of this pathway thus presents a therapeutic target to address a central pathophysiology in PCOS.

Study design, size, duration: We undertook a randomized, double-blind, placebo-controlled trial with daily oral dosing of 20, 40 or 80 mg of AZD4901 or placebo for 28 days. *Primary outcome:* Change in 8 h LH area-under-curve (AUC) between baseline (day-1) and day 7 vs. placebo. *Secondary outcomes* included changes in LH pulsatility and testosterone.

Participants/materials, setting, methods: *Key eligibility criteria:* Diagnosis of PCOS (≤6 cycles/year, hyperandrogenemia (Free T > 0.85 ULN) and

polycystic ovary morphology). *Statistical analyses:* LH AUC was calculated by trapezoid summation. LH pulsatility was analysed with blinded deconvolution. Comparisons between groups were performed using mixed effects models for repeated measures with baseline as a covariate.

Main results and the role of chance: Sixty-five women were randomized (27 ± 5 years, BMI 31.5 ± 6.0 kg/m^2, mean ± SD), with 13 to 16 patients contributing to the primary endpoint in each of the four arms. At day 7, LH AUC reduced by 52% (95% CI 30–67%) in the 80mg group (from 67.4 ± 1.6 to 36 ± 2.3 IU/L*h) compared to placebo (from 61.1 ± 1.9 to 69.8 ± 1.7 IU/L*h); $p = 0.0003$. LH pulse frequency also reduced from 5.8 ± 2.1 to 3.7 ± 2.1 pulses/8hr in this group (from 7.2 ± 2.3 to 6.8 ± 2.6); $p < 0.0001$ vs. placebo. Concurrently, testosterone decreased by 29% (14–41%) at day 7 in the 80mg group (from 2.2 ± 1.3 nmol/L to 1.6 ± 1.5) vs. placebo (from 1.5 ± 1.7 to 1.6 ± 1.9 nmol/L); $p = 0.0006$. Average T reduction was maintained in this group over the remaining study period (17% decrease from baseline vs. placebo at day 28).

Limitations, reason for caution: Larger studies with a longer duration of follow-up assessing clinical outcomes are required to fully assess therapeutic potential. Applicability of our findings to the subset of women with normo-androgenemic phenotype requires further investigation.

Wider implications of the findings: We have demonstrated the potential for Neurokinin B antagonism as a therapeutic approach to address LH and testosterone hypersecretion in PCOS. This approach addresses the central neuroendocrine pathophysiology in this common, yet unmet, medical need. Our findings are consistent with decreased LH secretion and pulse frequency observed in patients with NKB signaling defects. Neurokinin B antagonism may therefore have potential in other reproductive disorders where decreased gonadotropin secretion is of therapeutic benefit.

Study funding/competing interest(s): Funding by commercial/corporate company(ies) – AstraZeneca.

Trial registration number: Clinicaltrials.gov; NCT01872078.

Keywords: PCOS, testosterone, LH pulsatility

O-010 Randomized controlled trial of the effects of metformin versus combined oral contraceptives in adolescent PCOS women through a 24 months follow up period

A. Elnashar[1], H. El Maghraby[2], T. Nafee[3], D. Guiziry[2], I. Fourtia[4]

[1]*Benha University Hospital, Obs and Gyn, Mansoura, Egypt*
[2]*Alexandria University Hospital, Obs and Gyn, Alexandria, Egypt*
[3]*Keele University Medical School, Obs and Gyn, London, United Kingdom*
[4]*Fertility Center, Obs and Gyn, Misrata, Libya*

Study question: What are the effects of metformin and combined oral contraceptive pills (COC) over 24-month period on adolescent girls with PCOS presenting hyperandrogenemia and menstrual irregularities

Summary answer: Metformin and COC have comparable therapeutic effectiveness on cycle regularity and hirsutism. Metformin was associated with significant weight loss and improvement in the metabolic syndrome, while COC was associated with non-significant weight gain and deterioration of the metabolic syndrome.

What is known already: No studies for 24-month period. Follow up for 12-month only showed no difference in the therapeutic effectiveness between metformin and the COC on hirsutism and acne, but metformin treatment resulted in a reduction in fasting insulin and lower triglyceride levels than COC.

Study design, size, duration: Randomized controlled trial. The study included 119 adolescent girls. Participants were randomly divided into three groups, using computer-generated random-number tables. The duration of follow up was 24 months. Based on 0.8 power to detect a significant difference ($P = 0.05$, two-sided), 32 patients were required for each study group.

Participants/materials, setting, methods: PCOS was defined according to Rotterdam consensus workshop group, 2004. *Group A (n = 40):* received oral metformin 1700 mg/day, *group B (n = 40):* received low-dose combined oral contraceptives, and *group C (n = 39):* were followed without treatment in the outpatient clinic of Alexandria IVF/ICSI center.

Main results and the role of chance: In group B significant decline in serum testosterone reached the lowest value by the end of the 2-year (0.7 ± 0.2 vs. 1.3 ± 0.5 ug/ml). By the end of the study, group A showed a significant decline in fasting (18.6 ± 3.0 to 10.0 ± 3.0 μIU/ml) and after-load insulin levels (126 ± 43 to 64 ± 15 μIU/ml) with a significant rise in glucose/insulin ratio (GIR) from 4.1 ± 0.3 to 4.6 ± 0.5. Group B showed significant rise in fasting and after-load insulin (from 15.0 ± 3.0 mIU/ml and 103.0 ± 91.0 μIU/ml to 19.0 ± 4.0 and 187.0 ± 22.0 μIU/ml respectively) and GIR dropped significantly from 4.4 ± 0.2 to 3.1 ± 0.3. Metformin was associated with a significant loss of weight from 87.0 ± 6.0 to 72.0 ± 0.5 Kg while COC was associated with a non-significant gain in weight (from 84.0 ± 6.0 to 91.0 ± 9.0 Kg).

Limitations, reason for caution: None.

Wider implications of the findings: The choice of the proper line of therapy should be tailored for every patient, according to her age, stage in life, presenting symptoms, various personal and familial risk indices, as well as her own informed choices. This study suggests that insulin sensitizers are a proper choice for adolescent PCOS women presenting with acne and hirsutism, having a safer profile than combined oral contraceptives.

Study funding/competing interest(s): Funding by University(ies) – None.

Trial registration number: PACTR201307000567163.

[5]*University of Helsinki and Helsinki University Central Hospital, Department of Obstetrics and Gynecology, Helsinki, Finland*
[6]*Imperial College London, Institute of Reproductive and Developmental Biology, London, United Kingdom*

Study question: What are the respective roles of polycystic ovary syndrome (PCOS) and weight gain and/or overweight/obesity for the development of pre-diabetes [impaired fasting glucose (IFG) and/or impaired glucose tolerance (IGT)] or type 2 diabetes mellitus (T2DM) by the end of reproductive life (at 46 years)?

Summary answer: PCOS was associated with an increased risk of pre-diabetes and T2DM, and PCOS in association with overweight/obesity was the strongest risk factor for both disorders, whereas the risk was not increased in normal-weight women with PCOS.

What is known already: The risk of developing pre-diabetes and T2DM has been shown to be increased in women with PCOS. However, additional prospective longitudinal studies are needed to study the respective roles of PCOS *per se*, body mass index (BMI) and weight gain on the development of pre-diabetes and/or T2DM.

Study design, size, duration: In the prospective follow-up Northern Finland Birth Cohort 1966 ($n = 5889$) questions on oligo-amenorrhea (OA) and hirsutism (H) were asked at 31 years (81% answered) and diagnosis of PCOS at 46 years (72% answered). Clinical examinations were performed at 14, 31 and 46 years and 2-hour oral glucose tolerance test (OGTT, $n = 2780$) was performed at 46 years.

Participants/materials, setting, methods: Women reporting both OA + H and/or PCOS diagnosed by practitioner were considered as having PCOS ($N = 279$). The outcomes [(IGF ($n = 101$), IGT ($n = 217$) and T2DM ($n = 313$)] were diagnosed according to OGTT. T2DM diagnosis was also asked in questionnaires (31 and 46 years) and verified from the national drug and hospital discharge registers.

Main results and the role of chance: The increase in BMI between all three time-points (14, 31 and 46 years) was significantly greater in women with PCOS who developed pre-diabetes or T2DM than in women with PCOS and normal glucose tolerance. The risks of impaired glucose metabolism [IGM (defined as pre-diabetes and/or T2DM), odds ratio (OR) 1.97, 95% confidence interval (CI) 1.32–2.95] and T2DM (OR 3.00, 95% CI 1.68–5.36) were increased in women with PCOS. The risks of pre-diabetes (OR 3.89 95% CI 1.99–7.61), T2DM (OR 13.62 95% CI 5.72–32.42) and IGM (OR 6.22 95% CI 3.64–10.62) were increased in women with PCOS and BMI ≥ 25 kg/m^2, but not in women

with PCOS and BMI < 25 kg/m^2. All results were adjusted for consumption of alcohol, smoking and socioeconomic status at age 46.

Limitations, reason for caution: The diagnosis of PCOS was based on self-reporting, which may have led to information bias. Ovarian ultrasonography was not available to aid the diagnosis of PCOS. The relatively high rate of missing data after combining the 31- and 46-year data (questionnaire and clinical examination) may have biased the results.

Wider implications of the findings: The risk of IGM was increased in women with PCOS. Overweight/obesity in association with PCOS was the strongest predictor for pre-diabetes and T2DM, whereas the risk was not increased in normal-weight women with PCOS. Moreover, weight gain during the long follow-up played a crucial role for development of pre-diabetes or T2DM in women with PCOS. These results emphasize the role of weight gain prevention during adolescence and early adulthood.

Study funding/competing interest(s): Funding by hospital/clinic(s) Funding by national/international organization(s) Finnish Medical Society Duodecim, the North Ostrobothnia Regional Fund, the Academy of Finland, the European Commission, Medical Research Council, the National Institute for Health Research.

Trial registration number: NA.

O-012 Metabolism alteration in follicular niche: the nexus between intermediary metabolism, mitochondrial function, and classic polycystic ovary syndrome

H. C. Zhao[1], Y. Zhao[1], R. Li[2], Y. Yu[2], J. Qiao[2]
[1]*Peking University Third Hospital, Department of Obstetrics and Gynecology, Beijing, China*
[2]*Peking University Third Hospital, Department of Obstetrics and Gynecology, Beijing, China*

Study question: What is the function of intermediary metabolism in follicular fluid and mitochondria of cumulus cell from classic PCOS patients?

Summary answer: Follicular fluid intermediary metabolic profiles provide signatures of classic PCOS ovary local metabolism and establish close link with mitochondria dyfunction of cumulus cells and highlighting the role of metabolic signal and mitochondrial crosstalk involved in the pathogenesis of classic PCOS.

What is known already: Classic polycystic ovary syndrome (PCOS) is a high-risk phenotype accompanied by increased risks of reproductive and metabolic abnormalities; however, the local metabolism characteristics of the ovaries and their effects on germ cell development are unclear.

Study design, size, duration: This study analyzed Follicular fluid (FF) and cumulus cells (CCs) collected from PCOS and matched control group at the time of oocyte retrieval.

Participants/materials, setting, methods: 95 FF of PCOS group and 55 FF of Control group were collected for the targeted metabolomics study. 80 CCs of PCOS group and 91 CCs of Control group were collected to assess mitochondrial function by transmission electron microscopy, flow cytometer,immunofluorescence, real-time-PCR and luminometer.

Main results and the role of chance: The targeted metabolomics study showed that glycolysis pathway was down regulated, BCAA catabolism pathway was up regulated, acylcarnitines was decreased, ketone bodies was increased, TCA cycle was up regulated and dysregulated, metabolites of NAD catabolism was decreased in FF of PCOS group. The mitochondria in CCs from PCOS patients showed abnormal mitochondrial structure, a decreased transmembrane potential, an aggregated distribution of mitochondria and a decreased mtDNA content with a decrease PGC-1a mRNA expression and hypermethylation of PGC-1a promoter. Follicular fluid intermediary metabolic profiles provide signatures of classic PCOS ovary local metabolism and establish close link with mitochondria dyfunction of cumulus cells and highlighting the role of metabolic signal and mitochondrial crosstalk involved in the pathogenesis of classic PCOS.

Limitations, reason for caution: The relationship of those alterations with clinical parameters of PCOS such as metabolic parameters and pregnancy rate, need further analyzed.

Wider implications of the findings: All those changes of intermediates metabolites have important epigenetic modifying roles could influence post-translational modification. Those epigenetic and PTM alterations could induce dysfunction of mitochondrial, and vice versa. The study of crosstalk between intermediary metabolism and mitochondrial function confirm the important role of epigenetic and PTM in the pathogenesis of classic PCOS, and probably bring a more integrated understanding of pathogenesis and possibly, new therapeutic opportunities for women with classic PCOS.

Study funding/competing interest(s): Funding by national/international organization(s) – This work was supported in part by the Ministry of Science and Technology of China Grants (973 program; 2014CB943203 and 2011CB944504), the National Natural Science Funds for general program (31371521 and 31230047). The authors have no conflict of interest to declare.

Trial registration number: NA.

O-013 LncRNAs expression signatures of cumulus cells isolated from PCOS patients revealed by microarray

X. Huang[1], C. Hao[1], H. Bao[1], X. Liu[1], M. Wang[1], H. Dai[1]
[1]*Yantai Yu Huang Ding Hospital, Reproductive Medicine Centre, Yantai Shandong, China*

Study question: Polycystic ovary syndrome (PCOS) is the most common and complex endocrinopathy, being found in 6–8% of women at reproductive age and accounting for about 75% of anovulatory infertility. To date there has been no study of lncRNAs expression profiles or their functional roles in PCOS.

Summary answer: Clusters of lncRNAs were aberrantly expressed in PCOS patients compared with non-PCOS patients, which revealed that lncRNAs differentially expressed in cumulus cells may exert a partial or key role in hormone abnormalities of PCOS patients and maybe impact the oocyte development.

What is known already: Long noncoding RNAs (lncRNAs) are an important class of pervasive genes involved in a variety of biological processes including reproductive and metabolic pathways of the endocrine system.

Study design, size, duration: In this study, we described lncRNAs profiles in cumulus cells isolated from ten patients (5 PCOS and 5 non-PCOS patients) by microarray.

Participants/materials, setting, methods: Seventy patients (thirty-five women with PCOS and thirty-five normal women without PCOS) referred to our center for IVF were included in this study after obtaining written informed consent. The cumulus cells isolated from ten patients (5 PCOS and 5 non-PCOS patients) were used for microarray analysis of lncRNAs and that isolated from the other sixty patients (30 PCOS and 30 non-PCOS patients) were used for an extra evaluation.

Main results and the role of chance: From the data, we found 623 lncRNAs were significantly up-regulated or down-reguated, which could be used to discriminate PCOS from non-PCOS cumulus cells (≥twofold). Of them, the up-regulated lncRNAs (n = 620) were more common than down-regualted ones (n = 3). In addition, the distribution of the differentially expressed lncRNAs was unbalance in all human chromosomes, i.e., there are 74 lncRNAs were transcribed from regions on chromosome 2 while only 7 lncRNAs were transcripts from regions on chromosome 22. Further analysis showed the differentially expressed lncRNAs were classified into three subgroups: HOX loci lncRNAs (n = 2), Enhancer-like lncRNAs (n = 87) and lincRNAs (n = 6). Five differentially expressed lncRNAs (ENST00000454271, ENST00000433673, ENST00000450294, ENST00000432431 and XLOC_011402) were selected to validate of the microarray results by quantitative RT-PCR.

Limitations, reason for caution: More work will be needed to determine whether these lncRNAs can serve as new therapeutic targets and diagnostic biomarkers in PCOS.

Wider implications of the findings: As a common endocrine and metabolic disorder in women, the occurrence or abnormal oocyte development of PCOS was proved to be regulated by a lot of lncRNAs. To reveal the functions of differentially expressed lncRNAs will provide potential targets for further treatment of PCOS and novel insights into other endocrine diseases.

Study funding/competing interest(s): Funding by national/international organization(s) – National Basic Research Program (grant 81170622 and grant 81401172).

Trial registration number: The study is not a RCT research.
Keywords: PCOS, long noncoding RNA (lncRNA), cumulus cells, microarray

O-014 Combined effect of insulin resistance condition and environmental pollutant – cadmium on cell survival and steroidogenesis in human granulosa cells from follicular fluid of IVF patients

M. Belani[1], P. Shah[2], M. Banker[3], S. Gupta[1]
[1]*The M.S. University of Baroda, Biochemistry, Vadodara, India*
[2]*Nova Pulse IVF Clinic, Embryology, Ahmedabad, India*
[3]*Nova Pulse IVF Clinic, Director, Ahmedabad, India*

Study question: Environmental endocrine pollutant-cadmium (Cd) is a known risk factor for dysfunctional granulosa cell. Because insulin resistance (IR) is also involved in granulosa cell malfunctioning and is currently targeted predominantly, we questioned whether Cd along with insulin resistance is aggravating the functioning of granulosa cells ultimately leading to aberrations in follicular development.
Summary answer: Inhibition of steroidogenesis and decrease in cell survival with respect to decrease in protein expression of StAR, CYP19A1, 17β-HSD and 3β-HSD, progesterone and estradiol concentrations and increase in cleaved PARP-F2, active caspase-3 and ANNEXIN-V/PI staining respectively was observed in insulin resistant human granulosa cells treated with 32 μM Cd as compared to control.
What is known already: IR is prevalent in 60–80% of women with polycystic ovarian syndrome (PCOS). The tolerable weekly intake for Cd is 2.5 μg/Kg body weight. 32 μM Cd has been observed in follicular fluid of cigarette smoking females undergoing IVF. Cd inhibits hypothalamus pituitary ovarian axis, steroidogenic enzymes in ovary and granulosa cells, different developmental stages in rodents. Pre-clinical studies on combined exposure of Cd and IR on granulosa cells of rats revealed deleterious effect on reproductive function.
Study design, size, duration: *Control vs. treatment*: Granulosa cells were isolated from 18 donors and 24 PCOS women. IR was confirmed in PCOS granulosa cells by protein expression of IR, p-IRS-1(307), PI(3)K, p-Akt, PPAR-g. Cd dose was standardized by MTT assay. Control and PCOS-IR granulosa cells were incubated with 32uM Cd for 24 hrs.
Participants/materials, setting, methods: *Invitro* granulosa cell culture: control, control + Cd, PCOS-IR, PCOS-IR + Cd, in triplicates, repeated 3 times. Estradiol and progesterone analysis from supernatant and protein expression analysis of StAR, CYP11A1, CYP19A1, 17b-HSD, 3b-HSD, cleaved PARP-F2, active caspase-3 from cell lysate. ANNEXIN-V/PI staining by FACS and Confocal microscopy for cell death.
Main results and the role of chance: In PCOS-IR significant decrease in protein expression of IR ($p < 0.01$), PI(3)K ($p < 0.05$),increase in p-IRS-1(307) ($p < 0.001$), p-Akt ($p < 0.01$) and PPAR-g ($p < 0.01$) as compared to control and PCOS-non IR granulosa cells. MTT revealed that 32 μM Cd revealed significant decrease in granulosa cell viability as compared to control ($p < 0.001$). In PCOS-IR + Cd group significant decrease in protein expression of StAR ($p < 0.001$, $p < 0.05$, $p < 0.05$), CYP19A1 ($p < 0.01$, $p < 0.01$, ns), 17β-HSD ($p < 0.001$, ns) and 3b-HSD ($p < 0.01$, $p < 0.01$, ns), progesterone ($p < 0.05$, ns, $p < 0.001$) and estradiol concentrations ($p < 0.001$, ns, $p < 0.001$). In cell death parameters increase in protein expression of cleaved PARP-F2 ($p < 0.001$ and $p < 0.05$), active caspase-3 ($p < 0.01$ and $P < 0.05$) and a positive ANNEXINV/PI staining as compared to control, PCOS-IR and Cd group was observed indicating granulosa cell death through apoptosis. (ns = non significant).
Limitations, reason for caution: Insulin resistance was confirmed at cellular level because of unavailability of serum samples from the patients.
Wider implications of the findings: Although individual parameters were variedly affected at protein level in different groups, overall effects seemed to me more deleterious in PCOS-IR + Cd group. Increase in apoptosis and decrease in steroidogenesis would affect the normal developmental programme of the follicle by depriving nutrients required for the achievement of a healthy oocyte and its release ultimately compromising fertility at the level of preconception. Research on IR and pollutants needs to be emphasized for better understanding of idiopathic infertility.
Study funding/competing interest(s): Funding by national/international organization(s) – CSIR-SRF.

Trial registration number: Registration number is not required for this study.
Keywords: insulin resistance, cadmium, human granulosa cell, apoptosis, steroidogenesis

SESSION 04: TESTIS FUNCTION: DIAGNOSIS AND RISKS

Monday 15 June 2015 **10:00–11:30**

O-015 Opioid receptors are present in male germ cells and modulate meiosis

N. Subiran[1], N. Estomba[1], I. Muñoa[1], M. Gianzo[1], I. Urizar[1], L. Casis[1], J. Irazusta[1]
[1]*University of Basque Country, Physiology, Bilbao, Spain*

Study question: To analyze the expression and distribution of the three types of opioid receptors in male germ cells and analyze its role during the spermatogenesis
Summary answer: Male germ cells express active mu-opioid receptor (MOR), delta-opioid receptor (DOR) and kappa opioid receptor (KOR) in mice and describe its function as a modulator of mice spermatogenesis
What is known already: Numerous studies have demonstrated the presence of endogenous opioid peptides in different testicular cell types, providing evidences that the opioid system participates in an important way in the regulation of testicular function. However, the exact role of the opioid system during spermatogenesis has not been clarified since the presence of the three receptors: MOR, DOR, KOR remain unknown.
Study design, size, duration: Transillumination-assisted microdissection technique we used to obtain the stage-specific segments of seminiferous tubules for qRT-PCR and Immunoblotting thecniques. Isolated total testis cells were treated for 1 h and 24 h, and used in functional experiments, immunocytochemistry and FACS analyses. Treatments: morphine, DPDPE and U-50488 as the MOR, DOR and KOR selective agonist respectively.
Participants/materials, setting, methods: Testis from 100 adult healthy *Swiss* male mice. qRT-PCR, Immunoblotting, Immunofluorescence and FACS approches.
Main results and the role of chance: We have evidenced for the first time that active MOR, DOR and KOR are present in male germ cells by qRT-PCR, Immunoblotting and Immunofluorescence techniques. By using flow cytometry and qRT-PCR approaches we found that the three receptors act as a modulator of spermatogenesis, being the response time-exposure dependent. Our results suggest that the three opioid receptors are involved in meiosis of the mice spermatogenesis by modifying the expression of synaptonemal complex proteins SYCP1 and SYCP3.
Limitations, reason for caution: *In vitro* studies.
Wider implications of the findings: The presence of opioid receptors in mice spermatogenic cells, contribute to resolve several long-standing issues concerning the role of opioid receptors in spermatogenesis and open up novel avenues of research of the opioid system as a biochemical tool for the diagnosis and treatment of male infertility.

O-016 Environmental exposure to selected endocrine disrupting chemicals adversely influences reproductive hormone levels in men

J. Knez[1], B. Kovacic[1], M. Reljic[1], V. Vlaisavljevic[1]
[1]*University Medical Centre Maribor, Department of Reproductive Medicine, Maribor, Slovenia*

Study question: Does environmental exposure to bisphenol A (BPA), phthalates and alkylphenols affect reproductive hormone levels (follicle stimulating hormone (FSH), luteinising hormone (LH), total testosterone (T), sex hormone

binding globulin (SHBG), oestradiol (E) and inhibin B) in men attending reproductive medicine clinic?
Summary answer: Selected endocrine disrupting chemicals (EDCs), as phthalates and their metabolites, can adversely affect the levels of reproductive hormones measured in serum of men attending reproductive medicine clinic, however, there was no evidence confirming the adverse effects of BPA or alkylphenols.
What is known already: Reproductive toxicities of BPA, phthalates and alkylphenols have been extensively studied in laboratory animals. A number of recent epidemiologic studies have also suggested toxic effects of BPA and certain phthalates on human male reproductive system, but the results of these are not conclusive, since there is considerable amount of contradicting data. There are no epidemiologic studies to investigate the influence of environmental exposure to alkylphenols on human health.
Study design, size, duration: Prospective cohort study included 140 men of subfertile couples seeking fertility treatment at university-based tertiary centre. Data was collected from February 2011 until June 2012. Single-spot urine samples were obtained to measure EDCs and creatinine concentration to account for urinary dilution. Non-fasting blood samples were taken to measure hormone levels.
Participants/materials, setting, methods: Gas chromatography/mass spectrometry was used to measure: BPA, nonylphenol (NP), octylphenol (OP), di(2-ethylhexyl)-phthalate (DEHP), dibuthyl-phthalate (DBP), diethyl-phthalate (DEP) and their metabolites. Additionally to the measured hormones, free androgen index (FAI), inhibin B/FSH and T/LH ratios were calculated to evaluate Sertoli and Leydig cell function, respectively.
Main results and the role of chance: BPA was detected in 98% of all measured samples. Phthalates with their metabolites were detected in >95% of the urine samples, OP was detected in 90% and NP was detected in 79% of samples with 0.3 ng/mL limit of detection. After adjusting for confounding factors using linear regression models, DEHP and its metabolites showed negative association with T (primary metabolite mono-(2-ethyl-5-oxohexyl)phthalate b = -0.61, 95% CI -1.13 to -0.10), inhibin B (DEHP β = -12.24, 95% CI -23.06 to -1.44) and with inhibin B/FSH ratio (DEHP β = -0.19, 95% CI -0.32 to -0.05). DEP has shown inverse correlation with LH in univariate analysis, however this was insignificant in multivariable model (β = -0.05, 95% CI -0.11 to 0.01). There was no influence of BPA or alkylphenols on any of the observed outcomes.
Limitations, reason for caution: Urinary EDC exposure measurements are subject to temporal variability. EDCs can also cause negative reproductive effects by other pathways that are not reflected in altered serum hormone levels. Many studied outcomes provide a potential for incidental correlations.
Wider implications of the findings: We have shown that phthalates can adversely influence male reproductive hormone levels. This is in agreement with the previous laboratory and some epidemiologic studies showing negative effects on male reproductive function. BPA and alkylphenols do not seem to have a comparable effect, which suggests their minor relevance at environmentally present concentrations compared to phthalates. Still, our study was comprised of men attending fertility clinic and the results may not be representative of the general population.
Study funding/competing interest(s): Funding by national/international organization(s) – Slovenian Research Foundation (P3-334-0327).
Trial registration number: NA.

Study question: To assess whether in men with idiopathic infertility, the sperm DNA fragmentation (sDF) improves depending on the FSH receptor (FSHR) genotype as assessed by the non-synonymous polymorphisms (SNP) rs6166 (wild type or p.N680S).
Summary answer: FSH treatment improves sDF in a subgroup of idiopathic infertile men, although 40% of these men do not show any significant improvement. The response of sDF, a surrogate marker of sperm quality, together with the evaluation of FSHR SNP p.N680S might be useful to predict the response to FSH treatment.
What is known already: FSH is fundamental for spermatogenesis and is empirically used to treat male idiopathic infertility. Several studies suggest that sDF could be a candidate predictor of response to FSH treatment, in terms of probability to conceive. Furthermore, it is widely accepted that the FSHR SNP p.N680S influences ovarian response in women and testicular volume in men.
Study design, size, duration: Multicenter, longitudinal, prospective, open-label, two-arms clinical trial. Subjects enrolled were idiopathic infertile men and received 150 IU of recombinant FSH (Gonal f®) every other day for 12 weeks and were then followed-up for further 12 weeks after FSH-withdrawal. Patients were evaluated at baseline and at the end of the two phases.
Participants/materials, setting, methods: Eighty-eight men with idiopathic male infertility carrier of the homozygous FSHR p.N680S N or S genotype, FSH < 8 IU/L and sDF > 15%, were enrolled. 66 patients completed the sDF analysis. sDF was centrally evaluated by TUNEL/PI assay coupled to flow cytometry, resolving two different sperm populations, namely: PIbrighter and PIdimmer.
Main results and the role of chance: Thirty-seven men (56%) were carriers of the p.N680S homozygous-N and 29 (44%) of the homozygous-S genotype, respectively. Total sDF (PIbrighter + PIdimmer) was significantly lower at the end of the study in patients carriers of the p.N680S-N allele than patients carriers of p.N680S-S allele ($p = 0.008$). Only in patients carriers of the p.N680S-N allele, total sDF decreased significantly from baseline to the end of the study ($p = 0.021$) and this decrease was entirely sustained by the sperm population containing vital sperms (i.e., PIbrighter fraction) ($p = 0.008$). PIdimmer fraction, including only non-vital sperms, was significantly higher in patients carriers of the p.N680S-S allele than in carriers of N allele ($p = 0.018$). Total sDF was inversely related to total sperm number ($p = 0.020$) and progressive sperm motility ($p = 0.014$).
Limitations, reason for caution: The statistical power of the results obtained so far is 86.9%, with alpha-error 0.05. This is an interim-analysis.
Wider implications of the findings: The study suggests that FSH treatment induces a significant improvement of total sDF in men carriers of the p.N680S homozygous N allele. This sDF decrease awaits confirmation, since the study will be completed by June 2015.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – The study was supported by unrestricted grant by Merck Serono.
Trial registration number: EudraCT number 2010-020240-35.

O-018 Meiotic studies of ejaculate-derived spermatocytes in Robertsonian translocations and small supernumerary marker chromosomes carriers using a novel immunocytogenetic technique

S. Ma[1], G. Kirkpatrick[1], A. H. Ren[1], T. Liehr[1], V. Chow[1]
[1]*University of British Columbia, Department of Obstetrics and Gynecology, Vancouver, Canada*

Study question: What are the meiotic behaviors of the chromosome abnormalities in carriers of Robertsonian translocations (ROBs) and small supernumerary marker chromosomes (sSMCs)?

Summary answer: Carriers of ROBs and sSMCs showed decreased recombination, impaired synapsis, and an association of chromosome abnormalities with the XY body, as well as the improper segregation of uninvolved chromosomes.
What is known already: ROBs and sSMCs are associated with infertility and increased sperm aneuploidy. Chromosome segregation studies in ROBs have found variability in the percentage of unbalanced sperm produced. Reorganized chromosomes are shown to associate with the transcriptionally silenced XY body, which is suggested to cause spermatogenic arrest. Studies of reciprocal translocations have found evidence of transcriptional silencing at the breakpoints of rearrangements. The majority of sperm studies have shown that the segregation of sSMCs is variable.
Study design, size, duration: The ejaculate sperm was studied in three carriers of chromosome abnormalities: one sSMC only carrier, one ROB only carrier, and one sSMC plus ROB carrier. Control testicular sperm was retrieved from the testicular tissue of five normospermic fertile men with normal karyotypes who were undergoing vasectomy reversals.
Participants/materials, setting, methods: Meiotic recombination, synapsis and meiotic inactivation in ejaculate spermatocytes were investigated using immunostaining. The chromosomal origin of the sSMC was assessed by Multiplex Fluorescence In Situ Hybridization (M-FISH). The segregation of the ROB and sSMC in the sperm and incidence of an interchromosomal effect (ICE) were examined by FISH.
Main results and the role of chance: The sSMC-only and ROB-only carriers showed decreased global recombination compared to controls ($P < 0.05$), although impaired synapsis and an association of the chromosome abnormality with sex chromosomes were also observed. In the sSMC-only and sSMC plus ROB carriers, the sSMC was found in 13.5% and 11.5 % of sperm, respectively. Segregation analysis of the sSMC plus ROB case showed that 91.2% of the sperm were normal/balanced and 8.8% were unbalanced. ICE involving the sex chromosomes were greater in both sSMC carriers. The frequency of XX/YY disomy for the sSMC plus ROB case was higher than controls ($P < 0.0001$). In the sSMC-only case, total aneuploidy ($P = 0.0176$), XX/XY disomy ($P = 0.0003$), and XY disomy ($P = 0.0268$) were higher than controls.
Limitations, reason for caution: We compared ejaculate-derived spermatocytes to control testicular-derived spermatocytes. The differences observed may be a result of the spermatocyte source. However, our preliminary date comparing ejaculate and testicular derived spermatocytes in the same individuals saw no statistical differences in the meiotic characteristics examined in this study.
Wider implications of the findings: We observed impaired meiotic recombination, synapsis, and XY body association in carriers of ROB and marker chromosomes, marking the first such study in sSMC carriers. We report the first immunofluorescent study of meiotic defects on ejaculate-derived spermatocytes, providing an exciting new opportunity to study meiosis in infertile men. Furthermore, FISH studies on infertile carriers of marker chromosomes support previous observations that this population tends to produce sperm with markers at frequencies lower than theoretically expected.
Study funding/competing interest(s): Funding by national/international organization(s) – Canadian Institutes of Health Research.
Trial registration number: NA.

O-019 Infertile men have frequently leydig cell dysfunction: study on hypogonadism, vitamin d and bone mass in 5,177 subjects

A. Ferlin[1], A. Garolla[1], R. Selice[1], N. Caretta[1], D. Pizzol[1], C. Foresta[1]
[1]*University of Padova, Department of Medicine, Padova, Italy*

Study question: Are infertile men at risk of Leydig cell dysfunction?
Summary answer: Hypogonadism and low vitamin D levels are very frequent in infertile males. Both conditions, caused by Leydig cell dysfunction, are implicated in the frequent low bone mass seen and osteoporosis seen in these patients.
What is known already: Male factors are responsible for half of the cases of couple infertility. Whatever the cause, spermatogenic disruption is clinically and hormonally recognized by low sperm count and Sertoli cell markers (FSH levels). However, recent evidence showed that Leydig cell impairment is also frequent in subjects with primary testicular damage, as evidenced for example by reduced INSL3 and 25(OH)-vitamin D levels. The latter is caused by reduced expression of CYP2R1, a major enzyme involved in 25-hydroxylation of cholecalciferol, and lower 25(OH)-vitamin D levels are well known cause of low bone mass. Furthermore, testosterone (T) production by the Leydig cells might be also impaired in men with primary spermatogenic damage. These aspects have not been comprehensively analyzed in large number of subjects.
Study design, size, duration: Prospective cohort study on subjects referred to our tertiary Universitary Centre for semen analysis during the period January 2011–June 2014.
Participants/materials, setting, methods: We evaluated the presence and type of hypogonadism, 25(OH)-vitamin D status and bone mass in men who had semen analysis (*n*: 11,516), complete andrological program [including semen culture (*n*: 10,394), history and physical examination (*n*: 7,527), hormone analysis (FSH, LH, T, 25(OH)-vitamin D; *n*: 5,884), and ultrasound of the testes (*n*: 5,177)]. Men with total sperm count <10 million/ejaculate (*n*: 2,583) underwent also genetic analysis (karyotype, Y chromosome microdeletions, CFTR mutations; *n*: 2273) and DEXA (*n*: 855).
Main results and the role of chance: Azoospermia was present in 9.3% of cases (*n*: 481/5,177), oligozoospermia (with or without reduced motility and/or normal sperm morphology) in 40.6% (*n*: 2302), asthenozoospermia in 12.2% (*n*: 632), and normozoospermia in 34.5% (*n*: 1787). Main causes or risk factors were varicocele (28%), genetics (15%), obstruction/sub-obstruction of seminal tract (12%), cryptorchidism (6%), infections/iatrogenic causes/ejaculation disorders/prior surgery (14%) and idiopathic forms (25%). Primary hypogonadism (T < 10.4 nmol/L, LH > 8 IU/L) was found in 25.7% of cases, secondary hypogonadism (T < 10.4 nmol/L, LH < 1.5 IU/L) in 1.3%, subclinical hypogonadism (T > 10.4 nmol/L, LH > 8 IU/L) in34.2%. Men with all forms of hypogonadism have frequently insufficient (48.5%) or deficient (25.4%) 25(OH)-vitamin D levels and higher risk of low bone mass, osteoporosis (16.8%) and osteopenia (31.5%). The role of chance is limited by the high number of subjects studied.
Limitations, reason for caution: Longitudinal studies are necessary to confirm these data.
Wider implications of the findings: This study, performed in a very large cohort of subjects, showed that hypogonadism, low vitamin D levels, and low bone mass are very frequent in infertile males. Metabolic and other clinical conditions associated with low T and low vitamin D levels need therefore to be accurately evaluated in these subjects, and treatment should consider also these aspects other than specific treatment only of infertility.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s) – Department of Medicine.
Trial registration number: NA.
Keywords: male infertility, hypogonadism, vitamin D, osteoporosis, testosterone

O-020 Early diagnosis of testicular tumours in non-obstructive azoospermia: a comparative study

M. Hessel[1], L. Ramos[1], K.W.M. d'Hauwers[2], D.D.M. Braat[1], C.A. Hulsbergen-van de Kaa[3]
[1]*Radboud University Medical Center, Obstetrics and Gynaecology, Nijmegen, The Netherlands*
[2]*Radboud University Medical Center, Urology, Nijmegen, The Netherlands*
[3]*Radboud University Medical Center, Pathology, Nijmegen, The Netherlands*

Study question: In men with non-obstructive azoospermia (NOA) undergoing testicular sperm extraction (TESE) for fertility treatment, is immunohistochemical detection of intratubular germ cell neoplasia (IGCN) in AgarCytos, made of the remnants of the TESE specimen, equally accurate as in a standard testicular biopsy?
Summary answer: No cases were encountered in which the standard testicular biopsy was positive for IGCN, while the AgarCyto was negative. Therefore, the standard testicular biopsy did not have added value in this study.
What is known already: Infertile men are at higher risk for testicular cancer compared to the general population. IGCN can be detected by immunohistochemistry in standard testicular biopsies and, albeit less accurate, in semen using PLAP and OCT3/4. Previously we have shown that IGCN can also be successfully detected by immunohistochemical evaluation of AgarCytos, made of the TESE remnants. The observed incidence of a germ cell (pre)malignancy in NOA patients undergoing TESE for fertility treatment was 4.4%.
Study design, size, duration: Between January 2013 and May 2014 a prospective cohort study was conducted at a Dutch University Hospital. All males with NOA (*n* = 197) undergoing a urological work-up followed by a diagnostic

TESE (n = 303) for fertility treatment were included. Simultaneously a standard testicular biopsy was performed.
Participants/materials, setting, methods: After cryopreservation of sperm, if present, an AgarCyto was made of the remnants of these TESE biopsies. Sections of the AgarCyto and standard testicular biopsy were stained with hematoxylin-eosin for pathological examination as well as PLAP and OCT3/4 for immunohistochemistry to detect IGCN.
Main results and the role of chance: Six men (3.0%) were diagnosed with a germ cell (pre)malignancy. In three cases TESE and a (partial) orchidectomy were performed in the same setting because of a suspect ultrasound (n = 2) or inguinal located testis (n = 1). One of them had a negative AgarCyto but partial orchidectomy revealed IGCN, a subsequent TESE AgarCyto was positive for IGCN. Microscopic evaluation including immunohistochemical analysis of the AgarCytos diagnosed three (1.5%) more cases of a germ cell (pre)malignancy compared to scrotal ultrasound alone. Two patients opted for radiation without histological confirmation of a positive AgarCyto, in one case the standard biopsy was negative and in another case it was lost. In the other four patients result of the AgarCyto were either confirmed by the standard biopsy and/or by orchidectomy.
Limitations, reason for caution: Although very unlikely based on the test-characteristics of the immunohistochemical markers, the chance of a false-positive AgarCyto is not completely ruled out in two cases. Because of the lack of a standard biopsy when an orchidectomy was performed simultaneously with TESE, possible superiority of the AgarCyto could not be established.
Wider implications of the findings: Men undergoing TESE because of NOA should be offered simultaneous screening for IGCN because of the increased incidence of germ cell (pre)malignancies. The principal advantage of using the TESE remnants is that all available testicular tissue can be used for both sperm recovery and pathological evaluation, increasing the yield of spermatozoa as well as the chance to find (pre)malignant cells. Limiting the number of biopsies from the testis decreases the possibility of complications after TESE.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – This study was (partially) funded by Merck Serono (Schiphol-Rijk, the Netherlands), but there are no conflicting interests to disclose.
Trial registration number: NA.

SESSION 05: BASIC SCIENCE IN FEMALE INFERTILITY

Monday 15 June 2015 **10:00–11:30**

O-021 High-resolution imaging of meiosis in live human oocytes

Z. Holubcova[1], M. Blayney[2], K. Elder[3], M. Schuh[1]
[1]*MRC Laboratory of Molecular Biology, Cell Biology, Cambridge, United Kingdom*
[2]*Bourn Hall Clinic, Embryology, Cambridge, United Kingdom*
[3]*Bourn Hall Clinic, Assisted Conception Unit, Cambridge, United Kingdom*

Study question: How do live human oocytes develop into fertilisable eggs?
Summary answer: By imaging chromosomes and the microtubule spindle at high resolution over the entire course of meiosis in live human oocytes, we were able to determine the stages of meiosis and to gain insights into the causes of aneuploidy in human eggs.
What is known already: Chromosome segregation errors during meiosis in human eggs are the leading cause of pregnancy loss and human aneuploidy. Studies of chromosome segregation in live human oocytes that could reveal the causes of aneuploidy are currently missing.
Study design, size, duration: A long-term study involving the systematic collection and quantitative high resolution imaging of immature human eggs obtained from patients enrolled in the *in vitro* fertilization programme in Bourn Hall Clinic (Cambridge, UK) between September 2012 and November 2014. A total of 374 cells were analysed in this study.
Participants/materials, setting, methods: A total of 140 women (aged 23–43, mean age 33.5 ± 4.5 years) undergoing ovarian stimulation for intracytoplasmic sperm injection (ICSI) took part in this study. Donated immature eggs were collected for in depth analysis by high resolution live imaging of meiosis on automated confocal microscopes combined with immunofluorescence labelling.
Main results and the role of chance: We established methods that allowed us for the first time to study chromosome segregation and spindle assembly in live human oocytes. We labelled chromosomes and microtubules in immature human oocytes and used high resolution confocal microscopy to follow their maturation into fertilisable eggs. Quantitative image analysis of the time-lapse videos revealed the stages of meiosis in human oocytes and provided insights into the causes of egg aneuploidy.
Limitations, reason for caution: Immature human oocytes included in this study were developmentally delayed and would have been rejected for ICSI procedures and discarded, because they had not yet reached the required stage for sperm injection at the time of the fertility treatment.
Wider implications of the findings: Most of our knowledge about the development of eggs in mammals comes from studies in mouse oocytes. Our work generated the first comprehensive data set on the mechanism of spindle assembly and chromosome segregation in live human eggs. This work not only sheds light on a fundamental process at the beginning of our life, but it also provides a basis to improve and develop fertility treatments in the future.
Study funding/competing interest(s): Funding by national/international organization(s). Medical Research Council. European Research Council (grant agreement no. 337415). The Lister Institute of Preventive Medicine.
Trial registration number: NA.

O-022 Whole genome sequencing reveals the complex etiology of primary ovarian insufficiency

Hu-T. Seliger[1], R. Berro[1] D. E. Parfitt[1], N. Stong[1], B. Burnett[1], S. T. Globus[1], A. B. Copperman[2], P. Yurttas Beim[1]
[1]*Celmatix Inc, Research and Development, New York, NY, U.S.A.*
[2]*Reproductive Medicine Associates of New York, Reproductive Endocrinology, New York, NY, U.S.A.*

Study question: Our primary goal was to assess the level of genetic complexity underlying primary ovarian reserve disorders such as primary ovarian insufficiency (POI) and diminished ovarian reserve (DOR).
Summary answer: Our analysis identified 10,350 novel and known deleterious single nucleotide variants (SNVs) among patients in a POI cohort. While this is the first indication that many of these variants may be predictors of human ovarian reserve, of the 668 common to all patients, 94 are among genes that regulate apoptosis, estrogen-regulated inflammation, primordial follicle progression, and meiosis.
What is known already: A number of studies have linked individual genetic loci with the development of ovarian reserve phenotypes such as POI and DOR. While many of these loci have been characterized in mouse models and detected in different patient cohorts, the targeted nature of these studies means the full genomic landscape underlying ovarian reserve mechanisms in humans remains largely unexplored.
Study design, size, duration: Our cohort study included women with idiopathic POI diagnosed before 38 years of age and utilized blood samples collected between November 2012 and February 2014. Women with a natural parity of ≥1, history of gynaecological surgery, cancer treatment, genetic syndromes or major illness or trauma that would compromise fertility, were excluded.
Participants/materials, setting, methods: After obtaining IRB consent, blood samples were collected from all patients and whole genome sequencing performed on extracted DNA using Next Generation Sequencing platforms. Bioinformatics tools were then applied to report variant calls, novel and deleterious variants, and those shared across samples.
Main results and the role of chance: Of the variants we identified in the whole genome sequences of our POI cohort, 10,350 (including 223 novel) were predicted to be deleterious due to loss of function or protein structural changes. Additionally, many SNVs shared among our cohort were within conserved non-coding regions. We used an in-house, fertility specific annotation tool to filter genes according to their impact on reproductive potential. Thus, 94 deleterious variants common to all of our POI patients were identified among genes known to regulate processes such as primordial follicle progression and meiotic chromosome stability, as well as a number of maternal effect genes. Notably, featured among these genes were a number of NLRP family members, many

orthologues of which have been well characterized for their role in oogenic processes in animal models.
Limitations, reason for caution: The short read length used in our whole genome sequencing makes the detection of complex structural variants and repetitive regions more challenging.
Wider implications of the findings: The identification of rare, exonic and intronic genetic variants among our cohort highlights the power of whole-genome sequencing in the identification of variants that associate with altered human ovarian reserve. Our data emphasizes the complex, polygenic nature of ovarian reserve disorders and the likelihood that loci reportedly associated with these disorders represent only a small fraction of coding and non-coding loci regulating ovarian reserve.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Celmatix Inc.

O-023 Sirt2-mediated BubR1 regulation promotes oocyte maturation

H. Homer[1], A. Riepsamen[1], L. E. Wu[2], D. Sinclair[3]
[1]*University of New South Wales, School of Women's and Children's Health, Sydney, Australia*
[2]*University of New South Wales, School of Medical Sciences, Sydney, Australia*
[3]*Genetics Department, Harvard Medical School, Boston, U.S.A.*

Study question: Does the sirtuin family member, Sirt2, positively influence oocyte maturation and what is its mechanism of action?
Summary answer: Sirt2 over-expression stabilizes BubR1 in mouse oocytes, promotes the formation of attachments between chromosomes and spindle microtubules and accelerates progression through meiotic maturation.
What is known already: Sirtuins (Sirt1–7) are a family of NAD^+-dependent deacetylases with diverse functions and potent anti-aging properties. In somatic cells, Sirt2 modulates a key cellular regulator known as BubR1 (for Budding uninhibited by benzimidazole-Related 1). BubR1-depletion disrupts meiotic progression in oocytes and the formation of attachments between chromosomes and spindle microtubules. It is unknown whether BubR1 is regulated by Sirt2 in oocytes and if this could be important for meiotic control.
Study design, size, duration: In order to examine the effect of increased Sirt2 levels, we engineered a transgenic mouse model of the C57BL/6J strain that over-expresses Sirt2 (hereafter referred to as Sirt2Tg). Fully-grown germinal vesicle (GV)-stage oocytes ($n > 30$ per group in triplicate) were isolated from hormonally-primed wild-type (WT) and Sirt2Tg mice.
Participants/materials, setting, methods: The timing of first polar body extrusion – which marks the completion of meiotic maturation – was assessed. High resolution confocal microscopy was used for detailed analyses of spindle assembly, chromosome alignment and sub-cellular localization of BubR1. Protein expression was quantified using Western blotting.
Main results and the role of chance: We used immunoblotting to compare Sirt2Tg oocytes with WT oocytes and confirmed that Sirt2Tg oocytes specifically over-expressed Sirt2 but not Sirt1. We found that Sirt2Tg females produced twice as many fully-grown oocytes as age-matched wild-type animals ($P < 0.05$). Significantly, Sirt2Tg oocytes expressed ~threefold higher levels of BubR1 than wild-type oocytes consistent with Sirt2-dependent BubR1 stabilization. Furthermore, at the sub-cellular level, BubR1 was enriched on spindle microtubules in Sirt2Tg oocytes. Importantly, spindle-localized BubR1 in transgenic oocytes was associated with accelerated formation of stable attachments between chromosomes and microtubules suggestive of increased meiotic efficiency. Entirely consistent with this, Sirt2Tg oocytes completed meiotic maturation marked by first polar body extrusion ~2 h in advance of WT oocytes.
Limitations, reason for caution: Although Sirt2 over-expression was associated with increased BubR1 and the observed effects inSirt2Tg oocytes are consistent with potentiated BubR1 function, Sirt2 could influence additional non-BubR1 targets that could also contribute to our findings.
Wider implications of the findings: Increased Sirt2 levels were associated with increased BubR1 stability and with effects consistent with potentiated BubR1 function, notably accelerated chromosome-microtubule attachment formation. Intriguingly, a recent paper examined the effect of Sirt2-depletion in mouse oocytes and reported impaired attachment formation between chromosomes and microtubules entirely in line with our results. Permeable small molecule Sirt2 agonists provide a novel prospect for impacting BubR1 function to improve oocyte quality.
Study funding/competing interest(s): Funding by University(ies). Funding by national/international organization(s) – UNSW MREII Grant. Ramaciotti Establishment Grant.
Trial registration number: NA.

Study question: Would the effects of physical activity and exogenous administration of irisin be similar or different on parameters related with reproduction and metabolism in the high-fat diet-induced obesity model of the female C57BL/6J mice? We hypothesized that exogenous administration of irisin would have similar affects as physical activity.
Summary answer: Exercise promotes weight-loss and healthy metabolism. It seems that irisin administration provides similar results compared to exercise in a female mouse model. Reproductive and metabolic parameters in blood showed similar improvements between exercise and irisin groups compared to controls. Moreover, ovarian histology presented comparable improvements after exercise and irisin administration.
What is known already: Obesity affects every aspect of reproduction in females, while exercise promotes healthy metabolism and protects against metabolic disorders like obesity. It has been documented that exogenously administered irisin (FNDC5), which is a new polypeptide hormone regulated by PGC1-alpha, induces the browning of subcutaneous fat and thermogenesis, and it presumably could be prepared and delivered as an injectable polypeptide. Indeed, increased formation of brown fat has been shown to have anti-obesity effects in adult humans.
Study design, size, duration: 60 female C57BL/6J mice were gathered at approximately 5–6 week of age and were divided into three groups. They were fed with a high-fat diet. Control group remained sedentary. Irisin group remained also sedentary but intravenously received 10^{10} FNDC5-expressing adenovirus after 20 weeks. Exercise group performed treadmill after 12 weeks.
Participants/materials, setting, methods: The study was carried out in an university hospital. Mice were killed at 22wk and had their ovaries excised for histological assessment. Blood was obtained by cardiac puncture. E2, FSH, LH, AMH, BMP, ANP, BNP, FGF21, ghrelin, insulin, leptin, adiponectin, resistin, kisspeptin, RBP4, visfatin levels were measured in blood.
Main results and the role of chance: Final weight, blood levels of estradiol (E2), follicle stimulating hormone (FSH), luteinizing hormone (LH), anti-mullerian hormone (AMH), bone morphogenetic proteins (BMP), atrial natriuretic peptide (ANP), brain natriuretic peptide (BNP), fibroblast growth factor 21 (FGF21), ghrelin, insulin, leptin, adiponectin, resistin, kisspeptin, retinol binding protein 4 (RBP4), visfatin were statistically similar between exercise and irisin groups ($p > 0.05$). Final weight, blood levels of BMP, FGF21, ghrelin, insulin, resistin, kisspeptin, visfatin were significantly lower in exercise and irisin groups compared to controls ($p < 0.05$), while LH/FSH ratio, ANP, BNP, RBP4 levels were significantly higher in the controls ($p < 0.05$). AMH level was significantly higher in exercise and irisin groups ($p < 0.05$). Ovaries of mice in exercise and irisin groups manifested different stages of follicular development, whereas the ovaries of mice in control group were inactive.
Limitations, reason for caution: Data of this study revealed that short treatments of obese female mice with irisin improved reproductive and metabolic parameters and caused a small weight loss. Whether similar or longer treatments with irisin and/or higher doses would cause similar or more weight loss in human subjects remains to be determined.
Wider implications of the findings: The therapeutic potential of irisin is apparent. Exogenously administered irisin induces the browning of subcutaneous fat and thermogenesis, and it presumably could be prepared and delivered

as an injectable polypeptide. After comprehensive studies on human subjects, pharmacological induction of irisin may be of interest to promote weight loss and improve reproductive and metabolic parameters that were impaired due to obesity in patients who cannot benefit from the favorable effects of exercise.

O-025 Serum five-miRNA panel as potential therapeutic targets for POI

T. Fang[1], G. J. Yan[1], H. X. Sun[1], Y. L. Hu[1]
[1]*The Affiliated Drumtower Hospital Reproductive Medicine Center, Reproductive Medicine Center, Nanjing, China*

Study question: Our objective was to evaluate the levels of miRNA expression in serum samples of premature ovarian insufficiency (POI) patients to explore whether circulating miRNAs in serum can be used as therapeutic targets for POI.
Summary answer: These novel results may further indicate a physiological involvement of miR-21, miR-132, miR-145, miR-181a and miR-599 during follicle selection and ovulation in the ovary. miRNA profiling in serum has potential as a novel method for POI detection in the Chinese Han population. The five-miRNA panel in serum may serve as potential non-invasive therapeutic targets in POI patients.
What is known already: miRNAs are endogenous, nonprotein-coding, regulatory RNAs with important roles in health and disease. miRNAs are present in the circulation in a stable form and their levels are altered in diseases. The wide range of sources of circulating miRNAs makes it possible for circulating miRNAs to reflect every aspect of human physiological status and therefore, provides an advantage for them to serve as better biomarkers than other circulating molecules.
Study design, size, duration: We present the miRNA expression profiles in pooled serum of nine POI samples compared with normal volunteer samples by microarray, a panel of candidates (miR-21/132/145/181a/599) with highest expression patterns were selected. The differentially expressed miRNAs were further assessed in large cohorts of forty POI patients and twenty healthy volunteers in individual samples by qRT-PCR.
Participants/materials, setting, methods: *Paticipants:* Chinese Han women presenting with POI and normal volunteer. *Setting:* University affiliated hospital. *Methods:* We present the miRNA expression profiles in pooled serum of nine POI samples compared with normal volunteer samples by microarray, a panel of candidates (miR-21/132/145/181a/599) with highest expression patterns were selected. The differentially expressed miRNAs were further assessed in large cohorts of forty POI patients and twenty healthy volunteers in individual samples by qRT-PCR.
Main results and the role of chance: *Main results:* We present the miRNA expression profiles in pooled serum of nine POI samples compared with normal volunteer samples by microarray, a panel of candidates (miR-21/132/145/181a/599) with highest expression patterns were selected. The differentially expressed miRNAs were further assessed in large cohorts of forty POI patients and twenty healthy volunteers in individual samples by qRT-PCR. The large cohort also witnessed an increase compared with healthy volunteers (miR-21 (p = 0.0198)/miR-132 (p = 0.0429)/miR-145 (p = 0.0295)/miR-181a (p = 0.002)/miR-599 (p = 0.0165)). *The role of chance:* Further systematic analysis was used to validate these miRNAs involved in follicular cell survival (miR-181a and miR-145), proliferation (miR-599) and estradiol production (miR-21 and miR-132) in granular cells. It is promising to use circulatory microRNAs as therapeutic targets for POI. Evidence from *in vitro* studies in our lab also suggests specific roles for these miRNAs in regulating ovarian granular cell function.
Limitations, reason for caution: Serum miRNAs tests in POI patients have less time and money benefits compared with the FSH and AMH tests, but may witness great importance as therapeutic targets in Chinese Han population.
Wider implications of the findings: This finding suggests a phenotypic overlap expression of miRNAs in two cohorts of POI patients. These novel results may further indicate a physiological involvement of miR-21, miR-132, miR-145, miR-181a and miR-599 during follicle selection and ovulation in the ovary. Future research of microRNAs in physiologic and dysfunctional ovulation may offer new diagnostic and treatment strategies for POI.

[4]*G.EN.E.R.A Centre for Reproductive Medicine Ruesch, Valle Giulia Clinic, Rome, Italy*
[5]*University Magna Graecia, Unit of Obstetric and Gynecology. Department of Experimental and Clinical Medicine, Catanzaro, Italy*

Study question: Does the periostin (POSTN) content of follicular fluids (FFs), embryo wash-out or serum represent an additional non-invasive parameter to evaluate the oocyte/blastocyst quality and predict good implantation and pregnancy outcome?
Summary answer: POSTN expression in serum, FFs and embryo wash-out was significantly correlated with blastocyst quality. According to our data, POSTN levels combined with morphological criteria were able to predict pregnancy outcomes more than the morphological evaluation alone. Therefore POSTN could be used as an innovative non-invasive biomarker to improve IVF-outcome prediction.
What is known already: Embryo-endometrium cross-talk represents the limiting factor to have a good implantation and achieve pregnancy. Several extracellular matrix (ECM) proteins such as laminin, fibronectin and osteopontin have been already identified as key regulators of this interaction. Experimental data recently demonstrated that POSTN, a secreted protein belonging to the ECM family, may play a central role in regulating the embryo-endometrium cross-talk. Specifically, POSTN expression was able to predict endometrial receptivity and pregnancy outcome in spontaneous cycles.
Study design, size, duration: This is an experimental study with prospective collection and evaluation of 200 individual FF samples, collected from 50 female patients undergoing ICSI. A total of 50 wash-out medium derived from an equal number of transferred blastocysts were collected. From each patient, a serum sample at pick-up day was withdrawn.
Participants/materials, setting, methods: POSTN content was firstly verified in a random pool of samples by western blot (WB) and then measured by ELISA in 200 individual FFs, in 50 wash-out medium samples of transferred blastocysts and serum samples of patients. The relationship between POSTN levels, morphological blastocyst quality and pregnancy outcome was evaluated.
Main results and the role of chance: POSTN levels decreased with increasing patient's age and in case of poor ovarian reserve and of recurrent abortions history both in FF and serum. POSTN levels were significantly higher in women who got pregnant (17/50) than in those who did not both in FFs (63.45 ± 10.05 vs. 29.02 ± 14.47 ng/mL) and in serum (306.23 ± 41.40 vs. 120.92 ± 38.10). In FFs, levels were directly related to the blastocyst morphological quality and pregnancy outcome. POSTN levels were significantly higher in type A blastocysts and, in particular, in those giving pregnancy both in FF and wash-out (95.93 ± 18.20 vs. 41.83 ± 8.98 ng/mL; 10.74 ± 3.68 vs. 1.09 ± 2.95 ng/mL; in FF and wash-out medium of blastocyst resulted or not in pregnancy, respectively).
Limitations, reason for caution: Confirmation of our preliminary data on a large population may be required and on endometrial samples.
Wider implications of the findings: POSTN evaluation in individual FF samples might represent a new non invasive biomarker of embryo quality to use as a supplemental tool to predict embryo quality during IVF. Since this protein is a marker of embryo-endometrial cross-talk, POSTN concentration in FFs, wash-out or serum may give also information on the efficiency of endometrial receptivity and embryo implantation.

O-027 Endometrial biopsy prior to assisted reproductive techniques (ART) does not improve treatment outcome in unselected patients

L.T. Polanski[1], M. N. Baumgarten[1], A. Richardson[2], K. Sewell[2], J. J. Brosens[3], S. Quenby[3], B. Campbell[4], Raine-N. Fenning[2]
[1]*University of Nottingham, School of Medicine, Nottingham, United Kingdom*
[2]*University of Nottingham, NURTURE Fertility, Nottingham, United Kingdom*
[3]*University of Warwick, Reproductive Health, Coventry, United Kingdom*
[4]*University of Nottingham, Human Development, Nottingham, United Kingdom*

Study question: Does a timed mid-luteal phase endometrial biopsy (EB) affect the chances of a clinical pregnancy in an unselected population of women undergoing ART in the next menstrual cycle?
Summary answer: EB performed in the mid-luteal phase of the menstrual cycle does not increase clinical pregnancy rates in an unselected group of women undergoing ART.
What is known already: A growing number of studies employing different methodologies and assessing different populations of infertile patients indicate a possible beneficial effect of EB on ART outcome. This was mainly observed when women with recurrent implantation failure (RIF) were included in the studies, but little is known about that effect on women undergoing their first cycle or frozen embryo transfers (FET). The cause of the beneficial effect of the biopsy is unclear and is under investigation.
Study design, size, duration: The design was that of a prospective, randomized, non-blinded controlled study with 1:1 allocation. The target population of this UK-based study was 160 women based on recruitment period. All participants were screened and recruited from a university affiliated infertility clinic from January 2013 to January 2015.
Participants/materials, setting, methods: Women <49 years of age with no major uterine anomalies undergoing treatment using own oocytes were eligible. Research ethics committee approval was obtained. Pipelle EB was conducted on LH + 7–9 or on days 18–23 of cycle preceding ART when no LH surge. No intervention was performed in the control group.
Main results and the role of chance: The outcomes of 76 women in the EB group and 75 in the control group are known. No differences in age, BMI, smoking status, cause of infertility, number of previous live births, ovarian reserve, embryo quality, or day of transfer were observed. There were no significant differences in clinical pregnancy rates between the biopsy and control groups on an intention-to-treat basis [56.9% (41/72) versus 48.5% (33/68); RR 1.17 (95% CI = 0.85–1.61); $P = 0.319$] or per embryo transfer [65.1% (41/63) versus 55% (33/60); RR 1.18 (95% CI = 0.88–1.58); $P = 0.254$]. No differences were observed in the rates of biochemical pregnancy or first trimester miscarriage. Subgroup analysis of first cycle patients and treatment types showed no difference in outcome variables. One woman did not tolerate the EB and vasovagal episodes were experienced by another four women. There were no infectious or haemorrhagic complications.
Limitations, reason for caution: Lack of blinding can be a potential source of bias, however due to the nature of the intervention, blinding was not possible. Live-birth data is being collected and will be reported when available. Only 14 FER cycles were included which prevents any definitive conclusions in this group.
Wider implications of the findings: The findings of our study suggest that EB performed in the cycle preceding ART does not increase clinical pregnancy rates in an unselected population. Based on these results, routine EB in this population prior to ART should not be carried out. The procedure is well-tolerated, feasible and associated with minimal risks. Further research is needed to assess the effect of EB in selected women with RIF,uterine pathology and/or in women undergoing FET only.

O-028 Local endometrial injury: a treatment strategy to improve implantation rates: a systematic review and meta-analysis

C. Coughlan[1], C. Harrity[2], S. Laird[3], T. C. Li[4]
[1]*Rotunda Hospital, Reproductive Medicine, Dublin, Ireland*
[2]*SIMS Clinic, Reproductive Medicine, Dublin, Ireland*
[3]*Sheffield Hallam University, Biosciences and Chemistry, Sheffield, United Kingdom*
[4]*Chinese University of Hong Kong, Obstetrics and Gynaecology, Hong Kong, Hong Kong*

Study question: This is a systematic review and meta-analysis of RCTs comparing the efficacy of endometrial injury as compared to no intervention in women with recurrent implantation failure and an unselected group comprising patients with previous failed cycles and those embarking on their first IVF cycle.
Summary answer: Clinical pregnancy rate was significantly improved following local endometrial injury in women with recurrent implantation failure (OR 3.50, 95% CI 2.04–6.01, $p < 0.00001$) and points towards a benefit in women embarking on their first cycle but does not reach statistical significance (OR 1.32, 95% CI 0.93–1.86, $p = 0.12$).
What is known already: This is the first systematic review and meta-analysis to include only randomized controlled studies and the first meta-analysis to review the effect of local endometrial injury on women with recurrent implantation failure and an unselected group comprising patients with previous failed cycles and those embarking on their first IVF cycle.
Study design, size, duration: Systematic review of RCTs to September 2014 comparing the efficacy of endometrial injury as compared to no intervention in women with recurrent implantation failure and an unselected group comprising patients with previous failed cycles and those embarking on their first IVF cycle. 7 RCTs and 907 participants were included.
Participants/materials, setting, methods: Participants included women with recurrent implantation failure and patients with previous failed cycles and those embarking on their first IVF cycle. MEDLINE, EMBASE, Cochrane Library, National Research Register, ISI Conference Proceedings, ISRCTN Register and Meta-register were searched for RCTs to September 2014. 7 RCTs and 907 participants were included.
Main results and the role of chance: Meta-analysis showed that clinical pregnancy rate was significantly improved after local endometrial injury in patients with at least 1 previous failed cycle (OR 3.5 [95% CI 2.04 to 6.01, $P < 0.00001$]. The evidence points towards a benefit for local endometrial injury in the unselected population but does not reach statistical significance (OR 1.32, 95% CI 0.93–1.86, $p = 0.12$). In the unselected group the power of the analysis is diluted by including first cycle patients. This is probably where the difference lies. Inter-study variation is avoided by including randomized controlled studies only. Two reviewers assessed the quality of the studies independently.
Limitations, reason for caution: In the unselected group the power of the analysis is diluted by including first cycle patients. Further studies are required to examine the effect of local endometrial injury in first cycles only.
Wider implications of the findings: The evidence is strongly in favour of inducing local endometrial injury in the cycle preceding IVF in patients experiencing recurrent implantation failure. This study is clinically very relevant as it determines the group of patients most likely to benefit from this novel procedure. Further studies are required to determine the effect of local endometrial trauma in the cycle preceding ovarian stimulation in patients embarking on their first IVF treatment cycle.
Study funding/competing interest(s): Funding by hospital/clinic(s) – NA.
Trial registration number: 21463.

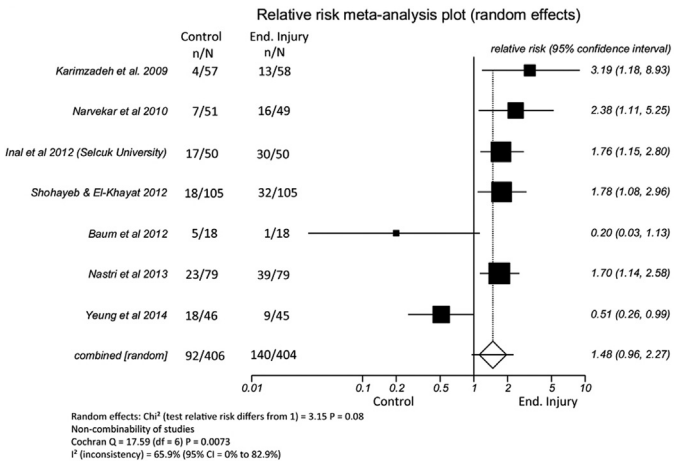
O-029 Endometrial injury: reflections about bias in meta-analyses

J.G. Franco Jr.,[1], C. G. Petersen[1], A. L. Mauri[1], F. C. Massaro[1], L. D. Vagnini[2], A. Renzi[2], Oliveira-Pelegrin, G.R.[2], J. Ricci[1], M. Cavagna[3], F. Dieamant[1], Baruffi, R.L.R.[1], Oliveira, J.B.A.[1]
[1]*Centre for Human Reproduction Prof. Franco Jr/Paulista Center for Diagnosis Research and Training, Research, Ribeirao Preto, Brazil*
[2]*Paulista Center for Diagnosis Research and Training, Research, Ribeirao Preto, Brazil*
[3]*Centre for Human Reproduction Prof. Franco Jr/Paulista Center for Diagnosis Research and Training/Women's Health Reference Center Perola Byington Hospital, Research, Ribeirao Preto, Brazil*

Study question: Do the data currently available from meta-analyses confirm that endometrial injury (EI) can truly improve clinical pregnancy rates (CPRs) in patients with implantation failure (IF) without any possibility of damage?
Summary answer: At present, EI has no definitive support in evidence-based medicine for use in ART.
What is known already: Meta-analyses are of primary importance as a source of findings for evidence-based medicine, but the quality is strictly dependent on the quality/quantity of available randomised controlled trials (RCTs). In 2012, three meta-analyses that examined EI showed beneficial effects on CPRs in patients with IF. However, these results were based on a few RCTs, which used restricted populations. In addition, further RCTs did not confirm this beneficial effect and suggested harmful effects, specifically in repeated IFs.
Study design, size, duration: A systematic review based on electronic searches of databases up to November/2014 was conducted to identify RCTs that compared any type of intentional EI in a cycle prior to the cycle of embryo transfer in ART cycles with no intervention or with a simulated procedure that could not cause EI.
Participants/materials, setting, methods: Seven RCTs (810 patients) were included as targets for data extraction and meta-analysis. The primary outcome was CPRs in patients with IF. Data management and analysis were conducted using StatsDirect statistical software. The measure of heterogeneity was evaluated using Cochran's Q and I^2 tests.
Main results and the role of chance: A random-effects model was used in the meta-analysis because of high heterogeneity between studies: Cochran's Q: 17.59, $P = 0.0073$; $I^2 = 65.9\%$. A chi-squared test statistic was used with its associated probability that the pooled Relative Risk was equal to 1. The general pregnancy rate did not differ between the group of patients submitted to EI (34.6%, 140/404) and the group not submitted to EI (control group: 22.7%, 92/406) ($P = 0.08$; RR = 1.47, 95% CI = 0.96–2.27). Figure 1 summarises the results.

Figure 1. Random-effect model. Forest plot for clinical pregnancy rate.



Limitations, reason for caution: Robust randomised trials comparing a standardised protocol of endometrial injury with no intervention are still needed before definitive conclusions can be reached.
Wider implications of the findings: Methodological problems caused by clinical heterogeneity (differences in inclusion criteria and in interventions performed) and insufficient power (low sample size) cause difficulties in drawing inferences from meta-analyses. Accordingly, meta-analyses must be analysed with extreme caution and not considered source of absolute truth. For EI, even a few new studies can change the initial expectations about the procedure. The observed heterogeneity challenges the validity of EI, indicating that it can, at least potentially, jeopardise the outcomes of ART.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Centre for Human Reproduction Prof. Franco Jr. Paulista Center for Diagnosis Research and Training.
Trial registration number: Not applicable. The study was authorised by the local ethics committee.

O-030 Endometrial receptivity evaluation in a natural cycle preceding IVF can predict the pregnancy success

L. Bissonnette[1], D. Haouzi[2], C. Le Saint[3], M. P. Lachambre[3], F. Entezami[4], I. J. Kadoch[3], S. Hamamah[5]
[1]*Université Montpellier1, UFR de Médecine, Montpellier, France*
[2]*INSERM, U1203, Montpellier, France*
[3]*Clinique OVO, R&D, Montréal, Canada*
[4]*Clinique de la Muette, Laboratoire Eylau Unilabs, Paris, France*
[5]*Hôpital Arnaud de Villeneuve, Département de Biologie de la Reproduction, Montpellier, France*

Study question: We assessed to what extent the endometrial receptivity status diagnosed with the Win-Test in a natural cycle preceding the IVF cycle can predict the IVF success?
Summary answer: Women with a receptive endometrium in the natural cycle preceding their IVF cycle, double their pregnancy rate after a fresh transfer following ovarian stimulation compared to patients which were evaluated with a non receptive endometrium.
What is known already: Implantation failures caused by endometrial receptivity problem is a major issue for IVF laboratories. Endometrial receptivity status can be assessed by the Win-Test (Patent EP10305561.2; PCT/EP2011/058757). This test allows personal care management by determining the cycle day where endometrium is the most receptive to identify the appropriate timing for embryo replacement. In which measure the endometrial receptivity status under a natural cycle can predict the success of a subsequent IVF attempt remains a full question.
Study design, size, duration: We conducted a mono-centric prospective study. All patients were treated at clinic OVO, Montréal, Canada. Women were recruited from February until December 2014.
Participants/materials, setting, methods: Fifty women undergoing ART with autologous eggs at clinic OVO were recruited. The cycle before their IVF, an endometrial biopsy was performed during the participant's implantation window. RNAs were extracted from the endometrial samples and 11 biomarkers of endometrial receptivity were assessed by RT-qPCR.
Main results and the role of chance: Among the 50 collected endometrial biopsies, 12 were discarded due to inappropriate timing of the endometrial sampling collection outside the theoretical implantation window. Thirty-eight endometrial biopsies were assessed to determine the prevalence of receptive endometria under natural cycle. Then, according to the endometrial receptivity status in natural cycle, the pregnancy outcome following IVF was analyzed in 18 patients which had an embryo transferred. We evaluated that 73% of the patients had a receptive endometrium during the implantation window in natural cycle. For the receptive patients ($n = 11$), 91% had a biochemical pregnancy and 82% had a clinical pregnancy (one pregnancy with early miscarriage), whereas only 43% of patients which were diagnosed as non-receptive ($n = 7$) had a clinical pregnancy following their embryo transfer.
Limitations, reason for caution: Further investigations with a larger number of patients are recommended.
Wider implications of the findings: The evaluation of endometrial receptivity status the cycle preceding the ovarian stimulation can predict IVF success, opening new perspective in the patient care management. Embryos from patients diagnosed as non-receptive in natural cycle should be cryopreserved for a later transfer once the best timing of the endometrial receptivity will be determined using the Win-Test.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Clinic OVO.

Trial registration number: NA.

O-031 Role of maximum endometrial thickness in prediction of clinical pregnancy rate in assisted reproduction treatment cycles

M. Khairy[1], R. Dhillon[1], M. Rajkhowa[1], K. Dowell[2], S. Fishel[2], A. Coomarasamy[3]
[1]*Birmingham Women's Hospital, Obstetrics and Gynaecology, Birmingham, United Kingdom*
[2]*CARE (Centres for Assisted Reproduction Clinics) Fertility Group, Assisted Reproduction, Nottingham, United Kingdom*
[3]*University of Birmingham, Academic Department of Obstetrics and Gynaecology, Birmingham, United Kingdom*

Study question: Is maximum endometrial thickness at fresh embryo transfer a useful predictor of clinical pregnancy rate?
Summary answer: Maximum endometrial thickness (MET) in fresh embryo transfer cycle is a clinically significant and independent predictor of clinical pregnancy and can be used for counselling patients and deciding on fresh embryo replacement or freezing all embryos and deferring transfer to frozen embryo replacement cycle.
What is known already: A systematic review of studies on role of endometrial thickness in prediction of clinical pregnancy has shown no predictive capacity yet reporting a good discriminatory capacity at lower cut off values of endometrial thickness. The risk of bias was considered high and there were no adjustment for important confounders as number and quality of embryos transferred.
Study design, size, duration: This is an observational cohort study of 24649 assisted reproduction cycles between 2008 till 2013 from all UK CARE (Centres for Assisted Reproduction Clinics).
Participants/materials, setting, methods: All patients having Assisted reproduction cycles and fresh embryo transfer in the period from January 2008 till December 2013 in CARE clinics were included. The maximum endometrial thickness (MET) recorded during ovarian stimulation at the time of HCG administration was recorded and used for the analysis.
Main results and the role of chance: Logistic regression analysis for prediction of clinical pregnancy rate (CPR) has shown that MET is an independent significant predictor of CPR in fresh embryo transfer cycles (OR 1.02,95% CI 1.01–1.03). MET has modest performance as a sole predictor of CPR (Area under receiver operating curve (AUROC) = 0.56). When used in combination with other predictors as woman's age, previous live birth, number of oocytes retrieved, number of embryos transferred, and embryo transfer day, the predictive performance is improved (AUROC = 0.68). Subgroup analysis by the day of embryo transfer, number of embryos transferred and transfer of euploid embryos after aneploidy screening of embryos has shown that MET is still a significant predictor. A multilevel Likelihood ratio (LR) analysis has shown that the likelihood ratio and 95% confidence intervals when MET is below the 5thcentile (<7 mm),3rdcentile (<6 mm) and 1stcentile (<5 mm) are 0.55 (0.49–0.66), 0.37 (0.27–0.50), 0.18 (0.09–0.35), respectively, corresponding to CPRs of 26.9%, 19.3%, and 10.6% respectively. At the upper end of MET, no adverse impact on CPR was detected with multilevel likelihood ratios and 95% CIs at 95thcentile (>15 mm), 97thcentile (>17 mm), 99thcentile (>18 mm) being 1.14 (1.03–1.26), 1.09 (0.92–1.28), 1.05 (0.84–1.31), respectively, with corresponding CPRs of 42.6%, 41.5%, and 40.6% respectively.
Limitations, reason for caution: This is a retrospective analysis of data which although including large number of patients and using statistical adjustment for confounding variables as age, number of oocytes, number and quality of embryos transferred could not adjust for all potential confounders e.g., as previous uterine surgery, infection, endometrial scarring or use of adjuvant treatment to correct thin endometrium.
Wider implications of the findings: With a current lack of any reliable endometrial receptivity test in ART cycles a simple test as MET has the potential to give clinically useful information. Knowledge of clinical pregnancy rate (CPR) at various cut-offs of MET can better inform patients and practitioners and may help them to make informed decisions regarding cancellation of fresh embryo transfer and freezing all embryos. This study has shown that MET is a significant independent predictor of CPR but its overall performance was modest. This is expected due to the complexity of the implantation process and involvement of multiple maternal (endometrial) and embryonic factors. The likelihood of clinical pregnancy is significantly reduced when the MET is below 7 mm. This may be clinically significant and impact on the decision of clinicians/ patients to proceed with embryo transfer.

O-032 Effect of long term combined pentoxifylline and tocopherol administration on the endometrial proliferation: a prospective cohort study of 368 cases of thin endometrium

F. Turki[1], A. Methni[1], R. Balet[1], M. Rahmati[2], El Irani, E.[1], N. Lédée[1]
[1]*Hopital Pierre Rouqués-Les Bluets, Service de PMA, Paris, France*
[2]*Hopital St Louis, INSERM UMRS-976, Paris, France*

Study question: Does long term administration of combined Pentoxyfylline and Tocopherol improve endometrial proliferation (thickness and volume) in infertile patients with a documented thin unresponsive endometrium?
Summary answer: Long term combined Pentoxifylline and Tocopherol administration significantly promotes endometrial proliferation and increases endometrial thickness and endometrial volume.
What is known already: Previous Meta-analysis reported that the probability of clinical pregnancy in patients with thin endometrium (<7 mm) is significantly lower compared with cases presenting an appropriate endometrial proliferation. Its Treatment remains a real challenge since repeated failure to achieve adequate endometrial development may request gestational surrogacy. Long term combined Pentoxyfylline and Tocopherol treatment has been previously reported to improve the endometrial growth, but no study has evaluated their long term endometrial effects on a large prospective cohort of infertile patients during the implantation window.
Study design, size, duration: We are presenting a prospective cohort study including 368 women with thin endometrium. Thin endometrium was defined as an endometrial volume below 2ml or an endometrial thickness below 7 mm during the mid luteal phase of a non conceptional cycle. Patients were included between 2012 and 2014.
Participants/materials, setting, methods: Patients were evaluated during mid luteal phase twice three months apart: once before, then after the introduction of the combined treatment including 800 mg of Pentoxifylline and 1000 UI of Tocopherol administered daily. An endometrial ultrasonic evaluation in two and three dimension defined the endometrial thickness and volume.
Main results and the role of chance: 15% of the included patients did not improve their endometrial volume, 67% normalised their volume while 18% improve their endometrial volume but without a complete normalisation after 3 months of treatment. The mean endometrial volume and thickness increased significantly from 1.6 ml (±0.4) and 4.7 mm (±1.6) before, to 2.1 ml (±0.3 ml) and 7.1 mm (±1.8) respectively after 3 months of treatment ($p < 0.001$, $p = 0.001$).No change was observed regarding Doppler of the uterine artery or the endometrial vascularization under treatment.
Limitations, reason for caution: Only a randomized trial using a placebo may definitely prove the effectiveness of a long term combined treatment with Pentoxyfylline and Tocopherol to improve thin unresponsive endometrium.
Wider implications of the findings: Approximately 80% of the replaced human embryos fail to implant. Multiple factors may contribute to this failure, but the majority of these failures are linked to a poor endometrium conjugated with a poor embryo quality. Even if an ideal thickness has never been able to predict pregnancy, deficiency of the endometrial proliferation is clearly associated with a poor prognosis for implantation and placentation. Preventive treatment optimizing the endometrial proliferation may be useful to increase implantation rates.
Study funding/competing interest(s): Funding by hospital/clinic(s). Hopital Pierre Rouqués – Les Bluets, Service de PMA, Paris, France. No conflict of interest.
Trial registration number: No trial registration number.

SESSION 07: SAFETY FOR ART CHILDREN: BIRTH AND BEYOND

Monday 15 June 2015 **10:00–11:30**

O-033 Perinatal outcomes following stimulated versus natural cycle IVF: analysis of 90,980 singleton live births following stimulated and unstimulated IVF

S.K. Sunkara[1], P. Seed[2], Y. Khalaf[3]
[1]*Aberdeen Fertility Clinic, Aberdeen Maternity Hospital University of Aberseen, Aberdeen, United Kingdom*
[2]*King's College London, Women's Health, London, United Kingdom*
[3]*Guy's and St Thomas' NHS Foundation Trust, Assisted Conception Unit, London, United Kingdom*

Study question: Does ovarian stimulation affect perinatal outcomes such as preterm birth (PTB) and low birth weight (LBW) following IVF treatment.
Summary answer: There was no increase in the risk of adverse perinatal outcomes of PTB, early PTB, LBW and very LBW following acceptable limits of ovarian stimulation (≤20 oocytes retrieved) compared to unstimulated IVF treatment.
What is known already: Pregnancies resulting from assisted reproductive treatments (ART) are associated with a higher risk of pregnancy complications compared to spontaneously conceived pregnancies. The possible reason of adverse obstetric outcomes following ART has been attributed to the underlying infertility itself and embryo specific epigenetic modifications due to the *in vitro* fertilisation techniques. It is of interest whether ovarian stimulation that is routinely used in IVF to optimise live birth rates, affects perinatal outcomes.
Study design, size, duration: Anonymous data were obtained from the Human Fertilization and Embryology Authority (HFEA), the statutory regulator of assisted reproduction treatment (ART) in the UK. The HFEA has collected data prospectively on all ART performed in the UK since 1991. Data from 1991 to 2012 involving at total of 90,980 singleton live births (78,761 following stimulated fresh IVF cycles and 12,219 following unstimulated IVF cycles) were analysed.
Participants/materials, setting, methods: Data on all women undergoing either a stimulated fresh IVF treatment cycle or an unstimulated IVF cycle during the period from 1991 to 2012 were analysed to compare perinatal outcomes of PTB, early PTB and LBW and very LBW among singleton live births. Occurrence of a live birth at <37 weeks gestation is defined as a PTB and at <32 weeks gestation as early PTB. Birth weight <2500 g is defined as LBW and <1500 g as very LBW. Logistic regression analysis was performed adjusting for female age, year of treatment, previous IVF cycles, previous live birth, number of oocytes (≤20 or >20) and day of embryo transfer (cleavage or blastocyst stage).
Main results and the role of chance: The unadjusted odds of PTB (OR 1.41, 95% CI 1.34, 1.49), early PTB (OR 1.57, 95% CI 1.44 to 1.71), LBW (OR 1.82, 95% CI 1.72 to 1.92), and very LBW (OR 1.83, 95% CI 1.61, 2.08) were significantly higher with stimulated compared to unstimulated IVF. However there was no significant increase in the risk of adverse perinatal outcomes following stimulated IVF after adjusting for the potential confounders: PTB (adjusted odds ratio (a OR) 0.92, 95% CI 0.80, 1.05), early PTB (a OR 0.93, 95% CI 0.74, 1.16), LBW (a OR 1.11, 95% CI 0.97, 1.28) and very LBW (a OR 1.07, 95% CI 0.79, 1.45).
Limitations, reason for caution: Although the analysis was adjusted for a number of important confounders, the dataset had no information on confounders such as smoking, body mass index (BMI) and the medical history of women during pregnancy to allow adjustment.
Wider implications of the findings: Analysis of this large dataset suggests that there is no increased risk of adverse perinatal outcomes following IVF involving ovarian stimulation within acceptable safe limits compared to unstimulated IVF. These findings support the use of safe ovarian stimulation aiming to retrieve ≤20 oocytes to maximise the chances of IVF success compared to unstimulated IVF without concerns of adverse effects.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Funding: none.
Trial registration number: NA.

O-034 A multivariate analysis of large-for-gestation risk factors in IVF and naturally conceived singletons

S. Korosec[1], H. Ban Frangez[1], L. Steblovnik[2], I. Verdenik[3], E. Vrtacnik Bokal[1]
[1]*Division of Gynaecology University Medical Centre Ljubljana, Department of Human Reproduction, Ljubljana, Slovenia*
[2]*Division of Gynaecology University Medical Centre Ljubljana, Department of Perinatology, Ljubljana, Slovenia*
[3]*Division of Gynaecology University Medical Centre Ljubljana, Research Unit, Ljubljana, Slovenia*

Study question: Does the frozen-thawed embryo transfer (FET) procedure act as a significant independent risk factor for a birth of a large for gestational age (LGA) singleton?
Summary answer: FET procedure was identified as significant independent risk factor for the birth of a LGA singleton in a larger group of singletons, born after FET, fresh ET and after natural conception.
What is known already: Pregnancy outcome after FET seems reassuring, but higher risk for birth of LGA singletons after FET has been revealed. The birth of a LGA neonate represents a higher risk for maternal and perinatal morbidity and mortality, therefore the reasons must be investigated. Moreover, there is a potential concern that LGA birth weight could derive from underlying epigenetic disturbances.
Study design, size, duration: In retrospective case-matched study the risk factors for LGA were analysed in 4508 singleton pregnancies and births after FET, fresh ET and natural conception. The IVF procedures were performed in the time period between January 2004 and December 2011 at University Medical Centre Ljubljana.
Participants/materials, setting, methods: For identification of LGA risk factors, 1127 IVF singleton pregnancies and births (211 after FET, 916 after fresh ET) and 3381 naturally conceived controls (for each IVF pregnancy 3 pregnancies, matched by maternal age, parity and hospital) were included into a logistic regression model.
Main results and the role of chance: Smoking, hypertension, multiparity, BMI, gestational diabetes and IVF procedure were included into the LGA logistic regression model. Smoking, hypertension and double embryo transfer reduced the risk for LGA, while multiparity, higher BMI and gestational diabetes raised the risk for LGA.
FET was found to be a significant independent risk factor for LGA ($p = 0.032$; OR 1.697 with 95% CI 1.047–2.752). Fresh ET and ICSI procedures did not influence the LGA rate at all, whereas the transfer of 2 embryos slightly reduced the LGA risk.
BMI between 25 and 30 was another significant independent risk factor for LGA in both IVF pregnancy groups: FET ($p = 0.041$, OR 2.460 with 95% CI 1.030–5.857) and fresh ET ($p = 0.003$; OR 2.188 with 95% CI 1.297–3.691).
Limitations, reason for caution: In our study 95% of embryos were transferred at the blastocyst stage on day 5, so influence of embryo development stage to the LGA birth in IVF groups was not performed.
Wider implications of the findings: FET and higher BMI are the main risk factors for LGA birth among IVF conceived singletons. The most obvious maternal and IVF reasons for higher LGA rate after FET procedure are being excluded, and it seems that more subtle reasons for this phenomenon exist. Besides speculating on epigenetic disturbances, we should continue to search for other, not yet revealed, causes.
Study funding/competing interest(s): Funding by hospital/clinic(s) – No special funding needed from Division of Gynaecology, University Medical Centre Ljubljana.
Trial registration number: No trial registration number needed.

O-035 Is peak estradiol during the follicular phase associated with neonatal birthweight in singleton pregnancies conceived after fresh or frozen embryo transfer? Analysis of 3600 pregnancies

T. Tarlatzi[1], C. Venetis[2], A. Sassi[1], F. Devreker[1], Y. Englert[1], A. Delbaere[1]
[1]*Hôpital Erasme–ULB, Fertility Clinic Department of Obstetrics and Gynecology, Brussels, Belgium*
[2]*University of New South Wales, School of Women's and Children's Health, Sydney, NSW, Australia*

Study question: Do singletons resulting from frozen thawed embryo transfer (FRET) have an increased birthweight compared to those after fresh embryo transfer and could this difference be associated with the estradiol (E2) serum concentrations during early stages of implantation?
Summary answer: Singletons born after FRET have an increased birthweight compared to those born after fresh embryo transfer and this seems to be associated with peak estradiol concentrations during the late follicular phase.
What is known already: Most studies report that singleton pregnancies resulting from FRET seem to have an increased neonatal birthweight compared to those from fresh embryo transfer. The different hormonal environment and especially the E2 serum concentrations during the late follicular phase between stimulated cycles with fresh transfer and FRET cycles has been hypothesized to be one of the main explanations for this finding. However, evidence directly linking late follicular phase E2 with birthweight are currently lacking.
Study design, size, duration: Singleton pregnancies resulting from FRET (n = 747) were retrospectively compared to those from fresh embryo transfer (n = 2885), during the period 1990–2013 at the Fertility Clinic of the Erasmus hospital of the French-speaking Free University of Brussels.
Participants/materials, setting, methods: The neonatal birthweight of singleton pregnancies after frozen (n = 747) or fresh embryo transfer (n = 2885) leading to a delivery ≥21 gestational weeks was compared. Generalized estimating equation (GEE) analysis was used in order to assess associations while accounting for the non-independence of data and also adjusting for important confounders.
Main results and the role of chance: A singleton delivered after a FRET cycle had a significantly higher birthweight by 102 grams (95% CI: 59.5–144.9, $p < 0.05$) even after adjusting for maternal age at delivery, parity, BMI, smoking status and gestational age at delivery. However, when the peak estradiol level at the end of the follicular phase was added to the regression analysis model, the birthweight difference between frozen and fresh embryo transfer cycles was not significant while for every 1000 pg/mL increase in the concentration of E2 the birthweight was reduced by 28.4 grms (95% CI: -49.7 to -7.01).
Limitations, reason for caution: The study was not adjusted for the number of embryos transferred or the type of culture media used. Although this study links E2 concentration and birthweight, the underlying mechanism remains to be elucidated. Furthemore, other factors might contribute to the difference in birthweight between pregnancies after fresh or FRET cycles.
Wider implications of the findings: Our findings confirm the observation that singletons born after fresh ET have a lower birthweight than those born after FRET. Furthermore, they support the hypothesis that this difference seems to be related to the altered endocrine environment following ovarian stimulation for IVF. Whether this altered endocrine environment during early embryo development is associated with other health aspects of the neonate is a question that warrants further investigation.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Erasme Hospital, Brussels, Belgium.
Trial registration number: None.

O-036 Academic performance in adolescent children at 9th grade of primary school born after assisted reproductive technology (ART) – a national controlled cohort study

A.L. Spangmose Pedersen[1], S. Malchau[1], L. Schmidt[2], D. Vassard[2], S. C. Rasmussen[3], A. Loft[4], A. L. Pinborg[1]
[1]*Fertility Clinic, Copenhagen University Hospital Hvidovre, Copenhagen, Denmark*
[2]*Institute of Public Health, University of Copenhagen, Copenhagen, Denmark*
[3]*Gyn/Obs Department, Copenhagen University Hospital Hvidovre, Copenhagen, Denmark*
[4]*Fertility Clinic, Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark*

Study question: Is academic performance, measured as test scores after ninth grade of primary school, different in ART than in spontaneously conceived (SC) adolescents aged 15–16 years? Do mean ninth grade test scores differ in ART singletons vs. ART twins?
Summary answer: Higher crude ninth grade mean test scores were observed in both ART singletons and twins compared to SC singletons and SC twins. The difference disappeared after adjustments for child sex, maternal age, birth weight, gestational age and socio-economic status. Similar mean test scores were observed in ART-singletons and ART-twins.
What is known already: Only few and smaller studies with selected control populations have explored IQ in ART children and no previous studies have included ninth grade test scores from a standardized national test in a complete national ART cohort of 15–16-year old adolescents. Most studies in younger aged children have found similar IQ in ART and SC offspring. One previous Danish study found similar test scores in the SC twins and singletons.
Study design, size, duration: National register-based controlled cohort study including all ART children (n = 8,251; n = 4,991 singletons and n = 3,260 twins) born in Denmark from 1995–2000 and two control populations conceived after spontaneous conception; (1) All twins born in Denmark (n = 10,833) and (2) A randomly selected singleton population two-times the ART singleton population (n = 10,052).
Participants/materials, setting, methods: Data on test scores and maternal socio-economic status were obtained in Statistics Denmark. All ninth grade students (age 15–16 years) complete a general test of academic achievements, scored on a scale from -3 to 12 (average 4.6). Ninth grade test scores were compared by student's t-test and multivariate linear regression analysis.
Main results and the role of chance: In the unadjusted analyses, ART singletons achieved higher test scores than SC singletons. Mean test score in ART singletons was 7.13 (SD 2.38) vs. 6.71 (SD 2.42) in SC singletons ($P < 0.001$). ART singletons achieved 0.213 (95% CI: 0.156–0.271) points higher grades than SC singletons. When adjusting for maternal age, birth weight, gestational age, sex and socioeconomic status, no difference was found. ART twins achieved a higher mean test score than SC twins 7.19 (SD 2.27) vs. 6.78 (SD 2.45)($P < 0.001$). Adjusted, ART twins achieved 0.098 (95% CI: 0.031–0.165) points higher grade than SC twins. ART twins vs. ART singletons had similar mean test scores in the unadjusted analyses, but in the adjusted analyses ART singletons achieved 0.36 (95% CI 0.187–0.538) points lower grades than ART twins.
Limitations, reason for caution: Adjustments were made for important confounders like child sex, maternal age and socio-demographic status. However, the risk of residual confounding from factors like family stability, parental educational length, etc. will be addressed in further analyses.
Wider implications of the findings: Even though ART children have higher risks of preterm birth and low birth weight, ART adolescents have similar school performance as SC adolescents in a compulsory national test performed by all students both from public and private schools in Denmark. Further ART singletons and twins had comparable scores hence the higher obstetric risk in twins does is not associated to poorer academic performance in adolescence. These findings are very important information for the infertile patients.
Study funding/competing interest(s): Funding by hospital/clinic(s), Funding by national/international organization(s) – Hvidovre Hospital, Copenhagen University Hospital: Danish Medical Association in Copenhagen (KMS).
Trial registration number: NA.

O-037 Risk of cancer in children born after assisted reproductive technology in Norway

M.M. Reigstad[1], I. K. Larsen[2], T. A. Myklebust[2], T. E. Robsahm[2], N. B. Oldereid[3], L. A. Brinton[4], R. Storeng[1]
[1]*Norwegian National Advisory Unit on Women's Health, Women and Childrens Division Oslo University Hospital Rikshospitalet, Oslo, Norway*
[2]*Cancer Registry of Norway, Institute of Population-based Cancer Research, Oslo, Norway*
[3]*Oslo University Hospital Rikshospitalet, Section of Reproductive Medicine Women and Childrens Division, Oslo, Norway*
[4]*National Cancer Institute, Division of Cancer Epidemiology and Genetics Hormonal and Reproductive Epidemiology Branch, Bethesda, U.S.A.*

Study question: Do children born to mothers who underwent assisted reproductive technology (ART) have an increased risk of cancer compared to children born to mothers not exposed to ART?
Summary answer: Although this population based cohort study did not observe overall increased cancer risk for children born to women after ART as compared to children born to women who conceived without ART, there were elevated risks of leukemia and Hodgkin lymphoma.

What is known already: The causes of childhood cancer are still unknown. Procedures used during ART have been speculated to cause epigenetic modifications in early fetal development that later could increase cancer risk. However, it has also been suggested that parental infertility itself could be a contributory factor. Several studies have reported increased risks of cancer in children conceived by ART, most notably for leukemia, although results have been inconsistent.
Study design, size, duration: The study cohort consisted of all children born between 1984 and 2011, registered in the Medical Birth Registry of Norway (MBRN). Cancers were identified by linkage to the Cancer Registry of Norway (CRN). Study subjects were followed from birth, until the first cancer, death, emigration, or 31st December 2011.
Participants/materials, setting, methods: Out of 1 628 677 children, 25 782 were born to mothers after ART. Hazard ratios (HR) and 95% confidence intervals (CI) were used to compare risk of cancer in ART children to non-ART children, adjusting for maternal age, birth order, calendar period, gender, birth weight and gestational age.
Main results and the role of chance: 51 cancers in the ART group comprised: 17 leukemias (33%), 12 cancers of the central nervous system (CNS) (24%), 5 soft tissue cancers (10%), 3 Hodgkin lymphomas (6%), 14 cancers at other sites (25%). 4503 cancers in the non-ART group included: 1021 leukemias (33%), 1020 CNS cancers (33%), 308 soft tissue cancers (7%), 258 Hodgkin lymphomas (6%), 1896 cancers at other sites (42%). Median age at diagnosis was 3.2 years in the ART group and 8.8 in the non-ART group. Median follow-up time was 6.9 and 13.7 years, respectively. HR for overall cancer in ART children compared to non-ART children was 1.21 (95% CI 0.90–1.63). Significantly increased HRs, however, were observed for leukemia (1.67, 95% CI 1.02–2.73) and Hodgkin lymphoma (3.63, 95% CI 1.12–11.72).
Limitations, reason for caution: The study may be underpowered due to few cancer cases in the ART group. This was especially true for Hodgkin lymphoma, which has not previously been described as elevated among ART children. In addition, our follow-up time, especially for ART children, was relatively short.
Wider implications of the findings: The demonstrated increased risk of leukemia in children conceived by ART is consistent with previous findings. An association between maternal subfertility and childhood cancer has also been found. The present study cannot determine whether it is the ART or the subfertility that may cause increased risk, and further research is necessary to make this differentiation. ART children should also be monitored in the future to ascertain whether their increased cancer risk persists into adulthood.
Study funding/competing interest(s): Funding by national/international organization(s). The study was funded by the Norwegian National Advisory Unit on Women's Health. All authors claim no competing interests.
Trial registration number: Not applicable, the study is not a clinical trial.
Keywords: ART, IVF, leukemia, Hodgkin lymphoma, childhood cancer

O-038 Risk of cancer in children and adolescents conceived by assisted reproductive technologies

M. Spaan[1], A.W. van den Belt-Dusebout[1], C. W. Burger[2], F.E. van Leeuwen[1]
[1]*Netherlands Cancer Institute, Epidemiology, Amsterdam, The Netherlands*
[2]*Erasmus University Medical Center, Obstetrics and Gynecology, Rotterdam, The Netherlands*

Study question: The aim of this study is to investigate whether offspring conceived by assisted reproductive technologies (ART) has an increased cancer risk, compared with the general population and with naturally conceived offspring from subfertile parents.
Summary answer: In preliminary analyses, after a median follow-up of 14.4 years no significantly increased risk of cancer was found in offspring conceived by ART compared with naturally conceived offspring from subfertile parents.
What is known already: It is estimated that more than 5 million ART-babies have been born worldwide. Each phase of the ART procedure is different from natural conception and there is growing evidence that ART procedures could perturb epigenetic processes during the pre-implantation period. Few studies examined cancer risk in ART-conceived offspring. Although the results of most studies are reassuring, recent studies showed slightly increased risks. However, most studies had a short follow-up and a small number of cases.
Study design, size, duration: The study population consists of all offspring of a nationwide historic cohort of subfertile women treated with ART between 1983 and 2000. The cohort includes ≈ 44,000 live-born children, of whom 26,000 were ART-conceived and 18,000 were naturally conceived. The median follow-up time is estimated at 18 years.
Participants/materials, setting, methods: Data on type of subfertility treatment and maternal risk factors are available from Study questionnaires and medical records from the mothers. Cancer incidence has been ascertained through linkage with the Netherlands Cancer Registry. Cancer risk is compared between ART-conceived offspring and naturally conceived offspring using multivariable Cox regression.
Main results and the role of chance: Since data preparation is still ongoing analyses could only be performed on the more recently born offspring of the cohort (5,184 ART-conceived and 4,526 naturally conceived). After a median follow-up 14.4 years, 32 cancers were observed of which 17 were observed in the ART offspring and 15 in the naturally conceived offspring. No significantly increased risk of cancer was found in the ART-conceived offspring when compared with naturally conceived offspring (hazard ratio = 1.45, 95% confidence interval 0.69–3.07). Adjusting for maternal age and birth weight did not materially change the risk.
Limitations, reason for caution: Since data preparation is ongoing, current results are based on a subgroup of the cohort. Therefore, results must be interpreted with caution. Results based on the whole cohort (≈44,000 children with 18 years follow-up time) are available in May 2015 and can be presented at the conference.
Wider implications of the findings: Despite the increasing use of ART techniques, information about the possible health risks for children conceived by these techniques is essentially lacking. This means that there is inadequate knowledge for physicians to advice parents who consider ART about potential health risks for ART-conceived children. Furthermore, pediatric oncologists caring for ART-conceived children/adolescents with cancer need evidence-based information about the presence or absence of a (causal) association between infertility treatment and risk of cancer.
Study funding/competing interest(s): Funding by national/international organization(s). Foundation Children Cancer Free.
Trial registration number: NA.

SESSION 08: PCOS: CLINICAL ASPECTS

Monday 15 June 2015 **11:45–12:45**

O-039 Polycystic ovary syndrome in adolescent girls: Assessment and health-related quality of life

A. Balen[1]
[1]*The Leeds Centre for Reproductive Medicine, Professor of Reproductive Medicine and Surgery, Leeds, United Kingdom*

The polycystic ovary syndrome (PCOS) remains a conundrum, not least because of its evolution during adolescence and difficulties in making the diagnosis. Many of the symptoms of PCOS occur naturally during adolescence, namely erratic menstrual cycles and acne. Furthermore the ultrasound appearance of the ovary can have a characteristic multicyctic or polycystic pattern – another topic of much debate and some disagreement. There are few studies that look at normative ranges of endocrine profiles or ovarian ultrasound parameters in the adolescent population, or for that matter how they may change over time in different populations. Consensus opinion suggests that PCOS should not be diagnosed until at least 2 years after the menarche, even though some individuals may have clear pointers to the likely diagnosis. At all ages obesity will amplify the expression of PCOS and increase the difficulties in management. Obesity also has the greatest impact upon quality of life, followed by signs of androgen excess and menstrual irregularity – concerns about fertility come later, but are often expressed by worried mothers. Management focuses on lifestyle interventions, where possible and anti-androgen therapy, often in the form of the combined oral contraceptive pill. Metformin therapy appears to confer minimal benefit as indeed is the case for adult women with PCOS.
Keywords: PCOS, adolescence, anovulation, hyperandrogenism, polycystic ovary

O-040 Aromatase inhibitors vs. clomiphene citrate for induction of ovulation in PCOS

R. Homburg[1]
[1]*Homerton University Hospital, Homerton Fertility Centre, London, United Kingdom*

For the past 60 years clomiphene citrate (CC) has been the first line treatment for those with absent or irregular ovulation but who have normal basal levels of endogenous oestradiol (almost all of whom have PCOS). The action of CC is by blocking hypothalamic oestrogen receptors, signaling a lack of circulating oestrogen to the hypothalamus and inducing a change in the pattern of pulsatile release of gonadotrophin releasing hormone (GnRH) and consequently a discharge of FSH. Although CC restores ovulation in approximately 80% of patients it results in pregnancy in only about 35–40%, a gap thought to be mainly due to the anti-oestrogen effect of CC on the endometrium. Aromatase inhibitors are non-steroidal compounds that suppress oestrogen biosynthesis by blocking the action of the enzyme aromatase which converts androstendione to oestrogens. Letrozole, the most widely used aromatase inhibitor, is given orally in a dose of 2.5 mg–5 mg/day, is almost free of side effects and does not affect the endometrium. Theoretically, it has several advantages over CC. These were confirmed in an RCT from Legro and colleagues in which 750 women with anovulatory PCOS were randomized to receive either CC or letrozole. A 44% increase in pregnancy rate was achieved by letrozole over CC (27.5% vs. 19.5%). Twinning rate was non-significantly higher in those who received CC (7.4% vs. 3.2%) with no significant difference in the rate of congenital abnormalities. The conclusion would seem to be that letrozole can be regarded as a serious competitor to CC for first-line therapy for induction of ovulation. More is the pity that letrozole is still deemed to be 'off label' due to spurious data, subsequently disproved, linking it with a possible teratogenic effect.

Keywords: clomiphene, letrozole, PCOS

INVITED SESSION

SESSION 09: DATA REPORTING SESSION (PGD CONSORTIUM)

Monday 15 June 2015 **11:45–12:15**

O-041 Data from the ESHRE PGD consortium

E. Coonen[1], M. De Rycke[2], G. Kokkali[3], C. Moutou[4], S. SenGupta[5], Traeger-J. Synodinos[6], V. Goossens[7]
[1]*Maastricht University Medical Center, Clinical Genetics/Obstetrics and Gynecology, Maastricht, The Netherlands*

[4]*Université de Strasbourg Hôpitaux Universitaires de Strasbourg, Service de la Biologie de la Reproduction, Schiltigheim, France*
[5]*University College London, UCL Centre for PG and D Institute for Women's Health, London, United Kingdom*
[6]*University of Athens St Sophia's Children's Hospital, Dept. of Medical Genetics, Athens, Greece*
[7]*ESHRE, Science office, Grimbergen, Belgium*

Introduction: The ESHRE PGD Consortium was set up in 1997 and from that time has been collecting data on PGD and PGS. In addition, the PGD Consortium has created different Working Groups (WGs) over the years to look at important aspects of PGD. Current WGs include the development and implementation of an on-line database for the annual data collections, retrospective data mining, a survey of new technologies introduced into PGD practice, evaluation of the clinical utility of PGD for HLA compatibility testing, evaluation of collaborative working practices between IVF and genetic teams and finally interactive webinars for PGD consortium members.

Methods: So far, 15 retrospective data collections, representing cycles performed until 2012 with babies born until 2013 have been analysed. All data collections were based on a Filemaker Pro database submitted via email by each centre. The data includes all aspects of PGD/PGS cycles and data curators include the ESHRE Scientific Officer along with volunteers from the PGD Consortium Steering Committee and other experts in PGD. Currently there are 125 registered centres worldwide, including from Europe, Argentina, Australia, Brazil, Canada, Egypt, India, Israel, Japan, Korea, Pakistan, Russia, Singapore, South Africa, Taiwan, Thailand, United Arab Emirates and the USA.

Results: Data from over 58,000 PGD/PGS cycles have been included in the ESHRE PGD database. As such, it comprises the world's largest collection of PGD / PGS data providing a valuable resource for data mining and for following trends in PGD practice. As a result of a huge increase in the number of reported cycles each year, the Steering Committee have found it very difficult and time consuming to mine the data and produce accurate tables. Moreover, the nature of PGD/ PGS treatments has changed significantly over the last years and today we face complexity in IVF cycle management and genetic analysis techniques. Therefore, the Steering Committee have found it timely to rejuvenate the data collection and make it more fit for purpose. To do so, we have invested time in strategic initiatives, first to determine what technologies are being used or are being introduced into genetic diagnosis and also how IVF cycles are being managed for PGD. This information has allowed us to restructure data collection and mining and has led to the setup of a new online PGD database. The design of the new database will allow centres to input and analyse their own data in real time. Now that the database is ready our focus will be to inspire and encourage all PGD centres to submit data and find out more about the advantages of the online database: Add your data prospectively from oocyte retrieval to analysis, embryo transfer and pregnancy / live birth. Keep track of your fresh and cryopreserved PGD / PGS cycles. Audit your centre's pregnancies and live births according to ART and genetic analysis techniques. And last but not least, network with PGD practitioners, discuss trends and identify good practice.

Discussion: The ESHRE PGD Consortium continues its activities as an important forum for PGD practitioners to share data and exchange experiences. The information extracted from the data collections helps to monitors quality issues in PGD and survey the introduction and effectiveness of new PGD technologies and methods. The WG activities of the Consortium are focused towards supporting PGD centres to continue their provision of high quality PGD services. The SC acknowledges the contribution of all active PGD centres to the aims of the Consortium.

Keywords: ESHRE PGD consortium, PGD data collection

INVITED SESSION

SESSION 10: FERTILITY SOCIETY OF AUSTRALIA EXCHANGE LECTURE

Monday 15 June 2015 **11:45–12:15**

O-042 Embryo morphokinetic development is the same for patients with and without polycystic ovaries and is not impaired by ivm treatment

M.L. Walls[1], J. P. Ryan[2], J. A. Keelan[1], R. Hart[1]
[1]*University of Western Australia, School of Women's and Infant's Health, Subiaco, Australia*
[2]*Fertility Specialists of WA, Embryology Laboratory, Claremont, Australia*

AIM: To determine if polycystic ovarian syndrome (PCOS) or *in vitro* maturation (IVM) treatment affect embryo development events and morphokinetic parameters after time lapse incubation.

Method: This paper represents a prospective case-control study. The study involved 83 participants who underwent 83 treatment cycles. Cycles were completed between November 2012 and July 2014. Participants were recruited for the study at the Fertility Specialists of WA and Fertility Specialists South, Perth, Western Australia. Of the PCOS diagnosed patients, 32 underwent IVM treatment (PCOS-IVM) and 23 had standard ICSI treatment (PCOS-ICSI). There were 38 patients without PCOS who underwent standard ICSI treatment comprising the control group (control-ICSI). All embryos were cultured in an embryoscope (Unisense Fertilitech) time-lapse incubator. Morphokinetic annotations were performed retrospectively. All normally fertilised embryos were included in the analysis of abnormal events and early embryo arrest; however, only embryos with annotations completed to the blastocyst stage (tB) were included in the final morphokinetic analysis.

Results: The PCOS-IVM group showed significantly more embryos with multinucleated two cells ($p = 0.041$), multinucleated four cells ($p = 0.001$) and uneven two cells ($p = 0.033$) compared with the control-ICSI group, but not the PCOS-ICSI group. There were no significant differences in the rates of any abnormal events between the PCOS-ICSI and control groups. Embryo arrest

between day two to three was higher in the PCOS-IVM and PCOS-ICSI groups compared to the controls ($p < 0.001$ and $p = 0.001$). Embryo arrest from day three to four was higher in the PCOS-IVM group compared to both the PCOS-ICSI and Control groups ($p < 0.001$). There were no differences in embryo arrest rates across all three groups at the compaction or blastulation stages. Cumulative rates of embryo arrest, from time tPB2 to time tB, result in a decreased proportion of useable PCOS-IVM blastocysts compared to the PCOS-ICSI and Control groups; however, of the embryos remaining, there was no significant difference in morphokinetic development between the three groups.
Conclusions: This study to compares the time-lapse analysis of IVM to standard ICSI for patients with and without PCOS. This allows for a more detailed and specific timeline of events from embryos generated using this approach for patients diagnosed with PCOS and shows that embryos generated from IVM have an increased rate of early embryo arrest, however; morphokinetic development is not impaired in embryos which progress to the useable blastocyst stage.
Keywords: IVM, ICSI, PCOS, morphokinetics

INVITED SESSION

SESSION 11: PARAMEDICAL INVITED SESSION: LABORATORY

Monday 15 June 2015 **11:45–12:45**

O-043 Artificial gametes: biology, implications and patient perspectives

S. Hendriks[1], E.A.F. Dancet[1], S. Repping[1]
[1]*Academic Medical Center, Center for Reproductive Medicine, Amsterdam, The Netherlands*

Reproductive medicine is awaiting novel Artificial Reproductive Techniques (ARTs) that no longer require couples with a wish for a child to have functional male and female gametes in order to conceive a child, which is genetically related to both intended parents. These ARTs will use 'artificial gametes', generated by manipulation of the intended parents' stem cells. Artificial gametes will fundamentally change the type of cells used by reproductive medicine and the patient groups that they can help conceive a genetically related child. Proactive consideration of the biological progress, the implications of clinical application and patients' interest is important and timely. To study the biological progress on artificial gametes, we conducted a systematic literature review. This review summarizes the findings of studies reporting on a priori defined starting-points and end-points including gamete formation, fertilization, and the birth of offspring. To study the implications of clinical application of artificial gametes we conducted another systematic review. This review summarizes reflections on the implications of clinical application of artificial gametes, reported on by all stakeholder groups (e.g., biologists, ethicists) and in all types of papers published in peer-reviewed journals (e.g., editorials, opinion papers). To study patients' interests, an anonymous survey questioning hypothetical treatment preference and important treatment characterizes was send to all 921 couples confronted with non-obstructive azoospermia and treated with TESE-ICSI in Dutch fertility clinics in the past 5 years. The review including 70 biological studies identified nine potential pathways to conceive offspring with the aid of artificial gametes. For seven of them, the formation of artificial sperm and/or artificial oocytes resulted in the birth of animal offspring. Animal offspring has even been born from artificial sperm from a female donor animal and fertilization has been achieved with artificial oocytes from a male donor animal. To date, no study has reported the birth of human offspring from artificial gametes. Nevertheless, the creation of human sperm and/or human oocytes was reported using six pathways to create artificial gametes. One of these pathways even resulted in fertilization. Human artificial sperm has also been created from women, while the formation of artificial oocytes from men has not been reported. Although these studies proof that artificial gametes can be generated, efficacy and long-term safety has not been unambiguously proven. The review including 84 papers on stakeholders reflections, identified the following eight overall objectives to be safeguarded during clinical application of artificial gametes: (i) timing the implementation of new treatments correctly, (ii) meeting 'plausible demands of patients', (iii) improving and safeguarding public health, (iv) promoting the progress of medical science in the interest of future patients, (v) providing treatments that are morally acceptable for the general public, (vi) controlling medical practice, (vii) offering treatments that allow acquisition of informed consent, and (viii) funding treatments fairly. The patient survey showed that the vast majority (88.5%) of couples confronted with non-obstructive azoospermia would opt for an artificial gamete based treatment as either a first or a last resort option. The most important treatment characteristics were safety for the child, pregnancy rates, and treatments ability to permanently cure infertility. Other treatment characteristics of influence are costs, burden, naturalness, advancedness of technology, *in vivo* versus *in vitro* conception, and moral acceptability. Achieved biological progress, ongoing preclinical research on effectiveness and safety, reflections on potential implications and patients' interest demonstrate the urgency of defining minimal conditions for clinical application. Given the broad scope of the identified objectives to be safeguarded during clinical application of artificial gametes, several (societal) stakeholders should be consulted during pre-implementation processes to define the minimal criteria to be met prior to clinical application.
Keywords: artificial gametes, biology, ethics, patient perspectives

O-044 Human semen quality in the new millennium: prospective studies of semen quality in Europe and other countries

N. Jørgensen[1]
[1]*Copenhagen University Hospital Rigshospitalet, University Department of Growth and Reproduction/GR-5064, Copenhagen, Denmark*

The debate whether semen quality in general has decreased re-emerged in 1992 when a meta-analysis showed that semen quality had decreased by 50% during a 50 years period. Several publications followed, and some detected a temporal trend whereas other did not. The overall conclusion that semen quality had declined is mainly based on retrospective, historic data, which limits their significance, and the topic has been controversial. On this background standardised and coordinated studies of semen quality of young men not selected due to fertility status and partners of pregnant women (i.e., fertile men) have been undertaken in various countries. Some of the studies of the young men, which have been ongoing since the late 1990s, have shown a somewhat heterogeneous temporal pattern. A decrease or more than 20% in total sperm counts and sperm concentration has been shown for Finnish men between 1998 and 2006, and a decrease of approximately 15% has also been indicated for young Spanish men during the recent decade whereas no changes were observed between 2000 and 2010 for Swedish men. In contrast, an increase in total sperm count and sperm concentration (approximately 14% and 12%, respectively) among Danish men in the period 1996–2010 was observed, however, still compatible with a pronounced reduction in both total sperm counts and sperm concentration when compared to the early 1940s. A French study corroborated the previously indicated decreasing trend among French men. Several studies have shown that chances of conception increase when sperm concentration increases towards 40–60 mill/mL and the number of spermatozoa with normal morphology increases to 9–12%. According to the current WHO guidelines a sample is classified as normal if the sperm concentration is 15 million per mill or more, the number of morphologically normal spermatozoa is 4% or more and more than 32% have good motility. There is little doubt that many men with semen parameters at that level or lower may be infertile with a need of fertility treatment if they want to reproduce. On the other hand, there is no guarantee that a man with better semen quality, including higher sperm counts has normal fecundity (ability to reproduce). A striking feature is the high frequency of young men with poor semen quality in all examined countries. When interpreted against studies describing associations between pregnancy chances and sperm counts and frequencies of morphologically normal spermatozoa it seems like only approximately 25% of men have an optimal semen quality, that 20–30% may be at risk of prolonged waiting time to pregnancy if they want to become fathers, and another 10–15% may have so low sperm counts that they may be at risk for need of fertility treatment. Humans are globally exposed to many classes of chemicals with endocrine disrupting potential via a variety of mechanisms. Exposure during fetal life may compromise testicular development, leading to reduced semen quality in adulthood, increased risk of testicular cancer and potentially also reduced capacity for testosterone production, besides an increased risk of being born with cryptorchidism and hypospadias as described by the Testicular Dysgenesis Syndrome (TDS) hypothesis. Since the first description of TDS hypothesis more and more evidence has emerged to support this hypothesis. Adverse effects caused by prenatal exposures do not exclude that exposures in adulthood may also alter testicular function; however, less focus has been on this aspect. Similarly,

limited attention has been on the effect of life-style factors. However, recent publications have also indicated a possible contribution from such factors to the impaired human testicular function.

Keywords: semen quality, general population, European countries

INVITED SESSION

SESSION 12: DEBATE: EMBRYO CULTURE SYSTEM: SINGLE STEP VERSUS SEQUENTIAL CULTURE MEDIA

Monday 15 June 2015 **14:00–15:00**

O-045 Single step media

R. Sturmey
University of Hull, Centre for Cardiovascular and Metabolic Research, Hull, United Kingdom

O-046 Sequential media

T. Pool[1]
[1]*Fertility Center of San Antonio, Assisted Reproduction Technology Laboratory, San Antonio, TX, U.S.A.*

Clinical embryologists currently enjoy a wide selection of commercially available components for the construction of their preferred culture system, to include embryo culture media. These media carry regulatory approval, both of the products and of the manufacturing facilities, and the literature makes clear that most, if not all, of these media can produce stellar clinical outcomes, at least in the right hands. The ability to produce viable human blastocysts, ones that implant at significantly higher rates than cleavage-stage embryos, is a crucial adjunct, not only in the strategy of expanding single embryo transfer with accompanying high pregnancy rates, but also in the melding of ART with molecular diagnostics and in cryobiology. It was historically the use of sequential culture systems that fostered blastocyst production and transfer in human ART as earlier versions of monoculture, meaning those in use prior to the advent of KSOMAA and its current derivatives, fell short in this respect. Without a doubt, contemporary single-step media derived from KSOMAA, of which there are several commercial variations, can generate viable human blastocysts at rates equivalent to sequential pairs. But the question of "is one better than the other" remains elusive for a number of reasons. First, it becomes clear that arguing "is one better than two" seems absurd as one views the breadth of intermediary metabolism. Both are compromises that average across the requirements of hundreds of pathways so that a more accurate question may be "which is least harmful?". Second, although there are many comparative studies in the literature, a number are flawed by a failure to optimize both medium systems so that managerial issues cloud results. Others present subpar clinical outcomes that reduce the sensitivity of the study to discriminate between the variables of medium composition/presentation. Still others are conducted over such an extensive period of time that isolating even the laboratory contributions to outcome is difficult. Lastly, we are debating a snapshot in time, one where we culture embryos on a two-dimensional, polystyrene surface under conditions developed originally for anchorage-dependent somatic cells. Will there be culture platforms of the future that reproduce, in a temporally correct fashion, the unique chemical and physical environments of the infundibulum, ampulla and endometrium, complete with nutrient gradients? Likely, yes and if so, it is certain that multiple media will best support such a culture system.

INVITED SESSION

SESSION 13: ARE YOU SURE IT IS ENDOMETRIOSIS?

Monday 15 June 2015 **14:00–15:00**

O-047 Adolescent endometriosis

C. Chapron[1], P. Santulli[1], L. Marcellin[1], V. Gayet[1], de D. Ziegler[1], B. Borghese[1]
[1]*Université Paris Descartes Faculté de Médecine, Service de Gynecologie Obstetrique II et Médecine de la Reproduction Unite de Chirurgie, Paris, France*

Endometriosis, histologically defined as functional endometrial glands and stroma developing outside of the uterine cavity, is a common gynecologic disorder. Pathogenesis of endometriosis is enigmatic and remains controversial, even if retrograde menstruation seems the most probable mechanism for the development of the disease. There three types of endometriotic lesions: peritoneal superficial endometriosis (SUP); ovarian endometrioma (OMA); deep infiltrating endometriosis. The economic burden of endometriosis is considerable notably because of repeated absenteeism from work, numerous medical (hormonal and non hormonal) treatments, repetitive surgery and long delay in diagnosis. If endometriosis is usually diagnosed in adults, the disease has its roots in adolescence. Clinical questioning is simple, cost-effective and essential for the diagnosis of endometriosis. A link exists between certain perimenarchial symptoms and the diagnosis of endometriosis, especially DIE. Markers at adolescence associated with the development of endometriosis are the following: family history of endometriosis (especially in first-degree relatives); severe primary dysmenorrhea; absenteeism from school during menses; dysmenorrhea resistant to nonsteroidal anti-inflammatory drug treatment; noncontraceptive use of oral contraceptives to treat severe dysmenorrhea. Questioning patients about their adolescent history can identify markers associated with endometriosis. A better awareness of these markers could help in singling those youngsters who are more prone to develop endometriosis. Today it can only be speculated that a prompter and more thorough handling of severe dysmenorrhea could lead to an earlier diagnosis and a better management. Studies are necessary to precise the relationship between endometriosis and oral contraceptive use, to determine whether we will have to reconsider the management of severe pelvic pain in adolescent and to be able to precise exactly when the disease starts.

O-048 The need to have a laparoscopic diagnosis of endometriosis before starting treatment

C.M. Becker[1]
[1]*University of Oxford, Nuffield Department of Obstetrics and Gynaecology, Oxford, United Kingdom*

Endometriosis is a common disease, affecting women mostly during their reproductive phase. The prevalence is estimated to range between 5–10%, however, due to the predominantly intra-abdominal presence of endometriotic lesions, a lack of clinically robust biomarkers and imaging techniques it remains unclear how common the disease really is. While adolescent girls typically present with dysmenorrhea, older women often also suffer from non-cyclical pain, deep dyspareunia, dyschezia and dysuria as well as fatigue. In addition, 30–50% of women with endometriosis experience fertility problems. There is no place for hormonal treatment in women trying to conceive naturally, however, it is one of the options for women suffering predominantly from pain symptoms. Laparoscopic identification, ideally coupled with the histological confirmation of endometriotic lesions, is generally considered the diagnostic gold standard. In the right clinical setting with sufficient surgical expertise this diagnostic procedure is then combined with surgical excision and/or ablation of endometriotic lesions. However, despite its wide use and years of experience since its introduction into the clinic, laparoscopy, as any surgery, is an invasive procedure associated with potential morbidity and, rarely, mortality. This lecture will discuss the potential pros and cons of empirical treatment, i.e., treatment without a surgical diagnosis of endometriosis assuming the presence of endometriotic disease. It will cover all aspects of diagnostic and therapeutic risks and aims to making a recommendation based on the existing evidence.

Keywords: endometriosis, laparoscopy, diagnosis

INVITED SESSION

SESSION 14: THE END OF THE END? TELOMERES IN HUMAN REPRODUCTION

Monday 15 June 2015 **14:00–15:00**

O-049 Normal telomere shortening and elongation

D. M. Baird[1]
[1]*Cardiff University, Institute of Cancer and Genetics School of Medicine, Cardiff Wales, United Kingdom*

Telomeres cap the ends of eukaryotic chromosomes, preventing the recognition and repair of the natural chromosomal terminus by the DNA damage response apparatus. As a consequence of end-replication losses, telomeres shorten with on-going cell division. Short telomeres can elicit a p53-dependent cell cycle arrest, referred to as replicative senescence, that provides a stringent tumour suppressive function. However, in the absence of a functional DNA damage checkpoint response, on-going cell division results in continued telomere erosion and ultimately the loss of the end-capping function. Telomeres can then be subjected to DNA repair activities, resulting in telomere fusion, the formation of dicentric chromosomes and the initiation of cycles of anaphase-bridging, breakage and fusion. The ensuing cellular crisis leads to a strong selection pressure for the up-regulation of telomere maintenance mechanisms, principally telomerase activity, which facilitates the escape from crisis. This process is considered a key mutational mechanism that drives genomic instability and clonal evolution during malignant progression. Our approach has been to develop high-resolution, single-molecule technologies, to study telomere length and fusion in detail; these methods have provided a level of clarity that was hitherto impossible to achieve in human cells. Our work has focused on understanding the mechanisms underlying telomere dynamics and the fusion of short dysfunctional telomeres in human cells. Importantly, this work has provided tools that have allowed us to translate our understanding of telomere dynamics into clinical situations resulting in the development of powerful prognostic markers that are likely to have broad utility in both solid and haematological malignancies. In addition to the role that telomeres play in replicative senescence and genomic instability in somatic tissues, telomere maintenance is also required in the germline to ensure that functional telomeres are passed between the generations. Despite this requirement, we have documented telomeric deletion events in the male germ-line that create extremely short telomeres. These events have the potential to drive large-scale chromosomal mutation events in the male germ line. Our work concerning telomere dynamics and dysfunction in replicative senescence, tumour progression and in the male germ line will be presented.
Keywords: telomere, senescence, DNA repair

O-050 Telomeres and reproductive aging

D. Keefe[1]
[1]*NYU Langone Medical Center, Ob/Gyn, New York, U.S.A.*

Aneuploidy condemns a large proportion of human embryos to implantation failure or miscarriage, and it underlies the aging effect on reproduction in women. Why so many human oocytes and embryos succumb to aneuploidy remains an enigma. Understanding how age increases non disjunction in oocytes and pre implantation embryos is an urgent priority because women increasingly delay childbearing. We have proposed a Telomere Theory of Reproductive Aging. Unlike male germ cells, oocytes and early embryos lack appreciable levels of telomerase activity. Moreover, late ovulating oocytes have traversed more cell cycles during fetal oogenesis and spend longer time in the ovary, exposed to the inevitable effects of reactive oxygen. We have tested this theory in mice and women, and shown that telomere shortening in oocytes drives oocyte aging. Experimental telomere shortening in mice, which in most strains have long telomeres and only modest oocyte aging, recapitulates the reproductive aging phenotype observed in women, including chromosome abnormalities, reduced chiasma and synapsis, spindle abnormalities, pre implantation embryo arrest and apoptosis. Telomere length in the polar body correlates highly with that in the oocyte, so it provides an approach to assess telomere length in oocytes and resulting embryos without perturbing them. Studies in women undergoing IVF show that short polar body telomeres are associated with embryo fragmentation, blastocyst aneuploidy, and failed IVF cycles. Telomere attrition in circulating leukocytes also has been associated with aging, recurrent pregnancy loss and aneuploid offspring. We employed a robust single cell qPCR based assay to measure telomere length in polar bodies and qPCR to measure telomere length in leukocytes from the same women. Telomere lengths in the female germ line and somatic cells showed minimal correlation. Moreover, oocyte but not leukocyte telomere length reflected ovarian function. Finally, experiments in mice show that long term administration of a potent antioxidant and the SIRUIN agonist resveratrol can mitigate the effects of reproductive aging and conserve telomere reserve in the ovary.

SELECTED ORAL COMMUNICATIONS

SESSION 15: NURSING INTERVENTIONS IN CLINICAL PRACTICE

Monday 15 June 2015 **14:00–15:00**

O-051 Training of assisted reproduction nurses in 3D folliculometry and individualized learning

A. Rodríguez[1], R. Vassena[1], A. Blázquez[1], J. J. Guillén[1], S. Franci[1], O. Coll[1], V. Vernaeve[1]
[1]*Clínica EUGIN, Barcelona, Spain*

Study question: Can nurses with no previous experience in transvaginal ultrasound learn to perform folliculometry with 3D transvaginal ultrasound (3DTVUS) during ovarian stimulation cycles (OSC) in assisted reproductive techniques (ART)?
Summary answer: Nurses with no previous experience in transvaginal ultrasound can learn 3D folliculometry during OSC, and they achieve competence within a reasonable timeframe.
What is known already: 3D folliculometry has been shown to be more accurate than conventional 2D ultrasound, producing less intra- and inter-observer variability. Qualified paramedical personnel such as nurses could play an important role in ART by performing specialized technical acts. As LC-CUSUM has been already applied to evaluate learning procedures in folliculometry during OSC in ART physicians, we applied this statistical methodology to nurses, in order to perform tailored training and assess their learning curve in 3D folliculometry.
Study design, size, duration: Prospective study including 8 nurses with more than 2 years experience in ART, carried out between February and September 2014. Study duration was determined by the scan number necessary to achieve competence by each nurse as assessed by LC-CUSUM curves. Fifteen gynecologists participated in the study as experts.
Participants/materials, setting, methods: 3DTVUS scans were performed in oocyte donors from the 8th day of OSC by the expert and the nurse. LC-CUSUM curves were used to assess learning. Success of each nurse measurement was defined as a deviation from the expert's of ≤3 follicles ≥10 mm and ≤2 follicles ≥14 mm measured with 3DTUVS.
Main results and the role of chance: Six of the eight nurses achieved competence in 3DTVUS folliculometry after 68, 106, 141, 153, 185 and 194 ovarian scans, respectively. Two of them did not achieve competence after 200 scans. Customized individual training is being offered outside the study to these two trainees in order to improve their learning and achieve competence. There was significant variability in the number of scans needed to achieve competence by the nurses; however, they were all within a reasonable timeframe. Scans were performed in oocyte donors, a relatively homogeneous population, thus eliminating the possibility of subject characteristics to influence the learning curve.
Limitations, reason for caution: This study cannot evaluate whether interrupting the training will result in longer learning curves, therefore, the results apply only to centers with high patients flow and continuous learning options. LC-CUSUM is an individualized approach to training; the curve must be monitored closely due to the variability in number of scans needed to achieve competence.
Wider implications of the findings: Easiness in achieving competence in 3DTVUS folicullometry in nurses, as shown by this study, may play an important role in standardizing performance in ART units not only in physicians

but also in nurses. No previous experience in ultrasound scanning is needed to become proficient in 3D folliculometry, making 3DTVUS a promising tool to improve the professional reach of nurses with beneficial implications for both the personnel and the ART center.
Study funding/competing interest(s): Funding by hospital/clinic(s).
Trial registration number: NA.
Keywords: 3D ultrasound, nurses training, folliculometry

O-052 Hospitalisation for ovarian hyperstimulation syndrome: prevalence and risk factors in a monocentric cohort study

A. Beltran Anzola[1], A. Amar-Hoffet[1], D. Montjean[1], V. Lubin[1], C. Geoffroy-Siraudin[1], P. Boyer[1], M. Gervoise-Boyer[1]
[1]*Hopital Saint Joseph, Service de Medecine et de Biologie de la Reproduction, Marseille, France*

Study question: How important is the prevalence and risk factors of hospitalisation for ovarian hyperstimulation syndrome (OHSS) in women undergoing induction of ovulation for *in vitro* fertilization in an IVF centre?
Summary answer: Results showed a low prevalence (17/867 patients) of hospitalization for OHSS with a short mean duration 4.75 ± 3.10 in patients undergoing induction of ovulation for *in vitro* fertilization. All cases with hospitalization, moderate capillary leak syndrome, ascites with or without hydrothorax were recorded. Neither hepatic, cardiac or thrombosis complications were observed.
What is known already: OHSS is a complication of hormonal IVF treatment, two clinical entities are known, early and late OHSS. Early OHSS that is the most iatrogenic can be predicted based on patient risk factors (e.g., polycystic ovary syndrome) and adapted ovulation stimulation or delayed transfers can be proposed to these patients. Late OHSS occurs after embryonic implantation and is prevented by single embryo transfer. Despite the precaution taken, severe OHSS cases were recorded.
Study design, size, duration: It was a 2-year observational study including 867 patients who benefited IVF treatment in a French Center. Cycles with hospitalization (n = 17) for OHSS were included in the "cases group" and were compared with cycles without hospitalization (n = 1082) based on following criteria: E2 > 900 pg/mL and number of oocyte at pick up >4.
Participants/materials, setting, methods: Database was obtained using medical records. Each patient was monitored at least 5 weeks after treatment, and longer when pregnancy occurred. Descriptive analysis of the population was performed and Khi2, fisher-exact-test or student-test analysis used to compare hospitalized for OHSS and non hospitalized cases.
Main results and the role of chance: There were 1099 cycles with ovarian follicles pick up, 17 patients (1.54%) were hospitalised for OHSS. These patients were younger (p = 0.017) and displayed more dysovulation (p = 0.015) than others. They have more frequently received a recombinant FSH than urinary FSH (p = 0.010). Number of oocytes were significantly more important in hospitalised cases (p < 0.001). There is no agonist short protocol in the cases group, neither statistical difference using long agonist protocol. The mean number of transferred embryo is less important in cases group (p < 0.001). Pregnancy rate per transfer was not significantly different. All patients hospitalized presented pain and ascites. Four of them were hospitalised for pleural effusion. Risk factors of OHSS were identified for three patients; one for previous uncontrolled response, and the others for polycystic ovary syndrome.
Limitations, reason for caution: The risk factors of OHSS in women undergoing induction of ovulation for IVF are consistent with literature, but a multicentric study is required to confirm the role of urinary FSH in limiting hospitalization. Increasing number of participant would allow evaluating the implication of body mass index in OHSS severity.
Wider implications of the findings: For patient with risk factors, we propose short ovarian stimulation protocols, single embryo transfer or postponed transfer to limit hospitalisation. The development of vitrification had a key role to play in the management of patients at risk of OHSS either by embryo freezing or by oocyte vitrification. The next step is to define the best strategy: oocyte or embryo preservation.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Hopital Saint Joseph.
Trial registration number: NA.
Keywords: hospitalisation, OHSS, IVF, risk factors

O-053 Fertility awareness in the Flemish population: optimism can be disadvantageous

I. Delbaere[1], T. Vanderplancke[1], A. Bogaerts[2], V. Provoost[3], P. De Sutter[4], T. Tyden[5]
[1]*Vives University College, Nursing/Midwifery, Kortrjik, Belgium*
[2]*KHLim University College, Nursing/Midwifery, Hasselt, Belgium*
[3]*Ghent University, BioEthics, Ghent, Belgium*
[4]*Ghent University, Obstetrics, Ghent, Belgium*
[5]*Uppsala University, Public Health, Uppsala, Sweden*

Study question: Do Flemish adolescents, students and people of reproductive age have sufficient fertility-related knowledge in order to make informed decisions?
Summary answer: There is a lack of fertility-related knowledge within the Flemish population. Adolescents, students and people of reproductive age overestimate both their fertility and the efficacy of assisted reproduction.
What is known already: Similar studies have been performed in student-populations. Our results confirm earlier findings. Our study is the first in the Flemish (Belgian) population and the first study including results of adolescents and people of reproductive age.
Study design, size, duration: This study has a cross-sectional design. We included 989 adolescents (mean age 15 years), 348 students (mean age 23 years) and 374 persons of reproductive age (mean age 35 years, range 25–45 years).
Participants/materials, setting, methods: Adolescents were recruited at school (different education types). Students were recruited at their University College or at their University. People of reproductive age were randomly addressed in hospitals, sports facilities, play courts and shops. The Swedish Fertility Awareness Questionnaire (Lampic, 2006) was translated and adapted according to the study group.
Main results and the role of chance: The majority of Flemish adolescents, students and people of reproductive age believe that female fertility starts to decline after the age of 35 years. More than 50% of Flemish adolescents believe that there is a marked decrease in female fertility after age 50. Thirty-five percent of Flemish students believe there is a marked decrease in female fertility at age 40–44, 12% think there is a marked decrease at age 45–49 and 20% think there is only a marked decrease after the age of 50. Similar results are found in people of reproductive age. The majority of the Flemish population believes that there is a 40–100% chance to become pregnant in one ART-cycle.
Limitations, reason for caution: Schools were randomly selected, but participating schools were located in only two (out of five) provinces of Flanders. The difficulty-level of the questionnaire was possibly too high for the adolescents.
Wider implications of the findings: These results indicate that more education is needed in fertility-related factors. Increased knowledge is desired in order to allow informed decisions in family planning. Lack of knowledge may contribute to the tendency to postpone parenthood in Western countries.
Study funding/competing interest(s): Funding by national/international organization(s) – Praktijkgericht Wetenschappelijk Onderzoek (PWO).
Trial registration number: NA.

O-054 Nursing use of failure mode and effects analysis (FMEA) to review incident reports in an infertility clinic

G. De Franco[1], T. Skuza[1]
[1]*Mount Sinai Hospital, CFRH, Toronto, Canada*

Study question: The objective of the study is to review and analyze, using FMEA, all incident reports submitted to the hospital safety reporting database primarily focusing on ART lab /nursing communication.
Summary answer: Thirty-three percent of the incident reports were related to failure in communication between nursing and laboratory staff. Eight percent of the incidents were classified as severe; however, the majority were classified as mild.
What is known already: Communication is key to the delivery of safe, quality care in a medical setting. The complexity of a IVF clinic together with its rapidly changing technology, can complicate the exchange of information among different care providers. FMEA is a risk assessment tool designed to identify failure that may occur in a process in order to understand how and why mistakes happen.
Study design, size, duration: Review of incidents reports submitted between December 2013 and November 2014. Seventy-three incident reports filed.

Participants/materials, setting, methods: Members of the clinic report incidents that may compromise care. This could include any deviation from protocols, documentation, and transcription errors. All reports submitted to the safety reporting database between December 2013 and November 2014 were divided between those pertaining to ART lab and nursing communication and all others.
Main results and the role of chance: Seventy-three incidents were submitted in the period of December 2013 and November 2014. Twenty four (24) of the reports (33%) were related to communication between nursing and ART lab. These reports were classified according to FMEA. They were divided into 3 categories: minor, moderate, and severe. Fifteen (63%) were minor, two (8%) were severe and the remaining seven were moderate (29%). The majority of the incidents covered issues such as consents, transcription errors, physicians orders and documentation. None of these incidents caused harm to the patient. Chance is not a factor.
Limitations, reason for caution: There is no bias or confounding factors in this study.
Wider implications of the findings: The findings of this study are in line with other studies about communication and its complexity in healthcare. By improving communication many of these errors could be eliminated. The streamlining of paperwork and obtaining an electronic medical records (EMR) could also reduce communication errors.
Study funding/competing interest(s): Funding by hospital/clinic(s) – None.
Trial registration number: NA.
Keywords: nursing, communication, ART lab, quality

SESSION 16: EMBRYO CULTURE SYSTEMS AND OUTCOME

Monday 15 June 2015 **15:15–16:30**

O-055 The beneficial effect of autologous endometrial cells in an *in vitro* coculture system on human early embryo development: a randomized study

C. Le Saint[1], M. P. Lachambre[1], C. Lévesque[1], S. Phillips[2], B. Couturier[2], F. Bissonnette[2], J. N. Gouze[3], S. Hamamah[4], I. J. Kadoch[5]
[1]*Clinique Ovo, Ovo R&D, Montréal, Canada*
[2]*Clinique Ovo, Ovo Fertilité, Montréal, Canada*
[3]*Genbiotech, Sophia Antipolis, France*
[4]*CHRU Montpellier Hôpital Arnaud de Villeneuve, ART-PGD, Montpellier, France*
[5]*Clinique Ovo, Ovo Fertilité/R&D, Montréal, Canada*

Study question: What is the influence of autologous endometrial cells in a coculture system on blastocyst rate at day 5/6 (D5/6) compared with conventional culture medium in *in vitro* fertilization (IVF).
Summary answer: Autologous endometrial cells in an *in vitro* coculture system significantly improved the available blastocysts (D5/6) for single fresh embryo transfer and cryopreservation compared with conventional extended culture medium.
What is known already: *In vitro* culture conditions, including culture medium affect early embryo quality. For mimicking the microenvironment of early embryo development under IVF conditions, autologous endometrial coculture (ECC) system using the patient's own endometrial cells (EC) has been reported.
Study design, size, duration: This interventional, monocentric, randomized, double-blind controlled trial was conducted at our clinic in Canada, from April 2013 to November 2014 and is still ongoing. Forty-four IVF couples were enrolled into one of two embryo culture systems: conventional culture medium (26 controls) or on a coculture system of EC (18 coculture).
Participants/materials, setting, methods: For each patient, an endometrial biopsy was performed during luteal phase of the cycle prior to IVF. For the coculture group, EC were isolated from biopsies and grown on the day after ovulation triggering. At day 2, top quality embryos were placed either on ECC or in conventional culture medium.
Main results and the role of chance: At day 2, a total 193 and 108 top quality embryos were compared between control and coculture (mean ± SD per patient 7.4 ± 3.7 and 6.0 ± 2.2 respectively). At days 5 or 6, the blastulation rate was 34.7% (67/193) versus 60.2% (65/108) in the control and coculture groups respectively (P =0.00002). Consequently, the proportion of useful blastocysts (for fresh replacement or cryopreservation) in the coculture group was significantly higher (25.5 %) compared to the control group.
Limitations, reason for caution: The cohort size is low and the study is still ongoing at our institution.
Wider implications of the findings: The data revealed that a coculture system on endometrial cells improves the percentage of blastocysts for fresh transfer or cryopreservation compared with conventional culture medium. The coculture system of endometrial cells could potentially lead to a reduction of IVF cycles by increasing the cumulative implantation and clinical pregnancy rates. This hypothesis remains to be demonstrated by further analysis.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Genbiotech supplied the ECC freezing/culture kits free of charge. There were no conflicts of interests to be declared.
Trial registration number: ClinicalTrials.gov ID: NCT01886118.
Keywords: autologous coculture, endometrial cells, *in vitro* fertilization, embryo quality, blastocyst

O-056 Single step versus sequential culture medium: effects on embryo development, genetic and clinical outcomes

C. Scarica[1], F. M. Ubaldi[1], G. Orlando[1], L. Dovere[1], R. Maggiulli[1], M. Stoppa[1], E. Ievoli[1], A. Capalbo[1], L. Rienzi[1]
[1]*Genera c/o Clinica Valle Giulia, Gynaecology, Roma, Italy*

Study question: What is the impact of performing embryo culture in sequential or single step culture medium on embryo development, genetic and clinical outcomes?
Summary answer: Single medium culture system has a positive effect on embryo development. In particular, embryos cultured in this system show an increased blastocyst developmental rate as compared to embryos cultured in sequential media. No significant differences were found in aneuploidy rate and clinical outcomes between the two groups.
What is known already: The embryo culture has an important role to determine IVF success. Two approaches have been proposed. The first, defined "back to nature" is based on sequential culture media, which mimic *in vivo* conditions. The second, defined "let the embryo choose" is based on a single medium, which contains all the components needed during embryo development. No clear evidences are available to understand which is the most efficient approach.
Study design, size, duration: Prospective randomized cohort study conducted from September 2013 to September 2014. Patients were randomly assigned to Group A (embryo cultured in sequential medium; SAGE, USA), or Group B (single step medium without refresh on day 3; IrvineScientific, USA). Blastocyst formation rate, aneuploidy rate and clinical outcomes were compared between the two groups
Participants/materials, setting, methods: A total of 3.652 embryos were cultured either in a bench-top incubator (MINC, Cook, USA) or in the Embryoscope (Unisense, Denmark). 1.617 reached blastocyst stage, among which 1.007 blastocysts underwent also comprehensive aneuploidy screening on trophectoderm biopsy. Logistic regression analysis was used to control for confounding factors.
Main results and the role of chance: Blastocyst developmental rate was 43.0% (766/1782) for group A, and 45,4% (877/1930) for group B ($p < 0.05$). Logistic regression analysis adjusted for female age, sperm quality, stimulation protocol, incubator type, aneuploidy rate and clinical outcomes confirmed this association (OR = 0.86, 95% CI = 0.74–0.98). Blastocyst formation rate was significantly different according to the incubator type, 48,2% (519/1077) and 42.6%(1098/2575) for embryoscope and bench-top incubator respectively (OR1.36, 95% CI = 1.17–1.57; $p < 0.001$). Aneuploidy rate was similar between the two groups after adjustment for female age (58.6% and 61.8% for group A and B, respectively P = NS). Biochemical (group A = 3.3% and group B = 6.6%, OR = 0.59, p = NS), miscarriage (group A = 8.0% and group B =7.0%, OR = 0.89, p = NS) and ongoing implantation rates (group A = 46.4% and group B = 42.2%, OR = 1.15, p = NS) were comparable between the two groups.
Limitations, reason for caution: Clinical outcomes analysis should be extended to cumulative live birth rate, including all the thawed embryo transfers of the involved patients, to have more evidences about the culture systems efficiency. From this study design it cannot be excluded that the advantages observed in the use of single media system is also due to the reduced manipulation of embryos.

Wider implications of the findings: Optimal *in vitro* conditions to support blastocyst development is crucial in the modern embryology. Most of the new approaches for embryo selection and evaluation require extending the culture to blastocyst stage. The possibility to increase the relative blastocyst formation rate up to 20% by adjusting some simply laboratory protocols, excluding any negative effect on clinical outcomes, is crucial to continue the progression of embryology.
Study funding/competing interest(s): Funding by hospital/clinic(s) – None.
Trial registration number: NA.
Keywords: embryo culture, human embryo development, single medium, sequential medium, clinical outcomes

O-057 Effect of oxygen tension on embryo development and live birth in clinical *in vitro* fertilization (IVF) – the reproductive medicine network physiologic oxygen (PhOx) study

C. Coutifaris[1], J. Nulsen[2], M. Cedars[3], E. Eisenberg[4], H. Zhang[5]
[1]*University of Pennsylvania, Division of Reproductive Endocrinology and Infertility, Philadelphia Pennsylvania, U.S.A.*
[2]*University of Connecticut, Division of Reproductive Endocrinology and Infertility, Hartford Connecticut, U.S.A.*
[3]*University of California San Francisco, Division of Reproductive Endocrinology and Infertility, San Francisco California, U.S.A.*
[4]*National Institute of Child Health and Human Development, Fertility and Infertility Branch, Bethesda Maryland, U.S.A.*
[5]*Yale University, Center for Biostatistics in Medicine, New Haven Connecticut, U.S.A.*

Study question: Does a more physiologic oxygen tension (5% pO_2) improve live birth and embryo development rates in clinical IVF?
Summary answer: In fresh IVF cycles, in spite of an increase in implantation rate with the use of 5% pO_2, there is no difference in live birth rates between 5% and 20% pO_2. However, culture in 5% pO_2 results in significantly increased numbers of blastocysts available for transfer and cryopreservation.
What is known already: Embryos *in vivo* are exposed to substantially lower partial oxygen tension than in air. Elevated pO_2 increases free radicals leading to DNA damage and even short term oxidative stress is detrimental to gametes and embryos. In animal studies a 5% pO_2 is preferable, but human studies have been more difficult to interpret either showing improvement in development and/or live birth in good prognosis patients or demonstrating no significant benefit.
Study design, size, duration: Prospective, randomized, multicenter, double blind clinical trial evaluating the use of 5% vs. 20% pO_2 for the culture of human embryos. Primary outcome: Live birth. Secondary outcomes: Embryo development and utilization rates, implantation rate, pregnancy loss rate.
Participants/materials, setting, methods: 840 couples undergoing their first or second fresh, autologous IVF cycle with female partner ≤42 years of age. Sample size calculated to detect a 10% absolute difference in live birth rate between 5% and 20% pO_2 with 80% power and a 2-sided Type I error of 5%.
Main results and the role of chance: "There was no significant difference between live birth rates following embryo culture in 5% vs. 20% pO_2 (40.4% vs. 38.3%; $p = 0.551$). However, culture in 5% pO_2 resulted in a lower rate of day 3 and a higher rate of day 5/6 transfers ($p = 0.004$), a higher implantation rate regardless of day of transfer (32.4% vs. 27.7%; $p = 0.044$) and a higher blastocyst utilization rate (20.2% vs. 14.8%; $p < 0.001$) and frozen blastocyst per retrieved egg rate (7.7% vs. 5.7%; $p < 0.001$). There were no differences in pregnancy loss rates, neonatal birth weights or the incidence of low birth weight between the two groups. Although singletons in both groups delivered at or close to term (38.4 ± 2.2 vs. 39 ± 1.5 weeks), this difference favored embryos cultured in 5% pO_2 ($p = 0.045$).
Limitations, reason for caution: This study was powered to evaluate overall differences in live birth rates between 5% vs. 20% pO_2. No conclusions can be drawn as to whether there may be subgroups of couples whose delivery rate following IVF may benefit from a reduced pO_2. Nevertheless, the statistically significant results presented are intriguing.
Wider implications of the findings: Although live birth rates per embryo transfer procedure for embryos cultured in 5% vs. 20% pO_2 do not differ, the highly significant improvement in embryonic development and the increased number of generated and cryopreserved blastocysts support the conclusion that the more physiologic 5% pO_2 is the preferred oxygen tension for the culture of human embryos in clinical IVF at the present time.
Study funding/competing interest(s): Funding by national/international organization(s). Eunice Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, Maryland, USA
Trial registration number: NCT01010386.
Keywords: IVF, oxygen tension, embryo development

O-058 Should we consider Day-2 embryo quality before Day-5 transfer when blastocysts reach a similar good quality?

C. Herbemont[1], N. Sermondade[1], C. Sonigo[2], J. Boujenah[3], I. Cedrin-Durnerin[2], J. N. Hugues[2], C. Poncelet[3], M. Grynberg[2], C. Sifer[1]
[1]*Hôpital Jean Verdier, Histologie-Embryologie-Cytogénétique, Bondy, France*
[2]*Hôpital Jean Verdier, Médecine de la Reproduction, Bondy, France*
[3]*Hôpital Jean Verdier, Gynécologie-Obstétrique-Médecine de la Reproduction, Bondy, France*

Study question: Does Day-2 embryo morphology have an impact on the outcome of good-quality blastocysts transfers (BT)?
Summary answer: The present investigation failed to find any significant difference in the clinical pregnancy rates (CPR) between the transfers of good-quality blastocysts derived either from good or poor-quality embryos on Day-2.
What is known already: Recently, extended culture strategy has considerably spread, as a consequence of advances in culture media. BT improves implantation rates, as a result of the synchronization between embryonic stage and endometrial receptivity, and the possibility to improve embryo selection. Actually, the efficiency of this strategy has been demonstrated in good prognosis population. However, nothing is known upon the impact of Day-2 embryo morphology on the outcome of BT having equivalent good quality.
Study design, size, duration: We retrospectively analyzed 124 BTs performed on Day-5 between January 2012 and September 2014. Inclusion criteria were: (i) female age <37 years; (ii) IVF/ICSI rank ≤2; (iii) transferred blastocyst quality: blastocoele B3/4, inner cell mass A/B, trophectoderm A/B, according to Gardner and Schoolcraft classification; (iv) known implantation data.
Participants/materials, setting, methods: Embryo quality on Day-2 was reported and sorted into «good» or «poor» quality for each transferred blastocyst. Day-2 good-quality embryos were defined by the presence of 3–5 adequately-sized blastomeres and <20% fragmentation with no multinucleation. CPR were compared between groups of transferred blastocyst(s) derived from "good" or "poor Day-2 quality" embryo(s).
Main results and the role of chance: Patients' characteristics were similar between the «good» and «poor Day 2 quality» groups. Overall, women's mean age was 30.3 ± 4.1 and 30.2 ± 4.2 years, respectively. In addition, in both groups, mean attempt rank was 1.2, and an average of 1.1 blastocyst was transferred. Finally, in group «good Day-2 quality», 51 clinical pregnancies were obtained following 99 BTs (51.5%), whereas 12 clinical pregnancies out of 25 transfers (48.0%) were reported in the «poor Day-2 quality» group. The difference between those two rates was not significant.
Limitations, reason for caution: The main weakness of this work is the low number of analyzed cycles. A further prospective randomized study enrolling a larger number of patients is required to confirm these present data. Moreover, the analysis of live birth rates among both groups would be relevant.
Wider implications of the findings: Taking those results into account, good quality blastocyst transfer should be performed irrespective of embryo quality on Day-2, since it may not compromise success rates in our good prognosis population.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s) – Jean Verdier University Hospital.
Trial registration number: NA.
Keywords: good quality blastocyst, blastocyst transfer, Day-2 embryo quality interest

O-059 Comparison of development and ploidy status obtained in 127 sibling embryos, cultured in one-step or two-step medium with time-lapse technology in preimplantation genetic screening cycles

M. G. Minasi[1], S. Bono[2], V. Casciani[1], T. Riccio[1], M. Mariano[2], F. Scarselli[1], M. Barberi[1], V. Zazzaro[1], E. Iovine[1], M. T. Varricchio[1], F. Fiorentino[2], E. Greco[1]
[1]*Reproductive Medicine, European Hospital, Rome, Italy*
[2]*Molecular Genetics Laboratory, Genoma Group, Rome, Italy*

Study question: The aim of this study was to evaluate possible differences among blastocyst formation rate, ploidy status and time-lapse morphokinetics

in 127 sibling embryos, cultured in one-step or two-step media from the same brand, in Preimplantation Genetic Screening (PGS) cycles performed with trophectoderm biopsy and array comparative genomic hybridization (aCGH).
Summary answer: A statistically higher percentage of blastocyst was obtained and biopsied in one-step compared to two-step medium. In addition, the blastocysts started to blastulate faster in one-step than in two-step medium. However, the percentage of euploid blastocysts was comparable in the two groups.
What is known already: Some reports showed that the choice of culture medium could have a significant effect on early embryonic and fetal development. The choice of the best culture medium is still controversial. Different culture media can lead to morphologically identical blastocysts, suggesting that preimplantation embryos have high capability to adapt to different culture conditions. To date, most studies comparing different media have not considered their impact on ploidy status of the derived blastocysts.
Study design, size, duration: The development of 127 sibling embryos, obtained in 16 PGS cycles performed from November to December 2014 with trophectoderm biopsy and aCGH, were analyzed. Mean female age was 36.1 ± 4.46 years old. All embryos were cultured in a time-lapse incubator, allowing the morphokinetic parameters to be analyzed.
Participants/materials, setting, methods: The oocytes from each patient were randomly incubated in 1:1 ratio in one-step or two-step media (SAGE, ORIGIO, USA). After denudation, all mature oocytes were injected and cultured until the blastocyst stage, maintaining the same culture medium. The obtained blastocysts were biopsied and vitrified waiting for the genetic analysis.
Main results and the role of chance: In both group, 85 oocytes were injected, obtaining equivalent fertilization rates of 77.6% ($N = 66$) and of 82.4% ($N = 70$) in one-step versus two-step medium, respectively (NS). The embryos obtained on day-3 were 63/66 = 95.5% and 64/70 = 91.4% in one-step and two-step medium, respectively (NS). The number of blastocysts obtained was higher in one-step (73.0%, $N = 46$) compared to two-step medium (50.0%, $N = 32$; $p = 0.0106$). Forty and twenty-five of them were biopsied in one-step and in two-step groups, respectively. The percentages of euploid blastocysts were 40.0% ($N = 16$) in one-step and 52.0% ($N = 13$) in two-step groups (NS). All the morphokinetic parameters were analyzed: the only significant difference observed between the two groups was the starting blastulation time, being faster in one-step compared to two-step medium (107.42 ± 11.55 vs. 100.74 ± 9.46 h, $p < 0.01$).
Limitations, reason for caution: There is still a considerable disagreement regarding which morphokinetic parameters are useful to predict blastocyst formation, implantation potential and ploidy status of the embryos. More data, including clinical pregnancy, implantation and take home baby rates, are necessary, in order to choose the best culture conditions.
Wider implications of the findings: Although it seems that employing single-step medium can lead to a higher number of blastocysts available for genetic analysis and cryopreservation, the final percentage of euploid transferable ones is comparable to that obtained with sequential-medium. It remains to be established whether faster and more numerous blastocysts will lead to improved clinical outcomes, especially in some categories of patients that usually have a high cycle cancellation rate, as poor responders or severe male infertility.
Study funding/competing interest(s): Funding by hospital/clinic(s) – No specific funding was obtained for this study. None of the authors have any competing interests to declare.
Trial registration number: NA.

SESSION 17: ASSESSMENT OF OVARIAN RESERVE AT YOUNG AGE

Monday 15 June 2015 **15:15–16:30**

O-060 Diabetes mellitus (DM) during pregnancy is associated with maternal hyperandrogenism and elevated anti-Müllerian hormone (AMH) levels in the female offspring

C. Villarroel[1], P. Lopez[2], A. Salinas[1], G. Rencoret[2], P. Kohen[1], E. Codner[1]
[1]*Universidad de Chile, IDIMI, Santiago, Chile*
[2]*Hospital Clínico San Borja Arriarán, Servicio de Salud Centro, Santiago, Chile*

Study question: Is DM associated with maternal hyperandrogenism during pregnancy and elevated AMH levels in the female offspring?
Summary answer: Hyperandrogenism is observed in pregnant women with DM during the 2nd trimester and at time of delivery (TOD), which is associated with higher insulin levels. Daughters of women with DM have higher AMH levels suggesting that DM during pregnancy affects ovarian function of the offspring.
What is known already: Non-pregnant women with DM have higher androgen levels compared to healthy women, but it is not known whether hyperandrogenism is observed during pregnancy in diabetic women and the effect of maternal DM on the ovarian function of the female offspring
Study design, size, duration: Prospective study of pregnant women with Type 2 DM (mT2D, $n = 20$), Gestational Diabetes (mGD, $n = 27$) and control (mC, $n = 22$) carrying a female fetus. Assessment of the ovarian function of daughters of women with mT2D (dT2D, $n = 20$), mGD (dGD, $n = 27$), and mC (dC, $N = 22$).
Participants/materials, setting, methods: Blood sample of the mother was obtained: 24–28 weeks, 32–34 weeks and at TOD. A venous blood cord sample (VBCS) of the offspring was obtained at TOD. Androgens, insulin, IGF-1 HbA1c, and AMH levels were measured. Data analysis: ANOVA and Dunnett post test and Pearson's r correlation coefficient.
Main results and the role of chance: mT2DM and mGDM group had higher testosterone and insulin levels than mC at 32–34 weeks (1.0 ± 0.1 ng/ml; 0.7 ± 0.1 ng/m vs. 0.5 ± 0.1, $P < 0.001$; 28.4 ± 7.1 uUi/ml; 17.2 ± 4.4 uUi/ml vs. 9.5 ± 1.1 ng/ml; $P = 0.03$, respectively) and at TOD (1.1 ± 0.1 ng/ml; 0.8 ± 0.1 ng/ml vs. 0.7 ± 0.1 ng/ml; $P = 0.001$; 18.5 ± 2.6 ng/ml; 13.9 ± 2.3 ng/m vs. 10.2 ± 1.5 ng/ml; $P = 0.04$, respectively). Maternal T levels had a positive correlation with insulin ($r = 0.2$; $P = 0.04$) and IGF-1 levels ($r = 0.3$; $P = 0.01$). dT2DM and dGDM had higher AMH levels than dC (2.5 ± 0.7 ng/ml; 2.2 ± 0.9 ng/ml vs. 0.6 ± 0.3 ng/ml; $P = 0.04$.
Limitations, reason for caution: The size of our study may have limited the power of the study to detect an association of metabolic control with testosterone levels in pregnant women with DM.
Wider implications of the findings: This is the first study that shows that hyperandrogenism is observed in pregnant women with T2DM and GDM during the 2nd half of pregnancy. Diabetic environment during pregnancy affects the ovarian function of the female offspring at TOD, as shown by elevated AMH levels in these newborns. Long term follow up of the offspring is needed to evaluate their predisposition to develop Polycystic Ovary Syndrome is needed.
Study funding/competing interest(s): Funding by University(ies) – FONDECYT grant No 11121460 to Claudio Villarroel.

O-061 The influence of *in vivo* exposure to nonylphenol ethoxylate 10 (NP-10) on the ovarian reserve

Y. Shufaro[1], A. Saada[2], B. Tsuberi[3], M. Simeonov[1], C. Belaiche[2], A. Kogot-Levin[2], T. Shochat[1], B. Fisch[1], R. Abir[1]
[1]*Beilinson Hospital Rabin Medical Center, Sackler Faculty of Medicine, Tel Aviv University, Infertility and IVF Unit, Helen Schneider Hospital for Women, Petach Tikvah, Israel*
[2]*Hadassah-Hebrew University Medical Center, Department of Genetic and Metabolic Diseases, Jerusalem, Israel*
[3]*Hadassah-Hebrew University Medical Center, Transgenic Mice Unit, Jerusalem, Israel*

Study question: To determine the effect of environmental exposure to nonylphenol ethoxylate 10 (NP10, Tergitol), a non-ionic detergent, on the ovarian reserve in a controlled mouse model.
Summary answer: Exposure to NP-10 in the drinking water delayed the expected age-related decline in the ovarian response to gonadotropins, most probably by inhibiting primordial follicle recruitment.
What is known already: NP-10 is a common non-ionic detergent and is a wide spread environmental polluent. It penetrates the cellular and mitochondrial membranes and was recently shown *in vitro* to inhibit respiratory chain complex I activity. Its impact on the ovarian reserve is unknown.
Study design, size, duration: Female CB_6F_1 mice were maintained in a plastic free environment from 3 to 7 weeks. They drank HPLC grade water

supplemented with 4 μmol/L NP-10. Controls drank HPLC water. Untreated control groups were 3-weeks and 7-weeks old mice. At the endpoint they were stimulated, mated and embryos were *in vitro* cultured.
Participants/materials, setting, methods: Identically treated mice were sacrificed without ovarian stimulation. Their ovaries were examined for follicular population composition, apoptosis and proliferation. The enzymatic activities of respiratory chain complexes I and IV (cytochrome *c* oxidase) and citrate synthase (control enzyme) and reactive oxygen species (ROS) production was determined in brain and liver mitochondria.
Main results and the role of chance: Untreated 7-week old mice produced less oocytes (23.3 ± 3.1 vs. 66 ± 15.9) and embryos (15.3 ± 3.5 vs. 60 ± 15.5) than untreated 3-week old mice. 7-week old mice exposed to NP-10 produced more oocytes (34.2 ± 8.5 vs. 21.7 ± 8) and embryos (26.7 ± 6.5 vs. 5 ± 3.9) than the 7-week old controls drinking HPLC grade water. In the histological cross sections, significantly more primordial and primary follicles were counted in the ovaries of 7-week old NP-10 treated mice, than in the ovaries of the 7-week old controls (drinking HPLC grade water or untreated). In liver and brain mitochondria, the respiratory chain activities in citrate synthase, as well as ROS production, were not significantly different in NP-10 treated mice in comparison to controls.
Limitations, reason for caution: Our findings may be limited to the specific animal model studied.
Wider implications of the findings: In-vivo exposure to NP-10, in an animal model, ameliorated the age related decline in the ovarian response to gonadotropins by inhibiting recruitment of primordial follicles, without any detrimental effect on the cellular respiratory chain in the brain or liver. To the best of our knowledge this is the first reported successful inhibition of physiologic ovarian aging *in vivo*. The mechanism underlying this process is yet to be investigated.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Hadassah-Hebrew University Medical Centre, Beilinson Hospital, Rabin Medical Centre, affiliated to the Sackler Faculty of Medicine, Tel Aviv University.
Trial registration number: NA.

[3]*University of Bristol, Department of Epidemiology, Bristol, United Kingdom*

Study question: Do girls in the upper end of testosterone range have higher anti-Müllerian Hormone (AMH) levels at age 7, 9, 11, 13 and 15?
Summary answer: Girls with relatively high testosterone at age 15 had relatively higher AMH levels at ages 7, 9, 11 and 15.
What is known already: Longitudinal studies assessing the trends in AMH levels from childhood up to puberty are scanty. They are needed to establish a wider predictive value for ovarian reserve and testosterone levels in girls. There is evidence to a strong intra-individual tracking in AMH levels between ages 7 and 9 and 9 and 11 in girls. A recent report found strong correlation between AMH and testosterone levels at age 16 and future PCOS and hyperandrogenism.
Study design, size, duration: A retrospective study on a prospective European birth cohort. The study includes longitudinal assessment of the relationship between AMH levels at age 7, 9, 11, 13, and 15 and the testosterone, SHBG and FAI at age 15–16 years in 486 girls from the ALSPAC birth cohort.
Participants/materials, setting, methods: AMH assayed in blood samples collected age 7, 9, 11 and 13 in 486 girls. AMH, Testosterone and SHBG assayed age 15–16 in 1770 girls including the previous 486. Correlational statistical analyses were conducted to assess the relationship between AMH (at different ages) and testosterone, SHBG and FAI at age15–16.
Main results and the role of chance: There was a statistically significant relationship between testosterone and SHBG levels at age 15–16 and AMH levels at ages; 7 ($P < 0.001$), 9 ($p < 0.001$), 11 ($p < 0.001$), 13 ($p < 0.001$) and 15–16 ($p < 0.001$). There was a negative correlation between AMH at age 15–16 and SHBG at the same age ($p < 0.001$). The relationship between AMH and testosterone and SHBG remained statistically significant after adjusting for age of menarche, body mass index and total body fat. We conclude that AMH measured in childhood from age 7 years onwards has the potential to predict testosterone levels after menarche.
Limitations, reason for caution: The relatively small number that limits the proportion of girls with high testosterone level may limit establishing a reliable cut off points to assess AMH value as an early predictor of testosterone levels and potentially PCOS risk in early adulthood.
Wider implications of the findings: The results of the study suggest that the ovarian testosterone production is decided from as early as 7 years of age and potentially earlier. This is encouraging that in a larger samples we would be able to establish cut off points of AMH in childhood to predict accurately future testosterone levels thence the risk of related conditions such as PCOS and potentially cardiovascular risk. This should help guide health care measures.

O-063 Ovarian reserve screening in young women

F. Raga[1], M. J. Esquembre[1], S. Cholvi[1], M. Aznar[1], A. Carratala[2], A. Cano[1]
[1]*Hospital Clínico Universitario, OB/GIN, Valencia, Spain*
[2]*Hospital Clínico Universitario, BIOCHEM, Valencia, Spain*

Study question: Do we have the capability to detect young women with a poor ovarian reserve through the ultrasonographic and hormonal assessment of its ovarian reserve (OR)?
Summary answer: Using 3D-ultrasound technology and serum anti-Müllerian hormone (AMH) concentrations we are capable of identifying women with a diminished OR at an early age.
What is known already: OR is generated by the net result of the original magnitude of primordial follicle endowment. The size of this reserve, evaluated by antral follicle count (AFC), seems to be decidedly variable between individuals of similar age. Currently, AFC can be accomplished by two different methods: ovarian ultrasonography and measurement of endocrine markers, as both have a notable agreement with histologically assessed primordial follicle number and the response to gonadotropin stimulation in IVF treatment.
Study design, size, duration: A prospective, population-based, cross-sectional study conducted in our Department of Obstetrics, Gynaecology and Reproductive Medicine, from January 2009 to January 2015. The study was approved by the institutional review Board and all participants gave informed consent for the trial.
Participants/materials, setting, methods: *Study group*: 653 healthy women (18–29 years) recruited from students at University of Valencia. *Positive control group*: 12 women with high risk of premature ovarian insufficiency. *Negative control group*: 15 women with BCRA mutation undergoing prophylactic salpingo-oophorectomy (PBSO). 3D-ultrasound AFC and AMH level were determined on days 2–5 of menstrual cycle.
Main results and the role of chance: *Positive control group*: Young women in high risk of premature ovarian insufficiency presented significant low levels of AMH as well as reduce AFC. *Negative control group*: BCRA mutation carriers with normal AMH and AFC presented obviously undetectable AMH/AFC following PBSO. *Study group*: The prevalence of young women with poor ovarian reserve under both ultrasonographic and hormonal test was 4.74%. On the other hand, 14.69% of the participants presented a high ovarian reserve as they fulfilled both ultrasonographic and hormonal features of polycystic ovary syndrome. Therefore, 80.57% of the participants presented a mainstream OR. The mean AMH levels and AFC in women with poor OR in the study group were comparable to those detected in the group of patients in high risk of premature ovarian insufficiency.
Limitations, reason for caution: We cannot exclude potential selection bias due to undetermined differences between our sample (tertiary educated women) and background community.
Wider implications of the findings: A later start of childbearing is a prominent feature of recent fertility trends in developed countries. This postponement of motherhood has resulted in couples having children in a period when women's fecundity is already in decline. OR screening at a young age gives women the possibility to plan their childbearing. Consequently, those women presenting

a poor OR have the opportunity of anticipating maternity or preserving their fertility trough oocyte vitrification.

Study question: What is the effect of anti-cancer treatment on the ovarian function of long-term female survivors of childhood cancer (CCSs)?

Summary answer: Female CCSs are at an increased risk of a diminished ovarian function as measured by FSH, AMH, Inhibin B, and antral follicle count (AFC). Radiotherapy to the abdomen and/or pelvis, total body irradiation, as well as the use of alkylating agents are treatment factors associated with this increased risk.

What is known already: Over the past decades major improvements in the treatment of childhood cancer have resulted in high survival rates. However, among female CCSs a compromised reproductive system is an important and frequently encountered late effect. Anti-cancer treatment, often consisting of a combination of radiotherapy and chemotherapy, may reduce fertile life span and induce premature menopause, since therapy may deplete or accelerate the decline of the non-renewable pool of primordial follicles in the ovaries.

Study design, size, duration: The study is part of the DCOG LATER-VEVO study, a nationwide retrospective cohort study on female fertility of Dutch CCSs. The control group consisted of sisters of survivors and females from the general population. Data collection took place between January 2008 and May 2014.

Participants/materials, setting, methods: The study population consisted of female 5-year CCSs who were between 1963 en 2002 in The Netherlands, and who were at least 18 years at inclusion. Of the 1,108 CCSs and 819 controls who participated in the study, 633 (57%) and 433 (53%), respectively, provided blood and/or ultrasound data.

Main results and the role of chance: In general, median (interquartile range) FSH values were higher for CCSs compared to controls, whereas AMH, Inhibin B, and AFC were significantly lower (see Table).

	FSH (U/l)		AMH AMH (μg/l)		Inhibin B (ng/l)		AFC (no.)	
	Surv	Contr	Surv	Contr	Surv	Contr	Surv	Contr
Age 18–30 years (n = 606)	5.5 (2.4)	5.5 (2.1)	2.7 (3.5)	3.4 (3.8)	72.3 (50.4)	77.7 (54.8)	13.0 (7.0)	20.0 (13.0)
	ns		p = 0.01		p = 0.02		p < 0.001	
Age 31–40 years (n = 317)	6.3 (3.3)	6.1 (2.7)	1.2 (2.3)	1.5 (2.6)	53.5 (70.6)	73.8 (51.4)	9.0 (8.0)	13.0 (11.0)
	p = 0.02		p = 0.004		p < 0.001		p < 0.001	
Age ≥ 41 years (n = 138)	14.7 (36.1)	9.3 (16.2)	0.1 (0.2)	0.2 (0.8)	5.0 (34.1)	28.7 (61.5)	3.0 (7.0)	5.0 (6.0)
	ns		p = 0.002		p = 0..002		ns	

CCSs were at risk of having elevated FSH levels (>10 U/l), low AMH levels (<0.5 μg/l), low Inhibin B levels (<50 ng/l), as well as a low AFC (no. ≤5) (all p < 0.001). Treatment with radiotherapy to the abdomen and/or pelvis, total body irradiation, and alkylating agents, were significant independent predictors of reduced ovarian function.

Limitations, reason for caution: Treatment for childhood cancer often involves multimodal therapies. The effect of interaction of different treatment modalities as well the effect of doses and age at time of treatment remains to be established and will be evaluated in the near future.

Wider implications of the findings: The results of the study greatly improve the physician's ability to counsel female CCSs on family planning. However, not only female CCSs will potentially benefit from this study. Also females who are about to undergo cancer therapy may benefit since proven high risk populations can be offered fertility preservation timely. All with the aim of maintaining or improving the quality of life of these women.

Study funding/competing interest(s): Funding by national/international organization(s) – This work was supported by the Dutch Cancer Society (grant no. VU 2006-3622) and by Foundation Children Cancer Free. None of the authors report a conflict of interest.

SESSION 18: PREDICTOR FACTORS IN FEMALE INFERTILITY

Monday 15 June 2015 **15:15–16:30**

O-065 Chlamydia trachomatis serostatus is an independent predictor of pregnancy and pregnancy outcome

A. Steiner[1], W. M. Geisler[2], E. Eisenberg[3], M. Diamond[4], R. S. Legro[5], The Reproductive Medicine Network[6]

[1]*University of North Carolina at Chapel Hill, Obstetrics and Gynaecology, Chapel Hill, NC, U.S.A.*

[5]*Penn State University, Obstetrics and Gynaecology, Hershey, PA, U.S.A.*

[6]*U.S.A.*

Study question: Does seropositivity to *Chlamydia trachomatis* (Ct) predict pregnancy and pregnancy outcome among infertile women with documented tubal patency?

Summary answer: Even in the presence of tubal patency, anti-Ct IgG3 seropositivity is associated with a lower likelihood of pregnancy and live birth. Anti-Ct IgG3 seropositive women have up to 3 times the risk of ectopic pregnancy. Women on letrozole who are seropositive for anti-Ct IgG3 experience the greatest reduction in fertility.

What is known already: Ct antibody titers have been shown to predict tubal patency as documented by laparoscopic chromopertubation or

hysterosalpingography. However, specificity and reproducibility of results of commercial Ct antibody assays have been questioned, and few studies have examined the ability of Ct antibody assays to predict pregnancy without ART.
Study design, size, duration: We conducted an analysis of serum samples obtained from 1251 women enrolled in one of two randomized controlled trials: PPCOS II, a randomized controlled trial comparing clomiphene citrate and letrozole for treatment of PCOS, and AMIGOS, a randomized controlled trial comparing gonadotropins, clomiphene citrate, and letrozole along with intrauterine insemination in the treatment of unexplained infertility.
Participants/materials, setting, methods: All participants had documented patency of at least one fallopian tube. Sera were analyzed for anti-Ct IgG1 and IgG3 antibodies using a research Ct elementary body (EB)-based enzyme linked immunosorbent assay. OD_{405} readings ≥0.35 and ≥0.1 were considered positive for IgG1 and IgG3, respectively. Primary outcomes included pregnancy, live birth, and ectopic pregnancy. Log linear regression was used to determine the relative risk after adjusting for age, race, treatment, smoking status, and current alcohol use. Interaction terms were used to determine whether the association was modified by medication or number of patent tubes.
Main results and the role of chance: 243 (19%) women were seropositive for anti-Ct IgG3. They tended to be non-White and smokers. Anti-Ct IgG3 seropositive women were significantly less likely to conceive (RR 0.65, 95% CI 0.52–0.83) or to have a live birth (RR 0.59, 95% 0.43–0.80); these associations were weakened after adjusting for number of HSG-documented patent tubes (RR 0.73, 95% CI 0.56–0.97) and (0.73, 95% CI: 0.50, 1.04). Anti-Ct IgG3 seropositive women who conceived had 2.7 (95% CI: 1.40–5.34) times the risk of ectopic pregnancy. The association between anti-Ct IgG3 seropositivity and treatment outcome was not modified by number of patent tubes but was modified by treatment type; women on letrozole who were seropositive for anti-Ct IgG3 had a significant reduction in risk of pregnancy (RR 0.47, 95% CI: 0.32–0.71). Seropositivity for anti-Ct IgG1 antibodies was not associated with any of the outcomes.
Limitations, reason for caution: This is a secondary analysis. Although no women received ART, all women received treatment, thus these results cannot be generalized to predict spontaneous pregnancy among infertile women. The Ct EB ELISA used in this study is not commercially available.
Wider implications of the findings: Women who are seropositive for anti-Ct IgG3 have a significantly lower chance of conceiving, even in the setting of documented tubal patency; this may be due to underlying damage to fallopian tubal architecture. Future assessment of infertile women may include both an assessment of anti-Ct IgG3 seropositivity and hysterosalpingography.
Study funding/competing interest(s): Funding by national/international organization(s) – National Institutes of Health (NIH)/Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD).
Trial registration number: NCT00719186 and NCT01044862.
Keywords: Chlamydia, pregnancy prediction, ectopic

O-066 Anti-Müllerian hormone did not predict time-to-pregnancy in 301 spontaneously conceived pregnancies in women of reproductive age

H. W. Hvidman[1], A. K. Bang[2], L. Priskorn[2], K. Birch Petersen[1], A. Loft[1], A. Pinborg[3], N. Jørgensen[2], A. Nyboe Andersen[1]
[1]*Rigshospitalet Copenhagen University Hospital, The Fertility Clinic, Copenhagen, Denmark*
[2]*Rigshospitalet Copenhagen University Hospital, The Department of Growth and Reproduction, Copenhagen, Denmark*
[3]*Hvidovre Hospital Copenhagen University Hospital, The Department of Obstetrics and Gynaecology, Hvidovre, Denmark*

Study question: Is anti-Müllerian hormone (AMH) serum levels associated with time-to-pregnancy (TTP) in spontaneously conceived (SC) pregnancies; and does serum-AMH concentration decrease in early second trimester of pregnancy?
Summary answer: AMH measured in pregnancy was not associated with TTP in SC pregnancies in younger women. Fecundability estimated by TTP declined with female age, nulliparity, and oral contraceptive (OC) use prior to conception. Circulating serum-AMH concentration decreased slightly but significantly with gestational week (GW).
What is known already: AMH is a sensitive marker of the ovarian reserve and the response to ovarian stimulation, and to some extend AMH predicts ongoing pregnancy rates in ART. TTP is a well-established measure of fecundability. Few studies have investigated the correlation between AMH and TTP in natural conception and it remains uncertain whether AMH can predict TTP in fertile women. AMH-levels are known to decrease during pregnancy, but knowledge of the changes in second trimester is still limited.
Study design, size, duration: A cross sectional study of 301 couples with a spontaneous conception. Participants were residents in the Capital Region of Denmark and recruited at the time of the nuchal translucency scan between 2012 and 2014. Women were aged 21–42 years and pregnant at inclusion.
Participants/materials, setting, methods: TTP was reported retrospectively in an online questionnaire. AMH was measured within 4 weeks of inclusion. AMH z-scores defined as the deviation from the mean AMH for the specific GW were calculated. Data were analysed by discrete-time survival-analysis adjusted for female age, AMH z-score and sperm concentration.
Main results and the role of chance: The mean (SD) female age was 31(3.6) years and the median(range) TTP was 2(1–32) months. Fourteen (4.7%) women had a TTP >12 months. The median(range) AMH was 23.0(<3.0;144) pmol/l. Median(range) GW at blood sampling was 13(11–19). In a linear regression analysis, AMH decreased with GW (0.93, 95% CI: 0.88–0.97). AMH z-score and TTP were unrelated in the unadjusted survival analysis (OR: 0.91, 95% CI: 0.78; 1.07). In the adjusted survival analysis, TTP remained unrelated to AMH z-score (OR: 0.87, 95% CI: 0.73; 1.03) and sperm concentration (OR:1.05, 95% CI: 0.92; 1.20), whereas TTP decreased with female age (OR: 0.94, 95% CI: 0.89; 0.99), preconception OC-use (OR: 0.61, 95% CI: 0.43; 0.86), and nulliparity (OR: 0.66, 95% CI: 0.44; 0.97). AMH remained an insignificant predictor if crude AMH-levels were used instead of AMH z-scores. Six women had a very low AMH (<5 pmol/l), of whom five conceived within 2 months.
Limitations, reason for caution: The retrospective design implies a risk of recall bias. No data on pre-pregnant AMH-levels were available. Few had an AMH <5 pmol/l and 85% were aged between 26 and 35, limiting our ability to conclude whether very low AMH-levels in women of advanced reproductive age are associated with prolonged TTP in natural conception.
Wider implications of the findings: We did not find a correlation between AMH and TTP in SC ongoing pregnancies, possibly because AMH reflects oocyte quantity rather than quality in younger women of reproductive age. Prospective studies including women of a broader age range, ensuring pre-pregnant measurement of AMH and sperm concentration in pregnancy-planners are needed. Identifying reliable measures to advice women on their future fecundity would be an important step towards preventing unwanted childlessness.
Study funding/competing interest(s): Funding by national/international organization(s), Funding by commercial/corporate company(ies) – The study received funding from MSD and the European Union (EU) Interregional projects "ReproSund" and "ReproHigh". The authors have no conflict of interest.
Trial registration number: NA.

O-067 Predicting live birth from *in vitro* fertilisation: a novel pre-treatment prediction tool

R. K. Dhillon[1], D.J. McLernon[2], P. P. Smith[1], K. Dowell[3], S. Fishel[3], J. Deeks[4], S. Bhattacharya[2], A. Coomarasamy[1]
[1]*University of Birmingham, School of Clinical and Experimental Medicine, Birmingham, United Kingdom*
[2]*University of Aberdeen, Division of Applied Health Sciences School of Medicine and Dentistry, Aberdeen, United Kingdom*
[3]*CARE Centres for Assisted Reproduction, John Webster House 6 Lawrence Drive Nottingham Business Park, Nottingham, United Kingdom*
[4]*University of Birmingham, School of Health and Population Sciences, Birmingham, United Kingdom*

Study question: The aim of this study was to build and validate a model to predict live birth for women undergoing their first fresh non-donor IVF cycle using key covariates *available before start of treatment*.
Summary answer: Our validated final model allows estimation of the probability of live birth, *before* commencing treatment, for women undergoing their first fresh non-donor cycle of IVF, while accounting for: age, body mass index (BMI), ethnicity, ovarian reserve, history of previous live birth, history of miscarriage, and cause and duration of infertility.

What is known already: The two most widely recognised prediction models for live birth following IVF were developed on data from 1991 to 2007. Given the advancements in assisted reproduction technology over time, there is a need for a more up-to-date model built on recent data. Furthermore, the existing IVF outcome prediction models do not incorporate key pre-treatment predictors, such as BMI, ethnicity and ovarian reserve, which are readily available.
Study design, size, duration: In this cohort study a model to predict live birth was derived using data collected from 9915 women who underwent IVF treatment at any CARE (*Centres for Assisted Reproduction*) clinic from 2008 to 2012. Model validation was performed on data collected from 2723 women who underwent treatment in 2013.
Participants/materials, setting, methods: Data were collected from 12 fertility clinics within the CARE consortium: Nottingham, Manchester, Northampton, Sheffield, Dublin, Bolton, Boston, Derby, Leicester, Mansfield, Northampton and Peterborough. Multivariable logistic regression was used to develop the model. Discriminatory ability and calibration were assessed using the c-statistic and calibration slope test respectively.
Main results and the role of chance: The predictors in the final model were female age, BMI, ethnicity, antral follicle count (AFC), previous live birth, previous miscarriage, cause and duration of infertility. Upon assessing predictive ability, the c-statistic for the final model and validation cohort was (0.6204; 95% CI 0.6088–0.6321) and (0.6167; 95% CI 0.5988–0.6401) respectively. The calibration slope was not statistically significant ($p = 0.28$), suggesting the model fitted the data. A 38-year-old Caucasian woman (BMI = 35; AFC = 14) with 5 years of male factor infertility and a previous miscarriage, would have a probability of live birth of 0.26. Other factors remaining the same, this probability would rise to 0.28 if her BMI was 25, and fall to 0.21 if her age was 30 and ethnicity was Black.
Limitations, reason for caution: Our model is unable to account for factors such as smoking and alcohol that can affect IVF outcome. In addition, patients and clinicians should understand this model is designed for use *before* treatment begins and does not include variables that become available (oocyte, embryo and endometrial) as treatment progresses.
Wider implications of the findings: We have developed a novel, up-to-date model, which encompasses key prognostic factors that have not previously been used, such as body mass index, ovarian reserve and ethnicity. The model can be used to build a user-friendly interface to help couples and their clinicians. It could then be possible to conduct a feasibility study of its implementation, focused on patient acceptability and impact on counselling and decision-making.
Study funding/competing interest(s): Funding by University(ies) – Dr. Dhillon is paid by the University of Birmingham, however, the study itself required no specific funding/grant.
Trial registration number: NA.
Keywords: prediction model, IVF, predictive factors, live birth

O-068 Does donor oocyte conception act as an independent risk factor for pregnancy complications?

Y. B. Jeve[1], N. Potdar[1], M. Khare[1]
[1]*University Hospitals of Leicester, Obstetrics and Gynaecology, Leicester, United Kingdom*
Study question: Are donor oocyte (DO) conceptions associated with increased risk of antenatal and obstetric complications compared to conceptions with autologous oocyte in vitro fertilization?

Summary answer: DO conception is associated with statistically significant increased risk of hypertensive disorders in pregnancy, intrauterine growth restriction, preterm delivery and caesarean section compared with autologous oocyte *in vitro* fertilization conceptions.
What is known already: The most common complications observed with DO conceptions are higher than expected incidence of pregnancy-induced hypertension and pre-eclampsia ranging from 16 to 40% of cases. It is suggested that immunologic intolerance between the mother and the fetus plays an important role in the pathogenesis of pre-eclampsia, however, advanced maternal age has been reported as a significant confounding factor in many studies.
Study design, size, duration: Evidence synthesis was done by performing a systematic review and meta-analysis of the existing literature. Literature search was done using Medline (1950-Oct 2014), Embase (1980-Oct 2014) and the Cochrane Library (Oct 2014) for relevant citations. In total, 16 prospective controlled studies with 82,947cycles were included in this study. Quality assessment was performed using Newcastle-Ottawa scale.
Participants/materials, setting, methods: All observational studies comparing various antenatal and obstetric outcomes in DO pregnancies with a predefined control group for comparison were included. Primary outcome measure was hypertensive disorders in pregnancy. Secondary outcome measures included gestational diabetes, intrauterine growth restriction, preterm delivery, intrauterine death and caesarean section.
Main results and the role of chance: The risk of developing hypertensive disorders in pregnancy was significantly higher in the DO conception than autologous oocyte conception (OR 3.85, 95% CI 3.06–4.85). Subgroup analysis showed increased risk in twin gestation (OR 3.77, 95% CI 2.59–5.49) and maternal age > 40 (OR 2.33, 95% CI 1.21–4.49). Similarly the risk of intrauterine growth restriction (OR 1.81, 95% CI 1.26–2.60), preterm delivery (OR 1.39, 95% CI 1.13–1.70) were significantly higher in DO conception. Risk for caesarean delivery was significantly higher (OR 2.71, 95% CI 2.23–3.30) for singleton DO pregnancies. The risk of intrauterine death and development of gestational diabetes were not statistically significant.
Limitations, reason for caution: The meta-analysis is performed on prospective observational studies since there were no randomised trials performed. Some heterogeneity between studies was observed and accordingly Fixed and Random effect models were used. We included. only published data in the review.
Wider implications of the findings: DO conception should be treated as an independent risk factor for various pregnancy complications including hypertensive disorders of pregnancy. Couples should be counselled carefully about the risks before undergoing fertility treatment. There may be a role for managing uch pregnancies be managed in dedicated Obstetric clinics with appropriate surveillance strategies to improve outcomes for mother and babies. Although hypertensive disorders of pregnancy are attributed to immunological origin by few authors, further research is required to explain the pathogenesis involved in donor egg pregnancies.
Study funding/competing interest(s): Funding by hospital/clinic(s) – None.
Trial registration number: NA.
Keywords: donor oocyte, pregnancy complications, IVF

O-069 The effect of small uterine dimensions on pregnancy and live birth rates after embryo transfer

S. Ates[1], T. Shaulov[1], M. H. Dahan[1]
[1]*McGill University, Gynaecology, Montreal, Canada*
Study question: Do small uterine dimensions affect the likelihood of pregnancy and live birth after single embryo transfer?

Summary answer: Shorter uterine cavity length and uterine width are associated with decreased chances of pregnancy after *in vitro* fertilization (IVF) after controlling for confounding effects, while a shorter baseline cervical length is associated with preterm delivery.
What is known already: Women with uteri that are enlarged due to pathology such as leiomyomata are prone to subfertility. The impact of smaller uterine dimensions on embryo transfer outcomes is not as clear. A study evaluating endometrial cavity length by sounding found lower pregnancy rates among women with shorter cavities, and consequently suggested a subsequent study using ultrasonographic measurements.
Study design, size, duration: This retrospective study includes 274 nulliparous and 37 multiparous who underwent their first single blastocyst transfer from 2010 to 2014 at a university IVF center. Uterine dimensions were divided into quartiles, and data was analyzed using stepwise logistic regression, controlling for age, ovarian reserve, smoking and body mass index.
Participants/materials, setting, methods: Baseline uterine dimensions were measured by transvaginal ultrasound using a General Electric Voluson E8 machine. The endometrial cavity length and thickness; uterine body length, depth, and width; and cervical length, were evaluated between cycle day 2 and 5. Women were excluded if they had any uterine anomalies.
Main results and the role of chance: For nulliparous women, there was a lower likelihood of pregnancy among those in the lowest quartile for endometrial length (EL) ($p = 0.05$) and uterine width (UW) ($p = 0.02$). Pregnancy rate was not affected by baseline endometrial thickness (ET) ($p = 0.34$), uterine length (UL) ($p = 0.12$), uterine depth (UD) ($p = 0.30$) or cervical length (CL) ($p = 0.95$). None of the following measurements predicted progression to a clinical pregnancy with a heart beat: EL ($p = 0.06$), ET ($p = 0.14$), UL ($p = 0.79$), UD ($p = 0.06$), UW ($p = 0.73$), or CL ($p = 0.10$). Progression to a live birth was less likely in the lowest quartile of cervical length ($p = 0.02$), but none of the other measurements were predictive of a term live birth. In multiparous women,

none of the measurements predicted the likelihood of pregnancy, clinical pregnancy or live birth.
Limitations, reason for caution: This is a retrospective study with its inherent limitations and bias. However, it is the first study in the literature to evaluate this question.
Wider implications of the findings: Since shorter endometrial length and uterine width were associated with lower pregnancy rates, this could be valuable prognostic information for those undergoing IVF. Uterine width may be a useful surrogate for endometrial cavity width. Women with shorter baseline cervical lengths could be identified for closer surveillance during pregnancy, as this seems to favour pre-viable preterm delivery. Future prospective studies would be useful in further examining the relationship between small uterine dimensions and pregnancy outcomes.
Study funding/competing interest(s): Funding by hospital/clinic(s) – None

SESSION 19: ADVANCES IN DIAGNOSIS AND PREVENTION OF MISCARRIAGE

Monday 15 June 2015 **15:15–16:30**

O-070 Is there an increased risk of Down syndrome in ART as often shown in the first trimester prenatal screening: results of a large multicentre study

M. Cohen Bacrie[1], S. Bourriquet[2], S. Belloc[3], T. Ternaux[3], J. de Mouzon[4]
[1]*Laboratoire d'Eylau Unilabs, ART Unit, Paris, France*
[2]*Laboratoire Biomnis, Prenatal Diagnosis, Paris, France*
[3]*Laboratoire d'Eylau Unilabs, ART Unit, Paris, France*
[4]*INSERM, Public Health, Paris, France*

Study question: The purpose of the study was to verify if the increased risk of Down syndrome (DS) calculated by the screening procedures, shown in ART, was related to a real increase of this syndrome or to a simple artefact of the equation, thus needing its adaptation for ART.
Summary answer: The equation for risk estimation at screening procedure showed an increased estimated risk of DS in ART compared to natural pregnancies. However, the total number of confirmed DS (abortions + births) was not significantly increased
What is known already: In first trimester screening for Down syndrome, risk calculation combines maternal age, nuchal translucency and 2 biochemical markers: pregnancy-associated plasma protein A (PAPP-A) and free b-hCG. Several authors reported decreased levels of PAPP-A in pregnancy after IVF/ICSI and, consequently, an increased of DS in ART pregnancies. However, which is questionable, is the origin of PAPPA-decrease, ART pregnancy itself or artefact due to treatments.
Study design, size, duration: This study is a retrospective cohort of tests performed from January 2010 to December 2013 in 2 centres performing first trimester screening of Down syndrome. In total, 28920 tests performed at gestational age 10–13 weeks were included in the analysis (19053 and 9867 in centres 1 and 2, respectively).
Participants/materials, setting, methods: The sample comprised 1510 IVF pregnancies, 436 ICSI, 351 frozen embryo transfers (FET), 719 egg donations (ED), 351 intrauterine inseminations (IIU), and 25430 natural conceptions. The risk of DS and the total percentage of DS (abortions + births) were compared. Main confounders were considered with analysis of variance-covariance and logistic regression.
Main results and the role of chance: Pregnancies with high DS risk (>1/250) were significantly more frequent in IVF (6.9%), ICSI (7.6%), FET (5.7%), IIU (6.3%), compared to natural conceptions (3.9%). In the multiple logistic model (including women's age, previous history, centre), IVF was associated to a higher risk (OR = 1.65, 95% confidence interval = 1.31–2.07), as ICSI (2.26, 1.54–3.32) and IIU (1.65, 1.11–2.46). FET and ED were not significant (1.17, 0.78–2.05 and 0.61, 0.33–1.11, respectively). Finally, PAPPA was decreased in ART, while βHCG and nuchal translucency was increased. In total, 52 DS were confirmed (1,80 *p* 1000). Their frequency was not higher with ART (2.58 vs. 1.69 *p* 1000, $p = 0.25$). In the multilogistic model, the risk was not significant higher for ART (OR = 1.57; 0.74–3.33, $p = 0.24$) and there was no difference according to ART type.
Limitations, reason for caution: This study is one of the largest performed on this topic. It relies on a retrospective cohort and on multivariate analysis. However, The number of cases with Down syndrome is still relatively low which is a limitation to analyse individual ART techniques.
Wider implications of the findings: This study clearly shows, on a large sample, that the current calculations performed to evaluate the risk of Down syndrome in the first trimester screening results in a doubling of risk in ART. On the other hand, the percentage of really diagnosed DS is not significantly increased. This still needs to be confirmed, but is also a strong argument to work on an adaptation of the equation in case of ART, to obtain a more reliable risk estimation.

O-071 Correlation between ultrasound findings and abnormal karyotypes in the embryos from early pregnancy loss after *in vitro* fertilization-embryo transfer

X. H. Li[1], Y. Yi[2], F. Gong[3], Y. Q. Tan[3], G. Lin[3], Y. Ouyang, [2], G. X. Lu[2]
[1]*Reproductive and Genetic Hospital of CITIC-XIANGYA, Medical Imaging Department, Changsha, China*
[2]*Central South University, Institute of Reproductive and Stem Cell Engineering, Changsha, China*
[3]*Reproductive and Genetic Hospital of CITIC-XIANGYA, Assisted Reproductive Center, Changsha, China*

Study question: To evaluate the correlation between ultrasound findings and karyotypes in the embryos from patients with early pregnancy loss (EPL) after *in vitro* fertilization-embryo transfer (IVF-ET).
Summary answer: ultrasound findings are associated with abnormal karyotypes in embryos from EPL after IVF-ET.
What is known already: Approximately 10–15% of natural pregnancies end with miscarriage in the first trimester, and about 50% of spontaneous miscarriages result from chromosomal abnormalities. Whether the ultrasound findings of embryos from EPL are related to specific chromosomal abnormalities remains unclear. Few studies have evaluated the correlation between ultrasound findings and karyotypes in embryos from EPL after IVF-ET, but existing results are inconsistent.
Study design, size, duration: The embryos data from 793 IVF patients who experienced EPL between July 2005 and December 2011 were retrospectively analyzed. The samples of chorionic villi from all miscarriage tissues were collected.
Participants/materials, setting, methods: This analysis included 793 subjects with EPL after IVF-ET. All subjected were examined by transvaginal ultrasonography before diagnosis EPL. Karyotyping of miscarriage tissues was performed using cytogenetic analysis by comparative genomic hybridization (CGH) analysis plus fluorescence in situ hybridization technology(FISH) technology. The correlation between ultrasound findings and karyotypes was evaluated.
Main results and the role of chance: In the 793 embryos from EPL, the abnormal karyotype rate was 44.77% (355/793). According to different ultrasound findings, the abnormal karyotype rates in the groups of small gestational sac, early symmetrical arrested growth, small embryonic pole, normal ultrasound, only yolk sac, and empty gestational sac were 58.33% (14/24), 56.17% (91/162), 50.49% (52/103), 44.67% (67/150), 44.51% (77/173), and 29.83% (54/181). Compared to the study population, the prevalence of chromosomal abnormalities was significantly higher in the early symmetrical arrested growth group, but markedly lower in empty sac group ($P < 0.05$). Trisomy 16 was the most frequent chromosomal abnormality in the only yolk sac, early symmetrical arrested growth and small embryonic pole groups. Monosomy X was the most common aneuploidy in the empty gestational sac and normal ultrasound groups.
Limitations, reason for caution: The abnormal karyotype rate in the small gestational sac group was 58.33% (14/24), and was not associated with a specific chromosomal abnormality. Thus, further study with a larger sample may be helpful to elucidate this inconsistency.

Wider implications of the findings: All patients in this study received IVF treatment and gestational age was accurate, which are helpful to assess the ultrasound findings. We used CGH technology to overcome the limitation of long-duration cell culture for conventional chromosome G-banding. DNA from chorionic villi was extracted for CGH analysis using conventional DNA extraction methods, and FISH detection was used to exclude polyploidy. The ultrasound findings may indicate the frequency of specific chromosomal abnormality in the embryos from EPL.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Reproductive and Genetic Hospital of Citic-Xiangya.
Trial registration number: None.

O-072 Miscarriages in female rheumatoid arthritis patients – associations with serology, disease activity and anti-rheumatic treatment

J. Brouwer[1], R. J. E. M. Dolhain[2], J. M. HazesW.[2], J. S. LavenE.[3]
[1]*Erasmus MC, Division of Reproductive Medicine – Obstetrics & Gynaecology/Rheumatology, Rotterdam, The Netherlands*
[2]*Erasmus MC, Rheumatology, Rotterdam, The Netherlands*
[3]*Erasmus MC, Division of Reproductive Medicine – Obstetrics & Gynaecology, Rotterdam, The Netherlands*

Study question: Are miscarriages in women with rheumatoid arthritis (RA) associated with RA serology, disease activity or periconceptional use of anti-rheumatic drugs?
Summary answer: RA patients who miscarried tended to be older, to have higher disease activity, to be anti-citrullinated protein antibody (ACPA) positive and to have a past of methotrexate use. This indicates that miscarriages are more likely to occur in RA patients with a more severe disease.
What is known already: Since human embryo implantation appears to be facilitated by local inflammatory reactions of the endometrium, chronic inflammatory conditions like rheumatoid arthritis (RA) may increase the risk for miscarriage. Several reports confirm an increased risk of miscarriage in women with RA. However, the association of miscarriage with RA disease activity or the use of anti-rheumatic medication is unclear, mainly due to lack of prospective studies.
Study design, size, duration: within a nationwide prospective cohort study on pregnancy in RA (PARA study), 213 patients were enrolled preconceptionally in 2002-2008 and followed until 6 months after delivery or miscarriage.
Participants/materials, setting, methods: Variables of interest were: maternal age, presence of rheumatoid factor, presence of ACPA, disease activity, use of non-steroidal anti-inflammatory drugs, use of sulfasalazine, past use of methotrexate, and total number of disease modifying anti-rheumatic drugs. Variables with a p-value <0.20 in the univariate analysis, were further analysed using logistic regression.
Main results and the role of chance: Amongst 162 pregnancies 28 miscarriages occurred [17% (95% CI = 12.2–24.0%)]. Women who miscarried were older than women with an ongoing pregnancy (33.9 ± 3.9 vs 32.0 ± 3.8 years, p = 0.022), tended to be more often ACPA positive (82 vs 60%, p = 0.058), to have higher disease activity scores (DAS 28 of 3.92 ± 0.94 vs 3.59 ± 1.17, p = 0.166) and more often to have used methotrexate in the past (82 vs 68%, p = 0.174).

Logistic regression showed a tendency towards a higher odds ratio to miscarry for increasing age [OR 1.11 (0.99–1.25) per year increase, p = 0.076], presence of ACPA [OR 2.49 (0.86–7.20), p = 0.092], and past methotrexate use [OR 2.52 (0.86 – 7.08), p = 0.091]. The association with disease activity was less significant in the multivariate analysis [OR 1.27 (0.86–1.88), p = 0.227].
Limitations, reason for caution: Although the PARA study is the world's largest prospective cohort on pregnancy in RA, the frequency of miscarriages was relatively low, limiting the possibilities for multivariate analysis. The relatively low number of miscarriages may be due to a known healthy cohort effect in the PARA study.
Wider implications of the findings: Since both ACPA positivity as well as previous methotrexate treatment, both markers for a more active disease, showed an association with the occurrence of miscarriage, it is likely that disease severity increases the risk for miscarriage. Chronic inflammation and the use of anti-inflammatory drugs may cause a disturbance in embryo implantation and decidualisation. This may also be true for other auto-immune diseases or for women using anti-inflammatory drugs periconceptionally for other conditions.
Study funding/competing interest(s): Funding by national/international organization(s) – Dutch Arthritis Foundation (Reumafonds).
Trial registration number: NA.

O-073 Decidualization of human endometrial stromal cells regulates cellular and extracellular retinoic acid levels at implantation

R. Ozaki[1], K. Kuroda[1], F. Tsutomu[2], M. Kitade[1], J. Kumakiri[1], M. Jinushi[1], A. Matsumoto[1], A. Itakura[1], J. Brosens[3], S. Takeda[1]
[1]*Juntendo University Faculty of Medicine, Obstetrics and Gynaecology, Tokyo, Japan*
[2]*Juntendo University Faculty of Medicine, Proteomics and BioMolecular Science Biomedical Research Center, Tokyo, Japan*
[3]*Clinical Science Research Laboratories Warwick Medical School, Division of Reproductive Health, Coventry, United Kingdom*

Study question: To investigate the role of retinoids in decidualization of human endometrial stromal cells (HESCs).
Summary answer: Decidualization decreases cellular levels of retinoic acid (RA) and retinal. Conversely, treatment of HESCs with RA inhibited decidualization, further emphasizing the importance of the retinol pathway in endometrial preparation. Decidualizing HESCs may regulate extracellular levels of retinoids, critical for post-implantation embryogenesis, through induction of metabolic enzymes and the transport protein.
What is known already: Optimal decidual transformation of HESCs is essential for embryo implantation and placental formation. Retinoids are key regulators of cellular differentiation/apoptosis and important for maternal tolerance of the embryonic semi-allograft. Excessive levels, however, are embryotoxic. Previous microarray data studies indicated that genes involved in retinol signaling and metabolism are highly regulated in the endometrium during the implantation window and upon decidualization.
Study design, size, duration: This study was approved by the Local Ethics Committee of Juntendo University, Faculty of Medicine (No.14–103). Timed endometrial biopsies (LH + 7–11) were processed for primary HESC cultures.
Participants/materials, setting, methods: Primary HESCs were decidualized with 8-bromo-cAMP, progesterone and cortisone in the presence or absence of RA or retinal. Various molecular techniques, including chromatography, RTQ-PCR, and Western blot analysis, were employed to define the role and mechanisms of retinoid metabolism signaling.
Main results and the role of chance: Compared to undifferentiated HESCs, cellular concentrations of RA and retinal were decreased in decidualizing cells. Treatment of primary cultures with RA suppressed the expression of decidual markers (PRL, IGFBP1, and 11bHSD1) in a dose-dependent manner. Decidualization also decreased the expression of the RA-binding proteins CRABP2 and FABP5 in HESCs. Expression of the RA receptors, RARalpha (associated with apoptosis induction) and PPARdelta (associated with cell differentiation), were inhibited and induced upon decidualization, respectively. Treatment with RA or retinal selectively upregulated the expression of CRABP2 and RARalpha, but not FABP5 or PPARdelta. In addition, decidualization was associated with induction of the enzymes, which convert retinal to retinol, and the retinol transport protein RBP4, and these expression was further enhanced in response to treatment with retinal.
Limitations, reason for caution: The present results were obtained by *in vitro* analysis of HESCs. These *in vitro* findings do not necessarily reflect the complex *in vivo* situations.
Wider implications of the findings: Apart from promoting differentiation of the endometrium, the wholesale reprogramming of the retinol signaling, transport, and metabolism pathways in decidualizing HESCs may be critical in limiting exposure of the implanting conceptus to RA in early pregnancy.
Study funding/competing interest(s): Funding by University(ies) – Funding by JSPS KAKENHI Grant Number 25861508, the Uehara Memorial Foundation, and Juntendo University Young Investigator Award 2013.
Trial registration number: None.

O-074 The effect of bone marrow mesenchymal stem cells (MSCs) on the recurrent spontaneous abortion (RSA)

Y. Meng[1], X. Zhu[1], L. Yan[1], Y. Zhang[1], R. Li[1], J. Qiao[1]
[1]*Peking University Third Hospital, Reproductive Medical Center Department of Obstetrics and Gynaecology, Beijing, China*

Study question: The aim is to study the effect of bone marrow mesenchymal stem cells (MSCs) on the recurrent spontaneous abortion (RSA).
Summary answer: Injection of MSC through uterine horn make the CD4 $^{+}$T cells and macrophages at the maternal-fetal interface shifted to the immune tolerance phenotypes.
What is known already: It is reported that MSCs have the effect on the innate immune sysytem and adaptive immune system, including neutrophils, DCs, monocytes, T cells and so on.
Study design, size, duration: The abortion-prone (CBA/J × DBA/2) mice were used.
Participants/materials, setting, methods: We utilized the abortion-prone (CBA/J × DBA/2) H-2$^{\delta}$ × H-2^{k} mice. The CBA/J mice were treated with RFP labeled mouse MSCs (MSC-RFP), and they were divided into the control group, the tail vein MSC-RFP group (MSC-vein), the uterine horn PBS group and the uterine horn MSC-RFP group (MSC-horn), and then they were mated 14 days after the treatment. Subsequently, the mice were killed at the Day 12.5 of gestation, and the embryo resorption rates were observed. The placentas and uteruses were collected, and the distribution of MSCs at the maternal- fetal interface was detected by immnohistochemistry. In addition, we collected the spleens and uteruses in each group and cultured the primary cells. Next, we analyzed whether there were differences in the phenotypes of CD4 $^{+}$T cells and macrophages, IL-4, IL-10, TNF-a and IFN-g among these groups by flow cytometry.
Main results and the role of chance: Compared with other groups, the embryo resorption rate of MSC-horn group dramatically decreased ($P < 0.05$). The immunohistochemical results showed that MSCs–RFP were observed at the maternal-fetal interface in the MSC-horn group. No matter which treatment was given, there were no significant differences in IL-4, IL-10, TNF-a and IFN-γ in CD4 $^{+}$T cells in spleens of each group ($P > 0.05$). There were no significant differences in IL-10 and IL-12 in monocytes in spleens of each group ($P > 0.05$). In contrast to the other groups, the levels of IL-4 and IL-10 in CD4 $^{+}$T cells at the maternal-fetal interface in MSC-horn group strikingly increased, and the TNF-a notably decreased ($P < 0.05$). IL-10 in macrophages was obviously higher than other groups ($P < 0.05$), and IL-12 in macrophages was significantly lower than other groups ($P < 0.05$).
Limitations, reason for caution: It need to be investigated further.
Wider implications of the findings: It may be used to treat the recurrent spontaneous abortion in the future.
Study funding/competing interest(s): Funding by national/international organization(s) – Postdoctoral Science Foundation of China.
Trial registration number: No. 2014M550573.
Keywords: MSC, recurrent spontaneous abortion, the maternal-fetal interface

O-075 Reduced clinical pregnancy rates by ART in women with a history of unilateral oophorectomy. Results of a large multi-center cohort study

T. Lind[1], J. I. Olofsson[2], J. Holte[3], N. Hadziosmanovic[4], L. Berglund[4], J. Gudmundsson[5], Rodriguez-K. W. R. Wallberg[6]
[1]*Karolinska Institutet, Oncology-Pathology, Stockholm, Sweden*
[2]*Reproductive medicine, Karolinska Sjukhuset, Stockholm, Sweden*
[3]*Akademiska Sjukhuset, Department of Women's and Children's Health Carl von Linné Clinic, Uppsala, Sweden*
[4]*Akademiska Sjukhuset UCR, Uppsala Clinical Research Center, Uppsala, Sweden*
[5]*Uppsala University Hospital, Reproductive Medicine Centre, Uppsala, Sweden*
[6]*Karolinska Institutet, Oncology-Pathology and Reproductive medicine, Stockholm, Sweden*

Study question: Is there a reduced pregnancy rate by ART treatment in women with unilateral oophorectomy (UO)?
Summary answer: Significantly reduced pregnancy rates after IVF/ICSI were found in women with previous UO when compared to women with both ovaries, both crude and after adjustment for age, and regardless if the transfer of embryos was performed in the fresh cycle or using frozen-thawed embryos.
What is known already: Previous case-control studies and small cohort studies have reported similar pregnancy rates by ART in women with UO when compared to control women. Consistently, women with UO had needed higher doses of gonadotropins and fewer oocytes were retrieved at ovum pick up (OPU). In all previous studies multiple embryos were replaced during the treatments.
Study design, size, duration: Multicentre cohort study including at three ART centres in Sweden. All women underwent IVF/ICSI treatments between 2003 and 2014. Single embryo transfer (SET) was performed in 77% of the treatments. The dataset included all fresh and frozen consecutive treatments.
Participants/materials, setting, methods: The exposed cohort included 76 women with UO who underwent 139 IVF/ICSI cycles and the unexposed cohort 12879 control women who underwent 22477 IVF/ICSI cycles. Primary outcome was clinical pregnancy rate. Clinical pregnancies were ultrasound-verified at week 8–9 and analysed per OPU and per embryo transfer.
Main results and the role of chance: The two groups were comparable and did not differ significantly with regard to age, BMI or performance of IVF or ICSI. Clinical pregnancy rate/OPU differed significantly between women with UO when compared to controls, both after fresh embryo replacement (24.5% vs. 32.4%) and cumulative (32.4% vs. 42.9%), and both crude ($p = 0.030$ and $p = 0.043$, respectively) and after adjustment for the women's age ($p = 0.021$ and $p = 0.031$, respectively). The cumulative pregnancy/OPU odds ratio was about 30% significantly lower in the women with UO; OR = 0.66 (CI 0.45–0.96, $p = 0.031$). The age-adjusted OR for live birth/OPU was also lower in women with UO compared to controls 0.71 (CI 0.47–1.05, $p = 0.090$).
Limitations, reason for caution: Although a significant reduction in clinical pregnancy rates was observed in women with UO, the reduced likelihood of achieving a live birth was not significant. The small sample size of exposed women might lack sufficient power for the investigation of differences in live births between the groups.
Wider implications of the findings: The present large cohort study is the first indicating reduced chance to pregnancy by ART, predominantly performed with SET, in women with previous UO. The findings contradict the earlier notion that fertility treatment outcome is not affected by a previous UO. As live birth events appear more seldom than pregnancy, our study might not have had enough power to detect a difference in live births.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s) – The local Research, Education and Development Council, Department of Obstetrics and Gynecology, Södersjukhuset. Clinical research grants from Stockholm County Council.
Trial registration number: NA.

O-076 Core-pulling Salpingectomy: A Novel Surgical for Hydrosalpinx before IVF-ET

X. R. Wang[1], H. C. Bao[1], C.F. Hao[1]
[1]*Yantai Yu Huang Ding Hospital, Reproduction Center, Yantai Shandong, China*

Study question: We investigated the effects of a new surgical procedure to treat hydrosalpinx prior to IVF-ET.
Summary answer: Patients who underwent core-pulling salpingectomy received IVF-ET and achieved increased clinical conception rate compared to the conventional salpingectomy, but the difference was not statistically significant.
What is known already: The fluids secreted by epithelial cells in dilated fallopian lumens are toxic to embryos. They interfere with embryo development, embryonic implantation, conception, and increase the rate of abortion.
Study design, size, duration: *In vitro* fertilization and embryo transfer (IVF-ET) is the primary treatment option for infertile patients with hydrosalpinx. However, if the hydrosalpinx is not treated first, outcomes of IVF-ET are compromised.
Participants/materials, setting, methods: Infertile females receiving treatment for hydrosalpinx ($n = 633$) were divided into one exposed group and two comparison groups. The exposed group was patients receiving pretreatment

with core-pulling salpingectomy (n = 105). The first comparison group were patients who had conventional salpingectomy prior to IVF-ET (n = 104), and the second comparison group were patients receiving IVF-ET without a history of previous hydrosalpinx (n = 424). Outcome in the exposed group, ovarian reserve, ovarian responsiveness and conception rates were compared to the two comparison groups.

Main results and the role of chance: After core-pulling salpingectomy, antral follicle number, endocrine profile, total dosage of ovulation-inducing agents required for ovarian stimulation, E2 level on the day of HCG administration and the number of oocytes retrieved following core-pulling salpingectomy were significantly higher compared to conventional salpingectomy, but not different from women without hydrosalpinx. Patients who underwent core-pulling salpingectomy received IVF-ET and achieved increased clinical conception rate compared to the conventional salpingectomy, but the difference was not statistically significant.

Limitations, reason for caution: All participants were women from 23 to 44 years old. They were included if they met the following criteria: (i) both ovaries present; (ii) FSH < 12 IU/l, estradiol <80 pg/ml and prolactin in the normal range before ovarian stimulation; (iii) normal uterine cavity; (iv) normal thyroid-stimulating hormone concentration or euthyroid as determined by the investigator; and (v) no current or past diseases affecting the administration of gonadotrophins. Couples with male factor and tubal tuberculosis were excluded.

Wider implications of the findings: Laparoscopic core-pulling salpingectomy should be recommended for patients with hydrosalpinx before receiving IVF-ET. This procedure did not interfere with ovarian reserve or responsiveness, and improved the conception rate.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Science and technology development plan of Yantai City.

Trial registration number: NA.

Keywords: infertility, hydrosalpinx, salpingectomy

O-077 Imaging of organ viability during uterine transplantation surgery

M. Y. Thum[1], S. Saso[1], N. Clancy[2], J. R. Smith[3]
[1]*The Lister Hospital, Fertility, London, United Kingdom*
[2]*Imperial College London, Biomedical Engineering, London, United Kingdom*
[3]*Imperial College London, Surgery and Cancer, London, United Kingdom*

Study question: Is there a role for biomedical photonics, and in particular, two novel, experimental techniques – a liquid crystal tuneable filter based multispectral imaging and laser speckle contrast analysis – in assessing uterine perfusion and viability pre-, intra- and post-transplantation surgery?

Summary answer: When assessing the overall picture, multispectral imaging may be an efficient tool to assess uterine tissue re-oxygenation in both time and space in the period immediately following the re-anastomosis, as well as in the post-operative period overall. Laser speckle contrast analysis has demonstrated potential with both qualitative and quantitative application.

What is known already: Uterine transplantation surgery has been proposed as a treatment for permanent absolute uterine factor infertility in the case of loss of the uterus. Due to the complexity of the vasculature correct re-anastomosis of the blood supply during transplantation surgery is a crucial step to ensure reperfusion and viability of the organ. While techniques such as fluorescent dye imaging have been proposed to visualise perfusion there is no gold standard for intraoperative visualisation of tissue oxygenation.

Study design, size, duration: This was a longitudinal study involving a small- and large-animal model (nine rabbit cross-transplants and five sheep auto-transplants). The study was performed at the Royal Veterinary College and Imperial College London, United Kingdom between June 2012 and June 2013.

Participants/materials, setting, methods: The above mentioned techniques were used to monitor uterine oxygen saturation and blood flow before and after transplantation. An absorption spectrum was calculated at each spatial pixel location using reflectance data from a reference standard, and the relative contributions from oxy- and deoxyhaemoglobin were calculated using a least-squares regression algorithm.

Main results and the role of chance: Results acquired during animal surgeries show that cornual oxygenation changes are consistent with those observed in point measurements taken using a pulse oximeter, showing reduced *SaO2* following re-anastomosis. Values obtained using the multi-spectral imaging laparoscope were lower than those taken with the pulse oximeter, which may be due to the latter's use of the pulsatile arterial blood acquired.

The preliminary results show that LASCA has the potential to determine blood flow, as well heart rate, respiratory rate and oxygen saturation.

As a first attempt to trial two experimental technique in a previously untested area of medicine, the experience may be considered as useful. With further trials in the future in both the animal and human models, a more definitive conclusion may be arrived at.

Limitations, reason for caution: Multispectral imaging and laser speckle contrast analysis remain a prototype. For the former, a major disadvantage is motion artefacts. They are introduced by breathing, peristalsis and relaxation of tissue during image acquisition, with cornual peristalsis an issue. For the latter, the acquired data was limited and difficult to conclude from.

Wider implications of the findings: The use of multispectral imaging and laser-speckle contrast analysis here is the first such case with respect to fertility surgery and has demonstrated promise of possible future use in a human model. Accurate, real-time, non-contact imaging modalities, which use a mathematical model to process the final results, are an improvement on current tools. In addition, other parameters can be derived: heart rate, respiratory rate and blood flow.

Study funding/competing interest(s): Funding by national/international organization(s) – Research was funded by Womb Transplantation UK (registered charity).

Trial registration number: NA.

Study question: Is there a difference between various hemostatic methods used in laparoscopic endometrioma excision with regard to preservation of ovarian reserve measured by serum anti-Müllerian hormone (AMH) levels?

Summary answer: Bipolar cauterization (BC) use for hemostasis after laparoscopic endometrioma excision is associated with a greater loss of ovarian reserve than suturing the cyst bed or applying hemostatic sealent (HS).

What is known already: Excisional surgery for endometrioma has a negative effect on ovarian reserve. Hemostatic methods may contribute further to this effect. Several studies have compared BC with suturing or HS. No systematic review has been undertaken previously.

Study design, size, duration: Cochrane Central Register of Controlled Trials, MEDLINE, EMBASE and OVID MEDLINE(R) In-Process and Other Non-Indexed Citations databases were screened until August 2014. Abstracts of the annual meetings of the American Society of Reproductive Medicine, the European Society of Human Reproduction and Embryology, and the American Association of Gynecological Laparoscopists were searched.

Participants/materials, setting, methods: Seven-hundred-twelve articles were identified and 18 were assessed in detail. Of these, 6 studies were included in the qualitative analysis. Four studies evaluating 213 women in total were included for meta-analysis. The main outcome measure was the rate of change in serum anti-Müllerian hormone (AMH) 3 months after surgery, expressed as a percentage of the preoperative AMH level. Subgroup analyses were done for studies comparing BC with HS or sutures. The Cochrane risk of bias tool was used for risk assessment. Grade system was used to evaluate quality of evidence. Study-to-study variation was assessed by using the Chi^2 statistic. The results were combined for meta-analysis using the Mantel-Haenszel model. All results were combined for meta-analysis with Revman Software.

Main results and the role of chance: This meta-analysis showed that alternative hemostatic methods were associated with a significantly lesser decline in ovarian reserve than BC. The mean decline in serum AMH levels was 6.95% less with alternative hemostatic methods than BC (95% CI –13.0% to –0.9%, p = 0.02) 3 months after surgery. When subgroup analysis of the studies comparing BC with HS or with sutures was performed, neither hemostatic method appeared to protect ovarian reserve significantly better than BC. Qualitative analysis concluded that 5 out of 6 studies reported greater decline in serum AMH levels with BC compared to alternative hemostatic methods. While HS was suggested to protect ovarian reserve better than BC, it was not clear whether suturing was more protective than BC.

Limitations, reason for caution: Limited number of studies were published on the subject, and some authors of original trials did not provide the required information. Blinding was not possible in any trial. The quality of evidence is low to moderate.
Wider implications of the findings: Available evidence suggests that alternative hemostatic methods preserve the ovarian reserve better than BC. However, taking the cost and possible adverse effects of HS in to consideration, choosing HS over BC may not be justified. Suturing may be preferred by experienced surgeons and more high quality studies comparing BC with sutures are needed.
Study funding/competing interest(s): Funding by University(ies) – Koc University School of Medicine.
Trial registration number: PROSPERO CRD 42014013848.
Keywords: endometrioma, laparoscopy, ovarian reserve, excision

O-079 Vascularity after laparoscopic myomectomy depends on suturing methods

A. Fujimoto[1], C. Morimoto[1], Y. Hosokawa[1], K. Kubota[1], Y. Nishimori[1], A. Hasegawa[1]
[1]*Sanraku Hospital, Obstetrics and Gynaecology, Chiyodaku Tokyo, Japan*

Study question: Does vascularity of uterus after laparoscopic myomectomy vary depending on operative procedure?
Summary answer: Simple interrupted suturing is superior to continuous suturing in terms of vascularity evaluated using contrast enhanced magnetic resonance imaging (CE-MRI).
What is known already: Uterine rupture during pregnancy is a rare but serious complication associated with myomectomy. Uterine scar repair after myomectomy has been evaluated with ultrasound examination, but there has been no clear evidence regarding appropriate operative procedure or contraception period to minimize the risk of uterine rupture.
Study design, size, duration: A prospective cohort study was conducted in a single institution. In total, 21 patients with symptomatic intramural uterine fibroids underwent laparoscopic myomectomy (LM) between June 2013 and April 2014.
Participants/materials, setting, methods: In 12 patients, continuous suturing of uterine wound in 2 or 3 layers was performed using braided absorbable suture thread (group A). In 9 patients, simple interrupted suturing was performed (group B). Three-months after surgery, uterine wound vascularity was evaluated using CE-MRI.
Main results and the role of chance: The ratio of avascular area to cross-sectional area of fibroids before surgery was measured in each patient. In group B, there was a statistically significant decrease of avascular area compared to that in group A (1.3% vs. 5.6%, $p < 0.01$).
Limitations, reason for caution: This is a prospective cohort study and not a randomized trial.
Wider implications of the findings: Simple interrupted suturing of the uterine wound might be associated with prompt uterine healing, shortening of contraception period or reduction of uterine rupture after LM.
Study funding/competing interest(s): Funding by hospital/clinic(s) – There is no funding to support the present study. We also have no conflict of interest.(We cannot check the option of "no Funding").
Trial registration number: NA.

SESSION 21: STRESS IN INFERTILITY AND ENDOMETRIOSIS

Monday 15 June 2015 **15:15–16:30**

O-080 Men living with endometriosis: perceptions and experiences of male partners of women with the condition

N. Hudson[1], L. Culley[1], H. Mitchell[1], C. Law[1], E. Denny[2], N. Raine-Fenning[3]
[1]*De Montfort University, Applied Social Sciences, Leicester, United Kingdom*
[2]*Birmingham City University, Centre for Health and Social Care Research, Birmingham, United Kingdom*
[3]*University of Nottingham, Faculty of Medicine and Health Sciences, Nottingham, United Kingdom*

Study question: How do male partners of women with endometriosis understand the condition and what role do they play in supporting women in managing their symptoms and access medical treatment?
Summary answer: Endometriosis and its management significantly disrupts the lives of both women and men in many domains. Men experienced a disruption to their own quality of life and a corresponding impact on the couple relationship. Male partners played an important role in women's decision-making around and subsequent management of endometriosis.
What is known already: Endometriosis is a chronic gynaecological condition affecting women of reproductive age with an estimated incidence of 5–15%. Symptoms include dysmenorrhoea, chronic pelvic pain, fatigue, heavy menstrual bleeding and dyspareunia. It is associated with 40% of attendances at infertility clinics. Studies report strain on social and marital relationships, as well as identifying partners as an important source of support. Such studies only capture women's experiences with scant evidence about the specific impact on the male partner.
Study design, size, duration: The UK-based 'Endopart' study is a qualitative, cross-sectional interview study. Inclusion criteria for couples were a laparoscopic diagnosis of endometriosis and that couples were living together at the time of interview. Interview data were collected between April 2012 and December 2012.
Participants/materials, setting, methods: In-depth, face-to-face interviews with 22 heterosexual UK couples were conducted. Women and their partners were interviewed separately ($n = 44$). This paper draws on the interviews with the male partners. Data were analysed *in vivo* using a systematic, thematic method, informed by an interpretivist relational approach.
Main results and the role of chance: The practical and emotional impact on men of living with endometriosis was found to be substantial. Whilst all chronic conditions will affect the "well" partner to some extent, endometriosis can be particularly problematic for couples because of its potential impact on fertility and sexual relationships. Involvement in treatment-seeking and associated decision-making was one way in which men provided support to their female partners. In particular, our data demonstrate men's involvement in interactions with healthcare providers; decisions about treatment; and supporting their partners through treatment regimes.
Principles of systematic sampling were employed to ensure sample diversity regarding age, ethnicity, illness trajectory, and recruitment route. Interim outcomes from the study were discussed at an expert stakeholder workshop in order to enhance interpretive validity.
Limitations, reason for caution: The cross sectional design makes it difficult to capture the dynamic nature of the impact of endometriosis across the life course. The sample contained a significant proportion of well educated individuals. It would be helpful to confirm findings from the rich and detailed interview data with a larger quantitative study.
Wider implications of the findings: An estimated 176 million women are affected by endometriosis worldwide. There is no known cure, and treatment has variable impact on symptoms. Finding effective ways to manage the condition is crucial. Discussions of management are focused on the woman, largely ignoring the impact on men/couples. These findings have implications for the development of couple-centred management and counselling, adding unique data to the knowledge base of clinicians and others providing support to people living with endometriosis.
Study funding/competing interest(s): Funding by national/international organization(s)
The study was funded by the UK Economic and Social Research Council, grant reference: ES/J003662/1. The authors have no competing interests to report.
Trial registration number: NA.

O-081 E-therapy to reduce symptoms of anxiety and/or depression in women after unsuccessful artificial reproduction technology (ART): a randomised controlled trial

M. A. J. C. van Dongen[1], M. W. L. D. Nelen[2], J. IntHout[3], J. A. M. Kremer[2], C. M. Verhaak[4]
[1]*Radboud University Medical Center, Obstetrics and Gynaecology Huispostnr 791, Nijmegen, The Netherlands*
[2]*Radboud University Medical Center, Obstetrics and Gynaecology, Nijmegen, The Netherlands*
[3]*Radboud University Medical Center, Health Evidence Section Biostatistics, Nijmegen, The Netherlands*
[4]*Radboud University Medical Center, Medical Psychology, Nijmegen, The Netherlands*

Study question: Does an e-therapy program for women during fertility treatment reduce the chance of having clinically relevant symptoms of anxiety and/or depression after an unsuccessful artificial reproduction technology (ART) treatment?
Summary answer: This study did not prove that this personalised e-therapy program reduces the chance of having clinically relevant symptoms of anxiety and/or depression shortly after a first unsuccessful ART treatment.
What is known already: Internet-based interventions are promising in reducing psychological distress, especially when treatment is personalised to specific risk profiles of patients. However in fertility care, the beneficial effects of personalised therapy on psychological distress still have to be evaluated.
Study design, size, duration: A prospective, two-arm, parallel group, single blind randomised controlled trial with a 1:1 allocation was conducted. To reduce the percentage of women suffering from emotional distress from 48% to 20%, 72 non-pregnant women were needed. In total, 120 women were randomised between February 1st, 2011 and June 1st, 2013.
Participants/materials, setting, methods: Women at risk for emotional maladjustment were included. We used symptoms of anxiety and depression measured by the Hospital Anxiety and Depression Scale (HADS) as outcome measure. The control group received psychological support on request (usual care), whereas the intervention group also received access to a personalised e-therapy program.
Main results and the role of chance: We were able to analyse 38 women in the intervention group versus 42 in the control group. There was no significant reduction in the percentage of women scoring above the cut-off level for clinically relevant symptoms of anxiety and/or depression 2 weeks after the first unsuccessful ART treatment; intervention group 30% (95% CI: 17%–42%) vs. control group 41% (95% CI: 23%–58%), risk difference 11%, $p = 0.30$. However, exploratory analysis showed that the e-therapy might have a positive effect 3 months after ART, reflected by the risk difference of 19% (intervention group 22% versus control group 40%, $p = 0.06$).
Limitations, reason for caution: Of all women screened as at risk, 151 (55.8%) declined participation. Moreover, exclusion of women with HADS >13 could have reduced the possible benefit of the e-therapy program. Finally, the e-therapy program only focused on women, whereas in fertility care it is important to involve the partner as well.
Wider implications of the findings: Internet interventions for treating mood and anxiety disorders have produced encouraging results, although the effect sizes vary. In fertility care, this is the first randomised controlled trial that evaluates a personalised e-therapy program to reduce symptoms of anxiety and depression during ART treatment. Future research should focus on a detailed process evaluation and the timing of offering personalised psychosocial care.
Study funding/competing interest(s): Funding by national/international organization(s) – NutsOhra (Study Number 0702-94) funded this study. There were no competing interests.
Trial registration number: ClinicalTrials.gov NCT 01283607.

O-082 Three Natural cycle IVF treatment imposes less psychological stress than one conventional IVF treatment cycle

K. Haemmerli Keller[1], G. Alder[1], M. Faeh[2], S. Rohner[2], M. von Wolff[2]
[1]*University of Zurich, Clinical Psychology, Zurich, Switzerland*
[2]*University Women's Hospital, Division of Gynaecologic Endocrinology and Reproductive Medicine, Bern, Switzerland*

Study question: Is the psychological stress reduced during and following three natural cycle *in vitro* fertilization treatment cycles (NC-IVF) compared to one conventional IVF treatment cycle (cIVF; classical *in vitro* fertilisation with gonadotropins)?
Summary answer: Women undergoing three NC-IVF treatment cycles showed significantly less depressive symptoms and were more satisfied with the treatment compared to women undergoing one cIVF treatment cycle. The psychological distress decreased and the quality of life increased during the course of three NC-IVF treatments.
What is known already: IVF is the one of the most stressful infertility treatments, leading to high levels of psychological stress. NC-IVF has been shown to be less or equally expensive per achieved pregnancy than cIVF and imposes less discomfort and risks. The pregnancy rate following three modified NC-IVF treatment cycles is similar than one cIVF treatment cycle. Until know it has never been systematically evaluated if NC-IVF is less psychological stressful for infertile patients than cIVF.
Study design, size, duration: A prospective study was performed with NC-IVF (without and with 25 mg clomifen citrate per day) and cIVF patients May 2013 until December 2014. The level of mental distress was analysed by validated psychological questionnaires filled in online before, during (NC-IVF) and after completed treatment cycle(s) at home.
Participants/materials, setting, methods: We analysed psychological distress (BSI), depression (CES-D), infertility specific distress (IBS), influence of fertility problems on daily life (FertiQoL) and quality of life (WHOQOL-Bref). The outcome measures were assessed before starting the treatment (T1), before the first (T2), second (T3), third NC-IVF treatment (T4) and after the pregnancy test (T5).
Main results and the role of chance: Data of 32 NC-IVF and 26 cIVF patients who completed the T1 and T5 questionnaires were evaluated. At T1 were no differences in psychological variables between the two groups. At T5 the pregnancy rate was equal in the two groups. At T5 NC-IVF patients had a significant lower level of depression (CES-D; $z = -2.156$, $P < 0.02$) and a higher satisfaction with the treatment (FertiQoL Treatment; $z = -1.727$, $P < 0.04$) than cIVF patients. During the course of NC-IVF treatment there was a reduction of infertility specific distress (IBS; $t(40) = 2.2$, $P < 0.03$), an increase of quality of life (WHOQOL-Bref; $t(39) = 2.5$, $P < 0.02$) and lower influence of fertility problems (FertiQol; $t(23) = 2.3$, $P < 0.03$).
Limitations, reason for caution: Even though all patients were offered both treatment options, some bias concerning a more positive expectation concerning the NC-IVF treatment cannot be excluded. It cannot be excluded that the dropout rate has some impact on the study results.
Wider implications of the findings: NC-IVF treatment seems to be less stressful for infertile patients. Furthermore, previous studies have shown that modified NC-IVF treatments can be equally effective and less risky compared to cIVF. Therefore this kind of treatment should be considered as an alternative treatment option in certain cases, especially in psychologically distressed women.
Study funding/competing interest(s): Funding by University(ies), Funding by commercial/corporate company(ies) – MSD Merck Sharp & Dohme GmbH. No competing interests.
Trial registration number: NA.

O-083 The risk of clinically diagnosed unipolar depression among men in ART treatment – a national register-based cohort study of 37,913 men

C. S. Sejbaek[1], A. Pinborg[2], I. Hageman[3], A. M. S. Sørensen[1], J. L. Forman[4], L. Schmidt[1]
[1]*University of Copenhagen Faculty of Health and Medical Sciences, Department of Public Health Section of Social Medicine, Copenhagen, Denmark*
[2]*Copenhagen University Hospital Hvidovre Hospital, Department of Obstetrics and Gynecology, Copenhagen, Denmark*
[3]*Copenhagen University Hospital Rigshopitalet, Psychiatric Center Copenhagen, Copenhagen, Denmark*
[4]*University of Copenhagen Faculty of Health and Medical Sciences, Department of Public Health Section of Biostatistics, Copenhagen, Denmark*

Study question: Are men who initiated assisted reproductive technology (ART) treatment, due to male factor infertility, at a higher risk of a clinically diagnosed unipolar depression compared to men in ART treatment due to female factor or unexplained infertility?
Summary answer: Men who initiate ART treatment due to male factor infertility are not at a higher risk of developing a clinically diagnosed unipolar depression compared to men in ART treatment due to female factor or unexplained infertility.
What is known already: Studies have shown that men in fertility treatment for male factor are more distressed and experience more negative emotions in relation to feelings of stigma, loss and self-esteem compared to men in fertility treatment due to other causes. Furthermore, low semen quality may be associated with depression. Previous studies on these topics are both qualitative and quantitative and limited in sample size. Only one previous study has explored clinically diagnosed depression in men ART treatment.

Study design, size, duration: A national, register-based cohort study; 37,913 cohabitant male partners to women in ART treatment recorded in the Danish IVF register were identified via the Central Personal Register. Data were linked to the ICD-8 and ICD-10 codes for clinically diagnosed unipolar depression from the Danish Psychiatric Central Research Register (1969–2009).
Participants/materials, setting, methods: For the initial analysis the full cohort of 37,913 male partners were used. A Cox regression analysis was used to investigate the association between male factor infertility and unipolar depression subsequent to initiating ART treatment in a sub-population of 34,817 men without clinically diagnosed unipolar depression prior to ART treatment.
Main results and the role of chance: Of the 37,913 men cohabiting with a female partner who initiated ART treatment, 446 (1.2%) had a clinically diagnosed unipolar depression either before or after initiating ART treatment. Among the men with a unipolar depression diagnosis, 32.7% were diagnosed prior to initiating ART treatment, while the remaining 67.3% were diagnosed with unipolar depression after initiating ART treatment. In the sub-population (n = 34,817), only 266 men had a clinically diagnosed unipolar depression. The full sub-population was included in the further analysis. Men with male factor infertility did not have an increased risk of unipolar depression compared with men in ART treatment due female factor or unexplained infertility (adjusted Hazard Ratio = 1.04 (0.79–1.36), p = 0.804).
Limitations, reason for caution: Only men with a clinically diagnosed unipolar depression recorded at a psychiatric hospital are included in the national registers; i.e., only severe cases of depression. Men who were treated with antidepressive medication and/or in counselling outside the hospital setting were not recorded in the Central Psychiatric Register.
Wider implications of the findings: Though previous studies have shown that male factor infertility is a potential severe stressor for men in fertility treatment, it is very reassuring to see that in this large national cohort study, male factor infertility was not a risk factor for developing a clinically diagnosed unipolar depression subsequent to treatment when compared to men in couples with different infertility diagnoses. Counselling men in fertility treatment should include this very important information.
Study funding/competing interest(s): Funding by national/international organization(s) – Research grants are funded by the Danish Health Insurance Foundation and Merck Sharp & Dohme. The funders had no influence on the data collection, analyses or conclusions of the study. No conflicts of interests to declare.
Trial registration number: NA.

O-084 Infertility coping strategies and their effect in infertility stress: is the relationship equivalent across cultures?

M. P. Sobral[1], M. E. Costa[1], L. Schmidt[2], M. V. Martins[1]
[1]*University of Porto Faculty of Psychology and Education Sciences, Center for Psychology at University of Porto, Porto, Portugal*
[2]*University of Copenhagen Section of Social Medicine, Department of Public Health, Copenhagen, Denmark*

Study question: Is the relationship between infertility-related coping (namely, active-avoidance and meaning-based strategies) and infertility-related stress (personal, marital, and social domains) in women significantly invariant across cultures?
Summary answer: Culture can affect the way infertility-related coping strategies influence infertility stress. The effects of active-avoidance coping on personal, marital, and social stress depend on the country of origin. While meaning-based coping had similar impact on stress domains across all countries, the effect on social stress was only significant in Sweden.
What is known already: The effect that coping strategies have on the way women deal with the infertility stressor is widely known. A large number of studies have shown the negative influence of avoidant coping strategies on infertility stress, and some have reported a mitigating effect of seeking a positive meaning in infertility. However, there are no studies comparing these relationships between countries.
Study design, size, duration: This study emerges from multinational collaborations with the Copenhagen Multi-centre Psychosocial Infertility (COMPI) research programme. Data was collected administrating the same measures across countries between 2000 and 2013, with samples differing only in culture. Among the nine collaborating countries, three samples were eligible to this study: Denmark, Sweden and Greece.
Participants/materials, setting, methods: Participants were 1609 women seeking fertility treatment in Denmark, Greece, and Sweden. The *COMPI Coping Strategies Scales* assessed the use of active avoidance and meaning-based coping strategies. The *COMPI Fertility Problem Stress Scales* assessed personal, marital and social stress. Multi-group analyses were conducted and critical ratios ($|Z|$) were used to compare parameters.
Main results and the role of chance: Positive associations between active-avoidance coping strategies and personal, marital, and social stress were found in all countries. The deleterious effect of active-avoidance coping on personal and social stress was significantly higher for Danish women ($|Z| > Z_{0.975}$). Stronger effects were also found on personal and marital stress in Greek women when compared to Swedish ($|Z| > Z_{0.975}$). Meaning-based coping was found to have a decreasing effect on all stress domains, but the association with social stress was significant only in the Swedish sample. Meaning-based coping had similar impact on stress domains across all countries ($|Z| < Z_{0.975}$).
Limitations, reason for caution: Although the design of this study is based on solid theoretically driven hypotheses and replicates other longitudinal designs based on a single culture, claims of directional influence cannot be made due to its cross-sectional nature. Because samples were derived from European countries, results cannot be generalizable to other continents.
Wider implications of the findings: Understand the impact of culture when coping with infertility has became especially relevant with cross-border reproductive care. This research represents a first step towards increasing practitioners' knowledge on cultural specificities. Results suggest that active-avoidance strategies can be particularly harmful to Danish and Greek women.. Meaning-based coping strategies are important for clinicians to train, as they can be protective of personal and marital stress independently of the patient's country of origin.
Study funding/competing interest(s): Funding by national/international organization(s)
This work is supported by European Union Funds (FEDER/COMPETE – Operational Competitiveness Programme) and by national funds (FCT – Portuguese Foundation for Science and Technology) under the projects PTDC/MHC-PSC/4195/2012 and SFRH/BPD/85789/2012.

INVITED SESSION

SESSION 22: RISKS AND BENEFITS OF BEING MALE

Monday 15 June 2015 **17:00–18:00**

O-085 Sex-specific aspects of meiotic failure in relation to meiotic checkpoints and genome integrity of germ cells

W. M. Baarends[1], A. Enguita[1], M. Ooms[1], L. H. Looijenga[2], G. R. Dohle[3], J. A. Grootegoed[1]
[1]*Erasmus MC, Department of Developmental Biology, Rotterdam, The Netherlands*
[2]*Erasmus MC, Department of Pathology Erasmus MC Cancer Institute, Rotterdam, The Netherlands*
[3]*Erasmus MC, Department of Urology Erasmus MC Cancer Institute, Rotterdam, The Netherlands*

During meiotic prophase, all chromosomes have to stably associate (synapse) with their partner chromosome, and exchange genetic information, in order to ensure correct segregation and ploidy reduction. These processes both depend on the formation and repair of around 200 programmed DNA double-strand breaks (DSBs) at hotspots that are located throughout the genome. In male meiotic prophase, the presence of the largely heterologous X and Y provides a challenge to the system. An intricate regulatory system ensures that an obligate crossover is formed in the small homologous region that they share, the so-called pseudoautosomal region. The heterologous regions remain unsynapsed, and display persistence of DSBs. This triggers global transcriptional inactivation of both the X and Y chromosome, culminating in formation of the XY body in the periphery of the spermatocyte nucleus. When meiotic DSB repair, or chromosome pairing, or both, are somehow impaired for multiple or all chromosomes, overall DSB repair stalls, and XY body formation fails, and this

triggers a very robust checkpoint in male mice, leading to a complete arrest in meiotic prophase. This prevents further meiotic and postmeiotic progression of cells with a damaged genome. In addition to this prophase checkpoint, a very efficient meiotic metaphase checkpoint can be activated by even a single chromosome misalignment in male mice. It is not clear to what extend similar checkpoints are activated in men that display a maturation arrest phenotype in testicular biopsies, based on morphological criteria. We are using a fluorescent immunostaining approach, to investigate whether similar checkpoints are activated in human males with meiotic arrest. We are analysing remnant material of paraffin embedded testis biopsies of azoospermic patients with Johnson score 3–6 (JS3–6; $n = 21$) and Johnson score 9–10 (control; $n = 15$), using specific antibodies to asses meiotic entry, XY body formation, meiotic metaphases, and the presence or absence of postmeiotic spermatids. Complete failure of XY body formation was observed in only 10% of the JS3–6 patients. Analyses of activation of other checkpoints and of the efficiency of meiotic DSB repair in relation to checkpoint activation are currently underway. The results from this type of approach may help to estimate the risk of obtaining elongated or condensed spermatids with a damaged or aneuploid genome that might have escaped checkpoint activation mechanisms in testis biopsies of azoospermic men.

Keywords: meiosis, sex chromosomes, spermatogenesis, meiotic checkpoint, DNA repair

O-086 Why are males dying younger? Evolutionary and functional aspects of maternal mitochondrial inheritance and mitochondria in ageing

N. J. Gemmell[1]
[1]*University of Otago, Allan Wilson Centre Department of Anatomy, Dunedin, New Zealand*

Mitochondria are central to eukaryotic life. They retain their own genome (mtDNA) and this molecule has important roles in energenesis and a growing list of other processes. mtDNA is almost universally inherited solely through the female lineage, which provides opportunity for selection to operate asymmetrically between males and females. A growing body of work suggests that mtDNA mutations may have stronger effects on phenotype in males than females – an idea I termed 'Mother's Curse". In particular, I pointed out that male specific traits, such as sperm function, would be profoundly affected by this asymmetry in selection. Recent work also implicates this selection asymmetry in the strong sexual dimorphism in ageing observed across a diversity of species. In this talk I will review some of the background around the development of the Mother's Curse hypothesis, particularly around the effects predicted on male reproductive functions, evidence that supports the hypothesis, and then consider areas in biology where this theory might have impact.

Keywords: mitochondria, fertility, sperm, fitness

INVITED SESSION

SESSION 23: HOW TO ORGANIZE EARLY PREGNANCY CARE IN YOUR DEPARTMENT

Monday 15 June 2015 **17:00–18:00**

O-087 Early pregnancy units: Are they worth it?

R. Farquharson[1]
[1]*Miscarriage Clinic, Gynaecology Department, Liverpool, United Kingdom*

The emergence of early pregnancy units (EPU) began in the late 1980's following triage audit of emergency gynaecology patient admissions which demonstrated unnecessary admissions to hospitals and bed blockage. The seminal paper of Bigrigg and Read (1991) heralded the cost-effective analysis of setting up an out-patient, ultrasound- based assessment of early pregnancy symptoms and complications which remain the commonest gynaecology emergency. This acted as a spring well for the local development and delivery of emergency assessment of early pregnancy leading to the appearance of a national network across the UK (earlypregnancy.org.uk) under the aegis of the Association of Early Pregnancy Units.

The bewildering array of terms used to describe the plethora of early pregnancy events and complications was rationalised in 2005 by the Early Pregnancy specialist interest group of the European Society of Human Reproduction and Embryology (ESHRE) and soon after by the Royal College of Obstetricians and Gynaecologists (Farquharson et al, 2005: RCOG guideline 2006). The basis for this initiative was to emphasise the ultrasound scan assessment as a more patient-orientated understanding and to make the distressing diagnosis of early pregnancy loss (EPL) involve a fully trained team who are empathic and caring when dealing with breaking bad news.

The sheer scale of national demand for EPU capacity is reflected, certainly within the UK, with provision of over 250,000 scans each year which correlates with the estimated number of miscarriage (200,000) and ectopic pregnancy (15,000) diagnoses. These impressive figures are seen against the backdrop of 700.000 births many of whom self-refer for reassurance scan in early pregnancy prior to antenatal booking. It is of utmost importance to provide adequate educational support for all EPU health care professionals. As a result, the level of competence at scanning remains the biggest variable in care provision across the European Union (EU).

The adoption of high resolution transvaginal ultrasound allied to serial measurement of serum HCG levels has helped discriminate cases of life-threatening ectopic pregnancy amenable to both medical and/or surgical management. The NICE guideline (2012) on ectopic pregnancy and miscarriage has attempted to assess evidence based practice in a highly diverse area of practice. Early pregnancy has been the subject of increasing research interest with international collaborative RCT's planned, in recruitment phase or completed.

In terms of training and education, early pregnancy has 'come of age' and is a popular choice for trainees in areas of specialisation for healthcare professionals.

Keywords: early pregnancy, the value of early pregnancy units

O-088 Recurrent pregnancy loss programs: optimizing care and research opportunities

M. Stephenson[1]
[1]*University of Illinois at Chicago College of Medicine, Obstetrics and Gynaecology, Chicago, U.S.A.*

Recurrent pregnancy loss (RPL) affects as many as one in 20 couples seeking parenthood. Despite extensive research worldwide, causes of recurrent pregnancy loss remain elusive. Genetic testing of miscarriage tissue offers the promise to identify pregnancy loss due to numeric chromosome errors and submicroscopic additions or deletions to the genome, which may be responsible for lethal embryonic developmental defects. Without answers, patients are left to make decisions without information, and prolonged unresolved grief.

Recurrent pregnancy loss evaluation is complex, requiring an interdisciplinary rather than traditional specialty-based approach. Therefore, this requires changes in the standard organizational model of health care delivery to optimize clinical care and research, and teaching across disciplines. Proximity to an IVF Program allows convenient access to assisted reproductive technologies, if required. Following evaluation and development of a management plan, close monitoring and supportive care in early pregnancy is associated with high live birth rates.

A robust RPL database is essential for clinical research. Informed consent at time of consultation allows prospective collection of demographics, evaluations, diagnosis and management to be entered into a database, along with subsequent pregnancy outcomes. A data dictionary is essential to optimize data entry consistency. Data entry and management personnel can optimize data entry and storage.

Concurrent storage of blood (from both partners), urine, endometrial and miscarriage tissue, and placental tissue and cord blood with ongoing pregnancies, facilitates RPL clinical and basic science research, rather than selectively collecting for a specific study. Research banking is essential to advancing the field in our lifetime. International collaboration is essential for clinical trials since the sample size is usually not attainable with a few RPL centers.

INVITED SESSION

SESSION 24: LONG-TERM CONSEQUENCES OF TREATED CHILDHOOD CANCER

Monday 15 June 2015 **17:00–18:00**

O-089 Ovarian function in long-term survivors of childhood cancer

J. S. E. Laven[1], W. van Dorp[1], M. M. Heuvel-Eibrink[2], R. Pieters[2]
[1]*Div. Reproductive Medicine, OBGYN Erasmus MC, Rotterdam, The Netherlands*
[2]*Pediatric Oncology, Prinses Maxima Centre for Pediatric Oncology, Utrecht, The Netherlands*

Childhood cancer has become a curable disease. Currently, two-third of all children with cancer reach long-term survival. Overall survival of childhood cancer has increased dramatically over the past decades, which has urged clinicians to pay attention to short- and long-term adverse effects of cancer treatment (Anderson, 2013).

Th emost frequent long-term side effect of cancer treatment is gonadal dysfunction, often resulting in impaired fertility (Lie Fong et al., 2008, 2009). Gonadal dysfunction does occur especially after treatment with alkylating agents or pelvic radiotherapy. Fertility can also be impaired as a result of cranial irradiation by disruption to the hypothalamic-pituitary-gonadal axis. The magnitude of this impairment depends on the treatment modality, the total cumulative dosages, as well as on the genetic susceptibility of a cancer survivor (Anderson 2013; Van Dorp et al., 2013a). Besides infertility in women cancer treatment might also cause a subsequent loss of bone mass due to the depletion of estrogens.

Ovarian function is nowadays assessed by measuring the serum levels of anti-Müllerian hormone (AMH) (Visser et al, 2012). In adult women it has been shown that AMH levels are already reduced before the start of chemotherapy (Lawrenz et al., 2012). This indicates that not only therapy but also the disease- and general health status may influence ovarian function at the time of diagnosis. Similarly, in adolescent and young adult women diagnosed with cancer significant damage to gametes has been observed before the start of treatment (Fabbri et al., 2011). We have recently shown that AMH levels in pre-pubertal girls with newly diagnosed cancer are already compromised before treatment starts, suggesting that the disease itself affect ovarian function (van Dorp et al., 2014).

The occurrence and the magnitude of gonadal dysfunction after cancer treatment varies according to chemotherapy regime and dosages, pelvic radiotherapy used as well as age at diagnosis. Moreover, genetic variation, which determines ovarian reserve in normal healthy women, may modify ovarian reserve in female childhood cancer survivors as well (van Dorp et al., 2013b).

Ovarian dysfunction after chemotherapy has been well described; premature follicular depletion will result in early menopause. Byrne and colleagues followed up women treated for cancer before the age of 20 years and recorded that nearly half of those treated with radiotherapy and chemotherapy had reached menopause by the age of 31 years, compared with 5% of controls (Byrne et al.,1992).

Potential ovarian mechanisms behind increased infertility include a loss of ovarian reserve and genotoxic effects on oocytes. One study (Barton et al., 2013) has prospectively analyzed reduced ovarian reserve in relation to fecundity in young women. They and others concluded that there was no delay in conception in women with low concentrations of AMH (Hagen et al., 2012). The genotoxic effects on germ cells of both radiotherapy and alkylating agent chemotherapy have long been a cause for concern, although the risk of genetic disease does not seems to be increased in the children of cancer survivors (Wallace et al., 2012; Anderson 2013).

Women who have had radiotherapy treatment to a field that included the uterus are at increased risk of adverse outcome in pregnancy, including late miscarriage, premature delivery, low birth weight and postpartum hemorrhage. Preconception counseling may be appropriate and these women should be advised that pregnancy needs to be supervised in a high-risk obstetric unit (Lie Fong et al., 2012; Wallace et al., 2013).

Last but not least one should consider cryopreservation of ovarian tissue in girls at high risk of premature ovarian insufficiency. Cryopreservation of ovarian tissue in pre-pubertal girls remains experimental. In post-pubertal girls, oocyte cryopreservation may be an option (Wallace et al., 2013).

Keywords: ovarian function, childhood cancer, survivor, management, fertility

O-090 Testicular function in long-term survivors of childhood cancer

K. Jahnukainen[1]
[1]*Helsinki University Central Hospital, Children´s Hospital, Huch – Helsinki, Finland*

Testis has been shown to be highly susceptible to the toxic effects of cancer therapy at all stages of life, even in childhood despite the relative quiescence of the hypothalamic-pituitary (HP)-gonadal axis. Future fertility relies on the presence of spermatogonial stem cells (SSCs) to produce a constant supply of spermatozoa from puberty onwards. It is generally accepted that cancer treatment which results in a complete loss of SSC will lead to permanent infertility.

Chemotherapy: Acute leukemias, the most common cancer type in children, involve treatment with antimetabolites and vinca-alkaloids which inhibit DNA and RNA synthesis and mitosis. Long-term follow-up of leukemia survivors indicates that treatment with these chemotherapeutic drugs does not completely deplete the SSCs. Treatment with a high cumulative dose of alkylating agents is one of the major factors decreasing the probability of fertility. Many studies have described threshold doses for long term subfertility. However, a recent large study of non-irradiated childhood cancer survivors failed to identify any threshold dose for alkylating agent exposure that predicted impaired spermatogenesis after long-term follow-up. There may be other factors, in addition to absolute doses and regimen, such as genetic variation in drug metabolizing pathways that modulate the impact of alkylating agent exposure on spermatogenesis or its recovery.

Radiotherapy: Even low scattered irradiation doses can damage spermatogonia: permanent azoospermia can result when the testes are exposed to doses higher than 6–10 Gy. Leydig cells are more resistant to radiation damage. Leydig cell dysfunction is associated at doses ≥25 Gy. Radiotherapy exposing the HP region ≥25 Gy contributes to risk of androgen deficiency.

Hematopoietic stem cell transplantation: Germ cell failure with raised serum levels of FSH and decreased testicular growth in puberty are observed among most of the male patients after hematopoietic stem cell transplantation (HSCT) irrespectively to conditioning therapy. However, the probability for recovery of spermatogenesis post-treatment, is associated with the type of conditioning therapy, age of the patient, time interval since transplantation and absence of chronic graft-versus-host-disease. One third of adult HSCT patients receiving high dose cyclophosphamide had sperm in the ejaculate after a recovery period of 1 year. But after total-body-irradiation (TBI), recovery of spermatogenesis never occurred before the 4th year after transplantation. Similar findings have recently been reported in the pediatric population. HSCT conditioning with busulfan or cyclophosphamide was associated with better pubertal growth with larger adult testicular volumes, lower serum levels of FSH and the more frequent presence of spermatozoa than TBI conditioning.

Assessment of gonadal dysfunction: Semen analysis is a gold standard as the primary surveillance modality for evaluation of spermatogenesis. Monitoring of growth and pubertal development and progression is recommended for pre- and peri-pubertal survivors treated with radiotherapy exposure of the testes and HP region. Referral to a reproductive medicine clinic is recommended for survivors treated with potentially gonadotoxic therapy. Counselling regarding the risk of androgen deficiency is recommended for survivors treated with radiotherapy exposure of the testes or HP region. Survivors treated with one or more potentially gonadotoxic treatment should be aware of the risk of physiological sexual dysfunction including erectile and ejaculatory dysfunction.

Male fertility preservation: The gonads should be shielded from irradiation when possible. Sperm cryopreservation should be offered to pubertal and post-pubertal cancer-diseased boys. In adolescents, measurements of testicular volume are helpful in predicting the chance for successful retrieval of spermatozoa and semen production. The chances of improving fertility after sterilizing cancer therapy remain poor. Rapid progress in the development of novel experimental strategies to generate fertile gametes from cryopreserved testicular tissue may provide new methods for fertility preservation among pre-pubertal patients in the future.

Keywords: infertility, androgen deficiency, childhood cancer therapy, recovery

SELECTED ORAL COMMUNICATIONS

SESSION 25: PARAMEDICAL SELECTED ORAL SESSION – LABORATORY

Monday 15 June 2015 **17:00–18:00**

O-091 Organizing the lab: the effect of time to injection in intracytoplasmic sperm injection (ICSI) on ongoing pregnancy

L. Van Den Hoven[1], J. C. M. Hendriks[2], L. Ramos[3]
[1]*Radboud UMC, Obst. and Gynaecology, Nijmegen, The Netherlands*
[2]*Radboud UMC, Epidemiology, Nijmegen, The Netherlands*
[3]*Radboud UMC, Obst. and Gynaecology, Nijmegen, The Netherlands*

Study question: The purpose of this study is to investigate whether the timing of the start of ICSI after ovum pick-up (OPU) influences the probability to become pregnant. As, specifically, extreme poor semen quality requires a more time consuming ICSI procedure, the time that ICSI is started is inevitable subject to variation.
Summary answer: Differences of ICSI injection interval times between 1.0 h up to 6.0 h since ovum pick up does not influence the ongoing pregnancy rate (OPR).
What is known already: It is argued that 4 h are needed to complete nuclear and cytoplasm maturation of oocytes before injection, despite an omission of confirmative large studies. A fixed time-interval after OPU of the injection for all patients is not feasible, because of the variation of the laboratory workload (number of ICSIs per day) and semen quality. However, it is challenging to organize the lab procedures without causing detrimental effect on fertilization, embryo quality or pregnancy outcome.
Study design, size, duration: This retrospective study includes all first cycles of patients who visited our clinic between February 2002 up to April 2014. The ICSI injection interval is defined as the time interval between OPU and injection. The ICSI injection interval was categorized and evaluated in relation to: pregnancy, ongoing pregnancy and abortion.
Participants/materials, setting, methods: The first ICSI cycles of 3032 women were included in this study. The treatments were related to type of sperm used: either ejaculated, non-ejaculated, fresh/frozen. The median female age was 32.0 years (range: 19.8–43.8 years) and the median injection time interval was 2.3 h (range: 0.6–7.3).
Main results and the role of chance: The percentage of ongoing pregnancies was 39% (95% confidence interval (CI): 37 – 41%) and this was not statistically significant different between the ICSI injection time intervals and even so after adjustment for basic female characteristics: age, FSH doses, number of oocytes and of fertilized oocytes. In addition, on average the start of ICSI with fresh sperm was 36 min (95% CI: 30–43) earlier compared to frozen sperm, while the mean start of ICSI was similar with respect to ejaculated or non-ejaculated sperm. After OPU, injection can be started as soon as 1.0 h after OPU without reducing the chance to pregnancy.
Limitations, reason for caution: The groups with very early (<1.0 h) and the very late (>6.0 h) injection times are small, and may be related to lower pregnancy rates. The primary outcome in this study is OPR of the first cycle; we did not consider the cumulative outcome of the cryopreserved embryo's.
Wider implications of the findings: The work load in an IVF-lab is not constant. The limitations of personnel and ICSI- microscopes together with the difficulty of some ICSI's, implicate decision making of when to start an ICSI procedure. Although the ongoing pregnancy rate may be lower before 1.0 h and after 6.0 h, pregnancy rates are still good; extreme long or short periods between OPU and injection is not desirable, but in extreme conditions it could be acceptable.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Radboud University Medical Center, Nijmegen, The Netherlands.
Trial registration number: NA.
Keywords: ICSI, timing, pregnancy, injection, ongoing pregnancy

O-092 Reliable High Resolution SNP-Array Analysis of Human Embryos for Genomic's Aberration Screening and Karyomapping

R. Xiong[1], R. Duttagupta[2], E. Fung[2], B. Levy[3], G. Lin[1]
[1]*Reproductive and Genetics Hospital CITIC-XIANGYA, Genetics Center, ChangshaHunan, China*
[2]*Affymetrix Inc 3420 Central Expressway Santa Clara CA 95051. USA, RD, Santa Clara, U.S.A.*
[3]*Columbia University Medical Center, The New York Presbyterian Hospital 3959 Broadway CHC – Room 406b, Medical Center, New York, U.S.A.*

Study question: Can High-Resolution Single Nucleotide Polymorphism Array (SNP-A) analysis be reliably used to screen for genomic aberrations on human embryos from patients undergoing *in vitro* fertilization (IVF) treatment?
Summary answer: Empirical evidence demonstrates that High-Resolution SNP-A can be reliably used to detect chromosomal aberrations on embryos that have undergone trophectoderm (TE) biopsy. Previously characterized samples with known genetic profiles were analyzed by SNP-A in a blinded fashion to determine the ability of SNP-A to identify previously known and novel aberrations.
What is known already: FISH-PGD and BAC-arrays have been used in embryo screening but the resolution (size of the smallest aberration detected) and mosaic sensitivity are limited. SNP arrays can detect both chromosome segmental imbalances and aneuploidy, and may overcome the limitations of FISH and BAC arrays in embryo screening and PGD.
Study design, size, duration: This was a retrospective study of 84 samples with and without detectable chromosomal aberrations by alternative technologies (FISH, NGS, aCGH), The 84 samples included TE biopsies (N = 16), leukocytes from health individuals (N = 44).... The study was run and analyzed between June 2014 and January 2015.
Participants/materials, setting, methods: Samples were either TE biopsies comprising 2–5 cells or manually picked leukocytes from peripheral blood.
All samples were amplified using whole-genome amplification followed by CytoScanÒ Cytogenetics Suite Protocol. A reference file (for normalization purposes) was generated using the 44 normal leucocytes samples (from similar amount of starting cells) using Chromosome Analysis Suite Software.
Main results and the role of chance: The SNP-A methodology was robust; all analyzed samples (100%) yielded results. Aberrant/non-aberrant status was concordant with those obtained using a predicate methodology in all cases (100%). Further evaluation on the aberrations and genotypes is being conducted.
Limitations, reason for caution: The method evaluated provides a higher potential of detecting smaller aberrations when compared with BAC-array, aCGH or NGS. However, a bigger study to evaluate its clinical efficacy and utility is advisable.
Wider implications of the findings: This is the first study reporting analytical assessment of high resolution SNP-A for chromosomal aberrations screening in embryos obtained for IVF. High resolution SNP-A have the potential to discover smaller chromosomal aberrations that other methods (BAC arrays, acGH, FISH, NGS), with the additional value of the genotypes that could serve for karyomapping and forensic evidence of the embryos when compared to samples obtained by amniocentesis or after birth.
Study funding/competing interest(s): Funding by national/international organization(s), Funding by commercial/corporate company(ies) – National Science Foundation of China (No. 81222007). Affymetrix INC. RD.
Trial registration number: NA.
Keywords: single nucleotide polymorphism array, preimplantation genetic diagnosis, chromosomal aberrations

O-093 Frozen-thawed *in vitro* matured oocytes collected at the time of ovarian tissue processing, for the purpose of fertility preservation for transsexual persons, show normal spindle formations

S. Lierman[1], K. Tilleman[1], C. De Roo[1], K. Braeckmans[2], K. Peynshaert[2], S. Weyers[3], G. T'Sjoen[4], P. De Sutter[1]
[1]*University Hospital Ghent, Centre for Reproductive Medicine, Ghent, Belgium*
[2]*University Ghent, Department of Pharmaceutics Laboratory of General Biochemistry and Physical Pharmacy, Ghent, Belgium*
[3]*University Hospital Ghent, Department of Gynaecology, Ghent, Belgium*
[4]*University Hospital Ghent, Department of Endocrinology, Ghent, Belgium*

Study question: Does long term androgen treatment in female to male transsexual persons (FTMs) have an effect on the spindle structure and chromosome alignment of *in vitro* matured cryopreserved oocytes derived from cumulus enclosed oocytes (CEOs) isolated at the time of ovarian tissue (OT) processing and cryopreservation, before or after vitrification.
Summary answer: Spindle structure analysis and chromosomal alignment is normal in *in vitro* matured CEOs that were identified at the time of OT

processing. The metaphase II (MII) oocytes do not seem to be morphologically affected by long-term androgen treatment.
What is known already: It has been shown, for oncological patients, that after OT processing and cortex freezing, CEOs can be found in the remaining solution. These CEOs can be the result of tissue processing where cortical antral follicles are mechanically disrupted. Others have stated that the CEOs are derived from surplus medulla tissue. These CEOs can be *in vitro* matured until they reach metaphase II stage. This has not yet been described for fertility preservation programs for FTMs.
Study design, size, duration: *In-vitro* matured CEOs reaching MII stage were collected and split into 2 groups; group 1 was immediately fixed for spindle staining and group 2 was first vitrified and warmed and then analyzed for spindle structure and alignment of the chromosomes. Statistical analysis was performed by Fisher's exact-test.
Participants/materials, setting, methods: 16 FTMs were included with a mean age of 24.1 ± 6.2 years, following a period of testosterone treatment (53.6 ± 21 weeks). A total of 680 CEOs were collected, IVM culture was performed using supplemented M199-medium, open vitrification using the cryotop system, spindle structure analysis was assessed by immunostaining and confocal imaging.
Main results and the role of chance: After 48 h *in vitro* maturation, 38.1% CEOs were at MII-stage (259/680). Those MII-oocytes were split over 2 groups: (1) 126 MII-oocytes in the non-vitrification group, and (2) 133 MII-oocytes, which underwent vitrification. Immediately after warming, the survival rate was 73.7% (98/133); after 1 h of culture 68.4% (91/133) and after 2 h of culture 67.7% (90/133). These 90 survived MII-oocytes were fixed and stained for spindle/chromosome alignment analysis. Both the non-vitrified and the vitrified group, showed comparable results concerning normal spindle structure and chromosomes alignment, 85.7% (108/124) versus 92.2% (83/90) ($P = 0.269$).
Limitations, reason for caution: The results are based on transsexual persons whose ovaries were processed at the time of transition surgery, after long term androgen hormonal treatment. Although the *in vitro* matured frozen warmed oocytes seem morphologically normal, the biological competence of these oocytes like fertilisation capacity and implantation potential was not analysed.
Wider implications of the findings: CEOs can be collected during OT cryopreservation for FTMs. The MIIs from the FTMs show a normal spindle structure and chromosome alignment before and after vitrification. From a morphological point of view, the *in vitro* matured oocytes do not seem to be affected by the androgen treatment. This finding can maximise fertility preservation options for FTMs.
Study funding/competing interest(s): Funding by University(ies) – This study has not been supported by any grants and the authors declare no competing interests.
Trial registration number: This research is conducted with the approval of the local ethics committee (2012/780).
Keywords: human ovarian medulla tissue, metaphase-II oocytes, vitrification, spindle, *in vitro* maturation

O-094 Laser assisted hatching of blasotcysts prior to ET may improve outcome

S. Watson[1], N. Winson[1]
[1]*City Fertility Centre, Laboratory, ROBINA, Australia*

Study question: Does laser assisted hatching (LAH) and subsequent blastocyst collapse prior to Embryo Transfer affect pregnancy and implantation rates in fresh IVF cycles.
Summary answer: Fresh embryo transfer of a single blastocyst following laser assisted hatching may improve implantation
What is known already: While LAH studies have been very well documented, there is very little published regarding LAH of fresh blastocysts, a recent presentation at ASRM meeting 2015 (Henderson et al) concluded that LAH of fresh blastocysts may benefit patients over 40 years.
Study design, size, duration: · This was a prospective cohort study of 235 patients undergoing fresh blastocyst transfer between August 2013 and December 2014 at City Fertility Centre.
Participants/materials, setting, methods: · All patients undergoing fresh stimulated IVF cycles with either standard IVF or ICSI insemination were included; donor oocyte, CGH cycles and patients having double embryo transfer (DET) were excluded from analysis. Embryos were assessed on the morning of embryo transfer and LAH performed 5–15 min prior to embryo transfer. The results were compared using Fishers Exact test where $p < 0.05$.
Main results and the role of chance: A total of 272 cycles were included; 136 cycles with LAH with blastocyst collapse and 136 controls. The biochemical and clinical pregnancy rate for the LAH group was 52.2% and 45.6% and in the control group 38.8% and 31.3% respectively. These results were significant when compared using Fishers Exact test ($p < 0.5$).
Limitations, reason for caution: This was not a RCT
Wider implications of the findings: With greater numbers the aeitology of the patients could be reviewed to determine if this practice is more beneficial to a particular sub group of patients**.**
Study funding/competing interest(s): Funding by hospital/clinic(s) – CFC
Trial registration number: NA.

[2]*Maastricht University Medical Center, Department of Clinical Genetics School for Cardiovascular Research, Maastricht, The Netherlands*
[3]*Maastricht University Medical Center, Department of Clinical Genetics School for Growth and Development, Maastricht, The Netherlands*
[4]*Maastricht University Medical Center, Department of Clinical Genetics, Maastricht, The Netherlands*
[5]*Vanderbilt University Medical Center, Department of Molecular Physiology and Biophysics Center for Human Genetics Research, Nashville, U.S.A.*
[6]*Erasmus MC-Sophia Children's Hospital, Department of Pediatric Neurology, Rotterdam, The Netherlands*

Mitochondrial disorders are among the most common inborn errors of metabolism, in at least 15% caused by mitochondrial DNA (mtDNA) mutations, which can occur *de novo* or are maternally inherited. Considering the clinical severity and lack of treatment, preventing transmission to subsequent offspring is often being requested, but reproductive options are not always evident. Recurrence risks vary considerably, ranging from high and unpredictable for many familial mtDNA mutations to low for often *de novo*, large single mtDNA deletions. In the latter case prenatal diagnosis (PND) is offered for reassurance. We studied if the same applied to *de novo* mtDNA point mutations. We performed PND in 4 likely *de novo* mtDNA disease cases, based on absence of the point mutation in multiple maternal tissues. The mtDNA mutation was absent in all 4 prenatal samples. In literature 107 cases with *de novo* mtDNA point mutations were reported, but PND in a subsequent pregnancy was only performed in 6 cases. None showed the mutation. The absence of the mtDNA mutation in 64 siblings of individuals with a presumed *de novo* mtDNA mutation further adds to the low recurrence risk of *de novo* point mutations. However, for ethical reasons most asymptomatic minor siblings of an index patient were not tested for the mutation. Only few reports from family studies describe recurrence, but the data is not unambiguous. So, for *de novo* mtDNA point mutations and deletions the recurrence risk seems to be low and PND can be offered for reassurance. PND is also the most suitable option for female carriers with a low mutation load demonstrating skewing to the extremes. Preimplantation Genetic Diagnosis (PGD) is currently the best reproductive option for most maternally transmitted heteroplasmic mtDNA point mutations. Embryos with mutant load below a mutation-specific or, if

not possible, general expression threshold of 18% are transferred. A total of 19 PGD cycles were performed in our lab for 4 different mtDNA mutations (m.3243A > G, m.8993T > G/C, m.8344A > G, m.14487T > C). Of the 100 embryos diagnosed, 32 were transferable and 14 were transferred, leading to 4 pregnancies. Two have resulted in the birth of a healthy child. All carriers produced oocytes below the threshold. In general blastomere mutation load was representative for the whole embryo, but rare outliers occurred, which could lead to a wrong conclusion. Therefore, we always analyse 2 blastomeres of an embryo. Another patient carried both a *de novo* m.3243A > G mutation and was compound heterozygote for mutations in the polymerase gamma (POLG1) gene, the latter most likely explaining the clinical symptoms. PGD was performed for the mother on both the m.3243A > G and POLG1 mutations in separate blastomeres of the same embryo and a healthy embryo was transferred. None of the embryos carried the m.3243A > G mutation. Data on the oocytes and embryos of a carrier during multiple cycles generates further insight in the size of the individual genetic bottleneck and distribution of mutant load during oogenesis. Although the data is still limited, based on the m.3243A > G and m.8993T > G PGD cases only, and assuming the absence of selection, the size of the bottleneck ranges from about 10 tot 100 mtDNA molecules, which is less than the 200 reported in literature. The distribution pattern of the mutation loads varies, ranging from random (m.324A > G), derived from 2 populations (m.3243A > G) and skewed (m.3899T > G). These data can be used to resolve the mechanisms of the bottleneck further and to predict the chance of having offspring below the threshold of expression in individual carriers. Finally, nuclear genome transfer techniques have recently been approved in the UK and will offer additional reproductive options especially for carriers with high heteroplasmy levels or homoplasmic mtDNA mutations.

O-096 Towards therapeutic application of IVF-based techniques to prevent transmission of mtDNA disease

L. Hyslop[1], L. Irving[1], J. Richardson[1], L. Craven[2], M. Choudhary[3], A. Murdoch[3], D. Turnbull[2], M. Herbert[1]
[1]*Institute of Genetic Medicine, Wellcome Trust Centre for Mitochondrial Research, Newcastle Upon Tyne, United Kingdom*
[2]*Institute of Neuroscience, Wellcome Trust Centre for Mitochondrial Research, Newcastle Upon Tyne, United Kingdom*
[3]*Newcastle Fertility Centre at LIFE, NA, Newcastle Upon Tyne, United Kingdom*

The fertilised egg contains >200,000 copies of mitochondrial DNA (mtDNA). Unlike nuclear DNA, which we inherit from both parents, mtDNA is exclusively maternally inherited. Pathogenic mutations in mtDNA cause a range of debilitating and life-threatening diseases. MtDNA mutations may affect all, or only some, copies of mtDNA. In the latter case, known as heteroplasmy, the severity of disease is proportional to the ratio of mutated to non-mutated mtDNA. Because of random segregation and sampling effects during early embryonic development, women who are heteroplasmic for a given mtDNA mutation produce oocytes with varying mutation loads. It is therefore very difficult to predict the risk of serious disease in the children of affected women. While preimplantation genetic diagnosis (PGD) may be used to select embryos with the lowest mutation load, it is not useful for women who consistently produce oocytes with mutation loads above the threshold for mtDNA disease. An alternative approach, currently being developed, is to uncouple the inheritance of nuclear DNA from mtDNA by transplanting the nuclear DNA from the egg of an affected woman to that of an unaffected donor. This would enable women with mutated mtDNA to have a genetically related child with a greatly reduced risk of transmitting mtDNA disease. Following > 5 years of public debate and scrutiny, the UK Parliament has recently voted in support of a change to legislation to enable the UK Regulator to consider applications from clinics to offer the new techniques in clinical treatment to prevent transmission of mtDNA disease. We are currently engaged in preclinical studies to investigate the likely safety and efficacy of the new techniques. An update of progress towards clinical treatment will be provided.

INVITED SESSION

SESSION 27: ENDING TREATMENT: NOT OUR BUSINESS?

Tuesday 16 June 2015 **08:30–09:30**

O-097 Complicated Decisions: How individuals and couples end treatment

J. C. Daniluk[1]
[1]*University of British Columbia, Educational and Counselling Psychology, Vancouver BC, Canada*

The number of patients who elect to end treatment prior to achieving a viable pregnancy is estimated to range from 20% to 65%. Concerns have been raised about these high "drop out" rates, particularly in cases when the prognosis is good and patients do not have to bear the full financial costs of treatment. In response to these concerns, considerable attention has recently been paid in the literature to the importance of patient-centered care, early identification of psychosocial vulnerabilities, and the availability of adequate, stage-specific counselling and tailored interventions. Efforts to reduce treatment burden, improve the quality of medical care, and support patients through the physical, emotional, and psychological challenges of fertility investigations and treatments should be vigorously pursued. However, these efforts may not be sufficient to fully address "premature" treatment termination. The decision to end fertility treatment prior to achieving a viable pregnancy is indeed complicated. The literature indicates that these decisions are based not just on prognosis or the financial costs of treatment, but on a range of psychosocial factors specific to the individual, their significant relationships, their values and cultural beliefs, as well as their perceptions of the risks and personal costs associated with continued treatment. This presentation will include a brief overview of the research literature addressing the primary reasons that patients end treatment prior to achieving a viable pregnancy. The literature on the short- and long-term outcomes for individuals and couples who end treatment before they are able to realize their parenting dreams and goals will also be discussed. Emphasis will be placed on the importance of patient empowerment through patient-centered care, shared decision-making, language, and empathic communication. The need to expand our definition of successful treatment outcomes will also be underscored. While we may not always be able to ensure *happy* endings, this presentation will focus on what we can do to contribute to *helpful* endings.

Keywords: ending treatment, decision-making, helpful endings

O-098 Women's long-term trajectories of psychological adjustment during and after IVF treatment

S. Gameiro[1], A. W. van den Belt-Dusebout[2], D. Braat[3], F. E. van Leeuwen[2], C. M. Verhaak[4]
[1]*Cardiff University, School of Psychology, Cardiff Wales, United Kingdom*
[2]*Netherlands Cancer Institute, Department of Epidemiology, Amsterdam, The Netherlands*
[3]*Radboud University Nijmegen Medical Centre, Obstetrics and Gunecology, Nijmegen, The Netherlands*
[4]*Radboud University Nijmegen Medical Centre, Department of Medical Psychology, Nijmegen, The Netherlands*

Research on psychosocial adjustment to infertility and fertility treatment has mostly focused on group-based responses to treatment (means), but neglected to investigate how each individual adjusts across time. The goal of the present study was to describe the most common longitudinal adjustment trajectories (anxiety, depression) of women during and after In-Vitro-Fertilization (IVF) treatment and to explore demographic, diagnosis, treatment and psychosocial predictors of these trajectories. Finally we investigated differences in mental-health 11–17 years after treatment according to adjustment trajectories. Women attending the Radboud University Nijmegen Medical Center in The Netherlands (1998–2000, STRESSIVF study) were consecutively recruited. Before the start of the first IVF cycle (T1) data was collected on demographic, diagnosis and psychological (marital relationship, social support, helplessness and acceptance infertility cognitions, avoidant and problem-focused coping) variables. Anxiety (STAI-S) and depression (BDI) were assessed before start, 1 month after their 1st cycle (T2), 6 months

(T3) and 2.5 years after their last cycle (T4). Treatment outcome data after the first and last cycle and compliance behaviour (compliers, discontinuers, persisters) was collected. Mental-health data was collected from OMEGA project (n = 180). Latent class growth mixed modelling with maximum-likelihood-estimation was implemented to identify subgroups of patients with distinct longitudinal trajectories (T1–T4). Predictors of trajectory membership were investigated with multinominal-logistic regressions. Response rate was 84%. 36 women (9.4%) were excluded because they lacked data on more than two time-points. 348 were retained. Average age was 32. 23% had children before treatment. 26% achieved pregnancy after the 1st cycle and 51% after the last. 67% complied with treatment, 23% discontinued prematurely and 10% did more than 3 cycles. Four good-fitting anxiety trajectories were identified (BIC = 7579.71, AIC = 7506.51, posterior classifications ≥.79). Resilient trajectories (n = 232,66.7%) were characterized by stable positive functioning and Recovery trajectories (n = 85,24.43%) by an initial pathological response with return to normal functioning. Chronic (n = 15,4.31%) trajectories presented consistent low levels of psychological functioning and Delayed (n = 16,4.6%) trajectories were characterised by a late pathological response. Three good-fitting depression trajectories were identified (BIC = 4114.32, AIC = 4041.13, posterior classifications ≥.90). Resilient (n = 299,85.92%), Recovery (n = 32,9.2%) and Delayed (n = 17,4.89%). For anxiety, compared with resilient participants, chronic participants reported longer infertility duration (OR = 2.367), higher marital dissatisfaction (OR = 1.176) and were more likely to discontinue treatment prematurely (OR = 7.904). Compared with resilient participants, delayed participants were less likely to have children (OR = 0.55), reported higher marital dissatisfaction (OR = 1.172) and lower social support (OR = .722). Compared with resilient participants, recovery participants reported higher helplessness infertility cognitions (OR = 1.154). For depression, compared with resilient participants, delayed participants were less likely to achieve a pregnancy after the last cycle of treatment (OR = 1.154), reported higher marital dissatisfaction (OR = 1.098), lower social support (OR = .669) and lower infertility acceptance cognitions (OR = .671). Compared with resilient participants, recovery participants were less likely to achieve a pregnancy in their 1st cycle (OR = .161), reported higher marital dissatisfaction (OR = 1.069) and higher helpless infertility cognitions (OR = 1.272). Participants with a resilient anxiety trajectory presented better mental-health than participants with a delayed trajectory (p = .003). Participants with a recovery (p = .002) and resilient (p < .001) depression trajectory presented better mental-health than participants with a delayed trajectory. Most individuals adjust well. Only a very small percentage of patients will never adjust across treatment but 14–33% will present adjustment difficulties at some point during or after treatment. Patients with less satisfaction in the partnership, with less social support and a stronger focus on the child-wish are less likely to be resilient. Recovery trajectories seem to be associated with achieving pregnancy after the first cycle. Discontinuation from treatment is associated with a chronic anxiety trajectory. Overall results suggest that adjustment is multi-determined by demographic, psychosocial, behavioural (i.e., compliance) and treatment factors, and not only a function of treatment outcome.

INVITED SESSION

SESSION 28: ASRM EXCHANGE SESSION – IMPACT OF ENVIRONMENTAL TOXINS ON REPRODUCTIVE HEALTH

Tuesday 16 June 2015 **08:30–09:30**

O-099 Impact of environmental toxins on female reproduction

L. C. Giudice[1]
[1]*University of California San Francisco, Obstetrics Gynaecology and Repr. Sciences, San Francisco CA, U.S.A.*

Reproductive health and ultimately our reproductive capacity are under strain globally. Indicators of reproductive adversity include increased rates of infertility/longer time to pregnancy, premature pubertal onset, increased miscarriage rates, poor birth outcomes, developmental disorders, and reproductive disorders including male and female factor infertility, and endometriosis, polycystic ovarian syndrome (PCOS) and uterine fibroids. Since these changes have occurred in a relatively short timeframe, genetics alone is unlikely, and environmental factors are now considered part of reproductive risk. In developed and developing countries, air pollution, stress, nutrition, and chemicals in agricultural areas, personal care and household cleaning products, and in industrial waste, pesticides, and nearly ubiquitous plastics are of concern. This lecture will focus on representative examples of environmentally-based reproductive compromise and epidemiologic and experimental evidence for epigenetic and trans-generational persistence of some modifications and phenotypes with an eye to how to minimize risk and maximize reproductive success, with a focus on female reproduction.

Keywords: environment, reproductive risk, environmental toxicants, endocrine disrupters

O-100 Impact of environmental toxins on male reproduction

R. Z. Sokol[1]
[1]*University of Southern California Keck School of Medicine, Obstetrics and Gynaecology and Medicine, Los Angeles, CA, U.S.A.*

Occupational and environmental risks to the reproductive system are a public health concern. Population exposure to toxic environmental chemicals is global and ubiquitous. Reports of occupational exposure to chemicals harmful to the male reproductive system date back to Ancient Rome. More recently, epidemiologic evidence supports an association between environmental toxic exposures and reproductive outcomes in the male. A toxicant, whether a chemical, physical, or biologic agent acts by interrupting biologic processes either by a direct chemical action or indirectly when metabolic products alter physiologic control systems in the reproductive system. Potential sites of disruption include the hypothalamic-pituitary-testicular axis, spermatogenesis, sperm function and transport, fertilization and embryo development, and alteration of the epigenetic code. Animal *in vivo* studies suggest that adverse reproductive outcomes are dependent on age of exposure, dose and duration of exposure, and may be trans-generational. The relationship between exposure and outcomes in the human are primarily derived from observational studies that analyze the relationship between the chemical of interest and the change in incidence or prevalence of the reproductive disorder of interest. The most extensively studied toxicants can be categorized into industrial chemicals and agricultural chemicals. A unifying hypothesis proposes that select toxicants are endocrine disrupting chemicals or EDCs, which alter functions of the reproductive endocrine system, primarily via hormone receptors, and consequently cause adverse outcomes. Potential adverse effects have been documented through out the reproductive life cycle in laboratory animals and in some wildlife species. The evidence that human reproductive health has been adversely affected by exposure to chemicals is less definitive; however, a group of studies report a relationship between exposure to EDCs and decreases in sperm production and/or function; and an increase in GU abnormalities and testicular cancer. Current efforts are focused on better methods of laboratory and clinical evaluation; and on careful systematic review of the current scientific evidence to assess the quality and strength of both the animal data and the epidemiologic data, to determine, in as objective an approach as possible, the strength of the evidence of toxicity.

Keywords: toxicity, sperm, infertility, environment

INVITED SESSION

SESSION 29: PARAMEDICAL INVITED SESSION: NURSING

Tuesday 16 June 2015 **08:30–09:30**

O-101 Setting up a networking platform for single women using donor semen

M. Salomon[1], K. K. Schønning[1], H. S. Krogh[1], T. M. Loving[1]
[1]*Copenhagen University Hospital Rigshospitalet, Fertility Clinic, Copenhagen, Denmark*

Study question: Evaluate the use of a patient-network for single women undergoing fertility treatment with donor semen in terms of attendance,

benefits for mother and child and the duration and the value of the contacts they established.
Summary answer: Setting-up this patient-network requires minimal resources and the women evaluated it as beneficial, both during the fertility treatment and after their child was born. Women who stopped having contact with the Solo-mother network or those who didn't get pregnant recommend a similar network to other Solo-mothers.
What is known already: The decision to become Solo-mother using donor semen in Denmark is still controversial. For some women, the decision can be associated with many considerations and difficult choices. The Fertility Clinic, Rigshospitalet, Copenhagen have since 2010 create Solo-mothers networks that allows women to support each other, and allows a long-term opportunity to form relationships with other mothers and children with the same background.
Study design, size, duration: This study was conducted using online questionnaire (www.enalyzer.com). In total 135 women (16 networks) were invited. The survey was anonymous. Inclusion criteria: women who were active in one of 16 Solo-mother networks for at least 4 months. The 16 networks were initiated at least 9 months earlier. Six were excluded.
Participants/materials, setting, methods: There were 129 participants providing 78 responses (61%). All women participated in two introductory meetings facilitated by nurses, after which the Solo-mother networks were left alone. All 16 Solo-mother networks established each, their own group on Facebook for communication. The online questionnaire was launched using these groups on Facebook.
Main results and the role of chance: Responses (n = 78). Totally 79% (n = 62) were still active in the networks, whereas 21% (n = 16) were not active any more. In total 17% (n = 13) had a partner. Overall 69% (n = 54) delivered a child and 9% (n = 7) achieved the child with a partner. On a 5-point-Linkert-scale from very-important to not-important stated 90% (n = 70) it as very-important or important that a nurse facilitated the first two meetings, and they totally-agree or agree that the network has led to: 72% (n = 56) having a better network; 74% (n = 58) got new friends, and 77% (60) feeling less alone. When asking only women who had delivered a child (n = 54) they totally-agreed or agree the Solo-mothers network helped them: 61% (n = 33) during fertility treatment, and 65% (n = 35) after the child was born. They stated that 67% (n = 36) of their children have contact with each other.
Limitations, reasons for caution: The participants were invited through Facebook. If they were no longer active on Facebook they wouldn't receive the invitation. Some women did not attend the Solo-mother network because they worried that it might be stressful, if they did not get pregnant.
Wider implications of the findings: In Denmark number of single women treated with donor semen has increased since 2007, even though having a child with donor semen is not their preferred choice to parenthood (Salomon et al., in press, Obstetricia et Gynecologica Scandinavica 2015). We believe that the opportunity to join a Solo-mother network will contribute to the well-being of these women and their children. Setting-up a patient-network like this could easily be used to the benefit of other patients groups.
Study funding: The evaluation of the solo-mother networks was partly funded by a grant from Nordic Cryobank.
Trial registration number: NA.
Keywords: single women, solo mothers, donor semen, fertility treatment, network

O-102 Needs and determinants that have an influence on the intention to use preconception care among Flemish women

J. Goossens[1], I. Delbaere[2], C. Dhaenens[1], L. Willems[1], A. Van Hecke[1], S. Verhaeghe[1], D. Beeckman[1]
[1]*University Centre for Nursing and Midwifery, Department of Public Health, Ghent, Belgium*
[2]*VIVES University College, Health Care, Kortrijk, Belgium*

Study question: *The study question is two-folded (1)* what are the preconception-related needs of reproductive-aged Flemish women, and *(2)* which determinants and associated factors have an influence on their intention to use preconception care (PCC) in the future?
What is known already: Despite the increased use of prenatal care services, reproductive outcomes remain stable over the last two decades. Many of the adverse reproductive outcomes (such as preterm birth, low birth weight, congenital malformations …) are associated with maternal and paternal risk factors that can be addressed before conception through PCC. Although PCC has been recommended by internationally recognized bodies (such as WHO), most women do not request it. Little is known about women's reasons for not using PCC.
Study design: Cross-sectional study.
Participants/materials, setting, methods: *Study part 1:* 242 reproductive-aged women with a desire to have (additional) children were recruited online through social media and discussion forums, and in the Women's Clinic of Ghent University Hospital, Flanders, Belgium; *study part 2:* the study is ongoing and preliminary results will be presented at the conference.
Main results and the role of chance: *Study part 1:* reproductive-aged women are interested in PCC and prefer to receive this care directly from a professional caregiver. The gynecologist (93%) was the most preferred PCC supplier, followed by the midwife (73%) and the GP (63%). Preconception-related information needs were high. Most women wanted information about nutrition (82%), environmental exposures (76%), work conditions (80%), and medical conditions (54%-74%). Information needs were higher among women with certain medical conditions, such as a (history of) mental illness (OR = 3.50; 95% CI 1.08–11.36), a (history) of eye- and otolaryngological diseases (OR = 2.22; 95% CI 0.95–5.21), and being overweighed (OR = 2.22; 95% CI 1.01–4.93). Few women indicated that they need preconception-related support. Women with overweight had a higher need for lifestyle-related support (p = 0.001); *study part 2:* the study is ongoing.
Limitations, reasons for caution: *Study part 1:* women were recruited on a voluntary basis, which increases the risk of selection bias. Our sample tends to over-represent women with a higher socioeconomic profile. The actual needs and attitude towards preconception care can be different than our findings suggest; *study part 2:* the study is ongoing.
Wider implications of the findings: *Study part 1:* our study results indicate that PCC should be offered to women of reproductive age as they are interested in PCC and have high information needs. Midwives can have an important role in providing preconception care as more women prefer to receive PCC from a midwife than a GP; *study part 2:* the study is ongoing.
Study funding/competing interest(s): This study was funded by the Research Foundation – Flanders (FWO). The authors declare that they have no competing interests.
Trial registration number: (1) B670201420381, (2) B670201422053.

SESSION 30: INNOVATIVE ASPECTS OF BLASTOCYST DEVELOPMENT

Tuesday 16 June 2015 **10:00–11:30**

O-103 Qualitative and quantitative grading of human blastocysts and its association with live-birth rate and neonatal outcome

T. Ebner[1], O. Shebl[1], K. Tritscher[2], P. Oppelt[3], H. C. Duba[4], M. Maurer[4], G. Schappacher-Tilp[5], E. Petek[2], R. B. Mayer[1]
[1]*Landesfrauen- und Kinderklinik Linz, Kinderwunsch Zentrum, Linz, Austria*
[2]*Medical University, Institute of Human Genetics, Graz, Austria*
[3]*Johannes Kepler University, Medical Faculty, Linz, Austria*
[4]*Landesfrauen- und Kinderklinik, Department of Human Genetics, Linz, Austria*
[5]*Karl Franzens University, Department for Mathematics and Scientific Computing, Graz, Austria*

Study question: Does qualitative and quantitative blastocyst assessment on day 5 allow for prediction of neonatal outcome (placental and birth weight, live birth, malformation)?
Summary answer: After adjustment for gestational age vitrified blastocysts resulted in a higher birth weight as compared to fresh ones. Trophectoderm (TE) but not inner cell mass (ICM) or blastocyst expansion was associated with the sex of the embryo as well as the rates of implantation, pregnancy, miscarriage, and live birth.
What is known already: The practice of culturing embryos until blastocyst stage for transfer has become more common in the field of ART with the development of optimized culture media. However, it should also be noted that

several drawbacks have been reported for blastocyst culture, such as monozygotic twinning, preterm delivery, congenital malformations or increased birth weight. With respect to the latter it seems that in humans intrauterine growth is impaired as early as in the second trimester of pregnancy.
Study design, size, duration: This prospective analysis comprises all fresh and vitrified/warmed single blastocyst transfers meeting the inclusion criteria during an 18-month period.
Participants/materials, setting, methods: A total of 254 blastocysts (162 fresh and 92 vitrified/warmed) were included which showed at least full stage guaranteeing the presence of an extensive blastocoel and distinct cell lineages. Qualitative scoring of blastocysts was done according to the classical criteria expansion, inner cell mass as well as trophectoderm appearance. In parallel, all three parameters were quantified semi-automatically. Placental and birth weights and malformations, respectively, were provided by the maternity hospitals.
Main results and the role of chance: Vitrified blastocyst transfers led to a significantly higher birth ($P = 0.012$) but not placental weight ($P = 0.106$) as compared to the fresh counterparts. Degree of expansion was not related to outcome nor was ICM grade and area. However, hatching blastocysts had significantly smaller ICMs as compared to full ($P > 0.01$) and expanded blastocysts ($P < 0.05$). Trophectoderm quality and cell number were the only parameters that were significantly related to rates of implantation, pregnancy, and live birth. Pregnancies that went to live birth could be distinguished from those pregnancies that aborted (biochemical pregnancies, missed abortion with and without heart activity) on the basis of trophectoderm grade ($P < 0.05$) and cell number ($P < 0.001$). Male blastocysts had a 2.53 higher chance to show TE of quality A as compared to female ones ($P = 0.04$).
Limitations, reason for caution: Since the routine performance of the laboratory was to transfer and vitrify blastocysts with the largest ICM, number of study blastocysts that showed very small ICMs of class C was limited. In general, it should be kept in mind that two-dimensional measurement may not accurately reflect 3-dimensional structure of the cell-lineages.
Wider implications of the findings: The presented correlation of TE with outcome indicates that sooner or later trophectoderm scoring will replace inner cell mass scoring in terms of priority. This would automatically require a rethinking process in terms of blastocyst selection and cryopreservation strategy.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Landes-Frauen- und Kinderklinik Linz, Austria.
Trial registration number: NA.
Keywords: blastocyst expansion, inner cell mass, placental and birth weight, trophectoderm, live-birth

O-104 For patients with repeated implantation failures, a morphologically poor blastocyst could affect the implantation rate of a morphologically good blastocyst during a double blastocyst transfer

S. Ohgi[1], C. Nakamura[1], Y. Kurata[1], H. Anakubo[1], C. Hagihara[1], A. Yanaihara[1]
[1]*Yanaihara Women's Clinic, Division of Reproductive Medicine, Kanagawa, Japan*

Study question: Increasing the number of transferred embryos or blastocysts is sometimes selected as the strategy for patients with repeated implantation failure (RIF). Does this strategy actually contribute to an increase in the implantation rate for the patients with RIF?
Summary answer: Although double blastocyst transfer (BT) with two morphologically good blastocysts (MGBs) increases the chances for a multiple pregnancy, it does not increase the pregnancy rate compared with a single BT with a morphologically poor blastocyst (MPB) among patients with RIF.
What is known already: An increase in the number of transferred blastocysts is believed to also increase the pregnancy rate. Therefore, a double BT is sometimes selected as one of the strategies for patients with RIF. However, a double BT also increases the risk for multiple pregnancies. We previously demonstrated that the implantation rate for a double BT with morphologically good and poor blastocysts was significantly lower than that for a single good blastocyst.
Study design, size, duration: This retrospective study was performed between April 2009 and September 2014 and included 634 cycles for 354 patients who had experienced more than two failures with a single BT. Patients received either a vitrified-warmed single or a double BT in either the natural ovulatory cycle or the HRC.
Participants/materials, setting, methods: A MGB consists of an ICM and TE of grade A or B. The remainders are MPB. We compared pregnancy rates among the groups that received a single BT with a MGB, a double BT with two MGBs, or a double BT with both a MGB and a MPB.
Main results and the role of chance: The pregnancy rate in the group that received double BTs with two MGBs was 45.6%, which was comparable to the single BT group with a MGB (37.8%) and to the double BT group with both a MGB and a MPG (39.5%). The multiple pregnancy rate for the double BT group with two MGB was 14.6%, but there was no multiple pregnancy in the single BT group.

Table

	Single BT		Double BT	
	MGB	MPB	MGB + MGB	MGB + MPB
BT cycle, *n*	468	3	90	76
Transferred MGB, *n*	468	0	180	76
Transferred MPB, *n*	0	3	0	76
Pregnancy rate; %	37.8	0	45.6	39.5
Implantation rate; %	37.8	0	26.1*	22.4*
Multiple pregnancy rate; %	0	0	14.6	13.3

*$p < 0.001$ vs single BT

Limitations, reason for caution: In this study, patients with more than two unsuccessful IVF cycles were selected, because the definition of RIF in the literature usually ranged between 2 and 6 unsuccessful IVF cycles. Therefore, the patients in this study would have been categorized as falling somewhere between severe and mild RIF cases.
Wider implications of the findings: The implantation rates of a double BT with two MGBs or one each of a MGB and a MPB were significantly lower than that of a single BT with a MGB. A double BT didn't decrease the pregnancy rate, but it did increased multiple pregnancies. Therefore, even for treatment of RIF patients, we should avoid double BTs when two or more MGBs might be acquired.
Study funding/competing interest(s): Funding by hospital/clinic(s) – The authors have received no funding for this study, and they have no financial interests in any companies. Also, there are no competing interests.
Trial registration number: This study is not an RCT study, so no trial registration number was assigned.
Keywords: morphologically good blastocyst, morphologically poor blastocyst, mplantation rate, repeated implantation failure

O-105 Blastocyst development in single-step versus sequential culture media of the same brand: analysis of 386 sibling oocytes

A. Alteri[1], G. Fabozzi[1], E. Rega[1], M. F. Starita[1], P. Giannini[1], C. Piscitelli[1], A. Colicchia[1]
[1]*Villa Margherita, Ferticlinic, Roma, Italy*

Study question: To compare embryo development between sibling oocytes cultured in single-step and sequential media produced by the same manufacturer (SAGE).
Summary answer: Embryo culture in single-step medium (One-Step) is associated with significantly higher blastocyst formation rates (BFR) and overall blastocyst quality compared to culture in sequential media (Cleavage-Blastocyst).
What is known already: Embryo culture is a complex task, and culture media play a key role for embryo development *in vitro*. Two different approaches are commercially available: single-step, a medium formulated for the entire preimplantation period, based on the principle of 'letting the embryo choose', and sequential media, which mimic the environment of the female reproductive tract, requiring medium renewal at least every 48 h. The question of which system performs better remains highly contentious.
Study design, size, duration: Prospective randomized study of 386 sibling oocytes from 50 women (aged ≤ 39 years) undergoing oocyte retrieval procedure for intracytoplasmic sperm injection (ICSI) at Ferticlinic, Villa Margherita, from September to December 2014.
Participants/materials, setting, methods: A total of 386 injected oocytes were randomly allocated in two different dishes containing single-step (group A) and sequential medium (group B) respectively. Culture was performed up to blastocyst stage in multi-gas incubators (Sanyo) at 37°C, 5% 02, 5.5% CO2. Medium change was performed only for sequential medium on Day-3.
Main results and the role of chance: No significant difference was detected in the fertilization rate between group A and B, respectively 84.76% (178/210) vs.

79.55% (140/176). On day-3, the percentage of grade-A, (77.53% vs. 64.29%), grade-B (7.87% vs. 12.86%), grade-C (14.61% vs. 22.86%) and grade-D embryos (0% vs. 0%) did not differ as well. On day-5, culture in one-step yielded a significant higher BFR [144/178 (80.9%) vs. 94/140 (67.14%) $P = 0.04$] and more top-quality blastocyst rate [76/144 (52.78%) vs. 24/94 (25.53%), $P = 0.003$].

Limitations, reason for caution: This was a prospective randomized study with sibling oocytes. To confirm the result, it is necessary to evaluate clinical data in a prospective RCT with randomization of patients. Furthermore, studies evaluating epigenetic effects of the two different approach should be conducted.

Wider implications of the findings: Probably we should critically reexamine the conviction that sequential culture approach, mimicking the female reproductive tract environment, is the ideal strategy. The additional handling required for medium renewal and the lost of accumulated endogenous growth factors changing culture dish is likely to provide an environmental stress to embryos, making this choice not worthwhile and preferring the one which leaves embryos undisturbed.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Ferticlinic, Villa Margherita, Rome, Italy.

Trial registration number: NA.

Keywords: embryo culture, single medium, sequential media

O-106 Blastocyst inner cell mass and trophectoderm grading lends to euploidy predictability

R. E. Anderson[1], J. B. Whitney[1], N. L. Nugent[1], K. Waggoner[1], J. Borba[1], L. Gamboa[1], S. Zozula[1], M. C. Schiewe[1]

[1]*Southern California Institute for Reproductive Sciences, ART, Newport Beach CA, U.S.A.*

Study question: Can independent quality grades for blastocyst inner cell mass (ICM) and trophectoderm (TE) predict early embryo euploidy? Can a chart utilizing combined ICM and TE blastocyst grades be made to predict the best choice for embryo transfer?

Summary answer: ICM and TE grades show significance for euploid predictability. Blastocysts with a grade A resulted in higher euploid predictability. When combining grades to access overall blastocyst quality, TE grade is more predictive. Experience dictates that a grade A TE should be preferentially selected for transfer to optimize implantation success

What is known already: Morphology has been the most used and reliable method for embryo transfer selection. Ahlstrom and coworkers (ESHRE 2013) provided strong embryo transfer evidence that an 'A' quality TE grade versus ICM grades is more predictive of pregnancy success in fresh, non-PGS cycles. Early embryo aneuploidy is widely accepted as a major reason of implantation failures. However, to-date, there are no clear morphologic characteristics that accurately predict genetic normality.

Study design, size, duration: Retrospective analysis of ICM and TE quality grades was associated with 1,311 euploidy screened blastocysts. Patients autonomously chose to perform PGS-trophectoderm biopsy/microSecure vitrification-all cycles ($n = 288$), between January 1, 2014 and December 31, 2014. Array CGH and NextGen sequencing was used for aneuploidy determination.

Participants/materials, setting, methods: On day 5-6, all expanded blastocysts were assigned a quality grade for ICM and TE. Grades ranged from A (good) and B (fair) to C (poor). All blastocysts with ICM or TE quality grades of A or B were used for analysis. Statistical significance was determined by Fishers exact test.

Main results and the role of chance: Independent quality grade analyses indicate that grade 'A' blastocysts resulted in statistically higher euploidy predictability. Euploidy occurrence for ICM revealed: grade A-57%, grade B-43%; and TE: grade A-62%, grade B-37%. Combined blastocyst grade euploidy analysis indicated: AA-62%, BA-62%, AB-41%, and BB-33%. A comparative chart was made to determine which combined blastocyst grade had the best predictive ability for euploidy. The chart indicated that when TE was accessed as grade A, euploidy predictability was highest and when TE was graded B euploidy predictability was lowest. ICM grades were predictive with emphasis on grade A, but poor quality graded ICM embryos with top quality grade TE showed significance for similar or higher euploidy predictability. Overall, high levels of implantation (85%) and ongoing pregnancies (79%) were achieved.

Limitations, reason for caution: Morphology assessments are a non-diagnostic procedure, which is subject to technician and program variation. Although blastocyst grades are predictive of potential euploidy status, the morphological quality assessment is not absolute. Therefore, some poor morphological graded blastocysts may be euploid, while other high quality blastocysts are in fact aneuploid.

Wider implications of the findings: Euploidy determination in our clinic has facilitated routine single embryo transfer with increased success, while drastically decreasing twinning rates. Although this study highlights that morphology can be predictive, it clearly is not diagnostic. Many embryos could be incorrectly selected or de-selected for transfer, thus effecting overall take home baby rates. Preimplantation screening is the best option for embryo selection to eliminate the inherent variability associated with morphological assessments, with or without developmental time lapse imaging.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Southern California Center for Reproductive Medicine.

Trial registration number: NA.

Keywords: blastocyst, embryo grading, euploidy

O-107 Identifying chromosomes with significant roles in blastocyst development

D. H. McCulloh[1], H. L. Lee[1], C. McCaffrey[1], B. Hodes-Wertz[1], J. A. Grifo[1]

[1]*New York University Langone Medical Center, NYU Fertility Center, New York NY, U.S.A.*

Study question: Aneuploidy screening helps to identify embryos that will not become healthy babies; however, little is known about the influence of individual chromosome aneuploidies (ICAs) on embryonic development. Knowledge of which ICAs affect early embryonic development may help us to understand where critical genetic elements controlling early development can be found.

Summary answer: Trisomies were transmitted preferentially to blastocysts for chromosomes 1, 6, 9, 11, 17 and 20 whereas monosomy was transmitted preferentially for chromosome 18. This suggests that preferentially transmitted trisomic chromosomes carrying excess genetic material enable blastocyst formation whereas preferentially transmitted monosomic chromosomes carrying genetic material preclude blastocyst formation.

What is known already: Most aneuploid embryos are incapable of developing into living babies. We routinely identify aneuploid embryos and deselect them for transfer since their prospects for live birth are slim. However, we know that some aneuploid embryos are capable of blastocyst formation, implantation and development to advanced fetal stages since they may be found in products of conception and in live births.

Study design, size, duration: We compared the incidences of ICAs in embryos biopsied on day 3 with embryos biopsied as blastocysts. Knowledge of ICAs for which the incidence varies between day 3 and the blastocyst stage may help us to learn more about where genetic elements that control embryonic development are found.

Participants/materials, setting, methods: Array Comparative Genomic Hybridization (aCGH) Data for 560 day 3 embryos and 1014 blastocysts were assembled. Incidences of aneuploidy for each chromosome (ICAs) were determined and compared. Transmittance of each ICA from day 3 to blastocysts was calculated as the ratio of incidences for each ICA (blast/day 3).

Main results and the role of chance: Incidences of euploidy (day 3:28.8%; blastocyst: 35.8%) were significantly different. ICAs were found for every chromosome (1-22, X, Y) both on day 3 and in blastocysts. The mean incidences of aneuploid chromosome/aneuploid embryo (day 3: 2.06 ± 1.64; max = 23; blastocyst 3.23 ± 3.35 max = 13) differed significantly. Incidences of autosome ICAs (per aneuploid embryo) averaged 0.069 (range: 0.033 [trisomy 11] to 0.125 [monosomy 16]) for day 3; 0.046 (range: 0.013 [monosomy 3] to 0.096 [monosomy 16]) for blastocysts. Transmittances averaged 0.655 (range: 0.23 [monosomy 1] to 1.36 [trisomy 11]). Comparing transmittances of trisomy:monosomy for each chromosome, we estimated the effect of two copies of the chromosome. Trisomies 1, 6, 9, 11, 17 and 20 and monosomy 18 were transmitted preferentially to blastocysts.

Limitations, reason for caution: ICAs were assessed in two different groups of patients (day 3 versus blastocyst biopsy) rather than investigating the progression from day 3 to blastocyst in embryos with known ICAs. While our method avoids the issue of harm from day 3 biopsy, it lacks the statistical sensitivity expected from a paired approach.

Wider implications of the findings: ICAs occur with unequal incidences in both day 3 embryos and blastocysts. Lower incidence of multiple aneuploidies in blastocysts suggests that embryos with multiple aneuploidies progress poorly to the blastocyst stage. Accentuated inhomogeneity of incidences for ICAs in blastocysts suggests preferential transmittance. The significantly different transmittance of trisomies 1, 6, 9, 11, 17 and 20 and monosomy 18 suggest that genetic elements enabling progression to the blastocyst stage lie on these chromosomes.

O-108 Number of trophoectoderm cells removed for biopsy is correlated with first trimester miscarriage

J. Ten Morro[1], A. Rodriguez-Arnedo[1], M. C. Díaz[1], H. Blanca[1], J. Guerrero[1], B. Lledo[2], B. Moliner[3], F. Sellers[3], A. Bernabeu[3], J. Llacer[3], R. Bernabeu[3]
[1]*Instituto Bernabeu, Department of Biologia de la Reproduccion, Alicante, Spain*
[2]*Instituto Bernabeu Biotech, Molecular Biology, Alicante, Spain*
[3]*Instituto Bernabeu, Reproductive Medicine, Alicante, Spain*

Study question: Trophectoderm biopsy provides the possibility of removing several cells, which allows more accurate genetic diagnosis. Although it is recommended not to remove more than 10 cells, in many cases, the technique itself makes it difficult. This could affect embryo implantation and miscarriage in early stages, despite being euploid embryos.
Summary answer: The removal of more than 10 cells during trophectoderm biopsy increases the rate of miscarriage in the first trimester in euploid embryos after comprehensive chromosome screening (CCS).
What is known already: Day 3 biopsy is considered to be harmful to the embryo. The risk of misdiagnosis due to mosaicism and the aggression for the embryo decreasing dramatically the implantation rate making it unacceptable. In contrast, trophectoderm biopsy offers the possibility of obtaining several cells without apparent embryo damage. However, we have not enough information to ascertain which is the number of cells that can be drawn without affect clinical outcomes.
Study design, size, duration: Prospective study. We include the known clinical results of 161 euploid embryos transferred coming from 98 women that underwent CCS treatments from January to September 2014.
Participants/materials, setting, methods: At least one euploid embryo was transferred to 98 patients. Assisted hatching was performed on day 3 using laser pulses (Saturn Active, Research Instruments). On day 5 of development, conventional trophoectoderm biopsy was done. Images were recorded using Cronus software, and trophoectoderm cells were counted. Clinical outcomes were evaluated.
Main results and the role of chance: We removed ≤ 10 cells in 105 blastocysts (group I), and more than 10 in 56 (group II) according to the hatching of the embryos. These embryos were chromosomally analyzed by array-CGH. Euploidies embryos were transferred on day 6. The global clinical pregnancy rate (sac visualization after 6 weeks of gestation) was 51.8%. There was no statistically significant difference in the clinical pregnancy rate between groups I and II. However, an increase in the first trimester miscarriage was strongly associated with the biopsy of more than 10 cells (6.3 % in group I vs 25% in group II, with an odds ratio 6.45, 95% confidence interval 1.26-32.90).
Limitations, reason for caution: Study currently under development to increase the number of cases and test this assertion and to ascertain which is the ideal number of trophoectoderm cells for biopsy.
Wider implications of the findings: The results obtained in this preliminary study confirm that the cells that give rise to the placenta and extraembryonic tissues play a crucial role in the maintenance of early stages of embryo development. The biopsy of more than 10 cells in the blastocyst stage may be detrimental, perhaps not for the embryo implantation, but for the later development. According to our results we should remove less than 10 cells.

O-109 Efficacy of Dehydroepiandrosterone (DHEA) to overcome the effect of ovarian ageing (DITTO): a double blinded randomized placebo controlled trial

K. Jayaprakasan[1], A. Narkwichean[2], W. Maalouf[2], M. Baumgartean[2], L. Polanski[2], N. Raine-Fenning[2], L. Zujovic[2], J. Thornton[2], B. Campbell[2]
[1]*NURTURE University of Nottingham and Royal Derby Hospital, Reproductive Medicine, Nottingham and Derby, United Kingdom*
[2]*NURTURE University of Nottingham, Reproductive Medicine, Nottingham, United Kingdom*

Study question: To evaluate the effect of pre-treatment DHEA supplementation on the outcome of In-Vitro Fertilisation (IVF) treatment in women predicted to have poor Ovarian Reserve (OR).
Summary answer: Pre-treatment DHEA supplementation doesn't seem to improve the ovarian response as measured by the number of oocytes retrieved or clinical pregnancy rates during IVF treatment in women predicted to have poor OR.
What is known already: Ovarian ageing is a cause of subfertility and is associated with poor outcomes of IVF treatment. A few clinical studies have shown that DHEA can improve ovarian response and increase the chances of pregnancy after IVF treatment in women with a poor OR suggesting DHEA may help to overcome the effect of ovarian ageing.
Study design, size, duration: A single centre, double blinded, placebo controlled, randomized trial was performed over two years with 60 women undergoing IVF. Subjects were randomized, based on a computer-generated pseudo-random code using random permuted blocks of randomly varying sizes, to receive either DHEA or placebo with both capsules having similar colour, size and appearance.
Participants/materials, setting, methods: 60 with poor OR based on antral follicle count (≤ 10) or anti-Mullerian hormone (< 5 pmol/L) undergoing IVF were recruited. They were randomised to receive DHEA 75 mg/day or placebo for at-least 12 weeks before starting ovarian stimulation. They had long protocol using hMG 300 IU/day. Data analysed by "intention to treat".
Main results and the role of chance: The recruitment rate was 39% (60/154). A total of 53 participants (28 vs 25 in the study and the placebo groups respectively) were included in the final analysis after excluding seven, who did not commence the trial medication due to various reasons. The number (median; range) of oocytes retrieved (4; 0-15 vs. 4; 0-18 respectively; $P = 0.69$) and clinical pregnancy rates (7/28, 25% vs 9/25, 36% respectively; $P = 0.38$) were similar between the study and control groups. While the mean (± standard deviation) basal DHEA levels were similar at recruitment (9.1 ± 5.1 vs 7.5 ± 2.4 ng/ml respectively; $P = 0.3$), the DHEA levels at pre-stimulation stage were higher in the study group than in the control group (16.3 ± 5.9 vs 11.2 ± 4.5 ng/ml respectively; $P < 0.01$). No serious adverse events noted in both groups.
Limitations, reason for caution: The study was planned as both a proof of principle trial with the ovarian response as a surrogate for clinically important outcomes, and as pilot to evaluate the feasibility of conducting a late phase trial to test the effect of DHEA on live births. The successful recruitment suggests such a definitive trial would be feasible, but the lack of effect on ovarian response suggests it is a low priority.

Wider implications of the findings: The data from the study do not support the idea of using DHEA as an adjunct to IVF for improving treatment outcome in women predicted to have poor OR. While there has been a great deal of attention in the use of pre-treatment DHEA in predicted poor responders recently, this practice should be restricted to as part of large RCTs.

O-110 Effects of recombinant-LH supplementation on the proteomic profile of follicular fluid from poor responder patients: focus on follicular growth factors and oocyte maturity markers

M. Noventa[1], S. Gizzo[1], C. Zicchina[1], A. Vitagliano[1], F. Esposito[1], M. Quaranta[2], B. Abdulrahim[3], C. J. Aldrich[3], M. Gangemi[1], G. B. Nardelli[1], A. Andrisani[1]
[1]*University of Padua, Woman and Child Health, Padua, Italy*
[2]*University of Verona, OB/GYN Unit, Verona, Italy*
[3]*NHS Trust – Northampton General Hospital, Obstetrics and Gynecology, Northampton, United Kingdom*

Study question: May recombinant-LH supplementation during IVF cycles in poor responder patients influence the pathways involved in follicular growth and oocyte maturity? Which pathways of follicular signaling are influenced by recombinant-LH supplementation? Can these factors explain the clinical advantages observed in older poor responder patients after recombinant-LH supplementation?
Summary answer: In poor-responder patients, recombinant-LH supplementation during IVF influences the pathways involved in follicular growth and oocyte maturity. The treatment significantly increases follicular levels of EGF, ERK-1/2 and AKT-1 and particularly the availability of the phosphorylated forms (active forms). These evidences explain the improvements in qualitative and quantitative ovarian response.
What is known already: Poor/fragmentary data was available regarding the effects of recombinant-LH in in-vitro granulosa and theca cells of human origin. No data was available from in-vivo studies regarding the effects of recombinant-LH supplementation on SCF, EGF, ERK-1/2 and AKT-1 pathways in the follicular fluid of older-poor-responder women undergoing IVF cycle. Evidence from in-vitro and animal studies seems to confirm that recombinant-LH, in addition increasing cAMP levels (involved in steroidogenesis), activates the ERK-1/2 (proliferation) and AKT-1 (anti-apoptotic) pathways.
Study design, size, duration: Observational longitudinal crossover study on 28 poor-responder patients > 42 years older. All patients underwent COS using rFSH alone in the first cycle (s-COH group) and using rFSH with rLH supplementation (ex-COH group) in the second cycle. We compared follicular concentrations of SCF, EGF, Erk 1-2, p-Erk 1-2, Akt-1 and p-Akt-1 between the two groups.
Participants/materials, setting, methods: After the achievement of hypotalamic suppression (long-agonist protocol), stimulation was performed using rFSH-300IU/day (plus rLH150IU/day in ex-COH) for 5-days and subsequently adjusted according to biochemical/sonographical features (s-COH). Follicular levels of SCF, EGF, Erk 1-2, p-Erk-1/2, Akt-1, p-Akt-1 were detected using appropriate ELISA-Kit and reported in pg/mL, ng/mL or Unit/mL, according to the manufacturer's indications.
Main results and the role of chance: Follicular levels (56 samples) of EGF, Erk 1-2, p-Erk-1/2, Akt-1, p-Akt-1 were significantly different between s-COH versus ex-COH, with the exception of SCF. In detail, mean value of EGF was 9,40 ± 2,92 vs 11,75 ± 3,95 pg/mL [$p < 0.05$], ERK 1-2 184,82 ± 50,15 vs 332,14 ± 111,35 pg/mL [$p < 0.001$], p-ERK-1/2 20,89 ± 3,41 vs 40,18 ± 10,37 U/mL [$p < 0.001$], AKT-1 5,35 ± 2,45 vs 10,42 ± 2,08 ng/mL [$p < 0.001$], p-AKT-1 28,07 ± 8,98 vs 42,36 ± 10,06 U/mL [$p < 0.001$], SCF 830,25 ± 364,09 vs 735,43 ± 300,39 pg/mL [p:n.s.]. The increasing intra-follicular levels of proteins (particularly in their active conformation) involved in cellular proliferation and anti-apoptotic pathways may explain the better clinical outcome observed after rLH supplementation. The absence of significant variations in SCF levels confirmed both that this pathway is activated only by FSH stimulation and that differences collected in other pathways is generated by rLH signaling.
Limitations, reason for caution: The potential bias linked to the type of the study (pilot study with low sample size), the peculiar features of the patients (older poor responder), the collection and assay of total follicular fluid for any treatments and not for single follicle require caution in the interpretation of data.
Wider implications of the findings: The type of study and its results strongly suggests that the differences in terms of follicular growth factors and oocyte maturity markers are linked to LH-signaling. The lower levels of SCF in the ex-COH group, though not statistically significant, suggest that LH can partially replace/potentiate the effects of FSH on follicular growth (SCF is exclusively controlled by FSH-signaling). This is the first in-vivo study reporting these evidences, partially demonstrated by in-vitro/experimental studies on animals.

O-111 Beneficial effects of melatonin on oocytes and embryo quality in aged IVF patients

C. Valeri[1], G. Sbracia[2], H. Selman[1], G. Antonini[2], A. Pacchiarotti[3]
[1]*Praxi Provita, Embryology, Roma, Italy*
[2]*University La Sapienza, Department of Science, Roma, Italy*
[3]*Praxi Provita, Ginecology, Roma, Italy*

Study question: The aim of the present study was to evaluate the role of melatonin supplementation on the main IVF outcomes in aged patients underwent IVF
Summary answer: Data reported in the manuscript clearly demonstrate that melatonin administration during ovarian stimulation in IVF patients increases intrafollicular melatonin concentrations and improve oocytes and embryos quality in over 40 patients
What is known already: IVF patients treated with melatonin had a greater number of mature oocytes and a lower number of immature oocytes compared not treated patients. Indeed, it is very likely that melatonin promotes the elimination of oxygen free radicals. Furthermore we demonstrated that exogenous administrated melatonin is able to accumulate in the follicles.
Our suggestion is to give a melatonin supplementation to aged patients underwent IVF.
Study design, size, duration: From July 2009 to December 2013 358 patients were assessed for elegibility in this prospective double blind randomized controlled trial.
Participants/materials, setting, methods: 358 infertile women aged over 40 underwent a shortdown-regulation protocol with a gonadotropin-releasing hormone (GnRH) analogue and a combined stimulation protocol with urinary and recombinant FSH. The patients were randomized into two groups: Group A, 178 patients who received melatonin (5 mg); group B, with 180 patients who did not received melatonin.
Main results and the role of chance: There were significant statistical differences comparing group A with group B in terms of mature oocytes (48.2% vs 35.0% $p = 0.008$); oxidative stress (CARR U 190 ± 41 vs 388 ± 64 in group A and B respectively), antioxidative capacity (AOCs) (1,76 ± 0,4 vs 0,89 ± 0,2 in group A and B respectively), progesteron concentration in follicular fluid (10,4 ± 1.1 vs 4,3 ± 0,8 in group A and B) and grade I embryos (45,7% vs 30,4% $p = 0.0045$). Melatonin intrafollicular concentrations were significantly increased after melatonin treatment (213 ± 51 pg/mL versus 69 ± 23 pg/mL, $P = 0.0013$).
Limitations, reason for caution: Statistical power calculation was based on a level of 0.05 with 80% power to detect a 20% difference with 50 evaluable patients per group. Sample size needed was 214 (Confidence Interval 4; Confidence level 95%). The difference between treatments was evaluated using a two-sided, 95% confidence interval.
Wider implications of the findings: Melatonin supplementation during IVF protocols in aged patients improve oocyte and embryo quality increasing progesterone production and scavenging free radicals. Furthermore, melatonin is efficiently accumulated in the follicular fluid.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Praxi DS, Praxi Provita.

Trial registration number: NCT01540747.

O-112 Supplementation of medroxyprogesterone acetate in modified natural cycles to prevent premature ovulation for IVF/ICSI patients with diminished ovarian reserve

Y. Kuang[1], Q. Chen[1], A. Ai[1], Y. Fu[1], R. Cai[1], H. Tian[1], Y. Wang[1], Q. Hong[1], Q. Lyu[1], Q. Lyu[1], Z. Shoham[2]
[1]*Shanghai 9th People's Hospital, Department of Assisted Reproduction, Shanghai, China*
[2]*Kaplan Medical Center, Department of Obstetrics and Gynecology, Rehovot, Israel*

Study question: Is it possible to prevent premature ovulation using orally progestin (medroxyprogesterone acetate, MPA) in modified natural cycles based on freeze-all policy for patients with diminished ovarian reserve (DOR)?
Summary answer: Supplementation of MPA in modified natural cycles is an effective treatment to prevent premature ovulation and improve cycle programme for patients with DOR.DOR patients would have more chance to obtain oocytes/embryos for subsequently frozen-thawed embryo transfer (FET). The viable embryo rate per oocyte retrieved in modified natural cycle with MPA was not significantly increased.
What is known already: Premature ovulation is a current challenge for patients with DOR, even with using of GnRH anaglue. Our previous study indicated that progesterone can prevent premature LH surge in controlled ovarian stimulation in normal ovulatory women, both in the follicular-phase ovarian stimulation and luteal-phase ovarian stimulation. We analysed the clinical and embryological outcomes of using MPA in modified natural cycle in patients with DOR.
Study design, size, duration: A prospective controlled open-label cohort study was conducted between 2014 Jan and November at Shanghai Nineth People's Hospital, Shanghai, China. 204 infertile women with spontaneous cycle, higher basal FSH (10-30 IU/l) or no more than 5 antral follicles were included and allocated into two groups (MPA group and natural cycle) in alternatively order.
Participants/materials, setting, methods: In MPA group, MPA 10 mg/d was administrated from menstrual cycle day 3. After 5-7 days, follicular monitoring was conducted every 2–4 days, low dose of hMG was added if necessary. When one dominant follicle reached mature, triptorelin 100 μg and hCG 1000 IU were used for trigger. Oocyte retrieval was performed 35-36 h later. Natural cycle was as controls. All viable embryos were cryopreserved for subsequent embryo transfer. The primary endpoint was the number of oocytes retrieved.
Main results and the role of chance: In MPA group, the premature ovulation rate was significantly decreased into 2.0% compared with 10.8% in natural cycle ($P < 0.05$). The mean number of oocyte retrieved and viable embryos were significantly increased in MPA group (1.1 ± 0.6 vs 0.8 ± 0.6, $P < 0.05$; 0.6 ± 0.6 vs 0.4 ± 0.5, $P < 0.05$). The fertilization rate and cleavage rate were similar between the two groups. 14.71% (15/102) patients performed emergency advanced oocyte retrieval in natural cycle while no one advanced oocyte retrieval in MPA groups. The mean interval from trigger to oocyte retrieval in MPA group was significantly longer than those who were triggered in natural controls (35.3 ± 0.6 h vs 31.5 ± 5.8 h, $P < 0.01$). The cycle cancel rate of no viable embryos was slightly lower in MPA group but not reach significance (50.0% vs 61.8%, $P = 0.091$). The viable embryo rate per oocytes retrieved was similar between the two groups (51.3% vs 51.9%, $P > 0.05$).
Limitations, reason for caution: DOR patients have to accumulate enough viable embryos for subsequent FET in IVF clinic. No pregnancy outcome was reported due to the policy of transfer two embryos in our clinic.
Wider implications of the findings: Supplementation of MPA in modified natural cycle provides a novel sight to overcome premature ovulation for patients with DOR. DOR patients have more chance to accumulate embryos for subsequent FET. Progestin priming with using MPA in the follicular phase may permit folliculogenesis but delay or inhibit ovulation mechanism. The MPA treatment improved the oocyte quantity rather than the quality in modified natural cycle in patients with DOR.
Study funding/competing interest(s): Funding by hospital/clinic(s) – The Natural Science Foundation of Shanghai (grant number 14411934600).
Trial registration number: ChiCTR-OCH-14004176.
Keywords: natural cycle, progesterone, in vitro fertilization

O-113 The comparison of mild stimulation vs. controlled ovarian hyperstimulation protocol in poor ovarian responders: a prospective randomized study

R. Huang[1], B. Wang[1], X. Yang[1], T. T. Li[1], X. Y. Liang[1]
[1]*The Sixth Affiliated Hospital of Sun Yat-sen University, Reproductive Medicine Center, Guangzhou, China*

Study question: Is there any difference in clinical outcomes between mild stimulation and controlled ovarian hyperstimulation (COH) in-vitro fertilization (IVF) cycles in poor ovarian response (POR) patients?
Summary answer: Comparing with COH protocol, mild stimulation was associated with fewer gonadotropin (Gn) consumption and lower number of oocyte retrieved, while, no significant difference was observed in the number of good quality embryos, clinical pregnancy rate (CPR) per embryo transfer (ET), CPR per oocyte pick-up (OPU) and CPR per cycle.
What is known already: POR is associated with lower number of oocyte retrieved and poorer clinical outcomes, and represents a significant therapeutic challenge in assisted reproductive technologies, with no single effective stimulation protocol has been established to increase ovarian response. Mild ovarian stimulation, characterized by lower dose of exogenous gonadotropin consumption and shorter stimulation length has been utilized in poor responders, however, there is no consistent conclusion concerning the comparison between mild stimulation and conventional COH.
Study design, size, duration: This is a prospective randomized non-inferiority study, from Jan to Nov. 2014, POR patients were randomized to mild stimulation (letrozole + small dose of Gn) or COH group (GnRH-a long 'stop' protocol). The randomization is achieved by computer-generated list. Neither patients nor physicians are blinded to the treatment assigned.
Participants/materials, setting, methods: POR patients who met 'Bologna criteria' were recruited in this study, 50 patients were assigned to mild stimulation, while 55 to COH group. The two groups were matched in basic characteristics, such as, age, basal FSH, AFC and AMH etc.
Main results and the role of chance: No significant difference in basic characteristics, such as age (36.2 ± 4.8 vs. 36.2 ± 5.4), AFC (4.5 ± 1.8 vs. 4.9 ± 1.2), basal FSH (9.4 ± 4.1 vs. 9.4 ± 3.8), E_2(39.2 ± 18.2 vs. 42.9 ± 30.5) and AMH (0.8 ± 0.6 vs. 0.9 ± 0.7) levels was observed between mild stimulation and COH group (All $P > 0.05$). The cycle characteristics were listed in following table.

Table

	mild stimulation	COH group	*P*
Gn consumption (IU)	934.90 ± 298.75	3016.36 ± 711.92	0.000
E_2 level on Day_{hCG} (pg/ml)	615.46 ± 534.87	1335.48 ± 667.51	0.000
LH level on Day_{hCG} (IU/L)	7.33 ± 6.16	2.37 ± 1.72	0.000
Endometrial thickness	9.06 ± 2.38	11.79 ± 2.43	0.000
No. of mature follicles	3.10 ± 1.83	4.33 ± 2.68	0.007
No. of oocytes retrieved	2.67 ± 1.98	4.02 ± 3.12	0.013
No. of transferrable embryos	1.24 ± 1.15	1.90 ± 1.73	0.027
No. of good-quality embryos	1.06 ± 1.11	1.29 ± 1.32	0.352
No. of embryos transferred	1.59 ± 0.50	1.67 ± 0.48	0.561
CPR/ET	48.1% (13/27)	46.7% (14/30)	0.911
CPR/OPU	26.5% (13/49)	26.9% (14/52)	0.964
CPR/cycle initiated	26.0% (13/50)	25.5% (14/55)	0.954

Limitations, reason for caution: This study was part of an ongoing RCT research on the comparison of mild stimulation and COH in POR patients. After statistical calculation, the sample size should be 250 per arm to make sure enough patients recruited and analyzed. Therefore our conclusion needed to be interpreted with cautiousness.
Wider implications of the findings: Based on our results regarding less doses of exogenous Gn consumed and an equivalent CPR, mild ovarian stimulation protocol should be recommended to POR patients. Considering the higher number of transferrable embryos associated with COH group, the cumulative pregnancy rate should be used as the primary outcome in future study. At last, large-scale multi-center RCT is needed to verify our results.
Study funding/competing interest(s): Funding by hospital/clinic(s) – The reproductive medicine center of sixth affiliated hospital of SYSU.
Trial registration number: ChiCTR-TRC-13003454.

O-114 Serum stem-cell-factor assays in poor responder patients undergoing IVF: a new tool to establish sense or no sense in performing follicle aspiration

S. Gizzo[1], C. Zicchina[1], M. Noventa[1], M. Quaranta[2], A. Vitagliano[1], B. Abdulrahim[3], C. J. Aldrich[3], C. J. Aldrich[3], M. Gangemi[4], G. B. Nardelli[1], A. Andrisani[1]
[1]*Azienda Ospedaliera Padova Università di Padova, Women and Child Health, Padova, Italy*
[2]*Azienda Ospedaliera Verona – Universita' di Verona, OB/GYN Unit, Verona, Italy*
[3]*NHS Trust – Northampton General Hospital, Obstetrics and Gynecology, Northampton, United Kingdom*
[4]*Azienda Ospedaliera Padova Università di Padova, Women and Child Health, Padova, Italy*

Study question: In poor responder patients undergoing IVF, could the follicular stem cell factor concentration (f-SCF) be associated with the quantitative and qualitative characteristics of ovarian response? Is f-SCF correlated with serum concentration at ovulation induction (s-SCF)?May s-SCF be considered a new tool to establish whether to perform follicle aspiration or not?
Summary answer: The f-SCF correlates strongly with quantitative and qualitative ovarian response, oocyte fertilization-rate and number of viable embryos. s-SCF is strongly correlated with the f-SCF. s-SCF demonstrated good accuracy in predicting both cycles in which no oocytes are collected and cycles in which at least one or three oocytes are collected.
What is known already: Granulosa cells surround the developing oocyte, providing a critical microenvironment for follicular growth while in the developing follicles they produce SCF, which can act on theca cells, stromal cells and oocytes via c-kit receptor. The expression patterns of SCF and c-kit in the ovary, as well as the effects of SCF on oocytes and theca cells, suggest that SCF may be important for many stages of follicular development.
Study design, size, duration: Observational-longitudinal study on 28 poor-responder. All patients underwent Controlled-Ovarian-Hyperstimulation (COH) using rFSH in first cycle (s-COH group) while rFSH plus rLH supplementation (ex-COH group) in the second cycle. We compared f-SCF concentration between the two groups, f-SCF with s-SCF concentration and s-SCF value with qualitative and quantitative ovarian response
Participants/materials, setting, methods: Long-agonist-protocol was performed using rFSH-300 IU/day (plus rLH150 IU/day in ex-COH) for 5-days subsequently adjusted according to biochemical/sonographic features. f-SCF and s-SCF levels (pg/mL) were detected using appropriate ELISA-Kit. We considered as quantitative ovarian response number of follicles > 14 mm and MII oocytes while as qualitative oocytes fertilization-rate and number of viable embryos.
Main results and the role of chance: We collected and analyzed 112 samples (56-follicular fluid and 56-serum). The comparison of s-COH and ex-COH showed no significant differences in term of both f-SCF (830,25 ± 364,09 vs 735,43 ± 300,39 pg/mL) and s-SCF (884,98 ± 387,01 vs 783,18 ± 325,55 pg/mL). Considering all treatments, the correlation between f-SCF and s-SCF values showed a strong association ($R^2 = 0.982$, $p < 0.001$). The s-SCF value > 1400 was associated with 60% probability of collecting at least 3 oocytes, 85% of fertilization-rate and 75% probability of having at least 2 viable embryos. Patients with > 1000/s-SCF/ < 1400 showed a 27% probability of collecting at least 3 oocytes (58% of at least 1 oocyte), 65% fertilization rate, 46% probability of having at least 1 viable embryo. s-SCF < 1000 and < 400 showed respectively 21% and 0% probability of collecting at least 1 oocyte.
Limitations, reason for caution: The potential bias linked to the peculiar features of the patients (older poor responder), the exclusive use of recombinant gonadotropins, the collection and assay of total follicular fluid per cycle and not for single follicle requires caution in the interpretation of data.
Wider implications of the findings: If this pioneeristic data will be confirmed, s-SCF assay may be introduced in clinical practice when approaching older-poor-responder-patients. Particularly in a public health setting, in which usually the number of treatments offered is limited and linked to number of oocyte retrievals, the availability of a real-time/non-invasive/less-expensive serum-test able to predict with good accuracy the number of oocytes, fertilization-rate, and number of viable embryos may improve the cost-effectiveness of treatment offered to this cohort of patients.

Study question: Can next-generation sequencing (NGS) be used efficiently for preimplantation genetic screening (PGS) of embryos from IVF patients with clinical indications of recurrent pregnancy loss (RPL), recurrent implantation failure (RIF) and previous aneuploid conceptions (PAC) in a clinical setting?
Summary answer: This is the first randomized clinical study on the efficiency of NGS for preimplantation genetic screening in comparison to array comparative genomic hybridization (aCGH). Our data clearly demonstrate that NGS screening results in similarly high ongoing pregnancy and implantation rates for PGS patients compared to aCGH screening.
What is known already: Previous randomized clinical trials with FISH screening of a limited numbers (5-12) of chromosomes resulted in disappointing pregnancy outcomes. Recent studies with aCGH screening of 24 chromosomes have resulted in a significant increase in ongoing pregnancy and implantation rates for PGS patients. More recent advances in next-generation sequencing have provided new methods for screening embryos from IVF cycles. However, there is still limited information about clinical application of NGS in IVF and PGS treatments.
Study design, size, duration: IVF patients ($n = 172$) at mean age 35.2 ± 3.5 years were enrolled in this prospective randomized, single-blind, pilot interventional study in our multiple IVF clinics from July 2013 to June 2014. The cohort patients requested PGS treatments with the clinical indications of RPL ($n = 72$), RIF ($n = 63$) and PAC ($n = 37$).
Participants/materials, setting, methods: The enrolled patients were randomized into NGS (Group A, $n = 86$) and aCGH (Group B, $n = 86$). Blastocysts were vitrified after biopsy on day 5. One to two euploid blastocyst were transferred to individual patients based on the PGS results. Clinical pregnancy and implantation outcomes were compared between the two groups.
Main results and the role of chance: Comparative data analysis revealed that the demographic parameters of the enrolled patients in Group A and Group B were similar ($p > 0.05$). The fertilization and blastocyst rates were also comparable between the two groups ($p > 0.05$). NGS detected all types of aneuploidies including trisomy, monosomy, dual and complex chromosomal abnormalities accurately compared to aCGH. Moreover, NGS screening identified euploid blastocysts for transfer and resulted in similarly high ongoing pregnancy rates for PGS patients compared to aCGH screening (74.7% vs. 69.2%, respectively, $p > 0.05$). The observed implantation rates were also comparable between Group A and Group B (70.5% vs. 66.2%, respectively, $p > 0.05$). Additionally, there was no significant difference in miscarriage rate between Group A and Group B (1.3% vs. 2.6%, respectively, $p > 0.05$).

Limitations, reason for caution: Although NGS brings distinct clinical benefits for many IVF patients, the approach is not for all infertile patients, especially those with diminished ovarian reserve and with balanced translocations. Further randomized studies with a larger sample are required to define the role of NGS in assisted reproductive treatments.
Wider implications of the findings: With the observed high accuracy of aneuploidy screening across all 24 chromosomes and the resulting high clinical pregnancy and implantation rates after transfer of the screened embryos, NGS has demonstrated an efficient, robust high-throughput technology for PGS in IVF clinics. With the enhanced capability of detecting segmental imbalances, NGS platforms, at a high read depth, may detect aneuploidy and imbalance translocations at the same time.
Study funding/competing interest(s): Funding by hospital/clinic(s) – This study is supported by internal funding. CEM is a full time scientists at Illumina, which provided NGS chips and reagents for this study. All the other authors have no conflicting interests to declare.
Trial registration number: NA.
Keywords: NGS, aCGH, PGS, ongoing pregnancy, implantation

O-116 Comparison of comprehensive chromosome screening (CCS) results obtained from in vitro fertilization (IVF) cycles treated with low stimulation protocols and standard stimulation protocols

P. Colls[1], J. Zhang[2], L. Ribustello[1], T. Escudero[1], X. Zheng[1], A. Suhotliv[1], S. Munne[3], M. Konstantinidis[3]
[1]*Reprogenetics, Cytogenetics, Livingston New Jersey, U.S.A.*
[2]*New Hope Fertility Center, Obstetrics and Gynecology, New York, U.S.A.*
[3]*Reprogenetics, Research and Development, Livingston New Jersey, U.S.A.*

Study question: Is there any difference in aneuploidy rates and preimplantation genetic diagnosis (PGD) cycle outcome between blastocyst-stage embryos produced after low stimulation IVF cycles and standard stimulation cycles and if yes, which is the most advantageous?
Summary answer: No difference was seen in regards to aneuploidy rates between embryos produced using the two different treatments. Consequently, standard stimulation cycles which often result in higher number of embryos were found to have twice as much the chances of producing a euploid embryo for transfer and establishment of pregnancy.
What is known already: Stimulation procedures vary amongst different centers but are in general similar to methods considered standard. Usage of a low stimulation procedure could result in a better cycle outcome while, it is expected to be less stressful to the patient. Such protocols will be particularly useful in avoiding patient over-stimulation. Furthermore, embryos produced through IVF often show high aneuploidy rates. It will be valuable to determine if such strategy results in better CCS outcomes.
Study design, size, duration: A retrospective analysis of 69 PGD cycles performed between January 2014–December 2014 was carried out. All cycles were derived from a single assisted reproduction center in the USA. Results from CCS of 246 blastocysts were collected and analyzed.
Participants/materials, setting, methods: Average maternal age between the two groups of patients was similar (37 for the low stimulation patients, 35.3 for the standard stimulation patients; $p = 0.11$). Results obtained from samples derived from patients ³ 40 years old were excluded from the study. Array comparative genomic hybridization was used for CCS of biopsied samples.
Main results and the role of chance: The amount of embryos that were found to be euploid after CCS was determined to be similar between the two patient groups ($p = 0.26$). Specifically, 45.8% (22/48) of embryos derived from low stimulation cycles were determined to be euploid compared to 55.6% (110/198) of embryos derived from standard stimulation cycles. Only approximately half (19/37) of the low stimulation cycles were found to have a euploid embryo for transfer while, all standard stimulation cycles (32/32) had at least one euploid embryo for transfer. As a consequence, patients being treated with low stimulation protocols had to undergo twice the amount of cycles than patients being treated with standard stimulation protocols in order to find a euploid embryo to transfer for initiation of pregnancy.
Limitations, reason for caution: Although this study was of considerable size, more cycles and embryos have to be assessed and follow-up data from cycles that had a transfer need to be obtained before any definitive conclusions are drawn.
Wider implications of the findings: This study provides evidence that incidence of aneuploidy remains the same regardless of the stimulation protocol administered to each patient. As shown, patients being treated with standard stimulation protocols are expected to have higher chances of having a euploid embryo available for transfer per cycle completed. However, definitive conclusions about a potential benefit to patients can only be reached after acquisition and examination of clinical outcome follow-up data.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Institutional funding.

O-117 Preimplantation genetic screening using comprehensive chromosome screening technology improves embryo selection: a meta-analysis of randomized controlled trials

E. M. Dahdouh[1], J. Balayla[2], J. A. Garcia-Velasco[3]
[1]*ART-PGD Center CHU Sainte-Justine and Procrea Clinics, University of Montreal Department of Obstetrics-Gynecology, Montreal, Canada*
[2]*University of Montreal, Department of Obstetrics-Gynecology, Montreal, Canada*
[3]*Instituto Valenciano de Infertilidad-Madrid, Rey Juan Carlos University, Madrid, Spain*

Study question: Does preimplantation genetic screening (PGS) using comprehensive chromosome screening (CCS) technology improve embryo selection in in-vitro fertilization (IVF) cycles?
Summary answer: When used in patients with normal ovarian reserve, PGS using CCS technology increases clinical implantation rates (IR) and sustained IR (probability that an embryo would implant and progress beyond 20 weeks gestation).
What is known already: Most of the randomized controlled trials (RCTs) on PGS using fluorescence-in-situ-hybridization (FISH) technology after cleavage-embryo biopsy showed no increase in live birth rates. CCS technology, which analyses the whole chromosome complement, can be achieved using different genetic platforms, and has been extensively tested and validated in PGS cycles (PGS-CCS). Whether PGS-CCS improves embryo selection in IVF remains unclear.
Study design, size, duration: A meta-analysis of RCTs on PGS-CCS published before January 2015 was performed. The clinical outcomes of interest included in the meta-analysis are clinical IR and sustained IR. 267 embryos transferred after PGS-CCS were compared to 383 embryos transferred after selection based on standard morphology criteria alone.
Participants/materials, setting, methods: We searched Medline, Cochrane Central, EMBASE, Scopus, Web of Science, Google Scholar, as well as related articles from relevant authors on the subject. RCTs were eligible if they compared PGS-CCS to other methods of embryo selection. The three authors independently screened for eligibility, and assessed the quality of the RCTs.
Main results and the role of chance: Out of 750 citations identified, sixteen articles met initial eligibility criteria and were further analyzed. Of these, only three RCTs met full inclusion criteria, allowing direct comparison of PGS-CCS to routine IVF care based on embryo morphology selection. In one study, the CCS technology used was array comparative genomic hybridization (aCGH), and in the two remaining others, quantitative polymerase chain reaction (qPCR) was used. In these studies, all embryo biopsies were performed on day 5-6 of embryo development. PGS-CCS is associated with significantly higher clinical IR, with a relative risk [RR] of 1.29 [95% CI: 1.15–1.45], and also a significantly higher sustained IR, with a RR of 1.39 [95% CI: 1.21–1.60].
Limitations, reason for caution: Randomization was performed in the presence of blastocysts available for biopsy from patients with normal ovarian reserve, which may introduce selection bias and overestimate success rates for PGS-CCS. Extrapolation of these results to a different population (e.g. poor responders) and/or embryo stage biopsy remains uncertain for the time being.
Wider implications of the findings: By increasing IR in IVF cycles, PGS-CCS might be helpful when used in the setting of elective single embryo transfer practice. Therefore, it represents an ideal tool for embryo selection in order to overcome the marked differences in outcome of single- versus double-embryo transfer. Results from ongoing RCTs conducted on different patient populations

(e.g. decreased ovarian reserve), and different embryo stage biopsy (e.g. polar body, day-3) may further clarify the role of this technology.
Study funding/competing interest(s): Funding by hospital/clinic(s) – ART-PGD Center, CHU Sainte-Justine, Montreal, Canada.

O-118 Segmental abnormalities can be detected in the DNA of the blastocyst cavity extracted by blastocentesis

A. Pomante[1], M. C. Magli[1], G. Cafueri[1], M. Valerio[1], C. Tabanelli[1], A. P. Ferraretti[1], L. Gianaroli[1]
[1]*S.I.S.Me.R. s.r.l., Reproductive Medicine Unit, Bologna, Italy*

Study question: Can the array-Comparative Genomic Hybridization (aCGH) analysis of DNA extracted from the blastocoelic fluid predict the chromosomal status of the blastocyst, including segmental abnormalities?
Summary answer: The DNA from the blastocoelic fluid (BF) reflects the chromosomal status of the blastocyst trophectoderm (TE) cells. Also segmental abnormalities can be detected by aCGH analysis after blastocentesis
What is known already: Unbalanced segmental abnormalities can be a reason for embryo demise; or, if compatible with life, they can cause congenital abnormalities and mental retardation in the offspring. Identified in approximately 10% of clinical pregnancies, they are especially frequent in carriers of reciprocal translocations, but they can also originate as de novo rearrangements. Data from the analysis of BF suggest that it can be a reliable source of DNA to assess the embryo chromosomal status.
Study design, size, duration: Study: Prospective blinded study for the chromosomal analysis of 44 blastocysts on which aCGH had already been performed on Polar bodies (PBs) or blastomeres in a Preimplantation Genetic Testing program. Of them, 18 blastocysts from 6 couples, generated at least one embryo with a segmental abnormality. Duration: January-December 2014.
Participants/materials, setting, methods: Of the 6 couples with embryos having segmental abnormalities, 2 were carriers of a balanced translocation, 4 had a normal karyotype. Both BF and TE cells were retrieved from each blastocyst, and the DNA was blindly analyzed by aCGH. Results were compared with those previously obtained from PBs and blastomeres.
Main results and the role of chance: DNA was found in 43/44 tested BFs (98%). In the subgroup of 18 blastocysts, in 14 cases the aCGH analysis revealed full correspondence between BF and the results from PBs (n = 8) or blastomeres (n = 6). In the remaining 4 cases, aneuploidies predicted by blastomeres were found in the BF with the addition of new abnormalities. In 8 of the 18 studied blastocysts (44%), segmental abnormalities had been detected by PBs (n = 2) or blastomeres (n = 6). Three were found in embryos from translocation carriers, 5 in embryos from couples with a normal karyotype. In all 8 cases, DNA from the corresponding BF presented the same segmental abnormality predicted by the analysis at previous stage also for small alterations (33 Mb). All results were confirmed in corresponding TE cells.
Limitations, reason for caution: Small size of samples analyzed.
Wider implications of the findings: The present data confirm that blastocentesis can be an alternative source of DNA for preimplantation genetic testing, since the DNA from BFs reflects the chromosomal status of the corresponding embryo. Furthermore, these preliminary results suggest that this approach is reliable to the point to permit the detection of segmental aneuploidies, both in couples carrier of reciprocal translocation and in couples with normal karyotype.
Study funding/competing interest(s): Funding by hospital/clinic(s) – S.I.S.Me.R.
Trial registration number: NA.

O-119 Blastocyst chromosome distributions persist into pregnancy

K. Sorby[1], C. Sugiana[2], T. Osianlis[1]
[1]*Monash IVF, Embryology, Clayton Victoria, Australia*
[2]*Monash IVF, Genetics, Clayton Victoria, Australia*

Study question: Is there a pattern to chromosome copy number errors in a large, single centre cohort of blastocysts and does the testing platform influence the outcome?
Summary answer: Blastocysts display defined patterns in the type of aneuploidies observed and the chromosomes involved, with both reflecting the patterns seen in pregnancy loss, neither of which are influenced by the testing platform used.
What is known already: Limited studies have investigated the specific nature of the aneuploidies observed in blastocysts, with various rates of simple vs complex aneuploidies and equal prevalence of monosomies and trisomies being reported. Preliminary data obtained from a smaller, single platform data set in our laboratory, indicated the trend toward fewer complex aneuploidies, fewer monosomies and a distinct chromosomal pattern in blastocysts, prompting extended analysis of a large data set over multiple platforms.
Study design, size, duration: Retrospective analysis of the chromosomal complement of 1029 blastocysts biopsied for preimplantation genetic screening (PGS) between June 2012 and December 2014.
Participants/materials, setting, methods: All patients undertaking PGS with blastocyst biopsy in a single clinic were analysed. PGS was performed using either 24Sure array comparative genomic hybridization (CGH) or single nucleotide polymorphism arrays with parental support through Natera (SNP) at the patient's discretion.
Main results and the role of chancel: Euploidy rate varied by age as expected, averaging 52.3% with no difference between platforms (p = 0.493 age corrected). Although aneuploidy rates increased with age the mean number of errors per blastocyst did not (< 34 years, 2.44 errors versus > 40 years, 2.36 errors). Overall 59.5% of blastocysts contained a single error, with a total of 79.3% simple aneuploidies (1-2 errors) and only 20.7% complex aneuploidy (> 2 errors). The proportion of monosomies was 23.8% compared with 76.2% trisomies. Chromosomes 13, 15, 16, 18, 21 and 22 are the most commonly associated with pregnancy loss and interestingly were the most prevalent chromosomes in blastocyst aneuploidies. This distribution was significantly non-random (chi-square goodness of fit, $p < 0.0001$) and consistent across both CGH and SNP (chi-square test for independence, p = 0.941).
Limitations, reason for caution: This is a retrospective analysis of patients undergoing PGS for a variety of clinical indications and is potentially influenced by this population bias. The testing platform used was not randomized in this study but rather selected by patients based on cost, reported accuracy and information provided by the respective tests.
Wider implications of the findings: This large, single centre, multi-platform data set differs significantly from previously reported findings in regard to the prevalence of monosomies and trisomies in blastocyst samples, with the current data more closely approximating the frequencies seen in prenatal testing. The confirmation of a distinct pattern of chromosomal involvement, which mimics the chromosomal errors indentified in pregnancy loss, support the use of blastocyst biopsy as the most clinically relevant time to perform pre-implantation genetic screening.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Monash IVF.
Trial registration number: NA.
Keywords: PGS, blastocyst, aneuploidy

O-120 Do culture conditions, patient factor or female age affect incidence of segmental chromosome errors in preimplantation embryos?

S. Alfarawati[1], D. Babariya[2], K. Spath[2], D. Wells[2], E. Fragouli[1]
[1]*Reprogenetics UK, Cytogenetics, Oxford, United Kingdom*
[2]*University of Oxford, Nuffield Department of Obstetrics and Gynaecology, Oxford, United Kingdom*

Study question: Is the frequency of segmental chromosome errors related to a specific patient group? Does female age affect this frequency? Do culture conditions in different IVF clinics have an effect?
Summary answer: Cleavage stage embryos from younger patients (< 37 years) showed a significant increase in the frequency of segmental abnormalities. Moreover, differences in procedures at individual clinics appear to affect the incidence of segmental aneuploidy. This is important given that segmental imbalance can have significant mental and physical consequences for affected children.
What is known already: Chromosome abnormality affects almost half of all embryos generated through IVF and is believed to be the leading cause of implantation failure and miscarriage. The majority of these abnormalities affect entire chromosomes. However, a significant minority, accounting for 12-15%

of all errors, affect parts of chromosomes. The cause of such 'segmental' errors is unknown and their clinical impact is poorly defined.
Study design, size, duration: This is a retrospective analysis of the frequency of segmental errors in preimplantation embryos. 2794 embryos at the cleavage and blastocyst stages were studied, generated by 462 patients (average age 38.3 years, range 21-47 years) that had IVF treatment at 12 different clinics between 2008 and 2014.
Participants/materials, setting, methods: One blastomere was biopsied from cleavage stage embryos and 3-10 trophectoderm cells were biopsied from blastocyst stage embryos. Biopsy specimens underwent whole genome amplification (SurePlex), followed by labelling and hybridization to 24Sure aCGH slides (Illumina). Results were analysed using BlueFuse software, revealing aneuploidy affecting whole chromosomes and chromosome segments >5 Mb
Main results and the role of chance: In order to investigate whether specific patients produce high number of embryos with segmental errors only those that had 5 or more embryos were examined. A total of 30 patients had segmental errors affecting 50% or more of their embryos. Patients were sub-grouped according to female age into a younger (< 37 years) and an older (≥ 37 years) group. A significant increase in the frequency of segmental errors was found in cleavage stage embryos generated from the younger patient group (29% vs. 19%, $p = 0.0001$) while no significant difference was observed between the 2 groups at the blastocyst stage. The frequency of segmental errors affecting preimplantation embryos was significantly elevated in embryos derived from three of the referring IVF centres ($p = 0.001$, $p = 0.003$ and $p = 0.005$)
Limitations, reason for caution: The method used in this study only examines a part of the embryo and cannot rule out the possibility of mosaicism. Additionally, it is not possible to conclusively determine whether the segmental errors observed are meiotic or mitotic (postzygotic) in origin. Segmental imbalances <5 Mb in size cannot be accurately detected.
Wider implications of the findings: Younger patients had a higher incidence of segmental abnormalities, but this may be related to the increased proportion of male-factor infertility cases in our 'younger' patient group, rather than an effect of age. Segmental abnormalities involve chromosome breakage and could conceivably be related to sperm DNA fragmentation. Some clinics had higher rates of segmental abnormality in the embryos produced, arguing that optimisation of culture and/or simulation methods might help to avoid these abnormalities.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Reprogenetics UK.
Trial registration number: NA.

SESSION 34: CLINICAL ASPECTS OF ENDOMETRIOSIS

Tuesday 16 June 2015 **10:00–11:30**

O-121 Endometriosis does not alter antral follicle responsiveness to FSH administration as assessed by the Follicular Output RaTe (FORT)

T. Isnard[1], J. S. Cunha Filho[2], T. Tadros[1], Adda-E. Herzog[1], A. Oppenheimer[1], R. Fanchin[1]
[1]*Centre Hosp. Antoine Béclère, Department of OB/GYN & Reproductive Medicine, Clamart Cedex, France*

[2]*Insemine, UFRGS, Porto Alegre, Brazil*

Study question: To investigate whether responsiveness of antral follicles to FSH administration, as reflected by the Follicular Output RaTe (FORT), is altered in patients with endometriosis.
Summary answer: Our results indicated that, whereas endometriosis is associated with reduced antral follicle counts (AFC) and preovulatory follicle counts (PFC), the percentage of antral follicles that successfully respond to FSH administration (FORT) remains comparable to controls, thereby supporting the hypothesis that follicle quality is not altered by endometriosis.
What is known already: Endometriosis-linked infertility has been, at least in part, attributed to disorders in the oocyte reproductive competence. Yet, quantitative ovarian defects such as reduced antral follicle endowment and poor response to controlled ovarian hyperstimulation (COH) does not constitute necessarily an evidence of altered follicle-oocyte competence. Further, responsiveness to FSH presumably is characteristic of healthy ranulose cells and has been associated to IVF-ET outcome using the FORT index, therefore, constituting an interesting clinical appraisal of follicle quality.
Study design, size, duration: Case-control study. We compared 141 infertile patients, 25 to 43 years of age, with laparoscopically-documented endometriosis and having accomplished COH for IVF-ET with other 141, age- and BMI-matched, IVF-ET candidates without endometriosis. Endometriosis was staged according to revised AFS criteria.
Participants/materials, setting, methods: Similar COH protocols and initial recFSH doses (225 IU/day) were used in endometriosis and control patients. AFC (3-8 mm) before COH and PFC (16-22 mm; day of hCG administration) were determined. The FORT was calculated by the ratio PFC x 100/AFC.
Main results and the role of chance: As expected, by design, ages and BMI were similar in both groups. Whereas AFC (14.0 ± 0.3 versus 15.9 ± 0.4 follicles, $P < 0.001$) and PFC (6.4 ± 0.2 versus 7.3 ± 0.3 follicles, $P < 0.02$) were lower in endometriosis patients than in controls, FORT remained similar in the two groups of patients (47.1 ± 1.6% versus 47.4 ± 1.9%, respectively). Incidentally, FORT results were comparable in patients with stage I-II or III-IV endometriosis and in those with or without endometrioma.
Limitations, reason for caution: FORT could not be, by design, assessed in patients having discontinued FSH treatment before hCG administration (due to a markedly insufficient follicle recruitment), since their PFC could not be established. In addition, FORT implies that 3-8 mm follicles before COH respond coordinately to FSH, which is not always the case.
Wider implications of the findings: Endometriosis is a frequent finding among infertile patients. The present study constitutes the first clinical demonstration that, although this disease is associated with a significant reduction in the absolute number of FSH-sensitive and mature follicles obtained after COH, follicular responsiveness to FSH is not affected by endometriosis. This is in keeping with hypothesis that follicle-oocyte quality is spared in women with endometriosis.
Study funding/competing interest(s): Funding by hospital/clinic(s) – None.
Trial registration number: NA.
Keywords: endometriosis, IVF-ET, FORT, ovarian response, follicle quality

O-122 Reproductive and pregnancy outcomes in women with endometriosis: a Scottish national record linkage study

L. Saraswat[1], D. Ayansina[2], S. Bhattacharya[2], D. Miligkos[3], A. Horne[4], K. Cooper[1], S. Bhattacharya[2]
[1]*Aberdeen Royal Infirmary, Obstetrics and Gynaecology, Aberdeen, United Kingdom*
[2]*University of Aberdeen, Division of Applied Health Sciences, Aberdeen, United Kingdom*
[3]*Princess Anne Hospital, Obstetrics and Gynaecology, Southampton, United Kingdom*
[4]*The University of Edinburgh, Obstetrics and Gynaecology, Edinburgh, United Kingdom*

Study question: Are women with history of endometriosis more likely to have adverse reproductive and pregnancy outcomes when compared to women without the diagnosis of endometriosis?
Summary answer: Women with endometriosis were at increased risk of miscarriage and ectopic pregnancy. Pregnancies progressing beyond the first trimester, were at higher risk of complications, including antepartum haemorrhage, preterm birth, operative delivery and postpartum haemorrhage.
What is known already: The impact of endometriosis on pregnancy and reproductive performance of women is relatively unknown. The few studies exploring the relationship between endometriosis and pregnancy outcome have been conducted in infertile women undergoing medically assisted reproduction. There is lack of large studies tilizing population based data where a definitive diagnosis of endometriosis has been established at laparoscopy.
Study design, size, duration: A retrospective population based cohort study using record linkage of routinely collected anonymised discharge data from all Scottish NHS hospitals was conducted. A total of 14,655 women were followed up over a maximum of 30 years from 1981 to 2010.
Participants/materials, setting, methods: In a nationwide Scottish study, we compared reproductive and pregnancy outcomes in 5,375 women with surgically confirmed endometriosis to 8,280 women without the diagnosis of

endometriosis (a random sample of women without a diagnosis of endometriosis and pregnant during the same time-period) using univariate and multivariate logistic regression accounting for confounding factors.
Main results and the role of chance: Pregnant women with history of endometriosis were significantly older, more likely to be nulliparous and from a more affluent social class ($p < 0.001$) when compared to those without endometriosis. On multivariate analysis, after adjusting for age, parity, socioeconomic status and year of delivery, women with endometriosis had a significantly higher risk of early pregnancy complications with adjusted OR (95% CI) of 1.76 (1.44, 2.15) and 2.70 (1.09, 6.72) for miscarriage and ectopic pregnancy, respectively. A previous diagnosis of endometriosis was associated with a significantly increased risk of adverse later pregnancy outcomes [adjusted OR (95% CI)] including placenta praevia [2.24 (1.52, 3.31)], unexplained antepartum haemorrhage [1.67 (1.39, 2.00)], postpartum haemorrhage [1.30 (1.61, 1.46)] and preterm births [1.26 (1.07, 1.49)].
Limitations, reason for caution: The study suffers from limitations inherent to an observational study with limited availability of and missing data on important co-variables such as smoking, body mass index and use of medically assisted reproduction. It is possible that there is a small proportion of women with undiagnosed endometriosis in the unexposed cohort.
Wider implications of the findings: Endometriosis predisposes women to increased risk of early pregnancy loss and later pregnancy complications. These data can be used by clinicians when counselling women with known endometriosis. Data from this Scotland wide study should be taken into account when planning health care strategies for surveillance and early identification of potential complications in pregnancy to minimize their impact on pregnancy outcome.
Study funding/competing interest(s): Funding by national/international organization(s) – Chief Scientist Office, Scotland.
Trial registration number: NA.
Keywords: endometriosis, reproductive outcomes, pregnancy outcomes

O-123 Predicting the reproductive outcome in endometriosis – a comparison between EFI and AFS scores

N. Jayakrishnan[1]
[1]*Kjk Hospital, Obgyn, Trivandrum, India*

Study question: To determine the better tool, scored by r-AFS and EFI scores, for predicting the reproductive outcomes in patients with surgically documented endometriosis, attempting conception
Summary answer: Correlation with EFI, is a better prognosticator of the reproductive outcome in patients with surgically documented endometriosis attempting conception due to a highly significant relationship between EFI scores and pregnancy outcomes.
What is known already: r-AFS score can only stage the levels of endometriosis into minimal, mild, moderate and severe. It cannot predict the reproductive outcome after surgery for endometriosis.
Study design, size, duration: *Study Design:* Prospective cohort study. *Sample Size:* 166. *Study Duration:* 18 months. *Lost to Follow Up:* The subjects lost to follow up were excluded from the study.
Participants/materials, setting, methods: *Materials and Setting:* EFI score was calculated post operatively (score 0 to 10) for 166 women for whom r-Afs endometriosis staging was done (minimal, mild, moderate, severe) in a private tertiary reproductive and gynaecological research centre from January 2012 to July 2013.All the participants attempted conception within six months by timed intercourse or intra uterine insemination or controlled ovarian stimulation based on a pre designed protocol. Those patients failing to conceive within six months of intrauterine insemination or those who had severe endometriosis were offered ART techniques as an alternative. *Methods*: Six groups of EFI were identified (1-3,4,5,6,7-8,9-10) and pregnancy rates were calculated for each group. Patients were excluded when they were lost to follow up, had subsequent surgery for endometriosis, or was on ovarian suppression.
Main results and the role of chance: *Main Results and Role of Chance:* EFI score and pregnancy rates showed a highly significant relation ($p < 0.05$) with patients having an EFI score of 0 with 0% pregnancy rates and those patients having a score of 6 and above with pregnancy rates unto 73%. The least function score was an important parameter in determining the EFI score. The EFI score contains historical and surgical factors, thus being a better parameter for determining the reproductive outcomes post operatively, regardless of the r-Afs scores.
Limitations, reason for caution: *Limitations*: The EFI score cannot be used to predict post operative pain. *Reason for Caution:* This is a newly devised scoring system used to predict the reproductive capacity in patients undergoing surgery for enometriosis. Larger studies are needed to determine its disadvantages. *Bias and Confounding:* Bias and confounding is eliminated by taking same samples for both criteria.
Wider implications of the findings: The study was earlier published by Adamson in a European population. This new validated endometriosis staging system is now used in an Indian population. It appears that this scoring system can be used to counsel patients about their reproductive chances after a surgery for endometriosis as well as their post operative conception options.

O-124 Prognostic factors of ART outcomes in a continuous series of 359 endometriosis patients

C. Maignien[1], P. Santulli[1], D. Korb[1], L. Marcellin[1], V. Gayet[1], V. Blanchet[1], J. Gonnot[1], D. de Ziegler, [2], C. Chapron[1]
[1]*Institut Cochin INSERM U1016 Université Paris Descartes Sorbonne Paris Cité Paris France, Department of Gynecology Obstetrics II and Reproductive Medicine Groupe Hospitalier Universitaire (GHU) Ouest Centre Hospitalier Universitaire (CHU) Cochin 75679 Paris France, Paris, France*
[2]*Université Paris Descartes Sorbonne Paris Cité Faculté de Médecine, Department of Gynecology Obstetrics II and Reproductive Medicine Groupe Hospitalier Universitaire (GHU) Ouest Centre Hospitalier Universitaire (CHU) Cochin 75679 Paris France, Paris, France*

Study question: To evaluate the ART cumulative pregnancy rates (cPR) in a large cohort of endometriosis (OSIS) patients and to identify the determinant factors of ART outcome.
Summary answer: Globally pregnancy rates are good in endometriosis patients (44%); Yet, OSIS associated with intestinal deep infiltrating endometriosis (DIE) and past surgery for OSIS are associated with poorer ART outcome.
What is known already: ART is one of the therapeutic options offered for managing OSIS-associated infertility. Yet, published data on ART outcome in women affected by OSIS are conflicting and the determinant factors for pregnancy chances unclear.
Study design, size, duration: Observational cohort study on 359 consecutive OSIS patients, who underwent IVF-ICSI treatment at Cochin-Port-Royal Hospital between June 2005 and February 2013. Diagnosis of OSIS was histologically proven in women who had past surgery ($n = 279$ – 77.7%), or based on published imaging criteria using transvaginal sonography and magnetic resonance imaging.
Participants/materials, setting, methods: The main outcome measure was cPR per patient. We compared the characteristics of women who became pregnant and those who did not, using univariable and multivariable analysis, to identify determinant factors of fertility outcome.
Main results and the role of chance: 359 consecutive OSIS patients underwent 720 IVF-ICSI cycles. In the overall population the clinical pregnancy rate per cycle and per embryo transfer was 25.2% and 36.4% respectively. 158 (44%) patients became pregnant. Using multivariable analysis, intestinal DIE (OR = 0.31, 95% CI (0.2-0.6), $p < 0.001$), past surgery for OSIS (OR = 0.29, 95% CI (0.1-0.6), $p = 0.001$) or endometrioma (OR = 0.34, 95% CI (0.2-0.7), $p = 0.002$) were independent factors associated with lower pregnancy rates. AMH levels < 2 ng/mL and antral follicle count (AFC) < 10 were also associated with negative ART outcomes (OR = 0.49, 95% CI (0.3-0.9), $p = 0.014$ and OR = 0.41, 95% CI (0.2-0.7), $p = 0.002$ respectively).
Limitations, reason for caution: The patients in whom the diagnosis of OSIS was based on imaging rather than surgery are possibly not as accurately phenotyped as those who had surgery. This limitation is however one that affects most studies on OSIS and probably, not entirely avoidable.
Wider implications of the findings: Being a referral center for OSIS management, our OSIS population is likely to be uncommonly enriched in severe cases. A more common OSIS population is therefore likely to have even higher cPR than those reported here (44%). Our results are in line with previous studies showing that intestinal DIE is a major determinant of fertility outcomes. We also brought a new insight, concerning the negative impact of previous surgeries for OSIS on ART results.

O-125 MRI features correlate significantly with histological level of infiltration in the bowel wall in colorectal endometriosis

L. M. M. Fassaert[1], A. A. de A. A. Graaff[1], M. Maas[2], F. C. H. Bakers[2], L. F. S. Kooreman[3], G. A. J. Dunselman[1]
[1]*Maastricht University Medical Centre, Obstetrics & Gynaecology, Maastricht, The Netherlands*
[2]*Maastricht University Medical Centre, Radiology, Maastricht, The Netherlands*
[3]*Maastricht University Medical Centre, Pathology, Maastricht, The Netherlands*

Study question: Is there correlation between MRI features and histological infiltration in the bowel wall in deep colorectal endometriosis (DCE)?
Summary answer: Depth and length of the infiltration of a deep endometriosis lesion in the bowel wall based on measurements in MR images show a significant correlation and are positive predictors for the level of histological infiltration in the bowel wall in patients with DCE.
What is known already: Previous research demonstrated a relatively high sensitivity and specificity (87% and 93%, respectively) for MR imaging to diagnose the presence of endometriosis in the rectal wall and a high odds ratio (OR 39.74). However, studies that tried to define which layer of the bowel wall is infiltrated by MR imaging did not reach a definitive answer. Up to now, histopathology remains the gold standard for diagnosing deep colorectal endometriosis and level of infiltration.
Study design, size, duration: A retrospective, mono-centre study in a tertiary referral endometriosis centre between January 2001 and January 2014. Ninety-six patients with DCE, diagnosed by histopathology analysis after bowel surgery (low anterior resection or discoid resection), were enrolled in this study. Preoperative MRI was performed in all patients.
Participants/materials, setting, methods: MRIs were reassessed on level of bowel infiltration by two radiologists. They were aware that in all patients bowel resection was performed with positive histology for endometriosis. One pathologist, blinded to the MRI results, assessed infiltration of the bowel wall. MRI findings were compared with histopathology results.
Main results and the role of chance: Infiltration was scored as superficial (serosa/muscle layer) or deep (submucosa/mucosa). Lesion thickness, depth and length of lesion infiltration in the bowel wall observed by MRI correlated significantly with histological level of infiltration. Lesion thickness was significantly lower in superficial (2.54 cm) than in deep (2.92 cm)($p = 0.042$) OR 1.63 histological infiltration (reader 1). The same applied for depth of infiltration 0.74 vs. 0.96 cm ($p = 0.033$), OR 2.59 (reader 1) and 1.05 vs. 1.29 cm ($p = 0.044$), OR 2.16 (reader 2) and length 1.73 vs. 2.21 cm ($p = 0.028$), OR 1.57 (reader 1) and 2.24 vs. 2.89 cm ($p = 0.024$), OR 1.42 (reader 2). Presence of hyperintense spots, contact with bowel wall, traction of rectum, involvement of ureter, prestenotic bowel dilatation, and aspect of the infiltration did not show significant correlation.
Limitations, reason for caution: A possible limitation of the study is the long period of inclusion of patients in which quality of MRI scans conceivably have been changed and/or improved.
Wider implications of the findings: This study shows that there is a significant correlation between MRI features and the level of infiltration in the bowel wall of DCE in a large series of patients. To avoid unnecessary bowel resections the knowledge if the deep colorectal endometriosis lesion is infiltrating superficially (serosa/ muscle layer) or deep (submucosa/mucosa) could be helpful in deciding whether or not to perform bowel resection.
Study funding/competing interest(s): Funding by hospital/clinic(s) – No funding.
Trial registration number: NA.

O-126 Pain and quality of life assessment in ART patients suffering from endometriosis (OSIS): prospective controlled study

M. Bourdon[1], P. Santulli[1], M. Presse[1], V. Gayet[1], L. Marcellin[1], V. Blanchet[1], L. Marcellin[1], V. Gonnot[1], D. de Ziegler [1], C. Chapron[1]
[1]*Cochin Institute, Gynecology and Reproductive Medicine, Paris, France*

Study question: To evaluate the impact of ART on pain and quality of life (QOL) in women suffering from OSIS, as compared to disease-free controls.
Summary answer: During ART pain and quality of life scores are not different in OSIS and control women. No differences where observed according to the severity of endometriosis.
What is known already: The risk that ART might induce a flare of OSIS-related symptoms is not well known. Moreover the quality of life of infertile endometriosis patients undergoing ART has not been evaluated yet. This risk – theoretical but non-assessed – may dissuade gynecologists from offering ART to endometriosis patients, having them rather undergo invasive surgery.
Study design, size, duration: Prospective controlled observational cohort study conducted between January 2014 and June 2014 in a tertiary care university hospital. Diagnosis of OSIS was histologically proven in women who had past surgery (41/102; 40.2%), or based on published imaging criteria using transvaginal sonography and magnetic resonance imaging.
Participants/materials, setting, methods: 132 endometriosis patients were matched to 132 disease free women undertaking IVF immediately after each case. In all study participants, four points clinical evaluation were performed: Baseline, During synchronization, During stimulation and Post retrieval. Pain scores were evaluated using visual analogue scale. QOL was assessed using FertiQol International evaluation.
Main results and the role of chance: After excluding cancelled cycles (20 and 16, respectively) and patients lost to follow up (10 and 12 respectively), 102 OSIS and 104 controls women were retained for the study. Endometriosis women were phenotyped according to the surgical classification of endometriosis in superficial endometriosis (8; 7.8%), endometrioma (19; 18.6%) and deep endometriosis (75; 73.5%). Difference in Visual analogue scale (VAS) score between post retrieval and baseline evaluation in endometriosis reveals no significant increase of dysmenorrhea, dyspareunia, non cyclic chronic pain, gastro-intestinal symptoms during IVF compared to control group. Evaluations of quality of life with FertiQol international in endometriosis group are comparable to control group for core FertiQol (58.6 ± 15.2 vs 63.1 ± 17.1, respectively; $p = 0.131$) and treatment FertiQol (24.7 ± 6.8 vs 24.1 ± 7.0, respectively; $p = 0.670$) evaluation.
Limitations, reason for caution: Women in whom the diagnosis of endometriosis was based on imaging are possibly not as accurately phenotyped as those who had surgery. We cannot rule out that women who dropped out were those who experienced some deleterious effects nevertheless the small number of lost of follow up moderate such bias.
Wider implications of the findings: Quelling all the prevailing fears about ART in OSIS patients, our results strikingly showed no worsening of pain during ART in OSIS women, as compared to controls. During ART, pain scores followed similar pattern in OSIS and control patients. These data support the views that ART is a safe option when surgery can alter ovarian function or expose to undue surgical risks in case of extended endometriosis.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Cochin institute, Gynecology and Reproductive Médicine department, Université Paris Descartes, Assistance Publique—Hôpitaux de Paris (AP-HP).

Tuesday 16 June 2015 **10:00–11:30**

O-127 Obstetric and neonatal outcomes from trophoblast biopsy combined with frozen embryo transfer versus cleavage biopsy with fresh embryo transfer in PGD/PGS treatment

S. Jing[1], H. He[1], Y. Q. Tan[2], K. Tan[2], D. H. Cheng[2], K. L. Luo[3], F. Gong[3], J. Li[3], G. Lin[3], G. X. Lu[3]
[1]*Centra South University, Reproductive and Stem Cell Institute, Changsha Hunan, China*
[2]*Reproductive & Genetics Hospital CITIC-XIANGYA, Laboratory of Cell Genetics and Molecular Genetics, Changsha Hunan, China*
[3]*Reproductive & Genetics Hospital CITIC-XIANGYA, Outpatient, Changsha Hunan, China*

Study question: To investigate whether blastocyst biopsy combined with frozen embryo transfer increase the risk of pregnancy complications and adverse neonatal outcomes compared to cleavage biopsy with fresh embryo transfer.
Summary answer: The patients after blastocyst biopsy combined with frozen embryo transfer had a better neonatal outcome but associated with increased risk of placenta-related disease, especially for pregnancy induced hypertension (PIH), when compared to cleavage biopsy with fresh embryo transfer.
What is known already: The blastocyst biopsy and vitrification strategy is becoming more popular in PGD/PGS because of potential better pregnancy outcome when compared to blastomere biopsy and fresh embryo transfer strategy. However, the obstetric and neonatal outcomes of the new strategy is still to be determined.
Study design, size, duration: We undertook a retrospective study including all children born after PGD/PGS (n = 288) with cleavage biopsy with fresh embryo transfer (PGD#1) from March 2008 to November 2012 or blastocyst biopsy combined with frozen embryo transfer (PGD#2) from January 2012 to August 2013 in Citic Xiangya Reproductive and Genetic Hospital.
Participants/materials, setting, methods: Only pregnancies with gestation > 28 weeks were included in our study. Data was collected by telephone follow-up. Obstetric and neonatal outcomes were compared in PGD#1 and PGD#2 by student-t test, chi-square test and logistic regression.
Main results and the role of chance: PGD#1 (96 singletons and 33 twins pairs)and PGD#2 (124 singletons and 35 twins pairs) were included in our study. In PGD#2, the incidence of placenta-related diseases, including PIH, placenta previa and postpartum hemorrhage, were higher than in PGD#1. But limited to the sample size, only PIH have significant difference (2.6% vs 9.0%, P = 0.032). When compared to PGD#1, PGD#2 had lower incidence of VLBW (10.6% vs 0, P = 0.025), and better gestational age [median (rang)35.57 (30.60, 38.40) vs 36.71 (31.10, 39.30) (P = 0.001)] and birthweight [median (rang)2500.00 g (1225.00 g, 3750.00 g) vs 2700.00 g (1550.00 g, 3600.00 g) (P = 0.002)] in twin pregnancies. No differences were found at other neonatal outcomes such as birth defects, neonatal hospitalization, SGA, LGA both in singletons and multiplets.
Limitations, reason for caution: Our study is limited to the retrospective design and small sample size. The measure outcomes from questionnaires by telephone not medical records were the underlying risks.
Wider implications of the findings: The higher incidence of placenta-related diseases and better outcomes of gestational age and brithweight in PGD#2 revealed that the trophoblast biopsy and vitrification of embryos may have adverse influence on placenta function. Our findings can provide advice to the mother after trophoblast biopsy and vitrification during the perinatal, which should concerned about the occurrence of placenta related diseases.
Study funding/competing interest(s): Funding by national/international organization(s) – This study was supported by grants from the Major State Basic Research Development Program of China (973 Program; no. 2012CB944902).
Trial registration number: NA.

O-128 Female age, number of mature eggs and biopsied blastocysts effectively define the chance for obtaining one euploid embryo: counselling and decision-making during PGS cycles

S. Colamaria[1], A. Capalbo[1], F. Sapienza[1], R. Maggiulli[1], M. Giuliani[1], E. Gravotta[1], A. Vaiarelli[1], S. Ferrero[1], M. Schimberni[1], A. Giallonardo[1], L. Rienzi[1], F. M. Ubaldi[1]
[1] *Genera Centre, Clinica Valle Giulia, Rome, Italy*

Study question: Is it possible to effectively predict the chance of obtaining at least one euploid embryo during blastocyst stage preimplantation genetic screening cycles based on basal and cycle parameters?
Summary answer: Female age, number of mature oocytes and biopsied blastocysts effectively predict the chance of obtaining at least one euploid embryo per started stimulation cycle, allowing for an appropriate patient counselling and optimization of oocyte/embryo banking programmes for IVF centers performing PGS in outsource.
What is known already: Most of the IVF clinics using PGS in outsource perform oocyte/embryo banking in order to optimize genetic testing costs. Main drawback of this approach is the risk of performing supplementary ovarian stimulation cycles when not required. We aimed at deliver useful data to provide a better management of PGS cycles based on decisional tree models assessing the probability of each patient of obtaining at least one euploid blastocysts (EB) based on basal and cycle parameters.
Study design, size, duration: This is an observational longitudinal cohort study performed from October-2011 and December-2014 including 734 consecutive blastocyst stage PGS cycles. Primary outcome was the obtainment of at least one euploid embryos following trophectoderm biopsy and 24-chromosome screening. We included only cycles where all oocytes were injected and resulting blastocysts analysed.
Participants/materials, setting, methods: The effect of covariates (female age, FSH, AMH, duration of infertility, previous IVF failures, previous miscarriages, infertility factor, sperm quality, stimulation protocol, MII retrieved, biopsied blastocysts) on EB achievement was assessed using forward logistic regression analysis. Recursive partitioning analysis was used to generate decisional trees.
Main results and the role of chance: From 734 egg retrieval cycles, 4992 MII were injected resulting in 1640 biopsied blastocysts. Cycles with no blastocysts were 173 (23.6%,95%CI = 20.5-26.8). 1640 blastocysts were biopsied and 656 were euploid (40.0%,95%CI = 37.6-42.4). 249 were already transferred resulting in 134 ongoing implantations (52%,95%CI = 46.2-58.9). Only female age and number of biopsied blastocysts were independently associated with the probability of having EB (OR = 0.68,95%CI 0.60-0.76 and OR = 1.83 95%CI 1.56-2.15, respectively, $p < 0.01$). A classification trees to predict EB obtainment according to significant covariates showed that female patients aged between 35-39 have a EB in 43%, 80% and 99% with 1,1-5 and > 5 blastocysts, respectively. Females aged 40-43 have a EB in 25%,58% and 78% when 1,2-3 and > 3 blastocysts were biopsied, respectively. Older ones had an overall chance of EB of 23%.
Limitations, reason for caution: These data belong from a single centre using an effective culture system and an extensively validated aneuploidy screening technology. The lack of a prospective replication cohort to validate the prediction model developed should also be acknowledged.
Wider implications of the findings: The developed decisional tree can help practitioners to decide if additional egg retrieval cycles are necessary to increase significantly the chance of euploid blastocysts obtainment and improve the cost-effectiveness of IVF/PGS cycles. These data can thus potentially improve the management of PGS cycle and the patient's counseling
Study funding/competing interest(s): Funding by hospital/clinic(s) – None.
Trial registration number: NA.

O-129 Neonatal outcomes after the implantation of human embryos vitrified using a closed-system device

H. Iwahata[1], S. Hashimoto[2], M. Inoue[2], T. Inoue[3], K. Itou[3], Y. Nakaoka[3], N. Suzuki[1]
[1]*St. Marianna University School of Medicine, OB-GYN, Kawasaki Kanagawa, Japan*
[2]*IVF Namba Clinic, Researcher, Osaka, Japan*
[3]*IVF Namba Clinic, OB-GYN, Osaka, Japan*

Study question: Dose closed vitrification system (CVS) which is expected to minimize the risk of contamination poses a risk of adversely affecting embryo development?
Summary answer: There were no significant differences between the use of closed and open vitrification systems in embryo development after implantation, gestational age, birth weight, sex ratio, Apgar score, and congenital anomalies of newborns. Human embryos can be vitrified using a CVS without impairment of neonatal development.
What is known already: The freezing procedure known as an open vitrification system (OVS) maximized cooling and warming rates be by direct contact to liquid nitrogen and improved the embryo viability. However, there are some potential drawbacks of the OVS, such as the risk of cross-contamination during cooling and storage. To avoid the possible risk of contamination, several CVSs have been developed. However, new concerns such as a decrease in the cooling rate have emerged.

Study design, size, duration: Developmental competence of blastocysts vitrified by CVS after implantation, including gestational age, birth weight, sex, Apgar score, and anomalies of newborn was compared with that obtained in the case of OVS.
Participants/materials, setting, methods: The data pertaining to a total of 875 vitrified-warmed blastocysts that were single-transferred under hormone-replacement cycles between November 2011 and December 2013 were randomly divided into two groups according to the day of blastocyst vitrification (CVS, *n* = 313; OVS, *n* 562) after receiving informed consent.
Main results and the role of chance: One hundreds thirteen of 313 patients in CVS and 206 of 562 patients in OVS had deliveried. There were no significant differences between the use of CVS and OVS in embryo development after implantation, gestational age, (closed: 275.6 days, open: 274.1 days), birth weight (closed: 3127.9 g, open: 3056.8 g), proportion of Caesarian sections (closed: 36.5%, open: 40.5%), sex ratio (proportion of male babies (closed: 43.3%, open: 48.4%), Apgar score (closed: 9.3, open: 9.3), and congenital anomalies (closed: 2.9%, open: 0.5%) of newborns.
Limitations, reason for caution: It need further study will be required to assess the subsequent growth and development of the children.
Wider implications of the findings: Our study offers some insights into the safety of CVS. There were no significant differences in the developmental characteristics after implantation or in the neonatal status between the closed and open vitrification groups.
Study funding/competing interest(s): Funding by hospital/clinic(s) – IVFNamba Clinic.
Trial registration number: This study that was approved by the ethics committee of the IVFNamba Clinic (No.2012-5).
Keywords: closed vitrification system, human blastocyst

O-130 Morbidity and mortality among very and extreme preterm singletons born following assisted conception in Australia: a population study

E. A. Sullivan[1], A. A. Chughtai[2], K. Lui[3], Y. A. Wang[1]
[1]*University of Technology Sydney, Faculty of Health, Sydney NSW, Australia*
[2]*University of New South Wales, National Perinatal Epidemiology and Statistics Unit School Women's and Children's Health, Sydney NSW, Australia*
[3]*University of New South Wales, School Women's and Children's Health, Sydney NSW, Australia*

Study question: Do very preterm (gestational age 28 to < 32 weeks) and extreme preterm (gestational age < 28 weeks) singleton babies born to women after assisted conception have higher rates of adverse perinatal outcomes compared to spontaneously conceived very preterm and extreme preterm singleton babies.
Summary answer: This national study confirms that selected adverse perinatal outcomes including small for gestational age (SGA) and some birth defects as well as specific neonatal complications are higher among very preterm and extreme preterm singletons born following assisted conception compared to spontaneously conceived very and extreme preterm singletons.
What is known already: Preterm birth (gestational age < 37 weeks) is a global public health problem, accounting for more than one-third of neonatal deaths. Morbidity and mortality is even higher in the very preterm and extreme preterm babies. Internationally, assisted conception including assisted reproductive technology (ART) treatment (in vitro fertilization and gamete intra-fallopian transfer), artificial insemination (AI) and hyper-ovulation has been associated with increased risk of preterm birth.
Study design, size, duration: A population-based retrospective study using data from the Australian and New Zealand Neonatal Network (ANZNN) for the period 2001-2010. The network includes all neonatal intensive care units (NICUs) in Australia and New Zealand. The ANZNN data collection includes all babies born at < 32 weeks' gestation and admitted to a NICU.
Participants/materials, setting, methods: 24,069 live born singleton babies admitted to NICUs in Australia and New Zealand during 2001 to 2010. Mode of conception included spontaneous conception, hyper-ovulation, ART and AI. Outcomes included both mortality and morbidity measures, the latter categorized into birth conditions and NICU conditions. Descriptive and multivariate analyses were conducted.
Main results and the role of chance: Of the 24,069 singletons < 32weeks' gestation admitted to NICUs, 21,753 (90.4%) had information on mode of conception. Of those, 94.4% (20,530) were spontaneously conceived, 4.4% (*n* = 953) were born after ART, 1% (*n* = 216) after hyper-ovulation and 0.2% (*n* = 54) following AI. ART mothers were significantly older (mean age 34.6 versus 28.9 years), non-Aboriginal (1.0% versus 6.2%) and had a history of pregnancy-induced hypertension (20.9% versus 17.6%) ($p < 0.05$). Compared to spontaneously conceived singletons, ART singletons had significantly higher odds of birth defects (adjusted odds ratio (AOR) 1.71, 95% confidence interval (CI) 1.36-2.16), necrotizing enterocolitis (AOR 1.43, 95% CI 1.04-1.97) and major surgery (AOR 1.26, 95% CI 1.39-2.12). SGA was significantly associated hyper-ovulation (AOR 1.52, 95% CI 1.021-2.67) and AI (AOR 3.02, 95% CI 1.53-5.81) but not ART.
Limitations, reason for caution: Detailed information on ART treatment including number of embryos transferred, fertilization procedures, fresh versus thaw transfer and blastocyst versus cleavage stage embryo was not available in the ANZNN data. There was no information available on subfertile women who conceived without use of assisted conception.
Wider implications of the findings: A higher likelihood of very and extreme preterm birth remains for women giving birth after assisted conception. The differences in perinatal outcomes for singleton preterm births following different fertility treatments has implications for counselling of couples planning to access fertility treatment regarding their choice and type of treatment. More research is needed to determine whether the increased risk of adverse perinatal outcomes is due to the assisted conception itself or underlying subfertility.

[13]*Radboudumc, Scientific Institute for Quality and Healthcare, Nijmegen, The Netherlands*

Study question: What is the effectiveness of a multifaceted implementation strategy compared to usual care to improve professional adherence to guideline recommendations on tailored expectant management (TEM) in couples with unexplained infertility and a good prognosis of natural conception?
Summary answer: A cluster RCT (c-RCT) showed that the multifaceted implementation strategy improved guideline adherence with eight percent compared to usual care. This is mainly the result of an increased number of professionals calculating the couple's prognosis of spontaneous conception and advising a correct TEM of at least six to twelve months.

What is known already: In couples with unexplained infertility and a good chance of natural conception (> 30%), TEM of six to twelve months is equally effective as starting medically assisted reproduction (MAR) early. TEM is therefore recommended in national fertility guidelines. However, implementation of TEM is not optimal, as MAR often starts too early, leaving room for improvement. Based on an assessment of barriers and facilitators for TEM among professionals and infertile couples, we have developed a multifaceted implementation strategy.
Study design, size, duration: We performed a c-RCT in 25 Dutch clinics, embedded in the Dutch consortium for studies in women's health. Clinics were randomized for the intervention (implementation strategy for 12 months, N = 13) or usual care (N = 12). The strategy included audit and feedback, a local protocol, an E-learning communication module and a website.
Participants/materials, setting, methods: We studied couples with unexplained infertility and > 30% chance of natural conception within 12 months. The primary outcome was adherence to TEM. We also assessed three quality indicators associated with adherence to TEM. Data collection was obtained from medical records. We performed baseline and effect measurements in all clinics.
Main results and the role of chance: At the baseline measurement we included 544 couples. In the after measurement there were 247 couples exposed to the intervention and 238 couples exposed to usual care. In the intervention group (I) adherence increased from 49% to 69%; in the control group (C) from 49% to 61%. (unadjusted OR 1.5; 95% CI 1.03-2.20). Two quality indicators supported this effect: 1. Calculation of the prognosis of spontaneous conception (I:59% to 85%, C:75% to 81%). 2. Advising a correct TEM of at least six months (I:58% to 77%, C:58% to 68%). The third quality indicator, adhering to a correct advised expectant period of at least six months, showed no difference between the intervention and control group (I:85% to 91%, C:85% to 90%).
Limitations, reason for caution: There is possible selection bias since our included couples had a higher socio-economic status than non-responders. How this might affect adherence is unclear. Furthermore, the adherence to TEM has also been influenced by the government, which tried to make TEM obligatory simultaneously to the start of the intervention.
Wider implications of the findings: An implementation strategy, based on barriers and facilitators and targeting multiple levels (patients, professional and organization), improves guideline adherence to TEM. The increased adherence leads to less couples being exposed to unnecessary fertility treatment and the associated risks, complications and burdens. To further underline the importance of improved adherence to TEM it will be necessary to investigate the effect of the strategy on other outcome measures such as experiences with care and cost-effectiveness. In order to assess which of the strategy facets had the most effect, a process evaluation will have to take place. When these facets are identified, other clinics in the Netherlands as well as other European countries that make recommendations on TEM, can use these tools to improve implementation of TEM.

O-132 Long-term risk of endometrial cancer after ovarian stimulation for in-vitro fertilization

A. W. van den Belt-Dusebout[1], M. Spaan[1], C. W. Burger[2], F. E. van Leeuwen[1]
[1]*The Netherlands Cancer Institute, Epidemiology, Amsterdam, The Netherlands*
[2]*Erasmus University Medical Center, Obstetrics and Gynecology, Rotterdam, The Netherlands*

Study question: Since the 1980s, in-vitro fertilization (IVF) is widely used. However, late adverse health effects are still largely unknown. In view of the association of endogenous estrogen levels with endometrial cancer risk, the purpose of this study was to examine the long-term risk of endometrial cancer after ovarian stimulation for IVF.
Summary answer: After a median follow-up duration of 21.9 years after treatment, the risk of endometrial cancer was not significantly increased after ovarian stimulation for IVF treatment.
What is known already: Both endogenous and exogenous estrogens play a key role in the development of endometrial cancer. Because of their influence on endogenous estrogen levels, nulliparity, late menopause, late age at first birth, obesity, and lack of physical activity are well-established factors for endometrial cancer. Some causes of subfertility have been associated with increased risk of endometrial cancer, but results were inconsistent. Published studies have not yet examined the long-term effects of endometrial cancer after ovarian stimulation.
Study design, size, duration: This is a nationwide historical cohort study, the OMEGA study, comprising 19,158 women who started IVF and a non-IVF group of 5,950 subfertile women who underwent other fertility treatments in one of the 12 IVF centres in the Netherlands between 1980 and 1995.
Participants/materials, setting, methods: Information was collected on subfertility cause and treatment (medical records), reproductive and life-style factors (questionnaires). The Netherlands Cancer Registry provided endometrial cancer incidence (1989-2013). We calculated standardized incidence ratios (SIRs) for comparison with the general population. Multivariable Cox regression analysis was used to quantify treatment effects on endometrial cancer risk.
Main results and the role of chance: After a median follow-up duration of 21.9 years, 63 endometrial cancers were observed (SIR, 1.08; 95% confidence interval [CI], 0.83-1.38). Endometrial cancer risk was comparable after IVF (SIR, 1.16; 95% CI, 0.85-1.54) and after other fertility treatments (SIR, 0.90; 95% CI, 0.52-1.47). The SIR for nulliparous women was 1.83 (95% CI, 1.31-2.50), whereas the SIR for parous women was 0.62 (95% CI, 0.22-1.23). When comparing the IVF group with the non-IVF group, the risk after IVF was not increased (HR, 0.98; 95% CI, 0.53-1.80), adjusted for hormonal causes of subfertility and number of births. The risk did not significantly differ for 1-3, or 4 or more IVF-cycles compared with no IVF, and for different causes of subfertility, adjusted for number of births.
Limitations, reason for caution: The SIRs must be interpreted with caution, because of differences in parity and subfertility. Therefore, the direct comparison of the IVF group with the non-IVF group, while adjusting for important confounders, such as parity and subfertility cause, is very important.
Wider implications of the findings: We concluded that ovarian stimulation for IVF does not increase the risk of endometrial cancer after long follow-up. This is a reassuring finding for women who have undergone IVF treatments in the past. This reassuring result can also be used by women and their physicians in making a decision on starting or continuing with IVF treatments.
Study funding/competing interest(s): Funding by hospital/clinic(s), Funding by national/international organization(s) – This research is supported by the Dutch Cancer Society, grant nr NKI 2006-3631 and a Departmental grant from the Department of Obstetrics and Gynecology of Erasmus University Medical Center.

[7]*Odense University Hospital, Fertility Clinic, Odense, Denmark*
[8]*SISMER, Bologna, Italy*
[9]*ESHRE, Central Office, Grimbergen, Belgium*

Introduction: This is the sixteenth report of the European IVF-monitoring (EIM), the ESHRE register on assisted reproductive techniques (ART) organization. This report deals with the results of treatments initiated during 2012.
Methods: Data were collected from existing national registries in 33 countries (data sent in at the time of abstract deadline) and directly entered by each national coordinator into the EIM database through software developed by ESHRE. Data were analysed at ESHRE headquarters.
Results: In total, 1081 IVF clinics participated (81.2% of registered clinics in the participating countries. Next to these also 1083 IUI units reported their data. The IVF clinics reported 624 874 treatment cycles: IVF (144 914), ICSI (307 762), frozen embryo replacement (FER, 127 365), egg donation (ED, 30 437), preimplantation genetic diagnosis/screening (PGD/PGS, 8 426), in-vitro maturation (IVM, 421) and frozen oocytes replacements (FOR, 5 549). This preliminary data set shows that the number of cycles compared to 2011 increases with 2.4%. However since a number of countries still need to send in their data, the total number of ART cycles will increase even more. Data on intrauterine insemination using husband/partner's (IUI-H) and donor (IUI-D) semen were reported from 26 countries (data sent in at the time of abstract deadline). A total of 175 499 IUI-H and 43 498 IUI-D cycles were included. When interpreting the results, it is important to note that delivery rates may be underestimated due to lack of follow-up and incomplete reporting. For IVF, the clinical pregnancy rates (PR) per aspiration and per transfer were 29.4% and 33.8%, respectively and comparable to 2011. For IVF the delivery rate (DR) per aspiration was at 23.0%. For ICSI, the corresponding rates were 25.4 %, 29.5%, and 19.7%. For frozen embryos replacements, PR was 23.4% per thawing and 25.3% per transfer. The corresponding delivery rates were 16.2% and 17.5%. In oocyte donation cycles, PR and DR were 48.4% and 31.3% per transfer, respectively in the fresh cycles and 36.0% and 21.9% in the frozen cycles. For the ED cycles with FOR, the numbers are as follows: PR was 45.1% and DR was 26.2% per transfer. For PGD/PGS, in the fresh cycles the PR was 37.8% per transfer. In the frozen cycles this was 38.0%. For in vitro maturation, PR and DR were 25.5% and 22.1% per transfer respectively. Finally, 4645 replacements after oocyte freezing were reported, mainly from Italy and Spain. They resulted in 37.4% PR and 20.5% DR per thawing, respectively. Following IUI-H the pregnancy rate and delivery rate was 11.9% and 8.0%, while it was 16.6% and 11.9% respectively in IUI-D. The transfer of 1, 2, 3 and 4 or more embryos following IVF or ICSI occurred in 29.9%, 55.4%, 13.5% and 1.2% of cycles respectively. There were significant national differences in practice. The proportions of singleton, twin and triplet deliveries after IVF and ICSI showed only marginal differences compared to those in 2011, at 82.1%, 17.2%, and 0.7% respectively. The proportion of very preterm deliveries (≤ 33 weeks) increased from 9.0% for singleton pregnancies to 20.4% for twin pregnancies and 38.1% for triplet pregnancies, justifying a transfer policy aimed at decreasing the risk of multiples. IUI-H in women below 40 years of age resulted in 8.1% twin and 0.5% triplet pregnancies, thus not higher than in IVF-ICSI.
Conclusions: In comparison with previous years, 2012 will show an increase in the number of reported ART cycles in Europe. The numbers of embryos transferred remain relatively stable, as does the delivery rate. No significant change in the multiple birth rate was observed in these preliminary data.

Study question: An update of glossary on assisted reproductive technology (ART) became necessary because of evolution of techniques and concepts since the previous version (2009) and integration into WHO guideline processes.
Summary answer: The new version clarifies some important points. It was enlarged to new categories in order to cover all aspects of ART and related fields. The number of items increased from 87 to 247.
What is known already: ART practice is expanding worldwide, and is subject to large variations in availability, practice and results across the World. Its public health importance has lead to the implementation of many registries at national and international levels, and it is the topic of many publications. Thus, the need for standard definitions is critical to allow for evaluation of studies, centers, countries, and regions results. The International Committee for Monitoring Assisted Reproductive Technologies (ICMART), an entity responsible for the collection and dissemination of worldwide data on ART, worked with WHO to publish the first glossary on ART terminology in 2006 and a revision in 2009. Such revisions are regularly needed because of the evolution of techniques and concepts.
Study design, size, duration: The revision was organized with expert panels, literature review, and stakeholder consensus meetings. The total process will last 12-15 months.
Participants/materials, setting, methods: The process was organized in 4 steps, coordinated by ICMART (F. Zegers-Hochschild) and WHO (S. Vanderpoel). First, 4 working groups of 5-8 specialists were organized (September 2014), each reviewed a subset of definitions: clinical; laboratory (subsequently divided into Andrology and Embryology); outcomes; epidemiology and public health. New definitions were also proposed for items not already covered. The second step was a consensus meeting, at WHO headquarters, with 30 attendees including the 4 groups' coordinators and representatives of the main international societies. All proposed definitions were discussed at length and a first draft was produced. In a third step, comments from WHO regional representatives, some country offices, and other external agencies were compiled. This included discussions with the external expert technical advisor group facilitated by WHO, which is compiling the 11th ICD (international classification of disease) revision. Finally, the 4th step will be a debate process during the consensus discussions in September 2015 with the integration of the glossary and official WHO guidelines for infertility.
Main results and the role of chance: The ICMART/WHO Glossary has been largely expanded, from 87 to 247 definitions. Most previous definitions have been retained but some modified, clarified or expanded. Many new definitions have been added, particularly in infertility and epidemiology/public health. All current aspects of ART are clearly defined. The role of chance is minimal, given the large coverage of specialists in infertility and other stakeholders, and the use of evidence based medicine wherever it was possible.
Limitations, reasons for caution: The glossary definitions are based on a consensus process by many stakeholders, but it was not possible to achieve universal agreement. Also, as done in the past, the glossary will be translated into the recognized UN languages.
Wider implications of the findings: It is generally accepted that measurement of human activities improves quality and outcomes. However, this is only possible if all stakeholders speak a common language. The ICMART/WHO glossary intends to provide a common terminology platform. This will allow for better analysis of international comparisons and, subsequently, a potential improvement of quality and safety. The collaboration with WHO is important to allow for an unbiased development and a broader international use of the glossary.
Study funding: World Health Organization

INVITED SESSION

SESSION 37: HUMAN DEVELOPMENT AND EVOLUTION

Tuesday 16 June 2015 **11:45–12:45**

O-135 Critical periods of human development: ART effects?

J. Dumoulin[1]
[1]*Maastricht University Medical Center, IVF-Laboratory Dept. of Obstetrics and Gynaecology, Maastricht, The Netherlands*

The Developmental Origins of Health and Disease (DOHaD) hypothesis states that an adverse environment of the conceptus during early life can affect

development by inducing adaptive changes in physiology and metabolism leading to increased disease risk in adulthood. Evidence for this hypothesis can be found in the human as well as in several animal species. An increasing body of evidence from animal studies suggests that the periconception period is a very vulnerable period. Poor nutrition and sickness of the mother during this period, maternal obesity as well as in vitro culture of embryos have all been shown in animal models to increase the risk of developing chronic non-communicable diseases in adulthood. This raises concern for human IVF offspring. Although it must be stressed that the great majority of children resulting from assisted reproductive technologies (ART) treatment is healthy, adverse perinatal outcome and cardio-metabolic parameters in IVF children are reported. Patient-related factors such as type and duration of subfertility and lifestyle of the parents have been shown to be possible causal factors. However, evidence is accumulating that, similar to the animal models, also certain aspects of the ART technique itself, such as the type of culture medium used, may have an effect on the phenotype of IVF children. Whether or not these IVF technique induced effects are an indication for health-related consequences in later life is as yet unknown. In view of the fact that in the Western world, an estimated 1-3% of children born annually are conceived by IVF, more research is highly needed to investigate the effects and long-term safety of the IVF technique and culture medium on health of these children.

SESSION 38: MANAGING PATIENT EXPECTATIONS

Tuesday 16 June 2015 **11:45–12:45**

O-137 Infertile men's expectations and needs in relation to fertility treatment before and after their first ICSI-treatment

J. K. Fürbringer[1], R. Sylvest[1], A. Pinborg[1], J. Bogstad[1], L. Praetorius[1], K. Loessl[1], L. Schmidt[2]
[1]*Hvidovre Hospital, 455 Fertility Clinic, Hvidovre, Denmark*
[2]*University of Copenhagen, Social Medicine, Copenhagen, Denmark*

Study question: What are the infertile men's expectations to and needs in relation to fertility treatment?
Summary answer: Men with low sperm quality want to be involved on equal terms as their partner in the fertility treatment. The participants wanted professionalism, empathy, and face to face information about their sperm quality, treatment process, treatment results, and the future plan.
What is known already: Infertility concerns both partners in the couple. Medical fertility treatment is mainly directed towards the women and accordingly information and support are frequently focused on the women. Male infertility is a potential severe stressor and many men with low sperm quality would like more widely to talk about it. The infertile men want a dialogue concerning fertility treatment, male infertility, the role of the male partner, and information about the psychological consequences of male infertility.
Study design, size, duration: Longitudinal, semi-structured qualitative interview study with ten men with low sperm quality undergoing fertility treatment. Participants were interviewed before and after their first ICSI-treatment attempt. The participants were selected by purposeful sampling with maximum variation. The data collection takes place between November 2014 and May 2015.
Participants/materials, setting, methods: The participants were assigned to fertility treatment at the Fertility Clinic, Hvidovre Hospital, Copenhagen, Denmark. A total of 15 men were contacted, where five did not want to participate. The interviews were audiotaped and transcribed in full. Data were analysed using qualitative content analysis following Graneheim and Lundman (2004).
Main results and the role of chance: The interviews before the participants' ICSI treatment showed that the men wanted an overall plan and an overview of the process on the time of the referral. They wished that the information about their diagnostic sperm sample was given face to face with an opportunity to ask questions. The men expected involvement in the treatment process. They desired kindness, understanding, professionalism, and empathy from the fertility clinic staff. The participants wanted detailed information about the treatment plan, the results in the process, and information about how the treatment progress. Results from follow-up interviews will be added before the congress.
Limitations, reason for caution: We do not have information about men not wanting to participate in the study. The study included only infertile men seeking ICSI-treatment and hence caution should be taken to take transfer the results to infertile men in other fertility treatment as e.g., the use of donor semen.
Wider implications of the findings: These results are in agreement with other studies concerning that the men wants the clinical staff's support and a dialog concerning male infertility. Written information, which will be given to the men together with their results from their sperm test, could be a solution to the problem of information early in the process. We also suggest that the clinics work towards more structure on information on male diagnosis and future treatment plan.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Hvidovre Hospital, Copenhagen, Denmark.
Trial registration number: NA.

O-138 Using the same sperm donor for siblings: what it means to parents

S. Somers[1], A. Ravelingien[2], V. Provoost[2], I. Raes[2], H. Van Parys [3], E. Wyverkens[3], I. Stuyver[4], A. Buysse[3], G. Pennings[2], P. De Sutter[4]
[1]*Ghent University/Ghent University Hospital, Department of Philosophy and Moral Sciences/Department of Reproductive Medicine, Ghent, Belgium*
[2]*Ghent University, Bioethics Institute Ghent (BIG) Department of Philosophy and Moral Sciences, Ghent, Belgium*
[3]*Ghent University, Department of Experimental-Clinical and Health Psychology, Ghent, Belgium*
[4]*Ghent University Hospital, Department of Reproductive Medicine, Ghent, Belgium*

Study question: How do (prospective) parents perceive and experience the importance of a genetic link between siblings born after fertility treatment with donor sperm?
Summary answer: The use of the same sperm donor for subsequent conceptions appeared quasi univocal and was accompanied by uncertainty about the same donor being available over time. Feelings of luck or relief were mentioned by parents whose children were genetic siblings.
What is known already: Several authors have noted an interesting paradox: while gamete donation allows for detachment of social parenthood from biological relatedness, it is also becoming the area in which biological notions of kinship are reaffirmed. There is an increasing demand for the right to know one's gamete donor; donor offspring are also seeking genetic half siblings through online registries. It remains fairly unchartered territory how parents negotiate the importance of a genetic link between their donor-conceived children.
Study design, size, duration: In this study, we included 35 lesbian and heterosexual couples. The in-depth semi-structured couple interviews were performed between October 2012 and October 2013. Data were analysed through step-by-step inductive thematic analysis. A continuous auditing process by the co-authors resulted in themes that were grounded in the data.
Participants/materials, setting, methods: The participants were recruited at the Department of Reproductive Medicine of a University Hospital. Twenty couples had a child conceived after a fertility treatment with anonymous donor sperm and 15 were in treatment at the time of data collection. The study was approved by the appropriate Ethics Committee.
Main results and the role of chance: We distinguished between families with siblings from the same donor, siblings from a different donor, and siblings with a different biological mother (in lesbian couples). Overall, the couples showed a clear preference to use the same sperm donor for their children. In describing the reasons for this preference, common assumptions were that the genetic link between the children generated better sibling relations, and that (visible) resemblances between the siblings would facilitate social acknowledgement

of their family construct. Uncertainty about the availability of the same donor over time seeped through in their stories. For some lesbian couples who decided that both partners should carry a child, the genetic link between mother and child was perceived as more important than a full genetic link between the siblings.
Limitations, reason for caution: This qualitative study aimed at a better understanding of the participants' experiences of and importance attached to the genetic link between their offspring and does not intend to produce generalizable results. Only recipients of anonymous donor sperm were included.
Wider implications of the findings: These results suggest that, even when the non-biological parent is acknowledged in his role within the family, there is a tendency to favor full genetic bonds where possible. Full siblings are considered 'real', 'unambiguous' kin connections. The findings also have possible implications for the clinic: the opportunity to use the same donor for subsequent conceptions seems important for (prospective) parents and should ideally be discussed before the start of the treatment.
Study funding/competing interest(s): Funding by University(ies) – The project is funded by the Special Research Fund of Ghent University. There are no competing interests.
Trial registration number: NA.
Keywords: sperm donation, donor siblings, genetic relatedness, qualitative research

O-139 The effectiveness of psychosocial interventions that can be delivered by all staff members: a systematic review

E. Dancet[1], N. Vermeulen[2], J. Boivin[3], S. Gameiro[3]
[1]*Leuven University Hospital Campus Gasthuisberg, Fertility Centre, Leuven, Belgium*
[2]*ESHRE, Research, Brussels, Belgium*
[3]*Cardiff University, School of Psychology, Cardiff, United Kingdom*

Study question: Which psychosocial interventions can be delivered by all staff members (i.e. physicians, nurses, midwifes, embryologists) as they do not require a mental health professional, and what is their effect on the psychosocial wellbeing (e.g. stress, marital satisfaction, social concerns) of fertility patients?
Summary answer: Evidence indicates positive effects of some psychosocial interventions that can be delivered by all staff members. High quality trials, not contradicted by other trials evaluating similar interventions, proved the benefit of self-administered leaflets with preparatory information for patients' individual wellbeing and of self-administered online cognitive-behavioural-therapy for patients' social wellbeing.
What is known already: Fertility problems and treatments have a negative impact on patients' psychosocial wellbeing. Historically, patients have been referred to mental-health professionals (e.g. psychologists, social workers) if this was deemed required to ensure their psychosocial wellbeing. Recently, enabling all staff members to fulfil the need for psychosocial care of all their patients was suggested. A review of research on the nature and effectiveness of psychosocial interventions that can be administered by all staff members was missing.
Study design, size, duration: This systematic literature review followed a predefined protocol replicated by two reviewers. In August 2014 four electronic databases were searched for (randomized) controlled trials evaluating psychosocial interventions (potentially) delivered by all staff members (i.e. not requiring mental health professionals) and their effect on patients' psychosocial wellbeing assessed with reliable questionnaires.
Participants/materials, setting, methods: Self-administered interventions were differentiated from interpersonal interventions. Psychosocial wellbeing was operationalized as individual, relational and social wellbeing. We extracted data about the sample, nature of the intervention, study design, questionnaires' reliability, statistical tests and effect sizes. The trials' quality was rated and a meta-synthesis of the data was conducted.
Main results and the role of chance: Seven randomized controlled trials evaluated self-administered interventions and nine trials (all controlled, seven randomized) evaluated interpersonal interventions. Trials had high (n = 3), moderate (n = 9) or low (n = 4) quality. Evidence on similar interventions was contradictory. Four in seven trials found an effect of self-administered interventions (i.e. online psycho-education, expressive writing, information leaflet, online cognitive-behavioural-therapy) on individual wellbeing (i.e. stress, self-efficacy). One in two trials found an effect of self-administered interventions (i.e. online psycho-education) on relational and social wellbeing (i.e. sexual/social concerns). Six in eight trials found an effect of interpersonal interventions (i.e. complex interventions or group information sessions) on individual wellbeing (i.e. depression, anxiety, self-efficacy, adjustment, life-satisfaction). One in two trials found an effect of a complex intervention on relational wellbeing (i.e. marital and sexual satisfaction).
Limitations, reason for caution: The reliability of the findings of this review is restricted as only three trials received high quality ratings. Many interventions integrated multiple components (e.g. information provision combined with training in coping skills) and therefore it is not possible to specify which of their components were affecting wellbeing.
Wider implications of the findings: Although patient-centred care requires all staff members to show empathy with patients during all clinical procedures and interactions, high-level evidence on whether staff members other than mental health professionals can deliver effective psychosocial interventions is missing. Psychosocial interventions that can be delivered by all staff members with a theory-led rational should be tested while allowing assessing the individual impact of each of their components.
Study funding/competing interest(s): Funding by University(ies) – Cardiff University; Academic Medical Centre Amsterdam; Leuven University.
Trial registration number: NA.

O-140 Understanding the preferred role in infertility treatment decision making among Chinese infertile women in Hong Kong

H. Chan[1], T. H. ChanY.[2], M. Y. TamJ.[2], Q. S. Wong[2], I. P. LoY.[2]
[1]*HKU-QMH CARE, CARE, Hong Kong, Hong Kong*
[2]*The University of Hong Kong, The Department of Social Work and Social Administration, Hong Kong, Hong Kong*

Study question: What are the treatment decision making preferences in Chinese women undergoing fertility treatments in Hong Kong?
Summary answer: Results revealed majority of Chinese infertile women preferred relying on healthcare professionals and took minimal role in treatment decision-making. The findings align with qualitative reports from local healthcare professionals, highlighting a need to empower and facilitate Chinese women in fertility treatment decisions in order to improved clinical outcomes.
What is known already: Past studies have found treatment decision-making as central part of patient participation in healthcare which relates to patient autonomy and empowerment. In a local qualitative study professionals at local ART clinics described fertility patients in Hong Kong as unassertive, compliant and largely reliant on physicians in different aspects of treatment decisions, especially on whether to continue or terminate treatment. However, without recruiting patients as informers, little is known about their actual experience and preference.
Study design, size, duration: A cross-sectional survey was conducted with subfertile women currently undergoing IVF treatment in a local public hospital. Information was collected on infertility diagnosis, treatment history, their preferred decision making role, and demographic characteristics. The sample size is 198.
Participants/materials, setting, methods: Women undergoing IVF treatment were approached in a local hospital fertility clinic on the day of pregnancy test. Pregnant women and non-Chinese women were excluded. Of 465 eligible participants, 283 agreed to participate, 205 completed questionnaires were eventually returned. Data analysis were run on 198 valid set of response.
Main results and the role of chance: On average, participants were 37.0 years (SD = 3.5), married for 7.4 years (3.7), and suffered subfertility for 4.1 years. The majority of them received tertiary education and had full-time job. Most of them preferred shared by leaning passive role (41.9%) or total passive role (40.4%). 89.4% of them thought doctors should best decide diagnosis and evaluate treatment options, and only 10.1% preferred sharing responsibility. No one assumed an autonomous role. Similarly, most women preferred minimal role and relied heavily on physicians in deciding whether to continue or terminate further treatments (84.3%), only a small proportion preferred sharing responsibility (7.1%) or asserting autonomy (8.6%). Chinese infertile women appeared to be more compliant in making treatment decisions as compared to their Western counterparts.
Limitations, reason for caution: Self-selection bias was inevitable in questionnaire survey, and the cross-sectional nature of the study did not permit causal inferences. Only infertile women were recruited in the study, so the decision

making preference for men experiencing fertility problems in Hong Kong is yet to be investigated.
Wider implications of the findings: This study adds to our understanding of Hong Kong Chinese women's role preference and level of involvement in infertility treatment decision making by providing quantitative evidence from patients' experience. It highlights the importance of physicians and nurses in facilitating informed decision making.
Study funding/competing interest(s): Funding by University(ies) – None.
Trial registration number: NA.
Keywords: preferred role, treatment decision making, infertile women, Chinese, Hong Kong

INVITED SESSION

SESSION 39: TOWARDS SAFER AND BETTER IVF

Tuesday 16 June 2015 **14:00–15:00**

O-141 Towards an OHSS free clinic

NP Polyzos[1]
[1]*Universitair Ziekenhuis Brussel, Centre for Reproductive Medicine, Brussels, Belgium*

Over the last 20 years substantial progress has been accomplished in the field of reproductive medicine with an increase, not only in the annual number of treatment cycles, but also in the cumulative live birth rates following IVF/ICSI. Nevertheless, in spite of this progress, and despite that more than 5 million babies have been born from IVF/ICSI, we must not forget we treat "healthy infertile women" and we must deliver "healthy pregnant women". Ovarian hyperstimulation syndrome (OHSS) is the most serious complication for women undergoing IVF treatment. According to the 2010 annual report of ESHRE European IVF-monitoring (EIM) Consortium, 1500 cases of OHSS were recorded in 25 out of the 31 countries with an incidence of 0.3%. Although its incidence has reduced over the last decade, these figures may be underestimated, if we consider that OHSS frequency in well-designed randomized controlled trials is approximately 3%. Taking into account that, even after 25 years since the introduction of ovarian stimulation, OHSS is still present and considering that it can be a severe complication, strictly associated with high morbidity and potential mortality, we are obliged to aim for a "safer and better" IVF practice and work towards an "OHSS free clinic". The concept of OHSS free clinic, which has been introduced in 2010, appears to be more relevant than ever. Such a concept includes the use of GnRH antagonists for pituitary downregulation and ovulation triggering with a GnRH agonist, followed by segmentation of IVF treatment with elective embryo cryopreservation and embryo transfer in a subsequent cycle. This presentation aims to address the evidence supporting the use of the GnRH antagonist protocol with the use of GnRH agonist triggering for final oocyte maturation as a key strategy towards an OHSS free clinic. In addition it aims to address the safety and efficacy of a fresh embryo transfer following this concept and finally discuss whether segmentation of IVF treatment and embryo transfer in a subsequent cycle might be the future for all patients undergoing IVF treatment.
Keywords: OHSS, GnRH agonist triggering, GnRh antagonist, freeze-all, segmentation of IVF

O-142 Towards a "freeze all" policy

M. Roque[1]
[1]*ORIGEN – Center for Reproductive Medicine, Reproductive Medicine, Rio de Janeiro, Brazil*

The first pregnancy described after a frozen–thawed embryo transfer (FET) dates back to 1983 in Australia, and the first live birth dates back to 1984 in the Netherlands. Since that time, embryo cryopreservation techniques have dramatically improved and the number of FETs has increased. In 2012, around one-third of all assisted reproductive technology (ART) births reported by the Society for Assisted Reproductive Technology (SART) originated from FET. Nowadays, although fresh embryo transfer (ET) is the norm in most *in vitro* fertilization (IVF) centers, there is increasing interest in the freeze-all policy. In this strategy, the entire cohort of viable embryos is electively cryopreserved and a delayed FET is performed. The potential advantage of this strategy is that the embryo transfer is performed in a more favorable intrauterine environment, possibly improving IVF outcomes and overall safety. Although controlled ovarian stimulation (COS) is considered an essential step during IVF treatments, there are increasing concerns about the adverse effects of COS over the endometrial and uterine environment, as well as regarding the safety of COS in pregnancies that have originated from ART. Many genes related to endometrial receptivity are regulated by hormones, and COS may alter the gene expression of more than 200 genes related to implantation when compared to natural cycles without hormone stimulation. The supraphysiologic levels of estradiol and progesterone during COS could lead to morphologic and biochemical modifications, and would consequently impair endometrial receptivity. Conversely, endometrial development and priming are controlled more precisely during frozen–thawed cycles when compared to COS with gonadotropins, and this could be related to better endometrial receptivity, thus favoring those patients adopting the freeze-all policy. It is known that uterine contractions (UC) at the time of ET adversely affect IVF outcomes, and that supraphysiologic hormone levels may increase these UC. Some studies found that uterine contractility is much higher in stimulated cycles than in natural cycles. Considering all of the possible side effects of COS on endometrial receptivity, as discussed above, recent studies have shown better IVF outcomes when performing elective FET. Ovarian hyperstimulation syndrome (OHSS) is an iatrogenic, potentially lethal, and major complication encountered during COS in IVF. The prevention of OHSS is the most important aspect of its management. The freeze-all strategy virtually eliminates the onset of early and late OHSS. It seems that ectopic pregnancy occurs more frequently in pregnancies that result from IVF treatments when compared to natural pregnancies. This higher risk would be related to increased UC and supraphysiologic hormone levels during COS. Some observational studies have suggested that pregnancies that occurred after FET seem to have better obstetric and perinatal outcomes when compared to fresh ET, suggesting an advantage in performing FET over fresh ET. The COS and supraphysiologic hormone levels may be related to altered placentation, leading to an increased risk of pre-eclampsia, low birth weight, prematurity, small size for gestational age, antepartum hemorrhage, and perinatal death. Regardless of the growing evidence favoring the freeze-all strategy, there are few data concerning the cost-effectiveness of elective FET when compared to fresh ET. There is still a lack of higher-quality randomized controlled trials regarding the freeze-all policy and its relationship to IVF, obstetric and perinatal outcomes, the best developmental stage for embryo cryopreservation when applying this strategy, and the best endometrial priming method to perform FET. This presentation will evaluate the available evidence in the literature comparing fresh ET and the freeze-all policy regarding the possible interference of COS in implantation and endometrial receptivity, IVF safety, and obstetric and perinatal outcomes.
Keywords: freeze-all policy, elective frozen–thawed embryo transfer, delayed frozen-thawed embryo transfer

INVITED SESSION

SESSION 40: POWER BALANCE IN THE IVF LABORATORY

Tuesday 16 June 2015 **14:00–15:00**

O-143 Scientist vs. technology in determining success

D. H. Edgar[1]
[1]*Reproductive Services/Melbourne IVF, Royal Women's Hospital and Dept of Obstetrics and Gynaecology University of Melbourne, Parkville Victoria, Australia*

The definition of success in IVF has not remained constant over the past 35 years. Although originally designed to be a potential solution for women whose infertility was ascribed to tubal disease, advances in IVF quickly allowed it to become applicable to a wide range of indications. More recent advances have led to outcomes such as the time taken to achieve pregnancy, the overall/cumulative efficiency of a treatment cycle and the safety of any resultant pregnancy for both the mother and fetus, becoming significant considerations that have driven contemporary clinical practice. What have remained constant, however, are the critical laboratory aspects associated with

achieving success. In that context, the IVF laboratory has been charged with overseeing the formation, development, selection, and storage of human embryos ex vivo. The increased success of clinical IVF since its inception, is attributable to a familiar scientific process involving the interaction of the scientist and technology. Science is, by definition, the systematic acquisition of knowledge and the scientist has acquired this knowledge in part by developing technology to aid in the quest. The scientific knowledge gained has, in turn, driven the development of further technology for two reasons: a) to increase insight into the biological processes involved in human conception in vitro and b) to apply the scientific knowledge in attempting to achieve improved clinical outcomes. The latter aspect then involves the scientist as a practitioner whose skill is an important component of successful treatment. Examples of this interdependence can be seen in improvements at all levels of IVF treatment. For example, scientific knowledge on the physiology of fertilisation led to the introduction of sperm microinjection techniques culminating in the clinical introduction of ICSI which revolutionised the treatment of male infertility and dramatically increased the population of patients suitable for in vitro-based treatments over 20 years ago. The technology used for ICSI has also generated new knowledge on the critical events associated with fertilisation of the human oocyte. At a practitioner level, the skill required for optimal performance of ICSI is a crucial component of the scientist's contribution to clinical success. Basic scientific knowledge, some of it gleaned well before the introduction of clinical IVF, was instrumental in forming our current view of the nutritional/ metabolic requirements of the preimplantation mammalian embryo in vitro. The work of a number of notable scientists, building on the foundations laid by early experimental embryologists, resulted in this scientific knowledge being applied to the design of culture systems that resulted in dramatic increases in the viability of human embryos grown in vitro. A similar pattern can be observed in the knowledge, generated by cryobiologists over many decades, being applied to the development of optimal cryopreservation systems for human embryos. Scientific advances in these two areas have been pivotal in the trend towards a reduced number of embryos in transfer procedures and the growth of single embryo transfer (SET). Accurate prediction of embryo viability remains a major challenge to scientists in the field and, again, basic scientific knowledge of preimplantation genetics and, more recently, morphokinetics has led to the development of new technologies that hold much promise for the future. In summary, improvements in every facet of the IVF laboratory have been underpinned by scientific knowledge, acquired by scientists. This has in turn, led to the development of technology (specific tools and devices) that has allowed the knowledge to be applied and achieve optimal clinical outcomes. So, the scientist has been, and is, the key player in both development and utilisation of the technology responsible for success in IVF. It is unlikely that this pattern will be different in the future.

Keywords: scientist, technology, IVF laboratory

O-144 Embryology vs. clinic – the balance in decision making

S. Ziebe[1]
[1]*Copenhagen University Hospital Rigshospitalet, Fertilitetskliniken – Afsnit 4071, Copenhagen, Denmark*

All decision making in modern assisted reproduction with the aim of assisting the couples or the women in achieving a live birth of a healthy child must be based on all available information concerning the women, the man, the sperm, the oocyte, the uterus and their interaction. It is a decision of whether to treat, how to treat or not to treat at all. Decision making is about predicting outcome in a scenario of variable biology based on physiological indicators and previous responses. The tools are our knowledge and experience – mixed with and/or distorted by our wish to fulfill patient expectations and dreams. Real life decisions are much more than just selecting the best embryos for the patient. The challenge is to rank the different aspects and arguments. Should we transfer a poor quality embryo in order to provide closure to the patient after a series of failed treatments? Should we inject non-motile sperm cells into the oocytes from an ICSI couple who don't want a sperm donor? Should we proceed with the transfer or cryopreserve all the top quality embryos in a patient at risk of hyperstimulation? Should we cryopreserve poor prognosis embryos thereby risking that the patient have to go through numerous FER cycles in vain? In many situations there simply is no standard answer to these types of questions and the only way forward involves evaluating the individual couple, their history, their gametes and embryo and their wish and priorities. Only when including evidence based embryology and evidence based clinic will we be able to make balanced decision to the benefit of the patients. But what do we do when decisions are based on other things than clinic and embryology? Too often suboptimal or irrelevant aspects get in the way of an objective assessment and thus the best decision for the patients. This can be due to political, cultural, religious, financial or personal ethical issues. It can be due to lack of continued education both medical and biological or it can be financial considerations taking precedence over medical judgments. Would any of us accept to pay extra for the surgeon to use a sharp scalpel during surgery? The answer is of course "NO". When receiving medical treatment ourselves we – like everybody else – expect the highest professional standards when seeking cure for a health problem. In assisted reproduction we are the highest professional standard. How can we claim to make decisions with the intention to balance or optimize the chances for the patients and at the same time try to sell supplementary high cost services – often without any documented effect? Examples are numerous. With the growing praxis of fertility clinics selling these kinds of "additionals" the underlying decisions taking is no longer medical or biological but financial. And the patients have no chance to evaluate if these options are value for money. They expect us to provide expert recommendations for how to cure their problem – having a child. Unfortunately, our field of medicine may be moving in a direction that makes us less health professionals and more businessmen. Maybe the title for this talk should have been "*Finance department vs. Clinic – the balance in decision making"* because there is no "versus" between embryology and clinic.

Keywords: embryology, clinic, decision making

INVITED SESSION

SESSION 41: PATIENT SESSION – SOCIAL INFERTILITY VERSUS MEDICAL INFERTILITY

Tuesday 16 June 2015 **14:00–15:00**

O-145 Psychosocial differences between medical and social infertility

D. Guerra Diaz[1]
[1]*IVI Barcelona, Psychology, Barcelona, Spain*

In our countries (Portugal, Spain) there is little understanding of what conception by Assisted Reproduction Techniques is and even less knowledge of Gamete Donation, which can make the experience even more difficult for prospective parents.

Before and during pregnancy, patients have various concerns and fears regarding the personal and genetic health of the donor and the perception of family and friends and what to tell them.

The role of the mental health professional in counselling prospective donor gamete parents is to maintain a neutral stance with patients in order to facilitate their exploration of the pros and cons of an action, rather than giving direct advice or recommendations. With this in mind, an examination of the factors involved needs to be done to clear up recommendations.

All potential gamete recipients (sperm, eggs or both) who undergo first donation treatment at our centres completed a questionnaire regarding their emotional state, fears and opinions on the release of information about the manner of the conception, whether to others (peers, family etc..) and / or their children. All patients in the sample group received a booklet with frequently asked questions and some educational material along with the initial questionnaire.

The aim of this study was to examine Spanish potential gamete recipients' emotional state and attitudes towards the treatment, and their intentions to disclose. It was also intended to investigate differences between males and females and between couples and single or lesbian women.

Differences between single or lesbian couples and heterosexual couples will be explained, in order to enhance the understanding of factors that contribute to learn how counselling should benefit these patients.

This qualitative study highlights the factors that influence the feelings and decisions of patients undergoing anonymous gamete donation.

It also underscores the scope for the desirable modification of patients' emotional states, anxieties and plans regarding disclosure by use of educational materials and psychological counselling intervention.

The findings have implications in relation to the use of pre-treatment counselling and raise a number of issues which merit further investigation.

O-146 Are there other choices? Attitudes towards social freezing, gamete donation and surrogacy in young adults in reproductive age

A. Galhardo[1], N. Carolino[2], M. Moura-Ramos[3]
[1]*Instituto Superior Miguel Torga and CINEICC - Faculty of Psychology and Educational Sciences of the University of Coimbra, Psychology, Coimbra, Portugal*
[2]*Instituto Superior Miguel Torga, Psychology, Coimbra, Portugal*
[3]*CINEICC - Faculty of Psychology and Educational Sciences of the University of Coimbra, Psychology, Coimbra, Portugal*

Study question: What do childless young adults in reproductive age think about gamete donation, surrogacy and social freezing?
Summary answer: Participants show positive attitudes towards the use of gamete donation and surrogacy, not only regarding significant others' use but also regarding their own.
What is known already: Delaying childbirth is becoming increasingly common, particularly among higher educated women. Due to age-related fertility decline this has significant health and fertility implications. Moreover, research has highlighted a lack of fertility awareness in general population. Young adults tend to overestimate the probability of achieving spontaneous pregnancy as well as IVF-pregnancy rates. Social and legal acceptability of third-party reproduction diverges among countries. In Portugal, gamete donation is allowed within the regulatory framework but surrogacy is not.
Study design, size, duration: Cross-sectional study. Data were collected between February and April of 2015.
Participants/materials, setting, methods: A total of 480 childless, individuals between the ages of 18 and 40 years old completed an online questionnaire specifically developed for this study.
Main results and the role of chance: According to our results, 48,6% assume they would consider donating gametes and about 80% agree that if they were unable to get pregnant using their own gametes, recurring to gamete donation would make them happy by helping them achieving parenthood. About 83,7% also indicated that they would support or highly support friends decision of recurring to gametes donation. A total of 32,8% would consider the possibility of using surrogacy if all other possibilities were to be excluded. Results also showed that in case participants knew that they would have fertility problems in the future, they were most likely to freeze their own gametes for use in the future.
Limitations, reasons for caution: The online format and recruitment methods (snow ball sampling) may limit the generalizability of the findings.
Wider implications of the findings: Men and women in the current study indicated willingness to consider the use of third third-party reproduction treatments. Even in a legal framework that does not consent surrogacy, they would consider this possibility, maybe through cross-border reproductive care. They also express their willingness to freeze their gametes in order to prevent eventual fertility problems in the future.
Study funding/competing interest(s): There is no conflict of interests.
Trial registration number: The study was not a trial.

O-147 Missing the fertility train? Italian lifestyle, social structure, economy and how the country that loves kids is making it difficult to have them

K. Steckley[1]
[1]*Steckley Koren International PR, International Communications, Trieste, Italy*

This qualitative analysis of the fertility issue in Italy explores the personal side of infertility and how specific socio-economic factors contribute to the larger context of what has now come to be referred to as Social Infertility. Informal interviews with individuals and couples going through, or who have recently completed treatment highlight the obstacles and challenges they face in their quest for having a family. Not surprisingly, besides the often talked about decision to "put career before family," those interviewed cited the added stress of uncertainty resulting from an ongoing financial crisis which has produced high levels of unemployment as a significant factor in postponing family plans. This uneasy feeling about the future manifests itself as a source of anxiety and affects larger life decisions like whether and when to leave the family home. In this way, Italy, which has long been considered an idyllic environment for children to grow up with a strong sense of family, has become instead an increasingly difficult place in terms of meeting the needs of young people which allow them to become independent adults with promising futures and family possibilities. In other words, results indicate that the overall country situation is itself contributing to an increasing wave of Social Infertility.

Other factors included specifically:

1. An increase in educational expectations (staying in school longer than in the past).
2. The Desire to have "all ducks in a row" which translates to staying in the family home until able to buy a home of one's own with or without a partner.
3. Extended financial dependence on parents.
4. prolonged transition to adulthood/independence due to family dynamics.
5. Economic uncertainty as financial crisis continues to adversely affect Italian families.
6. Unemployment rates highest in 20–40 age range.
7. decrease in the number of permanent work contracts, especially for women.
8. lower salaries and little job security.

O-148 The late lessons of delayed motherhood – from a patient's perspective

I. Popova[1]
[1]*Zachatie Association, Member of Fertility Europe, Sofia, Bulgaria*

When does social infertility turn into medical infertility? Is age related inability to conceive still infertility?

Is media coverage of advanced-age celebrity moms sending a wrong message to the women?

The personal story of a woman who postponed her pregnancy till her late thirties for social reasons reveals the typical path of turning the social infertility into a medical condition. There are some things in life that just can't be postponed. Sharing patient's experience with delayed motherhood, the presentation is trying to find the reasons why so many women misread the signs of the biological clock.

INVITED SESSION

SESSION 42: PARAMEDICAL INVITED SESSION: LABORATORY

Tuesday 16 June 2015 **14:00–15:00**

O-149 Molecular networks of embryo-endometrium crosstalk during implantation

S. Altmäe[1], A. Salumets[1]
[1]*Competence Centre of Health Technologies, University of Tartu, Tartu, Estonia*

A prerequisite for successful embryo implantation is the adequate preparation of receptive endometrium and the establishment and maintenance of a viable embryo. The endometrium is receptive to blastocyst implantation only during a spatially and temporally restricted period in the secretory phase of the menstrual cycle, known as 'window of implantation'. During this window, ovarian estrogen and progesterone induce the endometrial cells to proliferate, differentiate, and secrete molecules that influence trophoblast development. Meanwhile, the presence of an embryo in the uterus triggers specific molecular and cellular responses within the endometrium. The success of embryonic implantation further relies upon a two-way dialogue between the blastocyst and the endometrium, which involves cell-cell and cell-extracellular matrix interactions, mediated by integrins, matrix-degrading enzymes and their inhibitors, a variety of growth factors and cytokines, and their receptors and modulator proteins. Disturbances in this bidirectional crosstalk are believed to represent a major reason why over 60% of all pregnancies are terminated at the end of the periimplantation period. As it is ethically and practically extremely difficult to study implantation process in humans *in vivo*, many studies have been performed on animal models in order to improve the understanding of the molecular mechanisms involved in embryo-maternal crosstalk. Animal models do provide important clues to the processes regulating implantation, nevertheless the results cannot always be extrapolated to

humans. With the development of 'omics' technologies, numerous transcriptome studies of the human endometrium have revealed hundreds of simultaneously up- and down-regulated genes that play a role in endometrial receptivity. Information concerning the molecular basis of human preimplantation development is steadily growing. Several molecules and molecular pathways have been found to have a role in the endometrium and/or in the embryo at the time of implantation, nevertheless the molecular basis of the reciprocal embryo-endometrium interactions still remains largely unknown. The novel findings and approaches to investigate the embryo-endometrium crosstalk in humans will be discussed.
Keywords: implantation, endometrial receptivity, embryo-endometrium interactions

O-150 Maternal metabolic disorders, oocyte quality and longterm offspring health

K. H. Moley[1]
[1]*Washington University School of Medicine, OB/GYN, St Louis, U.S.A.*

Obesity currently affects over one-third of reproductive-age women in the United States leading to overall health and metabolic disorders, including reproductive function. Obese women experience subfertility and infertility at greater rates but more importantly, when they do get pregnant, their offspring suffer significant health consequences. Offspring of obese women are more likely than those born to normal-weight women to be obese at one year of age; to have metabolic syndrome, hypertension, and liver disease as young children; and to experience developmental delay, intellectual disabilities, and autism spectrum disorder. Given the severity and intractability of the obesity epidemic, we must identify effective means of intervention to prevent these detrimental effects of maternal obesity; this requires determination of the underlying mechanisms. In this presentation, using a mouse diet-induced obesity model, I will discuss the rationale for attributing these offspring abnormalities to the maternal oocyte, specifically due to a metabolic aberration originating in the oocyte mitochondria. I will also present data to suggest that this process is not reversible by dietary changes or exercise in the mothers. Finally, I will introduce possible mechanisms to explain the intergenerational transfer of these maternal metabolic abnormalities to the offspring.
Keywords: obesity, developmental programming, spindle abnormalities, metabolism, oocyte

SELECTED ORAL COMMUNICATIONS

SESSION 43: OPTIMIZING BLASTOCYST CRYOPRESERVATION

Tuesday 16 June 2015 **15:15–16:30**

O-151 Vitrification of single blastocyst on day 5 or day 6 of development using the Rapid-I closed system: clinical outcome of 327 cycles

R. Sciorio[1], A. Kopakaki[1], L. Pastorelli[1], L. Kelly[1], K. J. Thong[1], S. J. Pickering[1]
[1]*EFREC, RIE, Edinburgh Scotland, United Kingdom*

Study question: To investigate the utility of the Rapid-I closed system for vitrification of blastocyst on day 5 and day 6 of development and to assess the implantation and pregnancy rate following single blastocyst transfer (SBT) of warmed day 5/day 6 blastocysts.
Summary answer: High survival rates after warming were achieved for both day 5 and day 6 blastocyst vitrified using the Rapid-I closed device. Similar pregnancy and implantation rate were achieved as those following SBT in fresh cycles. There was no significant difference in outcome following SBT of day 5 vs day 6 vitrified blastocyst.
What is known already: Vitrification is a highly efficient technique for the cryopreservation of human blastocysts, but there are a large number of commercial devices available, many of which allow contact between specimen and liquid nitrogen, thereby increasing the risk of cross contamination. This study aims to test the utility of the Rapid-I closed system for vitrification on day 5 and day 6, as well as assess the role of SBT in reducing multiple pregnancies.
Study design, size, duration: A two year retrospective study of frozen single blastocyst transfer (SBT) was carried out. The survival, pregnancy and implantation rate was compared for blastocysts vitrified on day 5/day 6 in 327 frozen SBT cycles. Miscarriage and multiple pregnancy rate was also compared between the two groups
Participants/materials, setting, methods: Embryo were cultured in sequential medium (Vitrolife G series) in low oxygen atmosphere. All good quality blastocyst were vitrified on day 5 or day 6 using Irvine Vitrification medium and Rapid-I device (Vitrolife). After warming blastocysts were cultured in G2 medium (Vitrolife) supplemented with 20% HSA for 2 h before the transfer.
Main results and the role of chance: The overall survival rate of vitrified blastocyst was 90.2% (295/327) and there was no significant difference in survival between the two groups: 89.9% (197/219) and 90.7% (98/108) respectively. 295 surviving blastocysts were transferred in 295 patients (all SBT). The implantation rate (fetal sac: IPR) and clinical pregnancy rate (fetal heart at 7 weeks: CPR) were 49.8% (147/295) and 39.0% (115/295) respectively. A higher IPR and CPR were achieved following transfer of day 5 vs day 6 blastocysts : IPR 52.3% (103/197) vs 44.9% (44/98) day 5/day 6 respectively and CPR 40.1% (79/197) vs 36.7% (36/98) day 5/day 6. Miscarriage rate were similar in two groups: 8.6% (17/197) on day 5 and 7.1% (7/98) on day 6. These differences were not statistically significant. Multiple pregnancy rate was 0.6% (2/295), both in day 6 group.
Limitations, reason for caution: Fewer Blastocysts were frozen on day 6 so the group sizes are not equal and further data is required to corroborate the results. In addition live birth rates should also be investigated to see if there is a difference in final outcome between the groups.
Wider implications of the findings: This study shows that vitrification using a closed system (Rapid-I) followed by a single blastocyst transfer can be considered an effective and practical method for cryopreservation of human blastocyst and may be a beneficial approach to reduce multiple pregnancies in ART. Embryos reaching the blastocyst stage on day 6 could be considered developmentally retarded and yet a reasonable pregnancy rate was achieved following transfer, demonstrating their clinical utility. Further studies are required to confirm this data.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Funding by Edinburgh Reproductive Endocrine Centre, RIE, Edinburgh
Trial registration number: NA.
Keywords: Blastocyst Vitrification, Closed System, Multiple Pregnancy Rate, Single Blastocyst Transfer

O-152 Seeking the optimal point for the vitrification and warming of blastocysts

Y. Panagiotidis[1], E. Kasapi[1], M. Goudakou[1], A. Papatheodorou[2,3], P. Vanderzwalmen[1], N. Prapas[1], Y. Prapas[1]
[1]*Iakentro Fertility Centre, IVF Laboratory, Thessaloniki, Greece*
[2]*Centre Hospitalier Inter Regional Cavell, IVF unit, Braine l'alleud, Belgium*
[3]*IVF Centers Prof. Zech, Bregenz, Austria*

Study question: In which degree do pregnancy outcomes of warming cycles are affected by the expansion stage of the blastocysts before vitrification?
Does warming point before embryo transfer affects pregnancy outcomes? Increasing culture duration after warming, does it improve implantation potential for certain embryos like younger blastocysts and morulae?
Summary answer: A linear increase of pregnancy outcomes was observed, between day 5 morulae and expanded blastocysts, followed by a decline for hatching and fully hatched vitrified blastocysts.
On the other hand, increasing the duration of post warming culture was only beneficial for morulae and young blastocysts, while the opposite was observed for the more expanded blastocysts.
What is known already: It is considered that the efficiency of vitrification may depend on the expansion of the blastocyst, with better survival in morulae or early blastocyst stages compared to full or expanded blastocysts, while the later, upon survival, demonstrate higher implantation probabilities. On the other hand, although supported with few published data, vitrification of fully hatched blastocysts is not a preferred situation. The importance of post warming culture duration has not been widely discussed. A duration of 3–4 h is generally adopted.
Study design, size, duration: A retrospective, observational study, based on 1291 vitrification/warming cycles, performed from 1/1/2012 to 30/10/2014. Embryo transfers were divided into six groups according to the expansion rate of blastocysts before vitrification. The number of cases that were included was 121,199, 279, 321, 306, 65 for Group 1–6, respectively. Each group was further divided into two subgroups according to the selection of warming point; one day before (18–20 h) or the day of the embryo transfer (4 h).

Participants/materials, setting, methods: Embryos from an oocyte donation program of a private ART clinic, ranging on day 5 from the morulae to the fully hatched stage, of good to top quality, were vitrified using the FertiPro vitrification kit combined with a closed carrier system (VitriSafe), by placing a maximum of 3 similar growth embryos per straw.
Main results and the role of chance: Heading from Group 1 (morulae and early cavitating blastocysts) to Group 6, (hatched and fully hatched blastocysts), the clinical pregnancy rates were 35.2%, 40.1%, 40.9%, 44.8%, 45.2% and 37.3% for the six groups respectively. Increasing the post warming duration of culture had a positive impact for the corresponding sub group of embryos in Group 1 (38.6% vs. 29.4%) while had a negative impact for the sub groups of blastocysts in groups 2–6, where short post warming culture lead to higher clinical outcomes. Most notably, in Group 6, long versus short post warming culture duration resulted in clinical pregnancy rates of 12.5% vs. 44.1%.
Limitations, reason for caution: The number of cases included in each group was not of equal strengh. Vitrification was performed on a standard time in the morning of day 5, approximately 115 h post ICSI. Additionally the allocation of the cycles to the early warming or not was based on the work load of the clinic, the day of the week, the need for an early morning transfer and various other parameters, but in general it cannot be considered as a random process.
Wider implications of the findings: Further studies need to be conducted in the way of investigating whether cryopreservation of the embryos strictly at an advanced stage, like the expanded blastocyst, even by increasing the duration of culture for those that are delayed, can improve the clinical outcomes of vitrification/warming cycles.
Study funding/competing interest(s): Funding by hospital/clinic(s) – NA.

O-153 Highly effective vitrification of human blastocysts using hyaluronate supplemented, non-DMSO containing solutions and the validation of a modified microSecure vitrification procedure

M. C. Schiewe[1], S. Zozula[1], N. L. Nugent[1], J. B. Whitney[1], R. E. Anderson[1]
[1]*Southern California Institute for Reproductive Sciences, ART Lab, Newport Beach, CA, U.S.A.*

Study question: After the discontinuation of CBS 0.3 ml Embryo straws (containing a hydrophobic plug), in August 2014, could traditional CBS 0.3 ml semen straws with cotton/PVA plugs be effectively modified to support optimal vitrification and warming outcomes, as monitored by blastocyst survival and development?
Summary answer: MicroSecure vitirification, incorporating an inner plug seal modification, proved to be effective with no difference in vitrification outcomes observed in blastocyst recovery, survival or post-warming development compared to control straws. Overall, this simple, highly repeatable aseptic closed method will continue to provide unparalleled success in recovering embryos and sustaining viability.
What is known already: MicroSecure VTF was developed in 2008 as an inexpensive, non-commercial, FDA compliant method which optimized quality control aspects of vitrification. It is unique by offering tamperproof internalized, dual colored labeling in a ionomeric-resin straw that completely weld seals. In combination with hyaluronate containing, non-DMSO vitrification solutions, vitrification has proven to be highly effective. However, due to the competitive marketing of commercial vitirification devices, the original CBS Embryo storage straw was eliminated from the marketplace.
Study design, size, duration: Since 2012, the overall clinical effectiveness of hyaluronate (HA) supplemented, non-DMSO containing vitrification solutions (Innovative Cryo Enterprises) with or without PGS treatment (n = 531 cycles) were retrospectively evaluated by age groups (<38 yo, 38–43 yo, donor egg). Furthermore, we prospectively validated the vitrification effectiveness of our straw modification using 70 blastocysts.
Participants/materials, setting, methods: Traditional microSecure vitrification was performed until 2015, straw modifications were then implemented. Using new CBS 0.3 ml Embryo/Semen straws, an internal seal is created to maintain separation between the vitrification tips and cotton plug. In addition, 2-stainless steel ball bearings are added to the shorter 30 mm ID rods to prevent buoyancy.
Main results and the role of chance: We warmed 1341 vitrified blastocysts between 2012 to June 2014, with 1341 embryos recovered (100%) and 1316 completely survived (98.1%). Biopsied blastocysts experienced over 99.5% survival. When transferring PGS-tested euploid embyo(s), clinical pregnancy (80.5–81.4%) and live birth rates (75.9% to 81.4%) were unaffected by age group (38 yo, respectively). Conversely, age related pregnancy differences (P < 0.01) were observed in VET cycles using untested blastocysts (clinical: <38 yo–64.7%, >38 yo–50%; live birth: <38 yo–55.3%, >38 yo–33.3%), being higher than fresh ET outcomes in the older age groups. Interestingly, vitrified blastocyst cycles using donor eggs (n = 85; 60% clinical) have been less successful than fresh ET (n = 48; 92.5% clinical). In validating our modified storage straws for use in 2015, we experienced 100% recovery and 100% survival with 70 re-vitrified aneupolid blastocysts.
Limitations, reason for caution: Innovators of effective, non-commercial devices can be subject to politics, when the outstanding performance of their low cost system competes with the marketshare of another VTF device (e.g., HSV). Until we can have a comparable embryo storage straw manufactured, we'll continue to effectively adapt the new semen/embryo straws for mS-VTF.
Wider implications of the findings: Sodium hyaluronate addition to solutions is a logical improvement to increasing viscosity and cell membrane stabilization during vitrification. Furthermore, since the cellular toxicity of DMSO has been debated for decades, its effective removal seemingly improves the overall safety of the vitrification process. Finally, the ability to easily modify conventional 0.3 ml CBS straws facilitates the continued use of microSecure vitrification as an inexpensive, aseptic closed system that eliminates recovery failure while optimizes post-warming survival and viability.

O-154 Randomised study on the effect of artificial blastocyst collapsing before vitrification on their behaviour after thawing: cinematographic and morphometric analysis and comparison of transfers outcome

B. Kovacic[1], M. Taborin[1], V. Vlaisavljevic[1]
[1]*University Medical Centre Maribor, Department of Reprod. Med. & Gynecol. Endocr., Maribor, Slovenia*

Study question: What is the impact of blastocoelic fluid reduction before vitrification on blastocyst survival rate, intensity of their shrinkage after thawing, speed and progressiveness of blastocoelic re-expansion, morphology of their trophectoderm and inner-cell-masses and implantation ability in comparison with blastocysts having no intervention before vitrification?
Summary answer: Although collapsed blastocysts showed in average more intensive shrinkage and faster and more regular re-expansion after thawing in comparison with unshrunk counterparts, they had the same morphological scores at the time of transfer and after transfer resulted pregnancies in the same percentages as unshrunk blastocysts from the control group.
What is known already: Several studies reported that an artificial shrinkage of blastocysts before vitrification improves survival rate and increases clinical success of blastocyst cryopreservation programme. Most of these reports are from earlier period of today well established human blastocyst vitrification. Blastocysts can be shrunk by using different methods: microneedle or laser puncture, blastocoel aspiration or pipetting of blastocysts with tight pipettes. To date the advantage of using this method is not evidence based.
Study design, size, duration: Prospective quasi-randomised study. From April 2012 surplus blastocysts from each patient were split. Half of them were artificially shrunk before vitrification. Blastocysts for thawing were selected by alternation: once shrunk, once nontreated. The study included single transfers of thawed blastocysts (118 in study, 119 in control group) till July 2014.
Participants/materials, setting, methods: Expanded Day-5 and Day-6 blastocysts were either left intact or shrunk with laser pulse on trophectoderm. They were then equilibrated for 10 min in DMSO/ethylene-glycol before vitrification in closed straws. The recovery of warmed blastocysts was recorded by time-lapse camera before transfer and the changing of their diameters was analysed.
Main results and the role of chance: Shrunk and control blastocysts survived vitrification in similar proportions (100% and 99.2%). Although the intensity of shrinkage was greater in the study group (65.3 ± 16.8 vs. 50.7 ± 15.3 μm; p < 0.001) they re-expanded faster (14.5 ± 12.5 μm/h vs. 5.5 ± 14.0 μm/h; p < 0.0001). One hour after thawing both groups had similar dimensions and

comparable morphology scores. Re-expanding blastocysts of control group reached zona faster (82.3 ± 38.9 min vs. 97.0 ± 31.2 min; $p = 0.03$), but hatching occurred more frequently in a group of shrunk blastocysts (53.4% vs. 16.9%; $p < 0.001$). The implantation rates (26.3% vs. 28.6%) did not differ between groups. Continuous monitoring of re-expansion shows curves with different patterns. Mean curves of study and control groups fit linear regressions ($Y_{study} = 9560 + 62.83*X$ vs. $Y_{control} = 12100 + 31.01*X$; $p < 0.05$) with significantly different slopes.

Limitations, reason for caution: There is a missing data about the proportion of hatching blastocysts before vitrification in both groups. Any opening in zona allows cryoprotectants to act immediately and directly on trophectoderm and theoretically more efficiently dehydrate the blastocyst. Hatching blastocysts from control group could therefore behave similarly as artificially collapsed blastocysts.

Wider implications of the findings: Our findings could not confirm previously published observations about beneficial effect of artificial collapsing before vitrification on clinical outcome. By using time-lapse photography we detected differences in thawed blastocysts behaviour during recovering *in vitro*. Many new parameters for description of blastocyst re-expansion after thawing were introduced, but none of them was predictive for implantation. Their prediction could probably increase, if blastocysts were cultured for a longer period before transfer.

Study funding/competing interest(s): Funding by national/international organization(s) – This work was supported by the Slovenian Research Foundation (P3-334-0327). All authors declare no conflict of interest.

Trial registration number: NA.

O-155 Clinical outcomes of Day-2, Day-3 and Day-5 embryos vitrified with a closed system

A. Van Langendonckt[1], G. Fasano[1], R. Antonacci[1], A. S. Vannin[1], J. Biramane[1], G. Mbongolo[1], C. Vanhelleputte[1], M. Nguyen Thi[1], A. Delbaere[2], F. Devreker[2]

[1]*Université Libre de Bruxelles- Erasme Hospital, ART laboratory Fertility Clinic, Brussels, Belgium*

[2]*Université Libre de Bruxelles- Erasme Hospital, Fertility Clinic Department of Obstetrics and Gynaecology, Brussels, Belgium*

Study question: To assess outcomes achieved after closed system vitrification of Day-2, Day-3 and Day-5 embryos and to test whether the day of embryo vitrification or the treatment for endometrial preparation has an impact on pregnancy outcomes.

Summary answer: Although survival rate were similar after warming of Day-2, Day-3 and Day-5 vitrified embryos, higher implantation and delivery rates were achieved after warmed blastocyst (Day-5) transfer. Similar implantation rates were obtained when embryos were transferred in natural cycle or after hormonal replacement treatment.

What is known already: Vitrification is an established technique to cryopreserve surplus embryos after embryo transfer and for cryopreservation because of a risk of hyperstimulation syndrome (OHSS) or impaired endometrial pattern. Closed and open vitrification devices are routinely used for this purpose. However, there have been concerns with closed vitrification devices that slower cooling rate may affect embryo developmental potential compared to open vitrification systems. Few large scale studies have evaluated the clinical outcomes after closed system vitrification.

Study design, size, duration: Retrospective observational study designed to analyze implantation and delivery rates according to the day of vitrification.

From 2008 till 2014, 4770 embryos were vitrified using a closed system. 2185 embryos were transferred (1239 Day-2, 590 Day-3 and 356 Day-5 embryos) in 1905 replacement cycles (59.8% natural and 40.2% after hormonal replacement treatment). The mean number of embryo replaced per transfer was of 1.1 and comparable between the three groups.

Participants/materials, setting, methods: Good quality surplus embryos (mean score 4.4 ± 0.6 on a 1–6 scale) were vitrified using the Irvine vitrification kit and High Security straws (CryoBiosystems) on the day of embryo transfer (Day-2, Day-3, Day-5). 5% of the embryos were obtained from donors in all three groups. After warming, embryos were cultured for 24 h before transfer in the replacement cycle.

Main results and the role of chance: Patients and cycles characteristics were similar for cleavage stage embryos and blastocysts warming cycles (mean age of the patients: 33.6 ± 5.2, 34.3 ± 5.3, day-5: 33.3 ± 5.2 years for Day-2, Day-3 and Day-5 respectively).

Embryo survival rates were similar whatever the stage of the embryo (92.1% at Day-2, 95.6% at Day-3 and 90.4% at Day-5). Implantation rates were significantly higher after transfer of warmed blastocyst (32.5%) compared to Day-2 embryos (18.2%) or Day-3 embryos (23.9%) ($P < 0.05$). Higher delivery rates were observed for Day-5 (22.7%) versus Day-2 (12.9%) and Day-3 (14.7%) vitrified embryos. Replacement of embryos in natural cycle or after hormonal treatment had no significant impact on the outcomes.

Limitations, reason for caution: This study was performed retrospectively on an unselected patient's population. However, the three groups had similar cycle characteristics, reducing potential selection bias.

Wider implications of the findings: Vitrification with a closed system allows the successful preservation of Day-2/Day-3 cleavage stages embryos and of Day-5 blastocysts and ensures high implantation rates after warming and transfer. When enough good quality embryos are available, it may be advisable to prolong culture till Day-5 and vitrify blastocysts.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Hôpital Erasme.

SESSION 44: ADVANCES IN OVARIAN STIMULATION

Tuesday 16 June 2015 **15:15–16:30**

O-156 Development of an orally active positive allosteric modulator (PAM) of follicle stimulating hormone receptor for infertility treatment in assisted reproductive technology

S. Nataraja[1], H. Yu[2], S. Palmer[3]

[1]*TocopheRx Inc, Biology, Burlington, U.S.A.*

[2]*TocopheRx Inc, Chemistry, Burlington, U.S.A.*

[3]*TocopheRx Inc, Scientific Office, Burlington, U.S.A.*

Study question: Can an orally active small molecule FSH receptor agonist or PAM (molecular weight < 650) be developed for human infertility treatment? This molecule will mimic the cellular and *in vivo* response of recFSH, with pharmaceutical properties compatible with a more convenient and safer treatment for patients undergoing controlled ovarian stimulation.

Summary answer: We have developed a novel PAM that selectively stimulates FSHR with similar estradiol production in rat and human granulosa cells as recombinant FSH. This molecule induces similar follicular development in rats as recombinant FSH, when administered orally. The molecule is undergoing preclinical safety and toxicity studies to enable clinical trials.

What is known already: Several approaches have been attempted to increase convenience and efficacy of ovarian stimulation for infertility treatments in women and men. Gonadotropins with modified glycosylation profiles to increase the half-life have been one approach that has met with moderate success, but they still have safety concerns. There have been attempts from pharmaceutical companies to develop oral FSH agonists, however none of them have been successful in demonstrating efficacy in humans sufficient for clinical use.

Study design, size, duration: The work reported here is conducted in preclinical models or in human granulosa cells obtained from discarded follicular fluid following oocyte retrieval during IVF procedure. Estradiol production in rat or human granulosa cells is measured after 24 or 48 h, respectively. Stimulation of follicular development is assessed in immature rats.

Participants/materials, setting, methods: This study was performed in a drug discovery setting. Initial selection of compounds were done by high through put screening (HTS) followed by rational drug discovery effort to identify suitable molecule for clinical development.

Main results and the role of chance: A chemical library of 750,000 compounds were screened by HTS with CHO cells expressing FSHR to measure cAMP production. Non-selective compounds were eliminated by counter screening molecules positive in HTS using CHO cells expressing, thyroid stimulating

hormone receptor (TSHR) and leutenizing hormone receptor (LHR) to identify 3 chemical series as 'hits'. Hits were further fine-tuned through extensive medicinal chemistry iteration to identify a compound (TOP00001) with similar efficacy in estradiol production as recombinant FSH in human and rat granulosa cells. TOP00001 stimulated follicular development in a dose dependent manner in immature rats upon oral administration with maximal effect at 50 mg/kg. Further profiling of the compound against 55 GPCR-ion channels, 211 kinase and 11 phosphodiesterases demonstrated the compound to be very selective to FSHR.

Limitations, reason for caution The compound is in the early phase of safety and toxicology evaluation prior to initiating GLP studies for IND filing. Safety and efficacy of the compound in humans is yet to be demonstrated.

Wider implications of the findings: Currently, a significant number of women drop out of infertility treatment following failure in OI with clomiphene due to the stress of multiple injections involved in IVF cycle. An oral therapy, like the TOP drug, would provide a more convenient treatment for all patients undergoing ovarian stimulation without compromising the efficacy. Furthermore, the convenience of this PAM is ideally suited for evaluation of efficacy in idiopathic oligospermic male patients to improve sperm production, and quality.

Study funding/competing interest(s): Funding by commercial/corporate company(ies) – TocopheRx Inc., EMD Serono.

Trial registration number: NA.

O-157 Kisspeptin-54 safely and effectively triggers oocyte maturation in women at high risk of the ovarian hyperstimulation syndrome (OHSS)

A. Abbara[1], C. N. Jayasena[1], G. Christopoulos[2], S. Narayanaswamy[1], C. Izzi-Engbeaya[1], G. M. K. Nijher[1], A. N. Comninos[1], D. Peters[1], A. Buckley[1], R. Ratnasabapathy[1], J. K. Prague[1], M. A. Ghatei[1], S. R. Bloom[1], G. H. Trew[2], W. S. Dhillo[1]

[1]*Imperial College London, Section Of Investigative Medicine, London, United Kingdom*

[2]*Imperial College NHS Trust, IVF Hammersmith, London, United Kingdom*

Study question: We have recently reported that kisspeptin-54 triggering induces high rates of oocyte maturation in women with normal ovarian reserve undergoing IVF treatment. We therefore evaluated whether kisspeptin-54 could be used to safely trigger oocyte maturation in women at high risk of ovarian hyperstimulation syndrome (OHSS).

Summary answer: We demonstrate for the first time that kisspeptin-54 can be used to safely and effectively trigger oocyte maturation in women at high risk of OHSS. Low rates of OHSS and high clinical pregnancy rates were observed using kisspeptin-54 triggering following a standard recombinant FSH/GnRH antagonist protocol.

What is known already: IVF is an effective treatment for infertility, however triggering with hCG can result in life-threatening complications such as OHSS. Kisspeptin is a recently discovered naturally occurring hormone that safely stimulates gonadotrophin release without known adverse effects. We have recently reported that kisspeptin-54 triggering induces high rates of oocyte maturation in women with normal ovarian reserve, however the safety and efficacy of kisspeptin-54 in women at high risk of OHSS has not previously been evaluated.

Study design, size, duration: This was a single-centre prospective clinical trial. Sixty women at high risk of OHSS underwent an FSH/GnRH antagonist protocol using kisspeptin-54 to trigger oocyte maturation followed by fresh embryo transfer and intensive luteal phase support for 12 weeks. Patients were randomised to kisspeptin-54 doses between 3.2 and 12.8 nmol/kg (adaptive design, $n = 5–20$ per dose).

Participants/materials, setting, methods: IVF cycles were performed at Hammersmith Hospital, London. Inclusion criteria were: age <35 years; body mass index < 30 kg/m^2; serum anti-Mullerian hormone >40 pmol/L or antral follicle count >23. The primary outcome was presence of mature (metaphase II) oocytes retrieved 36 h following kisspeptin-54 injection. All women were screened for early and late OHSS.

Main results and the role of chance: Oocyte maturation was observed in 95% (57/60) of women following kisspeptin-54 administration. Embryo formation did not occur in 3 women, and a clinical decision was made to electively freeze embryos in a further 3 women due to very high risk of OHSS prior to kisspeptin-54 trigger administration; thus 51 of 60 women had fresh embryo transfer. Biochemical and clinical pregnancy rates per transfer at all tested doses of kisspeptin-54 were 63% (32/51) and 53% (27/51), respectively. Highest pregnancy rates were observed following 9.6 nmol/kg of kisspeptin-54, which resulted in a 77% (10/13) clinical pregnancy rate per transfer. There were two cases of mild OHSS, but no cases of moderate, severe or critical OHSS, and no medical admissions or interventions for OHSS.

Limitations, reason for caution: Kisspeptin-54 can safely trigger oocyte maturation in women at high risk of OHSS achieving good clinical pregnancy rates and low rates of OHSS. Further work is required to directly compare the efficacy of kisspeptin-54 with other currently used triggers of oocyte maturation in women at high risk of OHSS.

Wider implications of the findings: We found that kisspeptin-54 safely and effectively triggers oocyte maturation in women at high of OHSS as identified by high AMH and antral follicle count on ultrasound. Good clinical pregnancy rates and no cases of moderate-severe OHSS were observed following kisspeptin-54 triggering. Kisspeptin-54 may therefore offer an entirely novel trigger for oocyte maturation during IVF treatment, especially in women at high risk of OHSS.

Study funding/competing interest(s): Funding by national/international organization(s) – Medical Research Council UK, National Institute for Health Research, Wellcome Trust. The authors have no competing interests.

Trial registration number: ClinicalTrials.gov Identifier: NCT01667406.

Keywords: kisspeptin, trigger, oocyte maturation, OHSS

O-158 The impact of high progesterone level prior to oocyte retrieval on endometrial morphology and uNK cell count in the peri-implantation period

L. Liu[1], S. Sailan[2], T. C. Li[3], N. Mariee[2], S. Laird[2], Z. N. Jiang[4], S. Y. Zhang[1]

[1]*Sir Run Run Shaw Hospital College of Medicine Zhejiang University, Reproductive Center, Hangzhou, China*

[2]*Sheffield Hallam University Sheffield England, Biomedical Research Center, Sheffield, United Kingdom*

[3]*Sheffield Teaching Hospital Sheffield England, Department of Obstetric & Gynecology, Sheffield, United Kingdom*

[4]*Sir Run Run Shaw Hospital College of Medicine Zhejiang University, Department of Pathology, Hangzhou, China*

Study question: Does high progesterone level prior to oocyte retrieval have any impact on the morphological development and uNK cell count of the endometrium in the peri-implantation period (seven days after hCG administration) in women undergoing IVF treatment?

Summary answer: High progesterone level prior to oocyte retrieval produced advancement in endometrial development as well as increased number of uNK cell count.

What is known already: High progesterone level prior to oocyte retrieval has been reported to adversely affect endometrial receptivity, resulting in reduced implantation rate. The exact molecular mechanism by which high progesterone level prior to oocyte retrieval affect endometrial development is still unclear. We were particularly interested in the impact of high progesterone on the uNK cell count because the latter has been reported to be elevated in women with recurrent miscarriage and recurrent implantation failure.

Study design, size, duration: This was a single-center, prospective cohort study carried out in a university-affiliated reproductive center between June 2013 and December 2013. Endometrial biopsy was obtained from 119 subjects

Participants/materials, setting, methods: Women undergoing IVF who did not proceed to have fresh embryo transfer were included. All subjects had blood sample taken for estrogen and progesterone measurement on the day of hCG and the day after hCG administration. Endometrial sample was obtained 7 days after hCG administration for histological dating and uNK cell measurement.

Main results and the role of chance: Multiple regression analysis showed that (1) progesterone level on the day after hCG administration was the only significant variable affecting the results of histological dating. The endometrial development in women with high progesterone level was significantly ($P < 0.001$)

more advanced than that of women with normal progesterone; and (2) progesterone level on the day of hCG administration was the only significant variable affecting uNK cell count. The median (range) of uNK cell count of 9.2% (1.3–21.6%) in women with high progesterone was significantly ($P < 0.001$) higher than the median (range) of uNK cell count of 6.3% (1.4–18.7%) in women with normal progesterone.

Limitations, reason for caution: Immunohistochemistry analysis for CD56 + uNK cell counting are semi-quantitative methods. The hypothesis could be further verified by genomic study in the future.

Wider implications of the findings: The adverse effect of high progesterone prior to oocyte retrieval in IVF treatment cycle may be mediated via its action on the uNK cell.

Study funding/competing interest(s): Funding by national/international organization(s), the National Natural Science Foundation of China (No. 81270657), the Major Science and Technology Projects of Zhejiang (No. 2011C13037) and the Natural Science Program of Zhejiang (No. Y14H040012).

O-159 Pharmacogenetic study of CYP19 in polycystic ovary syndrome patients undergo intrauterine insemination cycles

S. Ghazisaeidi[1], A. Akhlaghi[2], J. Ahmadi[3], M. Khosravifar[1], M. Sadeghi[3], M. Shiva[3], M. Shahhoseini[1], P. Afsharian[1]

[1]*Royan Institute for Reproductive Biomedicine ACECR, Department of Genetics at Reproductive Biomedicine Research Center, Tehran, Iran*

[2]*Royan Institute for Reproductive Biomedicine ACECR, Department of Epidemiology at Reproductive Biomedicine Research Center, Tehran, Iran*

[3]*Royan Institute for Reproductive Biomedicine ACECR, Department of Endocrinology and Female Infertility at Reproductive Biomedicine Research Center, Tehran, Iran*

Study question: Are polycystic ovary syndrome (PCOS) patients with different *CYP19* genotypes respond differentially to ovulation induction drugs such as Clomiphene Citrate (CC) or Letrozole compare to control group?

Summary answer: PCOS patients with AA genotypes (rs2414096) in intron 2 were poor responders to ovulation induction treatment. Although CC is the first line treatment, we demonstrated that Letrozole was more effective than CC in PCOS patients.

What is known already: Aromatase (encoded by *CYP19)* is a member of cytochrome P450 family. The role of aromatase is estrogen biosynthesis. A considerable amount of literature has been published on *CYP19* polymorphisms but none of them were about pharmacogenetic aspects of it. Previous studies have reported common polymorphisms of *CYP19* in PCOS patients. Base on literature three polymorphisms were nominated including (rs2414096 located in Intron2, rs700519 in Exon 7, TTTA repeat and TCT insertion on intron 4).

Study design, size, duration: One hundred and forty two young intrauterine-insemination (IUI) candidates (61 PCOS & 81 patients without ovulatory problem) referred to Royan institute during 2012–2014, were selected for this case-control study. PCOS patients were selected as a Definition in Rotterdam consensus. Both groups received CC or Letrozole plus gonadotropins for ovulation induction.

Participants/materials, setting, methods: DNA was extracted from blood; exon 7, Intron2, Intron4 and promoter PII of *CYP19* were amplified via PCR. Restriction fragment length polymorphism (RFLP) and sequencing was performed to investigate polymorphisms. Antral follicles were monitored by ultra-sonography and realtime PCR was perfomed to investigate gene expression in granulosa cells of patients.

Main results and the role of chance: Our study revealed no correlation between rs700519 (exon7), and average number of follicle >18 mm ($p = 0.9$), there were also no significant difference between TTTA repeats or TCT insertion (located in intron 4) and drug response ($p = 0.4$ & 0.2). No variation in PII region has been found. Average follicle count per cycle in cases with GG, GA, AA genotype in rs2414096 (intron 2), was 1.79, 1.6 and 1.04, respectively that represents AA genotype as the poor responders to drug. Multi variant analysis demonstrated that although PCOS patients bearing AA genotype were poor responders to both CC and letrozole, however they respond better to letrozole ($p = 0.008$) than CC. We also demonstrated that *CYP19* in PCOS paitents has a significantly lower gene expression compare to control group ($p = 01$).

Limitations, reason for caution: The results need to be confirmed by raising the number of IUI patients and functional analysis.

Wider implications of the findings: For the first time our study showed the probable role of aromatase gene in PCOS from personalized medicine view. Although sample size was 142, however they were distributed in two groups homogenously. Groups were matched by age ($p = 0.16$) and CC as the first line treatment was not superior to Letrozole in drug response ($p = 0.14$). It seems rs2414096 (AA) can be a proper candidate for more research in field of personalized medicine.

Study funding/competing interest(s): Funding by national/international organization(s) – This work was supported by a grant from the Royan institute, Reproductive biomedicine group, Tehran, Iran [91000262].

Trial registration number: There is no trial.

O-160 Fertility outcomes in women with hypopituitarism who undergo ovulation induction: a new study of 17 women

O. P. O'Donovan[1], M. C. Davies[1], G. S. Conway[1]

[1]*University College London Hospital, Reproductive Medicine Unit, LONDON, United Kingdom*

Study question: What are the fertility outcomes of women with hypopituitarism (HP) who undergo ovulation induction (OI)?

Summary answer: Reasonable OI rates and pregnancy rates can be obtained in patients with HP. However, high miscarriage rates mean that the live birth rate is significantly lower. Assuming no other contraindications, it is reasonable to consider vaginal delivery in these women who are likely to deliver normal weight babies at term.

What is known already: Studies in our unit have published poor outcome both in terms of pregnancy rates and pregnancy outcome (Hall, 2006; Overton, 2002). de Boer et al. also reported poor pregnancy outcomes in 13 women with growth hormone deficiency (DeBoer, 1997). These studies are still the only ones concerning the outcomes of ovulation induction in this group of patients. In addition, literature search has found a high level of obstetric complications in HP patients (Kübler, 2009).

Study design, size, duration: A local database was used to identify 17 women with HP not included in our previous study who underwent 70 cycles of OI at University College London Hospitals. This included patients between 1998 and 2013. Their notes were retrospectively reviewed along with audit information inputted contemporaneously into the the database.

Participants/materials, setting, methods: 17 hypopituitary patients treated with OI using human menopausal gonadotrophin in The Reproductive Medicine unit at University College London Hospital. Their notes were retrospectively reviewed along with audit information inputted contemporaneously into the database. The data was inputted onto a data collection tool and analysed.

Main results and the role of chance: Of 70 cycles 72% were ovulatory, 29% resulted in pregnancy and 16% in live birth. Ovulation was achieved in 82% of patients, 65% conceived and 56% had a live birth. There was only one multiple pregnancy; a triplet pregnancy which was selectively reduced to a twin pregnancy and resulted in a twin live birth. There were 7 miscarriages, 1 ectopic pregnancy and 1 termination for trisomy. 2 of the live births were by vaginal delivery, the rest by caesarean section, of which 7 (78%) were elective with the reason given in all being their HP. All the babies were born at term, with an average birth weight of 3.66 kg. Due to the rarity of the disease the study sample was small.

Limitations, reason for caution: Due to the rarity of the disease the study sample was small. The study is retrospective and is therefore potentially subject to bias and loss or absence of data. Caution should be taken as the results differ from a similar sized study published previously by our unit.

Wider implications of the findings: We hope that this study will go some way in helping to guide clinicians and patients in choosing the correct form of assisted conception for this rare group of patients. The findings will help manage expectations of treatment success and pregnancy outcome. The presence of successful vaginal births in this group is relatively novel and opens the door to

consideration of this mode of delivery. The findings suggest several ideas for possible further research.
Study funding/competing interest(s): Funding by hospital/clinic(s) – University College London Hospital.
Trial registration number: NA.

SESSION 45: FOR BETTER IVF RESULTS

Tuesday 16 June 2015 **15:15–16:30**

O-161 Mechanical stimulation of the endometrial lining to improve subsequent IVF cycle outcome: an analysis of 7 years of experience

D. Levin[1], A. Cohen[2], L. Barzilay[2], B. Almog[2]
[1]*Kaplan Medical Center, IVF Unit OB-GYN Devision, Rehovot, Israel*
[2]*Sourasky Medical Center, Racine IVF Unit OB-GYN Devision, Tel Aviv, Israel*

Study question: To assess the effect of mechanical endometrial stimulation (MES) on IVF treatment outcome in unselected infertility patients.
Summary answer: MES prior to-IVF did not result in improved clinical pregnancy, ongoing pregnancy, or implantation rates. Moreover, stratification of women according to repeated IVF cycles had no impact on treatment outcome when compared with control. Finally, in a stepwise Logistic regression analysis EMS was not associated with improved fertility outcome.
What is known already: Various randomized studies have been published on this topic. Most studies show improvement in cycle outcomes but lack power and uniformity in patient selection. Meta-analysis and systematic reviews have shown benefit from this procedure but the quality of studies included and the uniformity of treatment protocol have been criticized. Lately few larger prospective randomized studies have shown no improvement in subsequent cycle outcome after performing MES compared with controls.
Study design, size, duration: Retrospective matched case control study. Analyzing patients undergoing fresh IVF cycles at a tertiary center between January 2006 and December 2012.The study and control groups consisted of 238 patient cycles in each group. Study patients received MES in a natural cycle preceding the IVF cycle analyzed controls did not.
Participants/materials, setting, methods: Study patients were compared to controls on a 1 to 1 ratio. Patients were matched based on age, number of previous IVF attempts and number of embryos transferred. Only first time MES patients were included in the study group. Only one cycle was analyzed per patient in the control group.
Main results and the role of chance: Comparison of baseline and cycle characteristics showed no difference in: age (32.6 ± 4.5 vs.32.6 ± 4.5, $p = 0.11$, matched), number of previous cycles (0.96 ± 1.6 vs.0.96 ± 1.96, $p = 0.9$, matched), number of oocytes collected (8.7 ± 4.5 vs.8.13 ± 5.03, $p = 0.8$), estradiol level on hCG day (5027.9 ± 2904 vs. 4960 ± 2797 pMol/L, $p = 0.69$), number of embryos transferred (1.3 ± 0.46 vs. 1.29 ± 0.46,$p = 0.8$, matched) and quality of embryos transferred (1.21 ± 0.91 vs.1.13 ± 0.87, $p = 0.13$) in the study and controls respectively.
Clinical and ongoing pregnancy rates were 34.03% and 40.33% ($P = 0.18$) and 18.48% and 28.99% ($P = 0.33$) for the study and control group respectively.Implantation rates were respectively similar (28.06% vs. 30.08%, $p = 0.8$). Logistic regression performed to assess the weight of influence of various variables on pregnancy rates found no significant association between EMS and pregnancy rate.
Limitations, reason for caution: This is a retrospective analysis and as such harbors various limitations. The study and control groups are composed of un-selected infertility patients. Even though we found no improvement in outcomes when results were analyzed after stratification to number of previous IVF attempts, the number of patients in t in each subgroup of previous cycles are not sufficient to reach definite conclusions.
Wider implications of the findings: MES in un-selected sub fertile population has no advantage in improving IVF outcome, thus, it should not be used routinely as a means to improve fertility in un-selected women during IVF treatments. Further prospective studies are warranted to evaluate possible benefits in different subsets of patients such as high order implantation failures.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Kaplan Medical Center (internal funding).
Trial registration number: Retrospective analysis of patients charts in a tertiary IVF referral center. No registration was required.
Keywords: IVF, outcome, biopsy, endometrium

O-162 "I will use my own": until what age?

M. Devesa[1], R. Tur[1], F. Martínez[1], M. Parriego[1], M. Solé[1], I. Rodríguez[1], B. Coroleu[1], P. N. Barri[1]
[1]*Hospital Universitario Quirón-Dexeus, Departamento de Obstetricia Ginecología y Medicina de la Reproducción, Barcelona, Spain*

Study question: In women ≥38 years, what is the real efficiency of an IVF cycle plus the frozen embryo transfer (FET) resulting from the fresh cycle? What is the expected cumulative live-birth rate (CLBR) according to women's age and the number of oocytes retrieved?
Summary answer: CLBR significantly decreased with increasing age (23.6% in 38–39 years, 1.3% in ≥44 years). CLBR significantly rose with increasing oocyte yield. In women 38–39 years 5 oocytes provided a 20% CLBR, in ≥44 years CLBR of 3% was never reached (regardless of oocyte yield) and thus IVF with their oocytes should be discouraged.
What is known already: IVF is increasingly applied to advanced-aged women (in Spain >60% of IVF cycles are in ≥35 years). Live birth rates (LBR) decrease exponentially after 37 years due to diminished ovarian reserve and oocyte quality but little is known concerning CLBR in advanced-aged women.
The possibility of predicting the CLBR according to patients' age and number of oocytes retrieved is of great interest in order to counsel advanced-aged women willing to do IVF with their oocytes.
Study design, size, duration: Retrospective study carried out in a University-affiliated fertility clinic from 2000 to 2012, including 4195 women and 5841 IVF cycles.
Four age groups are distinguished: Group 1 (G1): 38–39 years; Group 2 (G2): 40–41 years; Group 3 (G3): 42–43 years; Group 4 (G4): ≥44 years.
Participants/materials, setting, methods: 4195 women ≥38 years underwent 5841 cycles (G1 = 2119; G2 = 1883; G3 = 1159; G4 = 680 cycles).
Fresh, frozen and cumulative live-birth rates are analyzed for each group. χ^2 and ANOVA tests were used for comparisons. CLBR is analyzed according to age and oocyte yield (Generalized Additive Model, software R).
Main results and the role of chance: Fresh LBR significantly decreased with increasing age (G1 = 20.3%; G2 = 13.2%; G3 = 6.1%; G4 = 1.2%).
The embryo cryopreservation rate and the number of embryos frozen significantly decreased with increasing age. 1384 frozen cycles were performed and LBR decreased as age increased ($p < 0.001$). Cryopreservation significantly increased LBR in the fresh cycle (compared to cycles that did not cryopreserve) but the extra benefit of the frozen cycles was limited.
CLBR were: G1 = 23.6%; G2 = 15.6%; G3 = 6.6%, G4 = 1.3% ($p < 0.001$).
GAM model revealed significantly higher CLBR with increasing number of oocytes. For a given number of oocytes, differences of CLBR among groups were significant (12 oocytes: 36% in G1 and 2% in G4). Irrespective of the number of oocytes, G4 did not reach 3% of CLBR.
Limitations, reason for caution: Our results are limited by the retrospective nature of the study.
Wider implications of the findings: This is the largest study analyzing CLBR (fresh cycle + subsequent FET) in women ≥38 years. Embryo cryopreservation significantly increased LBR in fresh cycles but added limited benefit after frozen cycles.
Women of ≥44 years should be advised against doing an IVF with their own oocytes. Women in the other age groups should be counselled regarding CLBR according to their age and oocyte yield. Being able to predict ovarian response in advance is of crucial interest.
Study funding/competing interest(s): Funding by hospital/clinic(s) – This study was performed under the auspices of Cátedra d'Investigació en Obstetricia i Ginecología of the Department of Obstetrics and Gynecology, Hospital Universitario Quirón Dexeus, Universitat Autónoma de Barcelona.
Trial registration number: NA.

O-163 Increased pregnancy rates following luteal GnRH agonist addition in natural thawed cleavage-stage embryo transfer cycles: a prospective, randomized, placebo-controlled study

I. Ben-Ami[1], Y. S. Gidoni[1], A. Raziel[1], Y. Barkat[1], D. Strassburger[1], O. Bern[1], D. Komarovsky[1], E. Kasterstein[1], B. Maslansky[1], D. Hadari[1], R. Ron-El[1]
[1]*Assaf Harofeh Medical Center Zerifin Israel affiliated to the Sackler Faculty of Medicine Tel Aviv University Israel., IVF and Infertility Unit, Tel-Aviv, Israel*

Study question: Does the addition of a single luteal GnRH agonist administration in natural thawed cleavage-stage embryo transfer cycles (NC-FET) influence pregnancy rates?
Summary answer: Luteal-phase GnRH agonist administration significantly increased pregnancy rates in NC-FET.
What is known already: In fresh IVF cycles luteal phase support is well proven to be associated with a significantly higher live birth rate. In contrast, the physiological rational of luteal phase support in NC-FET is less obvious. Indeed, the effect of such luteal phase support was examined in several studies, yielding inconsistent results.
A meta-analysis showed significantly higher clinical pregnancy rate, multiple pregnancy rate and live birth rate following GnRH agonist addition to the luteal support scheme in fresh ICSI/IVF-embryo transfer cycles. There are no data in the literature regarding the effect of GnRH agonist administration during the luteal phase in NC-FET.
Study design, size, duration: A prospective, randomized, placebo-controlled, assessor blinded study was performed including NC-FET cycles of at least two cleavage stage embryos, transferred 3 days after detection of the endogenous LH surge. All patients were treated with 4 injections of 2,500 I.U. hCG every 3 days starting on the day of ET. Patients were randomly assigned to receive a single injection of GnRH agonist 3 days following ET (triptorelin acetate 0.1 mg) or placebo (saline). NC-FET cycles performed between September 2013 and December 2014 at a university-based hospital were included for analysis.
Participants/materials, setting, methods: A total of 91 NC-FET cycles were included for analysis, of them 47 cycles were randomized to the GnRH-agonist group and 44 cycles were randomized to the placebo group. Maternal and paternal ages, maternal BMI, maternal gravity and parity, main cause of infertility, cycle rank, number and quality of embryos transferred, freezing method, maximal estradiol levels and maximal endometrial thickness were taken into account. Pregnancy rates were the primary outcome parameter.
Main results and the role of chance: The two groups did not differ in mean age, gravidity, parity, BMI, cycle number, maximal endometrial thickness and estradiol levels, number of embryo transferred per patient, freezing method and embryo quality. Administration of GnRH agonist significantly increased pregnancy rate compared to controls (57.4% versus 31.8% respectively, $P = 0.02$), clinical pregnancy rate per ET (51% versus 27.2% respectively, $P = 0.029$), and implantation rate (25.2% versus 13.6% respectively, $P = 0.036$). A multivariable logistic regression analysis showed a single significant predictor for pregnancy, namely luteal GnRH-agonist administration (OR 3.2, CI = 1.2–8.3, $P = 0.016$).
Limitations, reason for caution: The conclusions are limited by the study size, and lack of data about live births, as some of the pregnancies are still ongoing.
Wider implications of the findings: Luteal-phase GnRH agonist administration significantly enhances pregnancy rates in natural frozen-thawed cleavage-stage embryo transfer cycles, possibly by a combination of effects on the embryo, endometrium and the corpus luteum.
The beneficial effect of luteal GnRH-agonist on pregnancy rates in NC-FET cycles may imply a possible beneficial effect of luteal GnRH-agonist in other fertility treatments, such as ovulation induction, controlled ovarian hyperstimulation etc.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Assaf Harofeh Medical Center.
Trial registration number: NCT01933009.

[5]*Isala Clinics, Department of Obstetrics and Gynaecology, Zwolle, The Netherlands*
[6]*Academic Medical Center, Center for Reproductive Medicine, Amsterdam, The Netherlands*
[7]*The Robinson Institute, School of Paediatrics and Reproductive Health, Adelaide, Australia*

Study question: Is saline infusion sonography an accurate test for diagnosing unexpected intrauterine pathology before starting IVF?
Summary answer: Saline infusion sonography (SIS) has a high specificity in diagnosing intrauterine abnormalities, but sensitivity is limited.
What is known already: SIS is highly accurate in diagnosing intrauterine abnormalities in subfertile women with suspected uterine pathology, based on clinical symptoms. However, in a substantial part of asymptomatic subfertile women intrauterine abnormalities are detected at hysteroscopy. Current literature suggests that these intrauterine abnormalities might have a negative impact on IVF outcome. Screening for such abnormalities is usually done by hysteroscopy. Studies investigating the role of SIS in diagnosing unsuspected intrauterine abnormalities before starting IVF are lacking.
Study design, size, duration: Between 2011 and 2013, we performed a multicenter, prospective cohort study as part of a RCT in 5 of 22 hospitals in the Netherlands, that was positioned in a nationwide consortium for studies in women's health. Eligible were asymptomatic subfertile women with a normal transvaginal ultrasound and no history of recurrent miscarriage.
Participants/materials, setting, methods: All women underwent SIS (index test) and hysteroscopy (reference test) before starting the first IVF treatment. SIS and hysteroscopy were performed in the early follicular phase of the menstrual cycle. The hysteroscopy examiner was blinded for the SIS results. We calculated sensitivity, specificity, positive and negative predictive value (PPV and NPV).
Main results and the role of chance: In this substudy of the larger INSIGHT trial, we included 139 women, of whom 14 (10%) had intrauterine abnormalities detected at SIS. Hysteroscopy showed an abnormality in 37 (27%) of the women. Sensitivity and specificity of SIS for diagnosing intrauterine abnormalities were 0.38 (95% CI: 0.21–0.54) and 0.98 (95% CI: 0.96–1.00), respectively, resulting in positive and negative predictive values of 0.86 (95% CI: 0.67–1.04) and 0.84 (95% CI 0.87–0.91). For diagnosing endometrial polyps the sensitivity of SIS was 0.38 (95% CI: 0.20–0.64) and the specificity was 0.97 (95% CI: 0.94–1.00).
Limitations, reason for caution: In one center, for practical reasons, video recordings of the hysteroscopy procedure were assessed by an independent examiner blinded for the SIS results.
Wider implications of the findings: These results show a high false negative rate for SIS in diagnosing unsuspected intrauterine abnormalities. The clinical relevance of such small abnormalities not visualized by SIS must be questioned. SIS could possibly be an appropriate screening tool to detect more prominent abnormalities that may negatively affect pregnancy prospects. Further research is needed.
Study funding/competing interest(s): Funding by national/international organization(s) – ZonMW, the Dutch Organization for Health Research and Development.
Trial registration number: NCT01242852.

O-165 Supplementation of recombinant LH to poor responders in mid-follicular phase along with recombinant FSH results in better blastocyst formation and implantation rate in antagonist IVF cycles

R. M. Dravid[1], B. N. Chimote[2], A. N. Chimote[1], N. N. Chimote[2], N. M. Chimote[3]
[1]*Vaunshdhara Clinic & Assisted Conception Centre, Gynecology, Nagpur, India*
[2]*Vaunshdhara Clinic & Assisted Conception Centre, Embryology, Nagpur, India*

[3]*Vaunshdhara Clinic & Assisted Conception Centre, Embryology/Endocrinology, Nagpur, India*

Study question: Does addition of exogenous recombinant LH (r-LH) to an IVF/ICSI stimulation protocol with recombinant FSH (r-FSH) improve pregnancy rates in poor responders irrespective of age factor?

Summary answer: Women with poor ovarian reserve classified on the basis of their low AMH levels and antral follicle count (AFC) undergoing GnRH antagonist IVF/ICSI cycles when supplemented with recombinant LH during the late follicular phase show higher blastocyst formation, clinical pregnancy and implantation rates.

What is known already: Two of the several randomized studies using a GnRH agonist protocol have indicated a clinical benefit of r-LH supplementation in patients of advanced age (36 years or older). however, recent prospective RCTs conducted in mainly women of advanced age did not show a significant effect of LH supplementation in controlled ovarian stimulation for IVF/ICSI cycles with GnRH antagonists on pregnancy rates in patients of 35 years or older.

Study design, size, duration: In a randomized control trial (RCT) performed between 2012 and 2014, 106 poor responder women (basal serum AMH <1.2 ng/ml; AFC ≤ 6) undergoing IVF/ICSI irrespective of age, received ovarian stimulation with r-FSH (Gonal-F 150 IU/day) starting from cycle day 2 and GnRH antagonist (Cetrotide 0.25 mg/day) from stimulation day 6.

Participants/materials, setting, methods: On day 6 of stimulation, randomization was carried out such that along with GnRH antagonist (Cetrotide 0.25 mg/day) 54 women received both r-FSH (150 IU daily) and r-LH (Luveris 75 IU/day) whereas 52 women received only r-FSH (150 IU daily). 42 women in each group received day 5/6 blastocyst transfer.

Main results and the role of chance: There were no demographic or clinical differences between the two study groups. However, the r-LH supplementation group showed significantly higher blastocyst formation rate (50.0 vs. 32.53%; $p = 0.02$), top quality blastocysts (3.7 ± 0.8 vs 3.1 ± 0.6; $p = 0.0003$), clinical pregnancy rates (42.86 vs. 23.81%; $p = 0.03$) and embryo implantation rates (38.71 vs. 21.4%; $p = 0.02$) than with group receiving only r-FSH. Implantation rate was calculated as: Total number of embryo sacs × 100/ Total number of blastocysts transferred.

Limitations, reason for caution: A limitation of our study is its small number of cases. Secondly, only cycles involving day 5/6 blastocyst transfers have been taken into consideration.

Wider implications of the findings: Although Cochrane review indicates that LH supplementation has no benefit on ongoing pregnancy rates in elderly women ≥35 years of age, our study demonstrates that LH supplementation may immensely benefit poor responder patients if poor ovarian response is defined on the basis of basal serum AMH level and AFC rather than just on the basis of age. This study also indicates that proper classification of patients is required to analyze response to various drugs.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Self funded by our own IVF clinic: Vaunshdhara Clinic and assisted Conception Centre, Nagpur.

Trial registration number: NA.

Keywords: r-LH, r-FSH, antagonist, implantation, poor responder

SESSION 46: OPTIMIZING EARLY PREGNANCY MANAGEMENT

Tuesday 16 June 2015 **15:15–16:45**

O-166 Trends in ectopic pregnancy rates following assisted reproduction technologies. A 12 year nationwide analysis on 160.000 pregnancies

N. P. Polyzos[1], S. Santos-Ribeiro[1], H. Tournaye[1]

[1]*UZ Brussel, Centre for Reproductive Medicine, Brussels, Belgium*

Study question: What is the evolution of ectopic pregnancy (EP) rates following ART over time and how is this affected by the advancement of ART techniques and changes in the incidence of specific causes of infertility?

Summary answer: Ectopic pregnancy rates following ART have progressively decreased, practically halving, over a period of 12 years. This decrease may be partially due to both the progressive proportional reduction of tubal factor infertility as an indication and several optimizations of ART (such as reduction of embryos transferred and extended embryo culture).

What is known already: Ectopic pregnancy rates following ART are significantly increased compared with natural conception. Although the reasons behind this increased incidence of EP following ART are not completely understood, and several mechanisms have been proposed, no study up to date attempted to evaluate whether progress made over time in the optimization of the ART techniques and changes in the incidence of specific causes of infertility had any impact on the overall EP rate.

Study design, size, duration: Nationwide population-based analysis of anonymized data from the HFEA database including all pregnancies following ART cycles carried out in the UK between 2000 and 2012.

Participants/materials, setting, methods: Overall, data from 161.967 treatment cycles resulting in a pregnancy were included in the analysis. Among them 8852 pregnancies were derived through IUI and 153.115 pregnancies through IVF/ICSI.

Main results and the role of chance: During a period of 12 years (2000–2012) approximately 1.4% (2 244) of all pregnancies following ART were EPs. According to unadjusted analysis, EP was borderline significantly higher after IVF/ICSI (1.4%) compared with IUI (1.1%), $p = 0.043$.

Overall, EP rates decreased over time, crude odds ratio OR 0.96 per year, CI 95% 0.95–0.97 and results remained significant even after adjustment for potential confounders (aOR 0.97 per year, CI 95% 0.95–0.98).

However, analysis according the type of ART procedure demonstrated that the incidence of EP significantly decreased over time only in IVF/ICSI cycles (OR 0.96 per year, CI 95% 0.94–0.97), but not in IUI cycles (OR 0.96 per year, CI 95% 0.90–1.02).

When analysis was pertained only in pregnancies following IVF/ICSI, the major risk factor for EP was the presence of tubal infertility (aOR 2.23, CI 95%1.93–2.58), followed by the increased number of embryos transferred [(2 vs.1 embryo, aOR 2.23 CI 95% 1.10–1.48) and (3 or more vs.1 embryo transferred aOR 1.67 CI 95% 1.34–2.09)]. Finally the presence of unexplained infertility also increased the risk of EP.

On the contrary, the use of extended embryo culture to day 3 or day 5 significantly reduced the risk of EP compared with the transfer of early cleavage (day 1/2) embryos, aOR (95% CI) 0.85(0.76–0.94) and 0.73(0.63–0.84), respectively. Finally the use of ICSI compared with IVF resulted in a lower EP risk (aOR 0.78 CI 95% 0.70–0.87).

Surprisingly, and contrary to smaller previous studies, the use of exogenous ovarian stimulation or the use of frozen compared to fresh embryos had no impact on the EP rates following IVF/ICSI.

Limitations, reason for caution: Owing to the use of registry data, well established risk factors of EP such as smoking habits or even uterine surgery could not be assessed. As nationwide anti-smoking campaigns with very high success rates have been implemented in the UK over the last decade, it is highly likely that reduction in smoking prevalence would have had a substantial impact on the progressive decrease in the incidence of EP over time which we were not able to assess.

Wider implications of the findings: Our findings, for the first time, suggest that EP rates following IVF/ICSI progressively decreased over a period of 12 years. This decrease appears to be strictly associated with the reduction in the incidence of tubal factor infertility and the increased use of lower number of embryos transferred and extended embryo culture. Consequently, implementation of national programs aiming to reduce the incidence of tubal infertility, such as the National Chlamydia Screening Programme, should be further reinforced. In addition, campaigns towards the widespread introduction of single embryo transfer should be promoted since this may not only reduce the incidence of multiple pregnancies, but also the incidence of EP following IVF/ICSI.

Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s) – Vrije Universiteit Brussel(VUB)/Universitair Ziekenhuis Brussel (UZ Brussel).

Trial registration number: NA.

O-167 Subclinical hypothyroidism and live birth rate in women with unexplained recurrent miscarriage

M. M. van Dijk[1], R. Vissenberg[1], F. Dawood[2], M. Wely[1], P. H. Bisschop[3], M. Goddijn[1], R. G. Farquharson[4]
[1]*Academic Medical Centre, Reproductive Medicine, Amsterdam, The Netherlands*
[2]*Liverpool Women's Hospital, Obstetrics, Liverpool, United Kingdom*
[3]*Academic Medical Centre, Internal Medicine, Amsterdam, The Netherlands*
[4]*Liverpool Women's Hospital, Gynaecology, Liverpool, United Kingdom*

Study question: Is subclinical hypothyroidism (SCH) associated with a l ower live birth rate in women with unexplained recurrent miscarriage (RM)?

Summary answer: SCH in women with unexplained RM did not lower live birth rate. Ongoing pregnancy and miscarriage rates were not different between women with SCH compared to euthyroid women with RM.

What is known already: SCH is associated with adverse pregnancy outcomes including perinatal mortality, placental abruption and pre-eclampsia. The evidence of an association between SCH and miscarriage is controversial. Most of the published studies were cohort studies applying different TSH cut off levels. In overt hypothyroidism, low TSH is associated with miscarriage, fetal or neonatal death. The influence of SCH on live birth rate in women with RM is less well defined.

Study design, size, duration: All 1341 women were prospectively included in the database. The present study was defined retrospectively, and analyses were performed retrospectively. Primary outcome measure was live birth rate (LBR). Secondary outcome measures were ongoing pregnancy rate and miscarriage rate.

Participants/materials, setting, methods: Women with RM, 18–40 years, who visited a tertiary recurrent miscarriage clinic (Liverpool Women's Hospital) from 2000 to 2011. Women with TSH > 3.8 mU/L (95th percentile) and normal fT4 were classified as having SCH. The association between SCH and LBR was determined by logistic regression adjusted for age and previous miscarriages.

Main results and the role of chance: Of 1341 women with recurrent miscarriage, 68 (5.0%) had SCH, 1264 (94.2%) were euthyroid and 9 (0.7%) had an abnormal fT4 with a normal TSH. Baseline characteristics were comparable (age and previous live births). Previous miscarriages were lower in SCH compared to euthyroid women (3.0 vs. 3.4, $p = .03$).

The LBR was 33.8% in women with SCH and 34.1% in euthyroid women (OR 0.95, 95% CI 0.6–1.6). The ongoing pregnancy rate was 42.6% in women with SCH and 45.5% in euthyroid women (OR 0.9, 95% CI 0.5–1.5). The miscarriage rate was 22.1% in women with SCH and 18.2% in euthyroid women (OR 1.3, 95% CI 0.7–2.3). Comparable results were found when SCH was defined as TSH > 4.8 mU/L (97.5th percentile) and normal fT4.

Limitations, reason for caution: Data are prone to selection bias, since this is a cohort study. Only the most important potentially confounding variables were available. Couples had different follow-up times, therefore the actual live birth rates in both groups might be different. Missing data on outcome occurred in 36% of cases.

Wider implications of the findings: No difference in live birth rates, ongoing pregnancy and miscarriage rates were seen in women with unexplained RM with SCH compared to euthyroid women. This study supports current practice guidelines, that screening of women with RM for detecting SCH is not necessary.

Study funding/competing interest(s): Funding by University(ies) – Academical Medical Centre Amsterdam.

Trial registration number: NA.

O-168 Stress and depression at referral do not entail a lower chance of live birth/ongoing pregnancy for women with recurrent pregnancy loss

A. M. Kolte[1], L. R. Olsen[2], O. B. Christiansen[1], H. S. Nielsen[1]
[1]*Copenhagen University Hospital Rigshospitalet, Recurrent Pregnancy Loss Unit Fertility Clinic Section 4071, Copenhagen, Denmark*
[2]*Mental Health Services Capital Region of Denmark, 2 Child and Adolescent Mental Health Center, Glostrup, Denmark*

Study question: Is emotional stress or depression at referral associated with lower chance of live birth/ongoing pregnancy one year after referral to a tertiary Recurrent Pregnancy Loss (RPL) Unit?

Summary answer: High scores on stress and depression scales are not associated with a lower chance of live birth/ongoing pregnancy after 12 weeks' gestation one year after referral. Women with a live born child/ongoing pregnancy have lower scores on depression and stress scales at follow-up.

What is known already: We have recently established that high stress levels and moderate/severe depression frequently occur among women with RPL (Kolte AM et al, Human Reproduction, in press) in concordance with other studies. However, to our knowledge, this is the first longitudinal study of emotional distress and RPL.

Study design, size, duration: A prospective study of self-reported stress and depression at referral and one year after was performed from 2010 to 2014. 301 women completed an online baseline questionnaire and of these, obstetrical outcome was confirmed for 287 women (95%). 185 women completed a follow-up questionnaire.

Participants/materials, setting, methods: The study was conducted in the Danish RPL Unit. Psychological stress was evaluated by the Perceived Stress Scale (PSS) and depression by the Major Depression Inventory (MDI). We used logistic regression, paired samples T-test and independent samples T-test for comparisons.

Main results and the role of chance: Of the 287 women, 167 (58%) had a live birth in the year after referral or an ongoing pregnancy at follow-up. High scores on the PSS or the MDI at referral were not associated with a negative prognosis; OR 1.00 (95% CI 0.99; 1.05) and OR 1.00 (95% CI 0.97; 1.00), respectively. Women with a subsequent live birth/ongoing pregnancy showed a significant decrease in emotional distress from referral to follow-up. PSS scores: mean 16.94 versus 12.47, difference -4.47 (95% CI -5.94; -3.00). MDI mean: 13.59 versus 10.12, difference -3.47 (95% CI -5.95; -1.00). This was not observed for the remaining patients. PSS mean: 16.86 versus 15.49, difference -1.37 (95% CI -2.82; 0.08). MDI mean: 12.65 versus 12.92, difference 0.27 (95% CI -2.07, 2.61).

Limitations, reason for caution: Although both scales are validated and widely used, face-to-face interview data would have strengthened the conclusions. It would also have been interesting to include the women's partners in the study.

Wider implications of the findings: Feelings of guilt and self-blame are integral elements in depressive disorders and prominent among women with RPL. The results from this prospective study of emotional distress in RPL can be actively used in the care for women with RPL to assure patients that feelings of stress or depression do not lead to a poorer prognosis in the first year after referral.

Study funding/competing interest(s): Funding by hospital/clinic(s) – University Hospital Copenhagen, Rigshospitalet.

Trial registration number: NA.

O-169 Does dilatation and curettage (D&C) increase the risk of preterm birth in the subsequent pregnancy? A systematic review and meta-analysis

W. M. Ankum[1], M. Lemmers[1], M. A. C. Verschoor[1], A. B. Hooker[1], B. C. Opmeer[1], C. J. E. M. Limpens[1], J. A. F. Huirne[2], B. W. J. Mol[3]
[1]*Academic Medical Center, Department of Ob/Gyn, Amsterdam, The Netherlands*
[2]*Free University, Department of Ob/Gyn, Amsterdam, The Netherlands*
[3]*University of Adelaide, Robinson Inst Department of Ob/Gyn, Adelaide, Australia*

Study question: Does Dilatation and Curettage (D&C) for a miscarriage or induced abortion increase the risk of preterm birth in subsequent pregnancy?

Summary answer: This meta-analysis shows that D&C is associated with increased risk of subsequent preterm birth.

What is known already: D&C is a frequently used procedure in obstetrics and gynecology. The procedure is generally considered to be safe and easy to perform, but serious adverse effects, e.g., cervical tears, bleeding, infection, perforation of the uterus, bowel or bladder and Asherman syndrome, may occur.

As suggested by some, preterm birth in subsequent pregnancies might also be an adverse effect of D&C.

Study design, size, duration: We conducted a systematic review and meta-analysis of cohort and case-control studies.

Participants/materials, setting, methods: We searched OVID MEDLINE and OVID EMBASE form inception until May 2014. We selected cohort studies comparing subsequent preterm birth in women who had a D&C for miscarriage or IA and a control group, and case control studies assessing a history of D&C among women with and without D&C.

Main results and the role of chance: We included 21 studies reporting on 1,853,017 women. In women with a history of D&C, the odds ratio (OR) for preterm birth (<37 weeks) was 1.29 (95% CI 1.17; 1.42), while for very preterm birth ORs were 1.69 (95% CI 1.20; 2.38, <32 weeks) and 1.68 (95% CI 1.47; 1.92, <28 weeks). The risk remained increased for D&C when the control group was limited to women with a medically managed miscarriage or induced abortion: OR 1.19 (95% CI 1.10; 1.28). For women with a history of multiple D&Cs, the OR for preterm birth (<37 weeks) was 1.74 (95% CI 1.10; 2.76). When the analysis was limited to spontaneous preterm birth subsequent to D&C the OR was 1.44 (95% CI 1.22; 1.69).

Limitations, reason for caution: There were no randomized controlled trials comparing women with and without a history of D&C and subsequent preterm birth. Furthermore confounding influence the results since included studies were either cohort or case control studies and not all studies corrected their results for possible confounding factors.

Wider implications of the findings: This meta-analysis shows that D&C is associated with increased risk of subsequent preterm birth. Although confounding cannot be excluded, these data warrant caution in the use of D&C for miscarriage and induced abortion. This conclusion should contribute to the implementation of misoprostol as a non-invasive treatment option for both miscarriage and induced abortion.

[12]*University of Adelaide, The Robinson Research Institute, Adelaide, Australia*

Study question: What are the effects of curettage versus expectant management in women with incomplete evacuation of the uterus after misoprostol treatment for first trimester miscarriage?

Summary answer: Expectant management is effective in about 80% of cases. Surgical management (curettage) is effective in 93% of the women but has a higher risk of complications.

What is known already: Misoprostol is an inexpensive medical treatment for women with first trimester miscarriage. However, about 30% of women with a miscarriage treated with misoprostol are left with an incomplete evacuation of the uterus. Although these women are usually asymptomatic, curettage is often performed. While the effectiveness of curettage for these women is unknown, it might lead to intra-uterine adhesions and a higher risk of preterm birth in future pregnancies.

Study design, size, duration: Between June 2012 and June 2014, we performed a RCT in 27 hospitals positioned in the Dutch network for women's health research. Women with incomplete evacuation of the uterus after misoprostol for miscarriage were randomized to curettage or non-intervention. Women with a preference for a treatment were followed prospectively.

Participants/materials, setting, methods: We compared curettage (within three days after randomization) versus no intervention. Primary outcome was sonographic evidence of an empty uterus after six weeks. In case of missing sonography, uneventful clinical follow-up of 3 months was assumed to indicate an empty uterus. Complications were excessive blood loss, infection or thromboembolism.

Main results and the role of chance: We studied 259 women, of whom 59 were randomized (curettage (n = 30), expectant management (n = 29)), and 200 were treated according to their preference (curettage (n = 70), expectant management (n = 130)).

In the RCT the primary outcome occurred in 92% of women in the surgical group and 70% of women in the expectant group (RR 1.3, 95% CI 0.99–1.7). The rate of complications was 13% in the curettage group versus 9% in the expectant management group (RR 1.5, 95% CI 0.28–8.2). In the cohort the primary outcome occurred in 94% of women in the surgical group and 82% of the expectant group (RR 1.14, 95% CI 1.03–1.3), and there were more complications in the curettage group (12% versus 3%, RR 4.2, 95% CI 1.1–16).

Limitations, reason for caution: Because of strong preferences for expectant management, inclusions in the RCT were limited, thus affecting the power of the study. However, combining RCT and cohort participants resulted in sufficient power to answer the study question.

Wider implications of the findings: This study shows that in women with an incomplete evacuation of the uterus after misoprostol for miscarriage, expectant management is safe and effective. Curettage, being more effective, has a higher risk of complications. These findings might lead to a further implementation of misoprostol treatment for first trimester miscarriages.

Study funding/competing interest(s): Funding by national/international organization(s) – This study was funded by ZonMw, a Dutch organization for Health Research and Development. Project number 80-82310-97-12066.

O-171 Provision of intrauterine contraception at the time of abortion reduces subsequent abortions – first-year results of a randomized, controlled trial

M. Mentula[1], E. Pohjoranta[1], S. Suhonen[1], M. Gissler[2], O. Heikinheimo[3]

[1]*Helsinki University Central Hospital, Obstetrics and Gynaecology, Helsinki, Finland*

[2]*National Institute of Health and Welfare, Helsinki, Helsinki, Finland*

[3]*University of Helsinki, Helsinki, Helsinki, Finland*

Study question: Can the need of subsequent induced abortion be reduced already during the first year following an induced abortion by routine provision of intrauterine contraception at the time of abortion (either medical or surgical)?

Summary answer: Provision of intrauterine contraception as an integral part of abortion service is safe and effective in reducing the number of subsequent abortions by more than half already during the first year after the index abortion.

What is known already: Women requesting induced abortion are typically 20–30 years old and of high fertility. The need of subsequent abortions is high, approximately 30–40%. In cohort studies the use of long-acting reversible contraceptives (LARC), especially intrauterine devices (IUD) or levonorgesterel-releasing intrauterine system (IUS) have association with reduced risk of repeat abortion.

Study design, size, duration: In this RCT, conducted between 2010 and 2013 at Helsinki University Hospital, we compared early vs. patient-controlled IUD provision. The sample size calculation (80% power and 5% significance level) assumed a 15% risk of subsequent abortion during a five-year follow-up time and a 50% risk reduction with the study intervention.
Participants/materials, setting, methods: Altogether 756 adult women undergoing abortion during the 1st trimester were randomized. The intervention-group (n = 377) received IUD at the surgical abortion or 2–3 weeks after medical abortion. In the control group (n = 376) post-abortal contraception provision was patient-controlled. Subsequent abortions were identified from Finnish Abortion Registry and hospital records.
Main results and the role of chance: During the first year of follow-up 24 (3.2%) women requested a subsequent induced abortion according to intention-to-treat (ITT) -analysis. Kaplan-Meier analysis showed 98.4 and 95.0% cumulative proportions of women without subsequent abortion at one year among the intervention group and the control group, respectively (p = 0.012). During the first follow-up year the study intervention decreased the need of subsequent abortion [2(0.6) vs. 18 (5.0), p = 0.001; per-protocol analysis]. Early IUD provision did not induce any insertion-related complications. None of the subsequent pregnancies were conceived during IUD use.
Limitations, reason for caution: This single-center study was conducted in Helsinki responsible for 15% of all Finnish induced abortions. The power calculation was based on 5-year follow-up. However, a highly significant decrease in need of repeat abortion was evident during this one-year follow-up. In Finland all induced abortions are reliably tractable from Abortion Registry.
Wider implications of the findings: The present results have public health impact – in order to decrease the need of subsequent abortion, provision of LARC, and especially IUD/IUS for post-abortal contraception should be part of high quality abortion services.
Study funding/competing interest(s): Funding by hospital/clinic(s), Funding by national/international organization(s) – This study was supported by the Helsinki University Central Hospital Research funds and by research grants provided by Antti and Jenny Wihuri Foundation and by Yrjö Jahnsson Foundation. The City of Helsinki provided the IUSs and IUDs used.

SESSION 47: SPERM DAMAGE: A MATTER OF CONCERN?

Tuesday 16 June 2015 **15:15–16:30**

O-172 Oxidative stress in semen is not related to semen parameters and does not affect reproductive outcomes in cycles with donor oocytes

A. Pujol[1], A. Obradors[1], E. Esteo[1], B. Costilla[1], D. García[2], V. Vernaeve[1], R. Vassena[1]
[1]*Clínica EUGIN, Barcelona, Spain*
[2]*Fundació Privada EUGIN, Barcelona, Spain*

Study question: Does the level of oxidative stress detected in the ejaculate relate to semen characteristics or reproductive outcomes in assisted reproduction cycles with donor oocytes?
Summary answer: The level of oxidative stress detected in the ejaculate does not relate to either motility and proportion of normal spermatozoa, nor with the reproductive outcomes of assisted reproductive cycles carried out with the semen.
What is known already: A balance between reactive oxygen species (ROS) and antioxidants is required for efficient fertilization; an imbalance between these two factors in semen causes oxidative stress (OS). OS can harm fertilization by affecting the sperm membrane or by DNA damage. While oral treatment with antioxidant is currently being offered to patients with altered semen characteristics, the relationship between sperm OS and ART remains unclear, with conflicting data on its relationship to seminal characteristics and reproductive outcomes.
Study design, size, duration: This is a prospective cohort study, carried out in a fertility center between October 2013 and December 2014. The study was approved by the local IRB, and included 132 consecutive patients attending the clinic for IVF treatment with donated oocytes.
Participants/materials, setting, methods: Semen analysis was performed according to WHO guidelines. Ejaculate volume, concentration, motility (% of a + b forms) and morphology (% of normal spermatozoa) were measured. A colorimetric test based on nitro blue tetrazolium assay, which measures the level of O-2 in the ejaculate, was carried out within 1 h from semen collection to assess OS.
Main results and the role of chance: The OS assay classified samples into: very high (n = 2; 1.5%), high (n = 57; 43.2%), low (n = 40; 30.3%), and very low (n = 33; 25.0%). Overall values for seminal parameters were: volume (ml) = 4.2 (SD 2.1); motility (a + b%) = 47.7 (SD 18.0), and normal spermatozoa (%) = 8.2 (SD 5.1). Thirty (22.3%) of the patients did not start their IVF cycle at the time of analysis and there was 1 (0.8%) fertilization failure. Of the ninety-three cycles that reached embryo transfer, 55% evolved in biochemical, 45% in clinical, and 34% in ongoing pregnancy. We found no correlation between OS and seminal parameters, fertilization rate, or pregnancy outcomes. Additional regression analyses for pregnancy outcomes, adjusted for day of transfer and number of embryos transferred, showed no effect of OS level.
Limitations, reason for caution: This study was carried out in donation cycle and using ICSI, thus the high quality of the female gamete and the fertilization technique might have masked a partial functional damage to the sperm DNA. Caution should be exerted when extending the results to older women and classical IVF cycles.
Wider implications of the findings: The lack of relationship between sperm parameters and OS implies that prescribing antioxidant based on sperm characteristics might not be effective; reproductive results in ART with young oocyte and ICSI does not seem to be affected by OS levels in the ejaculate.
Study funding/competing interest(s): Funding by hospital/clinic(s).
Trial registration number: NA.

O-173 Assessment of the impact of oxidative stress on frozen seminal plasma in fertile and infertile men by examining the total antioxidant capacity

V. Rilcheva[1], N. Ayvazova[1], D. Martinov[1], C. V. Ivanov[2], E. Konova[3]
[1]*Clinical Institute for Reproductive Medicine, Andrology, Pleven, Bulgaria*
[2]*Institute of Biology and Immunology of Reproduction, Andrology, Sofia, Bulgaria*
[3]*Center for Reproductive Health, Medical University, Pleven, Bulgaria*

Study question: To explore the impact of oxidative stress on frozen seminal plasma in fertile and infertile men by examining the total antioxidant capacity
Summary answer: Total antioxidant capacity of the seminal plasma as measured by the luminometric assay is a reliable and simple test for the diagnosis and management of male infertility
What is known already: The most common cause of male infertility is defective spermatozoal function. It may result from testicular pathologies, genetic disorders, and exposure to drugs, toxins, or irradiations, or because of oxidative stress damage. The mechanism of action for loss of sperm function may be because of elevated levels of reactive oxygen species [ROS] beyond the available total antioxidant capacity in the semen. Low level of seminal total antioxidant capacity [TAC] has a key role in male infertility. Oxidative stress causes damage to the spermatozoa, oocyte, and embryos. Several reports relate low seminal plasma TAC levels to male infertility, as well as in embryo culture media from the oocytes, cumulus cell mass, and spermatozoa used for insemination in conventional IVF. The potential cellular sources of TAC in an intracytoplasmic sperm injection setting are the spermatozoa and the injected oocytes
Study design, size, duration: Seminal plasma from proven fertile men [n = 50] and infertile patients [n = 50] were examined for TAC level, semen paremeters as morphology, motility and concentration, and DNA integrity test.
Participants/materials, setting, methods: Infertile patients from male infertility clinic of various diagnoses and fertile mens
Interventions: Seminal plasma TAC measurement by luminometric assay using the TAC assay kit, semen analysis parameters, DNA integrity test
Main results and the role of chance: Fertile men showed higher TAC values [median and SD]: 1201 μM [SD ± 548]; compared with the infertile patients: 831 μM [SD ± 343]. The result from sperm morphology of fertile patients showed mean percentage of 4.8% [SD ± 1.68] and the percentage in infertile

group of 2.68% [SD ± 1.68]. The same group of samples, analyzed for DNA damage showed mean of DFI 10.38% [SD ± 5.17%] for fertile men and mean of DFI 17.22% [SD ± 7.22%] for infertile men

Limitations, reason for caution: No limitations

Wider implications of the findings: An oxidative stress test may accurately discriminate between fertile and infertile men and identify those with a clinical diagnosis of male-factor infertility who are likely to initiate a pregnancy if they are followed over a period of time. In addition, such a test can help select subgroups of patients with infertility in which oxidative stress is a significant factor, and those who may benefit from antioxidant supplementation. To assess seminal oxidants is concerning the inclusion of oxidative stress analysis as part of the routine diagnostic workup of an infertile male.

Study funding/competing interest(s): Funding by University(ies) – Scientific research project [no.3 -2013] of Medical University-Pleven.

Trial registration number: NA.

Keywords: ART, Semen, TAC

O-174 Fertilix, a novel antioxidant formulation designed to treat male infertility emanating from sperm oxidative DNA damage: Promising preclinical evidence from mouse models

P. Gharagozloo1, J.R. Drevet[2], A. Gutierrez-Adan[3], A. Moazamian1, A. Kocer[2], A. Calle[3], E. Pericuesta[3], J.R. Aitken[4]

[1]*CellOxess LLC, Medicinal Chemistry, Princeton, U.S.A.*

[2]*UMR6293-INSERM University of Clermont-Ferrand, GReD Lab CNRS, Clermont-Ferrand, France*

[3]*INIA University of Madrid, Animal Reproduction, Madrid, Spain*

[4]*The University of Newcastle, University Drive Callaghan, NSW 2308, Australia*

Study question: Does Fertilix, a novel antioxidant formulation designed for the male reproductive tract, reduce Sperm DNA Damage (SDD) and increase pregnancy rates in mouse models of sperm oxidative stress (SOS)?

Summary answer: Oral administration of Fertilix for a period of 2 weeks significantly reduces SDD in Glutathione Peroxidase 5 (GPX-5) knockout mice and restores pregnancy rates almost back to normal levels in mice subjected to Scrotal Heat Shock (SHS).

What is known already: Animal and human studies document the adverse effect of SDD on fertilization rate, embryo quality, miscarriage rates and the transfer of *de novo* sporadic mutations to the offspring. Semen samples of infertile men are known to be deficient in several key antioxidants relative to fertile counterparts. Antioxidants alone, or in combination, have consistently demonstrated a measure of efficacy against sperm oxidative stress or DNA damage in numerous human clinical trials.

Study design, size, duration: Fertilix efficacy was evaluated in two, well-established mouse models of SOS, SHS and GPX-5 knockout mice, each with $n = 12$, by independent laboratories. Mice were provided Fertilix in their drinking water for 2–4 weeks and compared with control groups for SDD and pregnancy rates.

Participants/materials, setting, methods: In SHS model, each male's fertility was tested by partnering with 3 females for 5 days. The percentage of pregnant females, number of vaginal plugs, resorptions per litter, and litter size were recorded. Sperm DNA oxidative damage was evaluated by immunocytochemical detection of 8-OHdG residues in GPX-5 KO mice.

Main results and the role of chance: 8-Hydroxy-deoxy Guanosine (8-OHdG) is a biomarker of DNA oxidation. The average background levels of 8-OHdG in WT mice is around 30%. This level doubles up to about 60% in transgenic mice deficient in the antioxidant enzyme GPX-5. Our results indicate that a 2 week pretreatment of GPX-5 KO mice with Fertilix provides complete protection of sperm DNA against oxidation. In mouse models of SHS, only 35% (19/54) female mice got pregnant resulting in 169 fetuses. This is in contrast to the Fertilix pretreated group where 74% (42/57) female mice got pregnant resulting in 427 fetuses. The role of chance in obtaining supporting results for the efficacy of Fertilix in both models is minimal.

Limitations, reason for caution: It was not possible to ensure that every mouse took 100% of the product for the treatment period.

Wider implications of the findings: The present situation is gravely concerning as clinical studies confirm moderate to severe SDD in about 60% of all men visiting IVF centers and about 80% of men diagnosed with idiopathic male infertility. These results, if confirmed in humans, will impact clinical fertility practice. Antioxidant supplementation will be an adjuvant therapy prior to undertaking ART procedures to improve fertilization rates, maintain a healthy pregnancy, and reduce *de novo* sporadic mutations being passed onto children.

Study funding/competing interest(s): Funding by University(ies) – The study was funded by the University of Clermont-Ferrand and the University of Madrid. The corresponding author, A.M., is an employee of CellOxess LLC, which has a commercial interest in the detection and resolution of oxidative stress. The author, *P*.G., is the Managing Director of CellOxess LLC, which has a commercial interest in the detection and resolution of oxidative stress.

Trial registration number: Not applicable. The local ethics committee authorized this study.

O-175 The influence of paternal age on reproductive outcome in Assisted Reproductive Techniques

A. M. Meijerink[1], L. Ramos[1], K. Fleischer[1], J. A. Veltman[2], J. Hendriks[3], D. D. M. Braat[1]

[1]*Radboudumc, Gynaecology & Obstetrics, Nijmegen, The Netherlands*

[2]*Radboudumc, Genetics, Nijmegen, The Netherlands*

[3]*Radboudumc, Health Evidence, Nijmegen, The Netherlands*

Study question: Does advanced paternal age affect reproductive outcome in assisted reproductive techniques (ART)?

Summary answer: No significant influence of paternal age on ongoing pregnancy rate (OPR) in ART was found in this study.

What is known already: The effect of delayed male parenthood has not been of much social or biological interest, as it has been noted that the risks are negligible compared to the maternal effect. Little is known about the influence of paternal age on the reproductive outcome after ART.

Study design, size, duration: We performed a retrospective cohort study. A total of 7051 first ART cycles between 2001 and 2013 were evaluated with regard to: age of men and women at the time of ovum pick up, *in vitro* fertilization (IVF) or intracytoplasmic sperm injection (ICSI), embryo quality and pregnancy results.

Participants/materials, setting, methods: Age effects on OPR were analyzed, using 3 age classes for males and females, based on odds ratios estimated by logistic regression. First, we analyzed the effect of paternal age on OPR by controlling for maternal age. In a second model we used interaction terms for paternal and maternal age.

Main results and the role of chance: When maternal/paternal interaction was not taken into account, we did not found a significant paternal age effect. After including interaction terms we did found significant age effect in couples with: males ≤35 and females 35–40 (OR 0.53 CI 0.39–0.73); males 35–45 and females 35–40 years (OR 0.69 CI 0.60–0.79); males >45 and females 35–40 (OR 0.75 CI 0.56–0.99); males 35–45 and females >40 (OR 0.40 CI 0.28–0.56); and males >45 and females >40 (OR 0.36 CI 0.21–0.62). Regardless female age, no evident decline in odds ratios was seen towards a decrease in OPR in ageing men. In subgroups analysis, based on treatment or number of embryos transferred, similar results were found. No paternal age effect was found in biochemical pregnancy rate and embryo quality as well.

Limitations, reason for caution: The study is limited by the lack of information on live births and other factors as indication for treatment, and time to treatment. OPR was therefore chosen as major outcome.

Wider implications of the findings: No significant influence of paternal age on OPR in ART was found in this study. As increased paternal age is associated with disturbance of spermatogenesis, increased DNA damage in sperm and late development effects such neurological disturbances, we should consider the possible increase in *de novo* mutations or epigenetic alterations affecting the offspring.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Radboud university medical center.
Trial registration number: None.

O-176 Predictive capacity of sperm DNA damage tests: A systematic review and meta-analysis

M. Cissen[1], I. Scholten[2], S. Mansell[3], S. Repping[2], J. P. de Bruin[1], B. W. Mol[4], B. C. Opmeer[5], M. van Wely[2]
[1]*Jeroen Bosch Ziekenhuis, Obstetrics and Gynaecology, 's – Hertogenbosch, The Netherlands*
[2]*Academic Medical Center, Center for Reproductive Medicine, Amsterdam, The Netherlands*
[3]*Medical Research Institute, Ninewells Hospital and Medical School, Dundee, United Kingdom*
[4]*The Robinson Institute/School of Paediatrics and Reproductive Health, University of Adelaide, Adelaide, Australia*
[5]*Academic Medical Center, Clinical Research Unit, Amsterdam, The Netherlands*

Study question: Can sperm DNA damage test predict success of assisted reproductive techniques?
Summary answer: Currently used methods to test DNA damage seem to have limited capacity to predict pregnancy rates achieved with the use of assisted reproductive techniques.
What is known already: In men with poor semen quality, sperm DNA damage has been associated with reduced fertilization rates, embryo quality and pregnancy rates, and higher rates of spontaneous miscarriage. The tests used to detect sperm DNA damage are mainly the Terminal deoxynucleotidyl transferase dUTP nick end labelling (TUNEL) assay, the Sperm Chromatin Structure Assay (SCSA), the Single Cell Gel Electrophoresis (Comet) assay, the Chromomycin A3 (CMA3) staining and the sperm chromatin dispersion (SCD) test.
Study design, size, duration: Systematic review and meta-analysis. The electronic databases Pubmed and Embase were searched from inception to December 2014, the search will be updated to April 2015 for the ESHRE congress. Studies that allowed comparison of results of sperm DNA integrity tests to pregnancy outcomes were included in couples.
Participants/materials, setting, methods: Quality assessment was performed with the QUADAS 2 checklist. Summary Receiver Operating Characteristic (sROC) curves were estimated to assess the accuracy of sperm DNA damage in the prediction of pregnancy. In case sROC analysis was not feasible, meta-analysis was done to evaluate whether mean (SD) values for the tests differed between pregnant and non-pregnant women. Analyses were stratified for IUI, IVF and ICSI.
Main results and the role of chance: Out of 504 non-duplicate studies, 31 were included in the meta-analysis. Eight studies reported on the TUNEL assay, 11 studies reported on the SCSA, five studies reported on the Comet assay, six studies reported on the CMA3 staining and four studies reported on the SCD test. The estimated sROC curve indicated a modest discriminatory capacity of the COMET assay and absence of discriminatory capacity of the TUNEL assay and SCSA in the prediction of pregnancy. For CMA3 and SCD, ROC curve analysis was not feasible. Meta-analysis for the CMA3 and SCD tests did not result in evidence of a difference in mean test result between pregnant and non-pregnant women (weighted mean difference -4.26, 95% CI -9.21 to 0.70 and -2.15, 95% CI -6.54 to 2.25, respectively).
Limitations, reason for caution: The studies included used different cut-off points to determine whether the DNA was damaged or not and results were limited by the number of available studies.
Wider implications of the findings: The currently used methods to test DNA damage in sperm do not appear to be useful for the prediction of pregnancy rates achieved with ART. In view of the increasing health care costs and to prevent over-testing these DNA damage tests should not be used as part of the standard pre-ART male assessment.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Academic Medical Center, Jeroen Bosch Hospital.
Trial registration number: NA.

SESSION 48: GENES IN MONOGENETIC DISEASE AND FERTILITY

Tuesday 16 June 2015 **15:15–16:30**

O-177 A novel preimplantation genetic diagnosis method for monogenic diseases by targeted sequencing

J. Li[1], X. D. Zhang[1], Y. W. Xu[2], S. J. Liu[1], Y. L. Huang[1], G. Vajta[3], H. F. Zhen[1], X. T. Shen[2], J. Wang[2], Y. H. Zeng[2], Y. T. Du[3], C. Q. Zhou[2]
[1]*BGI, Science&Technology, Shenzhen, China*
[2]*Sun Yat-sen University, The First Affiliated Hospital, Guangzhou, China*
[3]*BGI, Healthcare, Shenzhen, China*

Study question: Current preimplantation genetic diagnosis (PGD) methods for monogenic disease are either complex or expensive. To develop a simple, accurate and cost-effective PGD method for monogenic disease, we explored the applicability of targeted sequencing.
Summary answer: Our targeted sequencing based method is simple, accurate and cost-effective for PGD of monogenic disease. Particularly, it may be used for PGD by testing parents and embryos only.
What is known already: Current main PGD methods for monogenic disease are multiple fluorescence PCR (MF-PCR) and karyomapping. PGD by MF-PCR needs labor-intensive and time-consuming designing and optimizing for patient or disease specific test development, which is complex. Karyomapping has largely simplified PGD workflow. However, the costs of genome wide SNP arrays is high, particularly when testing of many embryos is needed. Moreover, both tests require analyzing parents together with child or other appropriate family members, besides embryos.
Study design, size, duration: Our methodology was based on haplotype linkage analysis and direct mutation detection. Disease causing genes together with thousands of polymorphic SNPs flanking each of the genes were analyzed for parents and their child. Data were generated by targeted sequencing with barcodes and analyzed by an in house-developed analysis pipeline.
Participants/materials, setting, methods: A family suffering from beta-thalassaemia major undergoing PGD was tested. Single blastomere WGA products together with genomic DNA from parents and child were subjected to targeted sequencing for PGD. Besides, a simulation analysis of PGD by testing parents and embryos using the same data set was carried out.
Main results and the role of chance: Results were provided directly by the integrated software analysis pipeline. An average of 380 informative SNPs flanking both sides of each targeted gene were detected, with an average SNP interval of 10.5 Kb. The haplotype linkage analysis and direct mutation detection results were consistent with those of the reference laboratory. All embryos carried a HBB mutation.
Multiple DNA copy number variation (CNV) and recombination in targeted area were detected and validated, which were not discovered by MF-PCR performed by the reference laboratory. In addition, simulation analysis of PGD by testing parents and embryos using the same data set in the study achieved accurate detection results of disease causing mutation, DNA CNV and recombination.
Chance plays little role in process of obtaining our results.
Limitations, reason for caution: CNV caused by inheritance of two identical haplotypes from one of the parents could not be detected by the method without quantitative analysis. Besides, for PGD by testing parents and embryos, the disease causing mutation should be possible to be detected directly and multiple embryos are available.
Wider implications of the findings: We describe here a simple, accurate and cost-effective method for PGD of monogenic disease that can be used by testing only parents and embryos. It may provide benefit to many patients requiring PGD for monogenic disease.

O-178 Types of abnormal embryos in inversion cases

A. Suhotliv[1], T. Escudero[1], L. Ribustello[1], P. Colls[1], M. Konstantinidis[2], S. Munne[3]
[1]*Reprogenetics, aCGH Team, Livingston New Jersey, U.S.A.*
[2]*Reprogenetics, Research, Livingston New Jersey, U.S.A.*
[3]*Reprogenetics, CEO, Livingston New Jersey, U.S.A.*

Study question: Does the outcome of inversion cases differ from translocation cases?
Summary answer: Our study shows differences in the proportion of abnormal embryos from inversion cases compared to those from translocation cases. These differences may point to a heightened interchromosomal effect (ICE) in inversion cases.
What is known already: Structural abnormalities are a cause of infertility as the segregation of the affected chromosomes has a greater chance of producing unbalanced gametes and affected offspring. Structural abnormalities may affect the segregation of other chromosomes not involved with the abnormality itself, also known as ICE. Most of the studied structural abnormalities are translocations. The scarcity of inversion makes its study more difficult, and as a result most of the publications are directed to single individual cases.
Study design, size, duration: This is a retrospective study involving 26 inversion carrier cycles with 127 embryos and 78 reciprocal translocation carrier cycles with 559 embryos. This study extended from cases tested between 6/5/2011 and 4/7/2014.
Participants/materials, setting, methods: Cycles from 47 centers across the USA and Canada. Embryos that underwent blastomere or blastocyst biopsies analyzed by aCGH.
Main results and the role of chance: a. 25.2% of embryos from inversion cases were normal or balanced compared to 17.9% of embryos from translocation cases, though not statistically different.
b. 29.9% of embryos from inversion cases are unbalanced compared to 57.4% of embryos from translocation cases ($p < 0.001$).
c. 33.1% of embryos from inversion cases were aneuploid for chromosomes not related to the inversion. 13.1% of embryos from translocation cases were aneuploid for chromosomes not involved with the translocation ($p < 0.001$).
d. The inversion group was split in subgroups by maternal age: under 35 and 35 or over. Both groups didn't show statistical differences.
e. In the inversion Group 71.1% of unbalanced embryos also carry another abnormality whereas in the translocation group this proportion it is only 51.1% ($p < 0.001$).
Limitations, reason for caution: Expanding the inversion group may show a statistical difference for the proportion of normal or balanced between inversion and translocation carriers.
It will allow us to compare further differences between the meiotic behavior of inversion and translocation cases
Wider implications of the findings: Maternal age may not be the only factor for the increase in aneuploidy of the inversion group because age subgroups had no differences. Therefore, ICE could be the other contributing factor.
The high proportion of aneuploid embryos and the lower proportion of unbalanced embryos may indicate Comprehensive Chromosome Screening as a better strategy in dealing with inversion cases as opposed to FISH technique focusing only on the affected chromosome.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – NA.

O-179 High cumulative success rate and excellent safety profile after trophectoderm biopsy, blastocyst vitrification and single thawed blastocyst transfer. A new era in PGD for inherited disorders

T. El-Toukhy[1], M. Khalil[1], M. Adel[1], P. Renwick[1], C. Mackie Ogilvie[2], Y. Khalaf[1]
[1]*Guy's Hospital Great Maze Pond, Assisted Conception Unit 11th floor, London, United Kingdom*
[2]*Guy's Hospital Great Maze Pond, Genetics, London, United Kingdom*

Study question: What is the cumulative ongoing pregnancy rate after trophectoderm biopsy, blastocyst vitrification and single thawed blastocyst transfer for PGD?
Summary answer: This approach has a high cumulative success rate and has the potential to eliminate OHSS and multiple pregnancy
What is known already: PGD has traditionally been performed on cleavage-stage embryos followed by fresh embryo transfer. The limitations include short analysis time, risk of OHSS and high multiple pregnancy rate in order to maximize the pregnancy rate after fresh transfer
Study design, size, duration: This is a prospective observational study of 161 consecutive couples who underwent PGD from October 2013 to August 2014
Participants/materials, setting, methods: A cohort of 161 couples who were carriers of either monogenic diseases (n = 127) or chromosomal rearrangements (n = 34) underwent oocyte retrieval after controlled ovarian stimulation employing a GnRH antagonist protocol and GnRH agonist administration for final oocyte maturation. Trophectoderm biopsy was performed on day 5 or 6 blastocysts, followed by blastocyst vitrification and single thawed blastocyst transfer in a natural or programmed cycle. DNA analysis was performed by whole genome amplification followed by PGH for monogenic diseases or array CGH for chromosomal rearrangements. Only one retrieval cycle per couple during the study period was included
Main results and the role of chance: In total, 546 blastocysts were biopsied and vitrified, of which 534 (98%) were diagnosed. Of the 161 couples, 132 (82%) had blastocysts suitable for biopsy; 16 had no unaffected embryos and 118 (73%) had genetically suitable vitrified blastocysts for transfer. Those 118 couples underwent 154 single thawed blastocyst transfers, resulting in 85 pregnancies (53% per retrieval cycle and 55% per transfer) with an implantation rate of 48%. The survival rate of vitrified blastocysts after thawing was 93% (154/166). The cumulative live birth/ongoing pregnancy rate per retrieval cycle was 40% (41% for monogenic diseases and 39% for chromosomal rearrangements, P = 0.80). There were no cases of OHSS and only 1 monozygotic twin pregnancy (1.1% per pregnancy) in this cohort
Limitations, reason for caution: This is a single centre cohort study of PGD patients. Implementation of this PGD approach requires advanced biopsy and vitrification techniques, which may not be widely available
Wider implications of the findings: This approach to PGD has high cumulative success rate and excellent safety profile, and has the potential to eliminate OHSS and multiple pregnancy. It allows flexibility in cycle programming and efficient scheduling of genetic testing
Study funding/competing interest(s): Funding by hospital/clinic(s) – Guy's and St. Thomas' Hospital NHS Foundation Trust.
Trial registration number: NA.

O-180 Carrier screening: an analysis of observed carrier rates among a European population from an expanded panel

S. Yarnall[1], N. Kumar[1], S. Rodriguez[1], S. Bristow[1], A. Bisignano[2], J. Horcajadas[3]
[1]*Recombine, Product, New York N.Y., U.S.A.*
[2]*Recombine, CEO, New York N.Y., U.S.A.*
[3]*Recombine-EU, CSO, Sevilla, Spain*

Study question: Based upon observed carrier rates among patients of self-reported European ancestry tested with an expanded genetic carrier screening panel, which autosomal recessive genetic diseases beyond Cystic Fibrosis, but with similar severity and frequency, may be appropriate for broad carrier screening among European patients?
Summary answer: Our analysis has identified several high-impact diseases with high carrier rates (greater than 1/100) which may be appropriate for screening; we also found that some diseases have higher carrier frequencies in our population than reported in the literature for patients of European ancestry, and may therefore be under-reported.
What is known already: Within the United States, professional societies provide carrier screening guidelines for a select few recessive genetic diseases based on ancestral background. Technological advancements in genomics now allow carrier screening to be performed for over 200 pan-ethnic genetic diseases in a

cost-effective and high-throughput manner. Carrier rates may be an impactful way to determine appropriate incorporation of diseases into such expanded panels, particularly for areas in which guidelines are not currently in place.
Study design, size, duration: Our retrospective analysis examined genotype data from an expanded carrier screening panel run on over 4000 patients over the past two years. Patients were referred for carrier screening by reproductive endocrinologists, obstetricians, and genetic counselors. Documented informed consent was obtained to use genotype information in a de-identified manner.
Participants/materials, setting, methods: The Illumina Infinium HD Custom Genotyping platform was used to identify 1,679 mutations associated with 213 autosomal recessive and X-linked genetic diseases. Carrier rates for each disease were calculated for the general population and by ethnic group and then compared with the literature. Diseases were also analyzed for severity.
Main results and the role of chance: American professional medical societies recommend screening for diseases with an impact on quality of life and high carrier frequency, e.g., Cystic Fibrosis. Our results identified several diseases with high carrier rates among patients of European ancestry and a significant effect on quality of life, but which are not currently screened for broadly. Identified diseases include but are not limited to syndromes such as Smith-Lemli-Opitz (observed rate of 1/47). Such diseases may be appropriate for screening in a European population to allow for the greatest reduction of reproductive risk. We also identified diseases with higher carrier rates among European patients than reported in the literature, such as Bardet-Biedel syndrome (1/168 vs. 1/376), highlighting the importance of continual carrier rate observation and comparison.
Limitations, reason for caution: Our study is limited by the self-reported nature of patients' ancestral backgrounds. It is possible that patients may be unaware of, or not identify with, their genetic ethnicity. However, this limitation highlights the importance of pan-ethnic carrier screening to accurately diagnose carrier states.
Wider implications of the findings: Our data identified several high-impact genetic diseases with carrier rates higher than 1/100. These results suggest that carrier states of such diseases may be under-diagnosed and indicate that the lack of broadly implemented screening programs within Europe may need to be re-evaluated. Proper observation and calculation of carrier rates, along with services such as genetic counseling, will be crucial to the effectiveness of carrier screening among all populations.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Recombine.
Trial registration number: NA.
Keywords: genetics, genetic testing, carrier screening

O-181 Mammalian Fertility Decoded: Over 3000 genetic loci implicated in female fertility potential

D. E. Parfitt[1], A. Conover[1], T. Hu-Seliger[1], B. Burnett[1], S. T. Globus[1], P. Yurttas Beim[1]
[1]*Celmatix Inc, Research & Development, New York, NY, U.S.A.*

Study question: The primary objective of this study was to compile and collate data implicating genes in female fertility, including where possible, data demonstrating how particular genes contribute to mechanisms of female reproductive physiology.
Summary answer: We have collated data for 3,000 genetic loci implicating them in mechanisms of female fertility in animal models, humans, or both. Our growing dataset includes cross-referenced details of gene expression in female reproductive tissues, biochemical data, phenotypes of genetic deletion/mutation, and meta- and bioinformatics analyses that collectively characterize the role of each loci in female fertility.
What is known already: Association studies in humans and targeted experiments in animal models have linked particular genes and genetic mutations to various aspects of reproduction and fertility. As the polygenic nature of infertility becomes clearer, our understanding of how different genetic elements **collectively** contribute to female reproductive biology becomes crucial. This is only possible with a fully comprehensive, cross-sectional understanding of the different levels of data describing the molecular mechanisms of female reproductive physiology.
Study design, size, duration: We collected and cross-referenced human- and animal model- specific expression data, phenotypic and genotypic data for more than 5,000 genetic loci.
Participants/materials, setting, methods: Data were iteratively cross-referenced and analyzed using meta-analyses and bioinformatics tools to demonstrate roles in particular reproductive processes.
Main results and the role of chance: Our developing understanding of the genetic regions involved in fertility currently encompasses 3,047 loci. Inclusion is based on: (1) Expression in reproductive tissues in humans and/or animal models; (2) Association with infertility or reproductive mechanisms in humans; (3) Infertility phenotypes in animal models and/or; (4) Meta- and bioinformatics analyses integrating data from 1 to 3. To systematize this dataset with respect to gene function, genetic loci were grouped according to their inferred and/or reported function(s) in reproductive physiology. For example, 318 genes are linked to mechanisms of oogenesis, while 320 genes are involved in endocrinological processes. Particular genes from both of these sets are among the 566 genes linked to mechanisms placentation. Thus, our big data approaches facilitate the identification of non-obvious associations among different genetic loci and a variety of fertility-related processes.
Limitations, reason for caution: Data relating particular genes and variants to reproduction in mammalian models or humans may have yet to be identified.
Wider implications of the findings: By using a big data approach to comprehensively classify genetic loci according to their role in mechanisms of reproduction and female fertility, our growing dataset helps to clarify how particular genes and genetic variants functionally contribute to the pathophysiology of infertility disorders. By highlighting genetic loci for which relatively little existing information links them mechanistically to human infertility, we provide a route for hypothesis driven translational research that could lead to clinically actionable molecular targets.

O-182 The usefulness of intrauterine hCG administration prior to blastocyst transfer in IVF-patients ≥38 years

B. Wirleitner[1], M. Schuff[1], P. Vanderzwalmen[2], A. Stecher[1], L. Hradeck[3], T. Kohoutek[3], N. H. Zech[1]
[1]*IVF-Centers Prof. Zech, Bregenz, Austria*
[2]*Centre Hospitalier Inter Régional Edith Cavell (CHIREC), Braine-l'Alleud, Belgium*
[3]*IVF-Centers Prof. Zech, Pilsen, Czech Republic*

Study question: Implantation rates decline with female age. Besides an increasing incidence of aneuploid embryos, alterations in implantation promoting factors such as human chorionic gonadotropin (hCG) are considered to contribute to IVF failure. Therefore, we evaluated whether intrauterine injection of hCG improves embryo implantation in women of advanced age.
Summary answer: We found that intrauterine infusion of 500 IU hCG prior to blastocyst transfer does not have a sustained effect on implantation-; pregnancy-; miscarriage- or birth rates in women at advanced age.
What is known already: Embryo-secreted hCG is crucially involved in the implantation process, including the modulation of endometrial receptivity and the attachment and invasion of the embryo into the decidualized uterus. Previous studies postulate a supportive effect of intrauterine hCG infusion on embryo implantation. Serum concentrations of hCG in early pregnancy in women at advanced age were shown to be reduced, probably due to functional impairment of trophoblast cells. Thus, hCG application might be helpful for older IVF-patients.
Study design, size, duration: This clinical trial was designed as a randomized patient-blinded single-center study. We included 480 stimulation cycles of women between 38 and 43 years with fresh embryo transfer (ET) on day 5. Primary outcome was pregnancy rate (PR), clinical pregnancy rate (cPR), miscarriage rate (MR) and delivery rate (DR).
Participants/materials, setting, methods: For controlled ovarian hyperstimulation (COH) the GnRHa long protocol was applied. Fertilized oocytes (IMSI) were cultured in single-step medium. Only IVF-cycles with fresh ET on day 5 were included. Just prior to transfer, patients received intrauterine injection of hCG (500 IU) or culture medium (control). Clinical outcome was compared.

Main results and the role of chance: Mean age of patients was 40.4 years (control) and 40.3 years (hCG group). Mean duration and stimulation dose (HMG) were 11.8 days and 3276 IU (control) and 11.8 days and 3230 IU (hCG group). No statistically significant differences were found in cause and type of infertility, endometrium build-up, as well as the number of retrieved oocytes per ovarian pick-up and the number and quality of transferred blastocysts. In the control group PR was 41.6%; cPR 36.9% and DR 30.2%; MR was 6.7%. In patients receiving hCG prior ET a PR of 44.0%; cPR 33.7%; DR 26.7% and a MR of 7.1% were found. No statistically significant differences in clinical outcome between hCG administration and control group were observed.
Limitations, reason for caution: This study does not encompass frozen transfers or transfer of cleavage stage embryos. For COH only the GnRH agonist (long) protocol was used. Thus, these findings might be only applicable for fresh blastocyst transfers and not for hormonal stimulation using the GnRH agonist protocol.
Wider implications of the findings: The detailed molecular mechanisms of hCG signalling are still not fully understood. Controversial reports underline that simple intrauterine administration might be insufficient to create a receptive endometrium. There might be molecular differences between embryo-secreted hCG vs. administered hCG. This trial indicates that the applied intrauterine injected hCG has no benefit for IVF-patients at advanced age undergoing blastocyst transfer in a fresh cycle.
Study funding/competing interest(s): Funding by hospital/clinic(s) – This study was not externally funded.
Trial registration number: CRT:355.
Keywords: Intrauterine hCG application, implantation, blastocyst quality, pregnancy rate, advanced maternal age

O-183 The optimal dose of medroxyprogesterone acetate (MPA) to prevent premature LH surge during controlled ovarian hyperstimulation in normal ovulatory women

J. Dong[1], Q. Chen[1], A. Ai[1], R. Cai[1], Y. Fu[1], Y. Wang[1], H. Tian[1], Q. Hong[1], Q. Lyv[1], Y. Kuang[1]
[1]*Shanghai Ninth People's Hospital Shanghai Jiaotong University School of Medicine, Department of Assisted Reproduction, Shanghai, China*

Study question: Which is the optimal dose of MPA during progestin-primed ovarian stimulation (PPOS) to prevent premature LH surge in normal ovulatory women?
Summary answer: MPA might be an effective oral alternative for the prevention of premature LH surge in woman undergoing controlled ovarian hyperstimulation (COH). 10 mg/d of MPA might be more effective to prevent premature LH surge than 4 mg/d MPA in woman undergoing COH.
What is known already: Premature LH surge is a major cause for cycle cancellation during COH. High levels of progesterone, such as during the luteal phase, is known to block the estrogen-induced GnRH/LH surge in the ewe. Our previous researches demonstrated consistent LH suppression in the luteal phase, with no spontaneous LH surge. The follow-up of over 500 children born from luteal-phase COH showed high progesterone status didn't increase the risk of congenital malformations compared with the short protocol.
Study design, size, duration: A prospective controlled study including 300 women undergoing ovarian stimulation for the treatment of infertility during August to November in 2014 was conducted. All women were recruited consecutively and allocated to the 10 mg group or the 4 mg group.
Participants/materials, setting, methods: MPA 4 mg/d or 10 mg/d were co-administered with hMG beginning on cycle day 2–3.Ovulation was induced with hCG or co-triggered by hCG and GnRH agonist when dominant follicles matured. Transvaginal ultrasound–guided oocyte retrieval was conducted 32–36 h later. Viable embryos were cryopreserved for later transfer in both protocols.
Main results and the role of chance: The number of oocytes retrieved in 10 mg group was similar to those in 4 mg group (9.81 ± 6.26 vs. 9.61 ± 5.94, $P > 0.05$). No differences were found in number of viable embryos, mature oocyte rates, fertilization rates, cleavage rates and viable embryo rate per oocyte retrieved between the two groups. No premature LH surge occurred in either group. The rate of cycle cancellation in 10 mg group was significantly lower than that in 4 mg group (4.7% (7/150) vs. 12.7% (19/150)). Logistic regression analysis found that the cycle cancellation rate was negative correlated to daily dose of MPA and positive correlated to patients' age.
Limitations, reason for caution: As a new regimen, a control group should be contained besides the two study groups such as the short protocol.
Wider implications of the findings: PPOS using MPA has the advantages of an oral administration route, easy access and more control over LH levels. It might become a new non-down-regulation regimen for ovarian stimulation in combination with embryo cryopreservation. 10 mg/d of MPA could help to achieve the best pregnancy outcome and reduce the probably adverse complications.
Study funding/competing interest(s): Funding by national/international organization(s) – National Nature Science Foundation of China (grant numbers: 31071275), Natural Science Foundation of Shanghai (grant number: 14411964300).
Trial registration number: ChiCTR-ONRC-14005127.

O-184 Effect of Dehydroepiandrosterone (DHEA) on ovine intra-follicular response prior and after controlled ovarian stimulation

A. Narkwichean[1], K. Jayaprakasan[2], W. E. Maalouf[1], C. Pincott-Allen[1], B. K. Campbell[1]
[1]*University of Nottingham, Division of Child Health Obstetrics and Gynaecology, Nottingham, United Kingdom*
[2]*Royal Derby Hospital, Reproductive Medicine and Fertility Unit, Derby, United Kingdom*

Study question: Does *in vivo* DHEA supplementation affect intra-follicular steroidogenesis and gonadotrophin receptor expression before and after ovarian stimulation in sheep?
Summary answer: DHEA stimulated antral follicle number in pre-stimulated ovaries ($P < 0.01$) but this effect was not associated with changes in either ovarian steroidogenesis or gonadotrophin receptor mRNA expression. However, higher intrafollicular progesterone levels and lower gonadotrophin receptor expression levels ($P < 0.05$) were observed in DHEA-treated animals after ovarian stimulation.
What is known already: DHEA has been used worldwide to improve ovarian response in women with diminished ovarian reserve undergoing IVF treatment. DHEA stimulates primordial follicles initiation and preantral/early antral follicular development in the gonadotrophin responsive stages by improving granulosa cell proliferation and modulating local growth factors, e.g., AMH. It is believed that DHEA increase ovarian susceptibility to FSH stimulation at the later stage but there has not been an established evidence to support at the follicular/molecular level.
Study design, size, duration: An animal experiment was conducted in 12 mature ewes which were equally divided into treatment and control group. In the treatment group, all 6 animals received DHEA implants for a 12-week period. One ovary was then removed to examine pre-stimulation effects of DHEA prior to ovarian stimulation for 5 days.
Participants/materials, setting, methods: Ovarian stimulation utilized recombinant human FSH (rhFSH, Gonal-F®) and GnRH-antagonist (Cetrotide®). Animals were sacrificed after hCG injection to harvest the remaining ovary. Follicles were dissected from both before and after-stimulation ovary for hormonal evaluation (fluid) and FSH/LH receptor mRNA expression (tissue).
Main results and the role of chance: DHEA treatment resulted in an increase in the number of antral follicles in pre-stimulation ovaries (19 ± 2 vs. 15 ± 2; $P < 0.01$). In pre-stimulation follicles, DHEA levels tended to be higher but there was large variation among follicles (107 ± 35 vs. 43 ± 8 ng/ml; $P = 0.84$). Levels of androstenedione, oestradiol, and progesterone showed no difference. Likewise, utilising the real-time PCR, FSH/LH receptor mRNA expressions in the follicular tissue were similar in both groups. After FSH stimulation, mean follicular DHEA and progesterone concentrations were significantly higher in the treatment group (76 ± 28 vs. 23 ± 7 ng/ml and 114 ± 13 vs. 83 ± 7 ng/ml, $P < 0.05$). No significant difference in follicular oestradiol was observed. However, there were approximately 40% and 30% reduction in both FSH and LH receptor mRNA expressions in the treated follicular tissue compared to the control (mean fold change 0.63, 95% CI 0.20–1.07 and 0.71, 95% CI 0.40–1.01, respectively; $P < 0.05$).
Limitations, reason for caution: Although sheep are a large mono-ovulatory species, direct interpretation of experimental findings to humans should be done so with caution, especially as experimental animals were of normal fertility. In addition, further studies to evaluate an impact of reduction in both FSH and LH protein receptor expression are required.

Wider implications of the findings: While evidence of using DHEA in clinical setting is currently uncertain, this study shows that DHEA can enter ovarian follicles and further modify the intrafollicular microenvironment. The detrimental effect of DHEA on gonadotrophin receptor mRNA expression warrants concern over quality of individual oocyte despite its positive influence on early folliculogenesis.

O-185 Ovarian Hyperstimulation Syndrome, Pregnancy, Live Birth and IVF Cycle Failure by Risk Category

P. Devroey[1], P. Humaidan[2], K. Gordon[3], D. Gates[4], B. Stegmann[3]
[1]*Centre for Reproductive Medicine Universitair Ziekenhuis Brussel, Fertility, Brussels, Belgium*
[2]*The Fertility Clinic, Fertility, Skive, Denmark*
[3]*Merck & Co. Inc., Women's Health, Kenilworth, U.S.A.*
[4]*Merck & Co. Inc., Statistics, Kenilworth, U.S.A.*

Study question: Among women undergoing ovarian stimulation with corifollitropin alfa (CFA) or recombinant follicle-stimulating hormone (rFSH) in a gonadotropin-releasing hormone (GnRH) antagonist protocol, did rates of ovarian hyperstimulation syndrome (OHSS), pregnancy, live births and *in vitro* fertilization (IVF) cycle failure differ between groups stratified by risk category for OHSS?

Summary answer: Rates of moderate or severe OHSS were significantly higher ($P < 0.001$) among the high-risk group versus the non-high-risk group. Pregnancy and live birth rates were slightly higher among the high-risk group versus the non-high-risk group. Rates of IVF cycle failure were similar in both groups.

What is known already: Prevention of OHSS, especially in high-risk populations, is a major goal in assisted reproductive technology. The use of a GnRH agonist trigger is almost 100% effective in eliminating early-onset OHSS, but may result in inferior pregnancy rates compared with hCG triggers with fresh autologous transfers.

Study design, size, duration: Analyses of data from ENGAGE (1506 women, aged 18–36 years) randomized controlled trial. Patients received 150 µg CFA ($n = 756$) or daily 200 IU rFSH ($n = 750$) from stimulation days 1–7, followed by ≤200 IU/d rFSH until criteria for hCG were met.

Participants/materials, setting, methods: Subjects were classified into high-risk and non-high-risk groups based on a threshold number of follicles [19 or more follicles of 11 mm or more in diameter on the day of hCG]). Rates of moderate or severe (Grades II and III) OHSS, pregnancy, live births and IVF cycle failure were compared between high-risk and non-high-risk groups and treatments.

Main results and the role of chance: Of the 1506 subjects, 391 (26%) were high-risk, 241 (31.9%) in the CFA group and 150 (20.0%) in the rFSH group. Rates of moderate or severe OHSS were significantly higher ($P < 0.001$) among the high-risk (28/391 [7.2%]) versus the non-high-risk group (23/1115 [2.1%]); the rate difference was consistent between treatments. Pregnancy and live birth rates were slightly higher for the high-risk versus the non-high-risk groups, respectively: 43.5% versus 38.1% (5.4% higher) for vital pregnancies, 42.2% versus 37.3% (4.9% higher) for ongoing pregnancies, and 38.1% versus 33.9% (4.2% higher) for live births; none of these differences achieved a descriptive *p*-value below 0.067 (Cochran–Mantel–Haenszel [CMH] test, controlling for treatment). Rates of IVF cycle failure were 63.2% for the high-risk group and 58.6% for the non-high-risk group ($P = 0.111$, CMH test).

Limitations, reason for caution: This was a retrospective analysis of patients. The women represent a subset of the normal patient population, as they were participants in a large clinical trial with pre-specified inclusion /exclusion criteria. Use of this cut-off threshold would not prevent all cases of OHSS as 23 cases occurred in the non-high-risk group.

Wider implications of the findings: Although pregnancy and live birth rates were slightly higher in the high-risk group with more follicles at day of hCG, the elevated rates of OHSS in this group may present an unfavorable benefit-risk profile for these patients. Use of a GnRH agonist trigger for those with >19 follicles ≥11 mm on the day of hCG would likely have avoided 28 cases of OHSS.

Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Merck & Co., Inc., Kenilworth, NJ, USA.

Trial registration number: NCT00696800.

SELECTED ORAL COMMUNICATIONS

SESSION 50: OOCYTE MARKERS AS PREDICTORS OF OUTCOME

Tuesday 16 June 2015 **17:00–18:00**

O-186 Do multiple IVF cycles increase the chance of having a euploid embryo in females of advanced age?

K. Spath[1], S. Alfarawati[1], D. Babariya[1], A. Raberi[1], D. Wells[1], E. Fragouli[1]
[1]*Reprogenetics UK, Obstetrics and Gynaecology, Oxford, United Kingdom*

Study question: What is the impact of female age on the incidence of aneuploidy during preimplantation development? How does this affect the probability of finding no euploid embryos after a cycle of preimplantation genetic screening (PGS)? Can batching of embryos from multiple IVF cycles increase the likelihood of identifying euploid embryos?

Summary answer: Increasing age adversely affects chromosome segregation. As expected, the risk of having no euploid embryos depends on the number of embryos suitable for biopsy and the aneuploidy rate. Patients batching embryos from more than one cycle display a 2- to 3-fold reduction in the risk of having no euploid embryos.

What is known already: Recent randomized controlled trials have shown increased implantation and/or ongoing pregnancy rates following transfer of euploid embryos after comprehensive chromosome screening. Importantly, provided that a euploid embryo was identified for transfer, high pregnancy rates were achieved regardless of maternal age. However, the likelihood of producing a euploid embryo in a single cycle is reduced for some patients due to elevated aneuploidy rates and/or an insufficient number of embryos generated.

Study design, size, duration: The effect of female age on aneuploidy rates, number of abnormalities generated, and the specific chromosomes affected during preimplantation development, was assessed. Furthermore, the probability of finding no euploid embryos for transfer in a single or multiple cycle(s) was evaluated in relation to female age and number of embryos produced.

Participants/materials, setting, methods: Microarray-CGH was applied to cells biopsied from 1780 cleavage-stage embryos and 1213 blastocysts generated by 262 (age range: 20–46, average: 38.6) and 234 (age range: 28–45, average: 38.2) couples, respectively. Twenty two couples having analysis at the cleavage-stage and 12 with blastocyst testing underwent multiple (2–4) treatment cycles.

Main results and the role of chance: In line with expectation, aneuploidy was correlated with advancing age at both cleavage and blastocyst stages ($p = 0.0006$ and $p < 0.0001$). Highly abnormal embryos (>3 errors) also became significantly more common ($p < 0.0001$, $p = 0.0035$). Increasing aneuploidy was associated with elevated risk of having no euploid embryos in a single cycle at both embryonic stages ($p = 0.0002$, $p = 0.0005$). An increased likelihood of having no euploid embryos was also apparent in younger females (20–32 years) generating ≤3 cleavage-stage embryos. At the blastocyst-stage a euploid embryo was always produced by women ≤32, but for patients ≥33 decreased embryo count was associated with increased probability of having no euploid embryos to transfer. Multiple cycle patients displayed a 3- and 2-fold increase in the chance of having euploid embryos at the cleavage- and blastocyst-stage.

Limitations, reason for caution: In order to firmly establish a beneficial effect of multiple treatment cycles on euploid embryo rates in females of different age, results need to be verified in a larger population study, ideally as part of a randomised trial.

Wider implications of the findings: Generation of an increased number of embryos by combining multiple treatment cycles significantly improves the chances of having a euploid embryo for transfer, even in women >41, an important fact given the rapidly declining fertility in this patient group. Younger patients with a poor response to ovarian stimulation may also benefit from

multi-cycle strategies. Another consideration is that batching of embryos may lead to reduced PGS costs, since samples from multiple cycles are analysed simultaneously.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Reprogenetics UK.
Trial registration number: NA.

O-187 Cohorts of donated oocytes showing smooth endoplasmic reticulum clusters produce clinical outcomes similar to normal cytoplasm oocytes cohorts

I. Maldonado Rosas[1], J. Pedraza[1], L. Cedillo-Garcia[1], J. Macias[1], L. Chiquillo[1], E. Rodriguez[1], M. Chirinos[2], F. Camargo[1], J. Liebermann[3]
[1]*Instituto Ingenes, Embriology, Mexico City, Mexico*
[2]*Instituto Nacional de Ciencias Médicas y Nutrición "Salvador Zubirán", Reproduction Biology, Mexico City, Mexico*
[3]*FCI Chicago/River North, Embriology Lab, Chicago ILL, U.S.A.*

Study question: Should cohorts of donated oocytes containing at least one oocyte with smooth endoplasmic reticulum clusters (SERC) be considered for oocyte donation?
Summary answer: Cohorts of donated oocytes with at least one oocyte presenting SERC may be safe to be used in oocyte donation programs.
What is known already: Several studies in the past reported that the presence of SERC in autologous oocyte cohorts affects fertilization, embryo development and pregnancy rates as well as neonatal data. However recent studies suggest comparable clinical and neonatal outcomes when employing normal and affected cohorts.
Study design, size, duration: A retrospective study was performed from January 2011 to September 2014 in a private IVF clinic that included 1092 oocytes obtained from 82 donors divided in two groups according to the presence or absence of at least one oocyte showing SERC. These were evaluated only in terms of clinical outcomes.
Participants/materials, setting, methods: 95 embryo transfers were divided as follows: **Group A:** 45 cycles with at least one SERC positive oocyte in the cohort; **Group B:** 50 cycles with SERC negative oocytes. Only cases with normal sperm parameters (WHO 2010) were included. Chi square and Student's t-test were used for data analysis.
Main results and the role of chance: 131 of 3178 cycles of ICSI with donor oocytes (4.0%) presented SERC in at least one oocyte; 13 out of 82 (15%) presented SERC in their oocyte cohorts at least twice during the period of this study, and 994/1092 (91%) oocytes were mature. No statistical significance ($P > 0.05$) was observed when comparing Group A vs. B regarding mean of recipients (42.2 ± 2.2 vs. 42.5 ± 3.4) fertilization rate [353/492 (71%) vs. 368/502 (73%)], pregnancy rate [31/45 (69%) vs. 36/50 (72%)], Transferred blastocyst (2.1 ± 0.25 vs 2.0 ± 0.18), Implantation (36.2 vs. 36.8%) and miscarriage rates [12% vs 15%]. Likely, there was no statistical difference between the SERC+ vs. SERC- oocytes in terms of fertilization [70/99 (70%) vs. 368/502 (73%)], cleavage [90/99 (91%) vs. 345/368 (93%)], and blastocyst formation [39/90 (43%) vs. 158/345 (45%)] rates.
Limitations, reason for caution: Taking into account that this retrospective study did not analyze the neonatal outcomes and that fresh donor oocyte cohorts have not been previously studied, the relevance of this findings must be taken with caution, even though it has been suggested that SERC oocytes produce healthy babies.
Wider implications of the findings: This study contributes to demonstrate that cohorts of donated oocytes presenting at least one SERC+ oocyte avoiding to transfer embryos derived from SERC+ oocytes may be safe to use in IVF cycles without an impact in clinical outcomes. This study is consistent with some previous reports suggesting the lack of impact of SERC+ oocyte cohorts in success rates derived from autologous oocytes. More studies should be performed to demonstrate the safety of SERC+ cohorts on neonatal outcomes.
Study funding/competing interest(s): No financial support was received for this study, and there are no potential conflicts of interest.
Trial registration number: NA.
Keywords: oocyte, SERc, ICSI

O-188 Is oocyte meiotic spindle morphology associated with embryo ploidy? A prospective cohort study

L. Tilia[1], C. A. Venetis[2], S. Kilani[3], S. Cooke[4], M. Chapman[2]
[1]*IVF Australia, Embryologist-PGD, Sydney, NSW, Australia*
[2]*University of New South Wales, School of Women's and Children's Health, Sydney, NSW, Australia*
[3]*IVF Australia, Laboratory Supervisor-Embryologist, Sydney, NSW, Australia*
[4]*IVF Australia, Scientific Director, Sydney, NSW, Australia*

Study question: Is there an association between oocyte meiotic spindle morphology visualised by polarised light microscopy (PLM) at the time of Intracytoplasmic sperm injection (ICSI) with the ploidy of the resulting embryo?
Summary answer: Oocyte spindle morphology is associated with the resulting embryo's ploidy. Oocytes with normal spindle morphology are significantly more likely to produce euploid embryos compared to oocytes with meiotic spindles that are translucent or not-visible.
What is known already: Embryo ploidy contributes significantly to successful reproduction. Aneuploid embryos fail to implant, lead to miscarriage or genetically abnormal offspring. A significant proportion of aneuploidy is maternal in origin, resulting from chromosome misalignment and errors in segregation. Current embryo morphological markers are not reliable predictors of euploidy or aneuploidy while pre-implantation genetic diagnosis (PGD) is an invasive procedure. Hence there is a need for additional non-invasive methods that will allow better prediction of embryo euploidy.
Study design, size, duration: PGD patients (n = 113 patients, 135 cycles, 745 embryos) of a private IVF clinic between June 2011 and July 2014 were included prospectively. The oocyte meiotic spindles were assessed by PLM and classified at the time of ICSI as normal, dysmorphic, translucent, telophase and not-visible.
Participants/materials, setting, methods: All embryos with suitable development were biopsied on Day 3 of culture following laser zona dissection. Biopsied blastomeres were analysed by array CGH. Spindle morphology and embryo ploidy association was evaluated by generalised estimating equation analysis while accounting for non-independence of data.
Main results and the role of chance: The frequency of euploidy in embryos derived from oocytes with normal spindle morphology (30.4%) was significantly higher than all other spindle classifications combined (18.4%) odds ratio (OR): 1.93 [95% confidence interval (Cl): 1.33–2.79], translucent spindle morphology (9.8%) OR: 0.24 (95% CI: 0.12–0.49) and not-visible spindle morphology (13.5%) OR: 0.35 (95% CI: 0.19–0.64). There was no significant difference between normal and dysmorphic spindle morphology (24.5%) OR 0.73 (95% CI: 0.49–1.08) while no telophase spindles resulted in euploid embryos (n = 11). Assessment of spindle morphology was also found to be independently associated with embryo euploidy after controlling for embryo quality (OR: 1.85, 95% CI: 1.26–2.71), i.e., regardless of embryo quality, the chances of a euploid embryo increased by 85% when spindle morphology was normal.
Limitations, reason for caution: The oocyte is not the only contributor to the embryo's ploidy. Paternally derived aneuploidy occurs less frequently but is still a risk to the outcome of the embryo. Hence, assessment of oocyte spindle morphology should be regarded as an additional useful tool for the non-invasive identification of euploid embryos.
Wider implications of the findings: A non-invasive method that can aid in the selection of euploid embryos has significant implications for patients. Visualisation of the meiotic spindle by PLM is an early marker that can impart additional information regarding the genetic integrity of an oocyte and aid in the selection of a euploid embryo for transfer, hence optimizing the chances of a live birth of a chromosomally normal infant.
Study funding/competing interest(s): Funding by hospital/clinic(s) – IVF Australia.
Trial registration number: None.

O-189 Characterization of the localization of some key factors of the spindle assembly checkpoint (SAC) during human oocyte's nuclear maturation

J. Lagirand-Cantaloube[1], C. Ciabrini[1], A. Ferrieres-Hoa[2], S. Hamamah[2], A. Castro[3], T. Lorca[3], T. Anahory[2]

[1]*Hôpital Arnaud de Villeneuve, Laboratoire de cytogénétique du DPI, Montpellier Cedex 05, France*
[2]*Hôpital Arnaud de Villeneuve, Biologie de la reproduction, Montpellier Cedex 05, France*
[3]*CRBM-CNRS UMR 5237-Université de Montpellier, Equipe "Contrôle de l'entrée et de la progression mitotique", Montpellier Cedex 05, France*

Study question: Are Bub1 and BubR1, key known kinases involved in the spindle assembly checkpoint functionality, correctly expressed and localized during human oocyte meiosis?
Summary answer: Through this analysis, we show that Bub1 and BubR1 proteins are expressed and localized on the kinetochores of oocytes's chromosomes at the metaphase I stage. As anaphase I takes place they are delocalized from these kinetochores. These observations suggest for the first time that SAC functionality is preserved during human first meiotic division (meiosis I).
What is known already: The SAC is the major molecular mechanism involved in accurate chromosome segregation in meiotic division and is being widely studied in mouse models. Considering the fact that the majority of human aneuploidies is due to errors arising during meiosis I in oocytes and increase with female age, it is important to transpose at least a part of these studies to human oocytes, what has not been done so far.
Study design, size, duration: One year study on immature oocytes from patients undergoing intra-cytoplasmic sperm injection (ICSI).
Participants/materials, setting, methods: Immature oocytes are collected after ovarian stimulation and fixed a few hours after punction and cumulus cells removal. Oocytes are then subjected to indirect immunofluorescence labelling and observed under a confocal Leica SP5 microscope.
Main results and the role of chance: Immunofluorescence analysis showed that Bub1 and BubR1 proteins are nearly undetectable at the germinal vesicle stage of oocyte's maturation. After germinal vesicle breakdown, Bub1 and BubR1 proteins strongly localized to kinetochores. This strong staining is lost as homologous chromosomes undergo segregation between the ooplasm and the first polar body. These results are correlated with those obtained in mouse models and strongly suggest that the SAC impairs precocious chromosome's separation and needs to be delocalized from kinetochores in order to allow the ending of the first meiotic division to take place in human oocytes.
Limitations, reason for caution: Very few human oocytes are available for research. This first study needs to be confirmed by more oocytes' staining.
Wider implications of the findings: These initial results will allow us to go further in understanding the molecular mechanisms that regulate the SAC in human meiosis. Further functional experiments may shed new light on the occurrence of women aneuploidy.
Study funding/competing interest(s): Funding by hospital/clinic(s) – CHU Arnaud de Villeneuve, Montpellier.
Trial registration number: None.

SESSION 51: GAMETE DONATION AND PATIENT EXPERIENCES
Tuesday 16 June 2015 **17:00–18:00**

O-190 Online sperm donation: a survey of men seeking to donate sperm via a connection website

T. Freeman[1], V. Jadva[1], E. Tranfield[2], S. Golombok[1]
[1]*University of Cambridge, Centre for Family Research, Cambridge, United Kingdom*
[2]*Pride Angel, www.prideangel.com, Liverpool, United Kingdom*

Study question: What are the demographic characteristics, motivations, expectations and preferences regarding information sharing and contact with recipient families of men who choose to donate their sperm via a connection website?
Summary answer: These men had diverse demographic characteristics and a variety of reasons for using the website (e.g., access to a greater range of recipients than at clinics; ability to choose, and communicate directly with, recipients); approximately one third favoured anonymous donation, the large majority of whom were heterosexual.
What is known already: Although substantially more sperm donors are registered on connection websites than with clinics, there has been very little research on this population. A common concern is that men may have financial or sexual motivations for using these websites. Studies of clinic donors highlight both altruistic and financial motivations for donating and find most prefer anonymity, although willingness to be identifiable may vary demographically; e.g., identity-release donation is associated with a rise in older, married donors.
Study design, size, duration: An online survey was completed by 398 men registered as sperm donors with Pride Angel, a UK-based website that facilitates contact between donors and recipients of sperm. All members of Pride Angel were invited to participate via an email invitation and the survey was live for 7 weeks.
Participants/materials, setting, methods: The survey comprised multiple choice and open-ended questions to obtain data on participants' demographic characteristics and motivations, expectations and experiences of online sperm donation, including preferences regarding contact with recipients and offspring. Data were analysed to examine differences according to participants' sexual orientation, marital and parental status, and age.
Main results and the role of chance: Most participants (77.4%) were heterosexual, 10.1% were gay, 8.8% were bisexual; ages ranged 18–69 years (mean 37.1, SD 9.6). Approximately half had a partner (46.5%) and children (51.8%); significantly more gay/bisexual men were partnered and/or childless than heterosexual men. Participants reported various reasons for using the website, including greater choice and communication with recipients than at clinics. The majority expressed altruistic reasons for donating. A greater proportion of gay/bisexual men desired open-identity donation ($p < 0.005$) and contact with recipients and offspring ($p < 0.005$) than heterosexual men; there were no significant differences by participants' age, marital or parental status. Seventy (17.6%) participants' donations had produced ≥1 successful pregnancy; of these, a minority (28.1%) were in contact with the child, comprising significantly more gay/bisexual than heterosexual men ($p = 0.001$).
Limitations, reason for caution: Although this study presents data from the largest sample of online sperm donors to date, a key limitation is that members of only one website participated. The findings may not be representative of all potential sperm donors using connection websites.
Wider implications of the findings: Since the removal of donor anonymity in many countries, concerns have arisen about the sharp increase in 'private' donors and falling numbers of clinic donors. This is the first in-depth study of donors who connect with recipients on the internet, including several who have successfully donated. The findings indicate that this is a diverse group and that sexual orientation may play a greater role in men's preferences regarding donation than marital and parental status.
Study funding/competing interest(s): Funding by national/international organization(s) – This study was supported by the Wellcome Trust [097857/Z/11/Z]. Erika Tranfield is Director and Co-Founder of Pride Angel and assisted with recruitment for this study.
Trial registration number: NA.

O-191 Psychosocial counselling in donor sperm treatment: exploring parents' expectations

P. A. L. Kop[1], M. Visser[1], T. Gerrits[2], F. van der Veen[3], M. H. Mochtar[3]
[1]*Academic Medical Centre, Centre for Reproductive Medicine, Amsterdam, The Netherlands*
[2]*Faculty of Social and Behavioral Sciences, Sociology and Anthropology, Amsterdam, The Netherlands*
[3]*Academical Medical Centre, Centre for Reproductive Medicine, Amsterdam, The Netherlands*

Study question: In donor sperm treatment (DST)**,** what are parents' expectations on psychosocial counselling, especially concerning the decision making process towards disclosure to their child**.**
Summary answer: All 24 parents had the intention to disclose donor conception to their child before they received psychosocial counselling. They felt that counselling had no influence on their decision making on disclosure, but they

were concerned about when and how to disclose and lacked professional and trustful advice on this.

What is known already: Psychosocial counselling is recommended before DST for coming to terms with issues such as psychosocial implications of donor conception and decision-making on disclosure. Parents' expectations on counselling and whether their needs are met is unknown.

Study design, size, duration: A qualitative study was performed from July 2012 until August 2013 with 24 Dutch parents, who had conceived children after DST between 2000 and 2012.

Participants/materials, setting, methods: Semi-structured in-depth interviews were held with heterosexual and lesbian couples and single mothers. The interviews were fully transcribed and analysed using the constant comparative method of grounded theory.

Main results and the role of chance: Psychosocial counselling before DST had not influenced parents' decision-making to disclose. The intention to disclose donor conception to their child was already a matter of fact before psychosocial counselling. In retrospect they lacked professional advice on when and how to disclose and how to handle future donor contact. Reading and hearing about trustful experiences on disclosure of other parents was considered important. Another important finding was that when psychosocial screening for DST was combined with psychosocial guiding and support in the same counselling session, parents felt very vulnerable and reluctant to address certain issues.

Limitations, reason for caution: Only parents who already disclosed DST to their children or intended to disclose volunteered for the study. This selection bias is a limitation of this study, and may be due to the sensitive nature of sperm donation.

Wider implications of the findings: The period of availability of psychosocial support and advice for parents of a donor child should be extended and be especially available after childbirth for guiding parents on when and how to disclose and how to handle future contact of their child with the donor.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Academical medical centre, Amsterdam

Trial registration number: None.

Study question: How does a tailored expectant management of 6–12 months (TEM) in couples with unexplained infertility and a good prognosis affect their experiences with fertility care compared to couples who are exposed to overtreatment, i.e., start treatment within 6 months after fertility-workup?

Summary answer: Adhering to TEM of at least 6 months in couples with unexplained infertility does not negatively influence their experience with care compared to couples who started treatment too soon.

What is known already: In couples with unexplained infertility and a good prognosis of natural conception (>30%) within one year, expectant management of 6–12 months, is equally effective as an immediate start of medically assisted reproduction. Therefore, TEM is recommended by various national clinical guidelines. However, implementation of TEM is still poor because of several barriers on both patient and professional level. Moreover, how adherence to TEM actually affects the couples' experiences with care is unknown.

Study design, size, duration: This cross-sectional study is nested within a large cluster randomized trial, which assessed methods to improve guideline adherence to TEM. A survey with written questionnaires was performed among all infertile couples who participated in a cluster randomised trial of guideline adherence on TEM in 25 Dutch clinics.

Participants/materials, setting, methods: Couples eligible for TEM after fertility work-up were included. We used questionnaires to collect data on couples' experiences with care (patient-centeredness of care and patients' trust in their physician) and on determinants for their experiences. Multilevel regression analyses were performed to investigate associations between adherence to TEM and care experiences.

Main results and the role of chance: Out of the 544 couples that were approached, 384 couples responded (response rate 71%). Couples who adhered to TEM scored equally on patient-centeredness of care (PCQ-Infertility, scale 0–3) as couples with overtreatment (2.28 vs. 2.29, OR 1.00; 95% CI 0.92–1.08). The couples' trust in their physician (Wake Forest Trust Scale, scale 0–5) was not significantly different between couples who adhered to TEM and couples with overtreatment (4.1 vs. 4.9, OR 2.17; 95% CI 0.5–9.2). Determinants that positively influenced patient-centeredness of care were; the fulfilment of the childwish, a higher fertility related quality of life (FertiQol score), attention for TEM during the first visit to the clinic, and education on psychological consequences of medically assisted reproduction. We did not find any determinants for the patients' trust in their physician.

Limitations, reason for caution: Since the questionnaires were collected retrospectively, recall bias might have occurred. For some participants the time between their first visit to the clinic and completing the questionnaire was 1.5 year. However, we expect the effect of the recall bias to be equal between couples with overtreatment and couples that adhered to TEM.

Wider implications of the findings: Our results underline that TEM does not lead to less patient-centeredness of care or patients' trust in their physician. However, physicians should be aware of patients' mental health status (e.g., FertiQol score) and a good education and counseling on the consequences of fertility treatments. Therefore, more research on improving counseling couples for TEM should be encouraged and educational tools should be developed to help professionals and patients.

Study funding/competing interest(s): Funding by national/international organization(s) – Netherlands Organisation for Health Research and Development (ZonMW).

Trial registration number: www.trialregister.nl. NTR3405.

Keywords: Unexplained infertility, Expectant management, Patient-centredness, Guideline adherence, Education and counseling

O-193 Tailored education improves fertility knowledge and awareness: a randomized controlled trial

D. García[1], R. Vassena[2], O. Coll[2], A. Rodríguez[2], V. Vernaeve[2]

[1]*Fundació Privada EUGIN, Barcelona, Spain*
[2]*Clínica EUGIN, Barcelona, Spain*

Study question: Which educational methods improve the most fertility knowledge and awareness in women attending a fertility center to donate oocytes?

Summary answer: The delivery of tailored oral information related to fertility significantly increased women's knowledge score (+2.4) compared to non-tailored information (+1.29) or no information (+0.46) (p = 0.003), as measured in a 10-point self-rating questionnaire (SRQ) completed just before and 1–8 months after the intervention.

What is known already: Fertility knowledge and awareness are insufficient in reproductive-aged women. Awareness is mainly lacking in reproductive life span, risk factors for infertility, and limitations of assisted reproduction

treatments. Consequently, this could lead to involuntary permanent childlessness. In contrast, it is known that relatively simple educational interventions can be used to increase knowledge and to promote reproductive health, but, no head to head intervention has been tested so far in the context of a fertility center.
Study design, size, duration: RCT with two parallel blind educational interventions versus control, powered to detect a difference ≥2 points after the intervention. A SRQ was administered at first consultation, before the intervention, and again at oocyte pick-up (1–8 months later). From 201 enrolled women and after eligibility evaluation, 85 completed the donation cycle.
Participants/materials, setting, methods: Participants were candidates for oocyte donation who were on average 25.3 years old (SD 4.7), 30.8% university educated, and 64.1% without children. There were 3 study arms: 31 tailored oral intervention (T = brochure plus review of wrong answers to the questionnaire), 31 untailored intervention (U = brochure only), and 24 control (C = no intervention).
Main results and the role of chance: Fertility knowledge score at baseline was poor (mean score = 3.7/10). After the intervention, the score remained low for U (4.9/10) and C (4.6/10), while significantly increased for T (6.37/10) ($p = 0.003$). We observed that the score after the intervention was positively correlated to the study group ($p < 0.001$), the pre-test score ($p = 0.012$), and the woman's age ($p = 0.004$), but not to the educational level ($p = 0.76$) or having children ($p = 0.12$). Tailored information related to woman's most fertile age and infertility risk factors were the most efficient, with 80% ($p = 0.027$) and 79% ($p = 0.004$) of correct answers after the T intervention. We found a higher proportion of women with children in T ($T = 44\%$, $U = 27\%$, $C = 37\%$), however it does not seem to affect fertility knowledge at either pre-test ($p = 0.70$) or post-test ($p = 0.12$).
Limitations, reason for caution: The target population was women between 18 and 35 years old, so caution should be exerted when generalizing the results to younger or older women and men from the general population, as information needs might be different and alternative communication channels might need to be identified.
Wider implications of the findings: This study highlights the value of providing tailored oral information about fertility lifespan and infertility risks factors to reproductive age women, regardless of education level and parity. Further studies are needed to evaluate the long-term effect of educational interventions and if there is an effect on family planning (advancement of planned age for bearing the first and last children).
Study funding/competing interest(s): Funding by hospital/clinic(s).
Trial registration number: Study registered in Clinicaltrials.gov, but NCT not yet assigned.

SELECTED ORAL COMMUNICATIONS

SESSION 52: EPIGENETIC PATTERN IN OOCYTE AND EMBRYO

Tuesday 16 June 2015 **17:00–18:00**

O-194 H3K4me3-dependent epigenetic memory regulates transcriptional reactivation in the oocyte

P. Navarro-Costa[1], P. Prudêncio[1], J. D. Becker[2], R. G. Martinho[1]
[1]*Faculty of Medicine University of Algarve., Department of Biomedical Sciences and Medicine, Faro, Portugal*
[2]*IGC – Gulbenkian Institute of Sciences, Gene Expression Unit, Oeiras, Portugal*

Study question: How does the oocyte regulate its transcriptional activity in light of its prolonged meiotic arrest?
Summary answer: A histone methylation-mediated epigenetic memory programed by the demethylase KDM5 is required for the correct temporal reactivation of the oocyte's transcriptional activity.
What is known already: During oogenesis oocytes transit from stages of transcriptional activity to those of transcriptional quiescence, and such transitions are believed to be essential for proper gamete formation. Although the temporal regulation of these transitions has been well documented across diverse organisms, the molecular mechanisms underlying these processes remain largely unknown.
Study design, size, duration: Basic research using the *Drosophila melanogaster* (fruit fly) model organism. The Drosophila ortholog of the human KDM5 gene family (hereafter referred to as dKDM5) was down-regulated specifically in the female germline by *in vivo* RNAi (knockdown efficiency: 97%). Outputs were compared to that of a mock RNAi.
Participants/materials, setting, methods: Transcriptional activity in the oocyte was temporally measured by an ex vivo ovary incorporation assay (Click-iT assay). Oocyte chromatin structure was analyzed and quantified by confocal microscopy after staining for DNA and H3K4me3. dKDM5 localization was analyzed by substituting the endogenous gene by a HA-tagged genomic construct.
Main results and the role of chance: Germline-specific dKDM5 knockdown results in severely reduced female fertility. Oocytes display precocious transcriptional reactivation and an equally precocious chromatin remodeling, leading to the premature acquisition of an open chromatin configuration. Both effects are a possible consequence of the significant up-regulation of H3K4me3 levels in the ovary, particularly in the meiotically-arrested oocyte. Increased H3K4me3 levels seem to solely impact the transcriptional status of the oocyte, as no evidence for either the activation of the DNA damage checkpoint or meiotic maturation defects were recorded. dKDM5 is evicted from the oocyte's chromatin by early oogenesis, indicating that the transcription defects recorded approximately 24 h later are the possible consequence of a H3K4me3-based epigenetic memory mechanism.
Limitations, reason for caution: The functional consequences of the reported transcriptional deregulation need to be fully elucidated.
Wider implications of the findings: Our results provide novel insight into the epigenetic mechanisms employed by the oocyte to regulate its transcriptional activity during the prolonged meiotic arrest. Given the significant evolutionary conservation of both dKDM5 and H3K4me3, it is likely that the in pre-ovulatory oocytes of our species the transition from a transcriptionally active to an inactive state is under equivalent epigenetic control. The deregulation of this process can therefore be an underlying cause of infertility in patients with low oocyte quality.

O-195 Histone H4 lysine 12 (H4K12) acetylation state as epigenetic marker of quality of oocytes from in vitro maturation (IVM)

M. Heiligentag[1], T. Trapphoff[1], S. Kalhori[1], C. Drechsler[1], I. Betzendahl[1], U. Eichenlaub-Ritter[1]
[1]*University of Bielefeld, Gene Technology and Microbiology, Bielefeld, Germany*

Study question: Can H4K12acetylation state be used as oocyte quality marker to improve IVM?
Summary answer: H4K12acetylation was low in *in vivo* ovulated (IVO) mouse metaphase-II oocytes and high in IVM denuded oocytes (DOs). Cumulus-enclosed (COC) and stimulated physiological oocyte maturation (SPOM) decreased acetylation. Most normal status was achieved after 3D-follicle culture. Therefore H4K12acetylation appears to be a marker of oocyte quality, useful to improve IVM.
What is known already: The activity of histone deacetylases (HDACs /sirtuins) is relevant for epigenetic remodeling of chromatin during maturation. While H4K12 is hyperacetylated in mature GV oocytes and hypoacetylated at the metaphase-II (MII) state, it becomes reacetylated in zygotes and preimplantation embryos. The level of H4K12 acetylation is increased in oocytes of older female mice, after postovulatory aging and in diabetic mice. Increased H4K12acetylation is linked to age-related aneuploidy in human oocytes.
Study design, size, duration: Denuded or cumulus-enclosed murine MF1 GV oocytes underwent IVM for 16 h or SPOM for 21 h. Preantral follicles from C57/Bl6xCBA/Ca-mice were cultured for 13d or 10d under adherent (2D) or non-attachment (3D) conditions. H4K12acetylation pattern was analyzed in IVO and IVM MII oocytes by semiquantitative immunofluorescence.
Participants/materials, setting, methods: MII oocytes from IVO and IVM from COCs ± SPOM, COCs from SPOM ± dbcAMP (dibutyryl-cAMP), SPOM ± carbenoxolone, and from 2D and 3D follicle culture were fixed after zona removal and stained by specific antibody to H4K12ac. Image analysis was by ImageJ software comparing ratiometric mean values between IVO and IVM oocytes.

Main results and the role of chance: The highest H4K12acetylation state was recorded in the DO group followed by decreasing signal intensity in the SPOM groups, and was similarly decreased in 2D follicle culture. dbcAMP did not lead to a further reduction in acetylation of H4K12 in SPOM. MII oocytes from 3D follicle culture had very low acetylation signal, most similar to the signal intensity found in IVO MII oocytes. Since oocytes from SPOM, 2D and especially 3D follicle culture had lowest acetylation levels and most closely resembled the IVO group, and studies by other groups have shown improved oocyte quality in these IVM conditions, H4K12acetylation appears to be a promising marker of oocyte quality and might be helpful to improve IVM conditions.
Limitations, reason for caution: H4K12acetylation is just one of the multiple posttranslational modifications accompanying oocyte maturation. Further studies are required to assess histone deacetylase activities and compare different histone patterns and developmental potential of MII oocytes from IVM to confirm that H4K12acetylation can serve as marker for oocyte quality in mouse and other species.
Wider implications of the findings: Stage specific alterations in chromatin conformation and gene expression characterize oocyte growth, maturation and have impact on developmental potential. Although we have no information on the relevance of H4K12acetylation for the developmental competence, aberrant acetylation patterns associated with aging and metabolic diseases imply that it reflects the activities of HDACs and oocyte quality. Our studies suggest that it can be used as marker to improve *in vitro* culture conditions, e.g., in ART.

O-196 Altered expression of imprinted genes in cord blood but not placenta from babies conceived via assisted reproductive technologies

R. Vincent[1], K. Louie[1], E. Chan Wong[1], S. Ma[1]
[1]*University of British Columbia, Obstetrics and Gynaecology, Vancouver, Canada*

Study question: Do children conceived by the assisted reproductive techniques of *in vitro* fertilization (IVF) or intracytoplasmic sperm injection (ICSI) have altered DNA methylation at imprinted regions or alterations of imprinted gene expression in placenta and/or cord blood samples compared to naturally conceived (NC) controls?
Summary answer: Our findings indicate that the imprinted *PLAGL1* gene may be susceptible to epimutations in the ART population as alterations in DNA methylation and gene expression in cord blood samples from ART infants were observed. Further, imprinted gene *KCNQ10T1* displayed altered expression in cord blood from IVF pregnancies.
What is known already: Studies in both animal and human models have indicated that ART is associated with increased rates of rare imprinting disorders and low birth weight. Altered DNA methylation and gene expression of imprinted genes has been found in ART infants; however results have been conflicting and inconclusive. Aberrant expression of *PLAGL1* has been linked to transient neonatal diabetes mellitus (TNDM), intrauterine growth restriction (IUGR) and numerous malignancies.
Study design, size, duration: Placental and umbilical cord samples from 271 infants were collected at birth for this prospective cohort study. Samples were divided into three experimental groups based on conception mode: (A) *in vitro* fertilization (IVF) (n = 105) (B) intracytoplasmic sperm injection (ICSI) (n = 79) and (C) naturally conveived (NC) controls (n = 87).
Participants/materials, setting, methods: DNA methylation at *PLAGL1*, *KvDMR1* and *PEG10* differentially methylated regions (DMRs) and *LINE-1* repetitive element expression levels were analyzed by bisulfite pyrosequencing. Quantative PCR (qPCR) was used in order to analyze imprinted gene expression levels in cord blood and placenta from ART and NC pregnancies.
Main results and the role of chance: We discovered a significant increase in DNA methylation at the DMR of the tumor suppressor *PLAGL1* in cord blood from IVF pregnancies (P = 0.0007) compared to NC controls, as well as decreased levels of *PLAGL1* gene expression in cord blood from both ART groups (IVF: P = 0.0013; ICSI: P = 0.016). We also found significantly altered gene expression levels of *KCNQ1OT1* (P = 0.0002) in IVF cord blood despite a lack of changes in DNA methylation. No significant differences were observed in DNA methylation or gene expression levels of analyzed regions in placental chorionic villi of ART pregnancies compared to NC controls (P > 0.05).
Limitations, reason for caution: As underlying subfertility has been shown to be associated with imprinting errors, it would be beneficial to control for fertility issues of the parents. However, in this study that clinical information was not obtained. Furthermore, we could not rule out the possible effects of ART techniques on aberrant imprinting.
Wider implications of the findings: These findings indicate that the imprinted *PLAGL1* tumour suppressor gene may be susceptible to epimutations in the ART population and could potentially lead to increased risk of imprinting disorders, IUGR and cancer susceptibility. Imprinted gene expression may be altered in ART pregnancies, despite a lack of change in DNA methylation.
Study funding/competing interest(s): Funding by national/international organization(s) – None of the authors has any competing interests. This study was funded by the Canadian Institute of Health Research (grant number MOP-77549 to S.M.)
Trial registration number: NA.

O-197 Genome-wide epigenetic evaluation of cord blood from in vitro-conceived babies

D. Gentilini[1], E. Rabellotti[2], L. Pagliardini[2], E. Somigliana[3], M. Zanirato[2], V. S. Vanni[2], E. Papaleo[2], A. M. Di Blasio[1], P. Viganò[4]
[1]*Istituto Auxologico Italiano, Molecular Biology Laboratory, Milan, Italy*
[2]*IRCCS San Raffaele Scientific Institute, Obstetrics and Gynecology Unit, Milan, Italy*
[3]*Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico, Infertility Unit, Milan, Italy*
[4]*IRCCS San Raffaele Scientific Institute, Division of Genetics and Cellular Biology, Milan, Italy*

Study question: Are there genome-wide epigenetic differences in cord blood between babies conceived *in-vitro* and *in-vivo*?
Summary answer: No significant changes in DNA methylation profiles of cord blood could be detected between *in-vitro* and *in-vivo* conceived babies, neither in the number of epimutations nor in their genomic localization.
What is known already: An increased incidence of rare imprint-associated disorders has been reported by epidemiological studies in babies born from human assisted reproduction technologies (ART). However, evidence for an association between ART and an altered DNA methylation status of the conceived babies are insufficient and principally focused on imprinted genes without taking into account the rest of the epigenome. No study with a genome-wide approach has been published so far.
Study design, size, duration: This was a prospective observational study conducted between December 2011 and July 2014. Women with a single pregnancy were enrolled at the 20th gestational week. Babies conceived by Intracytoplasmatic Sperm Injection (ICSI) (n = 18) were enrolled in the study as cases, while babies from natural conceptions (n = 29) represented the control population.
Participants/materials, setting, methods: DNA extracted from cord blood was bisulfite converted and the methylation status of more than 485.000 CpGs was analyzed using the Illumina Infinium HumanMethylation450K BeadChip. Methylation levels of each CpGs, global number of rare and stochastic epigenetic differences (epimutations) and their genomic localization were compared between cases and controls.
Main results and the role of chance: Hierarchical clustering did not demonstrate different methylation profiles in cord blood between cases and controls. None of the 485.000 CpGs had a significantly altered methylation status despite the 80% power to detect differences larger than 15%. Assuming that ART effects could be stochastic, we developed a specific analysis aimed at identifying subject-specific epigenetic alterations. No difference in the median number of epimutations was observed between cases and controls when the analysis was conducted using, as reference to detect outliers, population data from cord blood samples from an online database (n = 44, 1153 vs.1553, p > 0.05), peripheral blood samples from a general population (n = 167, 1242 vs. 1486, p > 0.05) and our study population (640 vs. 656, p > 0.05). No localized epimutation enrichment (lesion) was found even in imprinted genes.
Limitations, reason for caution: This study does exclude the presence of differences in methylation status smaller than 15%, but the biological relevance of such differences is doubtful. Moreover, only ICSI babies were evaluated and differences linked to other techniques, like cryopreservation, could not be excluded.

Wider implications of the findings: This study demonstrates that the ovarian stimulation, ICSI and the embryo culture are 'epigenetically safe', supporting the idea that factors associated with the diagnosis of infertility itself might underlie the causes of the imprinting disease enrichment in ART. The new developed analysis aimed at identifying rare and stochastic epigenetic differences could also be implemented in the safety evaluation process of new drugs and techniques potentially useful for ART procedures.

SESSION 53: FROM OOCYTE TO CHILD HEALTH – IMPACT OF TECHNOLOGY

Tuesday 16 June 2015 **17:00–18:00**

O-198 Understanding the impact of Assisted Reproductive Technologies (ART) on embryo health, child health and disease and longevity in later life

H. L. Smith[1], B. Minogue[1], A. Webber[1], S. Sneddon[1], L. Shaw[1], S. J. Kimber[1], D. R. Brison[2]

[1]*University of Manchester, Reproductive Medicine, Manchester, United Kingdom*
[2]*Central Manchester University Hospitals NHS Foundation Trust St. Mary's Hospital, Reproductive Medicine, Manchester, United Kingdom*

Study question: Can gene expression microarray data from different stages of human embryo development be used to investigate the expression of metabolic and epigenetic pathways contributing to embryo health? Such key pathways are likely to be affected by ART factors such as maternal oocyte age, embryo cryopreservation and prolonged embryo culture.

Summary answer: Several novel genetic and epigenetic regulatory pathways have been identified as important in embryonic genome activation and blastocyst formation. Expression of some of these are altered by ART factors. Further analysis into interacting partners of the novel genes reveal unique developmental networks important for healthy blastocyst formation.

What is known already: Many studies have shown the relationship between the maternal environment and offspring health, using animal models and epidemiological data. Mouse embryos removed from a diabetic environment before embryo replacement have an increased risk of developing obesity, diabetes and metabolic syndrome in later life and other studies demonstrate the importance of epigenetic DNA methylation stability during embryonic development. However few studies have attempted to clarify the link between the environment/ART technology and human embryo and future offspring health.

Study design, size, duration: Gene expression microarray data and QPCR analysis of amplified cDNAs from individual embryos and isolated blastomeres from different stages of human embryo development (n = four × oocytes, four × 4 cell, three × 8 cell, eight individual 8 cell blastomeres and ten × blastocyst stage embryos).

Participants/materials, setting, methods: Embryos were donated by patients undergoing IVF at St. Mary's hospital, Manchester, UK. cDNA was amplified via polyAPCR and analysed using the Affymetrix microarray HG U133 plus 2 chip, at the Paterson cancer Institute, Manchester. Arrays undergo rigorous AQM analysis within R, statistical analysis within Partek, Cytoscape and Ingenuity.

Main results and the role of chance: We identified a large epigenetic gene list which correlated with maternal age with two clear groups of gene expression profiles emerging, in embryos from women aged 35 and under, versus those aged >35. We detect a strong up-regulation of a selection of oxidative stress pathways as the embryo remains in extended culture; in particular the NRF2 mediated oxidative stress response. A more systems based network analysis resulted in the generation of novel embryonic developmental expression networks, network modules and module/gene hierarchy and causal networks. Data mining revealed many interesting genes, amongst them Zscan4, previously shown to restore developmental potency of mouse embryonic stem cells, identified as a key gene during EGA. A network of transcription factors and the epigenetic regulatory genes GATA2, TRIM8 and DNMT3L are significantly increased in the blastocyst and may represent important changes occurring during the period of *in vitro* culture in IVF.

Limitations, reason for caution: The number of samples per developmental stage was restricted in order to focus on individual embryos. Embryos are inherently different to one another, e.g., in genetic background and quality and therefore detailed analysis needs to be applied to identify trends in gene expression.

Wider implications of the findings: Understanding developmentally important pathways which contribute to human embryo health is critical for our understanding of potential risk factors to which human embryos are subject *in vitro*. Assessing the perturbation of such genetic pathways in response to ART is an essential part of a fully-informed risk assessment. This will ultimately lead to increased understanding of long term health outcomes for ART children and the consequent modification of risk factors will ultimately help to improve ART conditions and avoid unwanted impacts.

Study funding/competing interest(s): Funding by national/international organization(s) – This research is funded by the European Commission under the FP7 Health programme, as part of the EpiHealth consortium (co-ordinator Professor Andras Dinnyes).

Trial registration number: Embryos were donated with approval from Central Manchester Ethics Committee and the Human Fertilisation and Embryology Authority (HFEA licence R0026).

O-199 Elective frozen-thawed vs fresh transfer of euploid embryos identified by comprehensive chromosome analysis using next generation sequencing – interim analysis of a randomized controlled trial

S. Munné[1], J. S. Hesla[2], A. Kung[3], E. Mounts[4], B. Ata[5], A. Coates[6]

[1]*Reprogenetics, Genetics, Livingston New Jersey, U.S.A.*
[2]*Oregon Reproductive Medicine, Clinical, Portland, U.S.A.*
[3]*Reprogenetics, Genetics, Portland, U.S.A.*
[4]*Oregon Reproductive Medicine, Genetics, Portland, U.S.A.*
[5]*Koc University School of Medicine, OBGYN, Istanbul, Turkey*
[6]*Oregon Reproductive Medicine, Embryology, Portland, U.S.A.*

Study question: Is the transfer of a frozen thawed blastocyst in an artificial cycle associated with higher implantation and ongoing pregnancy rates than fresh blastocyst transfer in a stimulated cycle?

Summary answer: Frozen thawed transfer (FET) of euploid blastocysts in an artificial cycle seems to yield significantly higher implantation, clinical and ongoing pregnancy rates than fresh transfer of euploid blastocysts in the stimulated cycle.

What is known already: some data suggesting FET is associated with better clinical outcome than fresh transfers. Endometrial receptivity is thought to be disrupted by high estradiol levels during stimulation. However the quality of evidence is low to moderate, and generalizability of the findings is questionable. There's a need for properly sized randomized controlled trials controlling for other factors including embryo aneuploidy.

Study design, size, duration: Planned interim analysis of a randomized controlled trial, including 76 women over one year of recruitment. The study is halfway at the time of submission. We expect to have results from over 100 women by the time of conference.

Participants/materials, setting, methods: Women < 42 without poor ovarian reserve or azospermic partner were randomized to fresh transfer or FET. Assisted hatching was on day 3, and trophoectoderm biopsy was done on day 5 or 6. Comprehensive chromosome screening was by next generation sequencing (Ion Torrent PGM). Only euploid blastocysts were transferred.

Main results and the role of chance: Fresh and FET groups included 37 and 39 women, respectively. 15 women in the fresh group had no fresh transfer (13 had no euploid embryos, 2 other reasons). 31 women in the FET group were available for analysis (8 awaiting FET presently). Five women in FET group had no euploid embryos. Baseline and stimulation cycle parameters including number of blastocysts transferred were similar. Ongoing pregnancy rates (OPR) were 14/37 (38%) vs 20/31 (65%), in the fresh and FET groups, respectively (p = 0.03). Per protocol analysis revealed OPR of 14/22 (64%) vs 21/27 (78%), in the fresh and FET groups, respectively (p = 0.23). Implantation rates were 67 vs 82%, difference was not statistically significant but was in favor of FET (p = 0.23).

Limitations, reason for caution: The observed differences can change when the trial is completed.
Wider implications of the findings: In this trial effect of fresh transfer on endometrial receptivity is almost isolated as embryonic aneuploidy is eliminated through CCS. If the difference in favor of FET is maintained, this finding can change practice worldwide. FET with CCS can enable single embryo transfer with excellent pregnancy rates.
Study funding/competing interest(s): Funding by hospital/clinic(s), Funding by commercial/corporate company(ies) – Life, Technologies, Oregon Reproductive Medicine, Reprogenetics.
Trial registration number: NCT02000349.

[3]*Dipartimento di Scienze per la Promozione della Salute e Materno Infantile "G.D'Alessandro" Via del Vespro PALERMO, Dipartimento di Scienze per la Promozione della Salute e Materno Infantile "G.D'Alessandro" Via del Vespro PALERMO, Palermo, Italy*
[4]*Centro Di Biologia della Riproduzione Palermo, Centro Di Biologia della Riproduzione Palermo, Palermo, Italy*

Study question: The aim of the research was to investigate the apoptosis rate of individual cumulus cell–oocyte complexes (COC), associated to the level of *p*-Akt, to verify the difference between oocytes who produce embryos able to reach the blastocyst stage compared with embryos arrested during the *in vitro* culture.
Summary answer: It was demonstrated that DNA fragmentation in cumulus cells was remarkably lower in patients who achieved a pregnancy after ICSI cycles, related to the quality of oocytes and embryos. Akt pathway plays a critical role in the regulation of cell survival, and most growth factors activate this pathway.
What is known already: Studies on oocyte maturation have shown the importance of LH-induced activation of the epidermal growth factor (EGF)-like growth factors. This can be a potential mechanism for transducing the LH signal to oocyte. It is known that LH is an anti apoptotic agent. It is unknown the relationship between apoptosis and Akt in cumulus cell. Akt has been reported to coexist in a multimolecular complex containing also ribosomal S6 kinase 1 and phosphoinositide-dependent kinase 1
Study design, size, duration: The study had the duration of 24 month. 53 patients were involved after informed consent. In this observational prospective study, it has been measured the DNA fragmentation rate and the level of *p*-Akt in cumulus cells of single cumulus–oocyte complex (COC) for each follicle containing a mature oocyte
Participants/materials, setting, methods: Normo-responder patients have been selected. DNA fragmentation rate in cumulus cells has been examined with the use of a TUNEL assay *in situ*. *p*-Akt has been examined by immunological assay *in situ*. Statistic of molecule expression and DNA fragmentation was tested through the repeated measures ANOVA test of log-transformed variables
Main results and the role of chance: Out of 255 MII oocytes, 197 were fertilized and the derived embryos had the following evolution: 117 completed the development to blastocyst (day 5 or 6) and were transferred, 57 were vitrified at blastocyst stage and 23 were arrested during *in vitro* culture at different stages of cleavage. We found a statistical difference between the DNA fragmentation rate of cumulus cells between the arrested embryos compared to the transferred and vitrified blastocysts ($p = 0.004$), confirming that cumulus apoptotic rate of the cumulus cells could be considered as a marker of oocyte competence. Likewise we found a statistical significance between oocytes resulting in transferred blastocyst and arrested embryos in the ratio *p*-AKT/TUNEL ($p = 0.043$); Therefore, the ratio *p*-AKT/TUNEL could be considered also a marker of oocyte competence
Limitations, reason for caution: More studies are needed to confirm these data and to determine the how these molecular pathways are involved on the oocyte competence
Wider implications of the findings: We found that in the cumulus cells of the oocytes able to produce blastocysts apoptosis is significantly lower and the *p*-AKT/TUNEL ratio is higher than in cumulus cells of arrested embryos, indicating that DNA fragmentation is lower when *p*-AKT is higher. Data seems to demonstrate that DNA fragmentation rate and *p*-AKT value in cumulus cells could be considered a molecular marker of oocyte competence, to evaluated as a prognostic pattern of blastocyst formation
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Research awarded by "Grant for fertility innovation 2012".
Trial registration number: The trial is an observational study and no registration is needed.

O-201 Storage time does not modify the gene expression profile of cryopreserved human metaphase II oocytes

P. Scaruffi[1], P. Anserini[1], I. Casciano[1], L. Toccafondo[1], P. L. Venturini[2], S. Stigliani[1]
[1]*IRCCS AOU San Martino-IST, UOS Fisiopatologia della Riproduzione Umana, Genova, Italy*
[2]*IRCCS AOU San Martino-IST University of Genoa, UOS Fisiopatologia della Riproduzione Umana Clinic of Obstetric and Gynecology, Genova, Italy*

Study question: Does storage time impact on transcriptome of slowly frozen cryopreserved human metaphase II (MII) oocytes?
Summary answer: For the first time, we demonstrate that the length of cryostorage has no effect on the gene expression profile of human metaphase II oocytes.
What is known already: Oocyte cryopreservation is a largely-used technique in IVF for storage of surplus oocytes, as well as for fertility preservation (i.e., women undergoing gonadotoxic therapies) and oocyte donation programs. Although it is known that cryopreservation negatively impacts on oocyte physiology and it is associated with decrease of transcripts, no experimental data about the effect of storage time on the oocyte molecular profile are available to date.
Study design, size, duration: This study included 20 women undergoing IVF treatment, ≤38 years aged, without any ovarian pathology. Surplus MII oocytes were donated after written informed consent. A total of 21 non-cryopreserved oocytes and 44 surviving slow-frozen/rapid-thawed oocytes (24 oocytes cryostored for 3 years and 20 cryostored for 6 years) were analyzed.
Participants/materials, setting, methods: Pools of ≈10 oocytes for each group were prepared. RNA was extracted by miRNeasy Micro Kit (Qiagen), analyzed by RNA 6000 Pico kit on 2100 Bioanalyzer (Agilent), amplified by Ovation Pico WTA System (Nugen), labeled and hybridized on 4x44K v2 microarrays (Agilent). Analyses were performed by GeneSpring software.
Main results and the role of chance: Analysis of variance (ANOVA) showed 22 probe sets (corresponding to 19 genes) differently expressed between fresh and cryopreserved oocytes (fold change >2, Benjamini-Hochberg false discovery rate adjusted *p*-value ≤0.05). Specifically, 10 genes were down- and 9 were up-regulated in cryopreserved oocytes respect to fresh oocytes. Gene Ontology analysis by DAVID bioinformatics resource disclosed that genes that were down-regulated in frozen oocytes mainly belong to ribosome function (i.e., *MRPS31*, *RPL5*, *RPL10*, *RPL23*) and intracellular protein transport (*YWHAG*, *LRP2*, *AP1G1*) pathways. Moreover, cryopreservation deregulates acetylation through up-regulation of *HNRNPUL1*, *AP1G1*, *PYGO2* genes. Intriguingly, comparison of gene expression profiles between surviving thawed oocytes after 3 and 6 years of storage in liquid nitrogen found no differently expressed genes.
Limitations, reason for caution: Ongoing experiments are aimed to validate our data in a larger cohort of samples, i.e., analyzing additional pools of oocytes for each group, including "older" frozen oocytes.
Wider implications of the findings: Our study demonstrates that specific transcript levels are altered by cryopreservation, in agreement with literature that reported injuries of morphology, physiology and molecular integrity of oocytes following freezing. No data about effect of long-term oocyte cryopreservation are available. For the first time our data suggest that the length of storage does not alter the gene expression profile of frozen oocytes. This finding is noteworthy for safety issue of long-term oocyte banking, i.e., oncofertility, gamete donation.

Study funding/competing interest(s): Funding by national/international organization(s) – This study was supported by a grant of the Italian Institute of Health (CCM 2012).
Trial registration number: NA.

INVITED SESSION

SESSION 54: FERTILITY SPARING SURGERY IN BENIGN AND MALIGNANT CONDITIONS

Wednesday 17 June 2015 **08:30–09:30**

O-202 Fertility-sparing surgery (FSS) in severe endometriosis and adenomyosis: what is the gold standard approach?

S. Gordts[1], R. Campo[1], P. Puttemans[1], S. Y. Gordts[1], I. Segaert[1], M. Valkenburg[1]
[1]*LIFE (Leuven Institute for Fertility and Embryology), Unit Reproductive Medicine, Leuven, Belgium*

Several data are reporting on a possible negative impact of endometriosis and adenomyosis on reproductive performance, although a causal relation is not proven. It is hypothesized that endometriosis as adenomyosis are both a primary disease of the uterus, constituting a single entity with variable phenotypically expression. The disease is characterized by the grow of endometrial like tissue (glands and stroma) outside the uterine cavity. In his publication Larsen et al. (*Eur J obst. Gynecol, 2011*) found that endometriosis was associated with adenomyosis in 34% with an incidence of 42.8% in stage IV and with a disorder of the junctional zone in 39.9%. As endometriosis is a pleiotropic disease with increased inflammation and neoangiogenesis and with impact on the endometrium and ovarian function, it is utopic to believe that surgery will eradicate the disease. In the most optimal circumstances surgery will restore the normal anatomical relations. The advantages of surgery of ovarian endometriosis have to be balanced very carefully in each individual patient against the potential harm of damaging the ovarian reserve. This is upmost important as the presence of ovarian endometriosis without any previous surgery has as such already a negative impact upon the follicular reserve due to the smooth muscle metaplasia and fibrosis with diminished ovarian blood flow in the surrounding ovarian tissue *(Jun Jun Qui AOGS 2012, Kuroda M Obstet Gynecol 2012, Kitajima Fertil Syeril 2011*). Although the ESHRE guidelines recommend the performance of a cystectomy in case of ovarian endometrioma, based upon only one randomized controlled study, more data are now becoming available mentioning a lower impact upon ovarian reserve by an ablative surgical procedure. It can be questioned if cystectomy is the most adequate surgery in view of fertility preservation. Important factor in fertility preservation is the early detection and when indicated treatment of the disease in an early stage. In case of large endometriotic cysts a two-step operative procedure should be considered. If conservative surgery is not possible implantation of fresh normal ovarian tissue is an option. Where initially "adenomyosis uteri" was a diagnosis resulting from histologic examinations of hysterectomy specimens, it now changed in a clinical entity with the introduction of the Archimetra concept and the more performing indirect imaging techniques of MRI and 3-D ultrasound. A good classification is still lacking as adenomyosis can be seen under different forms like diffuse, focal, cystic, adenomyoma and polypoidal. Adenomyosis seems to have a negative impact on reproductive outcome in patients referred to IVF programs (*Vercellini P et al. Hum. Reprod. 2014;29:964–977*). It is obvious that in patients at reproductive age there is no place for hysterectomy. Hormonal suppression seems to have a positive effect on pregnancy rates after iVF. The conservative uterine sparing cytoreductive surgery is an alternative effective treatment for fertility preservation with a beneficial effect upon patient's wellbeing. Several surgical techniques are available. Non-excisional techniques using electrocoagulation are reported also to have a beneficial impact. Fertility sparing approaches for endometriosis and adenomyosis should be implemented wherever possible. It improves patient's fertility offering the possibility of spontaneous conceptions and increases patient's well being.
Keywords: endometriosis, adenomyosis, surgery, fertility sparing

O-203 Fertility-sparing surgery in cancer patients

C. Uzan[1]
[1]*Gustave Roussy, Sepatment of Surgery, Villejuif, France*

The issue of fertility preservation must be addressed early in the oncologic management of young patient. Conservative treatment can be offered in some well-defined situations; in other cases the data are more uncertain. A specialized multidisciplinary management (oncologist, surgeon, procreation specialist, and psychologist) had to be proposed. The physician must be able to explain that in some cases conservative treatment is not reasonable, and best oncological treatment prevails.
Keywords: fertility sparing surgery, gynecologic cancer

INVITED SESSION

SESSION 55: ICSI AND BEYOND

Wednesday 17 June 2015 **08:30–09:30**

O-204 Fertility in ICSI boys

O-205 RAMAN microspectroscopy: the new analytical tool for sperm, eggs and embryos

C. Mallidis[1]
[1]*Centre for Reproductive Medicine and Andrology, Spermatology, Muenster, Germany*

Despite recent technological and analytical advances in the field of reproductive medicine, fertility clinics worldwide are still confronted with the large disparity between the high fertilization rates now achievable by modern artificial reproductive treatments and the concomitantly low pregnancy and/or take home baby rates. The introduction of many and varied, modern techniques has significantly increased the amount of information available to scientist and clinician alike, however the utility of most of these new methods is limited as the processes usually necessitate the modification and/or destruction of the cell. What is needed is a non-invasive, non-destructive means of obtaining accurate information, whilst not affecting the integrity of the cell and which allows for its selection and use. Such a method would radically transform the way clinical reproductive medicine is currently being conducted. Raman spectroscopy is based upon the inelastic scattering resulting from the interaction between light and matter. This produces a unique pattern of changes in the vibrational state of each affected molecule and its environment which constitute the sample's chemical "fingerprint." Discovered in 1928, the molecular deformations detected by Raman have been used to identify and classify a variety of different substances, when complemented by the three-dimensional spatial resolution afforded by confocal microscopy (i.e., Raman microspectoscopy) it can detect changes in and location of defined molecules within a cell. In medicine, these advances have led to its successful utilization in the discrimination, classification and diagnosis of pathological conditions such as different malignancies and tumors. Being non-invasive it has also been employed in the investigation and analysis of various living cells (e.g., living bacteria and stem cells) providing specific data without any adverse effects to the cells themselves. As such, Raman microspectoscopy appears to possess the attributes for the desired gamete assessment and selection technique. In reproductive medicine, the first Raman investigations were primarily oncological in nature; however, the past few years have seen an increase in its application in the assessment of both male and female gametes. More specifically, the characterisation and localisation of different structural and chemical elements identified by the technique have been associated with the vitality and maturity of oocytes, the integrity of the zona pellucida and the health and implantation potential of embryos. Furthermore, it has been suggested that the Raman identified chemical constituents of the medium used for culturing are indicative of the metabolism and hence health of ART produced embryos. In the male, studies have been conducted into the constituents of seminal plasma and the function of the testis and prostate and associations made

with different pathological states. The greatest progress thus far has been made in the identification, characterization and localization of sperm nuclear DNA damage, an area of increasing interest for ART. With the incorporation of recent technological advancements into the instrumentation of Raman spectroscopy, the capabilities and information obtainable by the method have grown quickly and significantly. Not surprisingly so has the enthusiasm surrounding the technique. However, as with all new techniques, if Raman microspectroscopy is to achieve its true potential it must undergo stringent validation and verification processes. This is the challenge that awaits.
Keywords: Raman microspectroscopy, gamete selection

SESSION 56: OUTCOME AFTER ART; GENES, LIFE-STYLE OR TECHNOLOGY

Wednesday 17 June 2015 **08:30–09:30**

O-206 Towards comprehensive epigenomic profiling of the human ART embryo by genome-wide DNA methylation analysis

J. Huntriss[1], H. M. Picton[1]
[1]*Leeds Institute of Cardiovascular and Metabolic Medicine, Division of Reproduction and Early Development, University of Leeds, Leeds, United Kingdom*

The programming of epigenetic information is an essential requirement for normal development in mammals. DNA methylation is one particular epigenetic mark that is dynamically reprogrammed during gametogenesis and preimplantation development. In humans, these reprogramming events occur in the gametes and in preimplantation embryos at the time when ART is being performed. Inappropriate programming of epigenetic information, including DNA methylation, is associated with disease. Two genomic imprinting disorders may be associated with ART in humans although the precise cause remains to be identified. These cases are rare, however, it must be considered that ART cohorts may retain an epigenetic signature that reflects their exposure to the *in vitro* environment, and that this may in some cases have an adverse developmental legacy. The analysis of the epigenetic regulation of the human preimplantation embryo is of particular value for expanding our understanding of this critical period of development. If achievable at the single embryo level, the data may also reveal whether embryonic epigenetic programs are affected by assisted reproduction technologies (ARTs) and/or infertility or other parameters. Indeed, this information may eventually be useful for informing future approaches in ART. Whilst there have been numerous technology-driven advances in many fields of reproductive science (PGD/PGS for example), our progress in the understanding of epigenetic programming has until very recently been extremely limited in comparison, with experiments often limited to a small number of genes. Fortunately, the advent of next generation sequencing-based technologies such as Reduced Representation Bisulfite Sequencing (RRBS) and related techniques that allow the study of DNA methylation (5-methylcytosine) across the genome have now been applied successfully to the study of mammalian gametes and preimplantation embryos. Importantly, these techniques have been used to reveal very detailed information on the reprogramming of DNA methylation of human preimplantation development as reported recently by several research groups. These studies constitute a major leap in our comprehension of the biology of human gametogenesis and preimplantation development. In this presentation, these recent studies will be discussed in addition to the presentation of research from our laboratory which reveals that genome-wide DNA methylation analysis of single preimplantation embryos (human, bovine) by RRBS is indeed possible. Although much work remains to be done, such as mapping the reprogramming of the histone code and 5-hydroxymethylcytosine (5 hmC) in human gametogenesis and preimplantation development, collectively these advances will provide greatly enhanced understanding of normal human embryonic development and any developmental consequences that ART and/or infertility may have.

O-207 Increased morbidity and mortality after ART: related to the infertility or the reproductive technology?

L. B. Romundstad[1]
[1]*NTNU, Spirent Fertility Clinic, Trondheim, Norway*

Since the birth of Louise Brown, more than 6 million babies have been born world-wide as a result of assisted reproductive technology. The scope of fertility treatment is rapidly growing in both western and less developed countries. Debates related to the safety aspects of the reproductive technology are ongoing. Several studies have focused on safety aspects of the reproductive technology. Most studies have investigated differences in pregnancy complications, perinatal outcomes, maternal risks, long term morbidity and development by comparing pregnancies following assisted fertilisation with pregnancies after spontaneous conception in the general population. For several years, attention to safety has been towards the multiplets with higher risk of both morbidity and mortality. During the last decade, along the implementation of single embryo transfer, focus on safety aspects has turned towards the outcome of singletons born after assisted fertilisation. Singletons born after ART have poorer perinatal outcomes compared to children born after natural conception. There are, however, major methodological problems in many of the studies that have evaluated effects of ART. In particular, comparisons of outcomes in pregnancies achieved by assisted fertilisation in subfertile women and outcomes following spontaneous conception in fertile women is challenging. Although, various approaches have been used to explain the gap between ART and spontaneously conceived pregnancies, the recurring objection has been the identification of relevant comparison groups to avoid confounding by indication. Recently, attention has been towards potential effects on birth weight of different culture media, days of culture and cryopreservation following the steady increase in the proportion of children born after cryopreservation or vitrification. Cryopreservation both maximizes the biological potential of each fertilized oocyte and reduces the strain for the couples by reducing the number of stimulated cycles. However, several studies have shown that the risk of being large-for-gestational age is higher in FET singletons compared to singletons born after fresh cycles and natural conception. This may indicate that the foetal growth potential may differ in children born after transfer of cryopreserved/thawed embryos. Whether the increase in birth weight is associated with epigenetic modification is not known.
Conclusion: The future of ART is crucially depending on the short and long term safety aspects for both children and mothers, and research and careful monitoring of outcomes are essential. New medications used for controlled ovarian hyper-stimulation, changes of media used for embryo culture and the rapid development of laboratory procedures of embryos are examples of the plethora of important factors that must be observed and continuously evaluated.
Keywords: safety, epidemiology, sibling study, perinatal outcome

INVITED SESSION

O-208 Genome and transcriptome analyses of single human oocytes and preimplantation embryos

Jie Qiao
Peking University Third Hospital, Medical Center for Human Reproduction, Dept. of OB/GYN, Beijing, China

O-209 First healthy baby born after PGD (preimplantation genetic diagnosis) – noninvasive haplotype screening in couples both carrying deafness gene GJB2 mutation

Z. Chen[1], Y. Gao[2], S. Huang[2], J. Yan[2], J. Li[2], M. Gao[2], Y. Zou[2], K. Wu[2], P. Xu[2], R. Kang[2]
[1]*Centre for Reproductive Medicine Shandong University Shandong Province Hospital Shandong University, National Research Centre for Assisted Reproductive Technology and Reproductive Genetics China, Jinan, China*
[2]*Shandong University, Centre for Reproductive Medicine, Jinan, China*

Introduction: Nonsyndromic hearing loss and deafness is characterized by congenital, non-progressive, mild-to-profound sensorineural hearing impairment. Despite extraordinary genetic heterogeneity, mutations in one gene, GJB2, which encodes the connexin 26 protein and is involved in inner ear homeostasis, are found in up to 50% of patients with autosomal recessive nonsyndromic hearing loss. In this study, a family with a hearing loss son was recruited and the proband has compound heterozygous mutations in GJB2 gene, c.235 del C from mother and c.299_300 del AT from father. In order to block the vertical transmission of causative mutations, PGD was performed and an embryo free of hearing problems was placed back in the uterus. A haplotyping based on noninvasive prenatal test with maternal plasma DNA for target mutations confirmation was constructed and aneuploidy screening was performed as well. Our study indicates that the haplotype-assisted target mutation testing and aneuploidy screening with maternal plasma for monogenic disease has potential application in pregnant women after PGD.
Material and methods: 12 STRs in chromosome 13 were used for linkage analysis in PGD, including D13S141, D13S175, D13S633, D13S1275, D13S250, D13S232, D13S1830, D13S292, GJB2-AT1, GJB2-AT2, GJB2-TG2, GJB2-AC1. The parental haplotype was constructed using a trio strategy through two different processes, namely, the parent-assisted haplotype phasing process and the proband-assisted haplotype phasing process. The fetal haplotype was deduced afterward based on both the maternal plasma sequencing data and the parental and the proband haplotyping. The causative mutations in GJB2 gene were final confirmed with amniotic fluid DNA by Sanger sequencing as well.
Results: After STRs linkage analysis of PGD, we got 5 carriers and 3 affected embryos, but no normal embryos. The couple agreed to transfer a carrier embryo into the uterus based on completely genetic counseling. Haplotype analysis and aneuploidy screening with maternal peripheral blood showed that the fetus carried a heterozygous mutation of c.235 del C in GJB2 gene and had no aneuploidy problem. Data from Sanger sequencing with amniotic fluid was also in accordance with PGD and non-invasive prenatal testing data. Finally, a baby boy without hearing problem was delivered.
Conclusions: It was proposed that haplotype-based mutation detection and aneuploidy screening combined with PGD may be extended to prenatal testing of most monogenic disease.

Wednesday 17 June 2015 **10:00–11:45**

O-210 Predicting pregnancy outcomes using a non-invasive analysis of secretome parameters in spent blastocyst culture media using MALDI-ToF MS in ART

F. Sharara[1], R. K. Iles[2], S. A. Butler[2]
[1]*Virginia Center for Reproductive Medicine, RE/I, Reston, U.S.A.*
[2]*MAP Diagnostics, Research, London, United Kingdom*

Study question: Can the non-invasive analysis of spent blastocyst culture media by MALDI ToF MS predict ART outcomes?
Summary answer: Algorithms exploiting mass/charge variability in the spectra generated from spent blastocyst culture media can accurately predict pregnancy outcomes.
What is known already: All available technologies to evaluate successful implantation, such as PGS, require embryo biopsy. MALDI-ToF MS is successfully exploited in microbiology, but hasn't been reported previously in the context of ART. Proteins in media from embryos have been detected using MALDI and were consistent with gene expression studies; however the findings were not correlated with pregnancy outcomes. This study represents the first to correlate the spectral analysis of peptides in the embryo secretome with pregnancy outcome.
Study design, size, duration: Prospective pilot study examining 75 samples of spent media from embryo cultures using MALDI ToF mass spectrometry and subsequent correlation with pregnancy outcomes. Samples were collected and analyzed between March and December 2014.
Participants/materials, setting, methods: Spent culture media from blastocysts in culture prior to embryo transfer were collected as part of routine ART cycles and stored at –20°C. The samples were shipped frozen to the analytical laboratory and subjected to matrix assisted laser desorption ionization (MALDI), time of flight (ToF) mass spectrometry (MS).
Main results and the role of chance: Data from spectra was collected from the region 12,000 to 50,000 m/z and normalized. Quantitative characteristics of the spectral data were used to compare four groups: pregnant ongoing ($N = 32$), pregnant spontaneous abortion (SAB) ($N = 11$), pregnant biochemical ($N = 9$), and not pregnant (negative pregnancy test) ($N = 23$) alongside media controls ($N = 5$). Algorithms exploiting the m/z variability were designed to predict each outcome and all classifications were assigned using a combination of <20 cut-off based criteria. All outcomes could be predicted with 95% accuracy with only 5% incorrectly classified (1fp biochemical, 1fp SAB, and 2fp pregnant).
Limitations, reason for caution: Relatively small number of cycles and samples.
Wider implications of the findings: Predicting pregnancy outcome by embryo viability has focused on identifying single or multiple markers of success/failure, in combination with assessments of embryo morphological quality by light microscope or time-lapse video. Despite these approaches and technological developments, pregnancy successes are largely unimproved. Unlike these approaches, MALDI ToF MS of the culture media prior to embryo transfer represents an accurate, rapid and non-invasive method of determining embryo quality and likelihood of pregnancy success based on their secretome.

O-211 Blastocoel cavity contains miRNAs: novel potential biomarker of blastocyst quality

D. Cimadomo[1], L. Noli[2], A. Checchele[3], E. Scepi[1], R. Maggiulli[1], C. Scarica[1], D. Ilic[2], F. M. Ubaldi[1], L. Rienzi[1], A. Capalbo[1]
[1]*Clinica Valle Giulia, G.EN.E.R.A. Centre for Reproductive Medicine, Roma, Italy*
[2]*King's College, Assisted Conception Unit, London, United Kingdom*
[3]*Genetyx, Genetic Diagnosis Laboratory, Marostica, Italy*

Study question: Can we consistently profile and characterize miRNAs from blastocoel cavity?
Summary answer: MicroRNAs can be consistently profiled in human blastocoel cavity and the population of miRNAs detected within the blastocoel is mostly heterogeneous with respect to the cellular counterparts of the blastocyst, with some miRNAs significantly up-regulated or preferentially expressed in the former with respect to human ICM and TE.
What is known already: Only proteomic and metabolomic analyses have been published up to date characterizing human blastocoel, but no data have been ever reported profiling miRNAs within the inner cavity of a blastocyst. There are evidences of miRNAs secretion by donor cells in order to exert a gene regulatory effect upon recipient ones, highly suggesting the possibility of a miRNAs-mediated autocrine communication within the blastocyst via the blastocoel fluid.
Study design, size, duration: Five good quality expanded human blastocysts underwent blastocoel collection according to a previously published method between November and December 2014. Blastocoel samples were screened for miRNA content and compared to a reference database previously built on human ICM and TE miRNA expression profiles.
Participants/materials, setting, methods: MiRNA expression was evaluated using TLDA Cards A (Applied Biosystems) containing primer sets for 381 human miRNA sequences. Ct values at a level ≥37 cycles and miRNAs expressed in <60% biological replicates were excluded from the analysis. The mean expression level of expressed miRNAs was used for normalization.
Main results and the role of chance: Pearson's correlation of raw Ct values among blastocoel samples ranged between 0.69 and 0.78. It was instead comprised between 0.33 and 0.45 when comparing them to ICM, and between 0.29 and 0.39 to TE. Minimum and maximum number of miRNAs detected in

the blastocoel were 50 and 51. Thirty-three were expressed in at least 60% of samples run. Twenty-one out of them were also common to ICM (63.6%), 24 to TE (72.7%), and 19 to both (57.5%). Normalized Ct hierarchical clustering, built on complete linkage and Euclidean distance, highlighted a sharp division between ICM, TE and blastocoel. The volcano plot built on the parametric test Limma and Benjamini-Hochberg correction showed 6 and 7 miRNAs up-regulated ($p < 0.001$) in blastocoel versus ICM and TE, respectively. One and 2 were instead respectively down-regulated ($p < 0.001$).

Limitations, reason for caution: Since miRNAs secretion is a dynamic process throughout blastocyst expansion and only fresh good quality expanded blastocysts were included, we need data on blastocoels from thawed, bad quality and/or blastocysts of different expansion grades. Prospective studies are also needed to investigate correlations between blastocoel miRNA profiling and blastocyst implantation.

Wider implications of the findings: This is the first profiling of miRNAs from blastocoel. It can mirror important parameters such as blastocyst morphological quality, metabolic or degenerative processes, and reproductive competence. To this regard, we still lack methods to boost our predictive power upon blastocyst implantation potential beyond current limits, and blastocoel miRNA evaluation is an unexplored strategy in this scenario.

Study funding/competing interest(s): Funding by hospital/clinic(s) – G.EN.E.R.A. centres for reproductive medicine.

Trial registration number: None.

Keywords: blastocoel, miRNA, embryo selection

O-212 Association between blastocoel proteins abundance and embryo chromosomal status in humans

M. Poli[1], A. Ori[2], T. Child[1], S. Jaroudi[3], K. Spath[1], M. Beck[2], D. Wells[1]

[1]*University of Oxford, Nuffield Department of Obstetrics and Gynaecology, Oxford, United Kingdom*

[2]*European Molecular Biology Laboratory, Structural and Computational Biology Unit, Heidelberg, Germany*

[3]*Reprogenetics UK, Institute of Reproductive Sciences, Oxford, United Kingdom*

Study question: Can protein contained in single human blastocoels be accurately measured? Could this assessment be employed to identify an embryo's developmental competence?

Summary answer: We succeeded in developing a sensitive Mass Spectrometry (MS) method allowing characterization of the proteome of blastocoel fluid in pooled samples. Further refinements now enable reliable quantification of selected proteins in blastocoel samples from individual embryos, revealing two proteins with abundance potentially associated with the ploidy status of the embryo.

What is known already: To develop an accurate embryo assessment methodology, several groups have been investigating embryonic secretions. However, the vast quantity of protein compounds already present in the culture media may mask much less abundant (yet clinically meaningful) proteins of embryonic origin, making biomarker discovery and subsequent measurement for clinical purposes extremely difficult. Blastocoel fluid retrieval via microsuction (Blastocentesis) provides a sample of almost exclusive embryonic origin, minimizing exogenous compound contamination and thus allowing more reliable protein identification.

Study design, size, duration: Prospective study. Tandem MS was performed on 80 samples of human blastocoel fluid. Subsequently, gene expression analysis was performed on 27 human blastocysts to confirm embryonic expression of detected proteins. Parallel Targeted MS and comprehensive cytogenetic analysis were performed on 14 human blastocysts. This study was performed over 3 years.

Participants/materials, setting, methods: The blastocoel proteome was characterized using Tandem MS. Support for embryonic origin of identified proteins was obtained via transcriptomic analysis (microarrays and quantitative PCR) of whole blastocysts. Nine Selected Reaction Monitoring Assays for quantification of confirmed protein targets were developed and validated on single blastocoels using labeled synthetic peptides.

Main results and the role of chance: Tandem MS identified 288 proteins that exist within the human blastocoel (false discovery rate <1%). Comparison of transcriptomic and proteomic data suggests that >80% of proteins found within blastocoel fluid are derived from genes actively transcribed at the blastocyst stage. Using Targeted MS, we succeeded in measuring the concentration of specific proteins of interest in single blastocoels. Interestingly, we observed that cytoplasmic proteins with a role in metabolism show an apparent increase in abundance in aneuploid embryos compared to those that are chromosomally normal. Although non-significant in this small sample ($P = 0.089$) the apparent difference warrants further investigation. Nuclear markers detected within the blastocoel, involved in chromatin stabilization, also displayed a tendency towards altered abundance in embryos with an abnormal karyotype (Fisher's Exact $P = 0.087$).

Limitations, reason for caution: Although a trend in protein abundance can already be appreciated in the cohort of samples investigated, population size should be increased to evaluate statistical significance.

Wider implications of the findings: This study offers valuable information on the transcriptome and secretome of the human blastocyst. More importantly, we demonstrate that the detection and quantification of multiple embryo-derived proteins from single human blastocoels is feasible despite the minute size of the sample analyzed. Future expansion of this study may allow confirmation of a relationship between abundance of specific blastocoel proteins and embryo developmental competence, potentially introducing a novel embryo assessment methodology based on functional proteomics.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Oxford Fertility Unit.

Trial registration number: None.

O-213 Balancing between totipotency and differentiation in the human embryo

M. Krivega[1], M. Geens[1], H. Tournaye[2], H. Van de Velde[2]

[1]*Vrije Universiteit Brussel, Reproduction and Genetics, Brussels, Belgium*

[2]*UZ Brussel, Centre for Reproductive Medicine, Brussels, Belgium*

Study question: This study aimed to investigate the relationship between unique characteristics of the cell cycle and the developmental capacity of undifferentiated early blastomeres and embryonic stem cells (hESC) from human origin. We analyzed the role of cell cycle related protein Cyclin E1 (CCNE1) in totipotency and early differentiation of hESC.

Summary answer: We described a new CCNE1-dependent intermediate embryonic cell state balancing between totipotency and differentiation. Cells in this high developmental potential state are capable to develop into trophectoderm (TE) and three distinct inner cell mass (ICM) populations: pluripotent epiblast, hypoblast and a population with a visceral endoderm (VE)-like phenotype.

What is known already: We have chosen to study CCNE1 because it is abundantly expressed during human preimplantation development and because its activity is changing depending on the developmental capacity of the embryonic cells. The periodicity of CCNE1 expression is lost in pluripotent cells as compared to somatic cells. Therefore, constitutive expression of CCNE1 was suggested to be associated with the undifferentiated state in human embryonic cells.

Study design, size, duration: First, we analyzed the CCNE1 protein expression pattern in human preimplantation embryos and hESC and correlated it with the distribution of already known pluripotency and differentiation markers. Then, CCNE1 function was examined in hESC and extrapolated to human embryos using CCNE1 overexpression and downregulation studies.

Participants/materials, setting, methods: The project was approved by the Local and the Federal Ethical Committees for research on human embryos *in vitro*. Human embryos were obtained from patients at our IVF Centre after written informed consent. HESC lines were derived at our VUB research group. Samples were analyzed by qRT-PCR and immunocytochemistry.

Main results and the role of chance: CCNE1 was ubiquitously expressed in human embryos from embryonic genome activation onwards. It was downregulated in some of the ICM cells and all the TE cells during blastocyst expansion. On day 6, CCNE1-positive cells were found exclusively in a cluster of ICM cells negative for pluripotency (epiblast) and differentiation markers (TE and hypoblast). CCNE1 co-localized with the VE marker transthyretin (TTR) in embryos, including the early cleavage stages, and in spontaneously differentiating hESC. *CCNE1* overexpression induced a VE–like phenotype in hESC. TE cells from outgrowths of plated expanded blastocysts regained CCNE1 expression

and consequently NANOG expression and eventually were converted into a pluripotent state. Upon *CCNE1* siRNA addition, blastocyst outgrowths degenerated, proving that CCNE1 is critical for the growth of undifferentiated cells.
Limitations, reason for caution: These results are based on a limited number of good-quality human embryos donated for research.
Wider implications of the findings: Our study sheds light on the processes underlying the high developmental potential of early human embryonic cells. This unique characteristic allows embryos to recover after fragmentation, cryodamage or (single cell) biopsy on day 3 for preimplantation genetic diagnosis. Knowledge on the expression and function of genes responsible for this flexibility will help us to better understand the undifferentiated state in stem cell biology and may allow us to improve techniques in assisted reproduction.
Study funding/competing interest(s): Funding by University(ies). Funding by hospital/clinic(s) – Our research is supported by grants from the Fund for Scientific Research – Flanders (FWO-Vlaanderen), the Methusalem (METH) of the VUB and Scientific Research Fond Willy Gepts of UZ Brussel.

[6]*Ghent University, Center for Medical Genetics, Ghent, Belgium*

Study question: What are the differences and similarities between naïve human embryonic stem cells (hESCs) produced via different conversion protocols, specifically in their signaling mechanisms and lineage-specific differentiation potential?
Summary answer: Converted naïve hESCs exhibit unbiased lineage-specific differentiation. Unlike other naïve media, our Naïve Conversion Medium (NCM) generated naïve hESCs with significantly increased *KLF2* and *PRDM14* expression, known to induce robust naïve pluripotency in mouse ESCs. Furthermore, NCM revealed the role of PI3K/AKT pathway in inducing naïve pluripotency in hESCs.
What is known already: Until recently, hESCs were shown to exist in a state of primed pluripotency. Mouse stem cells display a naïve or primed state of pluripotency, depending on the embryo stage from which they are harvested and the used culture conditions. Naïve mESCs can undergo single cell bulk culture and are more homogenous leading to unbiased and efficient directed differentiation. Several culture conditions have been reported inducing conversion of primed hESC towards a more naïve state.
Study design, size, duration: UG11 (XY, primed state) hESC line was subjected to naïve conversion on mouse embryonic fibroblasts in low oxygen conditions in (i) Naïve Human Stem Cell Medium, NHSM, (ii) Reverse toggling protocol, RT and iii) our novel medium NCM containing PD0325901, CHIR99021, Forskolin, Ascorbic acid and basic fibroblast growth factor.
Participants/materials, setting, methods: The following outcome parameters were compared in the converted line induced by the 3 different culture conditions: doubling time, single cell clonogenicity, karyotype, spontaneous differentiation, pluripotency and directed differentiation towards ectoderm. Converted naïve hESCs were also assessed for signaling mechanisms via qRT-PCR.
Main results and the role of chance: Domed hESC colonies emerged within 5–7 days in NCM and NHSM conditions, whereas this occurred after 2 weeks using RT. NCM cells manifested a faster doubling time (16 h) compared to NHSM (19 h), RT (24 h) and the primed counterpart (48 h). Single cell clonogenicity was similar between NCM and NHSM (95%) but reduced in RT (77%). Converted hESCs were positive for *OCT4/NANOG* and spontaneously differentiated into all germ layers. NCM-hESCs showed significant upregulation of *KLF2* compared to other conditions whereas in NHSM-hESCs, *KLF4* was significantly upregulated. Differentiation towards ectoderm demonstrated upregulation of ectoderm markers in NCM and NHSM-hESCs whereas primed and RT-hESCs co-expressed mesodermal and endodermal markers. The role of PI3K/AKT pathway in naïve pluripotency was shown by upregulation of *PRDM14* and *TCL1B* ($p < 0.001$) in NCM-hESCs.
Limitations, reason for caution: To further validate these results, the number of hESC lines need to be increased including both male and female cell lines. Also, directed differentiation potential towards mesoderm and endoderm needs to be assessed.
Wider implications of the findings: Our results reveal subtle differences in signaling mechanisms controlling pluripotency, and more importantly, reveal a functional variety in naïve hESCs produced in different culture conditions. The unique properties of naïve hESCs facilitating unbiased lineage-specific differentiation and their ability to undergo single cell bulk culture makes them highly clinically relevant.
Study funding/competing interest(s): Funding by University(ies) – This research is supported by the Concerted Research Actions funding from Bijzonder Onderzoeksfonds University Ghent (BOF GOA 01G01112).

Study question: To establish if routinely applied protocol of cryopreservation causes any changes in mitochondrial DNA (mtDNA) sequence.
Summary answer: This preliminary data suggests that cryopreservation can cause an increase in mtDNA mutation/variants in human embryonic stem cells.
What is known already: Cryopreservation is a routine technique used in assisted reproduction for storage of embryos, sperm and oocytes. The negative impact of freezing has been extensively studied on the cellular level; however, much less attention has been paid to the potential effect of freezing on the integrity of genome. No studies have ever been done to assess direct effect of freezing on the DNA of human embryos or stem cells.
Study design, size, duration: MtDNA was sequenced in 4 lines of embryonic stem cells derived from embryos with no known genetic abnormalities (KCL), carrying Huntington disease (HD), Von Hippel-Lindau (VHL) or Myotonic dystrophy (MD) before cryopreservation, immediately and 72 h after cryopreservation (number = 135). Four different regions of mtDNA (CYT-b, ATPase6, ND-4 and loop) were analysed.
Participants/materials, setting, methods: Embryonic stem cells were derived from the blastocysts. Cells were vitrified using ethylene glycol and dimethylsulfoxide containing cryoprotectant media and straws. After multiple displacement amplification of mtDNA, the loci of interests were amplified and sequenced before and after cryopreservation. Multi-factor ANOVA was used to examine the differences in mutation frequency.
Main results and the role of chance: The analysis of mtDNA before and immediately after vitrification showed that the rate of mutation increased significantly to 0.03 per 100 bps ($p = 0.038$). The significant change in mutation rate persisted at the rate of 0.05 after cryopreserved-thawed cells were incubated for further 72 h. There was also a significant difference in the mutation rate between different cell lines ($p < 0.001$, ANOVA). For example, VHL-4 line had more prominent increase in mutation rate to 0.1, whereas HD and KCL lines had 0.013 and 0.039 respectively. The rate of mutations was significantly ($p < 0.034$) higher in Loop region (0.12) in comparison with CYT-B (0.18) or ND-4 (0.12). The majority of detected mutations was mostly substitutions ($n = 16$). There were also single base-pair deletions ($n = 9$) and insertions ($n = 2$).

Limitations, reason for caution: The above findings might be related to the individual cell lines or protocols used in this experience and cannot be generalised to a wider population. However, this study warns the need for further investigations if different protocols of cryopreservation may affect mtDNA in embryonic stem cells and human embryos.
Wider implications of the findings: Our results demonstrate that vitrification can cause an increase in mtDNA variations in human embryonic stem cells. However, this effect is not equally seen between different cell lines. It is necessary to elucidate further if these changes have any immediate or delayed effect on cell function. It is also important to establish, if similar effect is present in human embryos during cryopreservation.

O-216 The copy number of mitochondrial DNA detected by next generation sequencing (NGS) can effectively predict the genetic stability of human blastocysts

K. Tan[1], F. F. Wang[2], Y. Q. Tan[1], X. Y. Yin[2], S. P. Zhang[1], G. Vajta[2], F. Gong[1], B. Xiong[3], K. L. Luo[3], Y. Liang[4], Z. Wang[4], H. M. Yang[4], G. X. Lu[3], W. Wang[2], G. Lin[1]

[3]*Reproductive and Genetic Hospital of CITIC-Xiangya, Reproductive Center, Changsha, Hunan, China*
[4]*BGI, Research Institute, Shenzhen, China*

Study question: Is the copy number of mitochondrial DNA (mtDNA) correlated to the genetic stability and developmental potentiality of blastocysts?
Summary answer: Significant difference of the copy number of mtDNA can be found in blastocysts with both euploid and aneuploid genome. Blastocysts from young women contained significantly lower copy number of mtDNA compared to aged women. Meanwhile, developing faster and good quality blastocysts contained lower copy number of mtDNA.
What is known already: Mitochondria are important organelles providing energy for ovular activation and embryo development. Change of the copy number of mitochondria may lead to inadequate mitochondrial activities and result in abnormal development or even pregnancy failure. Whole genome amplification of single-cell and next generation sequencing (NGS) can be used to analyze embryo genome and mtDNA.
Study design, size, duration: A retrospective study was performed involving 440 couples with indications to *in vitro* fertilization treatment, 1528 blastocysts were biopsied and frozen embryo transplant was carried out using embryos with balanced genome. Embryos were subjected to preimplantation genetic diagnosis/screening using next generation sequencing (NGS-PGD/PGS) between October 2011 and September 2014.
Participants/materials, setting, methods: The study was performed at the Reproductive and Genetic Hospital of CITIC-Xiangya, and BGI-Health, China. The ratio between the mean sequencing depth of the mtDNA and the genome of each blastocyst was calculated, which represented the relative copy number of mtDNA. Mann-Whitney-Wilcoxon (MWW) was used for statistical analysis.
Main results and the role of chance: The sequencing data covered 5.5 ± 1.2% of the whole human genome and 98.7 ± 3.1% of mtDNA. The copy number of mtDNA in euploid blastocysts was significantly lower than that of the chromosomally abnormal blastocysts (291.46 vs. 317.39, $P < 0.001$). Significantly reduced copy number of mtDNA was also found in blastocysts from young women (age ≤35 years) comparing to blastocysts from the aged women (300.07 vs. 322.07, $P = 0.002$). Similarly, The copy number of mtDNA also correlated to the development rate of the embryo and the blastocyst quality, blastocysts with higher ranking contained considerably fewer copies of mtDNA than blastocysts with lower ranking and poor development ($P < 0.001$).
Limitations, reason for caution: Complete pregnancy outcomes could not be obtained as some blastocysts were not transferred yet. Future data collection is warranted.
Wider implications of the findings: Preimplantation genetic diagnosis/screening using NGS-based whole genome sequencing is able to achieve high coverage of mtDNA. It is possible to evaluate the potential of embryonic development by embryonic mitochondrial analysis. MtDNA copy number variation can be used as a potential marker to predict pregnancy rate and live birth rate.
Study funding/competing interest(s): Funding by national/international organization(s) – This work was supported by a grant from the Major State Basic Research Development Program of China (No. 2012CB944901) and National Science Foundation of China (No. 81222007). The authors have no competing interests to declare.
Trial registration number: NA.

O-217 Pregnancy rates and risk of ovarian hyperstimulation syndrome (OHSS) in a fixed GnRH-antagonist versus GnRH-agonist protocol: randomized controlled trial including 1099 first IVF/ICSI cycles

M. Toftager[1], J. Bogstad[1], K. Løssl[1], L. Prætorius[1], A. Zedeler[1], T. Bryndorf[2], L. Nilas[1], A. Pinborg[1]
[1]*Hvidovre Hospital, OBGYN Section of Infertility, Hvidovre, Denmark*
[2]*Private Gynaecologist, General and Infertility, Copenhagen, Denmark*

Study question: Are ongoing pregnancy rate (OPR) and risk of OHSS similar in a GnRH-antagonist vs. agonist protocol in first cycle patients <40 years of age including both low and high responders? What is the risk of hospital admission and ascites puncture due to OHSS in each treatment group?
Summary answer: Similar OPR (23.8 vs. 22.8%) ($P = 0.240$) and risk of OHSS (6.0 vs. 5.7%) ($P = 0.282$) were observed in the GnRH-antagonist vs. agonist group with a mean number of 1.1 embryos transferred. However 1.6 vs. 3.3% ($P = 0.055$) were admitted to hospital and none vs. 1.8% had ascites puncture in the GnRH-antagonist vs. agonist group.
What is known already: Previous studies on GnRH-antagonist vs. agonist protocol show similar pregnancy rates, but most studies are smaller and heterogeneous including selected groups. Most studies show reduced risk of OHSS with GnRH-antagonist protocol however the OHSS criteria differ. A meta-analysis reported no significant difference in OPR when GnRH-antagonist and GnRH-agonist was compared (OR = 0.88, = 0.05). And found a significant difference in OHSS favouring GnRH-antagonist (RD = -0.03, $p < 0.00001$). The largest RCT is from 2000 and included 730 infertile randomized 2:1.
Study design, size, duration: A prospective RCT including 1099 subjects randomized to GnRH-antagonist vs. agonist in a ratio 1:1 and enrolled over a period of 5 years. A non-inferiority study designed to detect a 2.5% difference in moderate/severe OHSS between the two groups, stratified for age, IVF-centre and IVF/ICSI. Women were <40 years.
Participants/materials, setting, methods: All first IVF/ICSI cycles ($n = 1099$) including women with irregular cycles were given fixed rFSH dose of 150 IU or 225 IU according to age <=36 years or >36 years, with dose-adjustment at stimulation day-6. OHSS parameters were obtained day 3- and 14 post-transfer. Ongoing pregnancy was determined by transvaginal ultrasound in gestational week 8–9.
Main results and the role of chance: OPR was 23.8 vs. 22.8% in the GnRH-antagonist vs. agonist group ($P = 0.240$) with a mean number of 1.1 embryos transferred. Mean age (32.1 vs. 32.0 years) and mean BMI (23.1 vs. 22.7) were similar in the groups. Furthermore both groups included low-responders and 12.7% women with irregular cycles. The overall incidence of mild OHSS was 29.6 vs. 32.2%, moderate OHSS 3.8 vs. 3.1% and severe OHSS 2.2 vs. 2.6% in the GnRH-antagonist vs. agonist group with no significant differences. In the GnRH-antagonist vs. agonist groups 4.2 vs. 7.5% were seen by a physician due to OHSS ($P = 0.009$) and 1.6 vs. 3.3% were admitted to hospital due to OHSS ($P = 0.055$). None had ascites-puncture in the GnRH-antagonist group vs. 1.8% ($n = 10$) in the GnRH-agonist group.
Limitations, reason for caution: Groups were equal with regard to age, BMI and women with irregular cycles, however a small difference in duration of infertility was observed. Ultrasonic measurements were performed by different

physicians and inter-observer bias may be present. Finally, the physicians were not blinded to GnRH-treatment group.
Wider implications of the findings: Both GnRH-antagonist and agonist protocol can be applied to first cycle patients <40 years including low and high responders as long as the fixed dose of rFSH does not exceed 150–225 IU. However caution should be taken as 1.8% in the GnRH-agonist group had ascites puncture. Future treatment should not be restricted to either of the two protocols, but can be individualised according to patient ovarian reserve and patient perceptions towards the two treatment approaches.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Research grants are funded by Merck Sharp & Dohme (MSD). The funders had no influence on the data collection, analyses or conclusions of the study. No conflict of interests to declare.

O-218 Transdermal testosterone pre-treatment in poor responders undergoing ICSI: a randomized clinical trial

J. K. Bosdou[1], E. M. Kolibianakis[1], C. A. Venetis[2], K. Dafopoulos[3], L. Zepiridis[1], K. Chatzimeletiou[1], A. Makedos[1], G. Anifandis[3], C. I. Messini[3], A. Daniilidis[1], A. Mitsoli[1], D. Savvaidou[1], I. E. Messinis[3], B. C. Tarlatzis[1]
[1]*Aristotle University of Thessaloniki Medical School, Unit for Human Reproduction – 1st Department of Obstetrics and Gynecology, Thessaloniki, Greece*
[2]*University of New South Wales, School of Women's and Children's Health UNSW Medicine, Sydney, Australia*
[3]*University of Thessalia Medical School, Department of Obstetrics and Gynecology, Larissa, Greece*

Study question: Does pre-treatment with transdermal testosterone increase the number of cumulus-oocyte complexes retrieved (COCs) in poor responders, undergoing intracytoplasmic sperm injection (ICSI) using recombinant follicle stimulating hormone (FSH) and gonadotropin releasing hormone agonists (GnRHa)?
Summary answer: Transdermal testosterone pre-treatment (10 mg for 21 days) does not seem to increase the number of COCs retrieved in poor responders undergoing ICSI.
What is known already: Androgens have been suggested to play an important role in early follicular development by enhancing ovarian sensitivity to FSH. In a recent meta-analysis, testosterone pretreatment has been shown to result in an increase of 1.5 COCs as compared to no pretreatment. However this effect was based on the analysis of two randomized controlled trials (RCTs) including 163 patients. Consequently, there is a need for more RCTs to confirm or deny these results.
Study design, size, duration: The present RCT has been designed to detect a difference of 1.5 COCs (sample size required = 42 patients). From 02/2014 until 12/2014, 39 poor responders fulfilling the Bologna criteria have been randomized (using a randomization list) to either testosterone pre-treatment for 21 days (n = 22) or no pre-treatment (n = 17).
Participants/materials, setting, methods: All patients underwent a long follicular GnRHa protocol. Recombinant FSH stimulation was started on day 22 following GnRHa initiation. In the testosterone pre-treatment group, a daily dose of 10 mg of testosterone gel was applied transdermally for 21 days starting from GnRHa initiation. Results are expressed as median (interquartile range).
Main results and the role of chance: No differences in baseline characteristics were observed between the two groups compared. Testosterone levels were significantly higher in the testosterone pre-treatment on the day of initiation of FSH stimulation [114 (181) ng/dL vs. 20 (26) ng/dL, respectively, p = 0.001]. Duration of FSH stimulation was comparable between the groups compared [13 (3) days vs. 12 (3.5) days, respectively, p = 0.39]. The number of COCs retrieved was not different between the testosterone pre-treatment and the no pre-treatment groups [3 (5) vs. 3 (2), 95% CI for the median: 1.26–4 vs. 3–4, respectively]. Similarly no differences were observed regarding fertilization rates [66.7% (27.8) vs. 66.7% (41.2), respectively, p = 0.71] and ongoing pregnancy rates per randomized patient (9.1 vs. 11.8%, respectively, rate difference: -2.7%, 95% CI: -23.0 to +17.7).
Limitations, reason for caution: An improvement in IVF outcome using a larger dose of testosterone or a longer pre-treatment period cannot be excluded. Moreover, due to sample size restrictions, no conclusions can be drawn regarding the probability of pregnancy.
Wider implications of the findings: The results of this randomized clinical trial, suggesting that pre-treatment with 10 mg of transdermal testosterone for 21 days cannot improve ovarian response by 1.5 oocytes or more, could be used to more accurately consult patients with poor ovarian response.
Study funding/competing interest(s): Funding by national/international organization(s) – This study has been partially funded by a Scholarship awarded to the principal investigator from the Academy of Athens.
Trial registration number: NCT01961336.

O-219 The optimal dose of triptorelin for triggering final oocyte maturation in patients at high-risk for OHSS: a randomized clinical trial

G. T. Lainas[1], J. K. Bosdou[1], C. A. Venetis[2], I. A. Sfontouris[3], K. Chatzimeletiou[1], L. Zepiridis[1], A. Makedos[1], A. Daniilidis[1], A. Mitsoli[1], D. Savvaidou[1], T. G. Lainas[3], B. C. Tarlatzis[1], E. M. Kolibianakis[1]
[1]*Aristotle University of Thessaloniki Medical School, Unit for Human Reproduction – 1st Department of Obstetrics and Gynecology, Thessaloniki, Greece*
[2]*University of New South Wales, School of Women's and Children's Health UNSW Medicine, Sydney, Australia*
[3]*EUGONIA, Eugonia Unit of Assisted Reproduction, Athens, Greece*

Study question: Does the dose of triptorelin, used for triggering final oocyte maturation, affect the maturity of the oocytes retrieved in patients at high risk for ovarian hyperstimulation syndrome (OHSS) undergoing ovarian stimulation for IVF using GnRH antagonists and recombinant follicle stimulating hormone (recFSH)?
Summary answer: The dose of triptorelin for triggering final oocyte maturation does not seem to affect the maturity of the oocytes retrieved in high risk for OHSS patients undergoing ovarian stimulation for IVF.
What is known already: Triptorelin is widely used, as a substitute to human chorionic gonadotropin, to eliminate the risk of OHSS in patients undergoing ovarian stimulation for IVF. However, no data is currently available regarding its optimal dose used to trigger final oocyte maturation.
Study design, size, duration: Currently 50 patients at high-risk for OHSS have completed the study. Patients were randomized to receive 0.1 mg [0.1 mg group (n = 17)], 0.2 [0.2 mg group (n = 18)] mg or 0.4 mg [0.4 mg group (n = 15)] of triptorelin to trigger final oocyte maturation.
Participants/materials, setting, methods: Ovarian stimulation was performed with recFSH and GnRH antagonists. Hormonal evaluation included assessment of FSH, LH, estradiol (E2) and progesterone (P) on the day of triggering, 8, 36 h as well as on days 3, 4, 7, 10 following triptorelin administration. Results are expressed as median (interquartile range).
Main results and the role of chance: No significant differences in patient baseline characteristics were observed among the 0.1 mg group, the 0.2 mg group and the 0.4 mg group. The number of COCs retrieved was not different among groups compared [25 (18) vs. 26 (19) vs. 27 (20) COCs, respectively, p = 0.86]. Regarding the primary outcome measure, the percentage of mature oocytes retrieved, no differences were observed among the groups compared [81.8 (18.7)% vs. 80.4 (25.2)% vs. 83.8 (12.6)%, respectively, p = 0.91]. Duration of luteal phase was also not significantly different among groups [7 (2) vs. 7 (3) vs. 7 (2) days, respectively, p = 0.47]. No significant differences were present in serum levels of LH, FSH, E2, P following triggering of final oocyte maturation among the groups compared.
Limitations, reason for caution: The results obtained refer to the comparison of various doses of the commonly used GnRH agonist triptorelin, according to the published literature. Whether these results are also valid for different types of GnRH agonist used for triggering final oocyte maturation cannot be deducted from this study.
Wider implications of the findings: Based on the results of the current study it appears that high doses (0.2 mg, 0.4 mg) of the GnRH agonist triptorelin as compared to a low (0.1 mg) dose, used to trigger final oocyte maturation, do not confer any apparent benefit.
Study funding/competing interest(s): Funding by University(ies) – Aristotle University of Thessaloniki, Greece.
Trial registration number: NCT01973842.

Keywords: agonist trigger, triptorelin dose, high risk for OHSS, oocyte maturity, OHSS prevention

O-220 A randomized clinical trial comparing two cycles of minimal stimulation IVF with single embryo transfer to one cycle of conventional IVF with double embryo transfer

J. Zhang[1], M. Feret[1], M. Yang[1], D. Bodri[2], A. Chavez-Badiola[1], S. Repping[2], F. Van der Veen[2], M. Van Wely[2], Z. Merhi[3]
[1]*New Hope Fertility Center, Fertility Clinic, New York, NY, U.S.A.*
[2]*Center for Reproductive Medicine, Academic Medical Center, Amsterdam, Netherlands Antilles*
[3]*NYU Langone Medical Center, Obstetrics and Gynecology, New York, NY, U.S.A.*

Study question: Are there differences in clinical outcomes between 2 cycles of minimal stimulation *in vitro* fertilization (IVF) with single embryo transfer versus one cycle of conventional IVF with double embryo transfer?
Summary answer: Although minimal stimulation IVF resulted in relatively lower live birth rates, it prevented ovarian hyperstimulation syndrome (OHSS), lowered multiple pregnancy rates, and decreased gonadotropin use.
What is known already: Minimal stimulation IVF with single embryo transfer is re-emerging in many centers worldwide as an alternative for conventional IVF.
Study design, size, duration: A randomized controlled trial was completed among 564 infertile women between 2009 and 2013 at a single fertility center.
Participants/materials, setting, methods: Women under the age of 38 who underwent their first IVF cycle were randomly allocated to either one cycle of conventional IVF (Group 1) or to 2 cycles of minimal stimulation IVF (Group 2). Women in Group 1 received high doses of gonadotropins following long GnRH agonist suppression protocol then fresh transfer of 2 blastocysts. Women in Group 2 received extended clomiphene citrate regimen and low-dose gonadotropins followed by freeze-all embryo strategy. Then, a single thawed blastocyst transfer was performed in 2 consecutive cycles.
Main results and the role of chance: 279 women were included in Group 1 and 285 women in Group 2. The number of oocytes retrieved (4.3 ± 3.2 vs. 12.8 ± 8.0; $p < 0.0001$), MII oocytes (3.1 ± 2.4 vs. 8.3 ± 5.8; $p < 0.0001$) and blastocysts formed (2.6 ± 1.9 vs. 5.9 ± 4.3; $p < 0.0001$) were significantly lower in Group 2 compared to Group 1. Group 1 had implantation rate of 56%, cumulative ongoing pregnancy rate of 74%, and live birth rate of 62%. Group 2, first cycle, had implantation rate of 47%, cumulative ongoing pregnancy rate of 47%, and live birth rate of 39%. Group 2, second cycle, had implantation rate of 48%, cumulative ongoing pregnancy rate of 48%, and live birth rate of 41% (RR = 0.73; CI: 0.62–0.86; $p = 0.0001$ compared to Group 1). There were 16 cases of moderate to severe OHSS cases in Group 1 but no cases of OHSS in Group 2. There were 34% multiple pregnancy rates in Group 1 compared to 9.3% in Group 2 ($p < 0.05$). Gonadotropin consumption per cycle was significantly higher in Group 1 compared to Group 2 (2079 ± 389 vs. 459 ± 131 IU, $p < 0.0001$).
Limitations, reason for caution: This trial compared two completely different protocols, thus it is unable to disentangle the effects of various components of minimal versus conventional IVF on the outcomes of the study.
Wider implications of the findings: This study was performed at a single center, thus hampering generalisability to other fertility centers.
Study funding/competing interest(s): Funding by hospital/clinic(s) – New Hope Fertility Center.
Trial registration number: The trial was registered before its start at clinicaltrials.gov: NCT00799929.
Keywords: IVF, oocyte, minimal stimulation, OHSS, multiple pregnancy

O-221 Double blind cross-over randomized controlled trial comparing letrozole versus clomiphene citrate for ovulation induction in women with polycystic ovarian syndrome

S. Amer[1], A. Fakis[2], J. Smith[2], R. Shaw[1], A. Mahran[3]
[1]*University of Nottingham, Obstetrics and Gynaecology, Derby, United Kingdom*
[2]*Derby Hospital NHS Foundation Trust, R&D, Derby, United Kingdom*
[3]*University of Minia, Obstetrics and Gynaecology, Minia, Egypt*

Study question: Would letrozole as a primary ovulation induction agent generate better pregnancy rates than clomiphene citrate (CC) in subfertile women with anovulatory polycystic ovarian syndrome?
Summary answer: Based on blind analysis, ovulation induction with treatment B produced a significantly ($p = 0.026$) higher pregnancy rate (61%) compared to that (43%) produced by treatment A in anovulatory women with PCOS.
What is known already: Theoretically, letrozole is superior to CC due its short half-life and absence of peripheral anti-oestrogenic effects. According to the most recent Cochrane systematic review (2014), Letrozole appears to improve live birth and pregnancy rates in anovulatory women with PCOS, compared to clomiphene citrate. However, the authors of this review stated that the quality of evidence in this review was rated low due to poor reporting of study methods and possible publication bias.
Study design, size, duration: This double blind RCT included 159 participants between April 2007 and June 2014. Subjects were randomly allocated to either Treatment A ($n = 79$) or B ($n = 80$) in a 1:1 ratio. Both drugs were encapsulated to look identical. Randomization was performed in mixed blocks and stratified by patients' BMI (<30 and 30–35 kg/m^2).
Participants/materials, setting, methods: Treatment started with one tablet (CC 50 mg, letrozole 2.5 mg) increasing to two in non-responders and continuing until pregnancy or for up to 7 cycles. Non-responders were crossed over to the other treatment after a 6-week break. Cycles were initially monitored with ultrasound follicle tracking then mid-luteal serum progesterone measurement.
Main results and the role of chance: Amongst the 159 participants included in the intention-to-treat analysis, four women conceived before treatment and four were lost-to-follow-up. The remaining 151 participants (74 on A and 77 on B) completed at least first treatment. Women receiving treatment B achieved a significantly ($p = 0.026$) higher pregnancy rate (61%) than those on treatment A (43%). Livebirth (LB) rates were not statistically different between the two groups, although there was a trend towards higher rates on treatment B (49 vs. 35%). Amongst the 76 women crossing over, pregnancy and LB rates on B (29 and 24%) were not statistically ($P = 0.604$ and $P = 0.781$) different from A (23 and 19%).
Limitations, reason for caution: This study was powered at 80% as a parallel head-to-head RCT to detect 20% difference in pregnancy rates (before the cross-over) at 5% significance level. An interim power calculation confirmed that at least 75 patients per arm were needed to achieve 80% power.
Wider implications of the findings: Although, the treatment code has not been broken at the time of writing this abstract, all the details will be presented in the meeting. Treatment B appears significantly more effective than A and should be considered a first choice in anovulatory PCOS women. We believe that these results are generalisable and will have an impact on clinical practice worldwide as our PCOS cohort has been selected according to the widely accepted Rotterdam criteria.
Study funding/competing interest(s): Funding by University(ies). Funding by hospital/clinic(s) – Derby Hospitals NHS Foundation Trust R&D funding Scheme. University of Nottingham Medical School at Derby. No conflict of interest to declare.
Trial registration number: www.Clinicaltrials.gov – NCT00478504.
PCOS, ovulation induction, letrozole, clomiphene citrate

O-222 A novel model of luteal phase ovarian stimulation in follicular phase is an alternative in women with polycystic ovarian syndrome: a pilot study

Y. Wang[1], H. Chen[1], H. Y. Guo[1], Q. J. Chen[1], Y. P. Kuang[1]
[1]*Shanghai Ninth Hospital Affiliated to Jiaotong University, Reproduction, Shanghai, China*

Study question: To clarify the effect of ovarian stimulation using hMG and medroxyprogesterone acetate (MPA) in terms of ovarian response and the subsequently pregnancy outcome in frozen-thawed embryo transfer (FET) cycles in women with polycystic ovarian syndrome (PCOS).
Summary answer: The study shows that hMG and MPA protocol lead to similar efficacy compared to short protocol in inducing oocyte maturation without adversely affecting the pregnancy outcome meanwhile eliminating the risk of OHSS.

What is known already: Our previous studies showed that no cases experienced a premature LH surge or moderate/severe ovarian hyperstimulation syndrome in PCOS patients during the luteal-phase ovarian stimulation cycles. Furthermore, luteal-phase ovarian stimulation is feasible for producing competent oocytes/embryos in women undergoing IVF/ICSI treatments, with optimal pregnancy outcomes in FET cycles. But it is difficult to perform ovarian stimulation during the luteal phase of the menstrual cycle since some PCOS cases have irregular menstrual cycles or anovulation.
Study design, size, duration: In the prospective controlled study, 120 PCOS patients undergoing IVF/ICSI were recruited between January 2014 and October 2014 and classified into two groups according to the ovarian stimulation protocols: hMG and MPA (group A, $n = 60$) or short protocol (group B, $n = 60$).
Participants/materials, setting, methods: In the study group, hMG (225 IU) and MPA (10 mg/day) were administered simultaneously beginning on cycle day 3. Ovulation was co-triggered by a GnRH agonist (0.1 mg) and hCG (1000 IU) when dominant follicles matured. A short protocol was used as a control. Viable embryos were cryopreserved for later transfer in both protocols.
Main results and the role of chance: No evidence of statistically difference was found in the proportion of mature oocytes retrieved (86.72 vs. 89.2%) and fertilization rate (76.82 vs. 68.78%) between the two groups. Doses of hMG administrated and serum E_2 on day of hCG in group A are significantly higher than group B ($P < 0.05$). Clinical pregnancy rates per transfer (45.65 vs. 44.15%), ongoing pregnancy rates (41.98 vs. 41.56%), implantation rates (33.08 vs. 31%) and cumulative pregnancy rates per patient (56.67 vs. 53.33%) were comparable between the two groups. The incidence of OHSS was low between the two groups (0 vs. 1.67%), with no significant difference.
Limitations, reason for caution: Current evidence about the safety of MPA used in COH is scarce. MPA was used during the follicle phase and was not further exposed after oocyte retrieval in this trial. No direct evidence demonstrated the role of MPA on oocyte development potential in previous reports.
Wider implications of the findings: MPA has the advantages of an oral administration route, easy access, more control over LH levels and eliminating the risk of OHSS, which will help to establish a new regimen of ovarian stimulation in PCOS patients in combination with embryo cryopreservation.
Study funding/competing interest(s): Funding by national/international organization(s) – This work was supported by grants from Shanghai Natural Science Foundation of China (14ZR1423900 to YW), National Natural Science Foundation of China (NSFC) the 81470064 (to YW).
Trial registration number: ChiCTR-OCH-14004424.

[3]*Zagazeg University, Obstetrics and Gynecology, Zagazeg, Egypt*
[4]*Cairo University, Obstetrics and Gynecology, Cairo, Egypt*
[5]*Vrije Universiteit Brussel, Reproductive Medicine, Brussel, Belgium*

Study question: Does endometrial scratching in the luteal phase of the preceding cycle improve live birth rate after IVF treatment in women with, at least one, previous IVF failure?
Summary answer: Endometrial scratching does not improve live birth rate in women undergoing IVF treatment with previous one IVF failure. Nevertheless, it may mprove live birth in women with two or more previous IVF failures
What is known already: A Cochrane review examining the effect of this intervention had found some evidence that endometrial scratching may improve IVF outcome.
Study design, size, duration: A parallel two arms multicentre RCT. The study was conducted between 2010 and 2014. We estimated that our intervention may increase clinical pregnancy rate from 30% in control group to 45% in the intervention group, hence, a total of 350 women is needed for trial with 80% power and 5% significance level.
Participants/materials, setting, methods: 387 Participants with at least one previous failed IVF cycle. Three participating Units; one university unite and two private units. Randomization through a computer generated tables of random numbers. Opaque sealed envelope to conceal allocation. Women were blinded to their allocation while physicians were not. Women in the intervention group were subjected to endometrial scratching twice in the luteal phase of the preceding IVF cycle while women in the control group were subjected to a placebo procedure (introduction of a sound intracervically).
Main results and the role of chance: Our results showed no difference in live birth rate between the two groups of women (47.2 versus 38.1%, $p = 0.08$). However, regression analysis revealed that endometrial scratching was an independent predictor of live birth in the subgroup of women with two or more previous failure after control of other independent predictors ((OR) 3.4, $p = 0.005$).
Limitations, reason for caution: We acknowledge that this study has two important potential sources of bias. The first is the use of intra-cervical manipulation in the control group and the second is the fact that 12/194 (6.2%) women in the control group had a hysteroscopy. Although regression analysis showed a potential benefit of this intervention in women with two or more previous failures, the number of women is underpowered to give firm evidence.
Wider implications of the findings: Endometrial scratching should not be performed in women without at least two previous IVF failures. Larger trial with adequate power is warranted to scrutinize the effect of this procedure and to clarify the real population that may benefit from this intervention.
Study funding/competing interest(s): Funding by University(ies) – Mansoura University, Egypt.
Trial registration number: ClinicalTrials.gov under identifier: NCT01245309.
Keywords: IVF, endometrial scratch

Study question: Have the experience of transplanting centers and the overnight transportation of ovarian tissue before cryopreservation an impact on the transplantation success? What is the success rate of transplantation into the pelvic peritoneum?
Summary answer: The success rate was higher in experienced transplantation centers and the overnight transportation of ovarian tissue did not have a negative impact on the transplantation result. Transplantation into the pelvic peritoneum resulted in high success rates.

What is known already: Cryopreservation of ovarian tissue before cytotoxic therapies and transplantation is increasingly performed. Centralized tissue banks and transplantations in specialized centers have been suggested to optimize these procedures. Ovarian tissue should be transplanted orthotopically. However, the impact of centers experience in tissue transplantation, the overnight transportation of tissue to centralized tissue banks as well as the transplantation success in the pelvic peritoneum has not been analysed.
Study design, size, duration: Retrospective analysis of 72 transplantations performed in the network Ferti*PROTEKT* (www.fertiprotekt.com) from 2007 till 2014. Transplantations performed within <12 month of data analysis, transplantations non-orthotopically, repeated transplantations and loss of follow up before 12 month after transplantation resulted in exclusion of cases, resulting in 37 analysed transplantations (one/woman) in 8 centers.
Participants/materials, setting, methods: Exclusions were due to: transplantation <12 month of data analysis (n = 17), transplantation non-orthotopically (n = 1), repeated transplantations (n = 14) and loss of follow up (n = 3). Success rate was defined as tissue activity (menstrual cycles) after 1 year and as achieved pregnancies and deliveries. Experienced centers were those who had performed ≥3 transplantations.
Main results and the role of chance: The first analysis compared the success rates in relation to the experience of the centers. Tissue activity in centers with low (n = 10) vs. high (n = 27) experience was 30 vs. 89% (p < 0.001). Pregnancy and delivery rates were 10 vs. 67% and 10 vs. 22%. Due to these differences, the following analysis included only transplantations in experienced centers. Tissue activity following no overnight transportation (n = 13) vs. overnight transportation (n = 14) was 77 vs. 100% (p = 0.05), pregnancy and delivery rates were 23 vs. 50% and 15 vs. 29%. Transplantation into the peritoneum (n = 22) resulted in tissue activity in 91% of cases, pregnancies in 36% and deliveries in 23% of cases. 86% (n = 5) of the 6 women following transplantation into the pelvic peritoneum conceived spontaneously.
Limitations, reason for caution: The data are drawn from a retrospective analysis and statistical analysis is based on low case numbers. Since 2008 the cryopreservation and transplantation techniques have been modified over the years.
Wider implications of the findings: The data suggest that centralizing ovarian tissue storage, requiring overnight transportation, is possible. Centralization of tissue allows transplantations in few experienced centers. Furthermore, centralization of these activity will improve the follow up of patients. As transplantation into the peritoneum result in high success rate, this approach might be an alternative to transplantation into the ovary. However, a randomized study is required to define the best transplantation site.
Study funding/competing interest(s): Funding by University(ies). Funding by hospital/clinic(s) – No competing interests.
Trial registration number: N/A.

O-225 Experience with 26 cryopreserved ovarian tissue grafts in a single centre: are there factors for predicting success?

G. Rozen[1], D. Gook[1], F. Agresta[2], C. J. Stern[2]
[1]*Royal Women's Hospital, Reproductive Services, Melbourne, Australia*
[2]*Melbourne IVF, Fertility Preservation Services, Melbourne, Australia*

Study question: Cryopreservation of ovarian tissue followed by transplantation has a unique role for fertility preservation however experience in humans is limited and there are uncertainties regarding its clinical efficacy, optimal grafting site, tissue volumes and factors which may predict success.
Summary answer: Clinical pregnancy occurred in 2/11 (18%) of patients who underwent stimulated cycles. Mature oocytes were largely harvested from non-ovarian graft sites and longer duration of ovarian activity was correlated with increased tissue volume and follicular density. All pregnancies occurred in women under 25 years at the time of tissue cryopreservation.
What is known already: While efficiency of this technique may have been overestimated in the literature, the main cause of follicular loss after grafting appears to be initial ischaemic injury during angiogenesis. Frozen-thawed ovarian tissue can be transplanted to the ovary, another pelvic site and outside the pelvis. While there are significant advantages of using heterotopic sites (i.e., not in or adjacent to the ovary), the clinical value of this approach has been questioned due to inferior pregnancy rates.
Study design, size, duration: We conducted a retrospective analysis of reproductive outcomes following ovarian tissue transplantations at our centre to date (2006–2014). This included 26 transplant procedures in 19 patients, following a diagnosis of premature ovarian failure.
Participants/materials, setting, methods: Ovarian tissue was harvested from 19 patients with malignant (14/19.74%) and benign (5/19.26%) diseases, and cryopreserved. Three of 19 patients had prior cytotoxic treatment. Following a diagnosis of premature ovarian failure ovarian tissue was grafted to pelvic and extra-pelvic sites, on average 5 years following extraction.
Main results and the role of chance: Ovarian activity resumed in 17/19 patients (19/26 grafts) after an average of 5.3 months. Seven patients underwent a second transplantation procedure 1–2 years after the first. Stimulated cycles in 11 patients with low dose rFSH, yielded 52 eggs (largely from non-ovarian grafts). MII oocytes were retrieved from mean follicular size 13.5 mm (range 6–20). The overall 2PN fertilisation rate was 64%. A total of 22 fresh and frozen embryos were transferred in 11 women, resulting in 2 clinical pregnancies (18%). The delivery of healthy twin girls has been reported and there is currently an ongoing 16 week pregnancy. All pregnancies occurred in patients under 25 years at cryopreservation. Follicular density and tissue volume grafted appear to be the strongest predictors of ovarian activity duration over 12 months.
Limitations, reason for caution: Trends alone can be observed from this data as the numbers are small.
Wider implications of the findings: These results add to our knowledge of worldwide experience with this technique and demonstrate the need for ongoing research to improve efficiency, especially by reducing the follicular loss which occurs prior to the establishment of neovascularisation. There is encouragement for continuing investigation into non-ovarian graft sites and optimal volumes of tissue to graft. These results support offering this technique to young women who are undergoing fertility threatening treatment.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Royal Women's Hospital and Melbourne IVF.

O-226 mTOR inhibitor can protect the primordial follicle pool in bovine ovarian tissue treated with cyclophosphamide after xenotransplantation

S. K. Kim[1], H. H. Lee[1], J. R. Lee[1], C. S. Suh[2], S. S. Kim[3], S. H. Kim[2]
[1]*Seoul National University Bundang Hospital, Obstetrics and Gynecology, Sungnam, Korea South*
[2]*Seoul National University Hospital, Obstetrics and Gynecology, Seoul, Korea South*
[3]*University of Kansas School of Medicine, Obstetrics and Gynecology, Kensas, U.S.A.*

Study question: Can administration of rapamycin or resveratrol with spermidine protect ovarian follicles from gonadotoxicity of cyclophosphamide (Cp)?
Summary answer: Coadministration of rapamycin or resveratrol with spermidine protected ovarian follicle reserve from chemotoxicity of Cp in xenografted bovine ovarian tissue.
What is known already: Cp exposure was found to induce developing follicle atresia and aberrant primordial follicle activation via the stimulation of phosphatidylinositol 3-kinase (PI3K)/Akt and mammalian target of rapamycin (mTOR) signaling pathways. Rapamycin inhibits the kinase activity of mTOR, which has been shown to result in apoptosis or autophagy depending on cell type studied. Two plant-derived agents with antioxidant properties, resveratrol (a polyphenol) and spermidine (a polyamine), enhance autophagy by modulation of S6 kinase 1 activity.
Study design, size, duration: Prospective experimental study. Fresh bovine ovarian tissue was transplanted to 6-week-old SCID mice. A total of 18 mice were randomly divided into four groups according to treated agents; group 1 PBS (control), group 2 Cp (75 mg/kg/weekly), group 3 Cp plus rapamycin (7.5 mg/kg 3 times a week), group 4 Cp plus resveratrol and spermidine (50 mg/kg 3 times a week, respectively).
Participants/materials, setting, methods: Two weeks after transplantation, these agents were injected for 2 weeks. Seven days after the last injection, ovarian grafts were recovered and processed for ovarian histology and apoptosis were analyzed by TUNEL assay. Phosphorylation of mTOR and ribosomal protein S6 (rpS6) and protein expression of LC3B were determined by Western blotting.
Main results and the role of chance: The percentage of primordial follicles was significantly higher in the group 1 and 3 (34.4 ± 17.2, 35.7 ± 17.1,

respectively) than the group 2 and 4 (20.6 ± 11.0, 20.7 ± 18.4). The percentage of apoptotic cells were similar irrespective of whether rapamycin or resveratrol was coadministered. Phosphorylation of mTOR and rpS6 were inhibited by rapamycin or resveratrol. Increased LC3B expression was noticed in the group 3 and 4 compared to in the group 2.

Limitations, reason for caution: We used a single dose of rapamycin and resveratrol with a fixed exposure time. Possible protective effects of various doses of rapamycin and resveratrol against Cp should be evaluated.

Wider implications of the findings: Rapamycin or resveratrol with spermidine may be applicable for fertility preservation in young cancer patients treated with cyclophosphamide containing regimens.

Study funding/competing interest(s): Funding by national/international organization(s) – The Korea Health Care Technology R&D Project, Ministry of Health and Welfare, Republic of Korea.

[3]*Koc University School of Medicine and MD Anderson Cancer Center, Radiation Oncology, Istanbul, Turkey*

[4]*American Hospital Women's Health Center, Assisted Reproduction Unit, Istanbul, Turkey*

[5]*Koc University School of Medicine and American Hospital Women's Health Center, Obstetrics and Gynecology/Assisted Reproduction Unit, Istanbul, Turkey*

Study question: Is there any molecular evidence for-or-against the protective effect of GnRH agonists in chemotherapy induced damage in human ovary?

Summary answer: Yes, this study provides the first evidence against the protective or attenuative effects of GnRH agonists in chemotherapy induced ovarian damage by using a novel experimental methodology utilizing real-time and quantitative transcriptional and cellular cytotoxicity indices, ovarian histomorphometry, and the markers of DNA damage, apoptosis and hormone production.

What is known already: There is an ongoing debate over the effects of GnRH agonists in the prevention of ovarian failure in women exposed to cytotoxic chemotherapy regimens since randomized controlled trials launched to answer this question yielded conflicting results. The question remained unanswered as to whether GnRH administration during chemotherapy is protective of ovarian function. We therefore aimed to investigate GnRH acting via its cognate receptors protects against cyclophosphamide induced DNA damage and cell death in human ovary.

Study design, size, duration: An in-vitro model of human ovary and granulosa cells.

Participants/materials, setting, methods: Ovarian cortical pieces (n = 10, age 14–37), nonproliferating human luteinized granulosa cells (HLGC) and proliferating nonluteinizing human granulosa cells (COV434) were cultured for 24 hrs with cyclophosphamide, paclitaxel, cisplatin, TAC regimen (docetaxel, adriamycin and cyclophosphamide) and ionizing radiation (RT, 2 Gy = LD_{50} of oocytes) with and without GnRH agonist Leuprolide acetate (12.5–25.50 ng/mL).

Main results and the role of chance: The expression of GnRH receptor in the samples were validated with qRT-PCR. E2, P and AMH productions and follicle counts in ovarian tissue samples exposed to chemotherapy and RT were significantly reduced compared to controls. The addition of GnRH did not cause any notable differences in hormone levels and follicle counts compared to chemotherapy and RT subgroups and controls (Fig-1). Similarly HLGC exposed to cytotoxic chemotherapy agents underwent apoptosis and their E2 and P productions were significantly reduced (Fig-2). COV434 cells treated with chemotherapy exhibited growth arrest and apoptosis in a dose dependent manner (Fig-3). GnRH did not prevent DNA damage or apoptosis in both cell types.

Limitations, reason for caution: These results do not rule out the possibility that GnRH may offer protection in-vivo by some mechanisms other than the interaction of GnRH with its cognate receptors in the ovary.

Wider implications of the findings: These results provide for the first time a solid molecular evidence against the protective effects of GnRH in cyclophosphamide induced damage in human ovary and granulosa cells. Therefore any patients who opt only to receive GnRH for gonadal protection should be warned about it.

Study funding/competing interest(s): Funding by University(ies) – Koc University School of Medicine and the Graduate School of Health Sciences, Istanbul Turkey.

Trial registration number: NA.

Keywords: GnRH, cyclophosphamide, ovary, apoptosis, AMH

O-228 Effect of ovarian reserve on undesirable estradiol elevation despite of letrozole co-treatment during controlled ovarian hyperstimulation for oocyte vitrification in breast cancer patients

T. Navarro González[1], E. Ceballos García[1], V. Moreno Molinero[1], L. Pérez Martín[1], Y. Gómez Sarabia[1], S. Guillén Cajo[1], M. Caballero[1], B. Gaspar Herrero[1], L. Ortiz Quintana[1], F. Pérez Milán[1]

[1]*Hospital General Universitario Gregorio Marañón, Obstetrics and Gynaecology, Madrid, Spain*

Study question: The aim of this study is to assess ovarian reserve effect on serum estradiol elevation above 500 pg/mL during controlled ovarian hyperstimulation (COH) with letrozole co-treatment in breast cancer patients undergoing oocyte preservation.

Summary answer: In letrozole-exposed controlled ovarian hyperstimulation cycles for oocyte vitrification, final serum estradiol correlates positively with basal antral follicular count (AFC), but it is not significantly associated and can not predict final estradiol elevation ≥500 pg/mL.

What is known already: Letrozole co-treatment is added to FSH activity under GnRH-antagonist protocol for COH in breast cancer patients who undergo fertility preservation, in order to avoid associated estradiol increase in positive estrogen-receptor tumours. Although security threshold in estradiol elevation in these cycles has not been established, estradiol production reaches conventional levels in some cases, in spite of letrozole administration. High ovarian reserve could be a risk factor for letrozole-resistant estradiol increase.

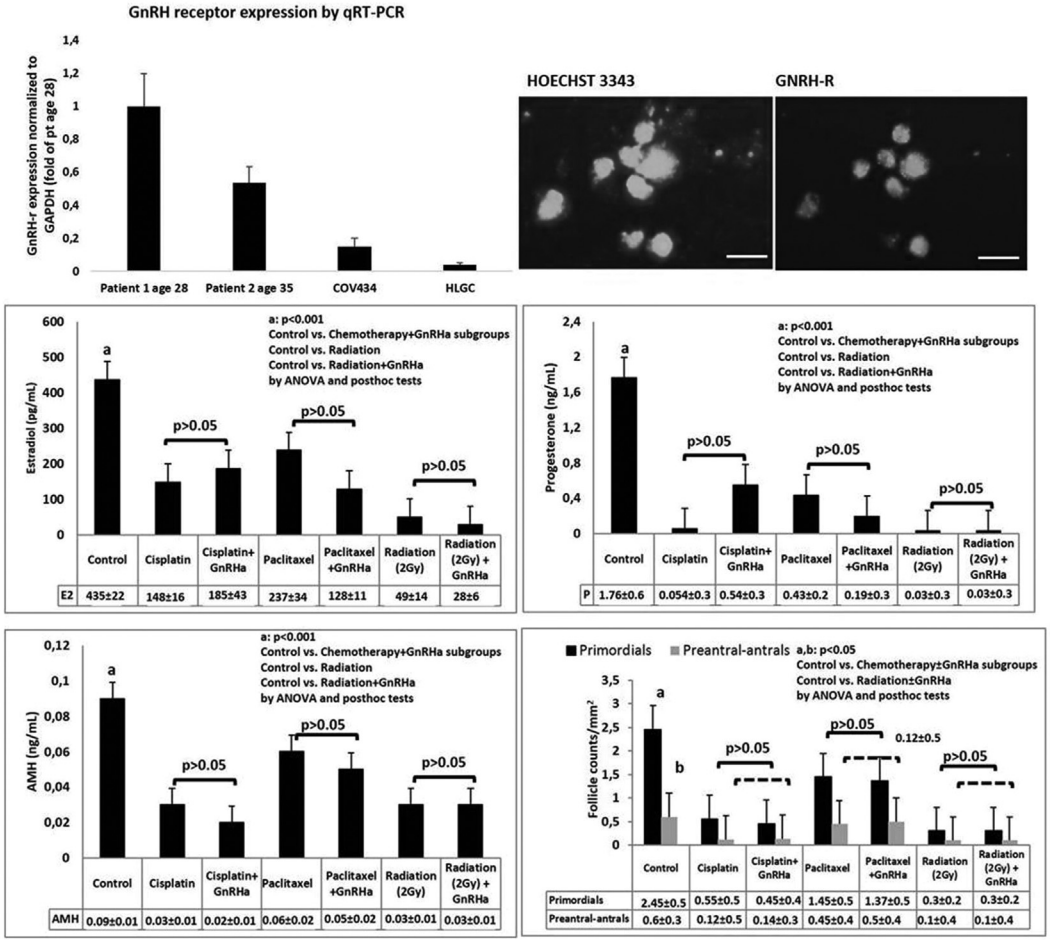
Study design, size, duration: Cohort-nested retrospective case-control study of an opportunistic sample of breast cancer patients treated between 2010 and 2014:16 cycles of COH for oocyte vitrification with final serum estradiol >500 pg/mL (cases) were compared with 71 cycles in which that level was not reached (controls) to estimate odds ratio for high AFC.

Participants/materials, setting, methods: During study period, 96 patients underwent COH with letrozole cotreatment for oocyte cryopreservation, and 88 achieved oocyte retrieval. We analyze the association between AFC and cycle characteristics with final estradiol increase over 500 pg/mL. Appropriate statistical tests have been applied; odds ratios have been estimated as effect size measure.

Main results and the role of chance: Final estradiol exceeded 500 pg/mL in 18.2% of letrozole-exposed COH cycles. Amongst pre-treatment variables, only AFC was significantly correlated with final serum estradiol (Rho: 0.20; p = 0.003). Nevertheless, AFC failed to predict estradiol elevation >500 pg/mL (AUC: 0.59; 95% CI: 0.45: 0.72; p = 0.72). An interval analysis of case frequency by AFC strata showed a considerable but not significant increase of cases from 15 to 19 follicles or more. However, this effect was not significant again (OR AFC > 15: 1.8; 95% CI: 0.6; 5.6; p = 0.73; OR AFC > 19: 2.24; 95% CI: 0.7; 7.15; p = 0.16).

Limitations, reason for caution: Applied cohort-nested case-control design could be appropriate for bias control. Assuming observed exposure differences between cases and controls for AFC >15 and >19, sample size determined low statistical powers (18 and 28% respectively).

Wider implications of the findings: Letrozole-resistant estradiol increase >500 pg/mL seems to be present in almost 1/5 breast cancer patients undergoing OCH for oocyte vitrification. Although estradiol levels at the end of ovarian stimulation correlates with ovarian reserve, our study has not



identified a critical level in AFC useful to predict a significant overexposure to estradiol.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Hospital General Universitario Gregorio Marañón.

Trial registration number: Cohort-nested retrospective case-control study.

Keywords: oocyte preservation, letrozol, estradiol, security, AFC

O-229 What threshold values of antral follicle count and anti-Müllerian hormone levels should be considered in cancer patients, candidates for oocyte vitrification following *in vitro* maturation?

C. Simon[1], C. Sonigo[1], M. Boubaya[2], A. Benoit[1], C. Sifer[3], M. Grynberg[1]

[1]*Hôpital Jean Verdier, Department of Reproductive Medicine, Bondy, France*

[2]*Avicenne University Hospital, Clinical Research Unit, Bobigny, France*

[3]*Hôpital Jean Verdier, Service d'Histologie-Embryologie-Cytogénétique-CECOS, Bondy, France*

Study question: What threshold values of ultrasonographic antral follicle count (AFC) and serum anti-Müllerian hormone (AMH) levels should be considered for ensuring the vitrification of different number of *in vitro* matured (IVM) oocytes, in cancer patients seeking fertility preservation (FP)?

Summary answer: The present investigation shows that AFC and serum AMH values above 21 follicles and 3.8 ng/mL, respectively, are required for obtaining at least 10 IVM oocytes vitrified. Given these relatively high values, the combination of IVM and ovarian tissue cryopreservation should systematically be discussed for optimizing the FP strategy.

What is known already: IVM of cumulo-oocyte-complexes (COCs) followed by oocyte vitrification has emerged recently as an option for urgent FP. Recent data have reported that, in healthy patients, 8–20 vitrified oocytes after ovarian stimulation would be required to obtain a live birth. Although both AFC and AMH have been reported as predictive factors of IVM success in polycystic ovary syndrome, there is a dramatic lack of data regarding the values of these parameters in oncologic patients.

Study design, size, duration: From July 2013 to December 2014, we prospectively studied 327 cancer patients, aged 18–40 years, candidates for oocyte vitrification following IVM.

Participants/materials, setting, methods: All patients had AFC and AMH measurements, 48–72 h before oocyte retrieval, whatever the phase of the cycle. COCs were recovered under ultrasound guidance 36 h after hCG priming. Logistic regression allowed determining threshold values of AFC and AMH, for obtaining at least 8, 10 or 15 vitrified IVM oocytes.

Main results and the role of chance: Among the 327 cancer patients included, 261 were diagnosed with breast cancers, 26 had a hematological malignancies and 43 underwent this procedure for others indications. Overall, the mean age of the population was 31.7 ± 0.26 years. Mean AFC and serum AMH levels were 21.2 ± 0.7 follicles and 4.7 ± 0.3 ng/mL respectively. IVM was performed in follicular phase for 46.5% of patients and during luteal phase for 36.4%. The statistical analysis shows that AFC and AMH values above 28 follicles and 3.9 ng/mL, 21 follicles and 3.8 ng/mL and 19 follicles and 3.3 ng/mL, respectively, are required for obtaining at least 15, 10 or 8 IVM vitrified oocytes.

Limitations, reason for caution: The potential of IVM oocytes vitrified in cancer patients is unknown. However, data obtained from infertile women showed a dramatically reduced competence of IVM oocytes when compared to oocytes recovered after ovarian stimulation. As a consequence, the optimal number of IVM oocytes vitrified in candidates for FP is currently unpredictable.

Wider implications of the findings: Vitrification of oocytes after IVM should be considered in the FP strategy when ovarian stimulation is unfeasible, in particular when markers of the follicular ovarian status are relatively high. Further investigation will be needed to objectively assess the real potential of these IVM oocytes after vitrification. Therefore, even when a good COCs yield is expected, we should systematically encourage IVM in combination with ovarian tissue cryopreservation.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Jean Verdier Hospital.

O-230 Mesenchymal stem cells facilitate *in vitro* development of human preantral follicle

X. Xi[1], Q. I. A. O. Jie[2]
[1]*Peking University Shenzhen Hospital, Reproductive Center, Shenzhen Guangdong, China*
[2]*Peking University Third Hospital, Reproductive Center, Beijing, China*

Study question: Whether mesenchymal stem cells (MSCs) could help to reconstruct a microenvironment to facilitate the human *in vitro* follicle development?
Summary answer: Human MSCs could effectively promote *in vitro* preantral follicle development in a dose-dependent manner.
What is known already: Biological folliculogenesis is a lengthy and complicated process and follicle growth microenvironment is poorly understood. The inaccessibility of rebuilding follicle growth niche is the main obstacle for the *in vitro* follicle development.
Study design, size, duration: Ovarian tissues were obtained from 7 women who underwent laparoscopic surgery. Ninety one morphologically intact preantral follicles, characterized as primary and secondary with a similar diameter ranging from 45 to 65 mm, were encapsulated and randomly assigned to be co-cultured with MSCs at different density for 8 days.
Participants/materials, setting, methods: During the *in vitro* culture (IVC) period, the morphology of each follicle was recorded and the diameter was measured. Follicle viability was assessed by Calcein-AM and Ethidium homodimer-I. The gene expression in IVC follicles was analyzed using single-cell RNA analysis. BMP4, TGF-b1 and estradiol were measured by ELISA and radioimmunoassay.
Main results and the role of chance: Human MSCs significantly promote the survival, increase the growth and improve the viability of preantral follicles in a dose dependent manner in a three-dimensional culture system. Further analyses revealed that GDF9 and BMP15 in oocytes and INHBA and TGF-b1 in granulosa cells within the follicles co-cultured with MSCs express notably higher than those in the follicles cultured without MSCs.
Limitations, reason for caution: Since follicle development is a lengthy and complicated process and different stages require different supporting gradients, the present study has limited ability to reveal the long-term effect of MSCs on follicles development.
Wider implications of the findings: Our findings demonstrate MSCs could promote preantral follicle development and provide a useful strategy to optimize fertility preservation and restoration by facilitating *in vitro* follicle growth.
Study funding/competing interest(s): Funding by national/international organization(s) – National Basic Research Program of China (2011CB944500), the National Science Foundation (No. 31230047, No. 81471508).

Wednesday 17 June 2015 **10:00–11:45**

O-231 Risk level of intracytoplasmic sperm/spermatid injection for 115 non-mosaic Klinefelter syndrome (KS) patients

T. Miki[1], A. Tanaka[1], M. Nagayoshi[1], I. Tanaka[1], Y. Takemoto[1], H. Kusunoki[2], S. Watanabe[3]
[1]*Saint Mother Obstetrics and Gynecology Clinic and Institute for ART, Fukuoka, Kitakyusyu, Japan*
[2]*Faunal Diversity Sciences Graduate School of Agriculture Kobe University, Hyogo, Kobe, Japan*
[3]*Department of Anatomical Science Hirosaki University Graduate School of Medicine, Aomori, Hirosaki, Japan*

Study question: Is the sex chromosome abnormality incidence for ICSI children increased when KS patient's sperm/spermatid is used?
Summary answer: Our data indicates the risk level of KS patients' intracytoplasmic sperm or spermatid injection into oocytes is much lower than previously expected.
What is known already: It has been reported that the sex chromosome abnormality incidence rate for ICSI children increased when KS patient sperm had been used. The thorough informed consent about the risk of this treatment should be carried out.
Study design, size, duration: We have performed a retrospective analysis of clinical outcome of ICSI in KS men using testicular sperm/spermatid during 2007 ~ 2012. In addition, we performed chromosomal analysis of 21 new born babies and FISH analysis of 500 round spermatids of KS patients.
Participants/materials, setting, methods: In a clinical IVF setting, this study dealt with 215 men who had previously been diagnosed as having non-mosaic KS. ICSI was performed using testicular sperm and spermatids were injected into electrically activated oocytes. We performed FISH analysis for remaining spermatids to confirm they are haploid cells.
Main results and the role of chance: 1. Out of 215 patients, slowly motile testicular sperms in 22 patients [A: 10.2% (22/215)], early stages of spermatid in 94 patients [B: 43.7% (94/215)] and no spermatogenic cells in 99 patients [C: 46.0% (99/215)] were found. Pregnancy rates per treatment cycles miscarriage rates and delivery rates in group A, B, were [A: 22.9% (8/35), 12.5% (1/8), 20.0% (7/35)], [B: 16.0% (36/225), 22.2% (8/36), 12.4% (28/225)] respectively. 37 healthy babies were born (male:female = 15:22) with 21 normal karyotype. No major congenital abnormalities were observed. 2. FISH analysis for early stage spermatids showed 100% monosomic, no disomic cells (X = 224/485, Y = 261/485, XX, YY, XY = 0/485).
Limitations, reason for caution: Total number of new born babies from KS patients so far are about 150 (including our data) and about only 35 (including our data) babies are proved to be chromosomaly normal. It might be premature to conclude the conception using KS gametes are not genetically safe.
Wider implications of the findings: This treatment is believed to indicate the risk level of KS patients' intracytoplasmic sperm or spermatid injection into oocytes is much lower than previously expected considering the facts the karyoplast of new born babies using KS men's gamete are 100% normal and FISH analysis for 500 spermatids from KS men were haploid.

Study question: The aim of this study was to assess meiotic recombination in primary spermatocytes, synaptonemal complex length and the correlation with chromosomal abnormalities in testicular spermatozoa from infertile men with idiopathic non-obstructive azoospermia (NOA).

Summary answer: Our study shows an increased sperm aneuploidy rates and decrease in recombination levels and in NOA patients compared to fertile controls. These findings would corroborate the correlation between both parameters and the higher aneuploidy risk for the offspring of NOA patients.

What is known already: During the first meiotic division in spermatogenesis there are two critical events. First, synapsis between homologous chromosomes and formation of the synaptonemal complex (SC), which regulates sister chromatid cohesion and provides the template for localization of recombination machinery proteins. Secondly, recombination between homologous chromosomes, which is essential for the correct segregation. Errors during these two processes may induce incorrect segregation of chromosomes and are a major cause of gamete aneuploidy.

Study design, size, duration: Prospective cohort study from January 2008 to December 2014. Meiotic progression, total length of SC, frequency of recombination and sperm aneuploidy were evaluated in samples obtained from testicular biopsies ($n = 13$) from NOA patients. The study group was compared with a control group ($n = 18$) from post-vasectomized (OA) patients.

Participants/materials, setting, methods: Immunocytogenetics with SCYP3, CREST and MLH1 antibodies for meiotic progression, SC length, and recombination. Fluorescence *in situ* Hybridization (FISH) for chromosomes 1, 4, 6, 13, 16, 18, 21, 22 in primary spermatocytes and chromosomes 13, 18, 21, *X*, *Y* on sperm. MicroMeasure 3.3 program was used for SC length.

Main results and the role of chance: The overall mean number of MLH1 foci per cell showed a significant decrease in NOA patients compared to the control group (45.2 vs. 48.7; $p < 0.0001$). Comparing mean number of MLH1 foci per chromosome we observed a significant decrease for chromosome 4 (2.5 vs. 3.0, $p < 0.0001$) chromosome 16 (1.7 vs. 2.0; $p < 0.0001$), chromosome 18 (1.8 vs. 2.6; $p < 0.0001$) and chromosome 22 (1.0 vs. 1.2; $p = 0.0394$) compared to the control group. Regarding the total length of the SC, no significant differences were observed between the groups (276.8 vs. 276.7 mm; $p = 0.9526$). FISH analysis in testicular spermatozoa showed an increase of chromosomal abnormalities in the NOA patients compared to the study group (0.4 vs. 0.2; $p < 0.0001$).

Limitations, reason for caution: The major limitation is the limitation of the sample size due to the difficulty in their identification and obtention, this is the main reason for caution.

Wider implications of the findings: These studies are crucial to understand the origin of aneuploidy and to better characterize different phenotypes that may contribute to higher spermaneuploidy risk.

O-233 De novo point mutations in the male gamete are directly associated with paternal aging and reduced fecundity

M. G. Katz-Jaffe[1], J. Parks[1], A. Strieby[1], B. McCallie[1], W. B. Schoolcraft[1]
[1]*Colorado Center for Reproductive Med., National Foundation for Fertility Research, Lone Tree, CO, U.S.A.*

Study question: Is there an increase of de novo point mutations in the gametes of an individual male in association with paternal aging and reduced fecundity?

Summary answer: Sperm exome sequencing detected the accumulation of significant de novo point mutations in the spermatozoa coding sequence of individual males as they aged. These de novo point mutations resulted in amino acid changes, which are predicted to affect protein/enzyme function in key biochemical pathways that may impact spermatogenesis.

What is known already: Increasing evidence supports an association between paternal aging and reduced reproductive function that includes significant declines in many semen traits. As an aging reproductive population in the developed world, a greater focus and recognition of the impact of parental age and the underlying mechanisms may lead to better patient outcomes during infertility treatment. Additionally, advances in sequencing technology have allowed for investigations of genome-wide mutations rates revealing 75% originating in the paternal lineage.

Study design, size, duration: Young outbred male mice ($n = 13$) with proven fecundity underwent surgery to remove a single testicle. Males were then routinely mated to monitor fecundity until 15 months of age, when the second testicle was surgically removed.

Participants/materials, setting, methods: Motile epididymal sperm was subjected to somatic cell lysis. cDNA fragment libraries were generated for exome capture, hybridization and sequencing on the ION PI v2 chip. DNA reads were aligned to mouse reference genome UCSC 10 mm and single nucleotide polymorphisms (SNPs) compared to UCSC dbSNP 137 with Avadis NGS platform.

Main results and the role of chance: All males experienced significantly reduced fecundity by 15 months of age. Sperm exome sequencing generated 75 million reads, high coverage and 99.5% accuracy in single base nucleotide calls. A total of 3,343 significant SNP effects passed QC, with 625 de novo point mutations (18.7%) observed only in sperm of individual old vs. young males, all resulting in amino acid changes that are predicted to affect protein/enzyme function ($P < 0.05$). Gene ontology and pathway analysis of these affected proteins/enzymes identified enriched biochemical pathways that may impact spermatogenesis including: cell surface receptor linked signaling pathway, signal transducer activity, transmembrane receptor activity and G-protein coupled receptor signaling ($P < 0.05$).

Limitations, reason for caution: This study was performed using a murine model, which was a limitation, however also a strength since the same male individuals were examined over their natural lifetimes. Additionally, exome sequencing does not identify de novo point mutations in the regulatory and intronic regions of the genome.

Wider implications of the findings: This novel study allowed for the direct association between paternal aging and the generation of de novo point mutations in an individual males' gametes. Characterization of these de novo point mutations revealed amino acid changes predicted to be responsible for protein/enzyme dysfunction that may provide the framework for perturbed spermatogenesis resulting in the observed decline in reproductive fecundity.

Study funding/competing interest(s): Funding by hospital/clinic(s) – National Foundation for Fertility Research.

Trial registration number: None.

O-234 Investigation of sperm telomere length as a potential marker of paternal genome integrity and semen quality

F. Cariati[1], S. Jaroudi[1], S. Alfarawati[1], A. Raberi[1], C. Alviggi[2], R. Pivonello[3], A. Colao[3], D. Wells[4]
[1]*Reprogenetics UK, Institute of Reproductive Science, Oxford, United Kingdom*
[2]*University of Naples "Federico II", IVF Unit, Naples, Italy*
[3]*University of Naples "Federico II", Andrology Unit, Naples, Italy*
[4]*University of Oxford, Nuffield Department of Obstetrics and Gynaecology, Oxford, United Kingdom*

Study question: Is measurement of sperm telomere length (STL) potentially useful for assessing semen quality?

Summary answer: Reduced STL is associated with chromosomal abnormality, especially meiotic failure producing diploid sperm, and may lead to increased apoptosis during spermatogenesis. Given the importance of aneuploidy and apoptosis, it is likely that measurement of STL can convey clinically relevant information.

What is known already: Telomeres are essential for maintaining chromosome integrity. Recent studies have shown that elongation of telomeres occurs during human spermatogenesis. Shorter STL has been reported in samples from men with idiopathic infertility, and one study has demonstrated a correlation with sperm count in young men. The biological reasons for different STL and its correlation with clinical features are still poorly understood. No data has been reported on STL in relation to chromosome abnormality in human sperm.

Study design, size, duration: For this prospective study, semen samples were collected from 73 infertile men.

Participants/materials, setting, methods: STL was assessed using quantitative polymerase chain reaction in combination with an assessment of sperm DNA fragmentation index (SDF), employing the Sperm Chromatin Dispersion Test. Chromosome abnormalities were evaluated in ~2000 sperm per sample using multi-colour fluorescence in situ hybridization (chromosomes 13, 18, 21, *X* and *Y*).

Main results and the role of chance: A significant correlation between STL and diploidy was found (r = -0.29, p = 0.02). The association between SDF and aneuploidy, previously reported, was confirmed (r = 0.31, p = 0.009). STL, the aneuploidy rate and SDF were each associated with sperm count (r = 0.34, p = 0.004; r = -0.27, P = 0.025; r = -0.49, p < 0.0001). Interestingly, samples with isolated oligozoospermia showed shorter STL (p = 0.002), higher aneuploidy rate (P = 0.048) and SDF (p = 0.0005) compared to normozoospermic men.

Limitations, reason for caution: A technical limitation of this study is the inability to assess the entire chromosome complement in individual sperm. Consequently, aneuploidy rates are likely to be underestimated and any potential correlations between SDF, STL and abnormalities affecting specific chromosomes cannot be determined.

Wider implications of the findings: STL has potential as a fast and inexpensive form of sperm quality assessment, which could be considered before undertaking DNA fragmentation and aneuploidy analysis. Combined together, the three tests represent a useful genetic assessment, providing information independent of traditional sperm parameters, assisting in the identification of men who might benefit from preimplantation genetic screening of their embryos due to elevated diploidy/aneuploidy risk. The finding of samples with atypical STL also raises interesting biological questions.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Reprogenetics UK.

O-235 Clinical outcomes of preimplantation genetic screening cycle are not related to male characteristics: observational longitudinal cohort study involving 734 consecutive cycles

A. Vaiarelli[1], L. Rienzi[1], D. Cimadomo[1], S. Colamaria[1], C. Scarica[1], M. Stoppa[1], R. Maggiulli[1], M. Giuliani[1], E. Gravotta[1], F. Sapienza[1], A. Capalbo[1], F. M. Ubaldi[1]

[1]*Clinica Valle Giulia, G.EN.E.R.A Reproductive Medicine Centres Italy, Roma, Italy*

Study question: Is male factor associated with laboratory and clinical outcomes of blastocyst stage aneuploidy screening cycles?

Summary answer: Secretory azoospermia is associated with lower blastocyst rate in PGS cycles. However, when blastocysts form, male factor does not impact on aneuploidy rate and on implantation potential of euploid blastocysts

What is known already: Chronological and biological female age is highly related to aneuploidy rate in blastocysts. It's thus generally recognize that the main indication for PGS are *advanced maternal age*, *recurrent pregnancy loss* and/or *recurrent implantation failure*. However, little is known about *severe male factor* incidence on embryo developmental competence and aneuploidies.

Study design, size, duration: This is an observational longitudinal cohort study involving 734 consecutive blastocyst stage PGS cycles from January 2012 to December 2014. Primary outcome measures were aneuploidy rate and implantation rate of euploid blastocysts in single cryopreserved embryo transfer cycles. Logistic regression analysis was used to exclude any possible confounding factor.

Participants/materials, setting, methods: Basal and cycle characteristics were recorded (female and male age, FSH, infertility factor, duration of infertility, previous miscarriages and IVF failures, number of mature eggs). Patients were clustered according to semen analysis following the parameters defined by WHO 2010. Blastocysts underwent trophectoderm biopsy with 24-chromosome screening analysis

Main results and the role of chance: From the 734 egg retrieval cycles, 4992 MII were injected resulting in 1640 biopsied blastocysts. Cycles with no blastocysts were 173 (23.6%, 95% CI = 20.5–26.8). 1640 blastocysts were biopsied and 656 were euploid (40.0%, 95% CI = 37.6–42.4). 249 were already transferred resulting in 134 ongoing implantations (52%, 95% CI = 46.2–58.9). As expected, female age and number of MII were associated with aneuploidy rate (OR = 0.68, 95% CI = 0.60–0.76 and OR = 1.83 95% CI = 1.56–2.15, respectively, p < 0.01). Male factors, male age, BMI, smoking habits and sperm parameters were all not related with blastocyst development and aneuploidy rate (OR = 1.03, 95% CI = 0.99–1.08; OR = 0.94, 95% CI = 0.85–1.04; OR = 1.02 95% CI = 0.98–1.07; OR = 1.18 95% CI = 0.39–3.6, respectively). Testicular sperm extraction was associated with a lower blastocyst rate (OR = 0.19, 95% CI = 0.4–0.81). None of the covariates was associated with implantation of euploid blastocysts, including female age and all male characteristics (intercept p-value = 0.24).

Limitations, reason for caution: Longitudinal cohort study from a single centre. Most of the couples included underwent PGS cycle for advanced female age. Overall, few azoospermic patients were included in this dataset, limiting the conclusion for this category. Furthermore, no additional functional semen analyses, such as DNA fragmentation, have been performed.

Wider implications of the findings: At present, it is still unclear whether severe male factor could be considered a valid indication for PGS. Our study on a large population of patients failed to identify a correlation between male characteristics and blastocyst chromosomal constitution and implantation potential. If the results are confirmed, PGS should not be proposed in these cases.

Study funding/competing interest(s): Funding by hospital/clinic(s).

Trial registration number: None.

O-236 Altered FISH in sperm, would you be indicated preimplantation genetic diagnosis (PGD)?

A. Fabregat Reolid[1], N. Baeza Pérez[1], J. A. Ortiz Salcedo[1], B. Lledó Bosch[1], R. Morales Sabater[1], E. V. A. García Hernández[1], J. Ten Morro[2], M. C. Tió Marquina[2], J. Llácer Aparicio[3], R. Bernabeu Pérez[3]

[1]*Instituto Bernabeu, Biotech, Alicante, Spain*

[2]*Instituto Bernabeu, Embriology Laboratory, Alicante, Spain*

[3]*Instituto Bernabeu, Reproductive Medicine, Alicante, Spain*

Study question: Is there a correlation between sperm aneuploidy and transmission of chromosomal abnormalities to their offspring?

Summary answer: The analysis of our results indicates that probability of finding a chromosomally altered embryo is significantly higher in those men with altered sperm FISH to at least one of the chromosomes analyzed respect for those men with normal FISH specially in couples with young women.

What is known already: The development of more sophisticated techniques such as ICSI, revolutionized the management of male infertility, allowing the use of sperm from men with severely compromised semen parameters. Nevertheless, approximately 20% of pregnancies end in miscarriage. Aneuploidy has a negative effect on reproductive outcomes and represents one of the main causes of implantation failure and miscarriage. PGD has been applied for the selection of euploid embryos aiming to improve clinical outcomes.

Study design, size, duration: We performed a retrospective observational study. Overall, 834 embryos (140 cycles) were biopsied and diagnosed. Of these, 634 embryos were analysed by FISH after biopsy on day 3 and 200 embryos were analyzed using a-CGH after biopsy on day 5. Study was performed from January 2007 to April.

Participants/materials, setting, methods: PGD (SGP or a-CGH) was performed to couples who attended the Instituto Bernabeu with recurrent miscarriage, implantation failure, severe male factor or altered karyotypes. We analyzed 7 chromosomes in spermatozoa and 9 in the blastomeres by FISH (SGP). For a-CGH, trophectoderm genome was amplified and performed Agilent SurePrintG3 8x60K.

Main results and the role of chance: Globally, 412 out of 834 biopsied embryos were aneuploid (49.4%). Significant differences were reported in terms of embryonic aneuploidy among those embryos from men with altered sperm FISH (64.5%) and normal (49.4%) (p < 0.05). For embryos diagnosed by a-CGH, we also found significant differences in the rate of embryonic aneuploidy depending on whether the man had altered sperm FISH (68.6%) or normal (39.6%) (p < 0.05). However, not significant differences were found (p = 0.196) when analyzing the embryos by SGP. We also considered other parameters such as semen quality, DNA fragmentation and implantation rate in relation to embryonic aneuploidy. We only obtained significant differences for semen quality (p < 0.05, p = 0.736 and p = 0.26 respectively).

Limitations, reason for caution: One limitation of the study is the use of FISH to determine aneuploidy in sperm and embryos biopsied on day 3, since in this way we only study a certain number of chromosomes. This could be the reason why no significant differences in SGP were found.

Wider implications of the findings: This study shows that altered sperm FISH could be an indication in itself for the performance of a PGD by a-CGH to reduce implantation failure and recurrent miscarriage.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Instituto Bernabeu Biotech.
Trial registration number: No trial registration number.

O-237 Epigenetic heterogeneity in sperm of infertile men

S. Laurentino[1], J. Beygo[2], V. Nordhoff[1], S. Kliesch[1], J. Wistuba[1], J. Borgmann[1], K. Buiting[2], B. Horsthemke[2], J. Gromoll[1]
[1]*University of Münster, Centre of Reproductive Medicine and Andrology, Münster, Germany*
[2]*University of Duisburg-Essen, Institute of Human Genetics, Essen, Germany*

Study question: Are the aberrant sperm DNA methylation levels detected in infertile males caused by widespread errors affecting all sperm produced by an individual or by the concomitant existence of populations of sperm with different methylation patterns?
Summary answer: In a distinct group of men with severe oligozoospermia, but not in normozoospermic individuals, sperm is composed of discrete populations of spermatozoa with opposing DNA methylation patterns at imprinted regions resulting in epigenetic mosaicism.
What is known already: Imprinted genes are silenced by methylation either in the oocyte (maternally imprinted) or the sperm (paternally imprinted). This parental-specific methylation pattern is maintained in the somatic lineages of the offspring but requires erasure and reprogramming in the germline. Recent studies have associated aberrant methylation of imprinted genes in sperm DNA with abnormal sperm parameters and male infertility. Moreover, a higher prevalence of imprinting disorders in children born after assisted reproductive techniques (ART) has been suggested
Study design, size, duration: Swim-up purified sperm was obtained from 42 men with normal (n = 19) and abnormal (n = 26) sperm parameters (according to the World Health Organization criteria). DNA methylation levels of imprinted genes were analysed by pyrosequencing-based Oligo-Sperm Methylation Assay (OSMA) and by Deep Bisulfite Sequencing (DBS).
Participants/materials, setting, methods: DNA was isolated and bisulfite-treated from pools containing 10 spermatozoa or the whole swim-up fraction. DNA methylation of *KCNQ1OT1* was measured in fractions of 10 spermatozoa by OSMA. DNA methylation of maternally (*KCNQ1OT1* and *MEST*) and paternally (*H19* and *MEG3*) imprinted genes was analysed by DBS at single cell level.
Main results and the role of chance: An increased variation in the DNA methylation values of the maternally methylated gene *KCNQ1OT1* was found by OSMA in samples with abnormal sperm parameters (such as those with a combination of oligo-, astheno- and teratozoospermia) but not in normozoospermic samples. DBS showed that normozoospermic samples have a homogenous pattern of DNA methylation (*KCNQ1OT1*: 3.78 ± 5.29; *MEST*: 0.76 ± 0.27; *H19*: 93.40 ± 2.49; *MEG3*: 0.88 ± 0.19), while oligoasthenoteratozoospermic samples show discrete populations with either normal or abnormal methylated patterns, resulting in aberrant average methylation values (*KCNQ1OT1*: 29.38 ± 7.49; *MEST*: 26.18 ± 4.65; *H19*: 2448 ± 6.71; *MEG3*: 69.50 ± 10.13). Aberrant methylation of *H19* appears to occur preferentially in the maternally inherited allele.
Limitations, reason for caution: OSMA could only be used for analysing one imprinted gene, *KCNQ1OT1*, due to the difficulty in working with such limited amounts of DNA. Analysis by DBS was only performed on a limited number of severely oligozoospermic samples and should be extended in the future to samples with milder defects.
Wider implications of the findings: The results presented herein demonstrate for the first time the existence of sperm populations with different imprinting status, ranging from normal to aberrant DNA methylation levels, coexisting in the semen of oligoasthenoteratozoospermic men, therefore providing an explanation for the findings of previous studies. These men produce portions of normally methylated sperm which, in the future, might be targeted and selectively used to improve ART outcome.

Study question: As endometrium beholds vast regeneration potential during menstrual cycle and also ability to establish endometriosis, we aimed to study how endometrial mesenchymal stem cells (eMSCs) differ as for their regeneration and migration potential from their presumable progenitors, bone marrow mesenchymal stem cells (bmMSCs), and their progeny, endometrial stromal fibroblasts (eSF).
Summary answer: In terms of differentiation, wound healing/regeneration and migration potential, the eMSCs were similar to bmMSCs, whereas the eSFs showed lower regeneration and migration capacity. The findings may give important insight to endometrial eMSCs-related regeneration and may underline the role of eMSCs in ectopic lesion formation in endometriosis.
What is known already: Recently, eMSCs were identified in the endometrium in perivascular space and their gene profile was established indicating eSFs being their progeny. Furthermore, according to previous studies in mice and humans, it has been suggested that eMSCs originate from bmMSCs. Although eMSCs have been characterized for their differentiation and proliferative potential, the role of eMSCs in endometrial tissue regeneration and migration (in response to cytokine/hormonal triggers) compared to bmMSCs or eSFs has not been well established.
Study design, size, duration: Prospective, university-based, case-control, *in vitro* study using endometrial biopsies (n = 8) and bone marrow aspirates (n = 6) obtained from fertile aged women undergoing surgery for benign gynaecological reasons or scoliosis. The study was designed to compare the regeneration (wound healing, WH) and migration properties of eMSCs to bmMSCs or eSFs.
Participants/materials, setting, methods: The eMSCs and eSFs were FACS-isolated (eMSC: $CD146^+/PDGF\beta^+$; eSF: $CD146^-/PDGF\beta^+$) and bmMSCs were obtained through culturing. All cell types were cultured and tested (passage 2–4) for stem cell regeneration (2% serum) and migration [serum (2 vs. 10%, estradiol (E_2, 10 nM) vs. progesterone (P_4, 1 μM) vs. E_2P_4 (10 nM/1 μM, IL-1b (10 ng/ml)] properties.
Main results and the role of chance: The eMSCs and bmMSCs were able to differentiate and as expected, the eSFs were not. Furthermore, the eMCs displayed high clonogenic potential and stem cell surface marker profile. The regeneration capacity of eMSCs was comparable to bmMSCs (although faster healing rate in WH assay) and significantly higher than in eSFs ($p < 0.03$). Furthermore, the eMSCs showed higher migration response to serum (2 vs. 10%, up till 96 h) compared to bmMSCs and eSFs ($p < 0.001$). In contrast, the hormonal trigger with E_2 or P_4 or E_2P_4 did not result into any migratory activity

in any of the three cells types. Interestingly, the IL-1b was shown to be the highest migration trigger for eMSCs ($p < 0.001$), whereas the IL-1b migration response of bmMSCs and eSFs was comparable to serum triggering.
Limitations, reason for caution: This is a pilot *in vitro* study with small sample size. The obtained results should be confirmed in a larger data set with synchronized endometrial samples and applied in *in vivo* models. For practical reasons, it was impossible to isolate all cell types from the same patient.
Wider implications of the findings: According to the present data, the eMSCs possess high regeneration potential and therefore most likely play an important role in monthly endometrium regeneration where cytokine-trigger seems to provoke more robust migration than hormones. Furthermore, these findings may indicate a key role of eMSCs in ectopic endometrium lesion formation in establishing endometriosis. The vast proliferative and migratory nature of eMSCs may also indicate involvement of these cells in other endometrium-related pathologies like adenomyosis and cancer.

O-239 Activating transcriptional factor 3 facilitates decidual prolactin expression in human endometrial stromal cells

X. Cheng[1], Z. Diao[1], L. Ding[1], X. Zhen[1], Y. Hu[1], G. Yan[1], H. Sun[1]
[1]*The Affiliated Drum Tower Hospital of Nanjing University, Reproductive Medicine Center, Nanjing Jiangsu, China*

Study question: To explore whether Activating Transcriptional Factor 3 (ATF3) participates in the process of regulating human endometrial decidualization.
Summary answer: ATF3 is responsive to the stimulation of sexual hormone and sequentially elevates the secretion of prolactin (PRL), a specific decidual factor, in human endometrial stromal cells (hESCs).
What is known already: Decidualization is tightly controlled by multiple genes that regulate the production of proteins, one of which is prolactin (PRL) that plays a key role during early pregnancy including the regulation of uterine epithelial cell differentiation, trophoblast growth, and the modulation of the immune response. Stress response gene ATF3, a member of the ATF/CREB family, is strongly associated with some specific physiological procedures such as inflammatory response, cytothesis and cellular anti-apoptosis.
Study design, size, duration: Human endometrial stromal cells were infected with Ad-CTL or Ad-ATF3 adenovirus, otherwise stimulated with 1 μM medroxyprogesterone acetate (MPA) and 0.5 mM 8-Br-cAMP after knockdown ATF3, all treated hESCs were applied for 3 and 6 days.
Participants/materials, setting, methods: Human endometrial stromal cells isolated from endometrial biopsy were treated with 8-Br-cAMP and MPA to induce decidualization. The expression of ATF3 was analyzed by the Q-PCR and western blot. ELFA was performed to measure secretion of prolactin.
Main results and the role of chance: Western Blot showed ATF3 was notably lower expressed in endometrial tissue of 13 repeated implantation failure (RIF) patients compared with 12 successfully concepted women with once embryo transplantation, all patients undergoing IVF treatment in Drum Tower Hospital. ATF3 mRNA expression in hESCs was significantly increased ($P < 0.001$) after decidualization stimulated by 8-Br-cAMP and MPA in early time. Adenovirus-mediated overexpression of ATF3 in hESCs markedly increased PRL mRNA expression and PRL secretion ($P < 0.01$) in a concentration-dependent manner, simultaneously making hESCs demonstrate a morphological transformation from fibroblast-like to decidual cell-like. On the contrary, knockdown of ATF3 in hESCs observably decreased decidual PRL mRNA expression and PRL secretion ($P < 0.01$) induced by 8-Br-cAMP and MPA.
Limitations, reason for caution: This study was a phenomenal investigation to illustrate ATF3 is involved in process of decidualization and further research is required to explain its concrete mechanism.
Wider implications of the findings: We provided convinced evidences that ATF3 is a relevant factor in decidualization due to its function in regulating the secretion of PRL in hESCs. Extra experiments have showed ATF3 can promote embryo adhesion with in-vitro attachment model of BeWo spheroids adhering to Ishikawa cells, indicating that ATF3 may also modulate endometrial capacity. Considering its immunological properties, ATF3 may take part in embryo implanting via adjusting uterine immune microenvironment.
Study funding/competing interest(s): Funding by national/international organization(s) – This work was supported by The National Natural Science Foundation of China Grant 81170570 and The National Natural Science Foundation of China Grant 81370683.
Trial registration number: None.

O-240 Regulatory mechanism of endometrial mesenchymal-like stem cells during menstruation

S. Xu[1], R. W. S. Chan[1], H. Y. Ng[1], W. S. B. Yeung[1]
[1]*The University of Hong Kong, Obstetrics and Gynaecology, Hong Kong Island, Hong Kong*

Study question: The human endometrium is highly regenerative in a woman's reproductive life. Endometrial stem cells have been shown to contribute to this remarkable process [1]. We hypothesized that endometrial niche cells during menstruation regulated the behavior of endometrial mesenchymal-like stem cells (eMSCs) and thereby regeneration of the endometrium.
Summary answer: The eMSC population (co-expression of $CD140b^+CD146^+$ cells) was enriched during menstruation. Soluble factors secreted by the endometrial niche (epithelial or stromal) cells from menstrual phase significantly increased the eMSCs' proliferative activity and phenotypic expression.
What is known already: Regeneration of the endometrial mucosa takes several days after menstruation [2]. A cascade of growth factors, cytokines and chemokines are present at the onset of menstruation [3].
Study design, size, duration: Sequential beading with magnetic beads coated with anti-CD140b and anti-CD146 antibodies was used to isolate eMSCs from menstrual ($n = 6$), proliferative ($n = 4$) and secretory ($n = 3$) phase. The eMSCs were seeded at low density, and indirectly co-cultured at a ratio of 1:30 with endometrial niche (epithelial or stromal) cells from menstrual ($n = 9$) and secretory phase ($n = 2$) for 15 days. The cloning efficiency and proportion of cells expressing the eMSC markers was evaluated.
Participants/materials, setting, methods: Menstrual phase samples are obtained from women aged 36.1 ± 4.1 years undergoing IVF treatment on their second day of menstruation. Proliferative and secretory phase samples are obtained from women aged 44.6 ± 2.8 years undergoing total abdominal hysterectomy. Endometrial cells are isolated enzymatically and the percentage of eMSCs was analyzed by flow-cytometry.
Main results and the role of chance: Overall, a significantly higher proportion of eMSCs was detected in endometria from the menstrual (4.02%) and proliferative phase (4.26%) than the secretory phase (1.46%). Menstrual phase eMSCs underwent more self-renewal passages (6 rounds) than those from other phases (4 rounds, $P < 0.05$). Indirect co-culture of menstrual phase eMSCs with menstrual phase niche cells significantly increased the cloning efficiency (control: 1%, epithelial: 14.77%, $P < 0.05$; stromal 8.09%, $P < 0.01$) and the proportion of eMSC markers expressing cells (control: 1%, epithelial: 1.67%, $P < 0.05$; stromal 1.83%, $P < 0.01$). Similar effect was observed for secretory phase eMSCs (cloning efficiency: control: 1%, epithelial: 11.79%, stromal: 3.32%, $P < 0.05$; phenotype: control: 1%, epithelial 1.49%, stromal 1.38%, $P < 0.05$). Interestingly, secretory phase niche cells did not affect the proportion of eMSC markers expressing cells.
Limitations, reason for caution: The behavior to the cells may be altered during *in vitro* culturing. The functionality and multipotency of the eMSCs after coculture needs to be determined.
Wider implications of the findings: Our findings provide preliminary evidence that at menses, specific regulatory factors contribute to maintenance of eMSCs. The identification of candidate proteins from menstrual phase niche cells will provide a better understanding of eMSC biology and may subsequently unveil causes of gynecological complications such as dysmenorrhea and Asherman's syndrome.

[3]*Mashhad University of Medical Sciences, Immunology, Tehran, Iran*
[4]*Avicenna Infertility Clinic, Endometriosis, Tehran, Iran*
[5]*Immunology Research Center Iran University of Medical Sciences, Immunology, Tehran, Iran*

Study question: Vitamin D3 has various immunomodulatory effects on many biological processes which are closely related to endometriosis development. Yet, vitamin D3 deficiency is the most common nutritional deficiency worldwide. In this study, we examined whether vitamin D3 modulates endometriosis-related features of human endometriotic stromal cells.
Summary answer: We showed for the first time that vitamin D3 significantly increased adhesion and apoptosis, while reduced invasiveness, proliferation, pro-inflammatory cytokine production and angiogenesis potential of endometrial stromal cells (ESCs) from women with endometriosis.
What is known already: The results of recent studies show that vitamin D3 lowers endometriotic lesion score, inhibits implantation and development of transplanted endometrial tissue and decreases peritoneal inflammation in animal models of endometriosis.
Study design, size, duration: The effects of vitamin D3 on the eutopic (EuESCs), ectopic (EESCs) and control (CESCs) stromal cells from 25 women with and 20 women without endometriosis at proliferative phase of the menstrual cycle were investigated *in vitro*.
Participants/materials, setting, methods: The effects of vitamin D3 on adhesion, invasion, proliferation, apoptosis and angiogenesis potential of ESCs from endometriotic patients and control women were examined with cell adhesion assay, matrigel invasion, XTT and real-time PCR, respectively. Concentration of IL-6, IL-8, IL-17, TGF-b, TNF-a and IFN-g in culture supernatants were determined using ELISA.
Main results and the role of chance: In all groups, vitamin D3 significantly increased cell adhesion ($p < 0.05$), while decreased invasion ($p < 0.05$) and proliferation ($p < 0.01$) of EuESCs and EESCs. Such treatment also resulted in a significant decrease in IL-6 production by EESCs ($p < 0.05$), but had no significant effect on the IL-8 production. Stromal cells from all groups, showed no detectable secretion of other cytokines. This vitamin also caused significant decrease in Bcl-2 gene expression by EuESCs ($p < 0.05$) and Bcl-xL by EESCs ($p < 0.05$), but exerted no significant effects on Bax and caspase-3 genes expression. In addition, vitamin D3 treatment reduced VEGF-A gene expression by EESCs ($p < 0.01$).
Limitations, reason for caution: The effect of vitamin D3 was investigated in patients with stage III-IV endometriosis.
Wider implications of the findings: With regard to the increased adhesion and apoptosis and also reduced invasiveness, proliferation and angiogenesis potential of endometrial stromal cells in the presence of vitamin D3 and having considered the worldwide pattern of vitamin D3 deficiency especially in women at reproductive age, it seems that this hormone can be viewed as the first and an effective therapeutic modality in patients with endometriosis.

O-242 The role of microRNAs in mediating a state of enhanced endometrial receptivity in response to trophoblast cells: an integrative analysis

T. Nafee[1], J. A. Sanchez-Lopez[1], P. R. Heath[2], B. Ola[3], A. Fazeli[1]
[1]*The University of Sheffield, Academic Unit of Reproductive and Developmental Medicine, Sheffield, United Kingdom*
[2]*The University of Sheffield, SITRAN, Sheffield, United Kingdom*
[3]*Sheffield Teaching Hospitals NHS FT, Obstetrics and Gynecology, Sheffield, United Kingdom*

Study question: Is there any role for microRNAs in mediating the early stages of the embryonic – endometrial communication prior to implantation?
Summary answer: The endometrium robustly alters its microRNA and transcriptomic profiles in response to very brief non – contact exposure to trophoblastic cells. MicroRNA – targeted differentially altered transcripts regulate subcellular pathways of known relevance to early implantation.
What is known already: *Background:* Besides synchronizing the adaptive cellular and sub-cellular changes that are necessary for implantation, early embryonic – endometrial communication may be a decision-making step for the maternal investment in the approaching embryo. MicroRNAs are large scale regulators of translation and an effective intercellular communication tool, and, as such, uniquely positioned to mediate both functions. In vitro studies on human endometrial stromal cell lines suggest that the process of decidualization is associated with an increased capacity for production of microRNAs coupled with some restriction in microRNA mediated silencing. Their role in the early stages of the embryo – endometrial dialogue is largely undefined.
Study design, size, duration: design: Experimental, *in vitro.*
Participants/materials, setting, methods: *Methods*: Human immortalised secretory endometrial epithelium monolayers were incubated with human trophoblast spheres for 4 h in a non – direct contact setting. Total RNA was extracted from the endometrial cells and profiled at the microRNA and transcriptomic levels using Affymetrix GeneChip microarrays. The results were validated using quantitative PCR. Target prediction followed by an integrated analysis to highlight microRNA – targeted transcript differentially expressed transcripts, and pathway analysis performed to highlight KEGG pathways enriched for microRNA regulation.
Main results and the role of chance: *Results*: The endometrium responded significantly to the brief non – direct contact co-incubation with trophoblast spheres. The response was present at the microRNA (65/3,391 human probes, $P < 0.01$) and transcriptomic (2023/39,000 human transcripts, $P < 0.05$) levels. 36 unique conserved microRNAs had a fold change of 1.5 times or more. They targeted 28% (444/2023) of all differentially expressed mRNAs in the same samples. Pathway enrichment analysis predicted the microRNA mediation of focal adhesion, regulation of the actin cytoskeleton and endocytosis. These pathways regulate plasma membrane transformation, water and ion channel regulation and the expression of cell adhesion molecules, all of which are well recognized epithelial adaptations involved in early implantation.
Limitations, reason for caution: *In vitro* experimental setting.
Wider implications of the findings: *Conclusion:* We demonstrated an early and important response of the secretory endometrium to approaching trophoblast cells prior to the establishment of physical contact. MicroRNA – targeted differentially regulated transcripts cluster into several subcellular pathways of known relevance to early implantation. MicroRNAs may therefore play an important role in mediating an early trophoblast – induced state of enhanced endometrial receptivity prior to embryo attachment. They have future diagnostic and therapeutic potentials in the management of patients with recurrent implantation failure.

O-243 Non-invasive and real-time assessment of peritoneal lesions generated from human endometrial cell transplants locally accumulated by magnetic force in immunodeficient mice

T. Maruyama[1], H. Masuda[1], N. Hida[1], H. Oda[1], K. Miyazaki[1], F. Miki[1], H. Hihara[1], K. Ota[1], H. Uchida[1], M. Tanaka[1]
[1]*Keio University School of Medicine, Obstetrics and Gynecology, Tokyo, Japan*

Study question: Can we make a mouse model of peritoneal endometriosis in which peritoneal lesions derived from human endometrial cell transplants can be assessed in a non-invasive, real-time, and quantitative manner?
Summary answer: Intraperitoneal accumulation and local placement of human endometrial cells by magnetic force enabled the formation of peritoneal lesions assessable with bioluminescence imaging (BLI) in a non-invasive, real-time, and quantitative manner in immunodeficient mice.
What is known already: Peritoneal endometriosis is the most common among various types of endometriosis. Several animal models of endometriosis have

been made through transplantation of human endometrial tissues, primary endometrial cells, or endometrial cell lines at various ectopic sites including the peritoneal cavity in immunodeficient mice. There has been, however, no mouse model of peritoneal endometriosis whose lesions can be assessed in a non-invasive, real-time, and quantitative manner.

Study design, size, duration: Immortalized human endometrial cells stably expressing a bioluminescent protein were labeled with magnetic beads and intraperitoneally transplanted into immunodeficient mice. A neodymium magnet was subcutaneously placed at the abdomen of each mouse to accumulate the labeled cell transplants onto the ventral peritoneum. These mice were then subjected to BLI.

Participants/materials, setting, methods: A stable cell line expressing enhanced green fluorescent protein (EGFP), a luciferase variant (CBR), and non-functioning nerve growth factor receptor (dNGFR) was generated from immortalized human endometrial cells using lentivirus and then labeled with magnetic-beads attached to anti-NGFR antibody.

Main results and the role of chance: We successfully constructed lentivirus harboring EGFP, CBR and dNGFR genes. Immortalized human endometrial cells were able to express EGFP, CBR and dNGFR simultaneously upon infection with the lentivirus. Furthermore, a stable cell line expressing EGFP, CBR and dNGFR was established from the infected immortalized cells through EGFP-positive cell sorting. BLI revealed that localized bioluminescent signals were detectable and assessable in a non-invasive, real-time and quantitative manner in mice transplanted with beaded cells, but no or little signals in mice transplanted with non-beaded cells, 4–10 weeks after cell transplantation and abdominal placement of a neodymium magnet.

Limitations, reason for caution: It remains to be elucidated whether peritoneal lesions generated from human endometrial cell transplants reflect and resemble endometriotic lesions.

Wider implications of the findings: Magnet force-driven engraftment of human endometrial or endometriotic cells at ectopic sites will be a possible novel strategy to develop *in vivo* models of various types of endometriosis in mice or other animals.

O-244 MAPK and VEGFR inhibition by sorafenib controls the progression of endometriosis

P. Santulli[1], M. Leconte[2], S. Chouzenoux[3], L. Marcellin[1], B. Dousset[2], C. Chapron[1], F. Batteux[3]

[1]*Cochin-Port Royal, Department of Gynecology Obstetrics II and Reproductive Medicine, Paris, France*

[2]*Cochin-Port Royal, Department of Digestive and Endocrine Surgery, Paris, France*

[3]*Université Paris Descartes, Department "Development Reproduction and Cancer" Institut Cochin INSERM U1016, Paris, France*

Study question: can Sorafenib, a multi-kinase inhibitor targeting serine/threonine kinases RAF (RAF-1 and B-RAF) and receptor tyrosine kinases (VEGFR-1, -2), controls the growth of endometriosis?

Summary answer: Our data suggest that Sorafenib is an orally active, dual action, RAF kinase and VEGFR inhibitor that targets endometriotic cell proliferation and angiogenesis. Sorafenib controls the growth of endometriosis *in vitro* and *in vivo*.

What is known already: Endometriosis is complex multistep process. Mitogen Activated Protein Kinases (MAPKs) and VEGFR are both involved in the proliferation and survival of endometriotic lesions. Sorafenib is a strong multikinase inhibitor targeting two different pathways of endometriosis pathogenesis: RAF kinase and VEGFR.

Study design, size, duration: We conducted a prospective laboratory study in a tertiary-care university hospital between January to September 2012. After complete surgical exploration of the abdominopelvic cavity, 10 histologically proven endometriotic women were allocated to the endometriosis group and 10 women without any evidence of endometriosis were allocated to the control group.

Participants/materials, setting, methods: Ex-vivo stromal primary cells were extracted from endometrial and endometriotic biopsies from patients with and without endometriosis. Proliferation, apoptosis and MAPKs and VEGFR-2 autophosphorylation were explored with and without Sorafenib treatment. Human endometriotic lesions were implanted in 30 nude mice randomized in two different groups according to Sorafenib or Placebo treatment.

Main results and the role of chance: Performed ex vivo on stromal primary cell lines extracted from endometrial biopsies of 20 patients with and without endometriosis, this study highlights the role of Sorafenib in the pathogenesis of endometriosis. Sorafenib exerts cytostatic effects in endometriotic stromal cells by decreased MAP kinase ERK1/2 activity. Treating endometriotic cells with Sorafenib abrogated the phosphorylation of ERK with significant reduced pERK/ERK ratio in stromal cells of endometriotic women as compared to controls. In addition, this study highlights the antiangiogenic role of Sorafenib in endometriotic tissues. Treatment with Sorafenib decreased VEGFR-2 autophosphorylation highlighted by decreased pVEGFR-2/VEGFR-2 ratio in endometriosis. Using our mice model of endometriosis, we confirmed that Sorafenib regulate the endometriosis activity *in vivo*, possibly targeting proliferation and endometriosis-related angiogenesis.

Limitations, reason for caution: The study was conducted in a referral center specialized in endometriosis surgery and therefore women operated in our center might have particularly severe forms of endometriosis. This referral bias might have amplified the difference in MAPK levels between endometriosis and controls women.

Wider implications of the findings: This study opens the doors to future, more mechanistic studies to determine the exact role of Sorafenib, and its safety, in the pathogenesis of endometriosis. This novel model (*in vitro* and *in vivo*) of non-hormonal treatment of endometriosis opens new avenue in the targeted non hormonal treatment of endometriosis.

O-245 Non-invasive prenatal testing for aneuploidy and beyond: challenges of responsible innovation in prenatal screening – an ESHG/ASHG position statement

W. J. Dondorp[1], G. M. W. R. De Wert[1], C. G. Van El[2], M. C. Cornel[2]

[1]*University of Maastricht, Department of Health Ethics and Society (HES), Faculty of Health Medicine and Life Sciences (FHML) Res Schools CAPHRI and GROW, Maastricht, The Netherlands*

[2]*VU University Medical Center, Section Community Genetics Department of Clinical Genetics and EMGO Institute for Health and Care Research, Amsterdam, The Netherlands*

Study question: In the past few years, several professional societies have issued position statements on the role of non-invasive testing (NIPT) in prenatal screening for common autosomal aneuploidies. Ethical aspects have not yet been a main focus of those statements. This ESHG/ASHG position statement aims to fill this lacuna.

Summary answer: Responsible innovation in this field requires guarantees of the quality of the screening process as a whole (including non-laboratory aspects such as information and counseling), education of professionals, systematic evaluation in the light of the aim of the practice, accountability to all stakeholders and promotion of equity of access.

What is known already: The relevant normative framework consists of a context-specific articulation of more general principles for population screening, as initially formulated by Wilson and Jungner and further developed in the past decades. In order to avoid ethical pitfalls related to (selective) abortion, relevant policy documents stress that prenatal screening for fetal abnormalities is aimed at enabling autonomous reproductive choices by pregnant women and their partners rather than at preventing the birth of children with the relevant disorders.
Study design, size, duration: This document is the result of a unique collaboration between the Public and Professional Policy Committee of the European Society of Human Genetics (ESHG), and the Social Issues Committee of the American Society of Human Genetics (ASHG). The final version was approved by the Boards of both Societies (December 2014).
Participants/materials, setting, methods: The first draft was written by the first author and discussed by members of both committees and external experts. After adaptation, the text was emailed and posted on the ESHG website for membership consultation, and sent to the ASHG and ESHG Boards to elicit further comments.
Main results and the role of chance: NIPT has the potential of helping the practice of prenatal screening better achieve its aim of facilitating autonomous reproductive choices, provided adequate pretest-information and non-directive counseling are available. With improving technologies and decreasing costs, it will become possible in the near future to significantly expand the scope of prenatal screening beyond common autosomal aneuploidies. As the widely endorsed 'autonomy paradigm' does not provide a ready answer as to what the scope of prenatal screening for fetal abnormalities should be, a qualification of this account of the aim of prenatal screening is necessary. This position statement argues for a cautious expansion to serious congenital and childhood disorders, only following sound validation studies and a comprehensive evaluation of all relevant aspects.
Limitations, reason for caution: This document is based on expert opinion and consensus. Its recommendations pertain to a highly dynamic field and new developments may require reconsideration, adaptation or fine-tuning.
Wider implications of the findings: Whereas the introduction of NIPT into clinical practice has until now been largely left to commercial laboratories, a core message of the statement is that in countries where prenatal screening is offered as a public health programme, governments and public health authorities should adopt a more active role to ensure the responsible innovation of prenatal screening on the basis of ethical principles.

O-246 Time to reconsider the time limit for human embryo-research?

G. De Wert1, W. J. Dondorp[1]
[1]*University of Maastricht, Faculty of Health|Medicine and Life Sciences, Maastricht, The Netherlands*

Study question: As new developments may well enable human embryo-research to move beyond the internationally accepted 'fourteen-day limit', the question whether this limit blocks promising medical research (e.g., exploring causes of miscarriage) is no longer hypothetical. What are the ethical and legal arguments behind the fourteen-day limit and how convincing are they?
Summary answer: The existing consensus reflects the will of policy-makers to draw a line somewhere rather than a shared understanding of why this should be at fourteen days instead of another developmental stage, for instance early brain-activity. None of the reasons given for a limit at fourteen days are argumentatively convincing.
What is known already: The reason why there has been no debate about human embryo research beyond the fourteen day limit is that until now, this has been regarded as hypothetical. This may change now that British researchers have developed a culture system that allows studying mouse post-implantation embryos, while others are considering research using (manipulated) human embryonic stem cells (hESC) that yields structures very similar to the post-implantation embryo.
Study design, size, duration: In this explorative study, we have 1. charted the arguments behind the fourteen day limit as presented in policy documents and in the relevant bioethical and legal literature; 2. determined their validity in terms of internal and external consistency; 3. proposed arguments and criteria for a possible alternative time limit.
Participants/materials, setting, methods: The study consists of interviews with scientists involved in human embryo/ESC research, a review of the bioethical and legal arguments behind the fourteen day limit (or alternatives), followed by a theoretical reflection and recommendations for further debate. The method is the 'wide reflective equilibrium', widely used in biomedical ethics.
Main results and the role of chance: Extended human embryo research *in vitro* may lead to important knowledge about early post-implantation development. Such research, however, would violate the widely accepted 14 day limit. An often proposed argument for this limit is that of 'ontological individuality': the moment after which twinning is no longer possible should be regarded as an ethically decisive transition point. Still, the question remains whether this and other arguments provide sufficient normative backing for a limit at 14 days. Those contesting this have pointed at other transition points that would be ethically more important, such as the beginning of brain-activity. However, as brain-related criteria are highly diverse and contested themselves, ethical scrutiny and societal debate of these alternative criteria for embryonic moral status are urgently needed.
Limitations, reason for caution: This is an explorative study, that does not itself answer the question regarding the time limit. However, it sets the agenda for a necessary new debate about what the limit should be, by confronting new developments in research with a review of arguments pro and con several different time limits.
Wider implications of the findings: Our conclusions make clear that an accepted element of the normative framework for human embryo research is less firmly rooted than many think. Instead of uncritically using the widely accepted limit to curb important scientific developments, policy makers should accept the need for fine-tuning the balance between embryo protection and reaping the benefits of human embryo research. This will require further ethical reflection and societal debate along the lines proposed in this study.
Study funding/competing interest(s): Funding by University(ies) – Maastricht University, The Netherlands.
Trial registration number: NA.

O-247 Infertility, fertility treatment and mammographic density in a large Swedish cohort

F. Lundberg[1], A. Johansson[1], K. Rodriguez-Wallberg[2], J. S. Brand[1], K. Czene[1], P. Hall[1], A. N. Iliadou[1]
[1]*Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden*
[2]*Karolinska Institutet, Department of Oncology-Pathology, Stockholm, Sweden*
Study question: is mammographic density influenced by hormonal fertility treatment?
Summary answer: Hormonal fertility treatment does not seem to cause any long term changes in mammographic density, with the possible exception of women who remain nulliparous after *in vitro* fertilization (IVF) or intracytoplasmic sperm injection (ICSI).
What is known already: Hormonal fertility drugs are used for ovarian stimulation in women with anovulation, and for controlled hyperstimulation as part of IVF or ICSI treatments. The drugs increase estrogen and progesterone levels and have therefore been suspected to influence breast cancer risk. Mammographic density is a useful marker for breast cancer risk which is also related to reproductive characteristics, such as parity and age at first birth.
Study design, size, duration: This cross-sectional study included 47,266 women recruited to the KARolinska MAmmography project between 2010 and 2013. Extensive background information, including fertility problems and treatment, was collected in a web-based questionnaire at mammography screening. Relative and absolute mammographic density were obtained from digital mammograms using the automated volumetric method Volpara™.
Participants/materials, setting, methods: Among the women who reported a history of fertility problems, 1,689 had gone through IVF or ICSI, 1,540 had had hormonal stimulation without IVF/ICSI and 6,528 had received no hormonal fertility treatment. The associations with mammographic density were calculated using linear regression, estimating mean ratios stratified by parity.

Main results and the role of chance: We found no differences in mammographic density between women with untreated or hormonally treated infertility compared to women without fertility problems. However, nulliparous women treated with IVF/ICSI had a small but significant increase in absolute dense volume (Mean ratio = 1.11, 95% CI = 1.06–1.17).
Limitations, reason for caution: Limitations of this study include inability to obtain information on cause of infertility and number of treatments. Information on treatment date was only available for a limited number of women.
Wider implications of the findings: While these results are reassuring, continued monitoring of cancer risk following IVF/ICSI is warranted since most women who have gone through treatment are still below the age at which breast cancer is usually diagnosed. The increased absolute density in nulliparous women may indicate that IVF/ICSI treatments have long term effects that are counteracted by having children. The association could also be the result of residual confounding by the underlying infertility.
Study funding/competing interest(s): Funding by University(ies). Funding by national/international organization(s) – 7th framework EU funding (the IDEAL project), the Swedish Research Council and Karolinska Institutet (strategic research grant in epidemiology).
Trial registration number: NA.

O-248 Poor response in IVF treatment and the risk of a trisomic pregnancy

T. C. Honorato[1], A. Hoek[5], A. A. Henningsen[2], A. Pinborg[3], O. Lidegaard[4], J. A. Land[5], H. Groen[7], M. L. Haadsma[6]
[1]*University Medical Center Groningen/University of Groningen, Department of Gynecology, Groningen, The Netherlands*
[2]*University of Copenhagen, Fertility Clinic Rigshospitalet, Copenhagen, Denmark*
[3]*University of Copenhagen, Department of Obstetrics and Gynaecology, Hvidovre, Denmark*
[4]*University of Copenhagen, Gynecological Clinic Rigshospitalet, Copenhagen, Denmark*
[5]*University of Groningen, Gynecology, Groningen, The Netherlands*
[6]*University of Groningen, Epidemiology, Groningen, The Netherlands*
[7]*University of Groningen, Genetics, Groningen, The Netherlands*

Study question: Is there an association between ovarian response in IVF treatment and the risk of a trisomic pregnancy resulting from that treatment?
Summary answer: Subfertile women with a poor response in IVF treatment are not at a higher risk of a trisomic pregnancy resulting from this IVF treatment.
What is known already: Poor response is mostly the result of low number of follicles available in ageing women, representing decreased ovarian reserve. The limited pool hypothesis states that decreased ovarian reserve may result in selection of low-quality oocytes prone for non-disjunction during meiosis, increasing the risk of aneuploidy. Supporting this hypothesis, we showed, in a previous study, an association between low ovarian response (≤4 oocytes) and trisomic pregnancy, independent of maternal age (Haadsma et al., 2010).
Study design, size, duration: This is a matched case-control study. Cases (n = 110) are women with a confirmed trisomic pregnancy from 1983 till 2011 resulting from IVF, regardless of pregnancy outcome (live birth, termination or stillbirth). Controls (n = 455) are women with a live born child without a trisomy, resulting from IVF treatment.
Participants/materials, setting, methods: Data were obtained from Danish and Dutch medical registries. Matching criteria were age and year of ART treatment. Number of controls matched per case ranged from 1 to 5. Analyses were performed for Danish, Dutch and combined cohorts using Generalized Estimating Equations and Spline Regression.
Main results and the role of chance: Results shown are from analyses of the combined Danish and Dutch cohorts. Cases and controls were compared by number of oocytes retrieved. Mean maternal age was 36 years. The mean number of oocytes retrieved for cases was 9.3 and for controls 9.4. Thirty three women had poor response (≤3 oocytes, 423 women had normal response and 109 women had unknown response. Poor response was detected in 9.1% of cases (8/88) and 6.8% of controls (25/368). Poor response was not associated with a higher risk of having a trisomic pregnancy (OR 1.2, 95% CI [0.77–1.89]).
Limitations, reason for caution: We were not able to adjust the analyses for dose of gonadotropin stimulation, cycle number, BMI and smoking due to limited database information.
Wider implications of the findings: In our study, there was no association between poor response in ART and aneuploidy of the resulting pregnancy. These results do not support the hypothesis that decreased oocyte quantity, reflected by poor response, is associated with decreased oocyte quality, reflected by aneuploidy, which is postulated in the limited pool hypothesis. However, confirmation of our findings in a larger population is warranted.
Study funding/competing interest(s): Funding by University(ies). Funding by hospital/clinic(s) – Gratama Stichting, University of Groningen and the University Medical Center Groningen, The Netherlands.
Trial registration number: NA.

O-249 Cumulative live birth rates following *in vitro* fertilisation in the United Kingdom: analysis of data from 107,347 women

D. J. McLernon[1], A. Maheshwari[1], A. J. Lee[1], S. Bhattacharya[1]
[1]*University of Aberdeen, Division of Applied Health Sciences, Aberdeen, United Kingdom*

Study question: What is the cumulative live birth rate following multiple *in vitro* fertilisation (IVF) treatment cycles in the UK for different patient and diagnostic subgroups?
Summary answer: Couples undergoing IVF in the UK have a cumulative chance of live birth of up to 50% (for term singleton live birth up to 25%) over 2 years.
What is known already: Live birth rates following IVF have traditionally been reported per cycle. However, many couples undergo multiple cycles with every subsequent cycle increasing their cumulative chances of success. Cumulative live birth rates (CLBR) have not been published in the UK and have only recently been reported in the USA. Also, cumulative rates for term singleton live birth, deemed to be the most favourable pregnancy outcome, have never been reported.
Study design, size, duration: In this retrospective cohort study, the cumulative live birth rates of 107,347 women who had their first in-vitro fertilisation treatment attempt in the UK from 1999 to 2007 were calculated. All cycles were included up to 2 years since the first attempt or first live birth occurrence, whichever came first.
Participants/materials, setting, methods: A database containing all UK IVF treatments was obtained from the Human Fertilisation and Embryology Authority (HFEA). Every treatment cycle, defined as a fresh treatment attempt or frozen embryo transfer attempt, was linked to the woman. Cumulative live birth and term (>37 weeks) singleton live birth rates were calculated.
Main results and the role of chance: A total of 107,347 women had 186,512 cycles over 2 years from 1999 to 2009. The most frequent cycle patterns were one fresh cycle (53.9%), two fresh cycles (22.8%), three fresh cycles (8.2%), and one fresh followed by one frozen cycle (4.5%). After the third cycle, the CLBR for women aged <31, 31–35, 36–40 and >40 years were 49.7, 48.3, 33.2 and 9.8% respectively. For term singleton live birth the corresponding rates were 27.4, 27.7, 21.4 and 7.3%. In couples with unexplained, tubal, anovulatory, or male factor infertility the CLBRs after three cycles were 39.9, 36.7, 37.3, 43.0% respectively (term singleton live birth: 24.0, 21.2, 21.1, 26.0%). In fresh cycles only, the CLBR for women who cryopreserved embryos was 44.2 versus 30.1% who could not.
Limitations, reason for caution: We could not account for treatment-independent live birth outcome due to the nature of the HFEA database. Information on IVF treatments in 2010 and 2011 were available from the HFEA. However, from 2010 patients had to opt for their data to be used for research purposes, lowering the numbers substantially.
Wider implications of the findings: The UK cumulative rates could be used in the counselling of patients commencing IVF treatment. The results could also be used by policy-makers and researchers to determine the provision of an optimum number of IVF cycles per patient based on their characteristics. The next stage will be to develop a clinical prediction model that can predict live birth after n number of cycles.
Study funding/competing interest(s): Funding by national/international organization(s) – Chief Scientist Office.
Trial registration number: PDF/12/06.

O-250 Cost per life birth after IVF/ICSI in France: a comparison of two gonadotropins based on published data from randomized trials and data from French practice

E. Arbo[1], C. Avril[2], P. Barrière[3], R. Fanchin[4], S. Hamamah[5], G. Porcu-Buisson[6]
[1]*Ferring SAS, Medical Affairs, Gentilly, France*
[2]*Clinique Mathilde, Centre AMP, Rouen, France*
[3]*Hôpital Mère-enfant CHU Nantes, Service de médecine et biologie de la reproduction, Nantes, France*
[4]*Hôpital Antoine-Béclère AP-HP, Service de Gynécologie-Obstétrique et Médecine de la Reproduction, Clamart, France*
[5]*Hôpital Arnaud de Villeneuve CHU Montpellier, ART-PGD Department, Montpellier, France*
[6]*Institut de Médecine de la Reproduction, IMR, Marseille, France*

Study question: What is the cost of a live birth (cost/LB) after an IVF/ICSI in France with two different gonadotropins (HP-hMG or rFSH) using the Markov model applied to two effectiveness scenarios (data from clinical trials and from French practice)? Which factors can influence the cost/LB and the incremental cost-effectiveness ratio (ICER)?
Summary answer: Using effectiveness data from clinical trials, cost/LB was €11,870 with HP-HMG and €13,928 with rFSH. Using data from French practice, these values were respectively €15,805 and €18,705. HP-hMG was more cost-effective. Expected effectiveness (LB rate – LBR) is the main contributing factor of final cost/LB, followed by gonadotropins total doses.
What is known already: Given that, in France, up to 4 IVF/ICSI attempts are fully reimbursed by the public health insurance system, cost of treatments is often and improperly neglected by patients and physicians. Whereas drugs used for controlled ovarian stimulation (COS) have different prices, data on costs/LB after IVF/ICSI still is lacking and should play a determining role in the choice of the most cost-effective COS protocol.
Study design, size, duration: A cost-effectiveness analysis using Markov model was performed. LB probabilities after IVF/ICSI, when HP-hMG or rFSH were used, were based on published randomized trials (Merit and Megaset). A correction factor was subsequently applied to accommodate published data to French practice, as reported by the national ABM registry (30% lower).
Participants/materials, setting, methods: Transition probabilities were applied to a virtual cohort of 30,000 IVF/ICSI candidates undergoing up to 4 COS cycles, including outcome possibilities as LB, cancellation/drops-outs, frozen/thawed embryos transfer... Costs encompassed all steps of infertility treatment and were based on French insurance system values. French experts validated all steps of the model.
Main results and the role of chance: In this decision analytic modelling where the Markov model was applied to a virtual cohort of 30,000 IVF/ICSI candidates, cost/LB with HP-HMG was €11,870 considering the published data and €15,805 considering the recalculated French registry data. These costs were lower than those observed with rFSH (€13,928 and €18,705, respectively). Further, in the first model, the ICER was estimated at €-11870 for any additional birth by using HP-HMG instead of rFSH. In the model using data from the French registry, estimated ICER was €-14,125. In both models expected effectiveness (LB rate) and total gonadotropin doses were the factors that influenced the most the ICER. Sensitivity analyses (one-way and probabilistic), performed to evaluate inaccuracies, corroborate these findings and attest their robustness.
Limitations, reason for caution: Markov model is a theoretic model of cost-effectiveness applied to a virtual cohort and limited to pre-defined transition probabilities. As treatment strategies are extremely variable, we needed to set some transition probabilities based on experts' opinion that reflect as far as possible French practice, but may not be universally applicable.
Wider implications of the findings: The present results indicate that HP-hMG is more cost-effective that rFSH for IVF/ICSI in France. They corroborate data from previous published data from international studies and should raise awareness for French health authorities on cost-effectiveness ratio of different gonadotropins for COS in the setting of their health policy on IVF/ICSI reimbursements. Also, potential economy related to the use of a less expensive gonadotropin is higher as the expected effectiveness increases.

SESSION 64: STEM CELLS: OUTSTANDING QUESTIONS FINALLY ANSWERED

Wednesday 17 June 2015 **12:00–13:00**

O-251 Human therapeutic cloning: advances and technical challenges

S. Mitalipov[1]
[1]*Oregon Health and Science University, Center for Embryonic Cell and Gene Therapy, Portland, Oregon, U.S.A.*

Cytoplasmic factors present in mature, metaphase II (MII)-arrested oocytes have a unique ability to reset the epigenetic identity of transplanted nuclei to the oocyte state. Using somatic cell nuclear transfer (SCNT), we demonstrated successful reprogramming of human skin fibroblasts into embryonic stem cells (NT-ESCs). A battery of genetic, epigenetic and transcriptional analyses performed on human NT-ESCs confirmed their close similarities to genuine IVF-derived ESCs than the traditional induced pluripotent stem cells.
Keywords: embryonic stem cells, somatic cell nuclear transfer, reprogramming

O-252 Naïve vs. primed pluripotency: a step further in regenerative medicine

J. Nichols[1], T. Boroviak[1], G. E. Guo[1], A. Smith[1]
[1]*University of Cambridge, Wellcome Trust (MRC) Medical Research Council Cambridge Stem Cell Institute, Cambridge, United Kingdom*

The mammalian embryo's ability to orchestrate the production of specific tissues in the correct time and place depends upon specification and control of a pool of pluripotent cells. We are interested in how these cells are segregated and the process by which they can be captured to produce naïve pluripotent embryonic stem cell lines. Using the mouse as an experimental system, we have generated transcriptional and functional data demonstrating that embryonic cells acquire the properties of naïve pluripotency (the capacity to self-renew from a single cell and contribute to all tissues of the adult organism, including the germline) during blastocyst expansion. Furthermore, we showed that the closest molecular counterpart to ES cells in the embryo is the epiblast just before blastocyst implantation. Because the pluripotent stem cell lines conventionally derived from human embryos have many divergent properties compared with mouse ES cells, we have used immunohistochemistry to establish whether markers of naïve pluripotency in the mouse are also present in human blastocysts. Reassured by the detection of Klf4 and Tfcp2l1 specifically in the inner cell mass, we have utilised a recently described culture regime to derive naïve pluripotent stem cell lines from human embryos by single cell explantation with high efficiency. Preliminary characterisation and expansion of these lines is consistent with their identity as naïve pluripotent ES cells. These will provide a useful resource for biomedical research and modelling human differentiation.
Keywords: epiblast, embryonic stem cell, naive pluripotency

INVITED SESSION

SESSION 65: ASRM/SOCIETY FOR ASSISTED REPRODUCTIVE TECHNOLOGY (SART) EXCHANGE SYMPOSIUM: "INCORPORATING NEW TECHNOLOGICAL APPROACHES INTO ART PRACTICE: CLINICAL AND LABORATORY COORDINATION"

Wednesday 17 June 2015 **12:00–13:00**

O-253 Why should I transfer 1 versus 2 embryos?

C. Coddington[1], B. Luke[2], G. D. Ball[3]
[1]*Mayo Clinic, Reproductive Endocrinology and Infertility, Rochester, MN, U.S.A.*
[2]*Michigan State University, Department of Ob/Gyn and Reproductive Biology, East Lansing, MI, U.S.A.*

[3]*Seattle Reproductive Medicine, Department of Obstetrics and Gynecology, Seattle, WA, U.S.A.*

The strong desire of patients dealing with infertility is having a healthy child – balancing cost versus increased pregnancy rate. Expectations by patients have increased as we have been more successful in creating the best embryo. However, there has been little linked National data to help provide an information benchmark regarding success and the individual parameters that surround the decision to transfer more than 1 embryo. Our hope is to provide a model for patients and physicians that can be used to clarify this choice.

Materials and Methods: Society for Reproductive Medicine (SART) collects data each year under a government mandate with the express purpose of informing patients. Data was studied from 2006 to 2012 utilizing a previously validated model. Cycles up to and including the first live birth were used.

Objective: To compare estimates of live birth rates (LBR) and multiple live birth rates (MBR) using autologous oocytes in one cycle with a double embryo transfer (DET) versus two successive cycles with single embryo transfer (SET) using either a fresh or frozen embryo in the subsequent cycle. Furthermore, other variables such as: age, body mass index (BMI), number of prior full term births, number of infertility diagnoses and infertility diagnoses were studied. From a previous validation paper, morphology and day of transfer and their role are discussed.

Results: Using logistic regression modeling a backward stepping algorithm was used eliminating variables until those remaining were $P < 0.05$. Models predicted LBR and MBR accounting for woman's age, BMI, prior births, and diagnosis, as well as number of embryos transferred. From over 320,000 patients and 500,000 cycles, the model used 33,065 for the first cycle SET and 126,921 for first cycle DET. In the subsequent cycle, SET included 8682 fresh cycles and 6747 thawed cycles. Results were calibrated to year 2012. An example of a 20 year old, BMI-40, and male factor might be used: her chance of pregnancy would be improved with 2 SET transfers (fresh or thawed) and her chance of twins reduced 18 fold. The LBR was found to be SET- 40.4%, 2 SET- 56%, 1SET/1FET- 60.5%, DET- 47.7%. Morphology and day of transfer may additionally alter these results; further refinement of the prediction model is planned.

Discussion and Conclusions: This predictive model utilized national linked data to predict live birth outcome. The prediction model included aspects of: age, BMI, full term births, diagnosis and number of embryos transferred. Limitations include the potential of errors of data entry (although validated annually) and that SET cycles may not be as representative of all cycles. Future plans include incorporation of day of transfer and morphology, as well as factors from prior cycles (successful and unsuccessful) to create a more in-depth model that physicians may use to counsel patients to establish expectations and thus strive to reduce the MBR.

Keywords: multiple birth rate, SART database, optimize IVF outcome, increase single embryo transfer

O-254 Coordination of new technology with laboratory resources

G. D. Ball[1], C. Bormann[2], A. Bartolucci[3], C. Coddington[4], E. Wantman[5]
[1]*Seattle Reproductive Medicine, ART Laboratory, Seattle, WA, U.S.A.*
[2]*Brigham and Women's Hospital, ART Laboratory, Boston, U.S.A.*
[3]*University of Connecticut, ART Laboratory, Farmington, U.S.A.*
[4]*Mayo Clinic, Reproductive Endocrinology, Rochester, U.S.A.*
[5]*Redshift Technologies, Development, New York, U.S.A.*

Introduction: Changing IVF treatment options have challenged the abilities of laboratories to provide the desired level of service to patients. These challenges have primarily been sourced in oocyte cryopreservation, embryo biopsy for preimplantation genetic screening (PGS), and cryopreservation of all suitable embryos prior to embryo transfer. Each of these technologies requires a unique laboratory technician skill set, equipment availability, and space for additional personnel and equipment. All these technologies, sometimes quite complex, also bring additional risks as the likelihood of an error increases due to the additional work load. In order to meet these challenges, it is imperative that clinics evaluate their experience and practice pattern trajectories in order to supply the required resources to meet these challenges.

Objective: The objective of this study was to evaluate the impact of overall cycle volume increase as well as three specific cycle types: oocyte cryopreservation, embryo biopsy, and "freeze all" cycles (where all embryos are cryopreserved with no intent to transfer embryos during the active treatment cycle) on laboratory workload. In turn, this may help laboratories determine which skill level and how many technicians may need training and how many, if any, technicians are required to meet clinic needs.

Materials and methods: The dataset available through the Society for Assisted Reproductive Technologies (SART) was evaluated for estimation of increased workload for US ART laboratories. Cycle volumes changes as well as cycle type change were evaluated from 2009 through 2013.

Results: There are clear US trends in ART cycle volumes and type which reflect both increased overall utilization of ART in the US as well as a shift toward more complicated cycles. Overall IVF volume increased 23% (+32,721 cycles) while egg banking cycles increased 749% (+4,269 cycles). Embryo banking cycles increased 359% (+14,881 cycles). Frozen embryo transfer cycles increased 76% (+18,659 cycles). PGD/PGS cycle numbers can only be estimated due to limited data requirements prior to 2014 cycle initiation. However, as example, the presenting author's ART program experienced an increase of 1,040% in PGD/PGS utilization

Conclusion and Discussion: Changing ART practice patterns have created resource challenges for the laboratory. These challenges are manifest in overall ART cycle volume and the complexity of each cycle. With each stage of complexity, a unique and increased chance for potential error is exposed. Especially with PGS, an error has significant impact on patients and increased liability for clinics. It is therefore imperative that laboratories anticipate practice changes and assess resources accordingly. These data reflect the nature of practice pattern changes in the US. Both the cycle volume and complexity of cycles present challenges to the laboratory in order to meet patient expectations as well as to avoid errors. Several strategies can be employed to meet these challenges including additional personnel, additional equipment, and space to house both. Additionally, coordination with clinical personnel to manage daily cycle volumes and types may maximize efficiency of staffing and equipment utilization.

INVITED SESSION

SESSION 66: PARAMEDICAL INVITED DEBATE SESSION: THE INTERNET DOES MORE HARM THAN GOOD

Wednesday 17 June 2015 **12:00–13:00**

O-255 Pro

S. Gameiro[1]
[1]*Cardiff University, School of Psychology, Cardiff Wales, United Kingdom*

This talk aims to provide evidence that the Internet can cause harm. In this context harm was defined as adverse events or bad outcomes, either physical or emotional, that occur after the use of materials, medications, and/or information obtained from a web site.

The literature regarding the use of the internet for assessing information, social-media (e.g., patient-foruns networking) and psychosocial-support (e.g., patient advocacy groups, psychosocial interventions) by infertile and medically assisted reproduction (MAR) patients was reviewed. The evidence collected supports the claims that the overall quality of infertility and MAR information available online is low, that infertility forums can have detrimental consequences and that internet-based interventions are not more effective than standard one-to-one psychosocial interventions.

First, there is considerable evidence showing that the overall quality of the information presented in infertility web sites is low and does not comply with existing guidelines. Infertility information in the Internet can also be overwhelming, distressful and subject to no content and quality control and regulatory mechanisms. There are examples in the health literature of events when specific online inaccurate information resulted in clinically significant emotional distress and physical harm, leading up to death. Other patient-reported negative effects of information consumption on the Internet are unnecessary visits to the physician, requiring that the physician take specific course of actions, taking up the physician's time and interfering with the patient-physician relationship.

Second, studies focusing on the disadvantages of using online infertility related forums show that up to 58% of patients report negative experiences such as

unjustified worry and anxiety, being exposed to the pregnancy of other people and inaccurate information, and addiction problems. Other less common experiences are aggressions and bullying, misunderstandings in communication and anxiety due to the time-lag of asynchronous communication.
Third, there is an overall agreement that peer-reviewed literature provides a gross underestimate of harm associated with health-related information and interventions because authors tend to concentrate on efficacy and effectiveness and rarely assess harm or other possible secondary effects. But even when this positive outlook is taken, evidence about the therapeutic benefits of internet-based interventions in not compelling. Overall the results seem to reproduce what is already known about infertility psychosocial interventions that are delivered in standard format: educational interventions increase knowledge and decrease anxiety but complex therapeutic or counselling interventions do not seem to increase patient quality-of-life during treatment. In the case of internet-based interventions, the causes for the lack of success become harder to disentangle. It may be that the psychosocial active components of the interventions are not effective, but it can also be that it is difficult to translate these from a one-to-one therapeutic context to an internet-based one. Overall the data suggests that treatments that include guidance from a mental health professional lead to better outcomes than unguided treatments.
In summary, while empirical evidence on the benefits of internet-based educational and therapeutic interventions within the infertility field is limited, the few studies that investigated the Internet harm potential produced worrisome results. Considering that the Internet has penetrated all areas of human life and numerous professional operations and that it is here to stay, more emphasis should be made to put in place the necessary regulatory mechanisms to avoid detrimental outcomes for infertile patients.

O-256 Con

Y. Khalaf[1]
[1]*Guy's Hospital, The Assisted Conception Unit and Centre for Pre-Implantation Genetic Diagnosis, London, United Kingdom*

The proposal is a one-sided view that focuses on the negative aspects of this phenomenal invention, which has changed lives of the inhabitants of planet earth for good!
Like all important discoveries, there is a method failure and there is use failure. Nobody can put forward a persuasive argument that the internet has failed as a method. However, any use failure is relatively limited and should not blind us to the incontestable fact that life can not be the same without the internet, be it for medical information, or any other type of knowledge.
I will be arguing against the motion and will elaborate further on the day!
Keywords: internet, harm than good, con

SESSION 67: IMPACT OF CRYOPRESERVATION TECHNIQUES

Wednesday 17 June 2015 **14:00–15:15**

O-257 Effects of vitrification of 8-cell mouse embryos on blastocyst and postnatal development

R. I. A. Raja Khalif[1], A. Aljahdali[1], B. Sheth[1], M. A. Velazquez[1], N. R. Smyth[1], T. P. Fleming[1]
[1]*University of Southampton, Centre of Biological Sciences, Southampton, United Kingdom*

Study question: Does vitrification of murine embryos at the 8-cell stage alter blastocyst formation and postnatal growth, blood pressure or blood glucose homeostasis?
Summary answer: Our results suggest that while vitrification alters blastocyst development it does not change postnatal body weight, blood pressure and glucose tolerance in mice.
What is known already: Animal models have shown that vitrification can impair ultrastructure and developmental ability of oocytes, embryo survival rates, pregnancy rates and result in a low birth weight but any long term effects on offspring is still unknown.
Study design, size, duration: Three different treatment groups were studied (10 litters in each, 1) controls (non-ART treatment) 2) embryos cultured from 8-cell to blastocyst and subsequently embryo transferred (ET) to pseudo-pregnant mothers and 3) vitrified 8-cell embryos, reanimated and cultured to blastocyst and ET. From each group developed blastocysts were also analysed for cell number and allocation to trophectoderm or ICM.
Participants/materials, setting, methods: Embryos were vitrified at the 8-cell stage and held in LN_2. Embryos were warmed and cultured until they formed blastocyst before embryo-transfer. Offspring were weighed weekly, systolic blood pressure (SBP) taken at weeks 9, 15, 21 and glucose tolerance tests (GTT) carried out prior to cull for organ collection at week 27.
Main results and the role of chance: Offspring body weight for both sexes showed a significant increase ($P < 0.05$) for both non-vitrified ET ($n = 54$) and vitrified-ET ($n = 32$) groups when compared to controls ($n = 81$). Analysis of organ weight showed that kidneys and liver were significantly heavier in both treatment groups for both male and female. Males demonstrated a significant increase in SBP and a significantly impaired GTT[n1]. However there were no significant differences between the vitrified and non-vitrified ET groups in terms of all the above parameters. Differential labelling of blastocysts showed vitrification reduced both trophectoderm and inner cell mass (ICM) cell number significantly when compared to controls ($n = 81$–95 blastocysts per treatment). Our results suggest that while vitrification alters blastocyst development, it does not *per se* change postnatal body weight, blood pressure and glucose tolerance in mice, rather *in vitro* culture may alter these parameters.
Limitations, reason for caution: Extrapolation of these results to other species requires caution as the culture protocols, and stage of embryos may differ between species.
Wider implications of the findings: In the authors' knowledge, this is the first report on the effect of vitrification on postnatal health in mice. Further studies with gene expressions from stem cell derived from vitrified embryos in mice would be useful to further explain the link between vitrification with the low ICM cell number and any effect on postnatal health.
Study funding/competing interest(s): Funding by national/international organization(s) – This work was supported by the European Research Council (FP7-EPIHEALTH) and MARA, Malaysia.
Trial registration number: None.
Keywords: cryopreservation, vitrification, postnatal health, mice, ART

O-258 Elective frozen embryo transfer does not improve reproductive outcome in normo-responder patients

P. Celada[1], E. Bosch[2], M. J. De Los Santos[2], J. Giles[2], A. Pellicer[2]
[1]*Hospital Universitario Doctor Peset, Gynaecology, Valencia, Spain*
[2]*Instituto Valenciano de Infertilidad (IVI), Human Reproduction, Valencia, Spain*

Study question: Does freeze all and differed embryo transfer improve reproductive outcome in normo-responder patients compared to fresh embryo transfer?
Summary answer: Freezing all embryos and differing transfer to a subsequent endometrial preparation cycle does not improve cycle outcome in terms of ongoing pregnancy and take home baby rates when compared to fresh embryo transfer.
What is known already: Several studies suggest that endometrial receptivity could be diminished during controlled ovarian stimulation (COS) due to morphological, biochemical and genetic changes. Some authors have suggested the solution by transferring the embryo in a delayed cycle in which the endometrium has not been exposed to the supra-physiological levels of gonadotropins. These findings support a freezing all approach.
Study design, size, duration: It is a single center retrospective observational cohort study. We include 882 patients aged 20–44 undergoing their first or second IVF/ICSI cycle between January 1st 2013 and December 31st, 2013, in which a normal oocyte yield (4–20) was obtained and embryo transfer was performed.
Participants/materials, setting, methods: The study was performed in the Instituto Valenciano de Infertilidad, Spain. Included 882 patients of which 364

(41.3%) had a fresh embryo transfer and 518 (58.7%) were submitted to freeze all according to doctor's preference. Ongoing pregnancy and take home baby rates are compared by multinomial logistic regression.
Main results and the role of chance: No differences were observed between both patients groups in terms of demographic characteristics and ovarian stimulation parameters. The raw analysis showed that ongoing pregnancy (33.2 vs. 32.9%, $p = 0.94$) and take home baby (36.2 vs. 33.8%, $p = 0.51$) rates for freeze-all vs. fresh cycles respectively were similar.
A multinomial logistic regression analysis that included all variables related to the cycle outcome (i.e: patients' age, serum E2, endometrial thickness, oocyte yield, fertilization rate, PGS, number of embryos transferred, and embryo stage at transfer) was performed. No impact of freezing-all could be observed, with an Odds Ratio (95% CI) of 0.90 (0.66–1.47) for ongoing pregnancy rate and 1.01 (0.73–1.40) for take home baby rate.
Limitations, reason for caution: The main limitation is that this is a retrospective study. Furthermore, the decision to transfer fresh embryos or freezing all was taken personally by each doctor.
Wider implications of the findings: These findings do not support a change in IVF practice moving to a freeze-all strategy in normo-responder patients. These may benefit patients since the treatment cost and the time to pregnancy is shorter when fresh embryos are transferred Only if well designed randomized controlled trials show different findings this change should be considered.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Instituto Valenciano de Infertilidad (IVI), Valencia, Spain.
Trial registration number: NA.
Keywords: frozen embryo transfer, fresh embryo transfer, ongoing pregnancy, freeze-all, IVF/ICSI

O-259 Laser-assisted zona pellucida thinning may negatively effect pregnancy outcome of frozen-thawed embryos

I. Har-Vardi[1], M. Friger[2], A. Zeadna[1], S. Alboteano[1], D. Richter[1], T. Priel[1], G. Alter[1], G. Bar[1], I. Bord[1], A. Harlev[1], L. Man[1], E. Lunenfeld[1], E. Levitas[1]
[1]*Soroka University Medical Center, Department of Obstetrics and Gynecology, Beer-Sheva, Israel*
[2]*Ben-Gurion University of the Negev, Department of Epidemiology, Beer-Sheva, Israel*

Study question: Can laser-assisted hatching of the zona pellucida (ZP) positively effect pregnancy outcome of frozen-thawed cleavage stage embryos?
Summary answer: Performing assisted hatching (AH) on frozen-thawed cleavage stage embryos prior to ET in women above 35 years was shown to reduce clinical pregnancy rate, to increase chemical pregnancy and missed abortion rates. No significant effect of AH was shown regarding those parameters in women below 35 years.
What is known already: Hatching of the embryo through the zona pellucida is a necessary step for successful implantation. AH, a laser opening in the ZP has been proposed as a method for improving embryo implantation. Controversy exists regarding the effect of AH on frozen-thawed embryos on clinical pregnancy, implantation and delivery rates. The most relevant conclusion obtained so far is that AH in fresh cycles has a beneficial effect in women with repeated embryo implantation failures.
Study design, size, duration: A retrospective study included 334 patients that underwent frozen-thawed embryo transfer between 2012 and 2013. AH was performed on embryos of 170 patients in 2012. We compared IVF outcomes: chemical and clinical pregnancy rates, implantation, abortion and delivery rates according to age groups above/below 35 years.
Participants/materials, setting, methods: The data were divided into 4 groups according to women's age and laser-AH performance; group 1 –below 35 years (245) and group 2 over 35 (89). AH performance: group 1a- below 35 (118) and group 2a- over 35 years (52). Statistical analysis was carried out using *t*-test and Chi-Square Tests.
Main results and the role of chance: No differences were found between AH/no AH groups regarding clinical pregnancy rate, chemical pregnancy rate, implantation rate, missed abortion rate and delivery rate in women below age 35 (mean age 28.5 + 3.41). Surprisingly, performing AH in women above 35 years (mean age 38.6 + 2.6) was shown to reduce clinical pregnancy rate (9.6 vs. 23.3%), $P < 0.05$, to increase chemical pregnancies (11.5 vs. 0%), $P < 0.05$ and to increase missed abortion rate (0 vs. 44%), $P < 0.05$. No differences were found between the groups concerning other confounding variables which could effect implantation and pregnancy rate. There were no differences in implantation and clinical pregnancy rates in the fresh cycles between the years 2012–2013.
Limitations, reason for caution: This study was carried out retrospectively. Patients were compared between cases and controls that were recruited in consecutive years (cases 2012 control 2013). To exclude bias, only cycles of frozen-thawed cleavage embryos (48–72 h) were included. Blastocysts were excluded from the study because of the thinner zona pellucida.
Wider implications of the findings: Performance of AH was suggested to improve the outcome of frozen thawed embryo transfer because of ZP hardening during the freezing and thawing process. However, our data shown that in cycle of frozen-thawed cleavage stage embryo transfer, AH in women over 35 years, could decrease IVF outcomes. In frozen-thawed cycles we would recommend to transfer the embryos with no further involvement. The potential value of AH for frozen-thawed embryos has to be weighed carefully.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Soroka University Medical Center.
Trial registration number: None.

O-260 The impact of cryopreservation on the oocyte transcriptome: vitrification versus slow freezing

V. Bianchi[1], S. Jaroudi[2], D. Wells[2]
[1]*Casa di Cura Città di Udine, Careggi Hospital Florence, Udine, Italy*
[2]*Reprogenetics UK, Institute of Reproductive Sciences, Oxford, United Kingdom*
[3]*Tecnobios Procreazione, N.A., Bologna, Italy*

Study question: Although clinical data exists concerning the survival of oocytes cryopreserved using different methods, there is little information on the biological impact of different technologies. This study evaluated the impact of cryopreservation on oocyte mRNA transcripts and considered whether any differences observed might have implications for clinical efficacy and safety.
Summary answer: Microarray data revealed low-level alterations in the expression profiles of cryopreserved human oocytes, with larger number of genes affected in vitrified samples. However, follow-up real-time PCR analysis, demonstrated that most alterations were not significant, suggesting that slow-freezing and vitrification are likely to be safe and suitable for clinical use.
What is known already: Oocyte cryopreservation is increasingly widely used. The main indications are related to fertility preservation preceding cancer treatment and for social reasons. Additionally, the use of cryopreservation in conjunction with oocyte donation is becoming more common. In the last decade, vitrification has become the dominant method of oocyte cryopreservation, however recent protocol improvements have led to some resurgence in the use of slow-freezing. Both methods have given numerous live births, but molecular studies remain limited.
Study design, size, duration: This study involved women undergoing IVF treatment for either tubal or male infertility factors (i.e., without any detectable ovarian pathology). All patients were under 36 years (range: 28–35; average: 33.4) and had given informed consent.
Participants/materials, setting, methods: A total of 25 metaphase II oocytes (8 fresh, 8 slow-frozen and 9 vitrified) were analyzed. Processing of samples was carried out rapidly to minimise RNA degradation. Gene expression real-time PCR analysis utilised validated TaqMan assays, targeting genes with potential alterations in gene expression, highlighted by previous microarray analyses.
Main results and the role of chance: A small reduction in the quantity of mRNA transcripts was detected for some genes in slow-frozen oocytes (fold-changes from 0.6 to 0.8; $p < 0.05$). The genes affected by loss of transcripts were *HSP90AA1*, *HSPD1* and *EIF2C2* (compared with fresh oocytes) and *EFCAB11*, *EIF2C2* and *PDPR* (compared with vitrified oocytes). No significant alterations in mRNA levels were detected in vitrified oocytes for any of the genes investigated. Results from multiple oocytes derived from different women were combined together in order to minimize the effect of any patient-specific variability in gene expression. The average female age was similar for the three groups of oocyte analysed (33 years for fresh and slow frozen and 34

for vitrified eggs). Samples were run in triplicate to avoid potential experimental errors.
Limitations, reason for caution: The number of potentially altered genes, highlighted by microarray analysis, which could be followed up, was limited due to the finite amount of RNA obtained from each sample. Analysis of microRNAs would be valuable for understanding mRNA utilization in the oocyte but could not be assessed during this study.
Wider implications of the findings: The growth in cryopreservation has led to an urgent need for improved understanding of the impact of different methodologies on the oocyte. Techniques in current use are associated with high clinical pregnancy rates, but there are few molecular studies to support one particular technique over another. This study provided reassurance that vitrification is not associated with significant changes to the oocyte transcriptome. Alterations seen for slow-frozen oocytes were modest and of questionable clinical significance.
Study funding/competing interest(s): Funding by national/international organization(s) – This study was supported by a grant to Casa di Cura Città di Udine from the Italian Institute of Health.
Trial registration number: NA.
Keywords: human oocyte cryopreservation, transcriptome, vitrification, slow freezing

O-261 Fresh vs. aseptically vitrified sibling oocytes in an oocyte donation program. A prospective, observational, comparative study

A. Papatheodorou[1], P. Vanderswalmen[2], Y. Panagiotidis[3], S. Petousis[3], L. Kasapi[3], M. Goudakou[3], G. Gullo[4], N. Prapas[3], K. Zikopoulos[1], I. Georgiou[1], Y. Prapas[3]
[1]*Ioannina University School of Medicine, Centre for Reproductive Medicine Department of Obstetrics and Gynecology, Ioannina, Greece*
[2]*Centers Prof. Zech, IVF, Bregenz, Austria*
[3]*Iakentro Fertility Center, IVF, Thessaloniki, Greece*
[4]*Univesrita di Messina, Department of Obstetrics and Gynecology, Messina, Italy*

Study question: The aim of this study was to compare the embryological and clinical outcome of sibling fresh versus vitrified (in a closed system) oocytes, in an oocyte donation program.
Summary answer: We found a difference in the embryological outcome between the compared groups but we found no differences in the clinical outcome. Although blastocyst rate is significantly lower in the vitrification group, this does not affect the clinical and the ongoing pregnancy rates which are similar compared to the fresh group.
What is known already: There are studies which show very promising results after vitrification of oocytes. Open vitrification systems are more popular and more frequently reported in literature. A debate on whether open vitrification is considered aseptic and a directive from EU, for aseptic manipulation of cryopreserved cells and tissue, led to the need of a valid closed system for vitrification. There are not many studies which compare directly fresh with vitrified in a closed system oocytes.
Study design, size, duration: A prospective, observational, comparative study was performed from January to November 2014. The retrieved oocytes of a donor were randomly assigned into group I (fresh oocytes) or group II (vitrified oocytes). During the pickup, oocytes were given sequential numbers. Odd numbers were assigned into group I and even numbers into group II.
Participants/materials, setting, methods: 75 cases were included in each group. In group I, fresh oocytes were fertilized, developed and transferred on day 5. In group II, retrieved oocytes were vitrified using a closed system vitrification carrier device. When the recipient couple was ready and properly prepared, oocytes were warmed, fertilized, developed and transferred on day 5.
Main results and the role of chance: Fertilization rate is similar between the compared groups (77.2 vs. 72.1%) but blastocyst rate (53.1 vs. 43.3%) and top blastocyst rate (32.8 vs. 22.5%) is statistically higher in fresh group. Respecting clinical outcome, pregnancy rate (60.9 vs. 58.4%), implantation rate (34.7 vs. 36.1%) clinical pregnancy rate (50.0 vs. 52.7%) and ongoing pregnancy rate (48.6 vs. 51.38%) were similar between group I and II. Although at the beginning it is obvious that vitrification of oocytes has a negative impact in an oocyte donation case, due to lower blastocyst rate, this fact finally does not affect the clinical outcome of the case.
Limitations, reason for caution: The cases in the two examined groups were sibling, originated from the same donors whose oocytes were randomly and equally allocated into these groups and thus, the results of this study can be considered important. It is very important to validate these results in a larger scale.
Wider implications of the findings: The findings of this study are very interesting. Transferring blastocyst derived from vitrified – warmed oocytes instead of embryos from fresh oocytes does not compromise the clinical outcome, although the blastocyst rate is lower. This study validates the clinical efficiency of closed vitrification devices, which are an alternative to vitrify and store oocytes in an aseptic way. Nevertheless, more research is needed in order to improve the embryological parameters of the vitrified oocytes.
Study funding/competing interest(s): Funding by hospital/clinic(s) – IAKENTRO Advanced Medical Center.
Trial registration number: The study was approved by the Institutional Review Board (Ref. no. 1/2014, granted 7 January 2014).
Keywords: vitrification, closed system vitrification, human oocytes, oocyte donation

SESSION 68: RESEARCH IN CLINICAL ENDOCRINOLOGY

Wednesday 17 June 2015 **14:00–15:15**

O-262 Kisspeptin mediates positive estrogen feedback on gonadotropin secretion in women

K. Skorupskaite[1], J. George[2], R. A. Anderson[1]
[1]*University of Edinburgh, Queen's Medical Research Institute Centre for Reproductive Health, Edinburgh, United Kingdom*
[2]*University of Oxford, Oxford Centre for Diabetes Endocrinology and Metabolism, Oxford, United Kingdom*

Study question: Does exogenous kisspeptin-10, administered concurrently with appropriately timed estrogen, increase gonadotropin (LH and FSH) secretion, mimicking the physiological mid-cycle surge in women?
Summary answer: In a model of estrogen-induced gonadotropin secretion in women, kisspeptin-10 markedly increased LH secretion, advancing an LH surge and additionally stimulating FSH secretion. This suggests a role for kisspeptin in mediating hypothalamic positive estrogen feedback, and the pre-ovulatory mid-cycle gonadotropin surge triggered by this feedback.
What is known already: The hypothalamic neuropeptide kisspeptin is a key regulator of GnRH and thus gonadotropin secretion. There is evidence from animal-models that kisspeptin neurones mediate sex-steroid feedback signalling. Gonadotropin response to exogenous kisspeptin varies across the menstrual cycle, increasing more than two-fold higher across the follicular phase. We hypothesised that kisspeptin mediates pre-ovulatory positive estrogen feedback in the human and have investigated it by assessing gonadotropin responses to kisspeptin following estrogen priming.
Study design, size, duration: Nine women were treated with transdermal estradiol (200 µg/day) from cycle day 9–11, known to increase LH secretion 48 h later. At 24 h (before the expected LH rise) they were randomised to receive kisspeptin-10 or saline infusion for 7 h: all women received the alternate infusion in a subsequent cycle.
Participants/materials, setting, methods: Women were healthy with regular menstrual cycles. Kisspeptin-10 was infused at 4 µg/kg/h iv. Blood samples were taken before estrogen treatment (time 0), pre and post kisspeptin-10/saline infusion and at 48 and 72 h. Hormone concentrations were compared by ANOVA with Bonferroni multiple comparison post hoc analysis.
Main results and the role of chance: *Model validation*: Estrogen treatment increased LH after 48 h but not 24 h (time 0: 4.4 ± 0.6; 24 h: 3.1 ± 0.3; 48 h: 8.6 ± 1.0 IU/l, $p < 0.0001$). Similarly, FSH secretion increased significantly after 48 h of estrogen treatment (time 0: 2.6 ± 0.3; 24 h: 1.7 ± 0.3; 48 h: 3.3 ± 0.6 IU/l, $p = 0.0017$).

Kisspeptin response: Kisspeptin-10 acutely stimulated LH secretion from 3.8 ± 0.6 to 18.1 ± 4.3 IU/l ($p < 0.0001$) at the end of infusion. LH remained significantly elevated at 48 and 72 h after the start of estrogen treatment (15.3 ± 4.0 and 8.1 ± 1.3 IU/l, both $p < 0.01$ vs. start of infusion). Saline infusion had no effect on LH secretion (3.1 ± 0.3–2.7 ± 0.3 IU/l, ns). Kisspeptin-10 also acutely increased FSH secretion from 1.6 ± 0.1 IU/l pre-infusion to 3.6 ± 0.6 IU/l post-infusion ($p < 0.0001$) while saline had no such effect (1.7 ± 0.3–1.3 ± 0.2 IU/l, ns).

Limitations, reason for caution: This model of positive estrogen feedback may not fully replicate the physiological system. The response to kisspeptin-10 varied between women, suggesting that additional complex signalling pathways might be involved in mediating the mid-cycle surge in gonadotropins.

Wider implications of the findings: These findings add to our understanding of sex steroidal feedback control of hypothalamic function and the mid-cycle gonadotropin surge, key aspects of reproductive biology. Manipulation of this system has potential translational application in regulating GnRH secretion in a wide range of conditions, specifically in promoting or preventing ovulation.

Study question: What is the causative gene mutation of the Chinese premature ovarian failure (POF) pedigree?

Summary answer: Whole-Exome Sequencing identified a truncation mutation in basonuclin 1 (BNC1), which was absent in 332 healthy controls, as a cause of POF. The truncated mutant protein exhibited obvious function disorder, and was related to POF in human.

What is known already: POF leads to infertility and premature menopause in women under 40, and increases all-cause mortality. Its known causes are highly heterogeneous. And in most POF cases, the cause remains unknown.

Study design, size, duration: Clinical basic research. A pedigree including seven members with POF, 80 sporadic POF patients, and 332 healthy controls. Five years.

Participants/materials, setting, methods: Our study enrolled a large Chinese pedigree in which seven members were affected by POF in an autosomal dominant manner, 80 sporadic POF patients, and 332 healthy controls. Whole-genome SNP scanning was performed in all the available family 1 members. Whole Exome sequencing was performed in three affected women with POF in family 1, and following Sanger sequencing verification was applied in all family members, sporadic POF patients, and healthy controls.

Main results and the role of chance: We identified a novel 5 bp deletion mutation within the *BNC1* gene completely co-segregated with POF in a Chinese family with POF, and a missense mutation within the *BNC1* gene in three sporadic POF patients. The 5-bp deletion within the *BNC1* gene led to a frameshift in translation and a premature TGA stop codon. The mutated BNC1 protein was truncated, losing its evolutionarily conserved three pairs of zinc fingers. We found BNC1 protein expressed in human oocytes, and *BNC1* knockdown inhibited human oocyte meiosis. The transfection of recombinant plasmids with truncation mutant in HEK293T cells led to obvious nuclear translocation disorder. These results suggest that the *BNC1* mutation resulted in the protein dysfunction, and could cause POF in humans.

Limitations, reason for caution: The size of sporadic POF patients was limited, and need to be expanded in our future research.

Wider implications of the findings: Our study provides the first evidence of a link between BNC1 dysfunction and human POF. Further studies are required to understand the underlying mechanism of ovarian aging.

Study funding/competing interest(s): Funding by national/international organization(s) – The National Basic Research Program of China (No. 2013CB967404, 2012CB944900), the National Natural Science Foundation of China (No. 81270664, 81471421), and the Science Foundation for Distinguished Young Scholars of Zhejiang Province (No.LR14H040001).

O-264 Identification of circulating microRNAs in human follicular fluid as biomarkers of ovarian disorders

S. Hamamah[1], S. Traver[2], A. Ferrières[1], V. Loup[1], S. Huberlant[1], S. Belloc[3], E. Scalici[2]

[1]*Arnaud de Villeneuve hospital CHU Montpellier, ART/PGD Department, Montpellier, France*

[2]*Institute of Research in Biotherapy, INSERM U1203, Montpellier, France*

[3]*Eylau Laboratory, Unilabs, Paris, France*

Study question: Could circulating microRNAs (miRNAs) in human follicular fluid (FF) be associated with ovarian reserve status and thus, represent new promising biomarkers of female infertility?

Summary answer: Few circulating miRNAs were differentially expressed in FF samples according to women's ovarian reserve status and to controlled ovarian stimulation (COS) protocols. They might constitute potential biomarkers for detecting ovarian disorders in women included in IVF/ICSI program.

What is known already: MiRNAs are small non-coding RNA molecules, involved in the regulation of gene expression. Some miRNAs can be detected in biological fluids, including FF. Circulating miRNAs are already used as diagnostic/prognostic markers of many diseases such as gynecology and pregnancy disorders. Moreover, several circulating miRNAs are regulatory role in ovarian function but their implication in female infertility remains unknown.

Study design, size, duration: This prospective monocentric study included 83 patients (aged 35 ± 4.7 years): 56 women with normal ovarian reserve, 7 with poor ovarian reserve and 20 affected by polycystic ovary syndrome (PCOS). A pool of FF were retrieved for each patient during IVF/ICSI procedure.

Participants/materials, setting, methods: At oocyte retrieval day, all FF were collected and pooled for each patient. MiRNAs were extracted from pooled FF samples and quantified by RT-qPCR, using TaqMan technology. The candidate miRNAs, detected in FF samples were miR 140, miR 230a and miR191. MiRNA levels were compared by using the Mann-Whitney test and Spearman's Rank correlation coefficients were reported.

Main results and the role of chance: Circulating miR-140 in FF was negatively and significantly correlated with serum Anti-Müllerian hormone (AMH) levels and antral follicle count (AFC), evaluated at day 3 of menstrual cycle ($r = -0.3$, $p = 0.02$; $r = -0.41$, $p = 0.001$ respectively). Interestingly, miR-140 was significantly decreased in FF samples from patients with PCOS compared to those with normal ovarian reserve ($p < 0.001$). Likewise, miR-320a were significantly lower in FF samples from women with high basal serum LH levels (>5 IU/l) ($p = 0.007$). Spearman correlation calculation revealed a significant and negative correlation between intra-follicular miR-320a levels and basal LH rates in serum ($r = -0.28$; $p = 0.01$). In contrast, circulating

miR-191 was highly and significantly expressed in FF from patients with high AMH levels (≥5 ng/ml) ($p < 0.001$). Moreover, female infertility or agonist long protocol were significantly related to low miR-140 levels in FF compared to male infertility or antagonist protocol, respectively ($p = 0.02$; $p = 0.02$, respectively). In addition, miR-320a levels in FF were significantly and positively associated with the number of mature oocyte (MII) ($r = 0.25$; $p = 0.046$).

Limitations, reason for caution: The involvement of miR-140, miR-191 and miR-320a in pathogenesis of ovarian disorders and the identification of their potential target genes should be explored by conducting further functional investigations.

Wider implications of the findings: The expression levels of some circulating microRNAs in FF were significantly associated with ovarian reserve status and ovarian response to COS protocols. They provide new useful tools to improve the diagnosis/prognosis of infertile women during IVF/ICSI procedure. The combination of several circulating miRNAs could be more efficient for the diagnosis of PCOS. Moreover, circulating miRNAs might represent promising therapeutic targets in human reproductive system.

O-265 Cardiovascular disease (CVD) in hyperandrogenic postmenopausal women

C. Meun[1], M. Kavousi[2], L. Jaspers[2], T. Muka[2], O. H. Franco Duran[2], J. S. E. Laven[1]

[1]*Erasmus University Medical Center, Obstectrics and Gynaecology, Rotterdam, The Netherlands*

[2]*Erasmus University Medical Center, Epidemiology, Rotterdam, The Netherlands*

Study question: To assess the potential association of postmenopausal androgen levels with the prevalence of CVD (defined as coronary heart disease and/or heart failure and/or stroke) in a population based sample.

Summary answer: Heart failure is more prevalent in postmenopausal women with hyperandrogenism compared to women with normal androgen levels, implicating that women with PCOS might be at greater risk to develop CVD in their postmenopausal years.

What is known already: Hyperandrogenism is one of the three key features of PCOS and has been associated with increased prevalence of the metabolic syndrome and increased cardiovascular risk factors. Hyperandrogenism is probably maintained into the postmenopausal period, which has led to the assumption that women with PCOS are at increased risk for CVD during the postmenopausal years.

Study design, size, duration: A large population-based prospective cohort of 3635 female subjects, aged 55 years or older, with long term follow up. The study was conducted in a defined area in Rotterdam, the Netherlands.

Participants/materials, setting, methods: All patients underwent standardized interviews assessing their general, cardiovascular health followed by a thorough physical examination and asubsequent assessment of steroid levels using LC-MS.

Main results and the role of chance: The median age was 69.6 (range 55.1–105.7). Women with testosterone levels exceeding P_{90} showed an increased prevalence (19/361; 5.3%) of heart failure ($P = 0.047$), compared to women with levels between P_{40} and P_{60} (20/777; 2.6%). However, no significant increase in the prevalence of coronary heart disease (CHD) (17/348; 4.9%, $P = 0.48$), stroke (15/367; 4.1%, $P = 0.87$), or CVD (coronary heart disease, stroke and heart failure combined) (43/348; 12.4%, $P = 0.14$) was found in these women. Surprisingly neither androstenedione nor DHEA levels were correlated with heart failure, CHD or stroke. Hence, CVD was not at all correlated with these hormones. Finally, no correlation between the free androgen index and CVD was found.

Limitations, reason for caution: A potential limitation of the current study is that our cohort is relatively healthy.

Wider implications of the findings: Heart failure is slightly more prevalent in postmenopausal women with hyperandrogenism compared to women with normal androgen levels, indicating that women with PCOS might be at greater risk to develop heart failure in their postmenopausal years. However, no significant increase in the prevalence of coronary heart disease and stroke was found.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Erasmus Medical Centre.

Trial registration number: NA.

O-266 Short term estrogen therapy improves endothelial function in menopausal women: a double blinded randomized controlled trial of flow mediated dilation

R. Hurtado[1], S. Geber[1], M. F. S. Celani[1], A. H. F. Brandao[1], B. B. Coimbra[1]

[1]*Hospital das Clinicas UFMG, Gynaecology and Obstetrics, Belo Horizonte – MG, Brazil*

Study question: Is Flow Mediated Dilation (FMD) able to detect changes in endothelial function of menopausal women after only 28 days of estrogen therapy?

Summary answer: The use of 0.625 mg of conjugated estrogens for only 28 days is effective in improving vascular Nitric Oxide (NO)-dependent dilation assessed by FMD in menopausal women.

What is known already: Estrogen therapy has been proven efficient in reversing estrogen deprivation features in both laboratory and animal studies but there is still no consensus to which type of hormone therapy, dosage, administration path and time of onset would be optimal for reducing cardiovascular risk and also safe for clinical use.

Study design, size, duration: This was a double-blinded RCT carried out for the past 4 years in Hospital das Clinicas of the Federal University of Minas Gerais, Brazil where participants were selected among over 500 subjects. Sample size calculation determined a number of 30 patients in each group in order to reach a power of 0.80 and an alpha error of 5% in detecting statistically significant difference between the groups.

Participants/materials, setting, methods: 64 healthy menopausal women were selected and randomly assigned into two groups of treatment: 0.625 mg of Conjugated Estrogens were administered in the study group and placebo in the control group. Simple randomization was performed through computer-generated sorting. All participants were blinded to the use of conjugated estrogens or placebo and FMD was assessed by a blinded examiner before and after only 28 days of medication. Mann-Whitney's statistical test was used to compare the results of FMD obtained in both groups. *P-value* lower than 0.05 was considered statistically significant.

Main results and the role of chance: FMD values were statistically different between the groups ($p = 0.025$), where the study group of estrogen therapy showed a FMD value of 0.011 when compared to the placebo group (FMD = –0.082). The two groups were additionally evaluated for homogeneity through the Shapiro-Wilk test in respect to variables that could interfere with endothelial function such as age ($p = 0.729$), Body Mass Index (BMI) ($p = 0.891$), and time since menopause ($p = 0.724$). There was no statistical difference between the groups for any of these variables. Other variables were excluded during selection of the participants such as chronic vascular conditions, smoking, and sedentarism.

Limitations, reason for caution: The main limitation of this study was the small number of patients evaluated, although this number met the sample size requirements previously considered. Another concern that could interfere with the results was the correct use of medication by the patients on a day-to-day basis. Patients were asked specifically whether or not they had taken the capsules as instructed, but there is no objective proof that they did.

Wider implications of the findings: Several studies have been published previously with similar results about estrogenic influence in endothelial function. Studies that will be performed in the future concerning menopause and hormone therapy, in particular RCTs, will benefit from the knowledge that a period

of only 28 days is sufficient to promote endothelial function changes in menopausal women. Such studies will be allowed to be shorter in duration with no loss in the reliability of the outcomes.

Study funding/competing interest(s): Funding by University(ies) – Universidade Federal de Minas Gerais – Hospital das Clínicas.

Trial registration number: This RCT was registered in *Clinicaltrials.gov* under the number NCT01482416.

SESSION 69: SELECTING EMBRYOS BY TIME-LAPSE

Wednesday 17 June 2015 **14:00–15:15**

O-267 The patterns and characteristics of day 3 human embryo fragments generation: a time-lapse study

M. Hao[1], S. P. Zhang[2], F. Gong[2], C. F. Lu[2], S. T. Yang[1], G. X. Lu[1], G. Lin[1]

[1]*Central South University, Institute of Reproductive and Stem Cell Engineering, Changsha Hunan, China*

[2]*Reproductive and Genetic Hospital of Citic-Xiangya, Changsha, Hunan, China*

Study question: In this study we investigated the generation patterns of cytoplasmic fragmentation in day 3 (D3) human embryos.

Summary answer: D3 embryo fragmentation was generated in cytokinesis of cell cycle. Most of embryos generated fragmentation in a pattern that majority of D3 total fragmentation was generated in the first mitotic division (C1 pattern), especially highly fragmented embryos. Strong unrhythmic cytoplasmic movements occurred before cytokinesis of the first mitotic division were correlated with high total fragmentation degree in D3 embryos.

What is known already: Time-lapse study have suggested that cytoplasmic fragmentation can occur as early as the first mitotic division. Pathogenesis of human embryo fragmentation is still controversial, referring to apoptosis, disordered organization and distribution of cytoskeleton, genetic defects, and so on.

Study design, size, duration: This retrospective and observational study was conducted on 780 bipronuclear (2PN) embryos, obtained from 81 patients undergoing time-lapse system monitoring in our IVF center from May to October 2013. D3 embryo time-lapse parameters were evaluated by a unique operator.

Participants/materials, setting, methods: Embryos (n = 780) were cultured in PRIMO Vision incubators from fertilization to D3. Division behaviors and morphological parameters about generation of cytoplasmic fragmentation were annotated, including the morphologic changes before cytokinesis of the first cleavage, degree of fragmentation generated in each cleavage, and the total degree of D3 embryo fragmentation.

Main results and the role of chance: 536 embryos had different degrees of fragmentation in 780 embryos. According to total fragmentation degree, D3 embryos were divided into four groups: 1–5% (group I), 6–20% (group II), 21–40% (group III), >40% (group IV). Incidence rates of C1 pattern were 57.43% (143/249), 61.68% (132/214), 80.00% (40/50), 100% (23/23), respectively. Significant differences were found in group II, III and IV ($P < 0.05$, respectively). Cytoplasmic movements existed in most embryos during PN period to the first mitotic cytokinesis and subsequent development. 9.36% (73/780) of embryos sufferedp movements before the first cleavage had significantly increased degree of embryo fragmentation in D3, compared with embryos moved lightly and rhythmically, the median and interquartile range were 15% (10%, 27.5%) vs. 5% (0%, 10%) respectively ($p < 0.001$).

Limitations, reason for caution: It was just an observational study, lacking of fundamental research to confirm the relationship between cytoplasmic movements and embryo fragmentation.

Wider implications of the findings: In this study we have analysed the whole generation process of D3 embryo fragmentation. These data show that the first mitotic division is the most crucial period to generation of fragmentation, especially for highly fragmented embryos. Unrhytimic movements occurred before mitotic division, with morphological changing of embryo cytoplasm, probably respresent an erratic cytoskeleton. It may be another evidence of the hypothesis that cytoskeletal disorder is the causation of cytoplasmic fragmentation.

Study funding/competing interest(s): Funding by national/international organization(s) – National Science foundation of China 81222007.

Trial registration number: None.

Keywords: embryo fragmentation, cytoplasmic movements, time-lapse

O-268 The influence of different oocyte insemination techniques (IVF versus ICSI) on early and late morphokinetic parameters: a retrospective study of 449 time-lapse monitored blastocysts

R. Kato[1], D. Bodri[1], T. Sugimoto[1], Y. Yao Serna[1], S. Kawachiya[1], T. Matsumoto[1]

[1]*Kobe Motomachi Yume Clinic, Assisted Reproduction Unit, Kobe, Japan*

Study question: How different oocyte insemination techniques (standard IVF versus ICSI) influence early (from fertilization to 9 cells) and late (from compaction to expanded blastocyst) morphokinetic parameters observed during prolonged embryo culture? Is it possible to normalize them so that mixed IVF/ICSI-fertilized embryo cohorts could be analyzed together?

Summary answer: During cleavage stages ICSI-fertilized embryos were developing faster than IVF-fertilized ones whereas at blastocyst stage it was ICSI-fertilized embryos which showed a gradually increasing delay. After normalizing (to the timepoint of PN fading) differences between cleavage-stage parameters disappeared but those observed at the blastocyst-stage increased in favour of IVF-fertilized embryos.

What is known already: Despite the increasing number of published time-lapse monitoring (TLM) studies the influence of different oocyte insemination techniques on morphokinetic parameters has been underinvestigated (Dal Canto 2012, Cruz, 2013). Most TLM studies included ICSI-fertilized embryos exclusively and so far no predictive models have been developed for IVF-fertilized or mixed embryos cohorts.

Study design, size, duration: A 2-year, retrospective study performed between October 2012 and September 2014 in a single private infertility centre. Oocytes stemmed from 186 infertile patients (median age 37.6 ± 4.1 years, range: 28–47) undergoing natural cycle IVF or minimal ovarian stimulation with clomiphene or letrozole coupled with a universal single frozen-thawed blastocyst transfer policy.

Participants/materials, setting, methods: Data from 449 consecutive blastocysts that were monitored in a time-lapse incubator (EmbryoScope, Unisense Fertilitech, Aarhus, Denmark) were analyzed retrospectively. Early (PNf, $t2$–$t9$) and late (start of blastulation and expanded blastocyst) morphokinetic time points were scored according to recently published consensus criteria (Ciray et al., 2014).

Main results and the role of chance: In total 68 and 32% of the whole cohort was fertilized with ICSI and standard IVF, respectively. Standard IVF-fertilized embryos developed significantly slower as reflected by statistically significant delays in early morphokinetic parameters: PNf (-1.68 h), $t2$ (-1.53 h), $t3$ (-1.39 h) and $t4$ (-1.44 h). In contrast at the expanded blastocyst stage IVF-embryos showed faster development (+2.7 to +3.6 h). After normalizing to the timepoint of PNf differences in cleavage-stage parameters disappeared but those at the blastocyst-stage increased even further in favour of IVF-fertilized embryos (morula: +2 h, start of blastulation: +3.4 h, expanded blastocyst stages +4.7 to +5.7 h).

Limitations, reason for caution: Our unselected patient cohort was biased towards advanced-aged, poor-prognosis patients who have undergone mild IVF treatment coupled with single blastocyst transfer which might limit generalizability to other less infertile populations or to centres which use different treatment protocols.

Wider implications of the findings: Differences between cleavage-stage morphokinetic parameters are related to the fact that fertilization occurs with a 1.4–1.7 h delay following conventional IVF (compared to ICSI). However at the blastocyst stage there might be genuine differences between IVF and ICSI-fertilized embryos possibly related to their different intrinsic quality and/or euploidy status. Normalization to a common time point after fertilization might permit the joint analysis of IVF and ICSI-fertilized embryos and increasing the size of studied cohorts.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Kobe Motomachi Yume Clinic.
Trial registration number: NA.

O-269 Cytoplasmic texture measurements of euploid embryos at a specific stage of development determined by time-lapse culture are indicative of their implantation potential

J. P. Ryan[1], E. Zuvela[2], N. Symons[2], R. Drew[2], K. Douglas[2], M. L. Walls[1], R. J. Hart[1]
[1]*Fertility Specialists of Western Australia and School of Women's and Infant's Health University of Western Australia, Perth, Australia*
[2]*Fertility Specialists of Western Australia, Perth, Australia*

Study question: After removing potential confounding effects associated with aneuploidy, are cytoplasmic texture parameters of zygote stage embryos indicative of their implantation potential?
Summary answer: Measures of cytoplasmic texture at the time of 2nd polar body (PB) extrusion are indicative of the implantation potential of euploid blastocyst stage embryos.
What is known already: Although morphokinetic differences between chromosomally normal and abnormal embryos have been identified, many abnormal embryos display characteristics of embryos otherwise capable of initiating full term pregnancies. Similarly, cytoplasmic texture measurements can vary with ploidy status but cannot be used exclusively to differentiate between viable and non-viable embryos. To better understand the relationship between cytoplasm morphology and an embryos implantation potential, it is desirable to restrict investigations to euploid embryos, thus avoiding confounding effects of aneuploidy.
Study design, size, duration: Retrospective study of 66 patients who had embryos screened for aneuploidy, cultured in a time-lapse incubator (Embryoscope), who had single embryo transfers between January 2013 and September 2014.
Participants/materials, setting, methods: Cytoplasmic texture measurements were recorded for 66 embryo images at five developmental stages of the first cell cycle: post injection (Inj), 2nd PB extrusion (PB2), pronuclei appearance (PNa), syngamy (Syn) and just prior to cytokinesis (Cyt). Embryos underwent PGS-CGH on Day 3 and transferred at the blastocyst stage of development.
Main results and the role of chance: Texture measurements were compared for a total of 25 embryos that resulted in the detection of a FH (FH+) with 41 embryos that failed to implant (FH-). No significant differences were observed between FH+ and FH- embryos at the Inj, PNa, Syn or Cyt stages of development. In contrast, 8/11 textural measurements differed ($p = 0.049$ to $p = 0.0003$) at the PB2 stage. ROC curves generated for each textural parameter following logic regression yielded AUC values up to 0.79 with 51/66 (77%) of outcomes correctly predicted.
Limitations, reason for caution: The effects observed are associated with embryos of patients requiring preimplantation genetic screening and may not represent embryos from other patient groups. This study represents a retrospective analysis and further prospective validation of results is necessary.
Wider implications of the findings: By restricting this study to euploid embryos we have removed the potential effects of aneuploidy on morphokinetic timings and textural measurements. As such, we have identified morphological parameters that can be identified using time-lapse culture techniques that are highly predictive of the implantation potential of human embryos. The development of algorithms incorporating textural variables may improve our capacity to select appropriate embryos for transfer or cryopreservation and to assess the impact of various treatment methodologies.
Study funding/competing interest(s): Funding by hospital/clinic(s) – No external funding was received for this study. Professor R. J. Hart has received educational sponsorship from MSD, Merck-Serono and Ferring Pharmaceuticals. The other authors have no conflicting interests.
Trial registration number: None.

O-270 Time-lapse monitoring of early embryo development may aid in the validation of the effect of sperm DNA fragmentation assay on reproductive outcomes – preliminary findings

B. Doroftei[1], G. Emerson[2], S. Cumpata[2], G. Simionescu[3], R. Maftei[3], M. Zlei[4]
[1]*Univesrsity of Medicine and Pharmacy, Obstetrics and Gynecology Department, Iasi, Romania*
[2]*Origyn Fertility Center, Embryology Laboratory, Iasi, Romania*
[3]*Teaching Hospital Obgyn "Cuza Voda", Obstetrics and Gynecology Department, Iasi, Romania*
[4]*Regional Institute of Oncology, Laboratory of Molecular Biology, Iasi, Romania*

Study question: Can time-lapse study of early embryonic development aid in the validation of the effect of DNA fragmentation assay (DFI – DNA Fragmentation Index) on ART?
Summary answer: Sperm DFI assessed by sperm chromatin structure assay (SCSA) by flow cytometry (FCM) impacts on the embryo-development and reproductive outcome of IVF/ICSI/IMSI in a group of couples with male infertility. Morphokinetics of early embryo development may aid in validation of new cut-off values for DFI.
What is known already: Current literature suggests that, when the sperm DFI value is above 25%, couples with infertility may have greater success with IVF/ICSI/IMSI procedures instead of IUI. However, when sperms with high DFI are involved, there are still uncertainties on the repair capacity of the egg and its further embryo-development.
Study design, size, duration: A retrospective analysis of 23 sperm samples from men undertaking ART in a private IVF center (May–December, 2014) compared the reproductive outcome and morphokinetic parameters (EmbryoViewer-Vitrolife) between patients groups divided by the DFI cut-off value of 25. Mean ± SD and p values with a significance threshold of 0.5 were calculated.
Participants/materials, setting, methods: Semen samples from patients (aged 35.6 ± 4.9 years) were analysed by SCSA (FACSAriaIII-BDBiosciences). Group A had a DFI <25 ($n = 17$) and Group B had DFI ³ 25 ($n = 6$). Twenty six treatment cycles were performed (23% IVF, 50% ICSI, 27% IMSI) and the development of 218 fertilised eggs was monitored by time-lapse imaging (EmbryoScope-Vitrolife).
Main results and the role of chance: All female partners were aged under 36 years and had >4 eggs collected. The following morphokinetic parameters were found to be significantly different in Group A vs. Group B: lower $t3$-tPNF (time to 3 cells minus time to pro-nucleai fading, in hours) (4.73 ± 4.57 versus 9.31 ± 4.57, respectively, $p = 0.0259$, lower $t3$–$t2$ (5.64 ± 7.65, 12.68 ± 9.73, $p = 0.0466$,, lower $t5$–$t3$ (9.23 ± 12.60, 23.46 ± 13.82, $p = 0.0173$, lower $t7$-tPNF (12.66 ± 13.13 vs. 29.31 ± 6.16, $p = 0.0044$, lower $t8$-tPNF (17.08 ± 15.53 vs. 34.51 ± 10.28, $p = 0.0111$) respectively and a reduced value of fragmentation time recording (57.86 ± 7.39 vs. 68.71 ± 6.53, $p = 0.0089$). A significant difference was found between the group of couples with positive (pregnancy rate of 61%) versus negative biochemical pregnancy (DFI of 13.5 ± 5.6 vs. 31.7 ± 23, $p = 0.042$).
Limitations, reason for caution: When the relationship of DFI with the reproductive outcome is assessed, the female bias cannot be completely excluded, although age and ovarian competence have been considered. However, with larger cohorts of patients, a more cautious selection will become possible.
Wider implications of the findings: When strictly controlled female factors and stable incubation conditions are available, the sperm DFI impact on embryo development can be properly assessed and, with larger study cohorts, new cut-off DFI values may be validated and used in conjunction with quantitative morphokinetic parameters for selecting viable embryos.
Study funding/competing interest(s): Funding by national/international organization(s) – National Authority of Scientific Research of Romania (POSCCE Grant 1357 "Infertility a tree pieces puzzle: couple investigation, infertility diagnostic, possible therapy").
Trial registration number: NA.

O-271 Selection of single blastocyst for transfer using time-lapse monitoring during *in vitro* fertilization in good prognosis patients: a randomized controlled trial

S. Z. Matyas[1], P. Kovacs[2], V. Forgacs[3], A. Sajgó[4], C. S. Pribenszky[5]
[1]*Kaali Institute, Embryology, Budapest, Hungary*
[2]*Kaali Institute, IVF Center, Budapest, Hungary*
[3]*Forgács Intézet, IVF Center, Budapest, Hungary*
[4]*Kaáli Institute, IVF Center, Budapest, Hungary*
[5]*Vitrolife Hungary Kft., Vitrolife Hungary Kft, Budapest, Hungary*

Study question: In our study we try to answer whether morphological and kinetic information in a combined score, observed via a time-lapse (TL) system improves outcome over standard procedures, when a single blastocyst is selected for transfer (SET). To standardize conditions, groups were cultured in the same incubator.

Summary answer: IVF cycles in which embryos were cultured in TL system and were selected based on combined kinetic and morphological score evaluated on TL images resulted in a 20.5% relative increase in pregnancy over standard morphology-based selection. The ongoing pregnancy rate (PR) was 16% relative higher in the TL group.

What is known already: Most embryology labs select embryos for transfer based on morphology that is evaluated after removing the embryos from the incubator. TL systems provide undisturbed culturing conditions and allow detailed embryo observation. The utility of various kinetic markers to improve outcome has been tested. TL culturing together with embryo selection based on TL parameters was shown to improve blastocyst selection, implantation rate but there is little information on pregnancy/live-birth rates.

Study design, size, duration: Ongoing (since 2013), multicenter randomized controlled trial involving patients <36 years with normal ovarian reserve, undergoing 1st/2nd cycle, who have at least 3 good embryos on day 3 and accept SET. Patients are randomly assigned to PrimoVision monitoring and single blastocyst selection based on TL parameters vs. standard morphology-based blastocyst selection.

Participants/materials, setting, methods: Participants (140 randomized, 20 dropped out) were randomized to TL culture ($N = 59$) and embryo selection based on a composite score made up of kinetic markers and blastocyst morphology vs. standard incubation/evaluation and selection for transfer based on blastocyst morphology ($N = 61$). Patient/cycle parameters and clinical outcome were compared.

Main results and the role of chance: Of the 140 patients 20 dropped out for various reasons. Among those who have completed per protocol patient and cycle parameters are comparable between the groups. The PR is 47.5% in the TL group vs. 37.7% in the control group (20.5% increase, $p = 0.2$). The ongoing PR is 39.5% in the TL and 33.3% in the control group (16% increase, $p = 0.3$).

Embryos in the TL group were selected based on a composite score made up of various early kinetic markers, presence of fragmentation and blastocyst morphology (maximum 17 points). Within the TL group the combined score for embryos resulting in pregnancy is significantly higher when comapared to those not resulting in pregnancy (14.5 vs. 12.3; $p = 0.002$).

Limitations, reason for caution: While we have found a 20% relative increase in PR and a 16% increase in ongoing PR these findings have not reached statistical significance. This is an interim progress report, the study is powered to reach significance with 110 patients per arm.

Wider implications of the findings: IVF is overall a safe treatment but not complication-free. Multiple gestations are undesired following ART. Tools that can aid embryo selection are needed to avoid multiple gestations without compromising PR. The combined scoring of morphology and kinetics in time-lapse systems seems to offer benefits over standard evaluation.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Kaali Institute.

Trial registration number: NCT01694641.

[9]*VU University Medical Center, Obstetrics and Gynaecology, Amsterdam, The Netherlands*
[10]*Netherlands Cancer Institute, Epidemiology, Amsterdam, The Netherlands*

Study question: Are there differences in the use and success rates of assisted reproductive techniques (ART) between female childhood cancer survivors (CCSs) and controls?

Summary answer: Preliminary data show that ART techniques are used more often by female CCSs compared to controls with the success rate of ART among CCSs being slightly, but not significantly, lower.

What is known already: Cancer treatment during childhood may impair female fertility. In combination with the general Dutch trend to postpone childbearing to the early thirties, this may put female CCSs at increased risk of requiring ART to achieve a pregnancy. However, information on the number of female CCSs actually using ART as well as on ART success rates is scarce.

Study design, size, duration: The study is part of the DCOG LATER-VEVO study, a nationwide retrospective cohort study on female fertility in Dutch CCSs. The control group consisted of sisters of survivors and females from the general population. Data collection took place between January 2008 and May 2014.

Participants/materials, setting, methods: Data on causes of infertility, the use and success rate of ART (=number of women achieving a pregnancy through ART/number of women who used ART) were assessed by questionnaire. Of the 1,717 survivors and 1,672 controls invited, 1,108 (65%) and 819 (49%), respectively, completed the questionnaire.

Main results and the role of chance: Preliminary data show that, after correction for age at study, CCSs had a higher probability of visiting a gynaecologist due to problems with achieving a pregnancy, compared to controls (OR = 1.7; $p < 0.01$). In addition, CCSs were significantly younger at the time of their first visit ($p < 0.001$). Compared to controls, CCSs more often reported a female factor as the cause of infertility (64.6% CCSs, 34.7% controls; $p < 0.001$). The proportion of CCSs having used any type of ART was 9.2% ($N = 103$) whereas this proportion was 6.1% ($N = 50$) in controls. After correction for age, CCSs had a higher probability of having used any type of ART (OR = 1.8; $p < 0.01$). Success rates of ART were 35% for CCSs and 50% for controls ($p = 0.05$).

Limitations, reason for caution: The study may have been subject to selection bias, since survivors with fertility-related problems might be more likely to participate in the study compared to survivors who do not experience problems in achieving a pregnancy.
Wider implications of the findings: These findings can assist clinicians in counselling childhood cancer survivors about their fertility and the use of ART to achieve a pregnancy. Clinicians should timely refer to reproductive specialists when survivors have a wish to conceive.

Study question: Does tubal patency testing by HSG with an oil-based contrast medium lead to higher ongoing pregnancy rates compared to the use of water-based contrast medium?
Summary answer: Tubal patency testing by HSG with an oil-based contrast medium leads to higher ongoing pregnancy rates during the first 6 months following HSG, compared to the use of water-based contrast medium.
What is known already: Tubal flushing during HSG is suggested to increase pregnancy rates in subfertile women. It is unclear whether the choice of contrast medium used during HSG, water or oil-based, affects this potential therapeutic effect. Prior randomised and non-randomised trials have shown contradicting results.
Study design, size, duration: The H2Oil study is a multicentre randomised controlled trial, which took place in the Netherlands between February 2012 and November 2014. The study was performed in the Dutch consortium for research in women's health, and 27 hospitals participated in this study.
Participants/materials, setting, methods: We studied subfertile women undergoing HSG during their fertility work-up. Participants were randomly allocated to oil-based contrast (intervention group) or water-based contrast (control group). The follow-up period was 6 months and primary endpoint was ongoing pregnancy. Since data on life birth are not all available, this abstract reports on pregnancy rates.
Main results and the role of chance: Between February 2012 and November 2014 we randomised 1119 patients, of whom 557 were allocated to oil-based contrast and 562 to water-based contrast. Mean age was 32 years, mean duration of infertility was 21 months and 68% of the women had primary infertility. Baseline characteristics were comparable between the groups. Hysterosalpingraphy showed bilateral tubal patency in 89% of the women randomised for oil-based contrast versus 90% of the women randomised for water-based contrast. Ongoing pregnancy rates in the first 6 months following HSG were 38,8% in the intervention (oil-based contrast) versus 28,1% the control group (water-based contrast) (RR 1.38, 95% CI 1.14–1.66). There were no adverse events reported.
Limitations, reason for caution: Presented results are preliminary, as data on the primary outcome ongoing pregnancy are still incomplete. Complete follow-up on ongoing pregnancy rates will be available at the meeting.
Wider implications of the findings: HSG with oil-based contrast medium improves pregnancy rates as compared to HSG with water-based contrast medium. These data implicate that flushing of the tubes with oil-based contrast medium should be offered to subfertile women in the fertility work-up.
Study funding/competing interest(s): Funding by hospital/clinic(s) – VU University Medical Center.
Trial registration number: Dutch Trial Register, NTR3270.

O-274 Chlamydia serology in triaging patients for tubal assessment in female subfertility

H. Tijani[1], M. Hamdan[2], Y. Cheong[2], N. Brook[1], N. Macklon[2]
[1]*University Hospital Southampton, Obstetrics and Gynaecology, Southampton, United Kingdom*
[2]*University of Southampton, Human Development and Health, Southampton, United Kingdom*

Study question: To assess how implementation of chlamydia antibody testing (CAT) into a clinical setting impacted on triage between tubal patency investigations and expectative management.
Summary answer: In clinical setting chlamydia serology is an appropriate and cost effective means of triage between tubal patency investigations and expectative management.
What is known already: CAT has predictive value in the detection of tubal damage and titres are quantitatively related to the severity of damage. CAT testing adds valuable information to a woman's risk profile based on her medical history. The combination of medical history taking and CAT testing has a better yield for diagnosing tubal disease than either of these alone.
Study design, size, duration: This is a prospective study of a cohort of 543 consecutive patients seen between August 2012 and July 2014.
Participants/materials, setting, methods: CAT testing was offered at initial infertility clinic consultation. Laparoscopy was offered to those testing positive. Those testing negative were offered HyCoSy, if considered for IUI, or proceeded to ovulation induction or expectative management. Theatre and medical records were reviewed for data collection. Statistical analysis was carried out using SPSS.
Main results and the role of chance: Out of 543 patients 110 (22.2%) were positive CAT + ve; 391 (72%) negative CAT - ve and 42 (7.7%) indeterminate CAT-Ind result. 41.8% CAT + ve underwent laparoscopy, out of which 47.8% had positive findings. 72.7% of those who had positive findings at laparoscopy were found to have tubal disease. However, in CAT - ve patients requiring tubal assessment by HyCoSy, 94.6% showed no abnormality. 88% of those testing positive had a past history pelvic infection. When compared to pre-implementation of CATs, there were 35 less laparoscopy done per annum, but extra 10 HyCoSy were performed for the same duration. This equates to about ≤80,000 (≤2,300 per laparoscopy) savings from laparoscopy but additional ≤3,500 (≤350 per HyCoSy) cost for HyCoSy.
Limitations, reason for caution: This study has a small number of participants and a larger cohort study is needed to validate these findings. There is significant number of participants who had the test but were lost to follow up due to spontaneous pregnancy and this may skew the data.

Wider implications of the findings: These findings indicate that implementing CAT into clinical practice can improve triaging of patients to further tubal patency testing and expectative management Therefore this may reduce unnecessary invasive tubal testing by laparoscopy which may translate into extra savings in term of time and money.
Study funding/competing interest(s): Funding by University(ies). Funding by hospital/clinic(s) – University of Southampton, Complete Fertility Centre.
Trial registration number: Nil.

O-275 Live birth in women previously experiencing recurrent implantation failure upon IVF: a retrospective cohort study

Y. E. M. Koot[1], S. Bever de[2], M. Goddijn[3], M. C. J. Eijkemans[4], M. Wely van[3], F. Veen van der[3], B. C. J. M. Fauser[1], N. S. Macklon[5]
[1]*University Medical Centre Utrecht, Reproductive Medicine and Gynaecology, Utrecht, The Netherlands*
[2]*Academic Medical Centre, Faculty of Medicine, Amsterdam, The Netherlands*
[3]*Academic Medical Centre, Centre for Reproductive Medicine, Amsterdam, The Netherlands*
[4]*University Medical Centre Utrecht, Biostatistics and Research Support, Utrecht, The Netherlands*
[5]*University of Southampton, Human Development and Health, Southampton, United Kingdom*

Study question: What is the subsequent live birth rate and time to pregnancy (by conception after IVF/ICSI or by natural conception) in women who experienced recurrent implantation failure (RIF)?
Summary answer: Cumulative live birth rate in women experiencing RIF was 50% (95% CI 44–56%), with a mean time to pregnancy of 64 months.
What is known already: RIF is a distressing situation in which women do not reach a pregnancy within 3 IVF or ICSI treatments after transfer of good quality embryos. Although multiple studies have been performed aimed at identifying the aetiology, prognosis for achieving live birth is not known.
Study design, size, duration: This retrospective cohort study was conducted in two university hospitals in the Netherlands, between January 2008 and December 2012. Two hundred twenty-three women had experienced RIF, defined as no positive pregnancy test after 3 IVF/ICSI treatments including transfer of good quality embryos in women ≤38 years of age, and were included.
Participants/materials, setting, methods: All women diagnosed with RIF were sent a letter inviting their consent for anonymous use of medical file data and a questionnaire enquiring about subsequent treatments, pregnancies and outcome. Data was extracted and analysed to determine the subsequent live birth rate and time to pregnancy during a maximal 5.5 years of follow-up.
Main results and the role of chance: Two hundred twenty-three women were identified to have met the criteria for RIF (7% of treated population), 127 women responded to the invitation letter (57%) and data from 118 women (53%) was available for analysis. During the 5.5 year follow up period the overall cumulative live birth rate was 50% (95% CI: 44–56%). Survival analysis showed a mean time to pregnancy of 64 (95% CI: 55–74) months after diagnosing RIF, with a median of 9 months in those who did achieve a pregnancy during the follow up period. Forty pregnancies (82%) were achieved after further assisted reproductive technique treatments (live birth rate 15%/cycle), five with use of a donor gamete. Nine pregnancies (18%) occurred after natural conception.
Limitations, reason for caution: The retrospective nature of the study and the limited participation rate may have introduced selection bias.
Wider implications of the findings: This study reports favourable pregnancy chances in women experiencing RIF, especially after continuation of IVF/ICSI treatments. These findings can be used when counselling couples after three failed IVF or ICSI treatment cycles despite the transfer of good quality embryos.
Study funding/competing interest(s): Funding by University(ies) – University Medical Centre Utrecht, Utrecht. Academic Medical Centre, Amsterdam.

O-276 Indometacin administration can prevent premature follicular repture before timed intra uterine insemination (IUI) and improve the cycle outcome

A. Sarhan[1]
[1]*Zagazig University, Obstetrics and Gynecology, Zagazig, Egypt*

Study question: Can administration of indomethacin prevent early follicular rupture before timed intrauterine insemination and does it improves the cycle outcome?
Summary answer: Indomethacin can significantly reduce the incidence of spontaneous follicular rupture before IUI and allow more cycles to have properly timed procedures done.
What is known already: Prostaglandins play an important physiological role in the process of ovulation particularly follicular rupture. It had been used in some trials to prevent spontaneous ovulation in IVF cycles.
Study design, size, duration: A prospective randomized study that was performed on 194 UI cycles for mild male factor and unexplained infertility over an 18 months period.
Participants/materials, setting, methods: Patients were classified into two groups; group A (96 patients) received indomethacin 50 mg every 8 h starting when a leading follicle reached a diameter of 15 mm till the time of human chorionic gonadotropins (hCG) administration and group B (98 patients) a control group where the patients did not receive indomethacin. Patients were followed by vaginal ultrasound daily to check for spontaneous ovulation. hCG was administrated when the dominant follicle reaches a diameter of 18 mm and IUI was performed 36 h later.
Main results and the role of chance: The indomethacin group had a significantly reduced cases of spontaneous follicular rupture till 24 h before schedueld schedueled IUI 4 cases (4.2%) compared to 18 cases (18.4%) in the control group. This was reflected as a non significant increase in the cycle pregnancy rate 15 patients (15.6%) in the indomethacin group compared to 12 patients (12.2%) in the control group.
Limitations, reason for caution: The study needs to expand to a larger number of patients with uniform etiology, type and duration
of infertility.
Wider implications of the findings: Indometacin suppression of follicular rupture can make timing of IUI more convenient for the couple and service provider.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Private infertility center.
Trial registration number: None.
Keywords: IUI, indometacin, timed IUI, follicular rupture

SESSION 71: DIAGNOSIS AND SELECTION OF SPERM FOR ART

Wednesday 17 June 2015 **14:00–15:15**

O-277 Processing of semen by density gradient centrifugation selects spermatozoa with longer telomeres for assisted reproductive technology

F. F. Zhao[1], Q. L. Yang[1], N. Zhang[1], W. L. Zhao[1], S. J. Dai[1], J. H. Liu[1], H. Xin[1], W. B. Niu[1], Y. P. Sun[1]
[1]*Reproductive Medical Center, First Affiliated Hospital of Zhengzhou University, Zhengzhou, Henan, China*

Study question: This study was carried out to investigate the role of density gradient centrifugation in the selection of spermatozoa with longer telomeres for use in assisted reproductive technology (ART).
Summary answer: Density gradient centrifugation is a useful technique for the selection of sperm with longer telomeres for ART.
What is known already: The ends of eukaryotic chromosomes contain specialized chromatin structures called telomeres, the length of which plays a key role in early human embryonic development.
Study design, size, duration: Case control study, 105 Semen samples, sperm before and after density gradient centrifugation processing, from July 2014 to November 2014.

Participants/materials, setting, methods: Semen samples were collected from 105 infertile men and then submitted to Sperm Chromatin Dispersion tests (SCD) and quantitative polymerase chain reaction (Q-PCR) to analyze the DNA fragmentation rates and telomere lengths, respectively, in sperm before and after density gradient centrifugation processing.
Main results and the role of chance: After density gradient centrifugation, the average telomere length of the sperm was significantly longer (6.07 ± .22 vs. 5.01 ± 0.94), the average motile sperm rate was significantly higher (77.9 ± 11.8 vs. 44.6 ± 11.2), but average DNA fragmentation rate was significantly lower (11.1 ± 5.9 vs. 25.9 ± 12.9) compared to raw semen. In addition, we found that telomere length was positively correlated with sperm count of the semen ($r_s = 0.58$; $P < 0.01$).
Limitations, reason for caution: Small number of samples and only one reproductive medicine center in our study.
Wider implications of the findings: In this study, we found that density gradient centrifugation could enrich for sperm with high motility and low DNA fragmentation, and for the first time, we found that this commonly used technique for processing semen for ART could effectively recover sperm with longer telomeres.
Study funding/competing interest(s): Funding by national/international organization(s) – National Natural Science Foundation of China (Grants 31271605 and 31471404) and the National Science Foundation for Young Scientists of China (Grant 31401274)
Trial registration number: No.
Keywords: telomere length, density gradient centrifugation, assisted reproductive technology, sperm, infertility

O-278 Sperm selection using MACS has similar obstetric and perinatal outcomes than standard preparation when ICSI was performed in ovum donation in a prospective and randomized trial

L. Romany[1], N. Garrido[2], B. Aparicio[1], Y. Motato[1], M. Muñoz[3], M. Meseguer[1]
[1]*IVI, IVF LAB, Valencia, Spain*
[2]*IVI, Andrology LAB, Valencia, Spain*
[3]*IVI, Gynaecologist, Alicante, Spain*

Study question: Does MACS technology have an effect on children born in ICSI procedures of our ovum program?
Summary answer: Magnetic activated cell sorting does not have any benefit or harmful effect on children born in ICSI cycles of our ovum donation program in unselected male patients.
What is known already: There is still little clinical information available about the wide employment of these selection techniques in *in vitro* fertilization and their impact in final assisted reproduction techniques (ART) outcomes although our findings not show anincrease in live birth deliveries rates when MACS was performed.
Study design, size, duration: Two arms, unicentric, prospective, randomized and triple-blinded trial, a total of 237 infertile couples, October 2010 and January 2013.
Participants/materials, setting, methods: IVI-Valencia. Children born after use of MACS in ICSI (60 deliveries) and control group, only swim up in ICSI (64 deliveries). In 11 and 13 cases from MACS and control group respectively no perinatal and obstetric outcome were obtained. A total of 65 and 66 newborns from MACS and control group respectively were described.
Main results and the role of chance: MACS had no clinically relevant adverse effects on obstetric and perinatal outcomes after adjusting for potential confounders. No differences were found between the both groups in the rate of obstetric problems including premature rupture of membranes 6.1% (CI 95% 0–12.8) vs. 5.9% (CI 95% 0–12.4), 1st trimester bleeding 28.6% (CI 95% 15.9–41.2) vs. 23.5% (CI 95% 11.9–35.1), invasive procedures as amniocentesis 2.0% (CI 95% 0–5.9) vs. 3.9 % (CI 95% 0–9.2), diabetes 14.3% (CI 95% 4.5–24.1) vs. 9.8% (CI 95% 1.6–17.9), anemia 6.1% (IC95% 0–12.8) vs. 5.9% (CI 95% 0–12.4), 2nd and 3rd trimester 10.2% (CI 95% 1.7–18.7) vs. 5.9% (CI 95% 0–12.4), urinary tract infection 8.2% (CI 95% 0.5–15.9) vs. 3.9% (CI 95% 0–9.2), pregnancy-induced hypertension 6.1% (CI 95% 0–12.8) vs. 15.7% (CI 95% 5.7–25.7), birth weight (g) 2684.10 (CI 95% 2499.48–2868.72) vs. 2676.12 (CI 95% 2499.02–2852.21), neonatal height (cm) 48.3 (CI 95% 47.1–49.4) vs. 46.5 (CI 95% 44.6–48.4) gestational cholestasis 0% (CI 95% 0–0) vs. 3.9% (CI 95% 0–9.2) respectively in MACS group compare with control group.
Limitations, reason for caution: We analyzed all the births for which we had notification, and not the whole series of ICSI pregnancies achieved in our Institution during the study period.
Wider implications of the findings: Our data suggest that MACS technology does not increase adverse obstetric and perinatal outcomes in children conceived when this technology was performed, being the largest randomized control trial with live birth reported results with MACS.
Study funding/competing interest(s): None.
Trial registration number: Given that the main intervention was conducted on sperm samples and not human beings, Clinical Trial registration is not needed.
Keywords: MACS technology, children born, obstetric and perinatal outcomes, prospective and randomized trial, ovum donation

O-279 Cytological evaluation of spermatogenesis: a novel and simple diagnostic method to assess spermatogenesis in non-obstructive azoospermia using testicular sperm extraction specimens

L. Ramos[1], M. Hessel[1], M. de Vries[1], K. D'Hauwers[2], K. Fleischer[3], C. Hulsbergen-van de Kaa[4], D. Braat[5]
[1]*Radboud University Medical Center, Obst. and Gynecology. Div. Reproductive Medicine (intern 791), Nijmegen, The Netherlands*
[2]*Radboud University Medical Center, Urology, Nijmegen, The Netherlands*
[3]*Radboud University Medical Center, Obst. and Gynaecology Div. Reproductive Medicine, Nijmegen, The Netherlands*
[4]*Radboud University Medical Center, Pathology, Nijmegen, The Netherlands*
[5]*Radboud University Medical Center, Obst. and Gynaecology Div. Reproductive Medicine, Nijmegen, The Netherlands*

Study question: Can spermatogenesis be evaluated by defining the ratios between Sertoli cells, pachytene spermatocytes and spermatozoa in a cell suspension obtained by testicular sperm extraction (TESE)? Subsequently, are these ratios associated with the outcome of fertility treatment in patients with non-obstructive azoospermia (NOA)?
Summary answer: Pachytene spermatocytes, spermatozoa and Sertoli cells can be easily identified and counted in a cell suspension and their ratios can be successfully used to diagnose the level of spermatogenic impairment. This pilot study indicates that once successful sperm retrieval is achieved, treatment outcome declines when spermatogenesis is impaired in NOA.
What is known already: Most of these NOA-patients have only focal spermatogenesis which results in insufficient numbers of spermatozoa to reach the ejaculate. In approximately 50% of NOA-patients TESE is successful and intracytoplasmic sperm injection (ICSI) is pursued. It is also assumed that in some cases, a genetic cause affects sperm maturation and development. To date, the predictive value of cytological evaluation of spermatogenesis for the TESE-ICSI outcome is unknown.
Study design, size, duration: This retrospective cohort study included 441 consecutive TESE-ICSI cycles in 212 couples, performed between June 2007 and August 2012. For each TESE biopsy the ratios between Sertoli cells, pachytene spermatocytes and spermatozoa were calculated. A control population of 38 vasectomised men was used to define cut-off values for complete spermatogenesis.
Participants/materials, setting, methods: NOA-patients were divided in three subgroups based on the pachytene to sperm ratio (P/Sp) and number of sperm per 100 Sertoli cells (#Sp/100SC). First cycle and cumulative ongoing pregnancy rates were calculated for couples with (partial) maturation arrest and hypospermatogenesis, and compared to rates in NOA couples with complete spermatogenesis.
Main results and the role of chance: The presence of sperm upon cytological evaluation of the TESE specimen is strongly correlated to the observations in the wet prep (Kendall's Tau-b = 0.86). Validation of the cytological diagnoses was performed by comparing the results of cytology to the histological evaluation of spermatogenesis in 40 cases. In 92.5% a perfect match was observed and in the 3 remaining cases cytology corresponded well with the results of the TESE. Couples with complete spermatogenesis have a higher ongoing

pregnancy rate after the first treatment cycle compared to couples with hypospermatogenesis (34 versus 16%; $p = 0.02$) and partial maturation arrest (34 versus 19%; $p = 0.11$).

Limitations, reason for caution: Cause-and-effect cannot be determined in a retrospective study and the predictive value of *cytological* evaluation of spermatogenesis has to be established in a future prospective trial. Due to the embryo transfer strategy in the Netherlands, these results might not apply to patients receiving three or more embryo's per cycle.

Wider implications of the findings: This study shows that the different types of spermatogenic disorder can be easily identified using quantitative *cytological* evaluation of the TESE specimen in the NOA-population. By defining the P/Sp and #Sp/100SC of TESE biopsies, information can be gained regarding the chances of successful TESE-ICSI. This can help couples adjust their expectations and decide about subsequent ICSI cycles or fresh TESE procedures.

Study funding/competing interest(s): Funding by University(ies) – Radboud University Medical Center.

Trial registration number: N/A.

O-280 Reproduction anomalies in male patients with Bardet Biedl syndrome, an emblematic ciliopathy

I. Koscinski[1], G. N. Goetz[2], M. M. Mark[1], B. J. J. Braun[3], R. S. Rossignol[4], D. H. Dollfus[2]

[1]*University Hospital of Strasbourg (HUS), Laboratoire de Biologie de la Reproduction, Strasbourg, France*

[2]*University Hospital of Strasbourg (HUS), Centre de Référence pour les Affections Rares en Génétique Ophtalmologique (CARGO), Strasbourg, France*

[3]*University Hospital of Strasbourg (HUS), Service ORL-CCF, Strasbourg, France*

[4]*University Hospital of Strasbourg (HUS), Service de Pédiatrie 1, Strasbourg, France*

Study question: Bardet-Biedl syndrome (BBS) is a classical ciliopathy with a wide spectrum of clinical features encomprising male microgenitalism. Furthermore, by extrapolation to another ciliopathy, the Kartagener syndrome, BBS patients were supposed to produce immotile sperm, resulting in a severe infertility.

Summary answer: The study focused on the global reproduction function in patients with identified BBS mutations, including genital examination, sperm analysis completed with electronic transmission microscopy, and sexual hormonal status evaluation.

What is known already: BBS is a rare recessive autosomic ciliopathy characterised mainly by many clinical manifestations due to primary cilia dysfunction. There is no publication of BBS fathering. Microgenitalism is one of the usual features. Cryptorchidism is found in more than 90% cases. A frequent low gonadotropic hormone level is mentioned suggesting an impaired hypothalamo-pituitary-gonadal axis. Neither previous sperm description nor motility precision is available. The "ciliopathy" denomination suggests that sperm axoneme of BBS patient is not functional.

Study design, size, duration: The present study is a prospective cohort study provided between 2007 and 2013 and concerns 11 BBS French patients included in PHRC National 2007 – ref HUS No. 4056. BBS mutations were identified in order to determine an eventual link between genotype and phenotype.

Participants/materials, setting, methods: 11 BBS patients beneficed of an andrology examination completed by ultrasonography, sperm analysis and transmission electronic microscopy when the sperm numeration allowed it, and exploration of the hypothalamo-pituitary-gonadal axis including a LH-RH test in addition to the exploration of the gluco-lipidic metabolism and olfactory function.

Main results and the role of chance: BBS patients presented with history of cryptorchidism (5 out of 11), short scrotum (4/8 accepting clinical examination), micropenis (5/8) and, unexpectedly, normal testis size (7/8). Ultrasonography highlighted epididymal cysts or agenesis in cases of extreme hypospermia under 0.5 ml. Kidney cysts or ectasia were observed in these patients but also in BBS patients presenting a normal semen volume. Despite usual severe obesity and impaired olfaction, sexual hormonal levels were normal in all patients except one. Sperm numeration was normal in 8 out of 10 cases of ejaculations. 5–45% of sperm presented a progressive motility. When performed, electronic microscopy did not reveal any homogeneous abnormality.

Limitations, reason for caution: The results should be confirmed in a greater BBS patient cohort, mainly focusing on epididymal cystic abnormalities and on putative sterility of these patients. Functional sperm analysis are expected, especially ART data, despite the difficulty that only a few BBS patients consult for fathering (1 out of 11).

Wider implications of the findings: BBS patients represent a well-defined genetic human model of primary cilium dysfunction with implication in embryology of the male genital tract, especially epididymis, as well as in the androgen fetal production. It results in a disruption of the last androgeno-dependent part of testis descent and a deficit in masculinization of the male genital tubercle, leading to cryptorchidism and short scrotum respectively. Furthermore, male gamete structure seems not impacted by BBS mutations.

Study funding/competing interest(s): Funding by hospital/clinic(s) – This study has been supported by the University Hospital of Strasbourg. No competing interests.

Trial registration number: This study is linked to the National French PHRC 2007 – ref HUS N° 4056 "Physiopathologie ciliaire neurosensorielle et métabolique du syndrome de Bardet-Biedl."

O-281 A prognostic model for the outcome of IUI-H in young woman with good ovary response

M. J. Soriano[1], I. Molina[1], S. Balasch[2], J. M. Rubio[1], A. Pellicer[1]

[1]*Hospital La Fe, Unidad de Reproducción, Valencia, Spain*

[2]*Universidad Politecnic, Bioestadistica, Valencia, Spain*

Study question: Although a variety of factors have been reported as affecting pregnancy rates (PR) after intrauterine insemination (IUI), there have been conflicting results on prognostic factors. This study aimed to develop a prognostic model for the outcome in patients undergoing their first IUI cycle taking into account male and female infertility factors.

Summary answer: In men with normal sperm samples according WHO 2010, the sperm count, motility and morphology before and after sperm preparation does not influence the IUI outcome. In woman younger than 36 years with good ovarian response, the age and the number of pre-ovulatory follicles recruited are strong predictors of success.

What is known already: Many factors can influence the pregnancy rates after IUI: woman's age, length and type of infertility, sperm quality, number of mature follicles and E2 concentration on the day of hCG. However, results on prognostic factors are still conflicting. Com-pared to IVF-ICSI, IUI is less invasive and associated with lower costs and a low incidence of complications, making it a relatively cost-effective treatment which remains a natural starting point for conveniently selected couples.

Study design, size, duration: Retrospective study of the first cycle of IUI performed in 800 couples between January 2010 and November 2014. Only couples with cervical, anovulation, and unexplained infertility of <4 years length in women younger than 36 years were included. When more than 4 follicles were obtained IUI was converted to an IVF cycle.

Participants/materials, setting, methods: Woman age, body mass index, number of mature follicles and E2 concentration and endometrial thickness were considered as clinical characteristics. Sperm count, motility and morphology (Kruger strict criteria) were asses before and after sperm preparation at the time of IUI. Multivariate logistic regression analysis was performed to evaluated the PR according to clinical and semen characteristics.

Main results and the role of chance: The overall PR was 12%. PR in IVF converted cycles was 42%. No sperm parameters in either the pre or post analysis, nor total motile sperm count or morphology predicted pregnancy. The highest PR (14.7%) was obtained for anovulation and the lowest for unexplained infertility (9.5%). Age was a strong predictor of success ($p = 0.0232$). The number of pre-ovulatory follicles recruited was observed

to be the strongest predictor of IUI success. According to the number of mature follicles the PR was 9.9% for 1, 15.2% for 2 and 20% for 3 follicles ($p = 0.0016$). Acceptable pregnancy rates were obtained when at least 2 mature follicles have developed at the time of insemination. The number of mature follicles and the woman age had the maximum power to predict the PR following IUI.

Limitations, reason for caution: none

Wider implications of the findings: IUI achieves the best results with two or three mature follicles in younger woman. Clinical characteristics of women are unchangeable. However, the number of mature follicles can be increased by increasing the doses of gonadotropins. In order to avoid multiple pregnancy, when more than 4 mature follicles are obtained IUI should be converted to an IVF cycle. Gonadotropin stimulation seems to be an important tool for improving the pregnancy rate in IUI.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Hospital Universitario y Politécnico La Fe, Valencia Spain.

Trial registration number: None.

ANDROLOGY

P-001 Nanotoxicity of mesoporous silica nanoparticles in human sperm following in vitro exposure

N. Barkalina[1], C. Jones[1], K. Coward[1]
[1]*University of Oxford, Nuffield Department of Obstetrics & Gynaecology, Oxford, United Kingdom*

Study question: Given encouraging data in animal models, do nanotoxicity profiles of mesoporous silica nanoparticles (MSNPs) in human sperm permit their use as a versatile multifunctional delivery tool for the *in vitro* transfer of molecular compounds into these specialized cells for investigative and therapeutic purposes.
Summary answer: Short-term *in vitro* exposure of human sperm from fertile donors to MSNPs does not compromise essential sperm function, thereby allowing us to consider this nanomaterial as a potential candidate tool for the internalisation of various molecular constructs into mammalian gametes *in vitro.*
What is known already: Interest is steadily growing in the application of nanoparticle-mediated delivery in reproductive biology, particularly in light of the fact that certain processes involved in gamete development appear to be mediated by natural cell-secreted nanoparticles such as prostatic/epididymal exosomes and granulosa cell microvesicles. MSNPs represent robust and versatile synthetic alternatives to 'natural' nanoparticles that are capable of carrying large amounts of cargo inside animal gametes without acute toxic effects. However, their effect upon human sperm remains untested.
Study design, size, duration: A pilot *in vitro* study, investigating the effects of MSNP exposure upon the motility, viability, and DNA fragmentation status of human sperm, and seeking to evaluate the binding potential of MSNPs with these highly specialised cells.
Participants/materials, setting, methods: Fluorescent MSNPs (~138 nm), synthesised using a surfactant-templated base-catalysed sol-gel reaction, were applied to cryopreserved/thawed sperm from 18 healthy donors in a series of particle/sperm ratios for a maximum of 4 h, followed by computer-assisted sperm analysis (CASA), fluorescence viability staining, sperm chromatin dispersion analysis, and fluorescence microscopy.
Main results and the role of chance: Exposure to MSNPs did not affect the key parameters of sperm motility (average relative% change from controls across all experimental samples after 4 hrs of incubation: +35.8 and +24.0% for total and progressive motility, respectively, $p > 0.05$), the proportion of viable sperm (average relative% change from controls across all experimental samples after 4 hrs of incubation: +21.5%, $p > 0.05$), or DNA fragmentation index (average relative% change from controls across all experimental samples after 4 hrs of incubation: +10.3%, $p > 0.05$). Binding rate between MSNPs and human sperm was dependent upon the time and dose of MSNPs, in contrast to previous findings in animal models, supporting the hypothesis that the effects of MSNPs upon sperm are species-specific.
Limitations, reason for caution: This pilot study focused upon the biocompatibility of MSNPs with human sperm from healthy donors. Therefore, the effects of MSNPs upon infertile/sub-fertile sperm with compromised function, which would represent the main candidate for nanoparticle-mediated supplementation with replacement therapies, remain unknown and should be evaluated in future studies.
Wider implications of the findings: MSNP-mediated delivery represents a promising tool for the transfer of investigative and therapeutic compounds into gametes, which are otherwise remarkably resistant to the uptake of exogenous substances. In applied assisted reproductive technology, biocompatible nanomaterials, including MSNPs, could be used to supplement sub-fertile gametes with fertility-augmenting compounds during *in vitro* culture, such as motility enhancers and/or artificial oocyte activating factors for sperm, or growth factors and other compounds that retain or promote the developmental potential of oocytes and embryos.
Study funding/competing interest(s): Funding by University(ies), Dr Barkalina holds scholarships from Clarendon, Scatcherd European and Cyril & Phillis Long funding schemes. The authors have a patent pending related to the work discussed entitled 'Delivery Method' (PCT/GB13/053394; 20/12/2013).
Trial registration number: NA.

P-002 Measurement of global methylation and acetylation level before and after swim-up in human ejaculated sperm

S. K. Kim[1], H. J. Lee[2], J. H. Park[3], J. Y. Lee[4], B. C. Jee[1], S. H. Kim[3]
[1]*Seoul National University Bundang Hospital, Obstetrics and Gynecology, Sungnam, South Korea*
[2]*CHA Gangnam Medical Center, Obstetrics and Gynecology, Seoul, South Korea*
[3]*Seoul National University, Obstetrics and Gynecology, Seoul, South Korea*
[4]*Hamchoon Women's Clinic, Obstetrics and Gynecology, Seoul, South Korea*

Study question: What changes will take place in global methylation and histone acetylation levels after swim-up preparation of human ejaculated sperm?
Summary answer: The 5-mC levels were significantly lower in the swim-up samples, while no changes were observed in the positivity of six acetylation markers.
What is known already: The swim-up technique could increase the percentage of motile sperms and normal morphology, and DNA fragmentation in sperms was found to be significantly decreased after the swim-up technique. Further, the swim-up technique resulted in a significant decrease in abnormal chromatin structure in sperm.
Study design, size, duration: Prospective experimental study. Normozoospermic semen specimens were obtained from 50 normal healthy volunteers between December 2012 and May 2014.
Participants/materials, setting, methods: The semen samples were processed by the conventional swim-up method. Main outcome measures were sperm motility, strict morphology, DNA fragmentation index (DFI) by TUNEL, abnormal chromatin structure by toluidine blue staining, and immunostaining of 8-hydroxy-2'-deoxyguanosine (8-OHdG), 5-methyl-cytosine (5-mC) and six acetylation markers before and after swim-up.
Main results and the role of chance: Swim-up sperms had significantly elevated motility and normal morphology. DFI and the percentage of abnormal chromatin structure were significantly lower in the swim-up samples; 8-OHdG levels were significantly higher in swim-up samples. The 5-mC levels were significantly lower in the swim-up samples, while no changes were observed in the positivity of six acetylation markers. Elevated normal morphology and decreased DFI and 5-mC levels were observed only in non-smokers; 8-OHdG level was significantly higher in swim-up samples only from smokers. After swim-up, 5-mC levels were positively correlated with DFI ($r = 0.337$, $P < 0.05$).
Limitations, reason for caution: The exact role of 5-mC in human sperms remains unclear. Further large studies are needed.
Wider implications of the findings: This is the first study demonstrating 5-mC reduction and unchanged acetylation patterns in human sperms after swim-up preparation. Our results suggest that measurements of global DNA methylation, DNA fragmentation, and DNA oxidation may be useful in the evaluation of sperm quality.
Study funding/competing interest(s): Funding by national/international organization(s). The Korea Health Care Technology R&D Project, Ministry of Health and Welfare, Korea.
Trial registration number: NA.

P-003 Are there differences in semen parameters among ethnic groups and among various professions?

G. Abdo[1], R. Naaman[2], J. Bauer[3], N. F. Sharara[4], F. I. Sharara[4]
[1]*Virginia Center For Reproductive Medicine, Embryology, Reston, U.S.A.*
[2]*American University of Beirut, Faculty of Medicine, Beirut, Lebanon*
[3]*Virginia Center For Reproductive Medicine, Statistics, Reston, U.S.A.*
[4]*Virginia Center For Reproductive Medicine, RE/I, Reston, U.S.A.*

Study question: Are there differences in semen parameters (volume, count, motility, TMC, WHO and strict morphologies, viscosity, and WBC) among different ethnic groups, and are there any differences when evaluated by profession?
Summary answer: No differences were detected among ethnic groups, or among different professions. However, as a group, men with high BMI had significantly worse parameters compared with men with normal BMI, and there were significant differences in viscosity and volume.
What is known already: Heat affects seminal parameters and there are professions requiring significant time sitting down such as IT and engineering. As far as we know, this is the first study evaluating the effects of various professions, including those that require significant sitting, on semen parameters.
Study design, size, duration: Retrospective study of 901 semen analysis performed between January 2010 and June 2014 at a private suburban Fertility Center.
Participants/materials, setting, methods: All semen analysis (SA) performed at a private suburban Fertility Center by a single technician (GAA). Only the first SA was evaluated. Race and ethnic groups, as well as profession, were collected on all men performing a SA.
Main results and the role of chance: In total, 901 SA including 596 Caucasians (66.1%), 123 South Asians (13.7%), 70 African Americans (AA) (7.8%), 68 East Asians (7.5%), and 44 Hispanics (4.9%) were included. Of these, 276 worked in Business/Finance/Sales (30.6%), 224 worked in Information Technology (24.9%), 77 were engineers (8.5%), 51 worked in government (5.7%), and 37 in Health Care (4.1%). As a group, there was a significant negative effect of BMI on semen parameters ($P < 0.0001$), but there were no differences in age or any semen parameter among different professions.
Limitations, reason for caution: Relatively low numbers of AA, East Asians, and Hispanics. The numbers of minorities are not reflective of the general US distribution.
Wider implications of the findings: As previously reported, higher BMI correlates negatively with semen parameters, however there were no ethnic differences among the main ethnic groups in the US. Different professions are not associated with poorer semen parameters, a reassuring novel finding.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Virginia Center for Reproductive Medicine.
Trial registration number: NA.

P-004 The decline of sperm concentration profile from 1995–2006 in Jos, Nigeria

A. Nanna[1], S. Shetson[2], P. Dakum[2]
[1]*Delta State University Teaching Hospital, Pathology, Sapele, Nigeria*
[2]*Centre For Reproductive Health Research, Reproductive Laboratory, Jos, Nigeria*

Study question: Is there increase in the number of azoospermic patients in Jos, is there increase in the oligoospermic patients What is the drop in sperm concentration over the years in Jos?, Do this sperm concentration abnormalities associated with mining of mineral elements in Jos or infection?
Summary answer: From 1995–2006, there was increase of sperm concentration abnormalities by 41% and decline in mean sperm concentration by 33.14%[21.95 M/ml] and these could be associated with infection, endocrinopathy and environmental factors.
What is known already: Infertility is a global problem to contend with and male factor infertility is on the increase. Male infertility varies from 20 to 50% in various parts of Nigeria. This study is to determine the prevalence of sperm concentration abnormalities and the degree of mean sperm concentration decline in Jos, Nigeria from 1995 to 2006.
Study design, size, duration: Semen samples were collected by masturbation after abstaining for 3–7 days from 2055 male patient of age between 20 and 45 years and who were also attending infertility clinic in the centre for reproductive health research, Jos, Nigeria from 1995 to 2006. 59% represent normal sperm concentration (20 Millions/ml-W.H.O) and 41% represent abnormal sperm concentration.
Participants/materials, setting, methods: Semen samples were collected by masturbation after abstaining for 3–7 days from 2055 male patient of age between 20 and 45 years and who were also attending infertility clinic in the centre for reproductive health research, Jos, Nigeria. The semen samples were analysed for sperm concentration, using Neubauer counting chamber in line with world health Organization procedures (1999).
Main results and the role of chance: Result We had 13% azoospermia,28% oligoospermia,59% normal sperm concentration, mean sperm concentration in 1996 and 2006 are,66.23 M/ml,44.28 M/ml (p-values of <0.00) The mean sperm concentration decline by 33.14% [21.95 M/ml]
Limitations, reason for caution: We do not have actual number of children by secondary infertile couples.
Wider implications of the findings: The drop in sperm concentration could be as result of high level of mining of minerals and a lot of people are exposed to this process in Jos, Nigeria. This mining process has disrupts the process of spermatogeneis in human over a period of time. Thus reduction of sperm concentration in male patients, in Jos, Nigeria between 1995 to 2006
Study funding/competing interest(s): Funding by hospital/clinic(s) – Centre for Reproductive Health Research.
Trial registration number: NA.
Keywords: male infertility, mean sperm concentration

P-005 Dietary habits and reproductive health – results of a sociological case-control study

A. Pecoraro[1], L. Boeri[1], A. Galdini[2], R. Scano[1], E. Ventimiglia[1], A. Serino[1], P. Capogrosso[1], G. La Croce[1], G. Castagna[1], S. Ippolito[1], L. Valsecchi[2], E. Papaleo[2], M. Candiani[2], F. Montorsi[1], A. Salonia[1]
[1]*IRCSS Ospedale San Raffaele Scientific, Division of Experimental Oncology/ Unit of Urology URI, Milano, Italy*
[2]*IRCSS Ospedale San Raffaele Scientific, Unit of Obstetrics and Gynecology, Milano, Italy*

Study question: Male infertility is a multifactorial disease with a number of potential contributing causes. How nutrition could have a beneficial impact on sperm count, motility, and ultimately, fertility?
Summary answer: Infertile Caucasian-European individuals have worse recreational and nutritional habits compared to fertile individuals. Fertile individuals reported more regular consumption of vegetables, legumes, fruits and eggs.
What is known already: Many nutritional therapies have been shown to improve sperm counts and sperm motility including carnitine, selenium, zinc and vitamin B12. Arginine – essential for the synthesis of putrescine, spermidine and spermine – gives a significant improvement in sperm count and motility after taking 4 g/day for three months**.** Numerous antioxidants are used in treating male infertility such as vitamin E, glutathione, coenzyme Q10 and vitamin C whose deficit correlates with damage to the sperm DNA.
Study design, size, duration: A cohort of 1134 consecutive individuals [n = 324 (28.6%) infertile; n = 810 (71.4%) fertile] anonymously completed a questionnaire related to nutritional and recreational habits, for above one year. Infertility was defined according to WHO definition.
Participants/materials, setting, methods: Descriptive statistics was applied to describe the overall cohort. Complete data collection was available for 585 (51.6%) women [mean (SD) age: 34.27 (6.44) years; range: 20–66)] and 549 (48.4%) men [mean (SD) age: 37.21 (9.97) years; range: 18–73)].
Main results and the role of chance: Both male [33.4 vs. 38.3; p = 0.001] and female [33.7 vs 34.7; p = 0.04] fertile patients were younger than infertile individuals. Infertile individuals were more frequently smokers (p = 0.02); a higher rate of infertile individuals were current alcohol drinkers ($p < 0.001$), and consumed more alcohol/week than fertile drinkers (p = 0.04). Fewer fertile people were coffee drinkers (p = 0.003). A higher proportion of infertile individuals reported a past use of illicit drugs (p = 0.02). Fertile individuals more frequently reported regular consumption of vegetables (p = 0.04), legumes (p = 0.001), fruits ($p < 0.001$), and eggs (p = 0.02), but less frequently consumed sweets (p = 0.04). No significant dietary differences were observed between fertile and infertile individuals in terms of cereals, red meat, poultry, and fish. A greater rate of fertile individuals thought that diet can significantly impact fertility (p = 0.02).

Limitations, reason for caution: We could substitute the clinical questionnaire with a diet diary in order to allow patients to be more accurate. In addiction some biological markers both in females and males could be used to objectify the improvement of fertility due to the diet. Also the time of follow-up might be increased in order to perceive how nutrition correlates to the number of pregnancies.
Wider implications of the findings: Literature has proposed as one of the possible etiologies of idiopathic male infertility the disruption of the delicate balance between oxidant and antioxidant elements. Probably food rich in antioxidants such as vegetables and fruit could protect polyunsaturated fatty acids and phospholipids from oxidative damage.

In addiction several studies have found that oligoelements such as zinc, available in legumes and cereals, and selenium, contained in eggs, correlate with proper testosterone levels and with stability of mid-piece.

P-006 Who is the most suitable candidate for clomiphene treatment? Findings of an observational survey in a cohort of primary infertile men

P. Capogrosso[1], L. Boeri[1], A. Serino[1], E. Ventimiglia[1], G. La Croce[1], M. Paciotti[1], A. Pecoraro[1], S. Ippolito[1], G. Castagna[1], R. Scano[1], D. Kuefner[1], F. Cantiello[2], R. Damiano[2], F. Montorsi[1], A. Salonia[1]
[1]*IRCCS Ospedale San Raffaele, Division of Experimental Oncology/Unit of Urology URI, Milan, Italy*
[2]*Magna Graecia University, Research Doctorate Program In Urology, Catanzaro, Italy*

Study question: We assessed seminal outcomes after clomiphene treatment; and, the most suitable candidate for clomiphen in a cohort of white-European men presenting for primary couple's infertility.
Summary answer: Clomiphene treatment was associated with an improvement of sperm concentration in a cohort of white-European men presenting for primary couples infertility. Patients who most benefited from this therapy are young, with a normal BMI and a short period of infertility.
What is known already: Clomiphene citrate is a well-tolerated anti-estrogen thought to increase sperm parameters in males attempting to conceive. Clomiphene has been widely used in idiopathic oligoasthenoteratozoospermia without proven evidence for its benefit. Further research is needed to clarify when clomiphene citrate is indicated in the treatment of male infertility.
Study design, size, duration: Observational study. Complete data from 307 consecutive men treated with clomiphene were analyzed.
Participants/materials, setting, methods: Comorbidities were scored with the Charlson Comorbidity Index (CCI). Semen analysis values were assessed based on the 2010 WHO reference criteria. Descriptive statistics tested the association between seminal outcome after therapy and clinical characteristics; logistic regression models tested the association between clinical parameters and clomiphene-related seminal improvement.
Main results and the role of chance: 194 (63.2%), 190 (61.9%) and 146 (47.6%) men presented with oligospermia, astenozoospermia and teratozoospermia. After 3 months of clomiphene, sperm concentration ($p < 0.001$) and total sperm progressive motility ($p < 0.001$) improved. Improvement of sperm concentration was more frequently reported in younger individuals ($p < 0.001$), with a lower BMI score ($p = 0.002$), and with a higher left testicular volume ($p = 0.03$). Similar findings were also found for sperm motility (all $p < 0.05$). Young patients ($p < 0.001$), with normal BMI ($p = 0.02$), and with a greater left testicular volume ($p = 0.003$) were more likely to fall within the normal range of sperm concentration and motility (all $p < 0.05$) after treatment. At MVA, age (OR 0.86; $p = 0.005$), BMI (OR 0.8; $p = 0.023$) and length of infertility (OR 0.95; $p = 0.46$) achieved independent predictor status for concentration improvement after treatment.
Limitations, reason for caution: The sample size is too small to draw general conclusions. We did not evaluate hormonal changes after clomiphene treatment.
Wider implications of the findings: This study confirmed a statistically significant increase in sperm concentrations after clomiphene and pointed out the importance of patient age and duration of infertility as predictors of seminal parameters improvement after treatment.
Study funding/competing interest(s): None.
Trial registration number: NA.

P-007 Testis development in the absence of SRY: chromosomal rearrangements at SOX9 and SOX3

A. Ben Haj Hassine[1], M. Basly[1], L. Kraoua[2], R. Arfaoui[1], R. Rachdi[1]
[1]*Military Hospital, Gynecology Obstetrics, Tunis, Tunisia*
[2]*Charles Nicolle Hospital, Department of Congenital and Hereditary Diseases, Tunis, Tunisia*

Study question: Is testis development possible in the absence of SRY.
Summary answer: SOX3 duplications may substitute SRY in some XX subjects.
What is known already: 46,XX disorders are congenital conditions in which, in the presence of a female karyotype, the development of gonadal and anatomical sex is atypical, ranging from various degrees of ambiguous genitalia to phenotypic males with azoospermia. These conditions are poorly characterized, at least in subjects whose DNA does not contain SRY, the gene triggering testis differentiation in mammals.
Study design, size, duration: Case report.
Participants/materials, setting, methods: We analyzed by conventional and molecular cytogenetics an SRY-negative unrelated 46,XX subject.
Main results and the role of chance: The patient, a 30 years old normal adult male, was investigated because of infertility. Physical examination showed normal male secondary sexual characteristics and bilateral gynecomastia. Laboratory investigations showed azoospermia, low serum testosterone and increased FSH and LH. The subject carried partially overlapping 17q24.3 duplications about 500 kb upstream of SOX9, inherited from a normal father. Breakpoints cloning showed that duplications were in tandem whereas the 17q in the reciprocal translocation was broken at about 800 kb upstream of SOX9.
Limitations, reason for caution: exceptional case, additional evidence are necessary.
Wider implications of the findings: in the absence of SRY, altered expression of genes crucial to gonadal development, such as SOX9 and SOX3, may invert the expected embryonic plan.
Study funding/competing interest(s): Military Hospital of Tunis.
Trial registration number: 122/2014 46, XX.
Keywords: disorders of sex development, infertility, non-coding 38 regulatory elements

P-008 Low birth weight is associated with a higher rate of health-significant comorbidities and worse seminal parameters – results of a cross-sectional study in primary infertile patients

L. Boeri[1], P. Capogrosso[1], E. Ventimiglia[1], A. Serino[1], G. La Croce[1], A. Pecoraro[1], M. Paciotti[1], S. Ippolito[1], G. Castagna[1], R. Scano[1], R. Damiano[2], F. Montorsi[1], A. Salonia[1]
[1]*IRCCS Ospedale San Raffaele, Division of Experimental Oncology/Unit of Urology URI, Milano, Italy*
[2]*Magna Graecia University, Research Doctorate Program In Urology, Catanzaro, Italy*

Study question: We assessed prevalence of, and clinical and seminal impact of different categories of weight at birth in a cohort of white-European men presenting for primary couple's infertility.
Summary answer: Low birth weight (LBW) was associated with a significant higher rate of adult diseases. Clinical, endocrine and semen parameters were significantly worse in the LBW group.
What is known already: Several theories pointed out the association between LBW and the subsequent risk of developing cardio vascular diseases, high blood pressure and type II diabetes mellitus in adulthood. The raise of the developmental origins of adult disease has positioned low birth weight as a significant health issue.
Study design, size, duration: Cross sectional study. Complete data from 757 consecutive infertile men were analysed.
Participants/materials, setting, methods: Birth weight ≤ 2500, 2500–4200, and ≥ 4200 g were considered as LBW, normal (NBW) and high (HBW). Comorbidities were scored with the Charlson Comorbidity Index (CCI). Semen analyses were assessed based on 2010 WHO criteria. Descriptive statistics detailed the association between semen parameters and clinical characteristics and the birth weight categories.
Main results and the role of chance: LBW, NBW and HBW were found in 52 (6.9%), 605 (79.9%) and 100 (13.2%) men, respectively. LBW reported a higher prevalence of comorbidities ($p < 0.001$). Likewise, hypercholesterolemia

($p = 0.04$) and hypertriglyceridemia ($p = 0.01$) were more frequently reported in LBW. LBW had a lower mean testicular volume ($p = 0.02$). LBW men showed a higher rate of both asthenozoospermia ($p = 0.02$) and teratozoospermia ($p = 0.02$). Overall, ejaculated volume ($p = 0.006$), sperm motility ($p = 0.02$) and normal morphology ($p = 0.04$) were significantly reduced in the LBW group. Likewise, LBW patients presented higher FSH levels ($p = 0.04$) but lower circulating testosterone levels ($p = 0.03$) as compared with the other groups. At MVA, LBW achieved independent predictor status for a higher CCI value (OR 3.7; $p < 0.001$), lower sperm motility (OR 2.7; $p < 0.04$), and lower normal sperm morphology (OR 2.3; $p < 0.04$).
Limitations, reason for caution: The sample size is too small to draw general conclusions. We did not evaluate the impact of birth weight on seminal parameters in non-infertile men.
Wider implications of the findings: This is the first study focused on the impact of birth weight on clinical and seminal parameters in a cohort of infertile men. This study is in line with previous data reporting that small for gestational age subjects have pituitary-gonadal axis function that tends toward hypogonadism.
Study funding/competing interest(s): Ospedale San Raffaele.
Trial registration number: NA.

P-009 Sperm retrieval at the time of tumor resection in azoospermic men with congenital adrenal hyperplasia and bilateral testicular adrenal rest tumors: a case series

P. K. Kavoussi[1], R. Summers-Colquitt[2], K. C. Odenwald[3], T. B. Pool[2], S. K. Kavoussi[3]
[1]*Austin Fertility & Reproductive Medicine/Westlake IVF, Reproductive Urology, AUSTIN, U.S.A.*
[2]*Austin Fertility & Reproductive Medicine/Westlake IVF, Embryology, AUSTIN, U.S.A.*
[3]*Austin Fertility & Reproductive Medicine/Westlake IVF, Reproductive Endocrinology & Infertility, AUSTIN, U.S.A.*

Study question: Is it feasible to offer sperm retrieval at the same surgical setting as tumor resection in azoospermic men with congenital adrenal hyperplasia (CAH) and bilateral testicular adrenal rest tumors (TARTs)?
Summary answer: Yes. After appropriate hormonal treatment, sperm retrieval should be performed concomitantly with tumor resections.
What is known already: CAH men have impaired cortisol and aldosterone production resulting in increased adrenocorticotropic hormone (ACTH) production leading to adrenal hyperplasia and adrenal androgen overproduction. Some will develop benign TARTs, typically bilateral and originating in the rete testis. TARTs commonly result in obstructive azoospermia and destroy normal testicular tissue. There are reports of testicular aspiration for use with in-vitro fertilization/intracytoplasmic sperm injection (IVF/ICSI) with the tumors in situ and reports of men remaining azoospermic after tumor resections.
Study design, size, duration: Case series, between October 2014 and December 2014, of two men with CAH, bilateral TARTs, and azoospermia.
Participants/materials, setting, methods: Bilateral TART resections and sperm retrievals were performed concomitantly in both men.
Main results and the role of chance: Both men had successful sperm retrievals, which were cryopreserved for future use with IVF/ICSI, at the same settings as bilateral TART resections. This eliminates the need for multiple procedures for these patients. The role of chance is possible, as this is a small sample size in this relatively uncommon scenario; however, successful sperm retrievals in these two patients is encouraging.
Limitations, reason for caution: This is a small sample size with this relatively uncommon scenario and needs to be validated with higher powered studies.
Wider implications of the findings: To our knowledge, this is the first report of men with CAH and bilateral TARTs undergoing successful sperm retrievals concomitantly with bilateral TART resections. As it has previously been shown that men remain azoospermic following TART resections, sperm retrieval and tumor resection in one surgical setting would seem to be the optimal approach rather than subjecting such patients to two separate procedures. Wider implications are that men in this scenario should undergo these procedures concomitantly.
Study funding/competing interest(s): No funding was required.
Trial registration number: NA.

P-010 Diabetes mellitus, spermatogenesis progression and sperm function: does a spoonful of sugar compromise male fertility?

R. S. Tavares[1], J. Portela[1], M. I. Sousa[1], P. C. Mota[1], J. Ramalho-Santos[1], S. Amaral[1]
[1]*CNC – Center For Neuroscience and Cell Biology, Department of Life Sciences, Coimbra, Portugal*

Study question: Is hyperglycemia, the major effector of the diabetes mellitus (DM) pathology, capable of promoting male reproductive dysfunction alone?
Summary answer: While high glucose levels impair some aspects of spermatogenesis, possibly through an effect on Sertoli cell functionality, mature sperm function does not seem to be affected at least *in vitro*. Nevertheless, the lack of available glucose in sperm vicinity severely suppresses their function, potentially jeopardizing fertilization.
What is known already: DM is associated with the emergence of several clinical complications, including reproductive dysfunction (RD). Alterations in testicular histology and decreased standard sperm parameters have been described in diabetic men. Given the multifactorial nature of DM-induced physiological changes, it remains unclear which are the mechanisms accountable for the reported RD.
Study design, size, duration: Normozoospermic sperm samples (minimum $n = 4$) were exposed to different D-glucose concentrations for 48 h (37°C, 5%CO_2) to mimic physiological and hyperglycemic conditions. Additionally, spermatogenesis progression ($n = 3$) was assessed using testis fragments of C57BL/6 mice pups following 3 weeks in culture under D-glucose concentrations (35°C, 5%CO_2). Osmotic controls were performed with L-glucose.
Participants/materials, setting, methods: Healthy individuals were recruited at the Human Reproduction Service from University Hospitals of Coimbra and animals were obtained from CNC animal facility. Motility, viability (eosin Y), mitochondrial membrane potential (MMP; JC-1), superoxide production (mitoSOX), capacitation status (detection of phosphotyrosines) and acrosome reaction (AR; PSA-FITC) were assessed daily. Organ culture was performed according to the interphase gas-liquid methodology. Histomorphometric analysis was determined using Image J software.
Main results and the role of chance: After evaluation of several sperm parameters, results highlight the absence of direct effects promoted by 25 mM and 50 mM D-glucose when compared to control (5 mM D-glucose; $p > 0.05$) following 24 and 48 h of treatment. Interestingly, data obtained with the non-metabolizable L-glucose showed a severe impairment of sperm function when compared to respective D-glucose concentrations. Indeed, an increase in reactive oxygen species production ($p < 0.05$) paralleled by a suppression in sperm motility ($p < 0.05$) and capacitation ($p < 0.05$) were already detected after 24 h of treatment while decreased MMP ($p < 0.05$), acrosomal integrity ($p < 0.01$) and viability ($p < 0.05$) were found later on. Organ culture experiments, showed that high glucose levels increase Sertoli cell number ($p < 0.05$) while decreasing tubular luminal area ($p < 0.01$), therefore suggesting an impairment of this somatic cell vital for spermatogenic control.
Limitations, reason for caution: This is an *in vitro* study, and caution must be taken when extrapolating to an *in vivo* situation.
Wider implications of the findings: This study indicates that high glucose levels *per se* influence male reproductive function but only at the spermatogenesis level, stressing the importance of other factors involved in the DM. Furthermore, it highlights the importance of available glucose for spermatozoa functionality, in accordance with previous reports. Additionally, our results lead us to suggest that the adverse *in vivo* effects of the disease at the sperm level might be explained by a cellular hypometabolism in diabetic conditions.
Study funding/competing interest(s): This study was supported by the Portuguese National Science Foundation (FCT) through the project EXPL/BEX-BCM/0224/2012 and CNC funding (FCT, PEst-C/SAU/LA0001/2013-2014). SA is also a recipient of a FCT fellowship (SFRH/BPD/63190/2009).
Trial registration number: NA.

P-011 Evaluation of the effect of cadmium and lead concentration in seminal plasma on sperm DNA fragmentation

A. Mroczkowski[1], A. Wdowiak[2], G. Bakalczuk[3], S. Z. Bakalczuk[4], I. Bojar[5]
[1]*Ovum, Ovum RiA Lublin, Lublin, Poland*
[2]*Medical University of Lublin, Diagnostic Techniques Unit Faculty of Health Sciences, Lublin, Poland*

[3]Medical University of Lublin, Department of Obstetrics Gynaecology and Obstetric-Gynaecological Nursing Faculty of Health Sciences, Lublin, Poland
[4]Ovum, Lublin Poland, Lublin, Poland
[5]Institute of Rural Health, Department For Health Problems of Ageing, Lublin, Poland

Study question: The aim of this research is to specify the influence of lead and cadmium on the semen DNA fragmentation.
Summary answer: It has been shown that the fragmentation of sperm DNA intensifies with the increasing concentration of Lead and Cadmium in seminal plasma.
What is known already: Lead (Pb) and cadmium (Cd) are two of the well-known reproductive toxicants which humans are exposed to occupationally and environmentally, and can lead to negative effects on the sperm chromatin DNA integrity. Both are pervasive in the human environment and accumulate in the human body over a lifetime. Heavy metals have a strong capacity to induce oxidative stress in body cells by disintegration of the lipid membrane.
Study design, size, duration: In order to determine the percentage of fragmented DNAin sperm, the SCD test was used (sperm chromatin dispersion), according to the instructions provided by the producers [Dyn-Halosperm® kit, Halotech DNA SL, Madrid, Spain]. The Pb and Cd measurements were performed by the electrothermal-atomic absorption spectrometry method.
Participants/materials, setting, methods: The presented study concerned 125-infertile men aged 25–35, and was conducted in 2013 and 2014 in the 'Ovum-Reproduction and Andrology' Non-Public Health Care Unit in Lublin, (Poland).The study has been approved by the ethics committee of the Institute of Rural Health in Lublin.
Main results and the role of chance: We have established that a statistically significant positive correlation occurs between the intensification of sperm DNA fragmentation and the concentration of Pb (r = 0,187, p = 0,032). Also, a positive correlation has been observed between damaged chromatin and the concentration of Cd (r = 0,185, p = 0,033).
Limitations, reason for caution: None.
Wider implications of the findings: The pollution of the environment with heavy metals, like Pb and Cd, may lead to decreased fertility of men by damaging the integrity of sperm chromatin. This phenomenon may affect the epigenetic changes of future generations.
Study funding/competing interest(s): International Scientific Association for the Support and Development of Medical Technologies.
Trial registration number: Local institutional registration.
Keywords: lead, cadmium, sperm DNA fragmentation

P-012 Effect of seminal transforming growth factorß1 (TGFß1) and glutathione on apoptosis in spermatozoa from Tunisian infertile men

H. Ben Ali[1], H. Amor[2], R. Hichri[2], M. Khamari[2], S. Elfekih[2], M. Ajina[2], A. Saad[2]
[1]Hospital Farhat Hached, Laboratoire Cytogénétique Génétique Moléculaire Et Biologie De La Reproduction Humaines, Sousse, Tunisia
[2]Hospital Farhat Hched, Laboratoire Cytogénétique Génétique Moléculaire Et Biologie De La Reproduction Humaines, Sousse, Tunisia

Study question: Human seminal plasma is a natural reservoir of biochemical constituents that cause apoptosis of sperm. The presence of TGFß1 and glutathione in the seminal plasma plays an important role in the death of the sperm by apoptosis. Our present study is the first approach carried out in Tunisia.
Summary answer: glutathione and seminal TGFß1 are important risk factors that can lead to a succession of morphological and functional alterations in sperm cells resulting in the necrozoospermia. Their rise in seminal plasma can lead to poor results of IVF.
What is known already: TGFb1 induces the production of free radicals or reactive oxygen species (ROS) which is derived from non-functional spermatozoa and leukocytes. The TGFß1 causes an increase rate of the oxidized glutathione (GSSG) with respect to the reduced intracellular glutathione (GSHr). Thus an increase in the production of ROS and a decrease of reduced glutathione indicates that the rate of TGFß1induit oxidative stress in the walls sperm. These ROS are largely due to DNA fragmentation.
Study design, size, duration: The study involved 120 men aged 28–56 years and characterized by idiopathic infertility. The men were divided into three groups: normozoospermics that were considered as controls (n = 40), asthénotératozoospermics (OAT; n = 45) and necrozoospermics (Necro; n = 35).
Participants/materials, setting, methods: For each patient, we evaluated sperm parameters according to WHO standards, TGFß1 rate by ELISA and the oxidized and reduced glutathione levels in seminal plasma method. The percentage of sperm DNA fragmentation was performed by the TUNEL technique.
Main results and the role of chance: With the significant increase in TGFß1 and DFI rates in groups and asthenoteratozoospermics necrozoospermics, there were positive correlations between these substances and sperm quality [TGFß1 / count; r = +0.42, $p < 0.05$), TGFß1 / Mobility; r = 0.494, $p < 0.001$) and TGFb1 / Morphology; r = -0.38, $p < 0.05$). In addition, high levels of reduced glutathione (GHSR) and oxidized (GSSG) seminal were observed in the control group, but there were conflicting associations that reflect the effects of antioxidants on sperm parameters. However, we found a significant increase in DFI in groups with abnormal semen analysis in particular necrozoospermic group. We showed negative associations between DNA fragmentation and the seminal parameters.
Limitations, reason for caution: These results suggest that glutathione and seminal TGFß1 are important risk factors that can lead to a succession of morphological and functional alterations in sperm cells resulting in the nécrozoospermie. Their rise in seminal plasma can lead to poor results of IVF.
Wider implications of the findings: the originality of this study lies in the fact that the TGFb1 and the seminal glutathione significantly increase the Necrospermia way through the voice of ROS. These ROS promote DNA fragmentation and triggeted the process of apoptosis.
Study funding/competing interest(s): Laboratory cytogenetic, molecular genetics and biology of human reproduction; University Hospital Farhat Hached Sousse Tunisia.
Trial registration number: Glutathione and seminal TGFß1 are important risk factors that can lead to a succession of morphological and functional alterations in sperm cells resulting in the necrozoospermia. Their rise in seminal plasma can lead to poor results of IVF.
Keywords: sperm, DNA, apoptosis, TGFb1, necrospermia

P-013 Sperm DNA fragmentation index and female age are two critical parameters in predicting IUI outcome

M. Sabbaghian[1], H. Hosseinifar[1], T. Modarresi[1], M. Chehrazi[2], L. Karimian[3], A. H. Shahverdi[3], M. A. Sadighi Gilani[1], F. Farrahi[1]
[1]Royan Institute For Reproductive Biomedicine ACECR, Department of Andrology At Reproductive Biomedicine Research Center, Tehran, Iran
[2]Royan Institute For Reproductive Biomedicine ACECR, Department of Epidemiology and Reproductive Health, Tehran, Iran
[3]Royan Institute For Reproductive Biomedicine ACECR, Department of Embryology At Reproductive Biomedicine Research Center, Tehran, Iran

Study question: To demonstrate whether DNA fragmentation index (DFI) as well as the other parameters including age can be used as main predictors of intrauterine insemination (IUI) outcomes.
Summary answer: IUI prediction will be possible through measuring sperm DNA damage and female age. We offered three equations with high validity to predict IUI outcomes.
What is known already: There is a need for new markers as well as sperm parameters that might predict pregnancy outcome and the risk of adverse reproductive events. Markers of sperm DNA integrity may help differentiate fertile from infertile men, but the clinical value of sperm DNA integrity testing remains to be defined.
Study design, size, duration: A prospective and cohort study was conducted at Royan Institute from May 2010 to April 2012. 576 Couples were diagnosed with idiopathic infertility referred for IUI.
Participants/materials, setting, methods: The choice of IUI method was based upon infertility diagnosis. Couples were diagnosed with idiopathic infertility by specialist in our center. For each couple, only one treatment cycle during the study period was included in the analysis. In order to obtain sufficient number of spermatozoa for sperm chromatin structure assay (SCSA) analysis, only those men having sperm concentration of at least 1×10^6 sperm/ml in neat semen were included. Moreover, men with ≤ 50 years old; women with ≤ 40 year of age, body mass index (BMI) < 30 kg/m^2 and female baseline FSH <12 IU/l were considered eligible for the study. Semen samples were collected at the day of IUI.
Main results and the role of chance: We compared mean of quantitative variables between pregnancy outcomes, assessed bivariate relationship between

continuous variables. Cut-off point for DFI was determined and ROC curve was used to measuring accuracy of predictive models of pregnancy outcomes. There were statistically significant differences regarding DFI in groups with and without biochemical pregnancy (21.7 ± 0.56 versus 34.86 ± 0.42, mean ± SE, $P < 0.001$). Odds ratio for DFI (95% confidence intervals) were 71 (66–76), 69 (64–74) and 56 (49–65) for biochemical and clinical pregnancy and delivery, respectively. Measured cut-off point for DFI was equal to 24.5%. In order to predicting IUI outcomes, it was created three equations on the basis of DFI and female age.

Limitations, reason for caution: There were not any limitations.

Wider implications of the findings: There are two merits in present study as compared with similar studies. First thing is that our study is the largest research about predictive value of DFI in IUI outcomes which has been ever done. Secondly, for the first time, we offered three formulas to predict IUI outcomes so that with being available the amounts of DFI and female age are resulted in partly accurate prediction. Besides, we have studied effects of sperm processing on our results that will be submitted later.

Study funding/competing interest(s): Funding by hospital/clinic(s) –Royan Institute.

Trial registration number: This study was not RCT.

Keywords: IUI, female age, pregnancy outcomes, sperm DNA damage

P-014 Predictive value of serum inhibin-B levels as an indicator of the presence of testicular spermatozoa in non-obstructive azoospermia

M. Alhalabi[1], H. Droubi[2], S. Alsamawi[2], A. Taha[2], R. Doghouz[2], A. Alkhatib[2], M. Mousa[2], A. Alhussaini[2]

[1]*Faculty of Medicine Damascus University., Embryology and Genetics, Damascus, Syria*

[2]*Orient Hospital, Assisted Reproduction Unit., Damascus, Syria*

Study question: What is the predictive value of serum Inhibin-B levels as an indicator of the presence of testicular spermatozoa in non- obstructive azoospermia (NOA), compared with other markers as AMH, FSH and testicular volume.

Summary answer: Inhibin-B as a potential marker of persistent spermatogenesis seems to reach a satisfactory clinical utility, and in association with other parameters such as AMH, FSH and testicular volume could allow to improve predictive value of male assessment in NOA.

What is known already: Inhibin-B is glycoproteins of the transforming growth factor-β superfamily, is produced almost exclusively by the Sertoli cells and has been proposed as direct markers of their function and indirect markers of spermatogenesis.

Study design, size, duration: Study design: prospective clinical study.
Size: 228 patients with idiopathic NOA.
Duration: from October 2009 to October 2013.

Participants/materials, setting, methods: Participants: 228 Middle Eastern males with idiopathic NOA.
Setting: Faculty of Medicine, Damascus University and Orient Hospital.
Materials and methods: Inhibin-B in Serum evaluated before sperm retrieval, in addition to AMH, FSH and testosterone. Testicular volume measured by sonography.
Interventions: Fine Needle Aspiration (FNA) and Testicular Sperm Extraction (TESE).

Main results and the role of chance: Spermatozoa were retrieved in 87 patients (38.16%), which classified as group I and were absent in 141 patients (61.84%) in group II. Mean serum Inhibin-B ± SD was significantly higher in group I than group II, (71.77) versus (27.49) respectively ($P < 0.001$), The odds ratio of Inhibin-B was 1.0409 (95% CI: 1.0286 to 1.0533). Serum Inhibin-B demonstrated that the best inhibin B value threshold for discriminating between successful and failed sperm retrieval was 35 pg/ml, with a sensitivity of 75.86 (95% Confidence interval [CI] : 65.5–84.4) and specificity of 80.85 (CI: 73.4–87.0) for the prediction of the presence of testicular spermatozoa as determined by the receiver operating characteristic (ROC) curve analysis and area under curve (AUC).

Limitations, reason for caution: The diagnosis of idiopathic non-obstructive azoospermia was based on clinical finding and several parameters as FSH, testicular volume and histo-pathology of a previous testicular biopsy (if available) although no standard method was used. And our study might reflect selection bias due to our referral pattern.

Wider implications of the findings: In the literature, attempts have been made to compare serum FSH and Inhibin-B levels as predictors of the recovery of testicular spermatozoa: Inhibin-B proved to be superior (Liu YC et al., 2006; Nagata Y et al., 2005) or equal (Tunc L et al., 2006; Halder A et al., 2005) to FSH, while in a other studies (Tsujimura A et al., 2004; Bohring C et al., 2002) combination proved to be better than any hormone alone.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Study Funding: from the scientific research budget of Faculty of Medicine and Orient Hospital.

Trial registration number: NA.

Keywords: inhibin B, sperm retrieval, spermatogenesis, azoospermia

P-015 Interferometric phase microscopy for label-free morphological evaluation of sperm cells

M. Haifler[1], P. Girshovitz[2], G. Band[3], G. Dardikman[2], N. T. Shaked[2]

[1]*Sheba Medical Center, Urology, Tel Aviv, Israel*

[2]*Tel Aviv University, Biomedical Engineering, Tel Aviv, Israel*

[3]*Sheba Medical Center, Male Fertility Clinic, Tel Aviv, Israel*

Study question: Is interferometric phase microscopy (IPM) superior to bright field microscopy (BFM) in evaluating sperm cell morphology for ICSI?

Summary answer: IPM is superior to label free BFM and equivalent to label based BFM in identification of sperm cell morphological abnormalities according to the WHO criteria.

What is known already: Approximately 70 million people a year worldwide need assisted reproductive techniques to bare children. To improve fertilization rates, the most suitable sperm cell has to be chosen. Sperm morphology, evaluated qualitatively by label free bright field microscopy, is a good predictor for fertilization success. Interferometric phase microscopy is able to quantitatively image a sample without staining and with great accuracy and In recent years, several initial researches have demonstrated utilization of IPM for sperm morphological characterization.

Study design, size, duration: We evaluated 350 sperm cells by IPM and label free BFM according to the WHO criteria. Furthermore, presence and relative size of head vacuoles was also compared. Label based BFM was considered the most accurate test for sperm cell abnormalities and IPM and label free BFM were compared to it.

Participants/materials, setting, methods: Continuous variables were compared by the student's *t*-test and Wilcoxon sign-rank test. Categorical variables were compared with χ^2-test of independence and Mcnemar test. Sensitivity and specificity of IPM and label-free BFM were calculated compared to label-based BFM.

Main results and the role of chance: No statistically significant difference was identified in the continuous variables evaluated with IPM and label-based BFM. In contrast, head width, acrosome area and midpiece width were statistically different between IPM and label-free BFM.

Categorical variables evaluated with IPM were not found to be independent of the variables evaluated by label-based BFM. In contrast, the variables evaluated with label-free BFM were statistically independent of those found by IPM.

All the vacuoles that were not identified with IPM were single and smaller than 5% of the sperm cell heads. However, 50% of the vacuoles that were missed by label-free BFM were identified by IPM.

Sensitivity and specificity of IPM was higher than those of label free BFM for all WHO criteria.

Limitations, reason for caution: The number of sperm cells needed to be evaluated was chosen to identify a 10% difference in any of the continuous variables at $p < 0.05$ and power of 80%. our main limitation is that we examined fixed cells and not live motile cells.

Wider implications of the findings: Portable IPM is a novel and affordable method for observing and analyzing sperm cell characteristics. This method is found equivalent to label-based BFM and superior to the commonly used label-free BFM in assessing static parameters of sperm samples and thus may be incorporated in the ICSI procedure.

Study funding/competing interest(s): Funding by University(ies) – Department of Biomedical Engineering, Tel Aviv University.

Trial registration number: NA.

P-016 An "in vitro" prepubertal porcine mini-testis: a new model to study the effects of gonadotropins on Sertoli and Leydig cells interactions

G. Luca[1], C. Lilli[1], C. Bellucci[1], F. Mancuso[1], I. Arato[1], G. Falabella[1], M. Calvitti[1], F. Fallarino[1], M. C. Aglietti[2], T. Baroni[1], M. Bodo[1], R. Calafiore[2]
[1]*Università Degli Studi Di Perugia, Experimental Medicine, PERUGIA, Italy*
[2]*Università Degli Studi Di Perugia, Medicine, PERUGIA, Italy*

Study question: At the present there is no reliable 'in vitro' model to achieve better understanding about gonadotropins effects on Sertoli and Leydig cells, to be possibly used for treatment of male infertility.
Summary answer: The aim of our study was to:
- set-up an 'in vitro' pre-pubertal porcine mini-testis as a useful tool.
- study the effect of gonadotropins (FSH and LH) on the mini-testis model.
What is known already: Gonadotropins (FSH, LH), whose secretion is induced by the hypothalamic hormone GnRH, are the principal regulators of the testis functions. Pre-pubertal age is characterized by physiologic hypogonadotropic hypogonadism state with the exception of AMH that is upregulated by FSH and down-regulated by androgen AMH was then proposed for potential marker of Sertoli cells function in the pre-pubertal age. Moreover, in this age range, most of damage, subsequently leading to male infertility will start.
Study design, size, duration: Set-up of an *'in vitro'* mini testis; evaluation of gonadotropins effects on Sertoli and Leydig cells by: (a) ELISA assay for AMH, inhibin B and testosterone secretion in the medium; (b) Real Time PCR analysis of FSH-r, inhibin B, AMH and MAPkinases (Erk1/2, AKT).
Participants/materials, setting, methods: Sertoli and Leydig cells, obtained by 15–20 days old neonatal pigs, were isolated and evaluated in terms of purity by AMH (unique pre-pubertal SCs marker), INSL3 (Leydig cells marker), ASMI (peritubular cells marker) and PGP9.5 (gonocytes and spermatogonial cells marker) immunocytochemistry. Finally, purified Sertoli and Leydig cells were co-cultured to obtain the 'mini-testis'.
Main results and the role of chance: We have obtained highly purified pre-pubertal Sertoli and Leydig cells culture.

In addition, our 'in vitro' mini-testis, demonstrated to be a functional model for studying the effects of gonadotropins on the cells.

In fact, AMH secretion was down-regulated in our *'in vitro'* mini testis by FSH treatment, while inhibin B increased after FSH and FSH/LH stimulation. Testosterone production was increased only by LH treatment.

Preliminarily, we have shown that ERK1/ERK2 expression was upregulated by FSH and FSH/LH stimulation while FSHr expression was down-regulated by FSH and increased by FSH/LH treatment; AKT was upregulated in all conditions.
Limitations, reason for caution: No.
Wider implications of the findings: These preliminary data could help to better understand the interactions between gonadotropins, Sertoli and Leydig cells possibly to be possibly used for treatment of male infertility.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – this work was supported by a grant from Mr. Gary Harlem (Altucell Inc. 3 Astor Court, Dix Hills, New York, NY). Gonadotropins were supplied by Merck-Serono (London, UK).
Trial registration number: NA.
Keywords: gonadotropins, Sertoli cells

P-017 An investigation of seminal plasma concentration of CRISP-1 as a marker for determining the type of azoospermia using a novel ELISA

J. Žáková[1], P. Kosztyu[2], P. Ventruba[1], Hlozánková, M.[2], I. Crha[1]
[1]*Faculty Hospital Brno, Gynaec. Obstet., Brno, Czech Republic*
[2]*BioVendor, Laboratory Medicine, Brno, Czech Republic*

Study question: Evaluation of the ELISA for the quantitative detection of human Cysteine-Rich Secretory protein 1 (CRISP-1) in seminal plasma as a non-invasive method for the distinction between obstructive and nonobstructive azoospermia.
Summary answer: The quantitative measurement of seminal CRISP-1 using BioVendor ELISA could potentially differentiate the cause of azoospermia.
What is known already: Cysteine-Rich Secretory Protein 1 is a member of the cysteine-rich secretory proteins (CRISPs) family. CRISPs show a strong expression bias to the mammalian male reproductive tract and have been implicated in many aspects of male germ cell biology spanning haploid germ cell development, epididymal maturation, capacitation, motility and the actual processes of fertilization. Human CRISP-1 is produced throughout the epididymis and plays important role in sperm-egg fusion process and inhibition of sperm capacitation.
Study design, size, duration: We developed a novel enzyme immunoassay for human CRISP-1 and measured CRISP-1 in seminal plasma samples from 24 normospermic donors, 19 asthenospermic donors, 23 oligospermic donors, 13 azoospermic donors and 2 donors after vasectomy.
Participants/materials, setting, methods: The BioVendor Human Cysteine-Rich Secretory Protein 1 ELISA was used for the quantitative measurement of CRISP-1 in seminal plasma. This sandwich ELISA is based on two specific polyclonal anti-human CRISP-1 antibodies. The standard used in this kit is the recombinant human CRISP-1 protein produced in *E. coli*.
Main results and the role of chance: Significant differences in mean concentration of CRISP-1 in seminal plasma samples of men with different diagnosis were observed. CRISP-1 was present at very low level in samples from donors after vasectomy. All seminal plasma samples from normospermic donors were CRISP-1 positive, whereas CRISP-1 was absent in two samples of azoospermic patients indicating the obstructive form of azoospermia.
Limitations, reason for caution: Only limited number of seminal plasma samples was used to produce these results. Therefore, a larger number of azoospermic semen samples is needed to make these results more reliable.
Wider implications of the findings: Previous findings indicate vasectomy has an effect on CRISP-1 expression. Moreover, the results have shown that the seminal plasma samples from normospermic and nonobstructive azoospermic donors are CRISP-1 positive, whereas CRISP-1 is absent or present at low levels in samples from patients with obstructive azoospermia. Therefore, the BioVendor Human CRISP-1 ELISA for the quantitative measurement of human CRISP-1 in seminal plasma could be used as a promising non-invasive method for the distinction between obstructive and nonobstructive azoospermia.
Study funding/competing interest(s): Funding by hospital/clinic(s) – funding by national/international organization(s) – Ministry of Health, Czech Republic – DRO (FNBr).
Trial registration number: FNBr, 65269705.

P-018 The relationship between body mass index and scrotal temperature

J. Jo[1], H. Kim[2], M. Kang[1], J. Lee[3]
[1]*Conmaul, Korean Gynecology, Seoul, South Korea*
[2]*Kyung Hee University, Department of Biofunctional Medicine & Diagnostics College of Korean Medicine, Seoul, South Korea*
[3]*Kyung Hee University, Department of Korean Gynecology College of Korean Medicine, Seoul, South Korea*

Study question: How closely does body mass index (BMI) correlate with scrotal temperature among male partners of subfertile couples?
Summary answer: BMI has a moderate and positive association with scrotal temperature.
What is known already: Scrotal temperature plays a role in spermatogenesis. Obesity may alter sperm parameters via testicular heat resulting from increased scrotal adiposity.
Study design, size, duration: A correlation study was performed using data collected from male partners of subfertile couples who had visited an infertility center between March 2013 and November 2014. Participants were classified into three groups according to their BMI (< 25.0, 25.0–29.9, and > 30 kg/m^2).
Participants/materials, setting, methods: Data of 471 (aged 25–56) subjects were included. Scrotal temperature index (STI) was mean left and right skin temperature difference (ΔT) between the thigh and testicle. Pearson's correlation coefficient between BMI and STI was calculated, and mean STI was compared using analysis of variance (ANOVA).
Main results and the role of chance: Among 471 men, 280 men being underweight and normal weight, 175 overweight and 16 obese. Pearson's correlation coefficient was 0.346, which indicated a moderate positive correlation between BMI and STI ($p < 0.001$). We then performed subgroup analysis using BMI. Mean STI and standard deviation (mean ± SD) of the underweight and normal, overweight, and obese groups were -1.50 ± 0.95, -1.08 ± 0.83, and -0.57 ± 0.93, respectively. ANOVA indicated significant differences of STI; the obese and overweight groups had higher STI than the underweight and normal groups ($p < 0.001$).

Limitations, reason for caution: This was an exploratory study, and results should be interpreted cautiously because of other possible confounding factors (i.e., sedentary lifestyle or daily activities) that affect scrotal temperature. Only 16 men were obese (3.4%), too few to draw general conclusions.
Wider implications of the findings: Increased BMI is associated with higher scrotal temperature. High scrotal temperatures could negatively affect the sperm parameters of obese patients. To discuss this causal relationship, further assessment of the role of weight loss or gain in scrotal temperature changes is warranted.
Study funding/competing interest(s): Funding by hospital/clinic(s) – None.
Trial registration number: NA.

P-019 Human papilloma virus and sperm DNA fragmentation

N. Grieco[1], G. D'Aniello[1], M. A. Di Filippo[1], T. Notari[1], S. Ronsini[1]
[1]San Luca Hospital, IVF Unit, Vallo Della Lucania Salerno, Italy

Study question: The aim of the present study was to analyse the effects of HPV infection on semen parameters, focusing our attention to DNA fragmentation.
Summary answer: Our results suggest that HPV infection is not responsible of an a impairment of sperm quality and of an a higher DNA fragmented index (DFI).
What is known already: Human papillomavirus (HPV) infection is a common sexually transmitted disease. It is related to anogenital warts and neoplasia. In males, HPV DNA has been found in external genitalia, in the urethra, in the ductus deferens, epididymis, testis and in the seminal fluids. Literature reports that the presence of HPV in a semen sample could modify spermatic parameters as volume, viscosity, pH, count, motility, and viability, but very few works links HPV infection to DNA fragmentation.
Study design, size, duration: From January to December 2014, at the Unit of Human Reproduction of the Hospital S. Luca, Vallo della Lucania (SA), 250 infertile couple were treated. 118 medical records were retrospectively analysed. Statistical analysis was performed using T Student test to compare sperm parameters between men affected and not with HPV infection.
Participants/materials, setting, methods: The patients underwent a conventional semen analysis.

Using the SCD test (Sperm Chromatin Dispersion test) we valuated the amount of DNA fragmented sperm expressed in DFI (DNA fragmented index).

To test the presence of HPV we used a highly sensitive nested polymerase chain reaction assay followed by HPV genotyping.
Main results and the role of chance: 21 (16, 15%) of the total semen samples were HPV-positive. Median value of sperm concentration was 42,19x106/ml and 46,75x106/ml in HPV-negative and HPV-positive groups, respectively (P = 0,62). HPV-non infected and HPV-infected semen samples had similar rapid progressive motility (medians 7,0% vs 7,1%; P = 0,88) and similar morphology (median 7,8% vs 6,3%; P = 0,23).

The amount of DNA fragmented sperm was similar into two groups (29,90 vs 30,6%; P = 0,69).
Limitations, reason for caution: None.
Wider implications of the findings: Seminal HPV infection was frequently associated with a lower quality, although other studies did not find any effect on sperm parameters. No studies focused attention on the relationship between HPV infection and DNA sperm fragmentation. Our results suggest that HPV infection is not responsible of an a impairment of sperm quality and an a higher DFI.
Study funding/competing interest(s): Funding by hospital/clinic(s) – San Luca Hospital Vallo della Lucania (SA).
Trial registration number: NA.
Keywords: sperm fragmentation, human papilloma virus, seminal parameters

P-020 The latest decade sperm quality evaluated and education in Taipei citizen

C. Chan[1], C. Lee[1]
[1]Taipei City Hospital, Dept. of Ob/Gyn, Taipei, Taiwan, R.O.C.

Study question: Since 2003, Department of Health, Taipei city administration has offered citizen married, prior to get pregnant, to receive sperm quality examination. Through further analysis and detailed data, we realize more health situation of our male citizens upon suitable ages for getting married in recent 10 years.
Summary answer: The more high-educated persons show higher-abnormal proportion.
What is known already: It's helpful to find problems with non-eugenics and infertility as soon as possible if men can take the sperm quality evaluated prior to get pregnant.
Study design, size, duration: From 2005/01 to 2014/12, there're more than 12,500 persons recruited for our study.
Participants/materials, setting, methods: The men have to abide sexual abstinence for 3–5 days, and then their semen were collected into the sterile specimen containers by masturbation. All semen samples were allowed to liquefy about 15–30 minutes at room temperature. After liquefaction, semen-sample analyses were displayed by the computer aided sperm analysis detector to evaluate sperm concentration and motility. Sperm morphology was identified by manual examination.
Main results and the role of chance: In our study, the average ejaculate quantity of is 4cc; the sperm number of per milliliter of ejaculate is 131 (10^6/ml); the sperm morphology is 50% and the sperm motility is 53%. The percentage of deficient sperm quality was increased in latest decade. The major abnormal state is low motility. The sperm motility was going down with each passing year from 2005.
Limitations, reason for caution: nil.
Wider implications of the findings: There're various factors to affect the sperm quality. It can be age, working under high temperature operating environment, toxic substances, environmental chemicals, and medication. We found the most abnormal conditions are low motility and less sperm concentration. The more high-educated persons show higher-abnormal proportion. Perhaps many high-educated persons are elder, long office hours, received more environmental chemical and medication, meanwhile lack of exercise in Taipei.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Taipei City Hospital.
Trial registration number: 103XDAA00095.
Keywords: sperm quality, education

P-021 Role of FSH level, testicular volume and histology in choosing the appropriate surgical technique of sperm retrieval for patients with non-obstructive azoospermia

E. Caroppo[1], E. M. Colpi[2], M. Castiglioni[2], G. Gazzano[3], L. Vaccalluzzo[2], G. D'Amato[4], G. M. Colpi[2]
[1]Asl Bari, U.O. Fisiopatologia Della Riproduzione Umana E P.M.A., Conversano (BA), Italy
[2]Ospedale San Paolo University of Milano, Andro-Urology and IVF Unit, Milano, Italy
[3]Ospedale San Paolo University of Milano, Pathology Department, Milano, Italy
[4]Asl Bari, U.O. Fisiopatologia Della Riproduzione Umana E P.M.A., Conversano (Ba), Italy

Study question: Are there clinical characteristics that may support the urologist in choosing the appropriate surgical technique for individual patients with non-obstructive azoospermia?
Summary answer: According to multivariate analysis, patients with FSH level higher than 12 mIU/ml, testicular volume lower than 7.1 ml and histology different from hypospermatogenesis were more likely to obtain a successful sperm retrieval (SSR) when microdissection testicular sperm extraction (microTESE) was chosen instead of the standard testicular sperm extraction (TESE) technique.
What is known already: FSH and inhibin B level combined with testicular volume seem predictive of SRR in patients undergoing TESE, but no clinical characteristic can predict the outcome of microTESE.
Study design, size, duration: Retrospective cohort study on 558 normoandrogenic infertile patients with non-obstructive azoospermia (NOA), evaluated from July 2002 through July 2009.
Participants/materials, setting, methods: 558 patients with NOA referred to a university hospital underwent TESE (n = 356) or microTESE (n = 202). Serum FSH level and testicular volume, assessed by ultrasound, were obtained from all patients. Testicular histology was performed on a fragment of subcapsular parenchyma by examining at least 100 different sections of tubuli seminiferi.

Main results and the role of chance: Patients in microTESE group had significantly higher FSH serum level compared to that of TESE group ($p < 0.01$), significantly higher incidence of histology of Sertoli cell-only syndrome (SCO) ($p < 0.0001$) and lower incidence of histology of hypospermatogenesis (HYPO) ($p < 0.05$), while testicular volume was comparable among groups. Sperm retrieval rate was also comparable among groups (44.4% in TESE group and 39.6% in microTESE group, $p = 0.27$). Neither FSH nor histology alone resulted predictive of SSR in either TESE or microTESE group. However, multivariate analysis showed that microTESE provided significantly higher sperm retrieval rate compared to TESE (35.6 vs. 22.3%, $p < 0.05$) in a subgroup of 162 patients with FSH level > 12 mIU/ml, testicular volume <7.1 ml and histology different from HYPO.

Limitations, reason for caution: The success of microTESE in terms of sperm retrieval was shown to increase with the number of the procedures performed, therefore it probably increased from the beginning to the end of the study period. Histology can be obtained only during surgery, therefore it may be useful only in patients with a previous testicular biopsy.

Wider implications of the findings: The pre-surgical combined evaluation of patients FSH serum level, testicular volume and histology could help in categorizing NOA patients spermatogenic pattern. According to our results, microTESE is indicated in those patients with a more severe impairment of spermatogenesis, as predicted by higher FSH level, lower testicular volume and histology suggestive for SCO or maturation arrest, while patients with less severe spermatogenesis impairment could be assigned to TESE, an easier and less invasive surgical procedure.

Study funding/competing interest(s): Funding by hospital/clinic(s) – None.
Trial registration number: NA.
Keywords: non-obstructive azoospermia, TESE, microTESE, FSH

P-022 Endometrial stromal cell-secreted factors improve sperm motility

I. Bochev[1], L. Veleva[1], A. Shterev[1]
[1]*SAGBAL "DR. SHTEREV" EOOD, IVF, Sofia, Bulgaria*

Study question: The aim of the study was to examine the influence of conditioned medium from *in vitro* cultured endometrial stromal cells (EnSCs) on sperm movement characteristics in cases with normozoospermia.

Summary answer: The incubation of spermatozoa from normozoospermic semen samples with EnSC conditioned medium significantly enhances the analyzed parameters: progressive motility; VCL (curvilinear velocity); VSL (straight line velocity); VAP (average path velocity) and hyperactivation. These results suggest that EnSC could facilitate the movement of sperm through the uterus by secreting motility-stimulating factors.

What is known already: Highly motile state of spermatozoa for extended durations is essential for their fertilizing capacity. Moreover, hyperactivation is necessary for the penetration through the cumulus oophorus and zona pellucida. Previous studies have reported an improvement in sperm motility parameters following co-culture with different cell types including Vero cells, skin fibroblasts, oviductal and endometrial cells. However, it remains unclear whether the beneficial effect is associated with cell-to-cell contacts or is due to the secretion of various factors.

Study design, size, duration: This 6-month prospective study includes semen samples from 10 normozoospermic donors (WHO, 2010). Semen samples were incubated with EnSC conditioned medium (1:1 mixture) for 4 h (37°C/5% CO_2). Control aliquots were incubated with DMEM/10% FCS. Sperm motility parameters (progressive motility; VCL; VSL; VAP; hyperactivation) were assessed using a CASA system.

Participants/materials, setting, methods: EnSCs were isolated from healthy donors and cultivated in DMEM/10% FCS. Conditioned medium was collected from a monolayer of EnSCs cultured for 48 h.

All sperm samples were prepared by DGC and divided into two aliquots. The first served as a control and the second was incubated with EnSC conditioned medium.

Main results and the role of chance: There was a significant improvement in the mean values of all motility parameters tested in the semen samples, treated with EnSC conditioned medium, compared to the controls (incubated with DMEM/10% FCS):

- progressive motility – 52,3 versus 41,5% (control), $p < 0.05$
- VCL – 62,3 μm/s versus 50,4 μm/s (control), $p < 0.05$
- VSL – 27,8 μm/s versus 22,9 μm/s (control), $p < 0.05$
- VAP – 34,5 μm/s versus 28,7 μm/s (control), $p < 0.05$
- hyperactivation – 22 versus 15,4% (control), $p < 0.05$

Limitations, reason for caution: These results should be verified on a larger number of samples (the study is in progress). Semen samples with pathological spermiogram parameters have to be included.

Wider implications of the findings: These findings may help to better understand the intimate mechanisms by which endometrium and its cellular components actively support the sperm during their passage to the site of fertilization.

In ART, the *in vitro* treatment with EnSC secreted motility-stimulating factors could have beneficial effects on sperm movement characteristics, especially in cases with pathological spermiogram parameters and, thus, could improve the fertilizing capacity of the semen.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Ob/Gyn Hospital "Dr. Shterev", Sofia, Bulgaria.
Trial registration number: NA.

Study question: Is the lipid profile of human sperm a prognostic tool of sperm quality?

Summary answer: Specific lipids that are differentially represented depending on the male age, sperm DNA fragmentation index and incidence of large nuclear vacuoles (LNV) sperm were detected. The MS fingerprinting may be a valuable, non-invasive tool for the prediction of semen sample quality.

What is known already: Semen analysis is the best tool available to assess male fertility; nonetheless, many infertility cases remain undiagnosed. Lipids are basic semen components that are involved in energy metabolism and in the events that lead to fertilization. In general, sperm fatty acids are suggested as markers of fertility disorders in men. Lipidomics is an emerging field of biomedical research. Not much is known about the association between sperm lipid profile and other assays for sperm quality.

Study design, size, duration: This prospective study enrolled 27 male patients seeking for reproductive treatment. Semen samples were analysed by motile sperm organelle morphology examination (MSOME), DNA fragmentation test and lipid profile. Samples were divided in quartiles according to patient's age, DNA fragmentation index and incidence of sperm with LNV.

Participants/materials, setting, methods: Mass spectra fingerprinting were acquired using a 7.2T LTQ FT Ultra-MS. Data were analysed using the Partial Least Square Discrimination Analysis (PLS-DA) combined with variable influence on projection (VIP) scores. The lipid profiles were compared between the different groups of male age, MSOME and sperm DNA fragmentation results.

Main results and the role of chance: Regarding male age, the model detected an increase of 4 lipids in the 1st quartile group (range: 28–32 years), 6 lipids in the 2nd quartile group (range: 33–36 years), 4 lipids in the 3rd quartile group (range: 37–42 years) and 1 lipid in the 4th quartile group (range: 43–54 years), with an accuracy of 60.0%. Regarding DNA fragmentation index, the model detected an increase of 5 lipids in the 1st quartile group (range: 7.7–12.5%) and 10 lipids in the 4th quartile group (range: 18.5–31.5%), with an accuracy of 84.6%. Regarding the incidence of LNV sperm, the model detected a significant increase of 10 lipids in the 1st quartile group (range: 2–6%) and 5 in the 4th quartile group (range: 22–42%), with an accuracy of 85.0%.

Limitations, reason for caution: The main limitation of this study is the low number of patients included.

Wider implications of the findings: The understandings that are provided by lipidomics studies of disrupted systems are expanding at a rapid rate. Several lipidomics publications in diverse fields of medicine are demonstrating the ability of these platforms to identify clinical biomarkers. While in its infancy, lipidome of human sperm may provide detailed insights into how lipid composition and metabolism affects sperm physiology and fertilization, and expand the scope of potential male infertility markers.

P-024 Comparison of pregnancy rates with intrauterine insemination with different abnormal semen parameters and all combinations of those parameters by the 2010 World Health Organization guidelines

A. Kuriya[1], C. Agbo[2], M. H. Dahan[3]
[1]*McGill University Health Center, Obstetrics and Gynecology, Montreal QC, Canada*
[2]*Stanford University, Medicine, California, U.S.A.*
[3]*McGill University Health Center, Reproductive Endocrinology and Infertility, Montreal QC, Canada*

Study question: To evaluate the effect on pregnancy rates in relation to one or more abnormal semen analysis parameters based on the 2010 World Health Organization (WHO) semen analysis guidelines.
Summary answer: Only low total sperm was a significant predictor for pregnancy when not controlling for other effects ($p = 0.04$). When controlling for confounding effects, only low total sperm count, low motility and low volume predicted pregnancy ($p = 0.049$). The parameters composing total motile sperm count failed to predict pregnancy ($p = 0.33$).
What is known already: Semen analyses consist of parameters including: volume, sperm concentration, progressive motility, and morphology. In prior studies total motile sperm count has consistently been shown to be a predictor of pregnancy. However, a pubmed search failed to detect any studies which classified semen analysis at the time of insemination in the presence of normal or abnormal parameters by the 2010 WHO semen analysis guidelines, and a combination of those parameters while investigating effects on pregnancy.
Study design, size, duration: A retrospective analysis was performed on 2.5 years of data collected at Stanford University. A total of 981 couples underwent 2231 IUI cycles. Couples had at least one year of either primary or secondary infertility with their current partner. Patients were treated with clomiphene citrate, letrozole or gonadotropin IUI.
Participants/materials, setting, methods: Data was classified as normal or abnormal by the 2010 parameters. Parameters analyzed included volume (1.5 ml), concentration (15mil/ml), minimum total count (39mil), forward motility (32%). Subjects with morphology <4% were treated with ICSI and were unavailable for analysis. All statistical analyses were performed using chi squared analysis. Data is presented as means ± SD.
Main results and the role of chance: Pregnancy rates were 13–25%. When comparing either normal or abnormal volume (3.2 ± 1.5 ml vs. 0.91 ± 0.25 ml, $p = 0.28$), concentration (59 ± 42 vs. 9.8 ± 3.5 mil/ml, $p = 0.11$), forward motility (58 ± 15 vs. 19 ± 8%, $p = 0.11$) or total sperm count (177 ± 142 vs. 24 ± 10mil, $p = 0.04$), only forward motility had a different likelihood of pregnancy. Mean parameters differed in each of the above groups ($p < 0.0001$, in all cases). To control for effects of the other parameters groups were subdivided in to all possible combinations for normal of abnormal volume, concentration, total sperm count, and forward motility. Statistically similar pregnancy rates were found in all cases except, abnormal total count (3.0 ± 2.3mil), volume (0.8 ± 0.3 ml) and motility (17 ± 8%), ($p = 0.049$). The combination of parameters making up total motile sperm count (volume 0.8 ± 0.2 ml, concentration 8.6 ± 3.2mil, motility 17.8 ± 8.7%, $p = 0.33$) failed to predict pregnancy.
Limitations, reason for caution: This is a retrospective study. Since Kruger-Tyberg strict morphology was unavailable, its role in pregnancy rates cannot be determined.
Wider implications of the findings: A reorganization of the semen analysis report should be done emphasizing total amount of sperm present and de-emphasizing concentration of sperm, possibly even removing it from reported results. However, even with abnormal semen analysis results likelihood of pregnancy remained excellent, at least 13% per cycle, in this study.
Study funding/competing interest(s): Funding by University(ies) – funding by national/international organization(s) – NIH grant 5K12HD01249 and the Stanford University Medical Scholars Program.

P-025 Establishing a threshold level for sperm DNA quality in the semen of donors versus patients using the sperm chromatin dispersion test

J. Gosálvez[1], C. Lopéz-Fernández[1], S. D. Johnston[2], C. Garcí-Ochoa[3], M. Ruíz-Jorro[4], M. Martínez-Moya[5], P. Sánchez-Martín[6], F. Sánchez-Martín[6], R. Nuñéz-Calonge[7], P. Caballero[7]
[1]*University Autonomous of Madrid, Biology, Madrid, Spain*
[2]*University of Queensland, School of Agriculture and Food Science, Gatton, Australia*
[3]*CEFIVA, Andrology, Oviedo, Spain*
[4]*CREA, Andrology, Valencia, Spain*
[5]*Centro Guntenberg, Andrology, Malaga, Spain*
[6]*GINEMED, Andrology, Sevilla, Spain*
[7]*TAMBRE, Andrology, Madrid, Spain*

Study question: In an attempt to establish a threshold level of sperm DNA fragmentation (SDF), baseline levels of SDF and sperm DNA longevity (SDL) were compared between patients undergoing their first seminogram at an IVF clinic and a control donor population.
Summary answer: Control donor sperm exhibited baseline SDF values 2.2x lower and SDL levels 2.8x higher than that observed in patients undergoing their first seminogram.
What is known already: SDF is a controversial parameter gaining acceptance as a potential predictor of fertility. While SDF values of 30 to 40% are typically considered as being predictive of poor fertility, some patients with high levels of SDF are still capable of obtaining a successful pregnancy, particularly when ICSI is used. The level of SDF in sperm donors is generally considered to be lower than in patients undergoing their first seminogram, but this assumption has not been analyzed in detail.
Study design, size, duration: Multicentre, independent, blind study that used two main criteria for cohort configuration: (1) First seminogram of patients attending a clinic for assisted reproduction and (2) Individuals selected as semen donors. Cryopreserved sperm samples were used to assess DNA damage in both cases.
Participants/materials, setting, methods: Multicentre study of 5 independent IVF centers and two Universities. Materials: 110 sperm donors and 875 patients. SDF was evaluated at T0 (baseline) and following incubation for 24 h at 37ºC, with sub-sampling performed after 2, 6 and 24 h incubation. SDF was assessed using the sperm chromatin dispersion test (SCDt).
Main results and the role of chance: Donor sperm exhibited baseline SDF values 2.2 times lower than patients undergoing their first seminogram; DNA stability of the donor sperm was 2.8 times higher than that observed in patients when the sample is tested after 2 h of sperm incubation at 37ºC. The results of this investigation revealed that a baseline SDF value of 8% would be regarded as a threshold level to produce discrimination between both groups with a sensitivity of 65% and specificity of 82%. Similarly, a DNA quality loss of approximately 1.9% per h, would be regarded as a threshold level to produce discrimination between both groups with sensitivity of a 77% and a specificity of 65%. Baseline SDF and SDL levels behaved as independent variables.
Limitations, reason for caution: With respect to the proposed threshold baseline SDF level of 8 and 1.9% per h of DNA quality loss documented in the present study, 20% of patient population would be regarded as possessing donor quality sperm.
Wider implications of the findings: Proposed threshold values for SDF and SDL can be used for the identification of high quality sperm donors.
Study funding/competing interest(s): Funding by University(ies) – Funding by hospital/clinic(s) – University Autónoma of Madrid, 20849 Madrid, Spain. University of Queensland, Australia. CEFIVA, clinic. CREA, clinic, Centro Gutenberg, clinic. GINEMED, clinic. TAMBRE, clinic.
Trial registration number: This investigation is a part of the experimental protocols included in the research project BFU-2013-44290-R, as approved by the University in accordance with the participating IVF clinics.

P-026 Was there a decline in sperm quality in the last 20 years in Portugal? A retrospective study

A. P. Sousa[1], C. Soares[2], T. Almeida Santos[2]
[1]*Center For Neuroscience and Cell Biology, University of Coimbra, Coimbra, Portugal*
[2]*Reproductive Medicine Service, Coimbra Hospital and University Center, Coimbra, Portugal*

Study question: The aim of this study was to evaluate if, similarly to the observed in many European countries, there was a decline in sperm quality in Portugal since the last 20 years (1994–2013).
Summary answer: In fact, in the last 20 years, there was a decrease in sperm quality, namely volume of the ejaculate, sperm concentration and quantity, and sperm morphology. On the opposite, sperm motility seems to have increased.
What is known already: In the last decades, a decrease in fertility along with a decrease in birth rate have been observed in the Portuguese population. However, it is not totally known which factors are responsible for that decreases, once social and economic factors only explain part of it. In several European countries, a decrease in sperm quality has been observed, where environmental pollutants seems to be the cause. In Portugal, the hypothetic change in sperm quality was never monitored.
Study design, size, duration: Cross sectional. 3146 sperm quality analysis from five time points of the last 20 years: (1st time point: years 1994/1995/1996, $n = 698$; 2nd time point: years 1999/2000, $n = 484$; 3rd time point: year 2005, $n = 698$; 4th time point: year 2009, $n = 640$; 5th time point: year 2013, $n = 626$) were retrospectively analysed and compared.
Participants/materials, setting, methods: Sperm quality analyses in five time points (years 1994/1995/1996; 1999/2000; 2005; 2009; 2013) were retrospectively analysed. Parameters like patient age; color, aspect, pH and volume of the ejaculate; presence of leukocytes and sperm agglutinates; sperm concentration and quantity, motility and morphology were recorded. Time point groups were compared.
Main results and the role of chance: When time point groups were compared, a decrease in volume was observed. In 1994/1995/1996 there was a higher volume (3.58 ml) than in the others: 1999/2000 (3.3 ml, $p = 0.056$), 2005 (3.29 ml, $p = 0.006$), 2009 (3.27 ml, $p = 0.004$), 2013 (3.3 ml, $p = 0.01$). Similarly, a decrease in sperm concentration/quantity was observed: 1994/1995/1996 presents higher concentration/quantity (81.97×10^6/ml and 279.35×10^6, respectively) than the others: 1999/2000 (54.5×10^6/ml and 175.03×10^6, respectively, $p < 0.001$), 2005 (43.7×10^6/ml and 147.45×10^6, respectively, $p < 0.001$), 2009 (51.55×10^6/ml and 168.79×10^6, respectively, $p < 0.001$), 2013 (68.68×10^6/ml and 194.77×10^6, respectively, $p < 0.001$). The percentage of patients presenting normal sperm morphology values also decreased ($p < 0.001$). Contrarily, sperm motility seems to have increased: 1994/95/96 (48.13%), 1999/2000 (52.01%, $p = 0.069$), 2005 (58.78%, $p < 0.001$), 2009 (56.85%, $p < 0.001$), 2013 (64.18%, $p < 0.001$). No differences were observed for the other parameters analysed.
Limitations, reason for caution: Criteria for some sperm parameters have changed in the last 20 years, especially sperm morphology. Taking this limitation into account, sperm morphology values were considered as normal or abnormal regarding to the reference value used in each time point.
Wider implications of the findings: As in other European countries, the sperm quality of the Portuguese population seems to have decreased in the last 20 years. For the volume of the ejaculate and the sperm morphology, these decreases occurred after the year 2000, however for sperm concentration/quantity this was already visible after 1996. Surprisingly, sperm motility seems to have increased. Larger studies should be conducted in order to validate these findings and identify the causes for these changes.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Coimbra hospital and university center. Nothing to declare in terms of competing interest.

P-027 The impact of sperm nuclear chromatin condensation and ploidy status on the outcome of assisted reproduction techniques

E. Hatzi[1], L. Lazaros[1], C. Kitsou[2], P. Ladias[2], P. Sakaloglou[2], K. Zikopoulos[1], T. Stefos[1], I. Kosmas[3], G. Vartholomatos[4], I. Georgiou[1]
[1]*Ioannina University Medical School, Department of Obstetrics and Gynecology Genetics and IVF Unit, Ioannina, Greece*
[2]*Ioannina University Medical School, Laboratory of Medical Genetics and Human Reproduction, Ioannina, Greece*
[3]*'Hatzikosta' Hospital, Department of Obstetrics and Gynecology, Ioannina, Greece*
[4]*Ioannina University Hospital, Laboratory of Hematology Molecular Biology Unit, Ioannina, Greece*

Study question: Do sperm nuclear chromatin condensation and ploidy status affect *in vitro* fertilization (IVF) / intracytoplasmic sperm injection (ICSI) outcome?
Summary answer: Sperm nuclear chromatin condensation and ploidy status were significantly associated with the fertilization rate, the embryo quality and the pregnancy rate of IVF/ICSI cycles. Consequently, sperm chromatin condensation and ploidy are critical parameters for the evaluation of semen samples before IVF or ICSI application.
What is known already: WHO parameters such as sperm concentration, motility and morphology are mainly taken into account in assisted reproduction. However, high percentages of IVF/ICSI cycles remain unsuccessful, suggesting the need of additional parameters, such as sperm nuclear chromatin condensation and ploidy, to estimate sperm contribution in assisted reproduction technique failures.
Study design, size, duration: Two hundred couples undergoing IVF cycles as well as 30 couples with male factor infertility and low sperm flow cytometry (SFC) parameters and 60 couples with male factor infertility and relatively high SFC parameters undergoing repetitive ICSI cycles in a period of four years constituted the study population.
Participants/materials, setting, methods: Conventional semen analysis and SFC analysis after Acridine Orange and Propidium Iodide staining, for the respective evaluation of sperm nuclear chromatin condensation and ploidy, were performed in the 290 men. The fertilization rate, the embryo quality and the pregnancy rate per cycle were the IVF/ICSI outcome measures.
Main results and the role of chance: In the IVF group, couples with lower euploidy rates and lower percentages of spermatozoa with fully condensed chromatin, presented with decreased fertilization rates ($p < 0.006$), diminished grade A embryo rates ($p < 0.004$) and decreased pregnancy rates ($p = 0.007$), compared to couples with higher SFC parameters. As concerns the ICSI group, the 65 ICSI cycles of the 30 couples with low SFC parameters were characterized by lower fertilization rates ($p < 0.004$), decreased grade A embryo rates ($p < 0.003$) and increased grade C embryo rates ($p < 0.01$), compared to the 86 cycles of the 60 couples with relatively high SFC parameters. Significantly elevated arrested embryos rates ($p < 0.001$) and decreased clinical pregnancy rates ($p = 0.019$) were observed in couples with severe SFC parameters undergoing ICSI. The above associations were independent from the conventional semen parameters.
Limitations, reason for caution: Larger population and multicenter studies are needed to verify our preliminary results.
Wider implications of the findings: SFC analysis may help in the discrimination of semen samples with elevated pregnancy potential post-IVF from those in need of ICSI application as well as in the identification of semen samples with reduced pregnancy likelihood post-ICSI, in which the use of testicular spermatozoa is potentially preferable. The combination of SFC with sperm selection methods could help in the fractionation and isolation of spermatozoa with normal genetic constitution and complete nuclear chromatin condensation from defective semen samples.
Study funding/competing interest(s): Funding by national/international organization(s). This study has been co-financed by the European Union (European Regional Development Fund- ERDF) and Greek national funds through the Operational Program "THESSALY- MAINLAND GREECE AND EPIRUS-2007-2013" of the National Strategic Reference Framework (NSRF 2007-2013).

P-028 Seminal transforming growth factor ß1, insulin-like growth factor I and epidermal growth factor status in male idiopathic infertility

S. Jellad[1], O. Kacem[1], A. Sallem[1], H. Ben Mustapha[1], I. Zidi[1], F. Hachani[1], A. Khelifi[2], A. Saad[3], M. Ajina[1]
[1]*Farhat Hached University Hospital, Unit of Reproductive Medicine, Sousse, Tunisia*
[2]*Farhat Hached University Hospital, Department of Gynecology, Sousse, Tunisia*
[3]*Farhat Hached University Hospital, Laboratory of Cytogenetic and Human Reproductive Biology, Sousse, Tunisia*

Study question: This study aims' at investigating the relationship between seminal plasma growths factors (TGF β1, IGF I and EGF) and semen parameters, sperm DNA fragmentation, and ART outcome among idiopathic infertile men and normal men.
Summary answer: The increase of Seminal TGFβ1 levels was significantly associated with low semen characteristics such as total sperm count, progressive motility and normal morphology, and with high rate of sperm DNA fragmentation in idiopathic infertile men. Nevertheless, we didn't found any correlation between growth factors and IVF or ICSI outcomes.
What is known already: It is becoming apparent that seminal growth factors have a definite role in fertility and their modulation can cause infertility in both men and women. These factors have also been shown to have both positive and negative effects on the function of spermatozoa in vitro. Therefore, their exploration may provide useful information in cases of male idiopathic infertility.
Study design, size, duration: A prospective study conducted during one year that included 104 couples undergoing ART cycles (IVF or ICSI). Two groups were identified according to semen analysis and infertility related factor. A first group ($n = 67$) with only male infertility factor (idiopathic OAT) and a control group ($n = 37$) with normal semen parameters.
Participants/materials, setting, methods: A part of each sample was prepared using a discontinuous sperm gradient after parameters analyze, for oocyte insemination or injection and the remaining pellet was fixed for subsequent measure of DNA fragmentation index (TUNEL assay).Subsequently, seminal plasma growth factors concentrations were measured by ELISA using commercially available kits.
Main results and the role of chance: The mean concentration of seminal plasma T**GF** β1 was significantly higher in OAT group 234.68 ± 41.32 vs. 97.25 ± 36.85 ng/ml in controls ($p = 0.001$). T**GF** β1 levels were correlated negatively with sperm total count, motility ($r = -0.437$, $p = 0.000$; $r = -0.556$, $p = 0.000$) but positively with teratozoospermia ($r = 0.705$; $p = 0.000$). No evident correlation was found between these growth factors and ART outcomes such as fertilization, cleavage, top embryos and pregnancy rates. Idiopathic infertile men showed a high degree of DNA damage20.21% as compared to controls 12.96% ($p = 0.02$). A strong significant negative correlation was found between DNA fragmentation and all semen parameters ($p < 0.01$). Moreover, a significant positive correlation was noted between seminal TGF β1 and sperm DNA fragmentation levels ($r = 0.350$, $p = 0.01$) but not with IVF or ICSI outcomes.
Limitations, reason for caution: EGF tented to be higher in OAT group but the difference was not significant. EGF levels were lower among patients with clinical pregnancy compared to those with ART failure but IGFI levels were higher in controls and in cases of pregnancy. This may due to our small sample size.
Wider implications of the findings: Seminal TGFβ1 may have a direct or indirect role in spermatogenesis-steroidogenesis and its derangement may be involved in male idiopathic infertility especially when mediated through low semen characteristics and high DFI which can be explained by reactive oxygen species (ROS) generated with excessive seminal TGFβ1 that leads to DNA disintegration and therefore to increase sperm DNA damage. However, the exact molecular mechanism of seminal TGF β1on spermatic cells inducing ROS production requires further investigation.
Study funding/competing interest(s): Funding by hospital/clinic(s) – University Farhat Hachad Hospital-unit of reproductive medicine.
Trial registration number: NA.
Keywords: growth factors, semen parameters, DNA fragmentation, ART outcome

P-029 Efficacy of follicle-stimulating hormone treatment in male idiopathic infertility: a meta-analysis

D. Santi[1], A. R. M. Granata[1], M. Simoni[1]
[1]*Unit of Endocrinology, Department of Biomedical Metabolic and Neural Sciences University of Modena and Reggio Emilia Italy, Modena, Italy*

Study question: To comprehensively evaluate whether follicle stimulating hormone (FSH) administration to the male partner of idiopathic infertile couples improves pregnancy rate, both spontaneous and after assisted reproductive technique (ART), using a meta-analytic approach and including controlled clinical trial.
Summary answer: The administration of FSH to infertile men is reported in the literature since 1991, improving fertilisation and pregnancy rate. A significant increase in pregnancy rate after ART and male treatment with FSH was already shown in several studies, since FSH improves the sperm quality. FSH treatment could improve sperm quality and pregnancy rate in idiopathic infertile men.
What is known already: The Cochrane Collaboration recently estimated the overall effect of FSH treatment of the man in couples attending ART, enrolled in randomised, controlled, clinical-trials. That meta-analysis demonstrated that FSH treatment significantly improves spontaneous pregnancy rate, whereas no improvement of pregnancy rate was observed after ART, using fixed and strict inclusion criteria. They excluded all trials in which the randomization was not provided leading to potential loss of useful information that could help clinicians in their routinely practice.
Study design, size, duration: We conducted a comprehensive literature search for controlled clinical trials in which FSH was administered for male idiopathic infertility, compared with placebo or no treatment. The randomization was not considered as inclusion criterion. We considered studies in which men with idiopathic infertility or subfertility were enrolled, chronicallty treated with any type of FSH, compared with placebo or no treatment.
Participants/materials, setting, methods: We found 15 controlled clinical studies. Concerning the type of FSH, eight studies included in the meta-analysis used recombinant FSH, whereas seven studies used purified FSH. Pregnancy rate, when evaluated, was considered spontaneous or after ART. Selected trials gave details about 1275 infertile-men, 614 treated with FSH and 661 not-treated.
Main results and the role of chance: Among the 15 studies included, nine studies evaluated the spontaneous pregnancy rate, resulting in an overall improvement of about 4.5 (CI 2.17–9.33 and $I^2 = 0\%$) ($p < 0.001$). Eight studies evaluated pregnancy rate after ART, showing a significant improvement of about 1.60 (CI 1.08–2.37 and $I^2 = 43\%$) ($p = 0.002$). Sub-dividing studies according to the FSH preparations (purified or recombinant), the pregnancy rate improvement remained significant ($p = 0.007$ and $p = 0.002$, respectively). Eleven studies considered sperm quality after FSH treatment, finding a significant improvement of sperm concentration (mean improvement of $2.66x10^6$ millions/mL, with CI 0.47–4.84, $p = 0.02$), but not of sperm motility (mean improvement of $1.22x10^6$ millions/mL, with CI -0.07–2.52, $p = 0.06$). Finally, three trials evaluated testicular volume, showing a non-significant increase in men treated (mean increase of 1.35 mL, with CI -0.44–3.14, $p = 0,14$).
Limitations, reason for caution: The heterogeneity of studies, together with the high risk of biases in this field of research could limit the strength of these results.
Wider implications of the findings: The results of controlled clinical trials available in literature indicate an improvement of pregnancy rate after FSH administration to the male partner of infertile couples, both spontaneous and after ART.
Study funding/competing interest(s): Funding by University(ies) – University of Modena and Reggio Emilia.
Trial registration number: NA.
Keywords: FSH, idiopathic male infertility, reproduction

P-030 Are obese men subfertile?

S. Alshahrani[1], A. Gabr[1], A. Ahmed[1]
[1]*Salman Bin Abdulaziz University, Surgery, Riaydh, Saudi Arabia*

Study question: Does obesity affects male fertility potentials?
Summary answer: BMI was proved, in our study, to have a significant effect on sperm concentration.
What is known already: Overweight and obesity can affect female fertility, in men the negative effects on reproductive system attributed to obesity are less evident and have been less often studied.
Study design, size, duration: Prospective, 439 male partners of couples presenting for evaluation of infertility, in the period from January 2013 to November 2014.
Participants/materials, setting, methods: Semen samples from 439 male partners of couples presenting for evaluation of their infertility, were collected. Men were divided into three BMI groups; normal, overweight and obese. Samples has been analyzed based on the WHO 5th edition guidelines. Meticulous scrotal examination and scrotal ultrasound were performed. Hormonal profile, including testosterone, FSH, LH and prolactin was done to exclude any possible causative hormonal factor.
Main results and the role of chance: Mean BMI was 29.67 ± 5.89. ANOVA testing revealed no significant differences in semen parameters between the 3 different BMI groups. Also, pair-wise multiple comparisons were found to be

non-significant ($P > 0.05$). The distribution of patients with normal sperm concentration per BMI group was as follows: normal weight, 46/75 (61.33%); overweight, 114/179 (63.69%); and obese, 116/185 (62.70%). BMI had a negative correlation with semen volume, sperm concentration, sperm motility and sperm morphology. However, this correlation reached a significant level only between BMI and sperm concentration ($r = 0.101$; $p = 0.035$).
Limitations, reason for caution: One semen analysis was performed in some cases.
Wider implications of the findings: Weight reduction may help to improve the semen quality.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Salman bin Abdulaziz University Hospital.
Trial registration number: IRB: SAU-2014-U-8-30PI.

P-031 The effects of indirect cigarette smoke inhalation and the antioxidant effects of curcumin on the morphology of spermatozoa and Leydig cells of the adolescent rats

A. Gumusel[1], F. Alkan[1], O. D. Demirkiran[1], E. Tokay[1], E. E. Guzel[1], O. Arda[2]
[1]*Istanbul University Cerrahpasa Faculty of Medicine, Histology and Embryology, Istanbul, Turkey*
[2]*Istanbul Kemerburgaz University Faculty of Medicine, Histology and Embryology, Istanbul, Turkey*

Study question: What are the combined morphological and functional effects of; indirect cigarette smoke inhalation that causes oxidative stress and curcumin on spermatozoa recovered from epididymis and the Leydig cells of the adolescent rats?
Summary answer: Cigarette smoke has adverse effects on spermatogenesis, and Leydig cell's morphology by provoking cellular stress. Curcumin plays an important role in suppressing the negative effects of cigarette smoke by inhibiting the cellular oxidative stress.
What is known already: Scientific research points out that toxic substances in cigarette smoke damage DNA of spermatozoa, Leydig cells and Sertoli cells. This affects the male fertility negatively. Curcumin has a wide range of pharmacological and biological activities. Numerous studies proved its antioxidant action and significant protective effect on the testes tissue.
Study design, size, duration: Two months old 32 male Wistar albino rats weighing 150–200 g divided equally into four groups of; control, cigarette smoked (CS), curcumin and CS + curcumin. Rats exposed to CS for 2 h per day for 28 days. DMSO and curcumin dissolved in DMSO; administrated to control and experiment groups respectively by gavage.
Participants/materials, setting, methods: Fluid samples obtained from tail of epididymis evaluated in Makler chamber to count spermatozoa and smears prepared to examine the morphology of spermatozoa. Testis specimens prepared with appropriate methods for light and electron microscopy. Statistic results of the cell counts, sperm morphology, and body weights analyzed by one-way ANOVA.
Main results and the role of chance: Light and electron microscopical examinations showed that cigarette smoke (CS) have adverse effects on spermatogenesis. The spermatozoa count reduced associated with increased number of abnormally formed spermatozoa. Invaginations and enfoldings of nuclear envelope, dilated SER, mitochondrial injury with reduced amount of crista, diminished lipid droplets, groups of SER, lipid droplets and mitochondria located in the periphery of cell, and multiple pinocytotic vesicles were the ultrastructural changes of Leydig cells. However, the antioxidant effects of curcumin; increased the number of spermatozoa and reduced the amount of abnormal ones. Ultrastructural morphology of the Leydig cells was similar in CS and CS + curcumin groups. Thus, curcumin plays an important role in decreasing the negative effects of cigarette smoke on sperm counts and abnormalities.
Limitations, reason for caution: In previous studies, the negative effects of oxidative stress on Leydig cells meliorated by antioxidant properties of curcumin, but in our study only sperm count and morphology improved while Leydig cell morphology showed similarities with the ones in cigarette smoke group.
Wider implications of the findings: Smoking causes most prominent social and health problems, specifically in young population of all countries. Evaluation of the cigarette smoke on the urogenital system is considerably important. Curcumin acts as an effective compound playing a significant role in suppressing negative effects of cigarette smoke on testis tissue due to its anti-oxidative property.
Study funding/competing interest(s): Funding by University(ies) – Research Fund of Istanbul University.
Trial registration number: Project No. 22934.

P-032 The superiority of swim down technique compared to density gradient technique in preparing semen samples before intracytoplasmic sperm injection (ICSI): a prospective randomized clinical trial

A. Metwalley[1], M. Fawzy[2], A. Ahmed[1], S. Jaya[1], B. Ghaith[1], M. Sabry[2], A. Barakat[1]
[1]*Al Baraka Fertility Hospital, IVF, Manama, Bahrain*
[2]*IbnSina IVF Center IbnSina Hospital, IVF, Sohag, Egypt*

Study question: Does swim down sperm preparation technique increase the blastulation rate and the ongoing pregnancy rate compared to density gradient sperm preparation technique in ICSI cycles?
Summary answer: There was a statistical significant increase in the blastulation rate (71%) ($P < 0.0001$) and the ongoing pregnancy rate (64%) ($P < 0.0001$) when using swim down sperm preparation technique before ICSI.
What is known already: Density gradient centrifugation while considered as a conventional technique for ICSI sperm preparation, recommended by the WHO laboratory manual 2010; it is not efficient enough to produce sperm populations free of DNA damage, because the technique are not physiological and not modeled on the sperm selection processes occurring at the female genital tract (Henkel 2012). Migration based protocols including the swim down, based upon the migration of the motile sperms down the discontinuous gradient.
Study design, size, duration: A prospective randomized multi-centric clinical trial of 890 couples enrolled into the study after singing the informed consent and after approved from ethical committees of the participating centers at the period from February 2013 to December 2014.
Participants/materials, setting, methods: Semen samples of 890 couples in two ICSI centers (Al Baraka Fertility Hospital, Manama Bahrain) and (Ibn Sina IVF Center- Ibn Sina Hospital, Sohag Egypt) were allocated randomly into two groups; group I prepared using direct swim down over a 100% silica containing media (ALL Grad® 100', Life Global®) and group II prepared using the conventional density gradient technique.
Main results and the role of chance: There were no statistical significant differences between both studied groups as regard mean age, body mass index, dose of FSH/HMG used, number of neither oocytes collected nor number of stimulation days. The blastulation rate in-group I show statistically significant increase (71%) compared to (53%) in-group II ($P < 0.0001$). We could also document a statistically significant difference increase in the pregnancy rate in-group I (64%) compared to (54%) in-group II ($P < 0.0001$).
Limitations, reason for caution: We excluded moderate to severe oligozoospermia cases, since the yielded sperm count is lesser in swim-down compared to the density-gradient technique. The inappropriate use of swim down-100% technique with non-progressive motility sperm due to very poor outcome. We did not study the effect of sperm exposure to Silica solution 100% solution for lengthy periods.
Wider implications of the findings: Utilizing sperm natural motility for sperm preparation can be applied at any ICSI units. Avoiding multiple centrifugation steps using swim down-100% considering the sperm natural powers for separation can reflect a semi natural sperm preparation for ICSI. Application for virally infected semen can also be evaluated.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Al Baraka fertility Hospital – Ibn Sina IVF Center- Ibn Sina Hospital.
Trial registration number: NCT02328534.
Keywords: Swim down semen preparation density gradient, swim-down, semen preparation, density gradient, silica solution

P-033 Is there any role of medical treatment or varicocele repair in infertile men who failed initial testicular sperm extraction?

S. Çayan[1], M. T. Çetin[2], A. Tok[3]
[1]*University of Mersin School of Medicine, Department of Urology Andrology Section, Mersin, Turkey*
[2]*Çukurova University School of Medicine, Department of Obstetrics and Gynecology, Adana, Turkey*
[3]*Private IVF Center, Department of Reproductive Endocrinology, Adana, Turkey*

Study question: Is there any role of medical treatment or varicocele repair in infertile men who failed initial testicular sperm extraction (TESE)?
Summary answer: The aim of this study was to investigate whether there is any role of medical treatment or varicocele repair in azoospermic men who had previous negative TESE procedure.
What is known already: Empirical medical therapy and varicocele repair have been controversial in infertile men with non-obstructive azoospermia. In addition, no evidence based medical treatment has been reported to induce spermatogenesis in men who failed initial TESE procedure.
Study design, size, duration: During a 4 years period, the study included 181 azoospermic men, who failed TESE procedure, who then underwent repeat micro-TESE procedure. All patients were evaluated and treated by a single clinician.
Participants/materials, setting, methods: The patients were divided into 6 groups according to treatment type. Of the patients, 76 had clinical palpable varicocele on either one or both sides, and 105 had no varicocele. Of the 76 patients with varicocele, 58 had microsurgical subinguinal varicocele repair (Vx): 42 had additional medical treatment (recombinant HCG, anastrozole, or clomiphene citrate), and 16 were followed without additional medical therapy. Eight patients received medical therapy with no Vx treatment, and 10 were only followed with no medical and Vx treatment. Of the 105 men with no clinical varicocele, 90 received medical therapy, and 15 were followed with no treatment. Sperm retrieval rates on micro-TESE were compared according to the treatment groups.
Main results and the role of chance: The mean age was 33.44 ± 6.82 years (21–51), and mean treatment duration prior to re-do micro-TESE was 10.4 ± 3.42 months (6–24). Testicular sperm retrieval rates were 30.9% (13/42) in the men with varicocele who had Vx repair + medical treatment, 12.5% (1/8) in the men with varicocele who had no Vx treatment, but medical treatment, 18.7% (3/16) in the men with varicocele who had only Vx treatment with no medical treatment, 0% (0/10) in the men with varicocele who were followed with no Vx treatment or medical treatment, 18.8% (17/90) in the men with no varicocele who had only medical treatment, and 6.7% (1/15) in the men with no varicocele who were followed only with no medical treatment.
Limitations, reason for caution: None.
Wider implications of the findings: Benefit of pre-medical treatment prior to micro-TESE is limited in selected cases. Men with varicocele who failed initial TESE had higher sperm retrieval rate with varicocele repair than men having no varicocele repair. The highest sperm retrieval rate was achieved with varicocele repair plus medical treatment with recombinant HCG.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Private IVF center.
Trial registration number: NA.

P-034 The cytotoxic effects of membrane lipid peroxidation products on human spermatozoa

A. M. Polhemus[1], R. J. Moazamian[1], P. Gharagozloo[1], R. J. Aitken[2]
[1]CellOxess LLC, Medicinal Chemistry, Princeton, U.S.A.
[2]University of Newcastle, Priority Research Centre In Reproductive Science Discipline of Biological Sciences, Callaghan, Australia

Study question: The cytotoxicity of malondialdehyde (MDA) was compared to that of two other common products of lipid peroxidation, 4-hydroxynonenal (4-HNE) and acrolein (ACR), in human spermatozoa.
Summary answer: While treatment of spermatozoa with 4-HNE and ACR consistently elicited cytotoxic effects in a dose dependent manner, congruent treatment with MDA failed to produce any effect on cell viability or oxidative status.
What is known already: Spermatozoa are particularly susceptible to oxidative stress largely due to high membrane content of polyunsaturated fatty acids (PUFAs). Reactive oxygen species (ROS) preferentially attack PUFAs and form a variety of highly reactive lipid peroxy radicals and aldehydes, such as MDA, 4-HNE, and ACR. Though MDA is used as a marker of lipid peroxidation, little is known about its cytotoxic effects as compared to other common lipid aldehydes in spermatozoa.
Study design, size, duration: Semen samples of healthy human volunteers were collected through the University of Newcastle's donor program. Pooled samples were treated with increasing doses of MDA, HNE, or ACR for 2 and 24 h, with an untreated replicate serving as a control. Treatments were conducted on at least three separate samples.
Participants/materials, setting, methods: Cytotoxicities at six concentrations (0, 12.5, 25, 50, 100, 200 μM) were assessed *in vitro* under physiological conditions using fluorocytometric assays for mitochondrial and cytoplasmic ROS production, caspase activation, lipid peroxidation and DNA damage in the form of 8-hydroxydeoxyguanosine (8-OHdG) formation. Sample motility and vitality were also assessed at each concentration.
Main results and the role of chance: After 2 h of incubation, 4-HNE and ACR induced a dose dependent reduction in motility ($p < 0.01$) and vitality ($p < 0.001$), while increasing mitochondrial ROS production ($p < 0.01$) in a dose dependent manner. Treatment with 200 μM 4-HNE alone increased lipid peroxidation and caspase activation after 2 h. After 24 h, both 4-HNE and ACR induced significant, dose-dependent increases in cytoplasmic superoxide formation ($p < 0.001$), mitochondrial ROS formation ($p < 0.001$), caspase activation ($p < 0.001$), 8-OHdG formation ($p < 0.001$), and reduction in motility and vitality ($p < 0.001$). MDA produced no observable cytotoxic effect compared to untreated controls in any of the aforementioned assays. Compared to controls, motility and vitality were unaffected by incubation with MDA after 24 h. MDA, at concentrations used, had little cytotoxicity in spermatozoa as compared to 4-HNE and ACR.
Limitations, reason for caution: MDA is a tautomer and its reactivity is pH dependent, increasing in acidic environments. However, sperm are exposed to near-neutral pH during spermatogenesis and storage. Since all experiments were conducted in a neutral environment, the observed cytotoxicities of MDA, 4-HNE, and ACR probably reflect those experienced by spermatozoa *in vivo*.
Wider implications of the findings: The observed cytotoxicities of 4-HNE and ACR are consistent with previous findings in spermatozoa, as are the similar patterns observed between the two molecules. However, cytotoxicity of MDA on spermatozoa had not previously been reported. Though aldehyde byproducts of lipid peroxidation are generally accepted to adversely impact cellular health, these data suggest considerable cytotoxic differences between species. As aldehydes are used as markers of lipid peroxidation, differing reactivity may influence biomarker preference in future experiments.
Study funding/competing interest(s): Funding by University(ies). The study was funded by the University of Newcastle. P. G. is the Managing Director of, CellOxess LLC, which has a commercial interest in the detection and resolution of oxidative stress. A.P. and R.M. are employees of CellOxess LLC, which has a commercial interest in the detection and resolution of oxidative stress.
Trial registration number: NA.

P-035 Validation of the American Society for Reproductive Medicine guidelines/recommendations in Caucasian-European men presenting for couple's infertility

G. Castagna[1], E. Ventimiglia[1], G. La Croce[1], P. Capogrosso[1], L. Boeri[1], A. Serino[1], A. Pecoraro[1], M. Paciotti[1], S. Ippolito[1], D. Kuefner[1], R. Scano[1], F. Montorsi[1], A. Salonia[1]
[1]IRCCS Ospedale San Raffaele Milan Italy, Division of Experimental Oncology/Unit of Urology URI, Milan, Italy

Study question: To retrospectively validate the American Society for Reproductive Medicine (ASRM) guidelines/recommendations concerning the endocrine evaluation in Caucasian-European men presenting for couple's infertility.
Summary answer: Current findings showed that ASRM guidelines/recommendations for male infertility work-up may not be suitable for Caucasian-European men. One out of four hypogonadal men may miss out on a proper endocrine assessment when adhering to the ASRM guidelines/recommendations prompting the EAU guidelines suggestion to have tT assessed in every infertile patients.
What is known already: The assessment of the hormonal milieu is not of unequivocal importance in the male infertility workup. We aimed to retrospectively validate the American Society for Reproductive Medicine (ASRM) guidelines/recommendations concerning the endocrine evaluation in Caucasian-European men presenting for couple's infertility.
Study design, size, duration: Complete socio-demographic, clinical and hormonal data from 1056 consecutive infertile men were analysed. Cross-sectional study. Semen analysis values were assessed based on the 2010 WHO reference criteria.

Participants/materials, setting, methods: Hypogonadism was defined as total testosterone <3 ng/ml (Endocrine Society classification criteria). ASRM indications (sperm concentration <10 million/mL; impaired sexual function; other findings suggesting a specific endocrinopathy) were used to predict hypogonadism in our cohort and compared with a novel nomogram including patient age, BMI, and left testis volume predicting hypogonadism.
Main results and the role of chance: Biochemical hypogonadism was diagnosed in 156 (14.8%) men. Overall, 669 (63.4%) patients would have necessitated tT assessment according to ASRM criteria; of these, only 119 (17.8%) were actually hypogonadal according to the Endocrine Society classification criteria. Conversely, 37 (23.7%) out of 156 patients with biochemical hypogonadism would have been overlooked. The overall predictive accuracy, sensibility, and specificity of the ASRM guidelines were 58%, 76%, and 39%, respectively. Our logistic regression-based nomogram, was not quite reliable enough to predict hypogonadism, despite demonstrating a significantly higher predictive accuracy (68%, $p < 0.001$) than ASRM guidelines.
Limitations, reason for caution: The cross-sectional nature of the study.
Wider implications of the findings: These results provide evidence that ASRM guidelines may not be suitable in a Caucasian-European setting.
Study funding/competing interest(s): Funding by hospital/clinic(s) – None.
Trial registration number: NA.
Keywords: ASRM, hypogonadism

P-036 Evaluation of varicocele patients using the testicular real-time elastography

S. Blgozah[1], M. Shaaban[2], M. A. Sakr[1], N. Salama[1]
[1]*University, Genitourinary, Alexandria, Egypt*
[2]*University, Radiodiagnosis, Alexandria, Egypt*

Study question: Are there any correlations between the testicular real-time elastography and varicocele, varicocele grades, hormones and semen parameters?
Summary answer: There were significant correlations between the testicular real-time elastography and varicocele, varicocele grades, and some semen parameters.
What is known already: To our knowledge this is the first study correlates real-time elastography with varicocele, varcocele grades, hormones and semen parameters.
Study design, size, duration: Prospective study, involved 50 patients with left varicocele and 20 controls,
Participants/materials, setting, methods: 70 testes (50 left varicoceles and 20 controls) were evaluated using real-time elastography (Hitachi HI VISION Avius® system) to identify testicular volume, strain ratio and tissue elasticity score. Serum FSH, LH, free testosterone, total testosterone, prolactin and estradiol were assessed. Semen analysis was checked using computer-assisted sperm analysis.
Main results and the role of chance: Main testicular volume was 16.17 ± 4.86 ml for the varicocele patients vs 24.46 ± 6.34 ml for the controls ($p < 0.001$). The main strain ratio was 0.40% ± 0.06% for the varicocele patients vs 0.33% ± 0.03% for the controls ($p < 0.001$). The elasticity score in the varicocele patients was significantly higher than the controls ($p < 0.001$). There was a positive correlation between the grade of varicocele and both elasticity score ($r = 0.884$, $p < 0.0001$) and strain ratio ($r = 0.992$, $p < 0.001$). There were also negative correlations between normal sperm forms and both strain ratio ($r = -0.398$, $p = 0.004$) and elasticity score ($r = -0.394$, $p = 0.005$). No more correlations were detected between elastography parameters and hormones or other sperm parameters.
Limitations, reason for caution: none.
Wider implications of the findings: new study.
Study funding/competing interest(s): Funding by University(ies) – Alexandria University.
Trial registration number: NA.

P-037 MIcro dissection TESE, a series of more than 300 men with non obstructive azoospermia from a developing country : obstacles encountered, success achieved and the path forward

S. Sankalp[1], S. Swati[1], C. M. Ashraf[1], P. Dharmaraj[2], R. Sujatha[3], S. Esteves[4]
[1]*Craft Hospital and Research Center, RM, Thrissur, India*
[2]*Craft Hospital and Research Center, Andrology, Thrissur, India*
[3]*Craft Hospital and Research Center, Embryology, Thrissur, India*
[4]*AndrofertBrazil, Andrology, Thrissur, Brazil*

Study question: How to implement micro dissection testicular sperm extraction (TESE) for men with non obstructive azoospermia (NOA) in a developing country, the expected obstacles in implementation and the overall success?
Summary answer: It is feasible to implement the technique in developing country like India. The difficulties encountered included the cost of setting up the technique, the training of the surgeon and convincing the other reproductive medicines specialists and general gynaecologists to refer the indicated men for the procedure.
What is known already: Microdissection TESE is a well known modality of surgical sperm retrieval in men with NOA preferred over conventional TESE and testicular sperm aspiration (TESA).It has been practiced since 1990s and has gained momentum in last few years. Though practice of this procedure started mainly in developed countries, the developing nations are slowly, but surely catching up.
Study design, size, duration: We performed a retrospective analysis of 300 men with NOA who have undergone micro dissection TESE from 2012–2014 at Craft hospital. The sperm retrieval rate and Intracytoplasmic sperm injection (ICSI) outcome were analysed. We also analysed the difficulties encountered in the implementation of the technique and steps taken to overcome them.
Participants/materials, setting, methods: 300 men with NOA underwent microdissection TESE for the first time in Craft hospital and research center. The procedure was done a day prior to the oocyte pick up. Initially, the larger testis was first and proceeded to the other side if no sperms were retrieved on the first side.
Main results and the role of chance: We were able to implement the procedure with considerable ease. The main hinderance was the cost of the procedure to the couple, which was dealt with dedicate counselling. The sperms were retrieved in 151/300 (50.33%) of men with non obstructive azoospermia undergoing microdissection TESE. The highest recovery rate was seen in men with testicular histopathology of hypospermatogenesis followed by maturation arrest and sertoli cell syndrome. ICSI was done for all but two couples due to extremely poor sperm morphology. For the 149 couples who underwent ICSI, fertilization rate of 75.1% was achieved. The clinical pregnancy rate and live birth rate were 29 and 26% respectively. There was one case of post operative testicular hematoma. There were no major complications in any other case.
Limitations, reason for caution: Since this was a case series, there is no control group to which the findings can be compared to.
Wider implications of the findings: Microdissection TESE as an sperm acquisition method for NOA can be successfully implemented in developing countries in units with dedicated andrology unit. It is associated with more than 50% sperm retrieval rate with low complication rate.

The hinderances are minor ones including cost, training, learning curve and dissemination of the necessary information to general gynaecologists.
Study funding/competing interest(s): Funding by hospital/clinic(s) – craft hospital.
Trial registration number: NA.
Keywords: non obstructive azoospermia, micro TESE

P-038 Is a second sperm analysis necessary in every infertile man?

E. Ventimiglia[1], P. Capogrosso[1], G. La Croce[1], L. Boeri[1], L. Serino[1], A. Pecoraro[1], M. Paciotti[1], S. Ippolito[1], G. Castagna[1], R. Scano[1], D. Kuefner[1], F. Montorsi[1], A. Salonia[1]
[1]*IRCCS Ospedale San Raffaele Milan Italy, Division of Experimental Oncology/Unit of Urology URI, Milano, Italy*

Study question: To develop 3 nomograms capable of predicting findings of a second pathological semen analysis.
Summary answer: Current findings showed that half of infertile men could ideally be spared from a second semen analysis in order to confirm pathological sperm parameters. This could speed up the diagnostic work-up, without a consistent risk of overtreatment.
What is known already: Current guidelines suggest andrological investigation in infertile men after at least two pathological semen analyses, with a potential considerable delay in couples who need infertility work-up.
Study design, size, duration: Complete data from 647 consecutive infertile men were analysed. Cross sectional study.

Participants/materials, setting, methods: Testicular volume was assessed with a Prader orchidometer. Two consecutive semen analyses carried out 3 months apart were requested for each patient (2010 WHO criteria). Three different nomograms (A, B, C) were developed and internally validated in order to predict pathological concentration (pC), total progressive motility (PT), and morphology (M) at the second semen analysis following a previous pathological one.
Main results and the role of chance: A) Left testicular volume, baseline concentration and number of baseline pathological sperm parameters (all $p \leq 0.03$) were independent predictors of oligospermia at second semen analysis. Nomogram predictive accuracy (PA): 88%. **B)** Baseline concentration and PT (all $p \leq 0.03$) were independent predictors of asthenozoospermia at second semen analysis. Nomogram PA:74%. **C)** Baseline normal M, baseline PT, number of baseline pathological semen parameters, and left testicular volume were independent predictors of teratozoospermia at second semen analysis found at MVA. Nomogram PA: 73%. Using a nomogram-derived probability of oligospermia at second sperm analysis > 70%, would spare 58% of repeating a second sperm analysis to confirm oligospermia. Similarly a 65% cut-off for asthenospermia and a 70% cut-off for normal M, would spare 39.1% and 32.8% men respectively from repeating sperm analysis.
Limitations, reason for caution: The cross-sectional nature of the study.
Wider implications of the findings: These results could speed up the diagnostic work-up, without a consistent risk of overtreatment.
Study funding/competing interest(s): Funding by hospital/clinic(s) – None.
Trial registration number: NA.
Keywords: sperm analysis, workup

P-039 How to predict success in ART: the impact of sperm cell origin on intracytoplasmic sperm injection (ICSI) outcomes of ejaculated versus testicular spermatozoa

M. Nadalini[1], N. Tarozzi[1], M. Di Santo[1], A. Borini[2]
[1]*Tecnobios Procreazione, Reproductive Medicine Laboratory Unit, Bologna, Italy*
[2]*Tecnobios Procreazione, Reproductive Medicine Clinical Unit, Bologna, Italy*

Study question: Is there a relationship of sperm origin, testicular [in testicular sperm aspiration (TESA)] and ejaculate with ART outcomes in couples treated with ICSI?
Summary answer: It's possible to achieve similar pregnancy and spontaneous abortion rates via ICSI with fresh non-ejaculated spermatozoa, although the fertilization, cleavage and sometimes the implantation rates, are significantly lower than those of counterparts using freshly ejaculated spermatozoa from men with different sperm characteristics.
What is known already: The literature evidence is quite limited, and conflicting reports exist regarding whether the ART outcome is affected by sperm origin; studies have reported either a decrease or no difference in pregnancy outcomes with ICSI in cases of non-obstructive azoospermia (NOA) and obstructive azoospermia (OA), respectively, and the results are similar to those reported with ICSI using ejaculated sperm.
Study design, size, duration: Retrospective cohort study at private IVF centre from 2002 to 2014: the results of 2818 fresh ICSI cycles using TESA and ejaculated sperm were compared. Main outcomes measures were fertilization, cleavage, implantation, pregnancy and spontaneous abortion rates. A complete workup was conducted to exclude female factor influence.
Participants/materials, setting, methods: A total of 426 TESA-ICSI cycles using fresh testicular aspirated sperm from men with different origin of azoospermia (obstructive and non-obstructive) and temporary ejaculation failure (TEF) and 2392 ICSI cycles using fresh ejaculated sperm from men with different sperm characteristics (normozoospermia, oligoasthenoteratozoospermia and cryptozoospermia) were included in the analysis.
Main results and the role of chance: Mean female age, number of inseminated oocytes and transferred embryos were similar among the groups. Overall, in ICSI-TESA cycles, fertilization, cleavage and implantation rates were significantly lower than in ICSI-ejaculated cycles (62.0 vs 72.6%, $p < 0.0001$; 94.0 vs 97.1%, $p < 0.0001$; 12.4 vs 16.9%, $p = 0.001$, respectively), but the differences tend to reduce with the lowering quality of sperm in ICSI-ejaculated subgroups (from normozoospermia to cryptozoospermia). On the contrary, the pregnancy and spontaneous abortion rates were similar among the overall groups (23.4 vs 28.7%, $p = 0.058$; 12.9 vs 16.1%, $p = 0.522$, respectively). Moreover, among ICSI-TESA cycles, NOA obtained significantly lower fertilization, implantation and pregnancy rates than OA (59.9 vs 64.7%, $p < 0.05$; 9.6 vs 17.0%, $p < 0.05$; 18.8 vs 34.0%, $p < 0.05$, respectively), while TEF obtained the lowest laboratory and clinical outcomes.
Limitations, reason for caution: It is a retrospective cohort study with different sample size in the groups. In addition, the study design with respect to statistical power, cases number recruitment and lack of data on ectopic and multiple pregnancy rates could be improved on.
Wider implications of the findings: Although pregnancy and spontaneous abortion rates in TESA-ICSI cycles are clinically satisfactory, they are lower than in ICSI-ejaculated cycles. This difference might be related to the severity of sperm defects, to major implications during spermatogenesis and to the 'incomplete' maturation process of testicular spermatozoa. Therefore, future investigation focusing on the functional and genetic integrity of ejaculated spermatozoa versus those retrieved from testicle would help identify the most competent gamete source for ART.
Study funding/competing interest(s): Funding by hospital/clinic(s) – no competing interests declared.
Trial registration number: NA.
Keywords: intracytoplasmic sperm injection (ICSI) outcomes, ejaculated sperm, testicular sperm, obstructive/non-obstructive azoospermia, temporary ejaculation failure

P-040 Treatment with zinc, D-aspartate and coenzyme Q10 protects bull sperm against exogenous oxidative damage

R. Gualtieri[1], V. Barbato[1], I. Fiorentino[1], S. Braun[1], A. Merolla[1], S. Sudhakaran[1], S. Longobardi[2], R. Talevi[1]
[1]*Università Degli Studi Di Napoli Federico II, Dept. Biology/Complesso Universitario Monte S. Angelo, Napoli, Italy*
[2]*Merck Serono SpA, Medical Division, Roma, Italy*

Study question: Do antioxidants Zinc, Coenzyme Q10 (CoQ10) and the micronutrient D-aspartate (D-Asp), present in dietary supplement Genadis, (Merck Serono), protect bull spermatozoa against exogenous oxidative damage?
Summary answer: Results demonstrated that in vitro treatment of bull spermatozoa with the xanthine-xanthine oxidase system (X-XO) determines a rapid and time-dependent decrease of sperm motility and kinetics, and a concomitant increase of sperm DNA fragmentation that are prevented by incubation with Zinc, D-Asp and CoQ10.
What is known already: Sperm oxidative stress in vivo and in vitro is thought to impair semen quality, fertilization and embryo developmental competence. We recently demonstrated that Zinc, D-Asp and CoQ10 have protective effects on human and bull sperm motility and DNA fragmentation in vitro in the absence of exogenous oxidative stress. Moreover, treated bull spermatozoa promoted the development of 8-cell embryos and good quality blastocysts endowed with a lower percentage of DNA fragmented blastomeres.
Study design, size, duration: The study was performed on 10 frozen/thawed bull semen samples. Each experiment included three groups: control, treated with X-XO alone or in combination with Zinc, D-Asp and CoQ10. Sperm kinetics was evaluated by computer assisted semen analysis (CASA) and DNA fragmentation measured by the TUNEL assay in all samples.
Participants/materials, setting, methods: Frozen/thawed bull spermatozoa were incubated for 2 h in culture medium (control), supplemented with 0.5 mM xanthine-0.05 U/ml xanthine oxidase alone or in combination with 10 μg/mL Zinc chloride, 500 μg/mL D-Asp, and 40 μg/mL CoQ10. Samples were analyzed by CASA at 0,30,60 and 120 min. DNA fragmentation was measured after 2 h of treatment.
Main results and the role of chance: Time 0 total (74 ± 9.6%), and progressive (72 ± 10.9%) motility and kinetics (VCL 122.8 ± 11.8, VSL 81.8 ± 9.49, VAP 96.7 ± 9.6 μm/sec) significantly decreased after 2 h of incubation with X-XO (control 2 h vs treated: motility 59 ± 15.2 vs 32 ± 12.1, progressive motility 52 ± 13.9 vs 23 ± 10.9, $P < 0.01$). Interestingly, treatment with X-XO and Zinc, D-Asp and CoQ10 prevented the drop of motility (2 h, total 60 ± 12%, progressive 47 ± 13.9%) and the increase of sperm DNA fragmentation (control time 0, 2,2; control 2 h, 5,2; X-XO 2 h, 8,4; X-XO plus Zinc, D-Asp and CoQ10, 4,5; $P < 0,01$).
Limitations, reason for caution: The study was carried out in vitro using frozen/thawed bull spermatozoa. Data could not reflect what occurs in vivo and/or in the human species.

Wider implications of the findings: Data demonstrated that antioxidants protect bull spermatozoa from exogenous oxidative stress in vitro. The supplementation of sperm culture media with Zinc, D-Asp and CoQ10 could protect spermatozoa from oxidative stress during in vitro handling. The use of an animal model will allow to understand the role played by sperm exogenous oxidative damage and its prevention by Zinc, D-Asp and CoQ10 on embryo developmental competence.
Study funding/competing interest(s): Funding by University(ies) – funding by commercial/corporate company(ies) – Merck Serono.
Trial registration number: NA.

Study question: Our currently restricted understanding of basic mechanisms driving human gametogenesis severely limits the improvement of proper clinical care of infertile patients. The goal of our team is to identify genes through whole exome sequencing that, when mutated, cause a male infertility phenotype that adversely affects gametes production.
Summary answer: Using exome sequencing, we identified mutations in two genes; a no-stop mutation in an X-linked gene, which causes the production of an extended protein by turning the stop codon into amino acid coding codon, and a stop-gained mutation in an autosomal gene leading to the production of a truncated protein.
What is known already: The World Health Organization estimates that one in four couples in developing countries is confronted with infertility. Despite 37 years of assisted reproductive activities, a significant number of cases remain idiopathic. Considering the high predicted numbers of genes involved in male gametogenesis, it is likely that most 'idiopathic' forms have genetic origin. At present, only a dozen of genes has been identified as being responsible for an infertility phenotype in men when mutated.
Study design, size, duration: This study has been performed at IGBMC, Strasbourg, France in collaboration with Bahceci Health Group, Istanbul, Turkey. Two Turkish consanguineous families having at least two well documented male infertility cases as well as two or more unaffected brothers, 86 Turkish men with spermatogenic failure and 107 fertile controls were included.
Participants/materials, setting, methods: Saliva samples were used as DNA source. A whole exome sequencing of two affected patients per family was performed by IGBMC microarray and sequencing platform. Suspected mutations were confirmed by Sanger sequencing first on family members, then on fertile controls and affected men with the same phenotype.
Main results and the role of chance: In family one, all affected males present a no-stop mutation which causes loss of the normal translational termination, leading to a 23 amino-acid extension of an X-linked gene. In family two, all affected males present, on the contrary, a stop-gained mutation on an autosomal gene, resulting in early translational arrest in the first 1/3 of the protein. Dramatic testicular size reduction was observed especially in affected males of the second family as well as in the corresponding KO mouse line. No mutation was found either in 107 healthy Turkish fertile controls or in 86 azoospermic and oligozoospermic Turkish infertile men. Additional tests were performed to define the effect of the mutations on the expression, localization and partners of the corresponding protein.
Limitations, reason for caution: Our study contains only a limited number of Turkish patients. Mutation screening should be continued on larger groups of infertile patients, including men of other ethnicities. Also for obvious ethical reasons, no in-vivo works were possible and only in-vitro experiments were done.
Wider implications of the findings: Understanding the genetic basis of male infertility has large implications not only for understanding the cause of infertility but also for determining the prognosis and management of such couples, and to provide maximally adapted therapeutics. It will then be possible to develop a diagnostic test and propose a molecular diagnosis to patients showing similar phenotype. It also opens the possibility to carry on more basic research on human spermatogenesis.
Study funding/competing interest(s): Funding by national/international organization(s) – Agence nationale de la recherché (ANR) and l'Agence de BioMédecine.

P-042 Making the embryologist's life easier during intracytoplasmatic sperm injection (ICSI): use of dimethylxanthine theophylline (SpermMobil®) for testicular sperm samples

F. Gagsteiger[1], M. Marques[1], N. Reeka[1], K. Eibner[1], C. Huober-Zeeb[1], N. L. Sandi-Monroy[1]
[1]*Kinderwunschzentrum Ulm, IVF Unit, Ulm, Germany*

Study question: Is it possible to facilitate the embryologist's work during ICSI when dealing with testicular biopsy samples (TESE) in the absence of motile sperm? Would the use of dimethylxanthine theophylline compromise fertilization, implantation and pregnancy rates, or affect perinatal outcomes?
Summary answer: The use of a commercially available compound improved fertilization but not implantation and pregnancy rates among the groups. Perinatal outcomes (gestational age at birth, GA, weight and height) was also similar among the groups with the live birth of 21 children so far.
What is known already: Derivatives of theophylline increase intracellularly the levels of cyclic AMP, thus stimulating sperm motility and reducing the time required to find viable motile sperm. There has been only a limited number of studies showing the effects of SpermMobil® on pregnancy rates and only one live birth report after the use of this compound.
Study design, size, duration: ICSI cycles using TESE from January 2012 to October 2014 were analyzed retrospectively. 57 cycles did not require the use of SpermMobil® (group A), whereas 42 TESE (group B) presented no motility and were treated with SpermMobil® before ICSI. Two patients were excluded due to lack of motile sperm.
Participants/materials, setting, methods: TESE were treated mechanically and enzymatically, cryo-preserved, and thawed for therapy. Female partners underwent controlled ovarian stimulation and harvested oocytes were injected with motile sperm only. Embryos were cultured for up to 5 days. Statistical analysis were performed by Fischer's exact test, t-test, or Mann Whitney test.
Main results and the role of chance: Fertilization rates were higher in group 2 (65.22 versus 53.11%, $p = 0.0431$), showing a beneficial effect of SpermMobil®. There were no statistically significant differences among the groups regarding pregnancy (34.78 and 44.11%) and implantation (21.91 and 27.11%) rates among groups A and B, respectively, although group B tended to have higher rates. In group A, there were two biochemical pregnancies and two aborts, whereas in group B two aborts and 4 still ongoing pregnancies. GA,

weight and height at birth also did not differ among the groups (A, *n* = 12 newborns; B, *n* = 9 newborns). The embryologist´s work was also facilitated, as the time required to obtain enough motile sperm decreased.
Limitations, reason for caution: This is a retrospective analysis of ICSI outcomes using testicular motile spermatozoa only. As the benefits of this compound have been already reported, we opted not to make a truly negative group (no spermatozoa motility, no SpermMobil® treatment) not to jeopardize patient's treatment outcome.
Wider implications of the findings: This is the first report of multiple healthy births after the use of this chemical compound. The use of such a compound may facilitate not only the embryologist's work, by reducing the time needed to recover enough motile sperm, but also optimize patient's treatment outcomes by increasing the number of fertilized oocytes.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Kinderwunschzentrum Ulm.
Trial registration number: NA.
Keywords: TESE, ICSI, theophylline, perinatal outcome

P-043 Antioxidant activity of CAPE (Caffeic acid phenethyl ester) in vitro can protect human sperm deoxyribonucleic acid from oxidative damage

S. Ayla[1], G. Tunali[1], B. E. Bilgiç[1], K. Sofuoglu[2], A. A. Özdemir[1], G. Tanriverdi[3], B. C. Soner[4], S. Özdemir[5], B. Öztürk[5], I. Seckin[3]
[1]Zeynep Kamil Gynecology and Maternity Training and Research Hospital, IVF-ET Unit, Istanbul, Turkey

[3]Istanbul University Cerrahpasa Medical Faculty, Histolology and Embryology Department, Istanbul, Turkey
[4]Necmettin Erbakan University, Pharmacology Department, Konya, Turkey
[5]Istanbul University Cerrahpasa Medical Faculty, Biophysics Department, Istanbul, Turkey

Study question: Oxidative stress is an important factor which influences fertility potential of spermatozoa by lipid peroxidation and formation of stable peroxidation products like malondialdehyde (MDA) in seminal plasma which may result in sperm dysfunction. Can CAPE Supplementation In Vitro Protect Human Sperm Deoxyribonucleic Acid From Oxidative Damage?
Summary answer: The results of this study emphasize the susceptibility of human spermatozoa to oxidative injury in vitro that preincubation of spermatozoa with the antioxidant CAPE offers protection against oxidative deoxyribonucleic acid (DNA) damage in vitro.
What is known already: Zini et al. have found that preincubation of spermatozoa with lycopene (5 µmol/L) effectively protected spermatozoa from DNA damage caused by subsequent incubation with H2O2.
Study design, size, duration: Prospective study. 30 control (fertile male donors), 30 treatment group (Oligoasthenoteratozoospermia male donors). Semen samples were obtained and allowed to liquefy at room temperature. After centrifugation and washing protocol spermatozoa were incubated in single step medium with 10, 50 and 100 µmol/L CAPE for 2 h at 36.0 °C.
Participants/materials, setting, methods: After incubation period, MDA levels of seminal plasma and spermatozoa were measured. Spermatozoa with fragmented DNA, as detected by Anilin Blue Assay with light microscopy, and morphology (spermatozoa structure) were analyzed by transmission microscopy.
Main results and the role of chance: Significant increase in percent DNA fragmentation index before the centrifugation (0.57 ± 0.15 respectively). Incubation of samples with 100 µmol/L CAPE resulted in a significantly lower percent DNA fragmentation index than samples incubated without CAPE (0.42 ± 0.12 respectively). ($P < 0.001$). Values are calculated, results are given as mean ± SD.
Limitations, reason for caution: Subject number has been limited with 30 participants. A limitation to our study is the relatively small sample size.
Wider implications of the findings: The results of this study emphasize the susceptibility of human spermatozoa to oxidative injury in vitro. The data suggest that preincubation of spermatozoa with the antioxidant CAPE offers protection against oxidative DNA damage in vitro. These data also highlight the differential effects of CAPE on sperm DNA integrity.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Zeynep Kamil Gynecology and Maternity Training and Research Hospital, IVF-ET Unit, Istanbul, Turkey.
Trial registration number: Basic science.
Keywords: sperm DNA damage, antioxidant, reactive oxygen species, CAPE

P-044 Evaluating the use of ubiquitin, a marker of defective sperm, as a potential infertility marker and selection tool within human sperm

N. Sota[1], R. Rivera[1], L. Alegre[2], A. Martínez-Romero[3], F. Quintana[4], M. Meseguer[2], N. Garrido[1]
[1]Instituto Universitario IVI Valencia, Andrology Laboratory, Valencia, Spain
[2]Instituto Universitario IVI Valencia, IVF Laboratory, Valencia, Spain
[3]Principe Felipe Research Center, Cytometry Technological Service, Valencia, Spain
[4]Clínica IVI Bilbao, Andrology Laboratory, Bilbao, Spain

Study question: Can we confirm a relationship between the presence and levels of ubiquitin (Ubiq) in human sperm samples (SS) and their ability to succeed and result in a clinical pregnancy after an ICSI treatment with own and donated oocytes?
Summary answer: Percentage of stained cells as well as Ubiq protein quantity in sperm from infertile males achieving or not pregnancy by means of ICSI are similar, irrespective of the oocyte source, after controlling for clinical and individual confounders, leading to conclude that Ubiq involvement in sperm function seems limited hitherto.
What is known already: Ubiq is a highly conserved protein of 76 aminoacids which function is to tag proteins that should be degraded by the proteasome inside the cell. However, some groups proposed the idea of sperm surface ubiquitination occurring along the epididymis. They suggested that defective spermatozoa are tagged and therefore eliminated along the epididymis, while some of them could escape from this system, and consequently, ubiquitinated spermatozoa could be found within the ejaculate and fail fertilization.
Study design, size, duration: Nested cases and controls study analyzing spermatozoa from 21 ejaculates that achieved clinical pregnancy (*P*+) and spermatozoa from 18 SS that did not achieve it (P-), after undergoing ICSI treatments with own or donated oocytes prospectively collected, where Ubiq was measured by means of flow cytometry.
Participants/materials, setting, methods: From SS prepared for ICSI treatments, aliquots were fixed and stored for ulterior analysis once the pregnancy results were known. SS were incubated with Anti-Ubiq-Ab followed by secondary FITC-conjugated-Ab. Ubiq positively stained cells and mean fluorescence intensity was quantified and groups compared using T-test and logistic regression controlling confounding parameters.
Main results and the role of chance: Mean volume, concentration, motility and total motile count were 2.3 ml CI 95%(2.0–2.6), 56.1 mill/ml CI 95% (41.9–70.4); A + B 45.3% CI 95% (40.1–50.5), 59.9 mill CI 95% (43.6–76.2), respectively. In prepared sperm, 12.0mill/ml CI 95% (9.8–14.1), A + B 96.7% CI 95% (95.5–97.9) and 4.3 mill CI 95% (3.2–5.4). A mean number of 1.8 CI 95% (1.7–1.9) embryos were transferred, in 25 donation and 14 own oocytes'cycles. Women's mean age was 38.4y CI 95%(37.0–39.7). Ubq + ve cells were 60.3% CI 95% (47.5–73.2) in P+, and 56.2% CI 95% (41.7–70.6) in P-, while mean staining intensity was 186.14 CI 95% (74.2–298.1) in P+ vs. 211.1(133.2–288.9) in P-. The odds ratio (OR) of P+/P- depending on the Ubq% of stained cells was 1.01CI 95% (0.98–1.03), B = -0.05, while staining intensity OR = 1.00 CI 95% (1.00–1.00), B < 0.001. Once adjusted for potential clinical confounders (day of embryo transfer, own or donated oocytes, age, female etiology, sperm features, embryos transferred, etc…), Adj (OR) Ubiq% of stained cells was 1.01CI95%(0.98–1.02), B = 0.05, while staining intensity Adj (OR) = 1.00 CI 95% (1.00–1.00), B < 0.001.
Limitations, reason for caution: Other sperm factors not included within this analysis could be biasing the studied relationships, given that sperm function has been demonstrated to be multiparametric. Further confirmation of our results is needed from other studies, confirming or not if our results are extrapolable to other subpopulations or different assisted reproduction protocols.
Wider implications of the findings: Ubiquitin is a sperm membrane protein, specific of malfunctioning sperm, that may be potentially used as an infertility marker, thus suitable for the development of a sperm selection tool based on the use magnetic activated cell sorting (MACS) technology to eliminate Ubq+ve cells and improve ART results. Nevertheless, there is a previous need to confirm the link between the protein in sperm and clinical results with ICSI, and this has not been accomplished yet.

Study funding/competing interest(s): Funding by national/international organization(s) – Department of Industry, Innovation, Trade and Tourism and FEDER funding (EU)(IG-2011/0000681 and IG-2012/0000497).
Trial registration number: NA.
Keywords: ubiquitin, spermatozoa, infertility marker, male fertility, flow cytometry

P-045 Virtual slide is a relevant tool for training when assessing human sperm morphology

T. Freour[1], J. Auger[2], A. Bourguignat[3], G. Férard[3], J. Pfeffer[4], S. Pilikian-Haond[5], F. Schmitt[6], E. Szerman[7], J. P. Siest[8]

[6]*CH Mulhouse, Cecos Alsace, Mulhouse, France*
[7]*CHU Caen, Cecos, Caen, France*
[8]*Biologie Prospective, Biologie Prospective, Villers Les Nancy, France*

Study question: Semen smears are traditionally used for training and QC in sperm morphology. However, it does not allow the evaluation of exactly the same cells between operators. Virtual slide is based on high-definition on-screen morphology assessment on numbered spermatozoa, allowing training, e-learning and QC, with comparison with a correction grid.
Summary answer: Yes, virtual slide is an efficient tool for training and QC in sperm morphology assessment, allowing operators to work on identified spermatozoa and compare themselves with correction grid.
What is known already: Sperm analysis suffers from intra and inter-operator variability, highlighting the need for training and QC in andrology laboratories. External quality control programs should concern sperm concentration, motility and morphology evaluation. Whereas sperm concentration and motility can be correctly assessed for QC with fixed-sperm suspension and movies respectively, morphology assessment is generally based on semen smears, which raises the issue of individual sperm classification and availability of corrected answers for trainers.
Study design, size, duration: Between 2006 and 2013, 5 e-learning case studies including sperm morphology assessment via virtual slide were proposed to the 470 Spermionet e-learning facility members.
Participants/materials, setting, methods: Participants had to classify 100 spermatozoa on a virtual slide available online obtained after high-definition scanning of a Shorr-stained smear. Each spermatozoa was numbered and participants had to classify them according to David classification. Individual sperm classification based on consensual evaluation by a panel of experts was presented afterwards.
Main results and the role of chance: There was an acceptable agreement between participants and consensual values provided by the steering committee of Spermionet. More than 50% of the participants had morphology results within the acceptability range according to Ricos tables.
Limitations, reason for caution: E-learning cases based on sperm morphology assessment performed up to now have not included WHO classification. In addition to e-learning facility for training, external QC programes for sperm morphology will also be based on virtual slide starting from 2016.
Wider implications of the findings: Virtual slide provides an opportunity to improve and standardize training and external QC for sperm morphology. It could easily be used for skill follow-up within lab's staff. Virtual slide could eventually also be used for training and QC in sperm vitality assessment.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Biologie Prospective.
Trial registration number: NA.

P-046 Is there a future for human round spermatid injection (ROSI)?

A. Tanaka[1], M. Nagayoshi[1], Y. Takemoto[1], I. Tanaka[1], H. Kusunoki[2], S. Watanabe[3]
[1]*Saint Mother Obstetrics and Gynecology Clinic and Institute For ART, Fukuoka, Kitakyushu, Japan*
[2]*Faunal Diversity Sciences Graduate School of Agriculture Kobe University, Hyogo, Kobe, Japan*
[3]*Department of Anatomical Science Hirosaki University Graduate School of Medicine, Aomori, Hirosaki, Japan*

Study question: Can an improved human round spermatid injection into the oocyte (ROSI) be considered a worthy clinical treatment despite the fact that conventional ROSI has been recognized as being ineffective for non-obstructive azoospermia due to its extreme low success rates?
Summary answer: In this study ROSI fully proved to be effective clinically when there is proper identification of round spermatid and oocyte activation.
What is known already: To date, the application of ROSI in clinical IVF has had disappointing results due to difficulties in accurate identification of round spermatids among other round spermatogenic cells and insufficient oocyte activation.

Patients who may be candidates for ROSI should receive careful and thorough pretreatment counseling to ensure they are clearly informed of the limitations and potential risks of the procedure.
Study design, size, duration: A total of 44 non-obstructive azoospermic men whose first MD-TESE conducted by andrologists showed no testicular spermatozoa or late staged spermatids but had round spermatids found at our hospital and received ROSI from September 2011 to October 2014. Study approved by the Japanese Ministry of Health, Labour and Welfare.
Participants/materials, setting, methods: Round spermatids, cytologically selected after thawing, were injected into ooplasm which was activated 10 minutes before the injection by electrical stimulation with an alternating current pulse of 2V/cm for 8s + direct current pulse of a single 1.2 kV/cm for 99 µs.
Main results and the role of chance: The percentage of occurrence of 1PN, 2PN and 3PN after electrical stimulation were 80% (8/10), 20% (2/10) and 0 respectively. Fertilization and rate to develop over 4 cell stage were 59.0% (315/534), 56.7% (303/534) respectively. The pregnancy rate per transferred cycle, miscarriage rate and birth rate in fresh embryo transfer cycles and freezing-thawed transfer cycles were [16.3%(16/98), 68.8% (11/16), 5.1% (5/98)], [36.8% (7/19), 42.9% (3/7), 21.1% (4/19)] respectively.

No abnormal karyotype and genomic imprinting abnormalities (IGF2, H19, SNRPN) were identified in any of the newborn babies. All of 4 female and 7 male babies are healthy and no serious physical or cognitive disorders have been reported so far.
Limitations, reason for caution: The limitation of this clinical study concerns the small size of the study group, patients who had received MD-TESE by other andrologists and sperm could not be found but had round spermatids found at the second MD-TESE performed at our hospital.
Wider implications of the findings: Application of ROSI in clinical human IVF is still considered experimental. However, this study presents evidence that ROSI has a high potential to help many non-obstructive azoospermic men whose most advanced spermatogenic cells are round spermatids.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Saint Mother Obstetrics and Gynecology Clinic and Institute for ART.
Trial registration number: UMIN Clinical Trials Registry UMIN000006117.

P-047 Molecular atlas of different stages of human spermatogenesis: Sertoli cells, spermatogonia and sperm

T. Skutella[1], H. Azizi[1], M. Amirian[1], M. Hatami[1], M. Kubista[2], I. Virant-Klun[3]
[1]*Institut Für Anatomie Und Zellbiologie, Stem Cell Biology and Regenerative Medicine, Heidelberg, Germany*
[2]*TATAA Biocenter, Molecular Biology, Göteborg, Sweden*
[3]*University Medical Centre Ljubljana, Department of Obstetrics and Gynaecology, Ljubljana, Slovenia*

Study question: The aim of this study is to establish the molecular atlas of human spermatogenesis. We started to optimize the methods for isolation of cell populations that are involved in spermatogenesis (especially Sertoli cells, spermatotogonia and sperm) and performed transcriptomic and immunocytochemistry analyses to better understand the human spermatogenesis.
Summary answer: Our results showed that it is possible to establish the gene expression profiles of selected cell populations of spermatogenesis with microarrays validated by Fluidigm real-time PCR. Detailed differential and functional bioinformatics analysis was followed by mapping and varifying the cellular localization of candidate genes by in situ hybridization and immunohistochemistry.
What is known already: Because of several technical limitations no detailed knowledge on the molecular profile of different stages of human spermatogenesis and the cell types involved is available at present. This would be an

important prerequisite to further develop strategies for diagnosis and treatment of male infertility by assisted reproduction, to better understand the manifestation of testicular cancer and to develop better opportunities for individualized diagnosis and therapy of cancer in the future.
Study design, size, duration: In this study, five groups of human spermatogenic cells were analyzed using transcriptomics and immunocytochemistry:

1.) laminin and alkaline phosphatase (AP)-enriched spermatogonia.
2.) lectin-enriched Sertoli cells (patients with obstructive azoospermia, with sperm),
3.) lectin-enriched Sertoli cells (patients with non-obstructive azoospermia, no sperm).
4.) testicular sperm (azoospermia),
5.) ejaculated sperm (normospermia).

Participants/materials, setting, methods: Each group of human spermatogenic cells was analyzed for its gene expression profile in three biological replicates using microarrays. The most interesting genes were further validated by qPCR and statistically evaluated using Principal Component Analysis (PCA), Student *T*-test, and one-way ANOVA to elucidate differences between groups.
Main results and the role of chance: Specificity of laminin/alkaline phosphatase-enrichment for germ cell lineage and lectin-enrichment of Sertoli cells were confirmed by UTF1/VASA and VIM/SOX9 expression, as revealed by immunohistochemistry. Principal component analysis (PCA) of the microarray data revealed that all cell populations clearly separated from each other. Expressions of specific genes related to Sertoli cells, sperm and spermatogonia in selected populations of cells confirmed the 'character' of selected cells. Bioinformatics elucidated the functional differences between the various groups of cells. According to F-test analysis, the most interesting genes were confirmed by Fluidigm real-time PCR. The validation experiments were also performed on various sections of testicular samples using automation of non-radioactive in situ hybridization in combination with cell type-specific immunohistochemical markers and some new interesting cell type-specific gene expression patterns were identified.
Limitations, reason for caution: The testicular biopsies used for this study were from patients with obstructive and non-obstructive pathologies. It was possible to select the enriched populations of cells that may still contain some other types of cells.
Wider implications of the findings: Our results provide a new set of genes that could serve as important biomarkers to better understand the human spermatogenesis in the future, especially in association with male age, testicular cancer (seminoma) and fertility/infertility to explore it in a more detail. Moreover, the selected populations of spermatogenic cells could serve as a model to study the effects of xenoestrogens and their potential involvement in infertility and manifestation of testicular cancer.
Study funding/competing interest(s): Funding by national/international organization(s). This study was funded by the German Federal Ministry of Education and Research (BMBF; bilateral collaborative research project) and the Slovenian Research Agency (ARRS).
Trial registration number: The study was performed after approvals of the Ethical Committee of University of Heidelberg and Slovenian National Medical Ethics Committee.
Keywords: human spermatogenesis, human sertoli cells

P-048 Prevalence of human papillomavirus (HPV) sperm infection and fertility outcome in 200 couples candidate to assisted reproduction techniques

D. Pizzol[1], A. Garolla[1], B. Engl[2], A. Bertoldo[1], M. Menegazzo[1], M. Ghezzi[1], C. Foresta[1]
[1]University of Padova, Department of Medicine, Padova, Italy
[2]Hospital of Brunico, Obstetrics and Gynaecology, Brunico, Italy

Study question: The objectives of this study were to evaluate the prevalence of human papillomavirus (HPV) semen infection in males of infertile couples and to compare the reproductive outcome in infected and non infected patients.
Summary answer: Our results demonstrated a very high prevalence of HPV sperm infection in infertile patients. Positive HPV patients had no spontaneous pregnancy and a lower cumulative pregnancy rate both by intrauterine insemination (IUI) and intracytoplasmic sperm injection (ICSI).
What is known already: Several studies showed the bond of HPV to sperm and/or exfoliated cells and its association with altered sperm parameters. Moreover, some authors demonstrated that infected sperm are able to transmit viral genes to oocyte and that HPV may cause pregnancy loss by DNA fragmentation and apoptosis of embryonic cells. Finally, a recent study performed in couples undergoing ICSI, showed a significant increase of pregnancy loss when HPV DNA was present at sperm level.
Study design, size, duration: Cross-sectional clinical study. Between 2012 and 2014, 182 consecutive infertile patients of couples candidate to assisted reproduction were evaluated at our unit. We included subjects with altered sperm parameters, at least 2 years of unprotected sexual intercourse without conception, and normal female partners with negative PAP test.
Participants/materials, setting, methods: All patients were evaluated for sperm parameters according to world health organization guidelines 2010 and HPV detection on semen was made by fluorescence in situ hybridization (FISH). Patients were followed from the time of diagnosis, through the ART period, to date.
Main results and the role of chance: Among patients, 38 (20.8%) had HPV semen infection (group A) and 144 had not (Group B). Infected males showed the virus bound to sperm or to exfoliated cells or to both cells in 52.6, 26.3 and 21.1% respectively. During diagnosis period, 12 spontaneous pregnancies were recorded only in Group B. IUI was performed in 16 and 49 couples, ICSI in 22 and 83 couples from groups A and B respectively and cumulative pregnancy rates were 13.1 and 38.9% ($p < 0.01$). We recorded 5 pregnancies in group A and 56 in group B and the follow up showed respectively: 1 and 16 healthy born, 2 and 38 ongoing pregnancies, 2 and 2 miscarriages. Interestingly, abortions of group A regarded only patients with infection on sperm.
Limitations, reason for caution: The exact mechanism by which the presence of HPV in sperm is able to reduce pregnancy rate remains unknown and it is worthy of further investigation. Moreover, a larger group of infertile patients with HPV semen infection should be considered to drive final conclusions.
Wider implications of the findings: The high prevalence of HPV sperm infection observed in infertile patients suggests a role for this infection in male infertility. We had no ongoing pregnancies in patients with HPV infection at sperm level. Results from this study rise concern about the possible role of HPV on natural and assisted reproduction outcome. Screening for HPV should be considered in the workup of infertile patients and before ART.
Study funding/competing interest(s): Funding by University(ies) – University of Padova.
Trial registration number: Protocol Number 2331P.

Study question: The study was designed to investigate the effect of *Croton caudatus* Geiseler supplementation on the spermatogenic activity and their histological parameters in the sexual dysfunction-induced rats.
Summary answer: The findings demonstrated that the supplementation of *C. caudatus* roots extract improves the sperm count and quality in Bisphenol A-induced rat model. The histological parameters also revealed that the extract improves the spermatogenesis activity within the seminiferous tubules and does not exhibit toxicity effect to liver and kidney.
What is known already: Sexual dysfunctions cover a wide variety of problems that may be due to low sperm count, poor sperm quality, or both. Advances in phytomedicine have allowed for more efficient and cost-effective treatment of infertility. However, to date, least information is available on the anti-infertility

properties of *C. caudatus* Geiseler. Furthermore, no scientific data about the mechanisms of reversible infertility of this herb have been reported.
Study design, size, duration: Thirty male Wistar rats (9 weeks old) were randomly divided into five groups, namely; the negative control (distilled water); the positive control (200 mg/kg BPA), and the treatment groups which received 16, 32, and 64 mg/kg doses of *C. caudatus* root extracts + 200 mg/kg BPA, orally for twenty one days.
Participants/materials, setting, methods: After twenty one days of treatment, blood were collected and proceeded for liver and renal function test, as well as testosterone level. Sperm parameters were examined using Hamilton Thorne Sperm Analyzer and testis were harvested for histological assessments.
Main results and the role of chance: Overall, results showed *C. caudatus* at 64 mg/kg significantly ($p < 0.001$) increased the total sperm count and progressive cells motility; as well as decreased abnormal sperm morphology. The testosterone hormones were slightly decreased but within normal range. The histological results revealed that normal morphology of germ cells organized in concentric layers of seminiferous tubules. Abundant and compact spermatogenic cells were found on the lumen of seminiferous tubules which indicate the influence of spermatogenesis process that facilitated by this herb.
Limitations, reason for caution: Whilst these animal experiments suggest that this herb improved the spermatogenesis activity, sperm count and motility; as well as reduced sperm abnormalities, future clinical trials should be done in human for scientifically proven.
Wider implications of the findings: Data from this study may serve as an important indicator for anti-infertility agent from this herb. Practising natural treatment for infertility then be carried out for the sterile males, thereby creating a more cost-effective option for infertility treatment. Therefore, combination of sperm parameter, immunological aspects, DNA integrity and understanding of the mechanisms as how this herb influences the sperm activity would give a better insight regarding anti-infertility potential of this herb.
Study funding/competing interest(s): Funding by University(ies) – Funding by national/international organization(s). This research was supported by the Research Acculturation Grant Scheme (RAGS) No: 600-RMI/RAGS 5/3(45/2014), Ministry of Education, Malaysia to Razif Dasiman, Fatimah Sham, Fatin Nadzirah Zakaria and Nina Keterina Hashim. P-050 The effect of microsurgery inguinal varicocelectomy by secondary infertile male patients with clinical varicocele

N. Badur[1], A. Karakeci[2], S. Cayan[3], I. Orhan[2]
[1]*Duzce Government Hospital, Urology, Duzce, Turkey*
[2]*Firat University Hospital, Urology, Elazig, Turkey*
[3]*Mersin University Hospital, Urology, Mersin, Turkey*

Study question: Is Micro Surgery Inguinal Varicocelectomy effective in secondary infertile male patients?
Summary answer: Microsurgery inguinal varicocelectomy is an effective therapy method by secondary infertile patients because of it's improving effect on semen parameters which results in rising of pregnancy rates.
What is known already: Varicocele is the most common correctable causes of male infertility.
Study design, size, duration: During the last four years, sixty primary infertile and thirty secondary infertile patients whom were referred to andrology clinic due to infertility and undergone Microsurgery Inguinal Varicocelectomy operation because of varicocele presence, were retrospectively investigated.
Participants/materials, setting, methods: Patients were assessed according to age, duration of the infertility history, grade of varicocele, pre and postoperative semen parameters and pregnancy rates.
Main results and the role of chance: It was detected that sperm motility and number of total motile sperms with primary infertile group and number of spermia, motile spermia and sperm motility by secondary infertile group have statistically significantly increased after surgical procedure ($p < 0,05$). Pregnancy rate by secondary infertile group was observed as higher as the rate in the primary infertile group which was not statistically significant.
Limitations, reason for caution: The number of participants, retrospective study.
Wider implications of the findings: Pregnancy rate by secondary infertile group was observed as higher as the rate in the primary infertile group which was not statistically significant.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Firat University Hospital.
Trial registration number: NA.
Keywords: varicocele, secondary infertility, microsurgery inguinal varicocelectomy.

P-051 Pharmacological stimulation of sperm motility in microdissection testicular sperm extraction (micro-TESE) using theophylline in patients with non-obstructive azoospermia (NOA)

T. Kartavenko[1], E. Zakharova[1], I. Kapralova[1], I. Krivokharchenko[1], O. Zharskaja[1], Y. Melnik[2], G. Mskhalaya[2], V. Zaletova[3]
[1]*Center for Reproductive Medicine MAMA, Embryology Laboratory, Moscow, Russia C.I.S.*
[2]*Center for Reproductive Medicine MAMA, Andrology Department, Moscow, Russia C.I.S.*
[3]*Center for Reproductive Medicine MAMA, Reproductology, Moscow, Russia C.I.S.*

Study question: To evaluate whether theophylline improves sperm motility and treatment outcomes in micro-TESE in patients with NOA.
Summary answer: Theophylline allowed the selection of live sperm from immotile testicular sperm for intracytoplasmic sperm injection (ICSI), significantly improving fertilization and blastocyst formation rates in patients with NOA.
What is known already: Micro-TESE was shown to be the most effective method of sperm retrieval in patients with NOA. However, few spermatozoa are present in these patients, and, as a rule, those are immotile. Theophylline has been known to be reliable in stimulating testicular spermatozoa. Micro-TESE and theophylline stimulation of sperm motility may significantly increase success rates in patients with NOA.
Study design, size, duration: The study included 43 patients with NOA. Spermatozoa retrieved from all 43 patients by micro-TESE were immotile. Theophylline activation was performed in 24 cases, and then motile sperm was used for ICSI (treatment group). In 19 cases there was no theophylline activation (control group).
Participants/materials, setting, methods: Sperm motility was stimulated by GM501 SPERMMOBIL (Gynemed), according to the manufacturer's protocol. Fertilization, blastocyst formation, and clinical pregnancy (% per ET, % per micro-TESE) rates were compared in the two groups.
Main results and the role of chance: Following activation, 13.44 ± 7.26% of spermatozoa became motile. The fertilization rate (63.41% [104/164] vs. 29.87% [46/154], $p = 0.001$) and blastocyst formation rate (64.42% [67/104] vs. 43.47% [20/46], $p = 0.03$) were significantly higher in the treatment than in the control group. Clinical pregnancy rates per ET (28.57% [6/21] vs. 10.52% [2/19], $p = 0.27$) and per micro-TESE (25% [6/24] vs. 10.52% [2/19], $p = 0.28$) were higher in the treatment than in control group, but the difference was not statistically significant.
Limitations, reason for caution: Micro-TESE and oocyte retrieval were performed simultaneously, using fresh spermatozoa for ICSI. This study is limited by its statistical power in pregnancy rates which is not very high due to the sample size (43 patients).
Wider implications of the findings: Pharmacological stimulation of sperm motility in micro-TESE, using theophylline in patients with NOA, significantly improved fertilization and blastocyst formation rates, as well as improving pregnancy rates comparable to those achieved with spermatozoa from semen.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Center for Reproductive Medicine MAMA, Moscow.
Trial registration number: NA.
Keywords: micro-TESE, pharmacological stimulation, theophylline, ICSI, NOA

P-052 Age independent of body mass index negatively affects semen quality

J. Ngeamvijawat[1], A. Sawangchaeng[1], S. Kiatpongsan[2], P. Virutamasen[2], K. Pruksananonda[2]
[1]*King Chulalongkorn Memorial Hospital, Obstetrics and Gynecology, Bangkok, Thailand*
[2]*Chulalongkorn University, Obstetrics and Gynecology, Bangkok, Thailand*

Study question: To find effects of age and body mass index on semen quality (volume, concentration, total number, motility, rapid movement, progressive movement, normal morphology).
Summary answer: Controlling for body mass index, age is negatively associated with semen volume, total number, motility, rapid movement, and progressive movement. Controlling for age, body mass index is associated with none of semen parameters.
What is known already: Age alone has been known to negatively affect semen quality while body mass index alone does not significantly affect semen quality. However, it is unclear whether age would have differing effects on semen quality at various levels of body mass index.
Study design, size, duration: We investigated the effects of age and body mass index on semen quality via a retrospective cohort study in male patients attending a fertility clinic at King Chulalongkorn Memorial Hospital. One thousand three hundred and seventy-seven patients were included in the study.
Participants/materials, setting, methods: We used multivariate regression models to test for effects of age and body mass index concurrently on each of sperm analysis parameters (volume, concentration, total number, motility, rapid movement, progressive movement, normal morphology). Statistical significance was determined at $p < 0.05$.
Main results and the role of chance: Our participants' mean age was 36.8 years (SD = 6.4). Mean body mass index was 24.9 (SD = 3.6). Controlled for body mass index, age was significantly, negatively associated with semen volume (coefficient = -0.15; $p < 0.001$), total number (coefficient = -0.07; $p = 0.018$), motility (coefficient = -0.16; $p < 0.001$), rapid movement (coefficient = -0.19; $p < 0.001$) and progressive movement (coefficient = -0.19; $p < 0.001$) but not with concentration and normal morphology. Controlled for age, body mass index did not associated with semen volume, concentration, total number, motility, rapid movement, progressive movement and normal morphology.
Limitations, reason for caution: Our study participants were from one fertility clinic. Future studies to include more diverse study population and with fertility outcomes in addition to semen quality can be helpful to validate our findings.
Wider implications of the findings: There was limited evidence on effects of age and body mass index on semen quality in Asian population. This study shows that age but not body mass index is associated with semen quality. With advantages of multivariate regression models, this study showed and confirmed that, independent of body mass index, age is negatively associated with semen quality. This information can be helpful in patient education and counselling.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s) – Chulalongkorn University and King Chulalongkorn Memorial Hospital, Thai Red Cross Society (Bangkok, Thailand)

Keywords: age, body mass index, semen quality

P-053 Effect of leukocytospermia and *in vitro* zinc supplementation on DNA integrity and seminal oxidative stress

A. Sallem[1], Z. Haouas[1], R. Bhouri[1], T. Ajina[1], I. Zidi[1], O. Kacem[2], I. Grissa,[1], H. Ben Cheikh[1], S. Ibala[3], M. Ajina[2], M. Mehdi[1]
[1]*Facullty of Medicine, Laboratory of Histology Embryology and Cytogenetic UR 12 ES 10, Monastir, Tunisia*
[2]*Farhat Hached Hospital, Unit of Reproductive Medicine, Sousse, Tunisia*
[3]*Farhat Hached Hospital, Laboratory of Cytogenetic and Reproductive Biology, Sousse, Tunisia*

Study question: To investigate whether leucocytes and *in vitro* zinc supplementation could interfere with sperm DNA integrity and seminal oxidative stress.
Summary answer: Even a low amount of leukocytes may lead to sperm quality impairment whereas zinc may enhance sperm quality.
What is known already: Oxidative stress is caused by the unbalance between amounts of reactive oxygen species and seminal antioxidant scavenging systems. It seems to be one of the main causes leading to male infertility.
Study design, size, duration: A prospective study performed on 94 semen samples.
Participants/materials, setting, methods: The nitroblue tetrazolium test was carried out for superoxide anion estimation, the TUNEL assay for DNA fragmentation and the acridine orange assay for DNA denaturation. Total antioxidant status and enzymatic antioxidants: superoxide dismutase and glutathione peroxidase were measured using an assay kit. Lipid peroxidation was evaluated by Malondialdehyde production.
Main results and the role of chance: The level of leucocytes was positively correlated with superoxide anion generation ($r = 0.46$; $p < 0.001$) and DNA denaturation ($r = 0.605$; $p = 0.013$). Samples containing leucocytes had a significantly higher DNA fragmentation index compared to control samples. Our results showed that zinc concentration of 6 µmol/L significantly reduced DNA fragmentation ($p = 0.014$) and seminal antioxidant status ($p < 0.001$). Both 2 and 6 µmol/L zinc concentration increased superoxide dismutase level and decreased superoxide anion production ($p < 0.001$). The impact of zinc on both glutathione peroxidase level and lipid peroxidation amount was not significant.
Limitations, reason for caution: DNA fragmentation assay and superoxide anion generation were investigated for each of the 98 samples. While oxidative stress parameters were assayed for only 35. DNA denaturation was performed for 24 samples.
Wider implications of the findings: The findings on the deletirious effect of leukocytospermia are contoversial. we demonstrated that even a few amount of leukocytes leads to sperm quality impairment. So in case of leukocytospermia it could be beneficial to associate zinc to antibiotics. Zinc could also improve assisted reproductive techniques outcomes when added to embryo culture media.
Study funding/competing interest(s): Funding by University(ies) – Laboratory of Histology Embryology and Cytogenetic (UR 12 ES 10), Faculty of Medicine, Street Avicenna, Monastir 5019, University of Monastir, Tunisia.

P-054 Seminal fluid biomarkers and IUI clinical outcome

L. Reisman[1], L. Park[1], Q. V. Neri[1], T. Paniza[1], Z. Rosenwaks[1], G. D. Palermo[1]
[1]*Weill Cornell Medical College, Reproductive Medicine, New York, U.S.A.*

Study question: We questioned whether assessment of fructose level in the seminal plasma of subfertile men can serve as a biomarker coadjutant to standard semen analysis. In addition, we questioned whether fructose and total antioxidant capacity (TAC) can be used to gain information on spermatogenic competence and to predict pregnancy outcome.
Summary answer: Our analysis detected an inverse correlation between fructose level and male age unconnected to sperm parameters. Oligo-/oligoathenospermic men had compromised fructose levels in comparison to the normal fertile cohort. In IUI treatments, men with higher fructose and TAC levels had significantly higher chances of pregnancies.
What is known already: Approximately 65–75% of the seminal fluid is provided by the seminal vesicles and one of the largest biochemical compounds found in this gland is fructose, the main carbohydrate energy source of spermatozoa. Seminal vesicles are also considered a major contributor of antioxidants that protect spermatozoa from oxidative insults and sustain their function and integrity. Fructose and TAC may elucidate genital tract patency and proper function of the male gamete, especially in men with severely compromised sperm parameters.
Study design, size, duration: A total of 80 men were included in this 5-month prospective study. Fructose and TAC were plotted against semen parameters in patients undergoing IUI or IVF.
Participants/materials, setting, methods: Specimens were collected at our center from consenting patients undergoing routine semen analysis. After liquefaction, semen parameters were assessed according to the WHO criteria (2010). The specimens were centrifuged and the cell-void seminal plasma was assessed for fructose and TAC concentrations using colormetric assays on an automated microplate reader ($\Delta OD_{405/570}$).
Main results and the role of chance: In 80 men (39.6 ± 8 years), sperm concentration was 26.7 ± 27 × 10^6/ml and motility 42.7 ± 14%. TAC inversely correlated to abstinence ($P = 0.01$) while positively with semen parameters ($P < 0.05$). TAC increased with fructose ($P < 0.001$) and both decreased with age ($P < 0.05$). Normozoospermic men ($n = 34$) exhibited a fructose (2.1 ± 0.9 µg/mL) higher than oligozoospermic ($n = 18$; 1.6 ± 0.9 µg/mL) and oligoasthenozoospermic ($n = 12$; 1.4 ± 1.2 µg/mL). NOA ($n = 8$; 2.5 ± 0.9 µg/mL) had the highest level of fructose ($P < 0.05$). In 22 men undergoing 41 IUI cycles with their female partner (35.5 ± 5 years), a clinical pregnancy of 17.1%, fructose of 2.8 ± 0.7 µg/mL, and TAC 2001.0 ± 133 nmol/ml, higher than the non-pregnant group (1.8 ± 1.3 µg/mL and 1.783.0 ± 195.6 nmol/ml) ($P < 0.05$). Five couples that failed IUI along with 20 others (maternal age 37.7 ± 5 years) underwent 35 ART cycles and achieved clinical pregnancies of 31.4% with a fructose level of 1.7 ± 1.1 mg and TAC of 1764.4 ± 261.5 nmol/ml.

Limitations, reason for caution: We have two identified seminal biomarkers that may be utilized in addition to a standard semen analysis to assess a man's fertility. While these results are promising, these are still preliminary data and need farther validation.
Wider implications of the findings: The inadequacy of a standard semen analysis to provide information on spermatogenesis has been widely recognized. Due to the concurrent dependence of seminal vesicle function and spermatozoa production under gonadotropic control, fructose assessment may provide insight on the germinal epithelium integrity**.** The interpretation of semen biomarkers such as the assessment of fructose and TAC may be particularly useful in diagnosing infertile men and to select appropriate insemination methods.
Study funding/competing interest(s): Funding by University(ies) – Reproductive Medicine, Weill Cornell Medical College.
Trial registration number: NA.
Keywords: total antioxidant capacity TAC, fructose, seminal plasma, ICSI, IUI

P-055 Seminal fluid ROS-buffering capacity relates to sperm parameters, chromatin integrity and embryo developmental competence

L. Park[1], Q. V. Neri[1], Z. Rosenwaks[1], G. D. Palermo[1]
[1]*Weill Cornell Medical College, Reproductive Medicine, New York, U.S.A.*

Study question: We question whether seminal plasma's total antioxidant capacity (TAC) has any effect on spermatozoa parameters, predicts male genome integrity, or impacts the ability of the male gamete to participate in embryo development. Therefore we wonder whether TAC measurement may aid in the prognostication of male factor infertility.
Summary answer: TAC decreases by lengthening the abstinence period, but increases with sperm concentration, motility, and morphology. TAC protects the sperm's chromatin's, as inferred by mean sperm DFI. Most importantly, a compromised TAC in the inseminating specimen was accompanied by a lower chance of pregnancy.
What is known already: The use of seminal biomarkers to predict gamete health and embryo developmental competence is under investigation. During spermiogenesis and throughout the genital tract, reactive oxidative species (ROS) are generated from developing, maturing, and decaying spermatozoa. The natural buffering capacity of seminal plasma reduces the effect of oxidative insults and sustains spermatozoa motility, preserving their competence. Direct and indirect assays to measure ROS are currently being validated to screen male factor infertility.
Study design, size, duration: Prospectively during the last 5 months, we assessed TAC in ejaculates of 65 men. We plotted TAC against semen parameters and sperm DNA fragmentation index (DFI). For subjects that underwent IUI and ART with their female partners, the relationship between TAC and clinical outcome was investigated.
Participants/materials, setting, methods: TAC, in Trolox equivalents was assessed by a colorimetric assay on an automated microplate reader (ΔOD_{405}). Direct ROS damage to sperm DNA was evaluated by TUNEL. For most of these men, their reproductive outcomes with IUI and ART were evaluated in relation to the TAC of the inseminating specimen.
Main results and the role of chance: In 65 men (39.7 ± 8 years), sperm concentration was 35.9 ± 25 × 10^6/ml, motility 42.7 ± 14%, and morphology 2.4 ± 1%. The TAC for normozoospermic men (n = 34) was 1965.9 ± 212 nmol/ml and for oligoasthenozoospermic (n = 12), 1720.2 ± 264.3 nmol/ml (P = 0.01). TAC inversely correlated to abstinence (P = 0.01) while positively with semen concentration, motility, and morphology (P < 0.05). In 13 subjects, a lower TAC was associated with compromised sperm DFI (P < 0.001). In 22 couples (maternal age 35.5 ± 5 years) treated in 41 IUI cycles, clinical pregnancies of 17.1% (n = 7) were accompanied by a TAC of 2001.0 ± 133 nmol/ml. This was higher than in couples whose treatments did not result in pregnancy (n = 15; 1783.0 ± 195.6 nmol/ml) (P < 0.01). Five couples (maternal age 37.7 ± 5 years) who failed IUI, along with 17 others with a suboptimal TAC (1,741.6 ± 296 nmol/ml) were treated in 32 ICSI cycles, resulting in a clinical pregnancy rate of 25.0%.
Limitations, reason for caution: Even though the benefit of a higher antioxidant capacity exerted by the seminal plasma has an undisputed benefit on the health and performance of the male gamete, this biomarker is not yet validated as a valuable screening assay for male gamete performance.
Wider implications of the findings: The limitations of the semen analysis to screen for male factor infertility are apparent and additional biomarkers are needed to acquire further insight on spermatozoa function and its structural integrity. Seminal TAC, an indirect measurement of ROS, provides information on sperm DNA integrity and may help predict IUI outcomes. TAC level in the ejaculate improves male factor infertility screening and helps steer the infertile couple toward the proper insemination method.
Study funding/competing interest(s): Funding by University(ies) – Reproductive Medicine, WCMC.

P-056 Seminal biomarkers to guide sperm sourcing

T. Paniza[1], T. Cozzubbo[1], Q. V. Neri[1], L. Park[1], M. Goldstein[2], Z. Rosenwaks[1], G. D. Palermo[1]
[1]*Weill Cornell Medical College, Reproductive Medicine, New York, U.S.A.*
[2]*Weill Cornell Medical College, Urology, New York, U.S.A.*

Study question: Insight on the protective effect of seminal antioxidant capacity on sperm DNA integrity and its effect on gamete characteristics and embryo developmental competence has guided us to perform this experiment. We question whether sampling the male gamete proximal to the germinal epithelium yields spermatozoa with a healthier genome.
Summary answer: DNA fragmentation index originates during spermiogenesis and progressively increases as the sperm traverses the male genital tract. When compounded by an impaired level of total antioxidant capacity (TAC) in the ejaculate, elevated DFI may justify offering alternative sperm sourcing to aid positive IVF outcomes.
What is known already: During the later stages of spermiogenesis DNA breakage is physiologically induced to allow tight chromatin compaction. While most spermatozoa undergo DNA repair, oxygen free radicals are the main cause of DNA injury. The buffering capacity of seminal antioxidants is the only agent protecting the DNA integrity of spermatozoa in the ejaculate. Therefore, testing the sperm's DFI and concurrent seminal TAC is essential to assess gamete competence.
Study design, size, duration: Over 15 months, men with extremely high DFI in their ejaculates (n = 36) received a TAC analysis on seminal fluid. Following counseling, men underwent surgical sampling, often bilateral, from vas deferens, epididymis, and testis. DFI and clinical outcome were recorded and compared for each individual sperm sourcing for men undergoing ICSI.
Participants/materials, setting, methods: Ejaculates processed in standard fashion were assessed for DFI and TAC. Surgical samples minced and smeared for DFI evaluation were cryopreserved for later use in ICSI. DNA fragmentation was measured by TUNEL on specimens isolated from all sites. TAC was determined by a colorimetric assay on an automated microplate reader.
Main results and the role of chance: In 51 ejaculates the average DFI was 49.8 ± 25.2% (range 26.0–96.0). In some men (n = 13), the DFI had a clear inverse correlation with TAC (P = 0.001). In 4 men aspiration of the vas deferens resulted in 19.3 ± 4.8% DFI (range 15.7–30.0) while in 16 men epididymal sampling yielded 19.0 ± 7.0% DFI (range 8.4–33.8) and in 33 the DFI on testicular spermatozoa was 13.2 ± 6.7% (range 2.0–27.0). The DFI progressively decreased as we retrieved proximally toward the vas deferens (P = 0.005), the epididymis (P = 0.0001), and testis (P = 0.0001). ART outcome achieved by ICSI treatment using these surgical sources yielded a clinical pregnancy of 34.3%, higher than with the ejaculate at 20.0%.
Limitations, reason for caution: Patients need to be informed of risks regarding surgery, anesthesia, and be aware that even with surgical spermatozoa a pregnancy may not occur. Thus, counseling should be conducted since many of these men have spermatozoa in their ejaculate. These data are still preliminary that require an evidence-based consensus.
Wider implications of the findings: The topographic sourcing of spermatozoa from different levels of the male genital tract indicates that disruption of DNA integrity, although starting during spermiogenesis, may actually suffer the additional effect of oxidative stressors that combined with a compromised TAC yield higher DFI in the ejaculate. Couples with recurrent pregnancy failures and ejaculated spermatozoa with high DNA fragmentation may benefit from undergoing surgical sampling for diagnostic and therapeutic purposes.
Study funding/competing interest(s): Funding by University(ies) – Reproductive Medicine, Weill Cornell Medical College.
Trial registration number: NA.

P-057 A seminal biomarker of germinative epithelium integrity

T. Cozzubbo[1], Q. V. Neri[1], S. Cheung[1], T. Paniza[1], Z. Rosenwaks[1], G. D. Palermo[1]
[1]Weill Cornell Medical College, Reproductive Medicine, New York, U.S.A.

Study question: To characterize the origin and meaning of round cells (RC) in the human ejaculate. We question the relationship of this sporadic marker with male gamete characteristics. We also wonder about the embryo developmental competence of spermatozoa presenting with RC.
Summary answer: RC are not related to infectious agents but are almost exclusively comprised of multiple, haploid nuclei generated during an offset spermatogenesis. RC may serve as an indicator of an injured germinal epithelium caused by a seasonal ailment affecting sperm production, chromatin integrity and sperm aneuploidy.
What is known already: The source of round cells in the ejaculate has always been a puzzling conundrum. The lack of an association of round cells with infectious agents together with their apparent beneficial effect on the competence of the male gamete's contribution to embryo developmental has further contributed to this equivocal interpretation.
Study design, size, duration: A total of 4,810 men undergoing male infertility screening over a 24-month period were included in this prospective study. Specimens utilized for ART were grouped according to [RC] 1–1.9 and ≥2 × 10^6/mL and compared to a control. LeucoScreen™, cytoplasmic markers, ploidy assessment, and TUNEL assay were used to typify RC.
Participants/materials, setting, methods: Ejaculates were grouped in relation to RC amount and evaluated for ART outcome. In men with repetitive observations, semen parameters were assessed in relation to the RC occurrences throughout the calendar year. To assess their spermiogenic stage, round cells were stained for ploidy, DFI, vimentin, inhibin, and protamine.
Main results and the role of chance: Prevalence of samples with RC was 5.4% (n = 261) with normal semen parameters. RC were comprised mostly of immature germ cells (IGC)(range 0.79–24.9 million) with the remainder being WBC at 26.7%. Most specimens (97%) were negative for uropathogens. IGC were composed of single or multiple haploid nuclei similar to that of spermatozoa, but decondensed with lower protamine content. Spermatozoa with IGC had a higher DFI (P = 0.0001) and aneuploidy (P = 0.0001). The DFI of IGC itself was higher than the accompanying spermatozoa (P = 0.0001). Men (n = 27) (42.3 ± 8 years) that underwent 33 ICSI cycles with their female partner (38.0 ± 4 years) reported decreased number of ongoing pregnancies and deliveries, but yielded higher pregnancy losses than a control (P < 0.05). Manifestation of RC had a biannual distribution overlapping the influenza profile of New York State.
Limitations, reason for caution: Seminal round cells are linked to the integrity of spermatogenesis and may bring new insights into the mechanism of recovery of the germinal epithelium following ordinary insult. However, ART outcome's correlation with the presence of this marker needs farther evaluation.
Wider implications of the findings: Genetic and epigenetic assessments of RC portray them as abnormal spermiogenic products engulfed in sloughed sertolicell cytoplasm. This suggests that the appearance of RC represent an effort by the germinal epithelium to restore spermatozoa production following an insult, as proven by the subsequent increase in sperm concentration. This accelerated turnover yields spermatozoa with increased DFI and aneuploidy. The apparent relation to seasonal illness may widen our understanding of the fluctuations of male fertility.
Study funding/competing interest(s): Funding by University(ies) – Reproductive Medicine, Weill Cornell Medical College.
Trial registration number: NA.

P-058 The total number of normal morphology and progressively motile sperm: a novel semen parameter as a predictor of *in vitro* fertilization

H. Liu[1], J. Cai[1], B. Yin[1], G. Li[1], T. Wu[1], M. Mo[1], Y. Zeng[1]
[1]Shenzhen Zhongshan Urology Hospital, Shenzhen Key Laboratory for Peri-implantation Reproductive Immunology, Shenzhen, China

Study question: At present, it is still not clear which patients with male factor subfertility would benefit from conventional *in vitro* fertilization (IVF) and which patients need intra-cytoplasmic sperm injection (ICSI). No single semen parameter can be used conclusively to predict IVF outcome.
Summary answer: We proposed a novel combined parameter, the total number of normal morphology and progressively motile sperm (TNPS), to predict the outcome of *in vitro* fertilization.
What is known already: In many IVF centers, post-wash total motile sperm count is assessed in male factor subfertility to predict pregnancy during intrauterine insemination. However, recent evidence suggests that strict criteria sperm morphology is more closely relate to fertilization outcome. But no studies have provided a clear rule to differentiate between patients who do or do not need ICSI for fertilization.
Study design, size, duration: This retrospective study contains 1831 couples who performed their first IVF cycle between January 2011 and December 2013 in our center. The average TNPS during three months before IVF were calculated and the effects of TNPS on the fertilization outcome were assessed.
Participants/materials, setting, methods: TNPS in the ejaculate is calculated by multiplying the semen volume by the sperm concentration by the percentage of progressively motile sperm by the percentage of normal morphology. We divided five groups according to TNPS percentile and compared fertilization rate, cleavage rate, good embryo rate and pregnancy rate between groups.
Main results and the role of chance: The median value of TNPS is 11.2 × 10^6 and the 5th percentile was 1.5 × 10^6. In the group of TNPS < 1.5 × 10^6 (Group A), the fertilization rate was significantly lower (72.9%) than in any of the subgroups with TNPS ≥1.5 × 10^6. With the TNPS increased, the fertilization rate was significantly improved. Besides, the cleavage rate, good embryo rate and pregnancy rate in group A were also less than other groups, although not significantly. Furthermore, when TNPS < 1.5 × 10^6, the incidence of poor fertilization (IVF fertilization rate ≤ 50%) increased significantly (12.6%), higher than in any other groups. In this case, ICSI should be admitted to avoid IVF failure.
Limitations, reason for caution: The cutoff value was set at the 5th percentile of TNPS (1.5 × 10^6) according to a retrospective analysis in this study. A prospective study with larger samples should be performed and receiver operating characteristic curve (ROC) could be used to get a more objective cutoff value.
Wider implications of the findings: TNPS could be considered as an evaluating indication of semen quality in IVF therapy, in order to avoid unpredictable fertilization failure and meanwhile avoid overuse of more invasive ICSI procedure. For those patients with TNPS <1.5 × 10^6, half-ICSI or ICSI could be suggested.
Study funding/competing interest(s): Funding by national/international organization(s) – This study was supported by Shenzhen committee of innovation of science and technology (no. JCYJ20140415114532535 and no. JCYJ20130401092000370).
Trial registration number: NA.

P-059 Sperm DNA fragmentation index is significantly associated with the total volume of vacuoles in the sperm head: a prospective study

C. Knight[1], S. Cooke[1], K. Boyle[1], C. A. Venetis[2], S. Khashaba[2], M. Chapman[2]
[1]IVF Australia, Embryology Lab Western Sydney, Sydney, NSW, Australia
[2]University of New South Wales, School of Women's and Children's Health, Sydney, NSW, Australia

Study question: Is there an association between the percentage of DNA Fragmentation Index (DFI) in a sperm sample and the distribution of the total volume of vacuoles (TVOV) present in the sperm head?
Summary answer: The finding of this prospective study shows that, in a sperm sample, DFI groups (0–14.9%, 15.0–29.9%, and ≥30%) are associated with the percentage of sperm with either a small (0–4.99% of the total sperm head volume) or a large (≥11% of the total sperm head volume) total volume of vacuoles.
What is known already: Previous studies have demonstrated that the presence of vacuoles in a sperm head may affect the outcome of any resulting embryos leading to implantation failure and miscarriage. Intracytoplasmic morphologically selected sperm injection (IMSI) has been proposed as a suitable intervention for such cases. It is hypothesized that the presence of these vacuoles is associated with DNA damage and thus determining DFI in a sperm sample will aid in identifying patients that would benefit from IMSI.
Study design, size, duration: This was a prospective study of 311 sperm samples (with ≥5% motility and concentration >2 million/ml) from men attending

an IVF clinic. DFI was determined and 400 motile sperm from each sample were assessed for the presence of vacuoles and the total volume of these vacuoles was measured.

Participants/materials, setting, methods: The DFI of sperm samples was analysed using the Sperm Chromatin Structure Assay (SCSA), with the high magnification assessment of sperm being carried out independently using 'IMSI Strict' (Hamilton Thorne) software program. Total volume of vacuoles was determined as 0–4.9%, 5–10.9%, and ≥11% in size.

Main results and the role of chance: 221 participants had a low-range (0–14.9%), 73 a mid-range (15.0–29.9%), and 17 a high-range DFI (≥30%). The percentage of sperm with 0–4.9 or ≥11% TVOV differed significantly between the three DFI groups ($p = < 0.001$). Using regression analysis, it was shown that the percentage of sperm with 0–4.9 or ≥11% TVOV was associated with the DFI group of a sample ($p = < 0.001$). For every unit of increase in the percentage of sperm with ≥11% TVOV the odds of a DFI ≥30% were increased by 5% [odds ratio (OR): 1.05, 95% CI: 1.03–1.08] while the odds of a DFI < 15% were decreased by 4% (OR: 0.96, 95% CI: 0.94–0.98). The percentage of sperm with ≥11% TVOV could discriminate between samples with a DFI ≥30% or < 30% (AUC: 0.903, 95% CI: 0.864–0.933).

Limitations, reason for caution: Patients with very poor sperm parameters (motility and concentration) were not included in this study. Although DFI cannot be determined in these patients, it cannot be excluded that, they might also have a high percentage of ≥11% TVOV and thus might benefit from IMSI.

Wider implications of the findings: This study shows that TVOV is associated with DFI and whilst diagnostic assessment of DFI and TVOV will be useful in the pre-treatment evaluation of subfertile couples, the use of IMSI in couples where the male has a high DFI might be of value to prevent highly vacuolated sperm being used clinically and thus create embryos that have a better developmental potential.

[4]Royan Institute for Reproductive Biomedicine ACECR, Department of Andrology at Reproductive Biomedicine Research Center, Tehran, Iran

[5]University of Sheffield, Academic Unit of Reproductive and Developmental Medicine, Sheffield, United Kingdom

Study question: What is the relationship between sperm DNA damage and Toll like Receptors (TLRs) expression, their signalling pathways, as well as inflammatory cytokine production in human fallopian tube cells?

Summary answer: Sperm with high DNA fragmentation increase TLRs and their signalling pathways gene expression as well as inflammatory cytokine production in human fallopian tube cells.

What is known already: Sperm DNA damage is a useful biomarker for male infertility which is associated with reduced embryo quality, fertility and pregnancy rate. TLRs are the major compartment of innate immune system. It is well established that microbial PAMPs are ligand for TLRs. However, it is becoming clearer that certain locally produced endogenous substances can also stimulate TLRs like reactive oxygen species (ROS). In addition, ROS and apoptosis are the most discussed causes of DNA damage.

Study design, size, duration: Ten Fresh semen samples were obtained from unexplained infertile couple with DNA fragmentation more than 20% (by TUNEL assay) and without infection. Ten normozoospermic healthy donors with DNA fragmentation less than 3% were selected as a control. All these semen samples, after washing were co-incubated with human fallopian tube cell line (OE-E6/E7) in triplicate for 24 h.

Participants/materials, setting, methods: TLRs genes and protein expression in OE-E6/E7 cell line was investigated By RT-PCR and Immunostaining respectively and compared with human fallopian tube tissue. After co-incubation of high and low DNA fragmented sperm with fallopian tube cell line, Toll like receptors 1–6 and their adaptor molecules were evaluated by quantitative PCR. Supernatant were used for the measurement of Interleukin 6 (IL6), Interleukin 8 (IL8), Tumor Necrosis factor alpha (TNFα) by ELISA.

Main results and the role of chance: TLR1–6 gene and protein were expressed in OE-E6/E7, like fallopian tube tissue. The mean relative expression of TLR genes 1–6 were higher significantly in response to sperm with high DNA fragmentation in compared to sperm with low DNA fragmentation ($P < 0.05$). Also, The mean relative expression of MyD88, TIRAP and TRIF(TICAM 1), were significantly increased in case group than control. However, in TRAM (TICAM2) pathway the result was not significant($P < 0.05$). Measurement of IL-6, IL-8 and TNFα by ELISA showed an elevation of IL-6 and IL-8 in response to sperm with high DNA damage than Low one ($P < 0.05$). TNFα in both groups were below the lower detection limit of the kit.

Limitations, reason for caution: The results need to be confirmed in more cases.

Wider implications of the findings: Sperm DNA damage plays an important role in immunological interaction of sperm with female reproductive tract. Excessive ROS production causes lipid peroxidation and oxidative DNA damage, which leads to DNA fragmentation. Besides, fatty acids and reactive oxygen species (ROS) are the endogenous ligands of TLRs. Maybe, by this mechanism, DNA fragmentation can increase TLR expression and more production of inflammatory cytokine as well as causes infertility in high DFI unexplained infertile men. So, evaluation of DNA damage should be considered in treatment of these patients due to exessive Inflammatory cytokine production.

P-061 The relationship between occupational exposures and semen quality among South Tunisian infertile men: a questionnaire study

S. Daoud[1], Chakroun-N. Feki[1], A. Sellami[1], R. Frikha[1], Bouayed-N. Abdelmoula[1], K. Chaabene[2], L. Ammar-Keskes[1], T. Rebai[1]

[1]Medical School of Sfax, Histology-Embryology Laboratory and Research Unit, Sfax, Tunisia

[2]Hedi Chaker Academic Hospital, Gynaecology and Obstetrics Department, Sfax, Tunisia

Study question: The aim of this study was to investigate the association between semen quality and self-reported occupational exposure using a questionnaire that was developed for use in routine consultation.

Summary answer: Self-reported exposure to pesticides and cement was strongly associated with impaired semen quality. Exposure to physical risk factors, such as mechanical vibrations and excess heat, was not associated with sperm anomalies.

What is known already: The decline in sperm quality reported over the last decades have raised concerns about the detrimental effect of occupational exposures on male fertility. Assessing effects of occupational risk factors on fertility is difficult given the wide variety and the limitations of epidemiologic methods used for this purpose (Job Exposure Matrices, quantitative measurements, questionnaires).

Study design, size, duration: We conducted a retrospective cross-sectional study among 2122 men who have consulted for couple infertility during the past 16 years. Subjects aged under 20 or above 55 years or with a known male infertility factor that wouldn't be linked to occupational exposures were excluded.

Participants/materials, setting, methods: All patients data were collected through a questionnaire designed to be used in routine consultation and to assess the most common occupational risks of male fertility impairment according to the literature. Data obtained were used to classify subjects into exposed and unexposed groups. Exposure effects on semen parameters were investigated.

Main results and the role of chance: An association between pesticides exposure and decreased semen volume, motility and vitality was found. Exposure to

pesticides was also associated with significantly higher risk of asthenospermia (adjusted odds ratio [OR] – 1.6; 95% confidence interval [CI], 1.0?2.4) and necrospermia (OR – 2.6; 95% CI, 1.4?4.7). Exposure to cement was found to be correlated to a higher risk of oligospermia (OR – 1.1; 95% CI, 0.9?1.4). Exposure to solvents, mechanical vibrations and excess heat was not associated with semen impairment.

Limitations, reason for caution: The retrospective collection of data and the lack of information on the intensity and duration of occupational exposures were the major limitations of this study.

Wider implications of the findings: There are few data in the literature about the relationship between cement exposure and semen quality. Further work is needed in the future in order to elucidate the mechanisms through which cement components could affect semen parameters. The present study validates the usefulness of questionnaires as a tool for occupational exposure survey. Thus, its use in routine consultation could be helpful for the prevention and management of occupational exposure in infertile men.

Study funding/competing interest(s): Funding by University(ies) – Medical school of Sfax, University of Sfax, Tunisia.

P-062 Prevalence and characteristics of isolated LH and isolated FSH deficiencies in white-European men presenting for primary couple's infertility – results of a cross-sectional survey

S. Ippolito[1], L. Boeri[1], E. Ventimiglia[1], P. Capogrosso[1], G. La Croce[1], A. Serino[1], G. Castagna[1], A. Pecoraro[1], M. Paciotti[1], R. Scano[1], D. Rocchini[2], F. Montorsi[1], A. Salonia[1]

[1]IRCCS Ospedale San Raffaele Milan Italy, Division of Experimental Oncology/Unit of Urology URI, Milano, Italy

[2]Magna Graecia University Catanzaro Italy, Research Doctorate Program in Urology, Milano, Italy

Study question: The prevalence of isolated Luteinizing Hormone (LH) and isolated Follicle Stimulating Hormone (FSH) deficiency is little known in the male population. We assessed prevalence, clinical and seminal characteristics of single LH and FSH deficiency in a cohort of white-European men presenting for primary couple's infertility.

Summary answer: Isolated deficit of LH and FSH account for roughly 2% each in men presenting for primary couple's infertility. Infertile men with isolated LH deficiency have an overall underactive endocrine testicular compartment. Both FSH and LH isolated deficiency are associated with higher prevalence of comorbidities and a lower left testicular volume.

What is known already: Isolated deficiencies of LH or FSH are thought to be extremely rare, but few reported data exists at this regard. Significant association with alterations in sperm parameters was found when considering normal sperm morphology and motility. No significant correlation with age or semen volume has been reported. Isolated LH deficiency has been related to decreased virilization, eunuchoidal proportions and hypogonadal testosterone levels despite normal testicular size and preserved spermatogenesis.

Study design, size, duration: A cross-sectional survey of 2100 white-European men seeking consult for infertility issues in the last ten years was performed. Prevalence of isolated deficit of LH (defined as LH <1.5 mUI/mL) and of FSH (defined as FSH <1.5 mUI/mL) were defined respectively.

Participants/materials, setting, methods: Health-significant comorbidities were scored with Charlson Comorbidity Index (CCI; categorized 0 vs. 1 vs. ≥2). Testicular volume was assessed with a Prader orchidometer. Semen analysis values were assessed basing on 2010 World Health Organization criteria. Descriptive statistics tested association between clinical characteristics /semen parameters and isolated LH or FSH deficiencies.

Main results and the role of chance: Isolated LH and FSH deficiencies were found in 55 (2.6%), and 46 (2.2%) men, respectively. Patients with isolated LH deficiency were older ($p = 0.02$), had higher mean BMI ($p = 0.02$), greater prevalence of obesity (NIH class ≥1) (Chi^2:9.51; $p < 0.01$) and more comorbidities, defined as CCI ≥1 (Chi^2: 20.2; $p < 0.001$), as compared with those with normal/high value of LH. Similarly, lower left testicular volume ($p = 0.025$), lower mean total testosterone and SHBG ($p = 0.002$ both) and higher prevalence of hypogonadism (Chi2:26.3; $p < 0.001$) were reported. On the other hand, patients with isolated FSH deficiency showed higher rate of comorbidities (Chi2:5.9; $p = 0.02$) and lower mean left testicular volume ($p = 0.04$) as compared with those with a normal/high value of FSH. No significant differences were observed in terms of seminal parameters in both cases.

Limitations, reason for caution: Major limitation is the cross-sectional design of our study.

Wider implications of the findings: We demonstrated that isolated LH or FSH deficiencies account together of almost 5% of patients in our population. Thus these conditions deserve consideration not only as infertility work-up issues but also as points of general health in the infertile male.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Ospedale San Raffaele, Milano.

P-063 Progressive stages of diabetes mellitus induce testosterone deficiency promoting a modulation of Sertoli cell metabolism

L. Rato[1], M. G. Alves[1], A. I. Duarte[2], M. S. Santos[2], P. I. Moreira[2], J. E. Cavaco[1], P. F. Oliveira[1]

[1]Health Sciences Research Centre, Faculty of Health Sciences – University of Beira Interior, Covilhã, Portugal

[2]CNC – Centre for Neuroscience and Cell Biology, University of Coimbra, Coimbra, Portugal

Study question: How does Sertoli cell (SC) metabolism responds to the reduced testosterone (T) levels induced by progressive stages of diabetes mellitus (DM)?

Summary answer: T deficiency promoted by progressive stages of DM does not favor glycolytic flux in SCs. Glucose taken up by SCs is not as efficiently converted into lactate in T deficient conditions, being partly redirected to other metabolic pathways.

What is known already: DM is a metabolic disease that compromises male fertility through the induction of hormonal deregulation. Within seminiferous epithelium, androgen receptors are exclusively expressed in SCs and under culture conditions androgens induce a metabolic shift from a Warburg-like into an oxidative Krebs cycle metabolism in SCs. Under detrimental conditions, SCs use alternative substrates as a compensatory mechanism to ensure the adequate conditions for germ cell development and to counteract the deleterious effects of DM.

Study design, size, duration: SCs obtained from normal Wistar strain rats ($n = 6$) and from rodent models of prediabetes (PreD) ($n = 6$) and type 2 diabetic mellitus (T2DM) ($n = 6$) were cultured during 96 h with sex steroid concentrations within the physiologic range (T-CTR group), PreD conditions (T-PreD group) and T2DM conditions (T-T2DM group).

Participants/materials, setting, methods: Metabolite secretion/consumption profile of cultured SCs was evaluated by ^{1}H-NMR spectrometry. Protein expression levels were assessed by Western blot. Intracellular glycogen content was quantified by using specific kits. Lactate dehydrogenase activity was determined using a commercial assay kit. Alanine aminotransferase activity was determined by spectrophotometric methods.

Main results and the role of chance: Both glucose and pyruvate consumption were significantly decreased in PreD conditions, whereas T2DM conditions reversed this profile. Lactate production was not significantly altered at the end of the treatment, although the expression and activities of the lactate production-associated proteins were increasingly affected by progressive T-deficiency conditions. Alanine production was significantly increased in SCs of both groups, suggesting an alternative metabolic fuel. Notably, intracellular glycogen content was only increased in SCs of the T2DM group.

Limitations, reason for caution: Not applicable.

Wider implications of the findings: These results illustrate that gradually reduced T levels, induced by progressive stages of DM, impair glycolysis favoring glycogen metabolism, with the more pronounced effects being concurrent with lower T levels. Even in the T2DM conditions, SCs were able to adapt their metabolism to sustain lactate metabolism. This report highlights the physiologic significance of T in the regulation of the glycolytic profile of SCs metabolism, in particular when associated with the progression of T2DM.

P-064 Serum micro-RNA-155 as a new biomarker of male fertility

A. Giwercman[1], J. Bobjer[1], H. Rastkhani[1], E. Dermitzaki[2], M. Katrinaki[2], A. N. Margioris[2], Y. Lundberg Giwercman[3], C. Tsatanis[2]
[1]Lund University, Department of Translational Medicine Molecular Reproductive Medicine, Malmö, Sweden
[2]School of Medicine University of Crete, Department of Clinical Chemistry-Biochemistry, Heraklion, Greece
[3]Lund University, Department of Translational Medicine Molecular Genetic Reproduction, Malmö, Sweden

Study question: Are serum levels of micro RNAs miR-155 and miR-146a potential biomarkers of male fertility?
Summary answer: Serum levels of miR-155 but not miR-146a were associated with risk of male subfertility and combination of miR-155 and FSH analysis gave higher predictive value than any of the markers separately.
What is known already: Male subfertility has been associated with low grade systemic inflammation (LGSI) as well as with androgen deficiency. MiR-155 and miR-146a are central regulators of inflammation and their levels in cells and in the serum has been associated with several inflammatory conditions but their possible association with male fertility is, so far, unknown..
Study design, size, duration: Case control study, based on two independent groups of 60 men – an exploratory and a confirmatory cohort. The subjects were selected among those included in a larger study performed during the period 2007–2012.
Participants/materials, setting, methods: Both the exploratory and the confirmatory cohort included 60 men each; 40 from infertile couples, without known female factor, and 20 age-matched population-based controls. Total RNA was isolated from cell-free serum. As internal control, the synthetic miRNA UniSp6 was added to each sample. Micro RNAs were measured by real-time RT-PCR.
Main results and the role of chance: Serum levels of miR-155 were associated with levels of miR-146a, but only miR-155 was associated with subfertility (means: for subfertile group 1.88 U vs. 1.15, 95% CI 1.0–1.2 U in controls; $p = 0.001$). ROC analysis indicated that miR-155 with a cutoff value of 1.77 U had 47% sensitivity and 95% specificity for identifying subfertility and positive and negative predictive values of 95 and 47% respectively. When used in combination with FSH, sensitivity and specificity were 80 and 100% respectively while positive and negative predictive values were 100 and 71% respectively, those values being higher than for the FSH alone.

In order to exclude the risk of chance, the results obtained in the exploratory cohort were repeated in an independent confirmatory cohort.
Limitations, reason for caution: Although our primary results were confirmed in the new cohort, studies from other centers are needed to establish the role of miR-155 as a new biomarker of male fertility. Furthermore, the role of this marker in distinguishing between different groups of male subfertility is to be elucidated.
Wider implications of the findings: Association of the inflammatory miRNA miR-155 with fertility may contribute to our understanding of the pathophysiology of subfertility and suggests a novel biomarker. Serum miR-155 in combination with FSH has higher diagnostic specificity and sensitivity compared to FSH. Thus, this finding may have interesting biological and clinical implications in relation to understanding and managing fertility problems.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s), Funding by national/international organization(s) – Lund University, Skane University Hospital, Swedish Governmental Fund for Clinical Research, Skane county council's research and development foundation.

[5]Centre for Reproductive Genetics Alberto Barros Director Av. do Bessa 240 1º Dto. Frente 4100-012 Porto Portugal and Department of Genetics Director Faculty of Medicine University of Porto Alameda Prof. Hernâni Monteiro 4200-319, Porto Portugal, Director, Porto, Portugal

Study question: Is Whole Exome Sequencing (WES) able to establish a genetic diagnosis of total sperm immotility in a patient with situs-inversus totalis?
Summary answer: WES analysis revealed a novel homozygous missense variant in *CCDC103* and a novel frame-shift variant in *INSL6*. These were considered the most plausible causes, respectively, of the absence of dynein arms and of the total sperm immotility in the patient with *situs inversus totalis*.
What is known already: Sperm immotility is one of the major causes of male infertility, but the genetic basis of sperm motility is not fully understood. In the present study, we analysed one patient with total sperm immotility and situs inversus totalis using WES, a technique not yet applied to the genetic screening of these patients.
Study design, size, duration: A genetic screening was performed in a patient with situs-inversus totalis in search for the cause of total sperm immotility due to complete absence of dynein arms and nexin links.
Participants/materials, setting, methods: The exome of a patient with situs inversus totalis and total sperm immotility due to complete absence of dynein arms and nexin links was sequenced using the AmpliSeq strategy on an Ion Proton next-generation sequencing platform using the optimized parameters for WES.
Main results and the role of chance: From more than 50,000 DNA sequence variants, with the GEMINI database framework, the Ion Reporter, bioinformatics and the BAM file, six were confirmed by Sanger sequencing as true variants. The novel homozygous variant c.104G > C at exon 2 of ***CCDC103*** (dynein arm attachment factor), is suggested as potentially pathogenic by three different bioinformatic softwares (SIFT, Polyphen-2, MutationTaster). The novel heterozygous deletion in the coding region (c.262_263del) of *INSL6* was also considered disease-causing. Two other heterozygous misssense variants were identified, in genes *DNAH10* and *DNAH6* (novel) that encode proteins of the dynein heavy chain. Although predicted to be damaging they need further studies. Finally, the two missense heterozygous variants were found in genes *GAS8* (novel) and *SPAG17* (novel), but no pathogenic impact was predicted.
Limitations, reason for caution: WES faces some limitations with a considerable rate of false-positive variants generated by misaligned reads or sequencing errors and consequently Sanger sequencing is still needed to confirm the results. Further, WES only covers the exonic regions, meaning that non-coding variants that may be associated with the disease are not detected.
Wider implications of the findings: WES appeared the most effective technical approach to study cases with total sperm immotility. With this work we expect to increase the knowledge on the genetics of sperm immotility to allow future identification of potential genetic biomarkers and treatments.
Study funding/competing interest(s): Funding by University(ies) – This work was financed by the Institutions of the authors and in part by UMIB, which is funded by National Funds through FCT-Foundation for Science and Technology, under the Pest-OE/SAU/UI0215/2014.
Trial registration number: NA.

P-066 Titanium dioxide nanoparticles reduce human sperm DNA stability

L. Rocco[1], M. Santonastaso[1], F. Caprio[2], F. Mottola[1], V. Stingo[1], N. Colacurci[2]
[1]Second University of Naples, DiSTABiF, Caserta, Italy
[2]Second University of Naples, Department of Woman Child and General and Special Surgery, Naples, Italy

Study question: In this study we investigated the damage to chromatin integrity and the consequent DNA fragmentation in human sperm exposed *in vitro* to two concentrations of nanosized titanium dioxide (n-TiO_2) (1 and 10 μg/L) for three different times.

Summary answer: Exposure to *n*-TiO_2 induced DNA damage in human sperm. The *n*-TiO_2 induced a loss of sperm DNA integrity and a high decrease in genomic stability, but did not increase sperm DNA fragmentation. The DNA damage was greatest at the highest concentration of *n*-TiO_2.

What is known already: The impact on the human fertility of the *n*-TiO_2 use is not well defined or unknowns yet. To date there are no data in the literature on the effects on human sperm DNA induced *in vitro* by TiO_2 nanoparticles. However it is known that the nanoparticles can penetrate the blood-testis barrier, due to their nanosize, acting at various biological levels and so could contribute to alter reproductive functions.

Study design, size, duration: Human semen ejaculates from 76 men between 25 and 35 years old were collected from April to November 2014. The seminal fluids with normal parameters according to WHO (2010) were selected for the study.

Participants/materials, setting, methods: The samples, after selection with Percoll gradient, were exposed to *n*-TiO_2 for 15, 30 and 45 min. One aliquot was treated with benzene (positive control) and a untreated aliquot was used as negative control. The genotoxicity was assessed by Comet Assay, TUNEL technique and RAPD-PCR technique.

Main results and the role of chance: The Comet Assay showed a statistically significant loss (p-value ≤ 0.05) of sperm DNA integrity already after 15 min of exposure for both concentrations tested. The DNA damage was greatest at the highest concentration of *n*-TiO_2.The results of the TUNEL test showed no increase in sperm DNA fragmentation. The RAPD-PCR analysis showed a variation of the polymorphic profiles of the sperm DNA exposed to *n*-TiO_2 respect to the DNA of the not-treated sperms. The genome template stability (GTS%) of sample treated with 1 µg/L *n*-TiO_2 was reduced of 18% after 15 and 30 min and 27% after 45 min, while the treatment with 10 µg/L *n*-TiO_2 reduced GTS% of 45% after 15 min, 54% after 30 min and 63% after 45 min.

Limitations, reason for caution: No limitations.

Wider implications of the findings: This research provides the first data on the evaluation of the potential genotoxicity of *n*-TiO_2 on human seminal liquid. Thanks to the qualitative analysis of the RAPD profiles, we hypothesized that the damage to sperm DNA induced by *n*-TiO_2 occurs through the production of reactive oxygen species (ROS). The data provide a starting point for investigations on the possible effects that other nanomaterial could have on sperm DNA and consequent infertility rate.

Study funding/competing interest(s): Funding by University(ies) – Second University of Naples (Italy).

P-067 Low values of *n*-3 polyunsaturated fatty acids in sperm cells are associated to lower fertilization rates in IVF cycles

L. Crisol Ortiz[1], R. Matorras[2], F. Aspichueta[3], A. Expósito[2], M. B. Ruiz-Larrea[4], F. Quintana[5], A. Guembe[1], J. I. Ruiz-Sanz[4]

[5]*IVI-Bilbao, Andrology Laboratory, Leioa Vizcaya, Spain*

Study question: Are sperm *n*-3 polyunsaturated fatty acids (PUFA) levels, especially docosahexaenoic acid (22:6 *n*-3; DHA), related to semen quality and *in vitro* fertilization (IVF) results in terms of fertilization and pregnancy rate?

Summary answer: High sperm *n*-3 PUFA levels are related with optimal semen quality and an accurate fertilization process.

What is known already: The lipid composition of spermatozoa plays an important role for the viability, maturity and functional characteristics of those cells. Long-chain PUFAs have been detected at high concentration in human spermatozoa and has been suggested that the proportion of PUFAs is closely correlated with sperm membrane fluidity and flexibility, being essential for fertilization process. However, there is a lack of information about the importance of PUFA composition of the sperm membranes in the outcome of IVF.

Study design, size, duration: Prospective study. Semen samples were obtained from 340 consecutive males from infertile couples participating in the FIV/ICSI programme of the Human Reproduction Unit at Cruces Hospital, during 2010. For the analysis of IVF results, only samples of subjects with a lack of detectable abnormalities in the female partner are included (n = 230).

Participants/materials, setting, methods: Seminal samples were classified according to WHO criteria in normal (≥15 millions/ml; ≥32% progressive motility and ≥4% normal forms) and pathological samples. Sperm preparation was performed by swim up. Sperm fatty acids were analysed by capillary gas-liquid chromatography. Results were expressed as nmole percentages of total fatty acids.

Main results and the role of chance: PUFA, *n*-3 PUFA and DHA sperm levels were significantly lower in samples assessed as pathological by 2010 WHO criteria (26.2%; 13.09 and 12.2% respectively, $p < 0.001$) than in normozoospermic samples (29.1%; 16.4 and 15.5% respectively). On the other hand, the levels of saturated fatty acids (SFA) were significantly higher in pathological samples (52.07%; $p < 0.001$) compared with normal samples (50.0%). PUFA, *n*-3 PUFA and DHA content showed a positive and significant correlation with sperm concentration, progressive motility and the percentage of normal forms ($p < 0.001$). Nevertheless, an inverse relationship was found for SFA and n6/n3 ratio ($p < 0.05$) with the seminal parameters.

Regarding IVF results, we found a positive and significant correlation between *n*-3 PUFA and DHA content of post-swim up spermatozoa and fertilization rate ($p < 0.05$), while the correlation was negative for SFA and n6/n3 ratio ($p < 0.05$). However, we did not detect any relationship between sperm fatty acids composition and pregnancy rates.

Limitations, reason for caution: This study did not involve proven fertile subjects; the results are limited to a population of patients from infertile couples with either male or female infertility factor. Our results show a correlation with fertilization rates, but not with the truly clinically relevant outcome (pregnancy and newborn rates). More studies are needs to ascertain if the lack of differences is due to the relatively small sample size

Wider implications of the findings: High *n*-3 PUFA content, especially DHA, is associated with optimal semen quality required for proper fertilization and with higher fertilization rates in IVF cycles. This is the first study, in our knowledge, to report a significant relationship between the sperm composition of *n*-3 PUFA and the IVF fertilization rates. The present findings suggest that measurement of *n*-3 PUFA levels of spermatozoa can be regarded as a useful tool for predicting sperm functionality.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Hospital de Cruces.

[4]*The University of Queensland, School of Agriculture and Food Science, Gatton, Australia*

[5]*Universidad Autónoma de Madrid, Unit of Genetics. Department of Biology., Madrid, Spain*

Study question: This study was conducted to assess the impact of reducing sperm DNA fragmentation (SDF) using a commercial Magnetic Cell Sorting system (MACs) on corresponding pregnancy and abortion rates

Summary answer: The use of the MACs procedure prior to ICSI reduced sperm DNA damage observed in neat ejaculate, resulting in an increase in pregnancy rate and a marked reduction in the incidence of abortion in patients with this predisposition

What is known already: High sperm DNA quality and homeostasis are essential for effective transmission of genetic information to the offspring. Evidence based medicine has now shown that abnormal sperm chromatin or damaged DNA can adversely affect fertility and contribute to abortion. A certain proportion of spermatozoa in the ejaculate of most species contain abnormal sperm because of DNA or protein damage. Recently, MACs has been used to remove a portion of the damaged DNA contained in the ejaculate.

Study design, size, duration: Retrospective study of couples attending an ART clinic over two years. All males (n = 305) presented SDF values higher than 30%. Two cohorts where established: Standard-ICSI (S-ICSI) and Ovodonation-ICSI (O-ICSI). Within each of these cohort, two further subgroups were created (1) SDF ranging from 30 to 50% and (2) SDF higher than 50%.

Participants/materials, setting, methods: IVF clinics and Universities. Female averaged age: S-ICSI:32.3; O-ICSI;43.7. Distribution of patients within each subgroup: S-ICSI: SDF ranging from 30 to 50% (Control n = 144 and MACs n = 42). SDF ≥50% (Control n = 23 and MACs n = 7). O-ICSI: SDF ranging from 30 to 50% (Control n = 40 and MACs n = 29. SDF ≥50% (Control n = 11 and 9 MACs n = 9). Pregnancy and abortion rates were assessed within each subgroup.

Main results and the role of chance: The overall pregnancy rate of the S-ICSI group was lower than the O-ICSI group (P = 0.005). When S-ICSI and O-ICSI cohorts were compared, the pregnancy rate was higher (P = 0.005) for subgroups were the SDF was less than 50%. Abortion was not detected in those females receiving MACs treated sperm. Pregnancy and abortion rate for all groups are reported in Table 1

Table 1: Pregnancy and abortion data within each established group.

		SDF 30–50%	SDF 30–50%	SDF ≥50%	SDF ≥50%
		Control	MACs	Control	MACs
S-ICSI	Preg	54	54	35	42
	Ab	5	0	8	0
O-ICSI	Preg	60	70	46	55
	Ab	3	0	8	0

Limitations, reason for caution: While our results clearly revealed treatment of sperm with MACs procedure prior to ICSI, results in a marked improvement in pregnancy rate and cessation of the abortion rate in couples whose ejaculates initially had high levels of SDF, further observations are required to confirm the statistical robustness of our preliminary findings.

Wider implications of the findings: While our results clearly revealed treatment of sperm with MACs procedure prior to ICSI, results in a marked improvement in pregnancy rate and cessation of the abortion rate in couples whose ejaculates initially had high levels of SDF, further observations are required to confirm the statistical robustness of our preliminary findings.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Ginemed Clinic. None of the authors declare conflict of interest.

Trial registration number: This investigation is a part of the experimental protocols included in the research project BFU-2013-44290-R, as approved by the University in accordance with the participating IVF clinics.

P-069 The relationship between chromatin condensation assay (aniline-blue) on testicular spermatozoa of non-obstructive azoospermia (NOA) patients and the testicular histology in ICSI cycles. A pilot study

F. Scarselli[1], G. Franco[2], M. C. Greco[3], A. M. Lobascio[1], R. P. Cotarelo[1], V. Casciani[1], M. Barberi[1], V. Zazzaro[1], M. G. Minasi[1], E. Greco[1]

[1]*European Hospital, Reproductive Medicine, Rome, Italy*

[2]*La Sapienza University, Gynaecological-Obstetrical and Urological Sciences, Rome, Italy*

[3]*European Hospital, Urology/Andrology, Rome, Italy*

Study question: The aim of the study was to investigate the correlation between testicular spermatozoa stained with Aniline Blue (AB) and the etiology of testicular patients with NOA. Besides, we wanted to study the relationship between the success rate of *in vitro* fertilization and AB staining

Summary answer: Our results show that NOA patients with mild testicular damage show a higher percentage of AB negative spermatozoa compared to those with severe damage, and that mild testicular damage in NOA patients is associated with a higher likelihood of finding mature spermatozoa in the testis and a higher IVF success.

What is known already: During spermiogenesis, the somatic histones are substituted by protamines for a normal nuclear condensation. A significant association between male infertility, imperfect spermiation and abnormal chromatin condensation has been reported. Aniline-Blue selectively targets lysine-rich histones showing completely or partially blue nuclei while protamine-rich nuclei of mature spermatozoa remain unstained.

Study design, size, duration: Thirty-four NOA patients performed Testicular Sperm Extraction between June/2013 and December/2014. Spermatozoa were retrieved in 27 patients (27/34 = 80%). These patients were included in the AB study ad were divided in two groups: group-a) mild hypospermatogenesis (n = 19); and group-b) severe hypospermatogenesis and Klinefelter-Syndrome (n = 8). AB-staining results were confronted with histological analysis.

Participants/materials, setting, methods: Mean male and female age were similar in both groups. Testis samples were smeared, fixed in 5% paraformaldehyde, stained with AB solution for 5 min, rinsed with water and observed at 100× under oil. One-hundred spermatozoa were evaluated per patient. All histological examinations were assessed by the same pathologist.

Main results and the role of chance: The average percentage of AB positive spermatozoa in group-a and b were respectively 34.6% ± 28.7 and 63.7% ± 29.4 (p = 0.03, t-test). Significance was set at $p \leq 0.05$. Levels of serum FSH and LH were respectively 5.2 ± 8.7 and 4.0 ± 2 in group-a and 18.6 ± 8.7, 7.1 ± 2.6 in group-b (P = 0.0012 and P = 0.025, t-test). In group-a, fertilization rate, day-3 cleavage rate and day-3–5 embryo degeneration were respectively 70, 65.4 and 37.2% while in group-b were 57.5, 76.1 and 71.4% (P = 0.08; P = 0.2; P = 0.0007, Fisher's exact test). Five babies and six clinical pregnancies have been obtained to date in group-a (14 embryo transfers). In group-b no clinical pregnancy has been obtained (7 patients). Our data show a positive correlation between the AB positive sperm number and the testicular etiology obtained by histological exam.

Limitations, reason for caution: Additional data are necessary. We were unable to analyze a higher number of spermatozoa due to the difficulty of the testicular sperm retrieval.

Wider implications of the findings: This study provides a novel insight into how abnormal protamination can affect testicular sperm. The Aniline-blue threshold for ejaculated spermatozoa is ≤30% in our laboratory. These value seems less important when considering testicular sperm. All NOA patients display AB staining higher than 30%, however clinical outcomes are good provided that the patients have mild testicular damage. Our results will contribute to a deeper understanding of the benefits and limitations of spermatozoa selection for ICSI.

Study funding/competing interest(s): Funding by hospital/clinic(s) – European Hospital, Medicina della Riproduzione.

P-070 Single nucleotide polymorphism rs 175080 in the MLH3 gene and its relation to male infertility

O. Markandona[1], K. Dafopoulos[1], G. Anifandis[1], C. I. Messini[1], A. Tsezou[2], P. Georgoulias[3], A. Tzavella[1], I. E. Messinis[1]

[1]*University of Thessaly, Obstetrics and Gynaecology, Larissa, Greece*

[2]*University of Thessaly, Cytogenetics and Molecular Genetics, Larissa, Greece*

[3]*University of Thessaly, Nuclear Medicine, Larissa, Greece*

Study question: To investigate the association between the single nucleotide polymorphism (SNP) rs 175080 in the MLH3 gene with male infertility in a Caucasian population.

Summary answer: The studied SNP in the MLH3 gene may be linked to oligozoospermia in Caucasian men.

What is known already: Male infertility accounts for approximately 50% of couple infertility. Studying the genetic basis of impaired spermatogenesis and male infertility is crucial for diagnosis and treatment. There is cumulative evidence associating different polymorphisms in genes involved in spermatogenesis with male infertility. MLH3 is a MutL homolog protein in mammals playing a role in DNA mismatch repair, but also associated to spermatogenesis and male infertility. There are scanty data regarding the association between certain MLH3 polymorphisms and male infertility.

Study design, size, duration: Cohort study in three hundred men that were subjected to IVF/ICSI-ET treatments between 2011 and 2013.

Participants/materials, setting, methods: Genomic DNA was extracted from 300 peripheral blood samples and conventional quantitative real time PCR was performed for genotyping 122 controls and 178 cases (men with sperm

concentrations above and below 15 million/ml, respectively). Serum concentrations of FSH, LH, estradiol, testosterone and prolactin, and the sperm parameters were compared between the three groups of genotypes (GG, GA and AA). Furthermore, the frequencies of these three genotypes were compared between cases and controls.

Main results and the role of chance: This is the first study that investigated the SNP rs 175080 in Caucasian men. There were no significant differences in anthropometric parameters and hormonal values between the three groups of genotypes. A significantly lower sperm concentration was found in men with the AA genotype as compared to men with the GG and GA genotypes ($p < 0.001$). The group with the AA genotype had the lower progressive motility values as compared to the two other groups ($p < 0.05$). Also, there was a significantly different distribution of the frequencies of the three genotypes between cases and controls ($p < 0.001$).

Limitations, reason for caution: The relatively small sample size of the present study does not allow drawing solid conclusions. Besides, our results refer to Caucasians, therefore, these conclusions should not be expanded.

Wider implications of the findings: Polymorphisms may be widely used for the investigation of male infertility. The present study provides data for further research in the context of larger studies.

Study funding/competing interest(s): Funding by University(ies) – University of Thessaly, Department of Obstetrics and Gynaecology.

P-071 A combination of eight micronutrients is superior to a mono preparation comparing improvement of variant groups of impaired sperm motility

F. Bodner[1], M. Lipovac[2], M. Imhof[2]

[1]Landesklinikum Weinviertel Korneuburg, Korneuburg, Austria

[2]Landesklinikum Weinviertel Korneuburg, Gynaecology, Korneuburg, Austria

Study question: The objective of this retrospective study was to compare the effect of a combination of 8 active compounds (l-carnitine 440 mg, l-arginine 250 mg, zinc 40 mg, vitamin E 120 mg, glutathione 80 mg, selenium 60 µg, coenzyme Q10 15 mg, folic acid 800 µg) with a single active compound (l-carnitine 1000 mg) on subgroups of impaired semen motility.

Summary answer: Both therapies increased semen motility to a significant level. A low previous fraction of fast and slowly progressive sperm results in a higher improved by means of micronutritient supplementation. The combination supplement was significantly superior in improvement of progressive and total motility.

What is known already: Approximately 50% of all infertile couples' cases are related to an impaired semen quality which is caused in 30–80% by oxidative stress. Oral intake of micronutrients can ameliorate sperm motility

Study design, size, duration: From 2006 to 2014 261 patients of the IMI Fertility Center, Vienna and the Med19 Study Center, Vienna were enrolled in the study. For 3 months patients took either the mono preparation or the combination treatment. Semen analysis was performed before and after intervention. Motility subgroups where statistically.

Participants/materials, setting, methods: Patients were 18–60 years old, suffered from subfertility over 1 year, had one or more recent pathologic semen analysis according WHO 2010 and didn't meet any exclusion criteria. 144 subfertile men were treated with a mono preparation and 127 patients received the combined preparation.

Main results and the role of chance: Within both therapy groups, treatment regimes increased semen motility to a highly significant level ($p < 0{,}001$). Subgroup analysis revealed that the lower the previous fraction of fast and slowly progressive sperm has been, the greater the improvement was. Motility counts of 40% progressive sperms and more couldn't be increased significantly any further. The combined therapy increased rapidly progressive motile sperms highly significantly ($p = 0{,}004$) and overall progressive sperm count significantly ($p = 0{,}01$) compared to the mono-substance group.

Limitations, reason for caution: –

Wider implications of the findings: –

P-072 Mycoplasmas and ureaplasmas infection and male infertility: a systematic review and meta-analysis

C. Huang[1], H. Zhu[1], L. Fan[2], W. Zhu[2]

[1]Central South University, Institute of Reproduction and Stem Cell Engineering, Changsha Hunan, China

[2]Reproductive and Genetic Hospital of CITIC-Xiangya, Sperm Bank, Changsha Hunan, China

Study question: The goals of this study were to evaluate the association between genital Ureaplasma (U. urealyticum and U. parvum), Mycoplasmas (M. genitalium and M. hominis) and risk of male infertility, and to compare the prevalence of genital Ureaplasma and Mycoplasmas infection in China relative to the world average

Summary answer: Our analysis supports that U. Urealyticum and M. Hominis, but not U. Parvum and M. genitalium is an etiological agent in male infertility

What is known already: The correlationship between Mycoplasmas, Ureaplasmas infection and male infertility has been studied widely. However, The role that U. urealyticum and M. hominis infections play in male infertility is controversial. Hitherto, M. genitalium and U. parvum have seldom been investigated in infertile men.

Study design, size, duration: There were 20 studies in this research between January 2000 and December 2014.Nineteen studies with 3975 case and 2249 controls were concerning U. urealyticum infection and 9 studies with 2410 cases and 1223 controls were about M. hominis infection. Other two infection (U. parvum and M. genitalium) were studied in 5 and 3 studies, respectively.

Participants/materials, setting, methods: The major criteria were as follows: (a) case-control studies about the associations of genital Ureaplasma or Mycoplasmas with male infertility; (b) the patient group was men who were diagnosed with infertile. The major exclusion criteria were as follows: (a) duplicate data; (b) abstract, comment, review and editorial.

Main results and the role of chance: This meta-analysis indicated that the U. parvum and M. genitalium might be not associated with the risk of male infertility. However, Ureaplasma urealyticum and Mycoplasma hominis was significantly associated with increased risk of male infertility[ORs were 3.81 (2.48–5.85) $P < 0.00001$; 1.84 (0.93–3.64) $P = 0.025$].Compared to the world average, a significantly higher positive rate of Ureaplasma urealyticum was observed in both the infetile and control groups in China. In contrast, a significantly lower positive rate of Mycoplasma hominis was observed in both the infertile and control groups in China.

Limitations, reason for caution: First, the sample size was small, which might potentially influence the combined results. Second, other environmental factors, such as smoking and drinking, were not considered in our meta-analysis due to data deficiency. Third, this meta-analysis was conducted based on case-control study that has risk of recall bias.

Wider implications of the findings: More detailed studies of these four species in China and the world could contribute to a better understanding of the epidemiology and pathogenesis, and facilitate the development of better strategies for treatment and prevention of male infertility.

Study funding/competing interest(s): Funding by national/international organization(s) – This work was supported by Changsha City Science and Technology Project (K1106001-31).

Trial registration number: NA.

P-073 Short-term hypothermic storage of human spermatozoa in electrolyte free medium (EFM): outcomes of 96 IVF cycles

D. A. Isaev[1], I. V. Kapralova[1], E. V. Zakharova[1], T. V. Kartavenko[1], I. S. Krivokharchenko[1], O. O. Zharskaya[1], V. V. Zaletova[2]

[1]Center for Reproductive Medicine MAMA, Embryology, Moscow, Russia C.I.S.

[2]Center for Reproductive Medicine MAMA, Medical Department, Moscow, Russia C.I.S.

Study question: To determine whether short-term hypothermic storage of human spermatozoa in EFM is effective in routine practice for IVF/ICSI.

Summary answer: Short-term hypothermic storage of human spermatozoa in EFM for up to 2 weeks is safe and effective, and may be used in IVF programs.

What is known already: Storage of human sperm at + 4°C in EFM composed of glucose and bovine serum albumin allows sperm preservation for at least 2 weeks (Saito et al., 1996; Kanno et al., 1998). This method was used to generate healthy murine offspring and was shown to be genetically safe (Riel et al., 2007, 2011). Short-term hypothermic storage of human spermatozoa in EFM has not been utilized in clinical practice for infertility treatment with IVF.
Study design, size, duration: This study included 96 couples who underwent IVF treatment between September 2010 and December 2013. Normospermia was the main requirement for participation. After 2-week hypothermic storage in EFM, the spermatozoa were used for fertilization by ICSI.
Participants/materials, setting, methods: Sperm was stored in EFM at +4°C and further processed according to standard protocol. Sperm motility and sperm DNA fragmentation were evaluated before and after hypothermic storage in EFM. Each newborn's physical status was evaluated by questionnaires sent to physicians and parents at conception and delivery.
Main results and the role of chance: After 2-week hypothermic storage in EFM, 56.2 ± 5.0% of spermatozoa regained motility. The sperm DNA fragmentation rate was slightly higher after than before storage (11.2 ± 3.1 vs. 8.5 ± 2.5%, $p = 0.11$), but the difference was not statistically significant. The fertilization rate was 78%, and the clinical pregnancy rate was 34.4% (33 of 96), with 26 pregnancies resulting in the successful delivery of 34 babies. Delivery date and birth length and weight complied on average with standards.
Limitations, reason for caution: The method was effective for ejaculated sperm with normal parameters stored for a period of up to 2 weeks.
Wider implications of the findings: Hypothermic storage of human spermatozoa in EFM is a simple and cost-effective option, if ejaculated sperm cannot be retrieved on the day of ovarian puncture. The method guarantees that the spermatozoa are safely stored for at least 2 weeks, and then regain their motility and viability, with preservation of DNA integrity. Hypothermic storage of human spermatozoa in our IVF/ICSI programs resulted in a high pregnancy rate and high physical status scores in the resulting newborns.

Trial registration number: NA.
Keywords: sperm, hypothermic storage

P-074 Who is the most suitable candidate for varicocele ligation? – Findings from a cross-sectional survey in a cohort of infertile Caucasian-European patients

A. Serino[1], L. Boeri[1], E. Ventimiglia[1], S. Ippolito[1], A. Pecoraro[1], M. Paciotti[1], P. Capogrosso[1], G. Castagna[1], F. Castiglione[1], A. Russo[1], U. Capitanio[1], F. Cantiello[2], R. Damiano[2], A. Salonia[1]
[1]*IRCCS Ospedale San Raffaele, Division of Experimental Oncology/Unit of Urology URI, Milan, Italy*
[2]*Magna Graecia University, Research Doctorate Program in Urology, Catanzaro, Italy*

Study question: We assessed i) the impact of health-significant comorbidities and hormonal milieu on semen parameters; and, ii) the main predictors of oligospermia in order to identify patients who will not significantly benefit from varicocele ligation.
Summary answer: Current findings demonstrate that almost half of patients presenting for couple's infertility had a clinically-significant varicocele. Our data would suggest not to submit infertile men with high serum levels of FSH to varicocele ligation.
What is known already: According to current EAU guidelines, clinical varicocele should be repaired in infertile patients with oligospermia and an infertility duration of ≥2 years. Indeed, patients' comorbidity profile and hormonal milieu seems to have no importance for therapeutic decision making.
Study design, size, duration: Complete data from 2100 consecutive infertile men were analyzed in a retrospective fashion.
Participants/materials, setting, methods: Comorbidities were scored with the Charlson Comorbidity Index (CCI; categorized 0 vs ≥1). Testicular volume was assessed with a Prader orchidometer. Color-Doppler US was used to detect spermatic vein reflux and to classify the grade of varicocele. Semen analysis values were assessed based on the 2010 WHO reference criteria. Descriptive statistics detailed the association between varicocele, clinical comorbidities and seminal parameters. Logistic regression models tested the association between clinical predictors and oligospermia. Serum FSH was included in the model as both a continuous and a categorized variable (according to the most informative cut-off: 11.1 mUI/ml).
Main results and the role of chance: Overall, varicocele was found in 982 (46.8%) patients. Patients with varicocele had a mean (SD) age, BMI and Prader of 42.5 (6.7), 25.46 (3.3) kg/m^2 and 16.48 (5.9), respectively. Patients with varicocele and CCI ≥1 presented a higher prevalence of oligospermia (x2: 10.8; $p < 0.001$); conversely, no differences were found in terms of rates of either asteno- or teratozoospermia. Patients with serum FSH > 11.1 mUI/ml more frequently had a higher BMI ($p = 0.04$), lower testicular volume ($p < 0.001$), lower serum inhibin B ($p < 0.001$) and lower AMH ($p < 0.001$), and testosterone levels ($p < 0.001$). At MVA, FSH was significantly associated with oligospermia as either a continuous (OR: 1.13; $p < 0.001$) or a categorical predictor (OR: 3.8; $p < 0.001$), after accounting for other variables. Likewise, CCI ≥1 (OR: 3.3; $p = 0.001$), duration of infertility (OR:1.1; $p = 0.03$) and testicular volume (OR:0.9; $p < 0.001$) achieved independent predictor status for oligospermia. Conversely, patient age and varicocele were not significantly associated with oligospermia.
Limitations, reason for caution: Cross-sectional, retrospective analyses.
Wider implications of the findings: A general consensus regarding indications for varicocele ligation still lacks. A better selection of patients would allow to identify who will not significantly benefit from surgery.
Study funding/competing interest(s): Funding by hospital/clinic(s) – None.
Trial registration number: NA.

P-075 Routine determination of sperm DNA fragmentation incorporating the sperm degradation index (SDi) is a useful noninvasive biomarker to identify patients with varicocele in seminograms

J. L. Fernandez[1], J. Gosalvez[2], C. Lopez-Fernandez[2], S. D. Johnston[3], S. C. Esteves[4]
[1]*Complexo Hospitalario Universitario A Coruña, Genetics Unit, La Coruña, Spain*
[2]*Universidad Autonoma de Madrid, Genetics Unit, Madrid, Spain*
[3]*University of Queensland, School of Agriculture and Food Science, Gatton, Australia*
[4]*Androfert Centro de Reprodução Masculina, Andrology, Sao Paulo, Brazil*

Study question: The study attempted to establish the incidence of sperm with degraded nuclei in a large population of semen samples obtained from donors and patients of varying fertility to explore the value of using this parameter as a noninvasive marker of varicocele.
Summary answer: Although not pathognomonic, if a neat ejaculate shows at least 1 in 3 spermatozoa with degraded nucleus, then there is high probability that the individual has varicocele.
What is known already: Sperm with degraded nucleus are a specific subpopulation of spermatozoa identified by means of the Sperm Chromatin Dispersion test (SCDt) that are characterized by massive levels of single and double strand DNA breaks and alteration of nuclear proteins. A high proportion of these sperm with degraded nucleus has been repeatedly observed in varicocele patients but its relative presence has not been systematically analyzed in patients exhibiting different sperm pathologies.
Study design, size, duration: Retrospective international multicenter study consisting of 1528 semen samples obtained from (1) Non-varicocele subjects: including fertile donors, patients with leukocytospermia, cancer or idiopathic infertility, and (2) Varicocele patients exhibiting clinical and subclinical varicocele.
Participants/materials, setting, methods: Sperm with degraded nucleus were identified using the Sperm Chromatin Dispersion test (Halotech DNA, Madrid), protein staining and 2-dimensional neutral and alkaline comets. The proportion of sperm with degraded nuclei in the total population with fragmented DNA was established as the Sperm Degradation index (SDi).
Main results and the role of chance: SDi was significantly higher in individuals diagnosed with varicocele (mean = 0.54; SD = 0.16; Range = 0.227 – 0.952) compared with non-varicocele. ROC curve analysis revealed that a SDi value of greater than 0.32 was able to identify varicocele patients with a sensitivity of 93%, a specificity of 90%, a negative predictive value of 99.5% and an area

under the curve (AUC) of 0.942 ($p < 0.001$); this high level of SDi was observed in 89.6% of the patients diagnosed with varicocele. While the frequency of sperm with fragmented DNA was statistically different among the different groups established in this protocol, this parameter on its own (not segregating degraded nuclei) was not as good a predictor of the presence of varicocele (AUC = 0.612; $p < 0.001$).

Limitations, reason for caution: Idiopathic infertility is a complex heterogeneous group of unknown etiology. Similar values for SDi as those observed in varicocele patients may occur in unidentified subsets of infertile patients.

Wider implications of the findings: Routine determination of sperm DNA fragmentation with the incorporation of SDi would be a useful noninvasive predictor of varicocele. SDi could be potentially used to identify patients more likely to have varicocele in seminograms when the SDi is >0.32.

Study funding/competing interest(s): Funding by national/international organization(s) – MINECO.

Trial registration number: This investigation is a part of the experimental protocols included in the research project BFU-2013-44290-R.

Keywords: varicocele, sperm DNA fragmentation, sperm chromatin dispersion test, degraded sperm nucleus

P-076 Genetic variability in bitter/sweet taste related genes and male infertility

P. Piomboni[1], D. Locci[2], D. Campa[2], L. Crifasi[1], A. Capaldo[1], M. Gori[1], A. Luddi[1], R. Barale[2]

[1]*University of Siena, Department of Molecular and Developmental Medicine, Siena, Italy*

[2]*University of Pisa, Department of Biology, Pisa, Italy*

Study question: The aim of this study was to determine whether the genetic variability of the taste receptors genes (TAS2Rs/TAS1R) and of the guanine nucleotide binding protein, alpha transducing 3 (GNAT3) was associated with male infertility.

Summary answer: Our preliminary results suggest a possible associations between the genetic variants in taste related genes and specific sperm parameters.

What is known already: Recent studies have demonstrated taste receptor expression also in testis and in sperms, highlighting their possible role in sperm maturation as well as in sperm behavior and fertilization by sensing chemicals in the milieu. The high frequency of human genetic variations of genes involved in taste perception results in a large variability from super-taster subjects to totally "non-taster" patients, that might be influence sperm functionality too.

Study design, size, duration: In this epidemiological study 163 male patients were enrolled and their DNA was isolated from buccal swab.

Participants/materials, setting, methods: The patients enrolled at the Centre of Couple Sterility, Siena University Hospital (Italy), were characterized for main sperm parameters, according to WHO (2010) guidelines: concentration, morphology, progressive and total motility. All subjects were then genotyped for 14 single nucleotide polymorphisms (SNPs) in TAS2Rs/TAS1R and GNAT3 genes. The genotyping was performed using the KASPar SNP genotyping system.

Main results and the role of chance: Association between the SNPs and the main sperm parameters was tested through chi^2 test. We found a statistically significant association between sperm concentration and the TAS1R2 rs35874116 SNP ($p = 0.049$) and with the TAS2R49 rs7135018 SNP ($p = 2.7 \times 10^{-6}$). Additionally, we observed a statistically significant association between progressive motility and the TAS2R14 rs11610105 variant ($p = 0.036$). Using the Bonferroni method in order to correct for multiple testing, only TAS2R49 rs7135018 SNP remains significant.

Limitations, reason for caution: The TAS2R49 rs7135018 SNP has a low frequency in the population and therefore a larger study needs to be carried out in order to validate the findings.

Wider implications of the findings: Our study, if replicated in a larger population, might contribute in further understanding the genetic components of male infertility.

Study funding/competing interest(s): Funding by University(ies) – University of Siena.

Trial registration number: NA.

Keywords: taste genes, spermatogenesis, SNPs, male infertility

P-077 In male factor infertility, the sperm aneuploidies of chromosomes 16 and 18 correlate with polymorphism of follicle-stimulating hormone receptor

I. Zhylkova[1], O. Feskov[1], I. Feskova[1], A. Ivanova[2], O. Somova[1]

[1]*Centre of Human Reproduction Sana-Med, IVF, Kharkiv, Ukraine*

[2]*Centre of Human Reproduction Sana-Med Municipal Enterprise Clinic, IVF Urological Department, Kharkiv, Ukraine*

Study question: Does the chance to observe a chromosomal aneuploidy in sperm correlate with the presence of genetic polymorphism Thr307Ala and Asp680Ser of follicle-stimulating hormone receptor (FSHR)?

Summary answer: A statistically significant correlation between the presence of alternative alleles of *FSHR* gene and the occurrence of sperm aneuploidy is observed for chromosomes 16 and 18 ($p < 0.01$), but is absent for chromosomes 13, 21, X and Y.

What is known already: The influence of alternative variants of FSH receptor (FSHR) on male infertility is not completely understood. In males, FSH is responsible for Sertoli cell's function and, by means of specific receptor FSHR, participates in induction and maintenance of spermatogenesis. However, any results regarding possible correlation of some specific type of semen chromosomal aneuploidy (that may cause male infertility) with FSHR genotype's particular abnormality have not been reported to date.

Study design, size, duration: The study was un-blindly performed for a group of 32 infertile men of age 32.33 ± 5.71 years old. The sperm aneuploidies in chromosomes 13, 16, 18, 21, X any Y and the genotypes of FSHR gene Thr307Ala and Asp680Ser were studied in the mentioned group. The karyotype abnormalities were also studied.

Participants/materials, setting, methods: The genotype distribution and allele frequency of FSHR Thr307Ala and FSHR Asp680Ser polymorphisms were analyzed by Taqman assays on the ABI PRISM 7500 real-time PCR system. The sperm aneuploidies in chromosomes 13, 16, 18, 21, X any Y were analyzed exploiting the method of fluorescence in situ hybridization (FISH).

Main results and the role of chance: The average level of sperm aneuploidy for chromosomes 16 and 18 was significantly higher in carriers of FSHR polymorphisms, compare with in normal-genotype patients ($p < 0.01$). A statistically significant positive correlation between number of alternative alleles 680Ser of *FSHR* gene in genotype and the level of sperm aneuploidies for chromosomes 16 and 18 was proved ($\mathbf{r_s = 0.694}$, $p < 0.01$; $\mathbf{r_s = 0.802}$, $p < 0.01$). Also a statistically significant positive correlation between number of alternative alleles 307Thr of *FSHR* gene in genotype and the level of sperm aneuploidies for chromosomes 16 and 18 was proved ($\mathbf{r_s = 0.784}$, $p < 0.01$; $\mathbf{r_s = 0.713}$, $p < 0.01$). There was no correlation between the presence of alternative alleles of *FSHR* gene in genotype and the sperm aneuploidy for chromosomes 13, 21, X, Y.

Limitations, reason for caution: Present technique can evaluate the DNA fragmentation level in cases, when the sperm count excides 2 mln/mL.

Wider implications of the findings: Because semen chromosomal aneuploidy is a possible source of male infertility, our findings allow us to speculate that genetic abnormalities of FSHR (Thr307Ala, Asp680Ser) might have some negative impact on the process of meiosis in spermatogenesis. Sperm aneuploidy level of chromosomes 16 and 18 is worse among patients with these FSHR polymorphic genotypes, compare with normal-genotype patients. The correlation is observed with certain statistical significance in a general comparison "normal genotype vs. all polymorphic ones".

Study funding/competing interest(s): Funding by hospital/clinic(s) – Center of Human Reproduction "Sana-Med Ltd" (Kharkov, Ukraine). No conflict of interests exist.

Trial registration number: NA.

Keywords: FSHR Thr307Ala, FSHR Asp680Ser, sperm aneuploidy

P-078 Anatomic vascular variations in sub-inguinal varicocelectomy

I. Orhan[1], S. Cayan[2], A. Karakeci[1]

[1]*Firat University Hospital, Urology, Elazig, Turkey*

[2]*Mersin University Hospital, Urology, Mersin, Turkey*

Study question: Is Knowing Subinguinal anatomy reduce preoperative and post operative complication?

Summary answer: Microsurgical subinguinal varicocelectomy is an effective method in the treatment of varicocele. However, the branching ratios of arterial and venous structures in this region are higher according to the inguinal and

high inguinal regions. Therefore it is very important to carry out a better dissection as it may lead to relapses in unconnected veins and may negatively effect the connection of functions of the testicular arteries.
What is known already: Microsurgical vaicocelectomy is a widely applied open surgical technique in the treatment of varicocele.
Study design, size, duration: During three years a retrospective study
Participants/materials, setting, methods: A total of 65 patients who underwent microsurgical subinguinal varicoselectomy and whom were contacted data were retrospectively assessed according to number and adjuvant conditions of perioperative artery and vein.
Main results and the role of chance: Per-operative single artery in 32% (21/65) patients, double arteries in 46% (30/65) patients and three or more arteries in 15% (10/65) patients was determined. The mean number of veins connected during the operation was found 9,76 ± 0,96 (3–14). The artery vein neighborhood was determined as a vein package in 91% (59/65) patients. However an artery was determined at a single vein neighborhood in 3% (2/65) of the patients where the artery was separated from the vein package. Arterial structures were not determined clearly in 6% (4/65) of the cases.
Limitations, reason for caution: Size of the study, retrospective study.
Wider implications of the findings: Microsurgical varicocelectomies requires detailed dissection.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Firat University Hospital.
Trial registration number: NA.
Keywords: varicocele, microsurgical varicocelectomy, infertility.

P-079 Relationship between urokinase-type plasminogen activator (uPA) in seminal plasma and spermatozoa with human sperm parameters

J. C. Martinez-Soto[1], J. Gadea[2], M. Mollá[3], L. Fernandez[4], M. Nicolas[4], J. Landeras[4]
[1]*IVI Murcia, Andrology Laboratory, Murcia, Spain*
[2]*University of Murcia, Physiology, Murcia, Spain*
[3]*IVI Murcia, FIV Laboratory, Murcia, Spain*
[4]*IVI Murcia, Reproduction, Murcia, Spain*

Study question: Urokinase type plasminogen activator (uPa), is together with tissue-type plasminogen activator (tPA) one of the activators for plasminogen-plasmin system. The aim of this research was evaluated the relationship between total and active uPA concentration in seminal plasma and spermatozoa with human sperm parameters
Summary answer: Active uPA in seminal plasma was directly and significantly related with the volume of the ejaculate, total number of spermatozoa in the ejaculate (x10^6) and motility.
What is known already: The plasminogen/plasmin system has been related to different reproductive process as spermatogenesis, sperm capacitation, and fertilization. Some authors have previously detected the presence of plasminogen activators in human seminal plasma and spermatozoa. Lison *et al*, 1993, correlated significantly plasminogens activators with seminal parameters. Huang et al. 1997. found that uPA activity was higher in fertile than astenozoospermic men. However, the specific role and importance of uPA for the male reproductive function is not well known.
Study design, size, duration: Semen samples from 182 patients attending IVI-Murcia clinic for infertility screening were enrolled in this Cross sectional study between 2012 and 2014
Participants/materials, setting, methods: Semen samples were examined for volume, sperm concentration, morphology and motility according to WHO 2010. Aliquots of each sample were centrifuged and seminal plasma and spermatozoa were stored at -80°C until uPA evaluation. Total and active uPA were determined by ELISA KIT and confirmed by Wester blotting
Main results and the role of chance: Total uPA contents neither seminal plasma nor spermatozoa was not related to the seminal parameters ($p > 0.05$). On the other hand, active uPA in seminal plasma was directly and significantly related to volume of the ejaculate, total number of spermatozoa in the ejaculate (x10^6) and motility($p < 0.05$). Total and active uPA in seminal plasma from the samples analyzed were not significantly related (Pearson correlation rate: 0.13, $p > 0.05$. The active uPA represented less than 10% of the total UPA in most of the cases (mean value 8.27%)
Limitations, reason for caution: 182 patients were included in this research although we could not analyze all parameters in every ejaculated. Regarding seminal plasma we analyzed 148 cases for active uPA and we evaluated 64 samples for uPA total. Whereas in spermatozoa we evaluated 68 samples for total uPA
Wider implications of the findings: Results of this research showed that active Upa play an important role in different semen parameters. Further research will be necessary in order to study whether the addition of UPA to ejaculated improve seminal characteristics like sperm motility.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s), Funding by national/international organization(s) – IVI MURCIA S. L, Murcia University, Spanish Ministry of Economy and European Regional Development Fund (Feder). CDTI ID-2012053.
Trial registration number: NA.
Keywords: plasminogen/plasmin system, uPA

P-080 Semi-quantitative assessment of superoxide anions in neat semen using OxiSperm®: a survey to compare visual, spectrophotometric and image analysis results

M. de la Casa[1], M. C. Cañadas[1], S. D. Jonhston[2], J. Gosálvez[3]
[1]*Ginefiv, Andrology-IVF Lab, Madrid, Spain*
[2]*The University of Queensland, School of Agriculture and Food Science, Gatton, Australia*
[3]*Universidad Autónoma de Madrid, Unit of Genetics Department of Biology, Madrid, Spain*

Study question: This investigation examined the efficiency of three colorimetric and semi-quantitative methods to assess the level of superoxide oxide (O^{-2}: SOx) in the neat human ejaculate using a Nitro Blue Tetrazolium (NBT) based protocol.
Summary answer: Discrimination amongst the different levels of SOx in the neat ejaculate was possible with a margin of error of <10% irrespective of whether colorimetric assessment was conducted visually, spectrophotometrically or via image analysis.
What is known already: An ability to assess oxidative stress in semen rapidly following collection is highly beneficial for the clinical andrologist as the balanced presence of SOx in neat semen is commensurate with high sperm quality. Unfortunately, the presence of these molecules has been typically difficult and/or expensive to quantify in neat semen.
Study design, size, duration: Prospective study consisting of 230 men aged between 25 to 53 years and attending their first visit to the fertility clinic. Sample was recruited over one year.
Participants/materials, setting, methods: IVF center and two public Universities. Two hundred and thirty ejaculates were assayed for SOx imbalance using OxiSperm® which uses NBT to produce a colorimetric reaction. Concentrations of NBT in the semen samples were assessed and compared using visual assessment (4 pre-established levels from L1 –low- to L4 –high-), spectrophotometry (4 levels) and image analysis of direct scanned digital images (4 levels).
Main results and the role of chance: The results show that a color change associated with the reaction of SOx with NBT in a reactive gel using OxiSperm® could be used to readily discriminate formazan precipitates and thereby successfully be used as semi-quantitative methodology for the assay of SOx in the human ejaculate. All three semi-quantitative techniques used here allowed discrimination amongst the different individuals with a margin of error between each methodology of < 10%. Of the semen samples analysed in this study using the OxiSperm® procedure, 15% showed a high level of SOx on the base of the threshold levels established for each detection system.
Limitations, reason for caution: The OxiSperm® assessment procedures tested in this study can all be easily incorporated into the routine andrology laboratory procedure but will need customized calibration for in house standardization in the case of image analysis assessment. Once this calibration is performed, image analysis using digital information provided by a standard digital scanner will be the cheapest and most reliable system for comparison.
Wider implications of the findings: Semi-quantitative assessment of SOx in the neat ejaculate can be used to confirm the efficacy of antioxidant treatments.
Study funding/competing interest(s): Funding by University(ies) – None of the authors declare conflict of interest.
Trial registration number: This investigation is a part of the experimental protocols included in the research project BFU-2013-44290-R, as approved by the University in accordance with the participating IVF clinics.
Keywords: superoxide anions, formazan

P-081 The emerging epigenetic role of altered chromatin condensing factors in male (in)fertility

R. Favaedi[1], M. Shahhoseini[1], Z. Eelaminejad[1], N. Heydaryan[1], F. Mirzaei Nasab[1], M. A. Sadighi Gilani[2]
[1]*Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive BiomedicineACECR, Tehran, Iran*
[2]*Department of Andrology at Reproductive Biomedicine Research Center, Royan Institute for Reproductive BiomedicineACECR, Tehran, Iran*

Study question: What is the potential epigenetic role of chromatin condensing factors (TNPs, PRMs, JMJD1A, CDY1 and CREM) in spermatogenesis impairment and male infertility?
Summary answer: Decreased expression of *TNPs*, *PRMs, JMJD1A,CDY1* and *CREM* also decreased incorporation of JMJD1A, CDY1 and CREM into regulatory regions of *TNPs* and *PRMs* genes were correlated with spermatogenesis impairment.
What is known already: Successful spermatogenesis requires a series of tightly controlled epigenetic events leading to condensation of sperm chromatin. Animal model based studies showed any failure in this process leads to impaired spermatogenesis and infertility. Many genes are involved in compaction of sperm chromatin including transition proteins (*TNPs*) and protamines (*PRMs*) which are replacements of histones, also epigenetic regulatory factors such as histone demethylases (e.g., JMJD1A) and actyle transferases (e.g., CDY1) and key master genes like *CREM.*
Study design, size, duration: Consent was obtained from azoospermic infertile men referred to Royan institute, according local ethical approval, then though ART procedure and based on pathological features, testes tissue samples were collected from three groups including complete maturation arrest, Sertoli cell only syndrome, and hypospermatogenesis as positive control (at least 30 samples in each group).
Participants/materials, setting, methods: Expression of *TNPs, PRMs, JMJD1A*, *CDY1* and *CREM* were evaluated by qRT-PCR. Also, ChIP-real time PCR was performed to evaluate the incorporation of JMJD1A, CDY1 and CREM regulatory factors into re-gulatory regions of *TNPs* and *PRMs* genes.
Main results and the role of chance: Relative expression profile of chromatin condensing genes of *TNPs* and *PRMs* showed significant decrease in complete maturation arrest and Sertoli cell only syndrome groups compared to hypospermatogenesis group ($p < 0.05$). Also expression of *JMJD1A, CDY1* and *CREM* as up-regulating factors of *TNPs* and *PRMs* showed significant decrease in two mentioned groups vs. positive control ($p < 0.05$). These findings also confirmed by ChIP data revealed decreased incorporation of histone modifying enzymes of JMJD1A and CDY1 as well as key regulator of spermiogenesis, CREM, into regulatory regions of *TNPs* and *PRMs* in both groups with spermatogenesis impairment vs. positive control ($p < 0.05$).
Limitations, reason for caution: The study population could be expanded and the interaction between other epigenetic factors such as activator of CREM (ACT) and bromodomain testis-specific protein (BRDT) could be investigated.
Wider implications of the findings: The findings implies significant association between deregulation of epigenetic sperm chromatin condensing factors with impairment of spermatogenesis and male infertility.
Study funding/competing interest(s): Funding by national/international organization(s) – Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran.
Trial registration number: NA.
Keywords: male infertility, spermatogenesis, epigenetic, chromatin

P-082 Analysis of nuclear spermatic quality: sperm DNA integrity, chromatin condensation and aneuploidy in men with total non syndromic teratozoospermia

A. Braham[1], H. Ghédir[1], I. Zidi Jrah[1], A. Sallem[1], A. Saad[1], S. Ibala Romdhane[1]
[1]*Hospital Farhat-Hached, Cytogenetics Laboratory Molecular Genetics and Biology of Human Reproduction, Sousse, Tunisia*

Study question: Can we assess the impact of a nuclear spermatic quality analysis in infertile patients with a total non syndromic teratozoospermia on the chances of success in assisted reproductive technology (ART)?
Summary answer: Men with non syndromic teratozoospermia have an impaired nuclear sperm quality as well as chromosomal aberrations focusing mainly on gonosomes which obviously affects the fertilizing sperm power. Analysis of sperm nucleus in these cases is very useful before assisted reproductive techniques.
What is known already: Male infertility is often associated with abnormal spermatogenesis resulting in abnormal sperm count, mobility or morphology qualified as teratozoospermia. Several studies have shown that patients with a syndromic teratozoospermia manifest various nuclear alterations such as abnormal chromatin structure, DNA fragmentation and aneuploidy. Whereas, the impact of a total non syndromic teratospermia prevailing on head abnormalities still not clearly known.
Study design, size, duration: This is a case control study carried out on 59 men: 34 patients with non syndromic total teratozoospermia and 25 fertile men with normal semen profiles who acted as controls. Patients are recruited between March 2014 and August 2014.
Participants/materials, setting, methods: Semen samples were analyzed according to the World Health Organization criteria. Chromatin condensation was assessed by aniline-blue Staining. Sperm DNA fragmentation was evaluated by terminal desoxynucleotidyl transferase mediated deoxyuridine triphosphate biotin nick-end labelling (TUNEL) assay and chromosome abnormalities by fluorescence *in situ* hybridization (FISH) for chromosomes X, Y and 18.
Main results and the role of chance: Semen morphology analysis performed more than one time shows a total teratozoospermia with a predominance of head abnormalities (acrosome abnormalities, microcephaly...) and no specific syndrome was characterized. The rate of aniline blue-reacted spermatozoa was significantly higher in patients compared to the control group (51,08 ± 17,58 vs 12,70 ± 6,02%; $p < 0,001$). The mean DNA fragmentation index (DFI) was also higher in patients compared to controls (27,25 ± 12,06 vs 10,25 ± 3,83%; $p < 0,001$). The results of aneuploidy frequencies showed a significant difference between both groups (1.52 ± 0.24 vs 8,31 ± 8,42%; $p < 0,001$). We found a significant increase in the mean disomy rate for sex chromosomes (1.05 ± 0.56 vs 5,2 ± 3,94%; $p < 0,001$) and chromosome 18 (0.15 ± 0.07 vs 2,76 ± 0,15%; $p < 0,001$).
Limitations, reason for caution: A limitation of this study is the low number of teratozoospermic patients considering the short duration of study.
Wider implications of the findings: Despite the small sample our results confirms the importance of morphologic sperm evaluation, study of sperm chromosomal aneuploidy, chromatin condensation and DNA fragmentation before ART for non syndromic teratozoopsermic patients.
Study funding/competing interest(s): Funding by hospital/clinic(s) – None.
Trial registration number: NA.
Keywords: male infertility, total teratozoospermia, sperm aneuploidies, DNA fragmentation, chromatin decondensation

P-083 Effect of positive bacteriospermia on IVF results

N. Frydman[1], M. E. Naud[1], L. Hesters[1], N. Bourgeois[2], R. Fanchin[3], F. Doucet Populaire[3]
[1]*Centre Hosp. Antoine Béclère, Service Biologie Genetique de la Reproduction, Clamart Cedex, France*
[2]*Centre Hosp. Antoine Béclère, Service de Microbiologie, Clamart Cedex, France*
[3]*Centre Hosp. Antoine Béclère, Service Gynécologie Obstétrique et Reproduction, Clamart Cedex, France*

Study question: Is there a detrimental effect of positive bacteriospermia detected the day of oocyte retrieval on IVF results?
Summary answer: Polymicrobian contaminations of sperm affect significantly quality of sperm and the embryonic cleavage rate.
What is known already: French guidelines recommend the practice of a culture of semen at least six months before each IVF attempts. While we respect this recommendation, we hypothesize that some sperm could be infected, although culture was negative six months earlier. The effects of bacteriospermia are supposed to be negative on the results of IVF, but the literature is controversial.
Study design, size, duration: This prospective study was conducted between September 2011 and April 2012, for its first part and between January 2014 and Mars 2014 for its second part, in Antoine Béclère hospital (Clamart – France). The day of oocytes retrieval, 133 and 104 semen culture were analyzed respectively in the first and second part of the study.
Participants/materials, setting, methods: In the first part of this study a semen culture analysis was performed on raw sperm the day of oocyte retrieval

while in the second part,semen cultures were performed in same conditions but with enhanced hygiene recommendations given to patients associated with a water intake. Three groups have been defined according the result of semen cultures *ie*: negative, polymicrobial or monomicrobial. Semen parameters and IVF results were analysed for each group.

Main results and the role of chance: In the first part of this study, out of 133 semen culture analysed, 94 (71%) were negative, 28 (21%) were positive polymicrobial and 11 (8%) were positive monomicrobial. The initial sperm count and progressive motility after preparation were significantly lower in polymicrobial group but no impact on IVF results was observed. In the second part, 104 semen cultures were analysed after enhancement of hygiene instructions and water intake. Fifty one (49%) semen cultures were positive with a bacteriospermia significantly higher in the second part of our study (45 polymicrobial and 6 monomicrobial). The analysis of combined data showed a significant decrease of the initial sperm count as also the embryos' cleavage rate (number of embryos obtained divided by the number of inseminated oocytes) in polymicrobial group. Embryos' morphology as well as the clinical pregnancy rates were comparable between the three groups. However, the miscarriage rates seem to be increased in the polymicrobial group compared to the negative group (8/18 (44%) vs 10/47 (21%)).

Limitations, reason for caution: The size of the cohort has to be increased to reach the power required. The increased miscarriage observed in this study remain under caution.

Wider implications of the findings: We showed in this study that polymicrobian contaminations of sperm affect significantly quality of sperm and the embryonic cleavage rate. Unexpectedly a water intake had no beneficial effect on bacteriospermia's incidence.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Assistance Publique des hôpitaux de Paris.

Trial registration number: NA.

Keywords: asymptomatic bacteriospermia, semen parameters

P-084 Correlation between sperm chromatin decondensation, density, aneuploidy and hyaluronic binding capacity

A. Jakab[1], M. Benyo[2], A. Mokanszki[3], Z. Bazsane Kassai[1], Z. Molnar[3]

[1]*University of Debrecen Faculty of Medicine, Obstetrics and Gynecology, Debrecen, Hungary*

[2]*University of Debrecen Faculty of Medicine, Urology, Debrecen, Hungary*

[3]*University of Debrecen Faculty of Medicine, Laboratory Medicine, Debrecen, Hungary*

Study question: Whether there is relation between sperm chromatin decondensation, concentration, hialuronic acid (HA) binding capacity and aneuploidy of semen samples of fertile, normozoospermic and infertile, oligozoospermic men?

Summary answer: There are correlations between sperm condensation and the examined biomarkers, irrespective to fertility status. The sperm condensation rate, HA bindig capacity related fertility potential and sperm density are strongly related. Also, there is relation between sperm condensation and aneuploidy rate.

What is known already: Importance of sperm biomarkers are increasing in male infertility. Beside genetic integrity and fertilization potential tests, epigenetic studies came to the front. Chromatin decondensation is related to persistent histones detected by aniline blue, while HA binding capacity reflects genetic integrity and maturity related fertilization potential. Paralel evaluation of test results improves the understanding the regulation mechanisms of spermatogenesis and fertilization, may help in choosing the most effective therapeutic approach and sperm selection for assisted reproduction.

Study design, size, duration: This is a cross-sectional study examining semen of 20 infertile, oligozoospermic and 20 fertile, normozoospermic men attending at the Andrology Center and the Sperm Cryopreservation Laboratory.

Participants/materials, setting, methods: The ejaculates were assessed as per WHO guidelines. Hyaluronic acid binding capacity test was the functional test. To determine the numerical chromosome aberrations we used multicolor fluorescent in situ hybridization (FISH) for chromosomes X, Y and 17. Aniline blue staining was performed as a nuclear decondensation marker test.

Main results and the role of chance: In normozoospermic samples mean sperm concentration was 73,4 M/mL, rate of decondensed sperm nuclei detected by aniline blue 16.2%, HA-binding capacity 82% and estimated aneuploidy rate 4.12%. In the oligozoospermic samples mean sperm concentration was 7.13 M/mL, rate of dencondensed nuclei 41.8%, HA binding capacity 47.5% and the estimated aneuploidy rate 6.17%. All examined parameters differ significantly, if samples below and over 20% decondensation compared. There are inverse correlations between sperm decondensation and sperm concentration (r = -0.876), as well as sperm decondensation and hyaluronic binding capacity (r = -0.876). Sperm decondensation rate is also related to aneuploidy rate (r = 0.559).

Limitations, reason for caution: Data on confounders influencing sperm characteristics such as smoking, occupational or environmental hazards, comorbidities were not collected.

Wider implications of the findings: Although chromatin condensation occurs in late phase of spermatogenesis, it shows correlation with cytogenetic abnormalities and membrane remodelling, irrespective to the fertility status. It can be explained with a common regulation mechanism, thus malfunction of it can result in various sperm defects on different levels. However, since examined biomarkers reflect different sperm defects, they cannot replace each other.

Study funding/competing interest(s): Funding by national/international organization(s) – This research was supported by the European Union and the State of Hungary, co-financed by the European Social Fund in the framework of TÁMOP 4.2.4.A/ 2-11/1-2012-0001

Trial registration number: NA.

Keywords: sperm function, sperm biomarkers, sperm decondensation, sperm aneuploidy, hyaluronic binding capacity

P-085 Role of plasma membrane Ca^{2+} ATPase 4 gene in sperm motility and male infertility – a preliminary study

J. Erenpreiss[1], I. Innashkina[2], B. Lace[2], M. Punab[3], E. Jankevics[2]

[1]*Latvian Biomedical Research and Study Centre, Andrology Unit, Riga, Latvia*

[2]*Latvian Biomedical Research and Study Centre, Genetic Laboratory, Riga, Latvia*

[3]*Tartu University Hospital, Andrology Unit, Tartu, Estonia*

Study question: A project aims to explore the role of the Plasma Membrane Ca^{2+} ATPase (PMCA) 4 in sperm motility and male infertility.

Summary answer: Mutations in PMCA4 gene seem to be associated with decreased sperm motility, and male infertility.

What is known already: Experiments on mice have demonstrated that spermatozoa of the animals with deleted PMCA4 loose their motility ability in the environment that requires the hyperactivation of sperms (corresponding the environment of the upper female genital tract) due to their defect in Ca^{2+} homoeostasis. There are no data available at the moment whether functional status of the PMCA4 (polymorphisms, mutations) in humans has any impact on sperm motility function and, thereby, on male fertility.

Study design, size, duration: Cross-sectional study of 191 patients, and a control group of 180 men

Participants/materials, setting, methods: Patient group consists of 191 Estonian men from infertile couples, with low progressive sperm motility (<20%). Control group consists of 180 young men (age 18–25 years) from general population with normal semen quality.

Main results and the role of chance: Apart from different synonymous polymorphisms with no functional impact, a known polymorphism variant G > A that causes the replacement of Glu to Lys has been detected in 11 patients in heterozygote state in exon 11, calling for the A allele frequency of 0.029. To assess whether the detected variant has been shown also in other populations, the available data from the worldwide 1000 genome project was examined. It showed that rs147729934 A allele in heterozygote state has been found only in 3 Finnish women among 93 Finns analysed (allele frequency 0.016). No A allele has been detected in other European populations (comprising in total 379 Europeans) analysed for this mutation, decreasing the frequency of the mutation among Europeans to 0.004. It makes the incidence of the mutation detected in this study among the 191 infertile male patients 7 times higher than in the other European populations. Analysis of the control group is under the process, the results will be reported during the congress.

Limitations, reason for caution: Since mutation has been also shown in some Finnish women, it should be checked whether the mutation found is really a disease associated, or the ethnicity specific variant – Estonians and Finns belong to the Finno-Ugric group.

Wider implications of the findings: Infertile patients with mutated PMCA4 most likely cannot benefit from the IUI or conventional IVF treatment due to the defected ATP synthesis needed for sperm hyperactivation, supposedly, ICSI is the method of choice for these patients. It will be also checked whether Latvians, Lithuanians and Russians that do not belong to the Finno-Ugric ethnicity group carry this mutation. These findings can shed the light on population genetics in Baltic-Scandinavian-Russian region.

P-086 Predictive factors influencing pregnancy rates after artificial insemination with donor semen: a prospective observational study of 935 cycles

A. Thijssen[1], H. Vankerrebroeck[2], W. Van der Elst[3], G. Mestdagh[2], N. Dhont[2], R. Campo[2], W. Ombelet[2]
[1]Hasselt University, Department of Physiology, Hasselt, Belgium
[2]Ziekenhuis Oost-Limburg, Department of Obstetrics and Gyneacology, Genk, Belgium
[3]Hasselt University, Centre for Statistics CENSTAT, Hasselt, Belgium

Study question: In this prospective observational study, we aimed to examine to which extent certain covariates such as female age, smoking/non-smoking, BMI, use of natural cycle, ovarian stimulation protocol, the insemination procedure itself, sperm quality parameters etc., can influence pregnancy rates after artificial insemination with donor semen (AID).
Summary answer: Taking all covariates into account, statistical analysis showed that the pregnancy rate significantly increases when the patient is young, stimulated with low dose gonadotrophins (hMG) or recombinant FSH (rec FSH) and when a high percentage of grade A sperm motility is observed.
What is known already: Many studies examining different factors predicting pregnancy outcome after AID treatment have been published before. The predictive value of covariates such as female age, smoking, BMI, ovarian stimulation protocols etc. was observed in many studies. However, in almost all studies these covariates were examined as independent of each other, which may result into misleading conclusions.
Study design, size, duration: During the period of July 2011 until November 2014, data from 935 AID cycles in 306 couples were collected prospectively in a tertiary referral infertility centre. Since the outcome results after AID cannot be analysed independently, statistical analysis was performed using a Generalized Estimating Equations (GEE) model.
Participants/materials, setting, methods: Covariates taken into account were female age, smoking/non-smoking, BMI, primary/secondary infertility, infertility diagnosis, cycle number, ovarian stimulation method, day 0 estradiol/progesterone levels, HCG-insemination interval, the insemination procedure itself, occurrence of blood loss after insemination, sperm quality parameters, inseminating motile count (IMC) and sperm washing procedure.
Main results and the role of chance: The clinical pregnancy rate, i.e., presence of fetal heart beat at 6–7 weeks of gestation, was 15,6% per cycle. A univariate statistical analysis of the dataset revealed the following parameters as predictive for a successful pregnancy outcome: age, primary/secondary infertility, stimulation method, estradiol levels at day 0, the percentage of grade A motility and the total motile sperm count (TMSC). By using the multivariate GEE analysis, we observed that only female age, the stimulation method and grade A motility were useful in predicting pregnancy after AID. Based on these predictive factors, we were able to build a Microsoft Excel sheet which can calculate pregnancy rates based on the values entered for female age, stimulation method and percentage grade A motility.
Limitations, reason for caution: It can be misleading to look at only one covariate at a time, because different observations are not independent of each other. Furthermore, GEE analysis has a low statistical power to detect statistically significant differences in groups with low success rates, such as observed in an AID programme.
Wider implications of the findings: According to our results, it seems that female age, whether or not using ovarian stimulation, type of ovarian stimulation and percentage grade A sperm motility are the most important factors influencing the success rate in a sperm donation programme. Ovarian stimulation with low dose protocols of hMG or rec FSH significantly improve the pregnancy rate per cycle, but one has to be careful for multiple pregnancies. Surprisingly, BMI and smoking didn't affect the outcome results significantly.
Study funding/competing interest(s): Funding by University(ies), funding by hospital/clinic(s), Funding by national/international organization(s) – This study is part of the 'Limburg Clinical Research Program (LCRP) UHasselt-ZOL-Jessa', supported by the foundation Limburg Sterk Merk, Province of Limburg, Flemish government, Hasselt University, Ziekenhuis Oost-Limburg and Jessa Hospital, Belgium.

P-087 Mission impossible? Improving ART outcome following unexplained total failed fertilisation

Abstract withdrawn by the author

P-088 Impact of clinical, hormonal and histopathological findings on sperm retrieval and pregnancy rates in azoospermic patients

I. Guler[1], M. Erdem[1], A. Erdem[1], E. Demirdag[1], N. Bozkurt[1], M. Oktem[1]
[1]Gazi University Faculty of Medicine, Obstetrics and Gynecology, Ankara, Turkey

Study question: Is it possible to predict sperm retrieval, fertilization, clinical pregnancy and live birth by clinical and/or hormonal factors in azoospermic patients with different testicular histolopathologies undergoing testicular sperm extraction (TESE) procedure after an ICSI cycle?
Summary answer: There was no significant variable to predict sperm retrieval, fertilization, clinical pregnancy and live birth among normal testicular histology, maturation arrest, sertoli only syndrome and peritubular hyalinization and tubular atrophy groups. However, in hypospermatogenesis group sperm retrieval (SRR) and pregnancy rates (PR) were higher in younger patients.
What is known already: Although testicular histology is the most significant variable regarding the success of TESE and ICSI outcome, this is the first study evaluating the impact of clinical and endocrinologic factors on sperm retrieval, fertilization, clinical pregnancy and live birth rates among azoospermic patients in most prevalent testicular histopathologic groups.
Study design, size, duration: A retrospective analysis of 271 patients with non-obstructive azoospermia who underwent TESE procedure for ICSI between 2003 and 2013.
Participants/materials, setting, methods: We searched our database for patients who were diagnosed with azoospermia and treated with TESE. Main outcome measures were the impact of male age, FSH, LH and testosterone levels, sperm parameters, duration of infertility on sperm recovery and pregnancy rates after TESE and ICSI cycles.
Main results and the role of chance: In baseline data, there was no significant difference between groups for male and female age, infertility duration, and total and free testosterone concentrations. FSH concentration was statistically higher in peritubular hyalinization and tubular atrophy group ($p < 0.0001$). Patients with motile sperm retrieved and conceived after TESE were younger in hypo-spermatogenesis group. There was no significant clinical and hormonal variable to predict sperm retrieval, fertilization, clinical pregnancy and live birth among normal testicular histology, maturation arrest, and sertoli only syndrome groups. The highest SRR and PR was in normal spermatogenesis (91,7 and 47,9%, respectively). The lowest SRR and PR was in maturation arrest (21,1%), and peritubular hyalinization + tubular atrophy groups (7,1%), respectively.
Limitations, reason for caution: Retrospective design was the major limitation of this study.
Wider implications of the findings: Younger azoospermic patients with hypospermatogenesis have higher chance for sperm retrieval and pregnancy after TESE. Only patients with testicular atrophy had higher FSH levels as compared to other histopathologic groups. This study also proposed that all azoospermic patients regardless of testicular histopathological diagnosis had some chance for sperm retrieval and pregnancy by TESE and ICSI.

Study funding/competing interest(s): Funding by University(ies) – Gazi University.

P-089 Sperm DNA fragmentation testing as a general marker for pregnancy outcome in IVF patients

K. Marron[1], C. Harrity[1], A. P. H. Walsh[1], D. Walsh[1]
[1]Sims International Fertility Clinic, Zentra Lab, Dublin, Ireland

Study question: Can sperm DNA fragmentation testing be used as a useful tool to predict ART outcome independent of female factors.
Summary answer: Sperm DNA fragmentation analysis was retrospectively shown to be an important independent variable in ART and thereby proves its inherent value as a useful laboratory test.
What is known already: Reactive oxygen species generated within sperm from IVF can have singularly destructive affects on susceptible sperm DNA and thus have knock on effects on fertilisation, embryo formation and pregnancy rate. Many techniques are available to determine this susceptibility but to-date none have shown a clear correlation between the technique used, the use of IVF or ICSI and the CPR.
Study design, size, duration: From January to August 2014 178 SDA tests were performed and centile charts created based on the distribution of the observed DNA fragmentation pattern. These outcomes were then retrospectively matched with the ART procedure employed and the clinical outcome.
Participants/materials, setting, methods: An in-house sperm DNA fragmentation test (SDA) was developed based on the technique described by Evenson in 2002. Following validation versus commercially available SCSA the test was offered commercially within Sims IVF clinic.
Main results and the role of chance: 231 sperm samples were analysed using this technique and centile charts of the distribution were calculated. At the time of analysis 137 cycles were performed in 104 of these couples, and the observed fragmentation rates were correlated with outcomes. Mean DFI was 21.4,with a standard deviation of 11.3. A DFI less than 21.4% was associated with a CPR with ICSI of 31.0% and IVF of 33.3% ($p = 0.84$). In the group with borderline DNA fragmentation (21.4–32.7%) CPR was higher with ICSI than IVF, 31.3 vs. 16.7% However, this difference was not statistically significant ($p = 0.44$). No patients with a DFI above 31.4% had IVF used as the method of fertilisation.
Limitations, reason for caution: There are a limited number of observations ($n = 231$), giving insufficient statistical power to draw conclusions in the borderline DFI group. Although not described, clinical decisions were made based on many factors and so may have influenced the ongoing CPR independent of SDA values or assessment.
Wider implications of the findings: Sperm DNA fragmentation analysis is an unbiased laboratory technique with merit as part of a male evaluation in preparation for ART. Further research is needed to assess if couples with DFI between 20 and 30% would benefit from ICSI rather than IVF. A power calculation demonstrates that 294 cycles would be needed to identify if the difference in pregnancy rates in this group of patients is statistically significant. A prospective RCT to assess this further would be beneficial to clarify the answer to this question.

[4]Department of Microscopy Laboratory of Cell Biology Institute of Biomedical Sciences Abel Salazar ICBAS and Unit for Multidisciplinary Research in Biomedicine Abel Salazar Institute of Biomedical Sciences UMIB-ICBAS University of Porto, and Centre for Reproductive Genetics Alberto Barros, Porto, Portugal

Study question: Do high levels of 17β-estradiol (E2) change the expression and functionality of solute carrier 4 (SLC4) bicarbonate transporters in rat Sertoli cells (SCs)?
Summary answer: In SCs treated with high levels of E2 we observed an increase in the expression levels of anion exchanger 2 (AE2) and of the electroneutral Na^+/HCO_3 – co-transporter (NBCn1), as well as altered transcellular transport, as perceived by the perturbation on the ATP-induced short-circuit transcellular current.
What is known already: Bicarbonate is essential not only for ion homeostasis but also for the maintenance of pH along the male reproductive tract. SCs play a major role in control of seminiferous tubules pH, partly due to the action of some of bicarbonate transporters. Previous studies support an association of high E2 levels with modulation of specific ion transporters expression involved in H^+ homeostasis in the efferent ductules.
Study design, size, duration: Primary cultures of SCs obtained from male Wistar rats were exposed to high concentrations of E2 (100 nM) during 24 h (at 33°C; 5% CO_2).
Participants/materials, setting, methods: Primary cultures of SCs were obtained from 22 days old male Wistar rats. SCs were cultured using a bicameral chamber system. mRNA expression was determined by conventional and quantitative RT-PCR. Protein expression was assessed by the slot-blot technique. Transcellular transport on cultured SCs was evaluated by voltage-clamp technique.
Main results and the role of chance: AE2, NBCn1, electroneutral Na^+/HCO_3^- co-transporters (NBCe1) and Na^+-driven Cl^-/HCO_3^- exchanger (NDCBE) were identified in SCs, being AE2 and NBCn1 the most abundant. E2-treated cells presented an increase in AE2 and NBCn1 protein levels, as well as altered transcellular transport. E2-treated SCs presented a perturbation of ATP-induced short-circuit current. This alteration was concurrent with augmented AE2 and NBCn1 levels. Overall, we report a relation between increased E2 levels and the expression/function of AE2 and NBCn1 in rat SCs, providing new evidence on the mechanisms by which E2 can regulate SCs physiology and consequently spermatogenesis, with direct influence on male reproductive potential.
Limitations, reason for caution: Although our study demonstrate significant effects of E2 on SCs physiology, an *in vitro* study (even when using primary cultures) does not exactly mimics the *in vivo* conditions, where cells are exposed to other biological influences.
Wider implications of the findings: E2 induces alterations on the expression levels of specific bicarbonate transporters and is able to modulate their functioning in rat SCs. In face to our results, it is imperative to further disclose the molecular mechanisms involved on bicarbonate transport and regulation in SCs, to identify and counteract possible alterations associated with pathological conditions associated with altered E2 levels that compromise the male reproductive potential.

[3]*University of Medicine and Pharmacy "Carol Davila"/Elias Emergency Hospital, Endocrinology Department, Bucharest, Romania*
[4]*MedLife Memorial Hospital, Materno Fetal and Human Reproduction Department, Bucharest, Romania*
[5]*University of Medicine and Pharmacy "Carol Davila"/MedLife Memorial Hospital, Obstetrics and Gynecology/Materno Fetal and Human Reproduction Department, Bucharest, Romania*

Study question: Are there any modifications in sperm count regarding demographic data, life-style and background pathology correlated to men age at Chernobyl event.
Summary answer: The reproductive health of men born after April 1986 is modified only by an increased BMI and mumps history while in men born before Chernobyl event the toxic environment and age have the highest impact on sperm count.
What is known already: Factors that determine the performance of sperm are supposed to be under intense selection because of their close correlation with fertilization success. A number of different factors have been suggested to account for fertilization probability including sperm concentration, sperm motility morphology. Sperm morphology and performance can be affected by radiation of the Chernobyl event. Some studies in humans have shown changes in ultra-structure of the sperm head when exposed to high levels of radiation.
Study design, size, duration: Cross-sectional study of 1442 men who performed a sperm evaluation for infertility between January 2014 and December 2014. The patients were divided in 2 groups according to the date of birth (before and after Chernobyl event – April 1986).
Participants/materials, setting, methods: 1442 men (mean age 35.2 years, range 18 – 82 years was recruited. A semen analysis count was performed by the same embryologist. Data regarding personal medical history, demographic data and life style (including smoking and alcohol frequency intake) were collected. Statistical analysis was performed using SPSS v.19. Linear regression analyzis and ANOVA test were applied for comparisons between groups.
Main results and the role of chance: In patients born after 1986 higher BMI was associated with a decreased percentage of sperm motility ($p = 0.03$) and the medical history of mumps was associated with a lower pH ($p = 0.012$).

For the patients born before April 1986 the results were completely different. In this group the age modifies semen volume ($p = 0.014$), pH ($p < 0.001$) and percentage of motile sperm cells ($p = 0.035$). Also for this second group the exposure to toxic environment affects the sperm concentration ($p = 0.002$) but the mumps medical history has no impact on sperm parameters. For both groups the alcohol consumption and smoking doesn't influence the sperm parameters.
Limitations, reason for caution: Although this is a prospective observational study and the statistical biases were excluded there are still potential errors in individual's questionnaire filling. Furthermore we cannot exclude that our findings are due to unmeasured factors including diet, exercise and stress.
Wider implications of the findings: Besides being a regional study of reproductive men health it has an international implication in how Chernobyl event affected male sperm parameters. Our study suggested that smoking and alcohol intake are not the most important factors in reproductive men health but BMI, age and toxic environment. In the group of men born before Chernobyl event the BMI is the most important (the age is not related with the sperm analysis) while in the second group the toxic agents affect the sperm count.

P-092 Reduced sperm quality is reflected in clinical outcome in advanced maternal age – independently of blastocyst quality – rendering sperm selection increasingly important

M. Schuff[1], B. Wirleitner[1], P. Vanderzwalmen[2], M. Bach[1], D. Schwerda[1], A. Stecher[1], A. Neyer[1], N. H. Zech[1]
[1]*IVF-Centers Prof. Zech, Bregenz, Austria*
[2]*Centre Hospitalier Inter Régional Edith Cavell CHIREC, _, Braine-l'Alleud, Belgium*

Study question: The aim of the study was to evaluate whether blastocysts derived from sperm with reduced quality have a reduced chance to implant. This question was tested for young IVF-patients as well as for patients with advanced maternal age (AMA).
Summary answer: Our results demonstrate that blastocysts originating from ejaculate with diminished sperm quality (quantity, motility and morphology and absence of intracytoplasmic morphologically selected sperm injection IMSI class I) have a reduced chance to result in a live birth in the AMA group as compared to blastocysts from normozoospermic men.
What is known already: It is well recognized that semen of sub-fertile men show higher rates of numerical and structural chromosomal abnormalities. Therefore sperm selection is important and will result in a higher blastocyst rate, especially in patients with severely reduced sperm quality. Maternal age plays an important role in oocyte competence and the efficacy of repair mechanisms, being one important reason why implantation rates decrease with AMA.
Study design, size, duration: We conducted a retrospective study on 247 IVF/IMSI cycles between 2012 and 2013. All patients received a fresh single embryo transfer (SET). Clinical outcome was evaluated in respect to sperm quality, blastocyst morphology and maternal age. Final outcomes were pregnancy rate (PR), birth rate (BR) and abortion rate.
Participants/materials, setting, methods: For all cycles fresh semen samples were collected on the day of ovum pick-up, sperm quality was evaluated and the samples were processed by discontinuous density gradient centrifugation before IMSI. Embryos were cultured in a single step medium. On day 5 blastocyst morphology was evaluated and SET was performed.
Main results and the role of chance: No differences in clinical outcome according to sperm quality were observed in 165 cycles of women ≤38 years. 51 patients presented with normozoospermic partners (PR:54.9%,oPR:47.1%,BR:45.1%), 90 with reduced sperm quality but IMSI class I sperm (PR:53.3%,oPR:48.9%,BR:45.6%) and 24 had reduced sperm quality without class I sperm (PR: 66.7%,oPR:58.3%,BR:54.2%). The rate of top-blastocyst transfers and mean female age was similar in all groups.

In contrary, sperm quality seems to play an important role in patients with AMA (>38 years, 82 cycles). 29 patients presented with normozoospermia (PR:44.8%,oPR:37.9%,BR:31.0%), 37 with reduced sperm quality but IMSI class I sperm (PR:35.1%,oPR:29.7%,BR:21.6%) and 16 had reduced sperm quality without class I sperm (PR:18.8%,oPR:12.5%,BR:12.5%). Again, rate of top-blastocyst transfers and mean female age was similar.
Limitations, reason for caution: These preliminary data have to be confirmed in a larger setting including more data on the health of children born.
Wider implications of the findings: Our results show that blastocysts originating from poor sperm quality have a reduced chance to result in a live birth in AMA-couples. This effect is not present in younger patients, underlining that the oocyte competency and repair mechanisms diminish over time rendering sperm selection more crucial. Our findings indicate that IMSI is most important in poor sperm quality in combination with AMA.
Study funding/competing interest(s): Funding by hospital/clinic(s) – This study was not externally funded.
Trial registration number: NA.

P-093 Comparison of ICSI outcomes between ejaculated versus extracted testicular spermatozoa in extreme oligozoospermic men and non-obstructive azoospermia

G. Robin[1], P. Plouvier[1], V. Lefebvre-Khalil[2], V. Mitchell[3], D. Dewailly[1], J. M. Rigot[4]
[1]*Hospital Jeanne de Flandre, Reproductive Medicine and Endocrine Gynaecology, Lille, France*
[2]*Hospital Jeanne de Flandre, Reproductive Biology, Lille, France*

[3]Hospital Albert Calmette, Reproductive Biology, Lille, France
[4]Hospital Albert Calmette, Andrology, Lille, France

Study question: To assess whether the origin of sperm (testicular or ejaculate) has any influence on ICSI outcomes (fertilization rates, embryo quality, implantation rates, pregnancy rates) in case of extreme alterations of spermatogenesis.
Summary answer: There is no difference in ICSI outcomes between cycles performed with ejaculated spermatozoa in oligozoospermic men and those performed with testicular spermatozoa in non-obstructive azoospermia. Testicular sperm extraction (TESE) is an invasive procedure, so, it should be recommended to use ejaculated spermatozoa as often as possible.
What is known already: Some patients have very low sperm count on direct examination (extreme oligozoospermia) or after centrifugation (cryptozoospermia). The therapeutic management of these patients is a real challenge for physicians and biologists. Some authors proposed the use of testicular sperm in case of very low sperm count to improve ICSI outcomes. However, data in the literature are controversial.
Study design, size, duration: We compared, in a retrospective study, 75 patients with extreme oligozoospermia who underwent 161 ICSI cycles with ejaculated spermatozoa (group 1) and 74 patients with non-obstructive azoospermia (NOA) who underwent 150 ICSI cycles with extracted testicular spermatozoa (group 2), between January 2007 and June 2013 at the Lille University Hospital.
Participants/materials, setting, methods: Physical, hormonal, and ultrasound assessments were performed. Semen samples were analyzed, followed by centrifugation. We chose the threshold of 10,000 spermatozoa per ejaculate to define "extreme" oligozoospermia. The testicular disorder of spermatogenesis in both group was defined by a testicular volume <16 mL and/or FSH levels >10 UI/L.
Main results and the role of chance: Cryptorchidism was significantly more common in the NOA group (60.8 versus 22.6%, $p = 0.001$). FSH levels were significantly higher (18.9 IU/L versus 15.3 IU/L, $p = 0.001$) and Inhibin B levels were more often undetectable (31.1 versus 10.7%, $p = 0.0004$) in NOA group, reflecting a deeper alteration of spermatogenesis in case of NOA. There were no significant differences in fertilization rates (48.9 and 43.3%, $p = 0.43$), implantation rates (17.4 and 15.9%, $p = 0.77$) and percentage of top quality embryo (22.4 and 20.4%, $p = 0.73$) between the two groups. The clinical pregnancy rates per embryo transferred were comparable in both groups (28.3 and 27.4%, $p = 0.89$).
Limitations, reason for caution: There is no threshold to define "extreme" oligozoospermia. We chose the threshold of 10,000 spermatozoa per ejaculate because below this threshold ICSI seems to be technically more difficult and may impair fertilization rates. Extreme oligozoospermia and cryptozoospermia were gathered into the same group because the therapeutic management is strictly similar.
Wider implications of the findings: This study shows similarly ICSI outcomes in extreme oligozoospermia (ejaculated sperm) and in NOA (testicular sperm). In case of extreme oligozoospermia, we should strive to use ejaculated sperm because: (1) TESE is an invasive technique, (2) it is in the epididymis that spermatozoa completes its maturation and undergoes epigenetic changes, (3) testicular sperm does not seem to improve ICSI outcomes. Moreover, few studies are available about future of children born after ICSI with testicular sperm.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Lille University Hospital.
Trial registration number: NA.

P-094 Sperm DNA oxidation: a new marker of fertility?

S. Vorilhon[1], F. Brugnon[1], A. Kocer[2], S. Dollet[2], C. Bourgne[3], M. Berger[3], L. Janny[1], J. Drevet[2], Pons-H. Rejraji[1]
[1]Clermont University Clermont Ferrand CHU Estaing Hospital, Laboratory of Developmental Biology and Reproduction: AMP-CECOS GReD, Clermont Ferrand, France
[2]Clermont University, GReD, Clermont Ferrand, France
[3]Clermont Ferrand CHU Estaing Hospital, Laboratory of Biological Hematology, Clermont Ferrand, France

Study question: Can the measure of human sperm DNA oxidation be standardized as a biomarker of sperm quality and men fertility in clinical practice?
Summary answer: Our study demonstrate accuracy and reliability of human sperm 7,8-dihydro-8-oxo-2 '-deoxyguanine (8-OHdG) immuno-detection to measure human sperm DNA oxidation by flow cytometry (FCM) or fluorescence microscopy (FM) in clinical practice, in relationship with semen parameters.
What is known already: Oxidative stress is involved in many disorders including male infertility, notably by inducing sperm DNA decondensation and fragmentation. Sperm nuclear integrity is essential to conduct paternal genome transmission to offspring and normal embryonic development. We previously validated an immuno-detection protocol to measure sperm 8-OHdG biomarker using microscopy in a murine model of oxidation (snGPx4 and GPx5 double mutant). To our knowledge, no standardized protocol exists to assess human sperm nuclear oxidation in clinical practice.
Study design, size, duration: In this prospective study, we compared immuno-detection methods of human sperm 8-OHdG to select standardized protocols to measure human sperm DNA oxidation in clinical practice. During 12 months, using the validated protocols, sperm DNA oxidation of 55 infertile patients (36 ± 6 years) were measured in relation with their semen parameters.
Participants/materials, setting, methods: Immuno-detection protocols were developed and compared to measure human sperm DNA oxidation using visible or fluorescence microscopy (anti-8-OHdG primary antibody and peroxidase-conjugated or Alexa488-conjugated secondary antibody), or FCM (anti-8-OHdG + Alexa488-conjugated antibodies or commercial OxyDNA assay® kit). FCM measures were confronted with semen parameters of infertile patients.
Main results and the role of chance: Oxidation values obtained after peroxidase-conjugated *versus* Alexa488-conjugated antibodies using microscopy detection were moderately concordant ($\kappa = 0.65$) but significantly correlated ($r = 0.60$; $p < 0.05$). In addition, oxidized sperm proportion detected with anti-8-OHdG and Alexa-conjugated antibodies were underestimated (-11%, $n = 5$) with FM in comparison with FCM. Finally, the proportions of 8-OHdG positive sperm revealed by FCM were significantly different for 8-OHdG/Alexa protocol (60 ± 3%) and OxyDNA kit (85 ± 1.7%) $p < 0.001$. The values measured with the two methods were positively correlated ($r = 0.43$; $p < 0.001$) but not concordant (bias of 25%). For this last comparison, sperm parameters of 55 infertile patients, presenting astheno- necro- leuco- or teratozoospermia, were confronted to oxidation measures. We observed significant correlation between sperm DNA oxidation and spermatozoa quality, notably vitality and mobility.
Limitations, reason for caution: All the protocols lack of a true negative control of human sperm DNA oxidation. Discrimination of the different patterns obtained after peroxidase-conjugated detection using FM was extremely difficult and presented an important inter-observer variability, which highlights the need for fluorescence detection and FCM.
Wider implications of the findings: Our study shows the accuracy and reliability of measuring human sperm DNA oxidation level by FCM and FM. The determination of an oxidation threshold would improve male infertility diagnosis, ART prognosis, and adapt the antioxidants taking for patients having abnormal DNA oxidation levels. Furthermore, our results open on studying prospect of the impact of sperm DNA oxidation on embryonic development and the pregnancy chances obtained by ART.

P-095 Trequinsin HCl: A novel specific human sperm motility inducer identified by high-throughput screening using intracellular Ca^{2+} signalling as a surrogate physiological response

H. Ruso[1], C. Cochrane[2], A. Hope[3], C. Barratt[2], S. J. Martins da Silva[2]
[1]Gurgan Clinic Women's Health and IVF Centre, IVF Unit, Ankara, Turkey
[2]University of Dundee, School of Medicine, Dundee, United Kingdom
[3]University of Dundee, College of Life Sciences, Dundee, United Kingdom

Study question: Does Trequinsin HCl, an ultrapotent phosphodiesterase type 3 (PDE 3) specific inhibitor, has any effect on human sperm motility and acrosome reaction?
Summary answer: Trequinsin HCl was found to be an effective drug in stimulating human sperm total and progressive motility at 10 µM without stimulating premature acrosome reaction (AR).
What is known already: Both Ca^{2+} and cAMP play a pivotal role in controlling human sperm motility. Thus, several non-specific PDE inhibitors (such as methylxanthines) have been used historically as motility inducers. However, their use is compromised by induction of premature acrosome reaction.
Study design, size, duration: This was a prospective study investigating the effect of Trequinsin HCl on human sperm motility and acrosome reaction. The effect of 10 µM Trequinsin HCl on motility was assessed by CASA and Kremer penetration over 2 h. The acrosome reaction was evaluated using FACS.
Participants/materials, setting, methods: All experiments were performed at University of Dundee, School of Medicine. Sperm from 4 healthy research donors and one patient (attending Assisted Conception Unit, Ninewells Hospital, Dundee) were treated with Trequinsin and motility responses were evaluated over 2 h. Acrosome reaction was evaluated by FACS by incubating sperm cells with PSA-FITC dye for 1 h, co-incubated with Trequinsin or controls.
Main results and the role of chance: 10 µM Trequinsin significantly increased both 40 and 80% fraction donor sperm total and progressive motility under both capacitating and non-capacitating conditions ($n = 4$, $p < 0.05$). There was a significant increase in sperm number following Kremer penetration assay ($p < 0.05$). Sperm from an ICSI cycle with total failed fertilisation case were also treated with 10 µM Trequinsin HCl and showed significant increase in both total and progressively motile sperm population under both capacitating and non-capacitating conditions ($n = 1$, $p < 0.05$). Acrosome reaction, on the other hand, showed no significant increase.
Limitations, reason for caution: This is an *in vitro* study using healthy donor sperm to investigate the effect of Trequinsin HCl on human sperm motility and acrosome reaction. Although the 40% fraction sperm is known to have similar motility parameters with asthenozoospermic specimens it is important to test Trequinsin HCl on patient samples.
Wider implications of the findings: It is clear that Trequinsin HCl is an effective and specific stimulator of human sperm motility with preliminary data also supporting its effectiveness in patient sperm, and may represent a novel therapeutic approach to male subfertility.
Study funding/competing interest(s): Funding by national/international organization(s) – Study funded by TENOVUS Scotland (Dr Sarah Martins da Silva Principal Investigator). The investigators have no competing interests.
Trial registration number: Ethical approval 08/S1402/6.

P-096 Impact of early apoptosis in sperm cells: our results in 598 patients

R. Lafuente[1], G. López[1], J. Canals[1], D. Rey[1], E. Carballo[1], M. Brassesco[2]
[1]CIRH. Clínica Corachan. ANACER, Andrology Lab, Barcelona, Spain
[2]CIRH. Clínica Corachan. ANACER, Medical Dpt, Barcelona, Spain

Study question: Apoptosis is a necessary process for natural cell regeneration, but how is it manifested in sperm cells depending on the basic semen parameters?, how useful is to know the level of cell apoptosis?
Summary answer: Oligozoospermic patients have a higher incidence of apotosis in live cells. The use of these cells in fertility treatments could jeopardize the success of the technique. It is important to identify the patients with elevated apoptosis to make a correct sperm selection, using magnetic activated cell sorting (MACs).
What is known already: Although there are numerous cytometry tests available to study functionality of the sperm cells, this technology is not routinely used for the diagnosis of male factor. Much work remains to set up new techniques and determine which one has more prognostic value.
Study design, size, duration: This is a retrospective observational study with a total of 598 advanced semen analysis by flow cytometry from patients undergoing infertility treatment since 2013.
Participants/materials, setting, methods: After a basic semen analysis (concentration, motility and morphology), assessment of % apoptosis was performed by flow cytometry (MACSQuant Analyzer, Milteniy Biotec), with Anexin V-FITC and propidium iodide. Results were grouped according to the etiology of male factor: normozoospermic (32.6%), oligozoospermic (12.0%), asthenozoospermic (22.3%), teratozoospermic (26.3%) and oligoasthenoteratozoospermic (OAT) (6.8%).
Main results and the role of chance: The major group of patients with increased % of apoptosis (>15%) presented also low sperm concentration (25.6% of oligozoospermic patients) followed of 18.6% of OAT patients. Only 9.7% of normozoospermic patients showed apoptosis (>15%).
Limitations, reason for caution: None.
Wider implications of the findings: The incorporation of new diagnostic tests in the Andrology Lab should improve treatment outcomes, applying techniques of sperm selection according to the etiology of each patient. Oligozoospermic patients have a major probability of early apoptosis, in this cases ii would be recommendable a selection by MACS prior to ICSI.
Study funding/competing interest(s): Funding by national/international organization(s) – CIRH Foundation, Barcelona, Spain

P-097 Analysis of meiosis in testicular biopsy: relationship to sperm DNA fragmentation (SDF), ploidy status and apoptosis measured by flow cytometry

G. López Granollers[1], R. Lafuente[1], P. Godoy[2], E. Fabian[2], García-A. Peiró[3], Ribas-J. Maynou[3], M. Brassesco[2]
[1]CIRH Clinica Corachan, Andrology Laboratory, Barcelona, Spain
[2]CIRH Clinica Corachan, Medical Department, Barcelona, Spain
[3]CIMAB Parc de Recerca de la UAB, Research Department, Bellaterra Barcelona, Spain

Study question: It is known that meiotic chromosomal anomalies can cause alterations to one or more of the basic seminal parameters including sperm count, motility and morphology. However, is there any relationship between meiotic abnormalities and advanced seminal parameters measured by flow cytometry such as DNA fragmentation, ploidy status and apoptosis?
Summary answer: Patients presenting alterations on the results of an advanced semen testing (>30% SDF, >3% diploidies and >40% apoptosis) are more likely to present also meiotic chromosomal anomalies.
What is known already: Basic semen analysis may not provide all information to completely evaluate male fertility status. Consequently, several investigators have considered optimizing conventional routine methods to improve male infertility diagnoses. These advances have resulted in numerous techniques for evaluating sperm chromatin quality and DNA fragmentation. Both sperm chromosomal alterations and sperm DNA integrity are important parameters of sperm quality in the prognosis of infertility and in the outcome of assisted reproductive.
Study design, size, duration: In this cohort study, the incidence of meiotic abnormalities and their relationship with different advanced seminal parameters was assessed prospectively in 29 male patients. All had a history of implantation failure after two cycles of IVF/ICSI and ≥6 embryos transferred. The study was carried out between January and December 2014.
Participants/materials, setting, methods: All male underwent both testicular biopsy (TB) and advanced seminal analysis. Each sample was analysed by flow cytometry for %SDF using Sperm Chromatine Structure Assay (SCSA), diploidy test based on propidium iodide and apoptosis markers. Altered tests were considered when %SDF was >30%, apoptosis was >30%, and diploidies >3.3%.
Main results and the role of chance: Meiotic abnormalities were found in 15 cases (51.7%). When comparing abnormal meiotic group with normal group, no differences were found on the %SDF average. However, none (0/14) of the normal meiosis, in comparison to 3/15 (20%) of the altered meiosis had a %SDF >30%. Average percentages of diploidy were 1.5% in normal TB and 2.2% in altered TB. 1/14 (7.1%) of patients with normal meiotic results and 4/15 (26.6%) of patients with meiotic abnormalities showed also abnormal values of diploidy. Regarding apoptosis percentages, no differences were found between both groups. However, half (5/10) of patients with >30% apoptotic sperm and 100% (3/3) of patients with >40% apoptotic sperm showed also meiotic abnormalities.
Limitations, reason for caution: The present findings should be interpreted taking into account some limitations of the study, including the small study population and the lack of stiffness of the inclusion criteria. Moreover, further

data regarding clinical outcome must be included in order to confirm the predictive value of the analysed parameters.
Wider implications of the findings: Our present findings suggest a positive relationship between the results obtained from the meiosis study in testicular biopsy and the data from the advanced seminal analysis. In agreement with the published literature it seems that meiotic chromosomal anomalies, besides causing alterations in basic seminal parameters, can also cause alterations to one or more of the advanced seminal parameters.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Fundación CIRH.
Trial registration number: NA.
Keywords: TESE, meiosis, sperm DNA fragmentation, ploidy, sperm apoptosis

P-098 Correlation between two parameters of sperm DNA integrity, DNA fragmentation index and big halo pattern, with respect to sperm decondensation index and semen characteristics

A. Crippa[1], M. C. Magli[1], F. Muzzonigro[1], E. Colpi[2], E. Feliciani[1], A. P. Ferraretti[1], L. Gianaroli[1]
[1]*S.I.S.Me.R. s.r.l., Reproductive Medicine Unit, Bologna, Italy*
[2]*I.I.R.M., Reproductive Medicine Unit, Pambio-Noranco Lugano, Switzerland*

Study question: Do the DNA fragmentation index (DFI) and halo pattern correlate with sperm decondensation index (SDI) and WHO sperm parameters?
Summary answer: Both parameters of sperm DNA integrity evaluated by the Halosperm test correlate with SDI and WHO sperm parameters. However, the DFI has a stronger prediction than the big halo pattern on the proportion of spermatozoa with DNA condensation.
What is known already: The halosperm test measures the susceptibility of sperm DNA to acid denaturation. Spermatozoa with fragmented DNA fail to produce halos of dispersed DNA, which are characteristic for intact DNA. The DFI estimates the proportion of spermatozoa with fragmented DNA. Among cells with intact DNA, the resulting halo shows different patterns of dispersion. Several studies have demonstrated that men with abnormal semen parameters are more likely to have a higher percentage of sperm nuclear DNA damage.
Study design, size, duration: Until December 2014, a prospective study included 190 males with both normal and abnormal semen parameters as a part of semen analysis for fertility evaluation. The sperm samples were analysed for WHO semen parameters, sperm DNA integrity by Halosperm test and DNA decondensation by aniline blue assay.
Participants/materials, setting, methods: The patients included in the study were 24 normospermic, 140 moderate OAT (sperm concentration $\geq 5 \times 10^6$/ml), and 26 severe OAT (sperm concentration was $< 5 \times 10^6$/ml). A big halo was defined as a dispersion greater or equal to the length of the minor diameter of the core.
Main results and the role of chance: For DFI, negative correlations were found with progressive motility (r = -0.54, p = 7.13E-16), total motility (r = -0.59, p = 2.60E-19) morphology (r = -0.44, p = 4.10E-10) and vitality (r = -0.51, p = 2.00E-13); while positive correlation was found with SDI (r = 0.44, p = 3.61E-10). For the big halo pattern, positive correlations were found with progressive motility (r = 0.34, p = 1.64E-06), total motility (r = 0.37, p = 2.03E-07) morphology (r = 0.38, p = 7.60E-08) and vitality (r = 0.40, p = 7.60E-08); negative correlation was found with SDI (r = -0.34, p = 1.90E-06). The degree of correlation was stronger for DFI than for the big halo pattern.
Limitations, reason for caution: The Halosperm test permits to discriminate between sperm with fragmented DNA and sperm with intact DNA. Unfortunately, the invasivity of the Halosperm tests does not permit its use as a selection technique at the time of ICSI.
Wider implications of the findings: Testing the semen conventional parameters provides limited prediction of male fertility potential and is not always able to explain the cause of infertility. Here, DFI has a stronger correlation than the big halo pattern with respect to the sperm chromatin condensation status and semen parameters. Given the reports documenting the negative effect of DFI and embryo viability, its evaluation on sperm cells could contribute relevant information to the prediction of the male reproductive potential.
Study funding/competing interest(s): Funding by hospital/clinic(s) – S.I.S.Me.R.

P-099 State of chromatin compaction and its impact on sperm DNA damage under oxidative stress conditions

F. Azpiroz[1], D. Lorenzi[1], F. Nodar[1], C. Álvarez Sedó[1]
[1]*CEGyR, Buenos Aires, Argentina*

Study question: Does chromatin compaction have an impact over DNA fragmentation under oxidative stress conditions?
Summary answer: Our results demonstrate that the induction of oxidative stress by hydrogen peroxide incubation significantly increased levels of sperm DNA fragmentation in sperms that have impaired chromatin compaction. The presence of sperm plasma has a protective function at initial incubation periods.
What is known already: It has been described that an altered chromatin compaction could be associated to DNA fragmentation in infertile patients.
Big vacuoles (over 50% of nuclear surface) are associated to DNA fragmentation in infertile patients.
Study design, size, duration: This is a case control study. Thirty samples (15 each group) were recruited for the present study. Six month were used to perform the study.
Participants/materials, setting, methods: Chromatin compaction (CC) was assessed by Acridine Orange and MSOME. Two groups: normal CC and altered CC. Incubated with hydrogen peroxide (15 min) (with (A) and without (B) seminal plasma) and incubated without hydrogen peroxide (with (C)and without (D)seminal plasma). An aliquot was obtained to assess DNA damage and lipid peroxidation at 0–2–4–22 h.
Main results and the role of chance: Seminal parameters of the group with alterations in the CC: volume 2.6 ± 1.1, concentration 63.2 ± 24.2, progressive motility 47.5 ± 14.3, vitality 76.8 ± 15.1, morphology 4.6 ± 1.5, DNA fragmentation 17.2 ± 5.1, lipid peroxidation 11.3 ± 5.2. Seminal parameters in the group without alterations in the CC were: volume 2.8 ± 0.9, concentration 20.2 ± 72, progressive motility 45.1 ± 10.8, vitality 79.2 ± 8.8, morphology 5.8 ± 2.5, DNA fragmentation 13.1 ± 2.9, lipid peroxidation 9.5 ± 2.4. After incubation with peroxide, lipid peroxidation levels progressively increased over time, being statistically significant after 4 h for both groups. Levels of DNA fragmentation increased significantly from 22 h in the group with normal CC and from 4 h in the group with alterations in the CC. In both groups after 22 h, samples A vs. C showed greater resistance (statistically significant) to peroxidation (31 vs. 42%) and DNA fragmentation (44 vs. 65%).
Limitations, reason for caution: Evaluation of the parameters might have been measured at 8 and 12 h in order to have a more precise increase over time.
Wider implications of the findings: We consider our findings significant since in infertile men it is of major importance to know the spermatic oxidative status in order to give genuine relevance to the chromatin state; since in previous studies we have shown that men with impaired CC and oxidative damage, DNA damage occurs in both sperm with chromatin abnormalities and those without it. However, in patients without CC alterations and without oxidative damage, sperm with alterations in chromatin specifically show greater DNA damage. Confirm the protective effect of seminal plasma against oxidative stress.
Study funding/competing interest(s): Funding by hospital/clinic(s) – CEGyR Fundation.
Trial registration number: No trial registration number-experimental design.
Keywords: sperm, DNA damage, oxidative stress, chromatin

P-100 Evaluation of the efficiency of two different cryoprotectants and two different protocols to preserve human spermatozoa from cryoinjury

M. F. Starita[1], A. Alteri[1], E. Rega[1], P. Giannini[1], C. Piscitelli[1], A. Colicchia[1], G. Fabozzi[1]
[1]*Villa Margherita, Ferticlinic, Rome, Italy*

Study question: To evaluate the efficiency of two different cryopreservation protocols and two common cryoprotectants (CPs), TEST Yolk Buffer (TYB) and Sperm Freeze (SF), to preserve sperm quality in terms of cryosurvival and post-thaw motility.
Summary answer: TYB resulted in the best cryoprotectant and CP addiction directly to seminal plasma without sperm washing appeared to be the most efficient freezing protocol.
What is known already: It is universally recognized that cryopreservation impairs sperm quality. In order to improve post-thawing sperm survival and motility, media of different composition have been proposed. Basically, all semen

CPs contain glycerol as main permeating cryoprotectants, in other cases they also contain other macromolecules, such as egg yolk. Sperm washing is often performed before CP addiction. However, no clear evidences are available to understand which is the most efficient protocol and CP for sperm cryopreservation.
Study design, size, duration: This prospective cohort study enrolled a total of 188 sperm samples undergoing sperm evaluation from September to December 2014. Samples were cryopreserved using two different CPs and two different protocols. Sperm vitality and progressive motility were the outcome measures assessed after thawing by a blinded observer according to WHO 2010.
Participants/materials, setting, methods: A total of 92 were split into 2 aliquots and cryopreserved by TYB and SF after washing and resuspension. Then, other 92 sperm samples, were split into 2 aliquots and cryopreserved using the same CPs adding them directly to the semen. Sperm vitality and motility were compared between the aliquots.
Main results and the role of chance: TYB provided better post-thaw vitality respect to SF whether for the washed aliquots, respectively 21.20 vs. 15.71% ($P = 0.00001$), or for the aliquots cryopreserved without washing, respectively 27.21 vs. 21.71% ($P = 0.022$). Progressive motility was significantly different in favour of TYB only when aliquots were washed and resuspended, respectively 18.41 vs. 13.99% ($P = 0.001$) and no when CPs were added directly to the sperm sample (16.63% TYB vs. 13.36 SF, $P = 0.14$). Then, the freezing protocol was investigated. Sperm vitality was significantly higher for not washed samples compared to washed ones, respectively 21.20 vs. 27.21% TYB ($P = 0.06$) and 15.71 vs. 21.71% SF ($P = 0.0003$). No significant difference was detected in post-thaw progressive motility comparing washed and not washed samples, respectively 18.41 vs. 16.63% TYB and 13.99 vs. 13.38% SF.
Limitations, reason for caution: This was a prospective cohort study of a limited sample size. Logistic regression analysis was used to control for possible confounding factors (i.e., sperm quality), however, a bigger sample size should be examined in order to confirm these preliminary data.
Wider implications of the findings: This study provides advice concerning the best strategy to cryopreserve sperm samples. Our data suggest that TYB provides better results especially when samples are washed before freezing. Probably, seminal plasma exerts a natural protective role and, when samples are washed before freezing, macromolecules such as egg yolk in addition to glycerol as main CP, can be crucial to protect sperm from cryodamage, replacing the role of seminal plasma.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Ferticlinic, Villa Margherita, Rome, Italy.
Trial registration number: NA.
Keywords: sperm cryopreservation, test yolk buffer, sperm freeze, cryopreservation protocol, sperm washing

P-101 Improved clinical outcomes of IVF-ICSI cycles with preimplantation genetic screening by CGH in couples affected of severe male factor and synaptic chromosome anomalies

L. Coll[1], J. M. Vendrell[1], M. Parriego[1], S. Mateo[1], I. Rodríguez[1], F. Martínez[1], M. Boada[1], B. Coroleu[1], P. N. Barri[1]
[1]Hospital Universitario Quiron Dexeus, Salud de la Mujer Dexeus, Barcelona, Spain

Study question: Is Preimplantation Genetic Screening by CGH (CGH-PGS) an alternative management for IVF-ICSI cycle in male factor with synaptic chromosome anomalies?
Summary answer: Clinical outcomes improved by using CGH-PGS, despite off risk of no embryo transfer.
What is known already: The incidence of meiotic chromosome anomalies limited to the germ cell line in patients with severe low sperm counts ($<5 \times 10^6$ sperm/ml) increases with decreased sperm count. Furthermore, oligozoospermic patients have a significant increase in de-novo sex chromosome and autosomal aneuploidies in a series of children born after IVF-ICSI.
Study design, size, duration: In a private IVF clinic, from January 2010 until March 2014, one hundred and nine couples with severe male factor and synaptic anomalies (abnormalities in chromosome pairing) underwent an IVF-ICSI cycle. CGH-PGS was offered to these couples and decided whether to undergo PGS or not. Clinical outcomes are presented.
Participants/materials, setting, methods: Synaptic anomalies were diagnosed in 109 males by FISH in severe oligozoospermia ($<5 \times 10^6$ sperm/ml) or by testicular biopsy in azoospermia. 129 IVF-ICSI cycles were analyzed: 60 underwent PGS and 69 did not. We compared the fertilization, implantation, ongoing pregnancy, miscarriage and live birth rates between both groups.
Main results and the role of chance: No statistically significant differences were observed between PGS and non-PGS groups in maternal age (34.6 ± 2.8 years vs. 34.5 ± 5.8 years), number of inseminated oocytes (14.0 ± 3.7 vs. 13.0 ± 5.8), sperm concentration (3.1 ± 3.9 million/ml vs. 2.2 ± 2.7 million/ml) and fertilization rate (67.7% vs. 70.6%). One hundred and thirty three embryos were chromosomally normal (25.6% of the biopsied embryos and 28.3% of the diagnosed embryos). Significant differences were observed in the number of transferred embryos (1.27 ± 0.80 vs. 2.17 ± 0.54) ($p < 0.0001$) and in the number of transfers (48(80%) vs. 69(100%)) ($p < 0.0001$). No differences between groups were observed regarding ongoing pregnancy rate (51.7% vs. 40.8%) and miscarriage rate (12.9% vs. 32.1%). Significant clinical differences were observed in implantation rate (56% vs. 24.7%) ($p < 0.05$) and in live birth rate (45% vs. 27.5%) ($p < 0.05$).
Limitations, reason for caution: This is an observational study, and further studies are needed in order to confirm these preliminary results. The risk transfer of non normal embryos cannot be excluded.
Wider implications of the findings: Selection of chromosomally normal embryos by CGH-PGS can improve clinical outcomes in couples affected by severe male factor and synaptic chromosome anomalies.
Study funding/competing interest(s): Funding by hospital/clinic(s) – "Cátedra de Investigación en Obstetricia y Ginecología" of the Department of Obstetrics, Gynecology and Reproduction, Hospital Universitario Quiron Dexeus.
Trial registration number: NA.
Keywords: severe male factor, synaptic chromosome anomalies, PGS

P-102 Association between adherence to the Mediterranean diet and semen parameters in men of subfertile couples undergoing in vitro fertilization treatment

D. Karayiannis[1], M. Kontogianni[1], C. Mendorou[2], C. Karamalegos[2], M. Mastrominas[2], N. Yiannakouris[1]
[1]Harokopio University School of Health Science and Education, Department of Nutrition and Dietetics, Athens, Greece
[2]Embryogenesis Centre for Reproductive and Fertility Studies, Assisted Conception Unit, Athens, Greece

Study question: Is adherence to the Mediterranean Diet (MD) associated with semen quality in men undergoing in vitro fertilization treatment (IVF)?
Summary answer: Greater adherence to the MD, as assessed through a Mediterranean Diet score (MD-score), was significantly and positively associated with higher semen concentration, total semen count, and total and progressive motility, after adjustment for potential confounders including age, body mass index (BMI), smoking, physical activity level and state/trait anxiety.
What is known already: A dietary pattern characterized by high intakes of fruits, vegetables, fish and whole grains was recently shown to be associated with better semen quality in men undergoing IVF treatment. In addition, a 'prudent' dietary pattern characterized by high intakes of fish, chicken, fruit, vegetables, legumes and whole grains was found to be associated with higher semen progressive motility in young men. Whether adherence to the MD affects semen parameters remains to be evaluated.
Study design, size, duration: This is an ongoing cross-sectional cohort study assessing dietary and lifestyle habits in men of subfertile couples undergoing IVF/ICSI at the Embryogenesis Unit, Athens, Greece. The study started in September 2014 and was designed to evaluate the influence of habitual dietary intake and lifestyle on fertility and pregnancy outcome.
Participants/materials, setting, methods: Seventy-one male participants filled out a general questionnaire comprising information on lifestyle/demographic factors and a validated food-frequency questionnaire to assess habitual dietary intakes. Adherence to MD was assessed with a MD-score (ranging from 0 to 55; higher scores indicate better adherence to MD) that incorporates the inherent characteristics of this diet.
Main results and the role of chance: Mean (±SD) sample age was 40.1 ± 4.5 y, mean BMI was 26.6 ± 3.5 kg/m^2 and mean MD-score was 29.6 ± 7.4, respectively. A highly significant positive correlation was observed between MD-score and semen concentration ($r = 0.72$), total semen count ($r = 0.69$), total motility ($r = 0.75$) and progressive motility ($r = 0.73$) (all p-values < 0.05). Moreover, subjects in the highest tertile of MD-score had significantly higher values in the above semen parameters, compared to subjects in the lowest

tertile of the score. The MD-score was unrelated to sperm morphology and volume. Multiple regression models controlling for potential confounders (age, waist, BMI, anxiety, physical activity) confirmed that MD-score is a significant predictor (β coefficient ± SE) of semen concentration (2.61 ± 0.23), total semen count (8.75 ± 0.95), total motility (2.26 ± 0.21) and progressive motility (1.51 ± 0.18), (all *p*-values < 0.05).

Limitations, reason for caution: The main limitation of the study stems from its small sample size, while its cross-sectional nature limits our ability to determine causality of adherence to the MD on semen quality parameters.

Wider implications of the findings: This study demonstrates that habitual dietary intake affects semen quality and support the suggestion that counseling men to increase adherence to the Mediterranean Diet may be an easy and safe way to improve measures of semen quality. Additionally, these findings are consistent with previous studies showing that dietary patterns with some of the characteristics of the traditional MD, i.e. rich in fruit, vegetables, legumes and whole grains, are associated with better measures of semen quality.

Study funding/competing interest(s): Funding by hospital/clinic(s) – None.

Trial registration number: NA.

[3]*Instituto Universitario IVI Valencia, IVF Laboratory, Valencia, Spain*

[4]*Principe Felipe Research Center, Cytometry Technological Service, Valencia, Spain*

[5]*IVI Bilbao, Andrology Laboratory, Bilbao, Spain*

[6]*Intituto Universitario IVI Valencia, Reproductive Medicine, Valencia, Spain*

[7]*Intituto Universitario IVI Valencia, IVF Laboratory, Valencia, Spain*

Study question: Is there a relationship between the protein presence and abundance of PLA2G2A in human sperm samples (SS) and their competence to achieve a pregnancy with an ICSI treatment once the main male, female and cycle potentially biasing factors are controlled?

Summary answer: The percentage of stained cells and protein levels for PLA2G2A in sperm from infertile males achieving or not pregnancy by means of ICSI are comparable, regardless the oocyte source, after controlling for potential clinical and phenotypical confounders, leading to conclude that PLAG2A2 involvement in sperm function seems limited so far.

What is known already: We previously reported all the sperm mRNAs exclusively present or differentially expressed in SS achieving or failing to achieve pregnancy in different assisted reproduction techniques (IUI, IVF and ICSI). Among all, the one that codifies for PLA2G2A (a membrane-associated protein whose main function is the regulation of the phospholipid metabolism in biomembranes) has been found to be overexpressed in samples unable to obtain pregnancies, then being considered as a potential sperm infertility marker.

Study design, size, duration: Nested cases and controls study analyzing spermatozoa from 48 ejaculates that achieved clinical pregnancy (*P*+) and spermatozoa from 25 semen samples that did not achieve it (*P*-) after undergoing ICSI treatment with own or donated oocytes, prospectively collected, where PLA2G2A was measured by means of flow cytometry.

Participants/materials, setting, methods: From SS prepared for the ICSI treatments, aliquots were fixed and stored for ulterior analysis once the pregnancy results were known. SS were incubated with Anti-PLA2G2A-Ab followed by secondary FITC-conjugated-Ab. PLA2G2A positive cells and mean fluorescence intensity was quantified and groups compared using U-Mann-Whitney's and logistic regression controlling confounding parameters.

Main results and the role of chance: Mean volume, concentration, motility and total motile count (TMC) were 2.8 ml CI 95% (2.6–3.1), 52.4 mill/ml CI 95% (43.6–61.2); A + B forms 42.1% CI 95% (38.6–45.6), TMC 59.1 mill CI 95% (48.8–69.4), respectively. In prepared sperm, 10.3 mill/ml CI 95% (8.8–11.8), A + B 95.6% CI 95% (94.4–96.9) and 4.0 mill CI 95% (3.0–5.0). A mean number of 1.9 CI 95% (1.8–2.0) embryos were transferred, in 49 donation and 23 own oocytes' cycles. Women's mean age 38.1y CI 95%(37.1–39.2). PLA2G2A + ve cells were 4.6 CI 95% (2.6–6.5) in *P*+, and 6.9 CI 95% (1.1–12.8) *P*-, while the mean staining intensity registered was 194.3 CI 95% (134.5–254.2) vs. 140.2(66.3–214.0). The odds ratio (OR) of *P*+/*P*- depending on the PLA2G2A% or stained cells was 0.98 CI 95% (0.93–1.03), B = -0.024, while regarding the staining intensity, OR = 1.00 CI 95% (1.00–1.00), B = 0.002. Once adjusted for potential clinical confounders (day of embryo transfer, own or donated oocytes, age, female etiology, sperm features, embryos transferred…) Adj (OR) PLA2G2A% of staining was 0.96 CI 95% (0.87–1.06), B = -0.042, while regarding the staining intensity, Adj (OR) = 1.00 CI 95% (1.00–1.00), B < 0.001.

Limitations, reason for caution: Other sperm factors not included within this analysis could be biasing the studied relationships, given that sperm function has been demonstrated to be multiparametric. Further confirmation of our results is needed from other studies, confirming or not if our results are extrapolable to other subpopulations or different assisted reproduction protocols.

Wider implications of the findings: PLA2G2A is a sperm membrane associated protein whose mRNA has been described as an infertility marker, making it suitable for the development of a sperm selection tool based on the use magnetic activated cell sorting (MACS) technology to eliminate PLA2G2A positive spermatozoa and improve ART results. Nevertheless, the first step towards it is to demonstrate the link between the protein in sperm and clinical results with ICSI, and this has not been attained yet.

Study funding/competing interest(s): Funding by national/international organization(s) – Department of Industry, Innovation, Trade and Tourism and FEDER funding (EU) (IG-2011/0000681 and IG-2012/0000497).

Trial registration number: NA.

P-104 Mitochondrial mass (MM) – the best candidate, among mitochondrial functionality markers in human spermatozoa for prediction of successful embryo implantation

T. Chaushev[1], D. Parvanov[1], S. Gogeva[1], D. Velikova[1], G. Stamenov[1], V. Staikov[1]

[1]*Medical Center Nadezhda Reproductive Sofia, Reproductive Health, Sofia, Bulgaria*

Study question: Which of the mitochondria-related parameters, measured in human spermatozoa, is the best prognostic marker for determination of embryo quality and implantation potential of resulted embryos.

Summary answer: Among all the measured mitochondrial variables (mitochondrial membrane potential (MMP), mitochondrial mass (MM), superoxide radical (SR) and adenosine triphosphate (ATP)) mitochondrial mass showed the best predictive value in relation to the embryo implantation.

What is known already: Mitochondria are best known to participate in ATP production, generation of reactive oxygen species (ROS), apoptotic pathway, and calcium homoeostasis. However, there are contradictory data published in the literature, connecting sperm mitochondrial functionality, measured by assessment of MMP, MM, SR and ATP production and ART outcome. According many authors sperm mitochondrial functionality seems to be critical for fertilisation, but it's still not clear which parameter is more important for predicting embryo quality and pregnancy rate.

Study design, size, duration: A retrospective study was performed during the period 2013–2014. A native sperm from 100 patients undergoing ICSI procedure were used for analysis of mitochondrial status, oxidative stress and ATP production.

Participants/materials, setting, methods: The integrity of the sperm mitochondrial membrane potential (MMP) is determined by JC-1, mitochondrial mass – using Mito Tracker Green and ROS production were assessed by MitoSOX Red. The described variables were tested by flow cytometry. ATP concentration in sperm was measured by using bioluminescence assay.

Main results and the role of chance: Significant differences were observed between the group One (successfully implanted embryos) and group Two (unsuccessfully implanted embryos) regarding – MM (28.69% vs. 16.64%, respectively) ($p < 0.041$). No significant differences were found between group One (good quality embryos) and group Two (bad quality embryos) regarding - MMP (44.51% vs. 39.33%); MM (32.45% vs. 24.65%) and ATP (0.04% vs. 0.03%). ATP values showed a statistically significant association with the outcome of fertilization process (r = -0.300; $p = 0.013$).

Limitations, reason for caution: Present technique allows evaluation of all mitochondrial parameters (MMP, MM, ATP and ROS production) for a patient only in cases when the sperm count exceeds 4 mln/mL.
Wider implications of the findings: Mitochondrial related parameters of human sperm can be useful for better prediction of embryo quality and pregnancy rate after ART. Mitochondrial variables can be included in basic semen analysis for quality assessment and sperm selection in reproductive biology.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Nadezhda Fertility Clinic, Sofia, Bulgaria.
Trial registration number: NA.

P-105 Age related effects on semen parameters in infertile men – results from a cross sectional study

M. Paciotti[1], E. Ventimiglia[2], L. Boeri[2], P. Capogrosso[2], G. La Croce[2], A. Serino[2], A. Pecoraro[1], S. Ippolito[1], G. Castagna[2], R. Scano[2], D. Kuefner[2], A. Briganti[2], R. Damiano[3], F. Montorsi[2], A. Salonia[2]
[1]Università Vita-Salute San Raffaele, Division of Experimental Oncology/Unit of Urology URI, Milano, Italy
[2]IRCCS Ospedale San Raffaele, Division of Experimental Oncology/Unit of Urology URI, Milano, Italy
[3]Magna Graecia University, Research Doctorate Program in Urology, Milano, Italy

Study question: We aimed at assessing possible impact of patient age over semen parameters in men with oligospermia.
Summary answer: Current findings showed a linear increase of sperm concentration with age in primary infertile men with oligospermia. No further correlation between age and either sperm motility or normal morphology was observed.
What is known already: Conflicting data exist in terms of relationship between age and semen quality in fertile men. If on one hand several studies suggest that increased male age is associated with a decline in semen volume, sperm motility, and sperm morphology on the other evidences exist supporting a relationship between medical relevant comorbidities and semen parameters.
Study design, size, duration: Cross sectional study. Complete demographic, clinical and laboratory data from 618 infertile men with pathological sperm concentration presenting for primary couple's infertility were analyzed.
Participants/materials, setting, methods: Comorbidities were scored with the Charlson Comorbidity Index (CCI). Testicular volume was assessed with a Prader orchidometer. Semen analysis values were assessed based on the 2010 WHO reference criteria. Descriptive statistics and linear regression models tested the impact of age over sperm parameters.
Main results and the role of chance: Mean (median) patient age, BMI, CCI, sperm concentration, total sperm progressive motility, morphology, left testis volume, FSH, and inhibin B levels were 42.1 (42) years, 25.7 (25.4) kg/m^2, 0.13 (0.0), 5.4 (4.5) million/mL, 11.6% (2%), 17.3% (14%), 15.3 cc (15), 9.5 (6.2) mUI/ml, and 99.3 (91.7) pg/ml, respectively. At univariable linear regression analysis sperm concentration increased with age (Beta: 0.08; $p = 0.04$), left testis volume (Beta: 0.27; $p < 0.001$), and inhibin B (Beta: 0.27; $p < 0.001$); conversely, sperm concentration decreased along with FSH (Beta: -0.18; $p < 0.001$). The linear association between age and sperm concentration was confirmed at multivariable regression analysis (Beta: 0.17; $p = 0.01$) even after accounting for CCI, left testis volume, FSH, and inhibin B values. No significant correlations were observed between age and other sperm parameters.
Limitations, reason for caution: Main limitation is the cross sectional design of our study.
Wider implications of the findings: This is the first study focused on the impact of age over semen parameters in men with oligospermia. Existing data suggest how semen quality may be a fundamental biomarker of overall male health, and an independent predictor of mortality.
Study funding/competing interest(s): Funding by hospital/clinic(s) – ospedale San raffaele

P-106 Hydrogen molecule treatment improves the sperm motility of the oligoasthenozoospermia patients

A. Ochi[1], K. Nakata[1], C. Ono[2], K. Yoshida[3], M. Yoshida[4], N. Kashiwazaki[5], M. Yoshida[2], N. Yamashita[4]

[4]Yamashita Shonan Yume Clinic, Dr., Kanagawa, Japan
[5]Azabu University school of Veterinary Medicine, Laboratory of Animal Reproduction Department of Animal Science and Biotechnology, Kanagawa, Japan

Study question: Does H_2 treatment improve the sperm motility and fertilization ability of oligoasthenozoospermia patients?
Summary answer: H_2 treatment seemed to be the powerful therapeutic alternative to the oligoasthenozoospermia patients.
What is known already: Oxidative stresses are thought to have detrimental effects on sperm motility of the oligoasthenozoospermia patients. However the precise mechanisms are not known, oxidative damages to the axoneme of the sperm and the depletion of intracellular ATP appear to be involved. Recently some researchers reported that H_2 molecule selectively reduces toxic reactive oxygen species, such as hydroxyl radicals, and that the effectiveness in the treatment of oxidative stress related diseases.
Study design, size, duration: Sperm suspension from 21 oligoasthenozoospermia patients divided into 4 groups: control was centrifuged by medium (equivalented N_2-mixed gas 5%CO_2, 20%O_2, 75%N_2). H2 treated group were divided into 3 groups by H_2 concentration, that is, 50, 75, 100%. In addition, fertilization ability of H2 treated sperm was investigated using mouse oocytes.
Participants/materials, setting, methods: Sperm suspensions were frozen on the collected day. H2 treated group were centrifuged with the H2 contained medium. The sperm of the H_2 treated 75% group and control group were injected to mouse oocytes by piezo micro-manipulator. Forward motility was measured with Makler chamber and Sperm Count Analyser.
Main results and the role of chance: In terms of sperm forward motility, 75% of H_2 concentration showed the best results compared with those of 50% and 100% ($P < 0.05$). We further found that the normal fertilization rate of the mouse oocytes was significantly increased by H_2-treatment ($P < 0.05$, versus the untreated sperm suspension.).
Limitations, reason for caution: This is a pilot study on a relatively small sample size with limited conditions. The confirmation using larger samples under various conditions may be required. Furthermore, we need to check the safety of H_2 treated sperm use in ART.
Wider implications of the findings: The findings of this study indicate that H_2 treatment improves the sperm motility of the oligoathenozoospermia patients. Possibly, men with severe sperm dysfunction could select IVF instead of ICSI by using H_2 treatment. It may also useful in the selection of the good sperm for ICSI or ROSI using the testicular sperm or round spermatid.

[4]Hospital Universitario y Politécnico La Fe, Department of Gynecology, Valencia, Spain
[5]IVF spain, Gynecology, Alicante, Spain
[6]University of Murcia Spain, Department of Cellular Biology and Histology, Alicante, Spain

Study question: The aim of this study was the analysis of presence, origin and morphometric parameters in human sperm nuclear vacuoles from

normozoospermic subjects assessed by Transmission Electron Microscopy (TEM).

Summary answer: Our findings determined that nuclear vacuoles are an usual structure in the sperm heads from normozoospermic subjects, mainly located in the anterior part of sperm heads. These vacuoles are originated from invaginations of the nuclear envelope

What is known already: The presence of sperm vacuoles seemed relatively common in sperm heads from both fertile and infertile men. However, the presence of larger vacuoles in size (which occupy between 13% and 50% of the sperm head's surface area) is relatively contradictory. Moreover, the molecular mechanism responsible of the nuclear vacuoles formation is unknown.

Study design, size, duration: Prospective, randomized study, 15 normozoospermic samples were processed for sperm head analysis by TEM, from March to December 2014. A total of 227 sections were analyzed, with an average between 15 and 20 sections per sample, magnification factor 2000x. Images were analyzed by computer image analysis software.

Participants/materials, setting, methods: Sperm samples collected after informed consent of 15 participants. After sperm analysis according to WHO-2010, fresh samples were fixed, included in EPON, and ultrathin sections were obtained and analyzed by TEM in order to better define the ultra structure of human sperm cephalic vacuoles.

Main results and the role of chance: It was observed that 43.91 % of sperm showed nuclear vacuoles. The mean values for area of vacuoles were 0.27 μm^2 versus total area of nucleus (2.62 μm^2). These vacuoles correspond to 9.136% of the total area of the nucleus. There is a positive correlation between vacuole area and total nuclear area ($r = 0.49$; $p < 0.0001$). Furthermore, TEM analyses confirmed that a high percentage of vacuoles (81.84 %) is located in the anterior part of sperm heads. Finally, regarding the origin of vacuoles we observed that these vacuoles are nuclear envelope invaginations.

Limitations, reason for caution: This work was performed using TEM, thus vacuoles cannot be entirely analyzed, only sections.

Wider implications of the findings: Our results describe, at ultra structural level, morphometric parameters related to sperm head vacuoles and provide new information about origin of these structures, which do not support the acrosomal or plasma membrane residues implication. These findings suggest the possibility of creation new diagnostic tests to differentiate structural from functional vacuoles.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Funding by private and public hospital/clinic.

Trial registration number: A trial registration number is only required for clinical trials.

Keywords: TEM, vacuole

P-108 How efficient is ICSI for treating infertile men with complete globozoospermia?

F. J. Osorio[1,2], S. Santos-Ribeiro[1], G. Verheyen[1], H. Tournaye[1]

[1]*Universitair Ziekenhuis Brussel, Centre for Reproductive Medicine, Brussel, Belgium*

[2]*Urology Unit and Centre for Reproductive Medicine, Clinica Alemana de Santiago, Chile*

Study question: What is the real efficiency of ICSI procedure with or without calcium ionophore (Ca-I) for treating infertile men with complete globozoospermia?

Summary answer: Infertile patients with globozoospermia had poor results after conventional ICSI in our study. Furthermore, these patients reached a plateau in their cumulative clinical pregnancy rates after the third ICSI cycle. Although Ca-I significantly increased the fertilization and clinical pregnancy rates, it did not increase time to pregnancy.

What is known already: Men with globozoospermia have an increased rate of fertilization failure following ICSI, possibly due to a hindered oocyte activation capacity associated with the absence of an acrosome. Oocyte activation measures, namely Ca-I, may increase these fertilization rates. However, since the evidence of this intervention is limited, we are unable to determine until when it is no longer reasonable to offer treatment to these patients using their own sperm.

Study design, size, duration: We performed a retrospective single-centre cohort study of all consecutive ICSI cycles (91 cycles performed in 34 couples) using sperm from infertile men with a confirmed diagnosis of complete globozoospermia between 1992 and 2014.

Participants/materials, setting, methods: Cycles were classified into three groups according to the percentage of oocytes in which ICSI was performed using Ca-I: in all (100% Ca-I, $n = 41$), half (50% Ca-I, $n = 10$) or none (0% Ca-I, $n = 38$). Baseline cycle characteristics and clinical pregnancy rates were compared amongst the groups using multivariable logistic regression.

Main results and the role of chance: The average female age, number of oocytes retrieved, embryo developmental stage and number of embryos transferred did not vary significantly amongst the groups. Fertilization rates were significantly lower in the 0% Ca-I group (27.0%) when compared to the 100% Ca-I (46.9%, $p = 0.004$), but not versus the 50% Ca-I (41.1%, $p = 0.190$). Most importantly, clinical pregnancy rates were significantly lower in the 0% Ca-I group (7.6%) when compared to the 100% Ca-I (30.9%, $p = 0.021$), but not versus the 50% Ca-I (10.0%, $p = 0.869$), even after adjusting for female age, number of oocytes retrieved and year of treatment. No globozoospermic patient in our sample was pregnant after the third ICSI cycle, regardless of their use of Ca-I (HR = 2.45, CI 95% 0.69–8.69).

Limitations, reason for caution: As this was a retrospective study with a small sample size, we were unable to account for all foreseeable heterogeneity or confounding amongst our study groups, namely the presence of the DPY19L2. Nonetheless, previous studies have shown that this mutation has a limited effect on pregnancy after ICSI.

Wider implications of the findings: Oocyte activation using Ca-I improves fertilization and clinical pregnancy rates during ICSI in infertile men with globozoospermia. However, this treatment does not seem to completely resolve the poor prognosis of these patients. Despite the use of Ca-I, it may be reasonable to advise patients to consider the use of donor sperm after three failed ICSI cycles.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Universitair Ziekenhuis Brussel.

Trial registration number: NA.

P-109 Comparison of two different globozoospermia groups according to prevalence of round headed forms

A. Ersahin[1], F. Cengiz[1], N. Dokuzeylül Güngör[1], B. Görgen[1], M. Kanter[2]

[1]*Istanbul Medicalpark Göztepe Hospital, ART Center, Istanbul, Turkey*

[2]*Istanbul Medeniyet Üniversitesi, Histology, Istanbul, Turkey*

Study question: Comparison of two different globozoospermia groups according to prevalence of round headed forms

Summary answer: Especially for teratozoospermia cases with the dominance of round headed spermatozoa, our results emphasize the necessity and the importance of detailed sperm morphology analysis before ICSI.

What is known already: Globozoospermia is one of the most severe form of sperm morphological defects which usually results in low fertilization.

Study design, size, duration: The aim of our study was to analyze and compare the ART outcomes of cases which are grouped according to the prevalence of round-headed spermatozoa in the initial semen samples.

Participants/materials, setting, methods: According to the round-headed sperm concentration in the semen, patients were classified into two groups: Group I consisted of 10 couples with 14 cycles with sperm sample containing >70% globozoospermic forms (between 70 and 100%). Group II included 21 patients with 27 cycles in which male partner was diagnosed as severe teratozoospermia and the abundance of round-headed forms were 70%. Semen samples of 7 patients in group I and 10 patients from group II were also analyzed with acridine orange staining method in order to assess the degree of nuclear maturity. In both groups the mean values of sperm concentration, motility, round head shape, acrosomal content and other accompanying abnormalities such as macrocephalic and multiple head forms, mid-piece and tail defects were compared.

Main results and the role of chance: No difference in sperm concentration and motility were observed ($p > 0.05$). However, statistically significant differences were found in terms of spermatozoa having reduced acrozomal content, macrocephalic head, multiple head as well as mid-piece defects between these two globozoospermia groups ($p < 0.01$). Low fertilization rate, which is a common finding for globozoospermia cases, was observed for both groups (21.3% and 39.9% for group I and group II, respectively). Also, no significant difference was found between these two groups with respect to embryo

developmental ability on each day starting from prezygote stage until embryo transfer, pregnancy rates and implantation rates ($p > 0.05$). Spermatozoa of the patients from both groups were observed as having higher immature nuclear structures according to acridine orange test results.
Limitations, reason for caution: No difference in sperm concentration and motility were observed ($p > 0.05$).
Wider implications of the findings: Although the degree of dominance may differ in different semen samples, once it is the dominant form, presence of round-headed spermatozoa can equally and negatively affect the ART outcome in both groups. Once fertilized, resulting embryos may develop normally and generate successful pregnancies. However, such patients should be informed about lower fertilization, embryo development and pregnancy rates.
Study funding/competing interest(s): Funding by University(ies). Funding by hospital/clinic(s) – Göztepe Medical Park IVF Center, Istanbul Medeniyet Üniversitesi.

Study question: Can type-1 diabetes (T1D) alter the metabolic profile of testicular tissue?
Summary answer: T1D depressed lactate and creatine content in testicular tissue and altered glycolysis-related enzymes and transporters.
What is known already: Diabetes mellitus (DM) is a metabolic disease that has grown to pandemic proportions and the number of diabetic patients is expected to grow further in the next decades. Recent reports have highlighted that T1D alters male reproductive function, but the mechanisms remain unknown.
Study design, size, duration: Testicular biopsies obtained from patients under treatment for recovery of male gametes were used after informed written consent, and after treatment. Ten men were selected: 5 with conserved spermatogenesis and 5 T1D patients, diagnosed for more than 10 years and following an insulin therapy to control blood glucose levels.
Participants/materials, setting, methods: Testicular tissue from normal and T1D men was analyzed by High-Resolution Magic-Angle Spinning (HR-MAS) Nuclear Magnetic Resonance (NMR) spectroscopy. mRNA and protein expression of glucose transporters and glycolysis-related enzymes were also evaluated.
Main results and the role of chance: Our results show that testicles from diabetic men presented decreased levels of lactate, alanine, citrate and creatine. The mRNA levels of glucose transporter 1 (GLUT1) and phosphofructokinase (PFK) were decreased in testicles from diabetic men, but only GLUT3 presented decreased mRNA and protein levels. Lactate dehydrogenase (LDH) and glutamate pyruvate transaminase (GPT) protein levels were also found to be decreased in testicles from diabetic men.
Limitations, reason for caution: Diabetes mellitus (DM) is often associated with several "silent" comorbidities difficult to address. Moreover, the biological material available was scarce. Nevertheless, to avoid major deviations, the same piece of tissue was used for all the analysis performed in this study providing robust metabolic cues in testicular tissue from diabetic men.
Wider implications of the findings: Since lactate and creatine are essential for germ cells development and support, the mechanisms discussed herein open new insight on the molecular mechanism by which DM promotes subfertility/infertility in human males.
Study funding/competing interest(s): Funding by national/international organization(s) – This work was supported by the 'Fundação para a Ciência e a Tecnologia' – FCT (PTDC/QUI-BIQ/121446/2010 and PEst-C/SAU/UI0709/2014) co-funded by Fundo Europeu de Desenvolvimento Regional – FEDER via Programa Operacional Factores de Competitividade – COMPETE/QREN. P-111 Three-dimensional sperm surface reconstruction analysis yields more consistent and accurate results than conventional bi-dimensional morphological analysis

B. A. Levine[1], E. Chung[2], J. Feinstein[3], Q. V. Neri[1], D. Goldschlag[1], S. Belongie[4], Z. Rosenwaks[1], G. D. Palermo[1]
[1]Weill Cornell Medical College, The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A.
[2]Boston University, School of Medicine, Boston, U.S.A.
[3]Cornell University, Department of Computer Science College of Engineering, Ithaca, NY, U.S.A.
[4]Cornell University, Cornell Tech, New York, U.S.A.

Study question: We are concerned that standard sperm morphological analysis may be limited by asymmetrical abnormalities, orientation, or unpredictable sperm head positioning; we question whether a three- dimensional (3-D) sperm surface reconstruction model of a specific single sperm offers superior information.
Summary answer: Because of our unique 3-D imaging modality, spermatozoa are kept in a fluid environment eliminating positional artifacts and allowing analysis of the entire sperm head; as such, 3-D sperm surface reconstruction generates a high-fidelity profile that is more detailed and reliable than standard morphological techniques.
What is known already: Abnormal sperm morphology has been correlated with unpredictable oocyte fertilization rates with standard insemination and is a frequent indication for intracytoplasmic sperm injection (ICSI) in subfertile males. Traditional/standard bi-dimensional microscopy gives information about a single plane of the cell, potentially ignoring unique facets/surfaces and highlighting optical artifacts. These limitations may decrease the accuracy of the male infertility assessment.
Study design, size, duration: In this prospective, randomized, double-blind study, a single aliquot of semen was analyzed; nine spermatozoa were imaged and processed; 93 images were obtained and 9 resultant sperm surface reconstruction models were generated as videos. A team of 7 andrologists independently participated in the study.
Participants/materials, setting, methods: Still images were obtained at 600x; sperm surface reconstruction results were displayed as video depictions. Images and videos were randomly displayed; sperm heads were assessed for the presence and severity of morphological irregularities. A two-sided paired student's t-test was performed with statistical significance evaluated at the 0.05 alpha level.
Main results and the role of chance: The semen sample used in the study had a concentration of 84 x 10^6/ml, motility of 49%, and 4% normal morphology according to 2010 WHO criteria. Nine sperm were selected, ten-second videos were obtained, 93 images were captured, and only spermatozoa that demonstrated at least an anterior, posterior, and two lateral images were included.

Participants' ability to see a 3-D profile of the sperm surface, which was generated from the bi-demensional images, caused more sperm to be scored as normal cells. When all scores across the 9 sperm were averaged (1 = major head defect, 2 = minor head defect, 3 = normal), the mean ± SD image-based score was 1.96 ± 0.09 vs. reconstruction video-based 2.44 ± 0.13 (P = 0.008).
Limitations, reason for caution: This sophisticated computerized method of assessing sperm morphology offers a detailed profile of the spermatozoa, a new mode of evaluation. Although we consider these results promising, this study was solely performed on a single aliquot of semen and on a limited number of cells.
Wider implications of the findings: These results emphasize the highly subjective nature of bi-dimensional morphological assessment. Our findings suggest that evaluating an individual spermatozoon in a single plane may increase false-negative interpretations. This 3-D sperm morphological analysis is promising in that it may not only allow for a new method of sperm morphological analysis during the infertility evaluation, but it may assist in the selection of live male gametes prior to ICSI.
Study funding/competing interest(s): Funding by University(ies) – Reproductive Medicine, Weill Cornell Medical College.
Trial registration number: NA.
Keywords: morphology, sperm, 3D three-dimensional, ICSI, bioinformatic(s)

P-112 Clinical outcomes of artificial oocyte activation with calcium ionophore in intracytoplasmic sperm injection (ICSI) using testicular spermatozoa on sibling oocytes

S. Mizuta[1], C. Takahashi[1], R. Nishiyama[1], K. Kitaya[1], H. Matsubayashi[1], T. Ishikawa[1]
[1]Reproduction Clinic Osaka, Department of Reproductive Medicine, Osaka, Japan

Study question: To analyze whether artificial oocyte activation (AOA) with calcium ionophore after ICSI using testicular spermatozoa improves fertilization, embryonic development and pregnancy outcome in patients with obstructive azoospermia (OA) or non-obstructive azoospermia (NOA).
Summary answer: AOA with calcium ionophore showed favorable effect on fertilization rate in patients with NOA but OA. The sperm source will strongly affect the fertility potential or clinical outcomes. Severe male factor infertility, especially NOA, is an indication for application of AOA.
What is known already: Even using normal-morphology oocytes, fertilization failure was often observed on poor morphology or poor motility from testicular spermatozoa. AOA using several materials (calcium ionophore, ionomycin or strontium) has been tried to prevent that. However, it is not clear whether AOA is effective which type of materials when and how to use them.
Study design, size, duration: This prospective study was performed between October 2013 and December 2014 at a reproductive center. All patients involved gave written consent, and institutional review board approval was granted. This study includes 18 OA and 37 NOA couples.
Participants/materials, setting, methods: AOA was randomly performed on sibling MII oocytes after ICSI with motile testicular spermatozoa from OA or NOA. Two pronuclei (2PN) oocytes, blastocysts development, good-quality blastocysts, biochemical pregnancies, and clinical pregnancies rates were compared between two groups.
Main results and the role of chance: In terms of OA couples, there are no significant difference in 2PN oocytes, blastocysts development, and good-quality blastocysts rates (70.3%, 56.5%, and 45.7% with AOA and 65.6%, 41.8%, and 42.9% without AOA, respectively). For NOA couples, 2PN oocytes with AOA (75.0%) was significantly higher than those without AOA (59.6%). Blastocysts development, and good-quality blastocysts rates for NOA couples were 54.3% and 42.1% with AOA and 56.0% and 41.5% without AOA, respectively (no significant differences). There are no differences in biochemical and clinical pregnancy rates with or without AOA regardless of OA or NOA. In AOA oocytes, blastocyst and good-blastocyst rates per MII were tended to be better than without AOA, although it was no significant differences, even pregnancy rates.
Limitations, reason for caution: The participants are limited to the azoospermia whom had retrieved motile testicular spermatozoa because immotile spermatozoa may have some confound factors. We included <39 years age of the spouses at the time of ICSI cycles and 8 or more MII oocytes in this study.
Wider implications of the findings: This is the first study of AOA in couples using testicular spermatozoa on sibling oocytes. Those data showed oocytes with AOA was better clinical outcomes compared with sibling oocytes without AOA. However, long-term follow-up studies of children born after AOA using a calcium ionophore are not yet available. Thus, ICSI with split AOA might be better in first ICSI cycle using testicular spermatozoa. In addition, we should consider which case is benefit from AOA.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Reproduction Clinic Osaka.
Trial registration number: NA.

P-113 Vitamin e and berberine counteract the adverse effects of ros on sperm and seminal parameters

N. Adel[1], H. El Maghraby[2], D. Ghareeb[3], M. Elmahdy[2]
[1]Madina Fertility Center, ICSI Unit, Alexandria, Egypt
[2]Alexandria University, Obstetrics and Gynecology, Alexandria, Egypt
[3]Alexandria University, Biochemistry, Alexandria, Egypt

Study question: is there a role of vitamin E and berbeine on results of ICSI in male infertility?
Summary answer: Treatment with vitamin E had a beneficial effect on improving sperm DNA integrity together with improvement of quality of embryo. In vitro treatment by Berberine during sperm preparation may be used as a substitute to medical treatment with antioxidants.
What is known already: Out of many causes of male infertility oxidative stress (OS) has been attributed to affect the fertility status and thus, it has been studied extensively in recent years. In a state of OS, DNA damage occurs due to oxidation of bases, strand breaks, cross- linking, deletions, frame shifts and rearrangement of chromosomes Also it is well known that the washing of the sperm during the first step in ICSI by centrifugation is associated with the generation of ROS and physical damage to spermatozoa
Study design, size, duration: Prospective controlled study, university based 54 male randomized into 3 groups (normal group, infertile treated with antioxidant, infertile not treated) 10 semen samples prepared twice. Once by traditional sperm wash media and once by addition of berberine to the wash media.
Participants/materials, setting, methods: In vivo study tracked through determination of pro-oxidants/antioxidants status in seminal plasma by determination of TBARs concentration / SOD, GPx & GSH activity and its harmful effect on DNA mutation when analysed against MP77 by RAPD assay and finally correlates these parameters with semen analysis alteration. In vitro study was assessed by measure the fertilization rate and good quality embryos upon adding Berberin on sperm wash media versus traditional media.
Main results and the role of chance: Antioxidant treated group shows a significantly lower seminal TBAR's concentration (9.74 ± 7.88). SOD activity of normal group (39.85 ± 31.45) and group treated with antioxidant (46.20 ± 27.21) were significantly higher than untreated group. Sperm DNA samples showed a RAPD profile with less fragmented bands with Primer MP77 in treated group than the untreated group. the group with Vitamin E showed the highest good quality embryos rate (78.06 ± 22.29). For *in vitro* study, sperm wash with berberine supplementation show higher good quality embryos (P 0.034).
Limitations, reason for caution: wide scale of sperm parameters in the infertile group.
Wider implications of the findings: in vitro supplementation of the sperm wash media with antioxidant (berberine) may be a substitute to long term in vivo antioxidant supplementation.
Study funding/competing interest(s): Funding by University(ies) – Alexandria university.
Trial registration number: NA.
Keywords: Berberin, SOD, GPx, TBAR, GSH

P-114 Validation of SCSA, an alternative to assess sperm DNA fragmentation (SDF) by flow citometry (FC)

I. Vilella[1], L. Medrano[1], L. García[1], García-Pollo, M.C.[1], E. Rocafort[1], M. Guijarro[1], A. Leza[1], S. Rogel[2], M. Fernández[1], J. Aizpurua[2]
[1]IVF-SPAIN, Embriology, Alicante, Spain
[2]IVF-SPAIN, Doctor, Alicante, Spain

Study question: To evaluate SDF in normozoospermic sperm samples comparing the two classical methods, SCD and TUNEL, with SCSA, a new technique implemented in our lab: Are they three measuring the same? Which would optimize better the laboratory workflow?
Summary answer: SDF values did not show any statistically significant differences. This means that the three techniques, SCSA, SCD and TUNEL, are partially redundant and mostly measuring the same damage. This approach with few runs of cytometry could improve the work flow in the lab assuring most relevant findings.
What is known already: SDF has become a biomarker for male infertility because it has been shown that it could cause defects in embryo development, risk of early pregnancy loss, or problems with foetal development. Several techniques have been developed for the measuring of SDF where studies have compared the specificity and sensitivity of these techniques (Ribas-Maynou, 2013). Their similarity, complementarity and compatibility are being discussed because each technique involves different DNA targets to measure SDF.
Study design, size, duration: A total of 30 normozoospermic human sperm samples were collected since September to November 2014 at a private clinic after 2 days of sexual abstinence. All samples were analyzed in fresh and the SDF was measured by using 3 different methods: SCD test, TUNEL assay and SCSA Test.
Participants/materials, setting, methods: All samples were centrifuged 8 minutes at 600 g in washing media. The pellet was resuspended in washing media. TUNEL assay was performed using the In Situ Cell Death Detection Kit by fluorescence microscope, SCSA methodology by flow citometry and SCD test by using Halosperm® kit.
Main results and the role of chance: For each assay, we calculated the percentage of fragmented DNA spermatozoa from the total sample. Comparisons of SDF between different groups were assessed using the ANOVA test for one factor with repeated measures. All statistical tests were performed taking into account the 95% of the confidence interval. We excluded systemical and technical deviations using appropriate positive and negative controls. The mean and SD of SDF obtained for each technique was: SCD test: 9.44 ± 4.78; TUNEL assay: 10.45 ± 5.45; SCSA: 10.62 ± 5.32. No statistical differences were found between TUNEL assay, SCSA and SCD test ($p = 0.093$). SCD test and TUNEL assay were time-consuming compared to SCSA, which gave the most accurate and precise results.
Limitations, reason for caution: Many factors should be considered to select the most appropriate technique: costs, timing, sensitivity and specificity of each technique. Higher number of samples would be necessary in order to improve the statistical power. Moreover, pathologic samples are missed in this study but further studies are ongoing with these samples.
Wider implications of the findings: To determine which SDF technique is most suitable, the use of FC offers consistent and reliable data in a short time, but it is an expensive tool. Alternatively TUNEL and SCD offer similar and reproductible results but many disadvantages. Thus SCSA is the most suitable technique. Moreover, the potential of FC seems not exhausted and more variables like ROS, apoptosis, sperm aneuploidy, mitochondrial status… are being evaluated and will contribute to a new enhanced spermiogram.
Study funding/competing interest(s): Funding by hospital/clinic(s) – University associated private clinic and its fundation
Trial registration number: A trial registration number was not required due to the retrospective study design.
Keywords: SCSA, SCD test, TUNEL assay, Sperm DNA fragmentation, Flow citometry

P-115 Environmental and lifestyle factors associated with sperm DNA methylation

C. Nevin[1], B. Altakroni[2], A. Povey[2], C. Murgatroyd[1], D. R. Brison[3], M. Carroll[1]
[1]*Manchester Metropolitan University, Healthcare Science, Manchester, United Kingdom*
[2]*University of Manchester, Institute of Population Health, Manchester, United Kingdom*
[3]*Department of Reproductive Medicine, Central Manchester University Hospitals, NHS Foundation Trust St. Mary's Hospital, Department for Reproductive Medicine, Manchester, United Kingdom*

Study question: Does lifestyle and environmental exposures influence sperm DNA methylation?
Summary answer: Exposure to environmental toxicants and life-style factors associates with changes in methylation at key imprinted genes in human sperm.
What is known already: Aberrant DNA methylation of imprinted genes and of genes important for spermatogenesis has been linked to male infertility. The epigenome is susceptible to modification by the internal and external environment, with risk factors including exposure to environmental toxicants, physical activity levels, alcohol consumption and diet. Therefore, these factors could contribute to male infertility through their influence on DNA methylation.
Study design, size, duration: Semen samples were obtained from consenting male patients recruited from a fertility clinic over 10 months. Lifestyle, occupational and environment data were acquired through a questionnaire completed by participants at the time of their treatment.
Participants/materials, setting, methods: Forty five neat samples were analysed for DNA methylation by bisulphite pyrosequencing. DNA methylation was analysed in prepared sperm from the same samples as a control. CpG methylation at imprinted genes for *H19*, *PLAGL1*, *PEG10* (among others) and genes for *MTHFR* and *CD247* were analysed using multiple regression analysis.
Main results and the role of chance: Here we report a number of key environmental factors linked to altered methylation in neat semen at specific imprinted genes. Additionally, increased weekly alcohol consumption and exposure to chemicals including solvents, pesticides and detergents (self-reported), are linked to an increase in *PEG10* methylation. However, there was no significant association between these factors and *H19*, *PLAGL1* or *MTHFR* methylation when controlling for age, BMI and smoking status. DNA methylation is lower in neat semen than in prepared sperm for all genes investigated. *CD247* had 0.6% less methylation in neat semen than in prepared sperm with individual cases having up to 2.2% lower methylation, which could be indicative of leukocyte contamination.
Limitations, reason for caution: We only focus on a limited number of CpG sites for analysis in each gene and so may miss more informative methylated sites. Lifestyle data was self-reported via questionnaire and may underestimate true lifestyle information.
Wider implications of the findings: Changing lifestyle habits could, to an extent, be part of a solution to improve male fertility as it influences the epigenetic regulation of gene expression. This could ultimately improve offspring health as inheritance of epigenetic dysregulation can have transgenerational implications. In addition, the possibility for environmental toxicants to aberrantly affect DNA methylation is an important risk to consider for fertility health in urban living spaces and industrial work places.
Study funding/competing interest(s): Funding by University(ies) – Manchester Metropolitan University accelerator fund to Michael Carroll.
Trial registration number: Approved by Central Manchester Ethics Committee and the Human Fertilisation and Embryology Authority (HFEA licence R0026).

P-116 Relevant lipids conditioning reproductive results found in sperm after assessment of the lipidomic profile in spermatozoa of infertile males undergoing assisted reproduction treatments with ICSI

R. Rivera[1], N. Sota[1], F. Dominguez[2], M. Meseguer[3], J. Remohí[4], N. Garrido[1]
[1]*Instituto Universitario IVI Valencia, Andrology Laboratory, Valencia, Spain*
[2]*Instituto Universitario IVI Valencia/INCLIVA, Fundacion IVI, Valencia, Spain*
[3]*Instituto Universitario IVI Valencia, IVF Laboratory, Valencia, Spain*
[4]*Instituto Universitario IVI Valencia, Reproductive Medicine, Valencia, Spain*

Study question: Are there any differences between sperm samples that failed (non-pregnant, NP) vs. those achieving pregnancy (*P*) regarding the sperm lipidomic profile exhibited after intracytoplasmic sperm injection (ICSI) cycles?
Summary answer: This work reveals statistically significant differences in the lipidomic profile between samples from group NP vs. P after ICSI, finding higher acylglycerophosphocholines levels, and an increase of ceramides and sphingomyelins in dysfunctional spermatozoa, thus being potential sperm fertility biomarkers deserving further attention and research, to improve assisted reproduction treatments' efficacy.
What is known already: Sperm membrane lipids are known to be involved in sperm key functions as capacitation, interaction between spermatozoa and oocyte and in sperm survival after freezing/thawing processes. Furthermore, their particular lipidic composition, with very high level of phospholipids, sterols, glycolipids, saturated and polyunsaturated fatty acids affects oxidative attack

sensitivity. Despite studying these lipids is of interest in Andrology, the available information until now is scarce given that metabolomics is a very recently applied analysis method.
Study design, size, duration: Prospective, analytical, nested cases and controls study evaluating the lipidomic profile of spermatozoa, from patients' ejaculates (Group NP, n = 16; vs. Group P, n = 22) after ICSI. Aliquots from the same samples employed in ICSI procedures were collected, frozen until the reproductive results were known, and then assigned to their corresponding group.
Participants/materials, setting, methods: Sperm samples from infertile patients undergoing ICSI were analysed using Ultra Performance Liquid Chromatography coupled to Mass Spectrometry with methanol platform for fatty acyls, bile acids and lysoglycerophospholipids and methanol/chloroform for glycerolipids, cholesteryl esters, sphingolipids and glycerophospholipids. Lipidic levels were compared using Wilcoxon-signed-rank test and Multivariate analyses after logarithmic transformation.
Main results and the role of chance: We detected 151 different lipids in the sperm samples, 10 of them significantly overexpressed in sperm samples from NP group with 1.10 to 1.30 fold change and a p value < 0.05. Among them, lipids found to be different, showing formula, mean and SD concentrations, between groups NP and P respectively, included Ceramides Cer(d18:1/22:0)6.04 ± 5.44vs.2.83 ± 3.38, Cer(d18:1/22:0)0.39 ± 0.37vs.0.17 ± 0.16 and Cer(d18:1/24:0)2.02 ± 1.99vs.0.89 ± 0.96, Sphingomyelins SM(38:1)1.74 ± 1.63vs.0.77 ± 0.99, SM(d18:1/22:0)0.95 ± 0.90vs.0.39 ± 0.51, SM(42:1)1.45 ± 1.34vs.0.59 ± 0.76, and SM(d18:1/25:0)0.28 ± 0.23vs.0.12 ± 0.13. Also 1 or 2-Monoacylglycerophosphocholines PC(0:0/20:0)0.07 ± 0.06vs.0.03 ± 0.04, 1-ether, 2-acylglycerophosphocholines PC(O-22:0/20:4)0.31 ± 0.26vs.0.13 ± 0.16 and 1-ether, 2-acylglycerophosphoethanolamines PE(16:1e/18:2)1.15 ± 1.08 vs.0.53 ± 0.54 showed different levels between groups. To be highlighted higher levels of monoacylglycerophosphocholine, and increased ceramides and sphingomyelins, mostly consisting of a sphingosine moiety of 18 carbon number (sphing-4-enine), amide-linked to a long-chain fatty acyl group. Multivariate analyses are not suitable for differentiating between the two groups of samples.
Limitations, reason for caution: Other sperm factors not included within this analysis could be biasing the studied relationship, given that sperm function has been demonstrated to be multifactorial. Further confirmation of our results in needed from other studies, confirming or not if our results are extrapolable to other subpopulations or different assisted reproduction protocols.
Wider implications of the findings: The description of lipids linked to optimal sperm function, open new possibilities regarding the development of male fertility diagnostic tools, culture media formulations to improve sperm quality and enhance reproductive results, or, given that lipids compose the major part of the plasma membrane, to design new sperm selection tools based on these molecular traits, using magnetic activated cell sorting of spermatozoa exhibiting specific lipids associated with the best reproductive results.
Study funding/competing interest(s): Funding by national/international organization(s) – Department of Industry, Innovation, Trade and Tourism and FEDER funding (EU).
Trial registration number: NA.

P-117 Non familial sporadic heritable retinoblastoma and it's correlation with sperm DNA damage

S. Gautam[1], S. Basant Kumar[1], B. Chawla[2], R. Dada[1]
[1]AIIMS All India Institute of Medical Science, Anatomy, New Delhi, India
[2]AIIMS All India Institute of Medical Science, Dr. RP Centre for Ophthalmic Sciences, New Delhi, India

Study question: Loss of sperm DNA integrity: Is it the cause of Non-familial Retinoblastoma?
Summary answer: Sperm DNA damage may be the cause of childhood Retinoblastoma and paternal factors may play a critical role in embryonic development.
What is known already: Sperm is highly vulnerable to oxidative damage to both nuclear as well as mitochondrial DNA and due to minimal cytosolic antioxidants. Paternal smoking may be the cause of childhood morbidity and mortality and Retinoblastoma is the most common childhood tumour but aetiology is not known.
Study design, size, duration: A case control study design with 26 cases and 30 controls. Study duration was 8 months.
Participants/materials, setting, methods: Somatic mutations in Rb1 gene were excluded by PCR. Semen samples were collected and analysed for semen parameters. Biological markers for sperm DNA damage such as DFI by SCSA and ROS levels by Chemiluminiscence assay were measured. Multivariate logistic regression was used to compute the OR for Retinoblastoma.
Main results and the role of chance: Seminal mean ROS levels were significantly higher [56.7 ± 46.3 vs 21.6 ± 7.9 RLU/sec/million sperm; $p < 0.0001$] in cases as compared to controls. There was significant increase in mean DFI levels [30.3 ± 5.9 vs 23.2 ± 9.4%;p = 0.0017] in cases as compared to controls. The adjusted OR for nicotine consumers was [4.2(1.1, 16.3); p = 0.037; 95%CI] with non-alcohol users and ROS ≤ 27 RLU/sec/million sperm (cut-off value) taken as reference whereas, the OR for alcohol users was [2.5(0.7, 8.5); p = 0.139; 95%CI] with nicotine non-consumers and ROS ≤ 27 RLU/sec/million sperm as reference. With non-alcohol users and DFI ≤ 28% as reference, the adjusted OR for nicotine consumers was [4.4(1.8, 16.7); p = 0.028; 95%CI] whereas the OR for alcohol users was [2.7(0.8, 8.6);p = 0.098;95%CI] with nicotine non-consumers and DFI ≤ 28% (cut-off value) taken as reference.
Limitations, reason for caution: Low sample size.
Wider implications of the findings: Nicotine consumption either in the form of smoking or oral tobacco and increased alcohol intake adversely affect DNA quality and thus lifestyle interventions like diet rich in fruits & vegetables, quitting smoking & alcohol intake and yoga & meditation may improve the DNA health and be therapeutic.
Study funding/competing interest(s): Funding by national/international organization(s) – Indian Council of Medical Research, New Delhi, India.
Trial registration number: IESC/T-80/28.02.2014.
Keywords: Retinoblastoma, ROS, DFI, Sperm DNA damage

P-118 Effect of progesterone on motility, kinetic parameters and acrosome reaction on native, vitrified and conventionally cryopreserved sperm

N. Saymé[1], L. C. Dite[1], D. A. H. Maas[1], T. Krebs[1], D. Töpfer[2]
[1]Team Kinderwunsch Hannover, IVF Clinic, Hannover, Germany
[2]Tierärztliche Hochschule Hannover, Reproduktionsbiologie, Hannover, Germany

Study question: Does progesterone have a positive effect on motility, kinetic parameters and acrosome reaction (AR) of human spermatozoa after preparation for ART treatment, cryopreservation or vitrification?
Summary answer: No significant improvement of motility, kinetic parameters (curvilinear velocity, average path velocity, amplitude of lateral head displacement) and AR could be observed after the progesterone treatment of cryopreserved or vitrified spermatozoa. Higher concentration of progesterone increases AR of native spermatozoa.
What is known already: Subfertile men show a reduced responsiveness to progesterone. Progesterone-induced rapid effects and fertilization in IVF are related in infertile men. Capacitation, hyperactivation, chemotaxis and acrosome reaction in mammalian spermatozoa are regulated by progesterone in a dose-dependent manner. Low concentrations seem to affect motility, while high concentrations increase hyperactivation. The effect of progesterone on acrosome reaction and the involved metabolic pathways are still controversial.
Study design, size, duration: This is an ongoing prospective and observer blinded study. We included all semen samples from men presenting in our clinic for diagnostic analyses or infertility treatment (n = 10) with a concentration ≥ 20 Mio/ml after processing by density gradient. The mean age of the cohort was 38.8 years.
Participants/materials, setting, methods: The samples were divided and cryopreserved either using cryoprotectant-free vitrification or conventional slow-freezing. Post-thawing spermatozoa capacitated for 2 h in GM501 Sperm Active at 37°C and treated with progesterone (0 nM, 25 nM and 50 nM) for 30 min. Motility (WHO), kinetic parameters (CASA), capacitation and AR (chlortetracycline staining) were compared.
Main results and the role of chance: No significant effect on motility, kinetic parameters and AR in conventional cryopreserved samples for all concentrations of progesterone could be observed. Furthermore, no statistic relevant effect of progesterone on motility, kinetic parameters and AR could be found. Only in the control group without cryopreservation a significant increase of

acrosome reaction ($p < 0.05$) was found after treatment with 50 nM versus 0 nM. This effect could not be observed after treatment with 25 nM versus 0 nM.
Limitations, reason for caution: The effect of progesterone on sperm function is dose- and time dependent and therefore, the experimental setup may not represent the actual situation at crucial points of sperm activation in the female reproductive tract and during fertilization, as well as after sperm reactivation and especially after cryopreservation.
Wider implications of the findings: Progesterone is a physiologically relevant molecule in the regulation of sperm function. So far, exact molecular pathways have not been completely elucidated. Spermatozoa already react to very low concentrations of progesterone. As premature hyperactivation and AR can be detrimental to sperm function, it is important to find out the threshold progesterone concentration. Therefore, detailed knowledge of the requirements of full functional capability may be helpful in further optimizing therapeutic strategies in ART and cryopreservation protocols.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Team Kinderwunsch Hannover.
Trial registration number: NA.
Keywords: progesterone, acrosome reaction, sperm function, cryopreservation, kinetic parameter

P-119 Associations between DNA double strand breaks and N7-methyldeoxyguanosine in human sperm and IVF/ICSI outcomes

B. Altakroni[1], J. Stocks[1], D. Brison[2], A. Povey[1]
[1]University of Manchester, Centre for Occupational and Environmental Health, Manchester, United Kingdom
[2]University of Manchester, Department of Reproductive Medicine, Old St Mary's Hospital, Central Manchester University Hospitals, NHS Foundation Trust, Manchester, United Kingdom

Study question: Human sperm DNA contains damage arising from exposure to genotoxic agents. To further characterize the significance of such damage in human reproduction, the associations between DNA double strand breaks (DSBs) and N7-methyldeoxyguanosine (N7-MedG), a marker of exposure to alkylating agents, and fertility outcomes, were investigated in a clinical assisted reproduction programme.
Summary answer: DSBs and N7-MedG can negatively affect pregnancy and live birth rate.
What is known already: DNA fragmentation (single and double strand breaks) might negatively affect embryo quality and pregnancy rate.
Study design, size, duration: 98 male partners of couples attending for infertility treatment (in *vitro* fertilization cycles $n = 46$, intracytoplasmic sperm injection cycles $n = 52$) were recruited over 10 months.
Participants/materials, setting, methods: In sperm prepared for treatment use, DSBs were measured by a neutral Comet assay and the median of % tail DNA (% Median) and proportions of sperm with Comet tails containing < 0.005% DNA (few DSBs: FDSB) or > 7.5% DNA (high DSBs: HDSBs) were determined. N7-MedG levels were quantified in extracted sperm DNA from neat sperm by immuno-slot blot assay. The fertilization rate and pregnancy outcomes (implantation rate, clinical pregnancy and live birth) were determined.
Main results and the role of chance: In all couples, regardless of type of treatment, % Median was correlated negatively with embryo implantation ($P = 0.02$). Conversely, % FDSBs was correlated positively with embryo implantation ($P = 0.001$). However, only % FDSBs, but not % Median or % HDSBs, was correlated positively with clinical pregnancy ($P = 0.02$) and live birth ($P = 0.04$). N7-MedG levels were negatively correlated only with live birth with a borderline significance ($P = 0.06$). Taking in consideration the type of treatment, % Median in IVF but not ICSI couples was correlated negatively with only embryo implantation ($P = 0.04$). On the other hand, % FDSBs in ICSI but not IVF couples had significant and positive correlations with embryo implantation ($P = 0.008$) and clinical pregnancy ($P = 0.03$). N7-MedG levels in IVF or ICSI couples were not associated with pregnancy outcomes.
Limitations, reason for caution: The numbers of biochemical pregnancy ($n = 6$) and late miscarriage ($n = 2$) are small and thus it is difficult to draw a conclusion about the impact of DSBs and N7-MedG on miscarriage.
Wider implications of the findings: These results suggest that the impact of DSBs (% Median or % FDSBs) on pregnancy outcomes appears in the early stage of embryo development and thus embryo implantation rather than in early miscarriage (biochemical pregnancy) or late miscarriage. On the other hand, alkylation damage to DNA (N7-MedG) might be a more significant factor in early and late miscarriage.
Study funding/competing interest(s): Funding by University(ies) – Damascus University.
Trial registration number: This study had Local Ethics Committee Approval (Central Manchester REC ERP/91/078) and approval from the UK Human Fertilization and Embryology Authority (HFEA research licence R0026).
Keywords: Infertility, IVF/ICSI, sperm DNA damage

P-120 The Kappa-opioid receptor modulates the human sperm capacitation and acrosome reaction

I. Urizar[1], I. Muñoa[1], M. Gianzo[1], H. Estomba[1], R. Matorras[2], A. Exposito[2], J. Irazusta[1], N. Subirán[1]
[1]University of Basque Country, Department of Physiology, Bilbao, Spain
[2]Cruces Universitary Hospital, Bilbao, Spain

Study question: Is the Kappa-opioid receptor involved in the regulation of human sperm capacitation and acrosome reaction?
Summary answer: The selective kappa-opioid receptor agonist, U50488, promotes the human sperm capacitation and inhibits the acrosome reaction modifying the calcium channels.
What is known already: Opioids exert their effects by binding to membrane receptors and nowadays, three types of opioid receptors (μ,δ and κ) have been found in human sperm cells As it is known, μ-opioid receptors and δ-opioid receptors are implicated in sperm motility but κ-opioid receptor doesn't have any effect on it. Therefore, the physiological function of κ-opioid receptor is completely unknown in human sperm cells, as the signalling pathways involved in both processes.
Study design, size, duration: We used 50 human seminal samples obtained from the Cruces Universitary Hospital. The samples were isolated and capacitated by swim up. The isolated sperm cells were used for inhibitory studies of calcium signalling pathways using the following substances: U50488: selective kappa-opioid receptor agonist, U73122: Phospholipase C inhibitor, Mibefradil 1.5 μM: calcium channel inhibitor, Mibefradil 30μM: calcium channel activator and NNC55-0395: CatSper calcium channel inhibitor. The samples were treated with the different substances for an hour, and the control was compared with the treated samples. ($p < 0.05$).
Participants/materials, setting, methods: After the treatments, the acrosome reaction was conducted by Flow cytometry using the anti-CD46 antibody. Immunoblotting studies were carried out to evaluate capacitation using the anti-phosphotyrosin antibody and the results were analyzed by densidometry.
Main results and the role of chance: Immunoblotting studies showed an increase on the tyrosine phosporilation in human sperm cells induced by the U50488 kappa-opioid receptor agonist. The inhibition of CatSper by Mibefradil 1.5 mM and NNC55-0395 also induced tyrosine phosphorylation and this effect was reversed by the U50488 kappa-opioid receptor agonist. The U50488 kappa-opioid receptor agonist inhibited the acrosome reaction in human sperm modifying the calcium channels. U50488 was able to blunt acrosome reaction induced by Mibefradil 30μM, a calcium channel activator. The inhibition of calcium channels and the Phospholipase C by Mibefradil 1.5 μM, NNC55 (CatSper selective inhibitor) and U73122 respectively inhibited acrosome reaction themselves and Kappa-opioid selective agonist had no any sinergic effect.
Limitations, reason for caution: We need further studies to describe the whole signalling pathway.
Wider implications of the findings: The kappa-opioid receptor participates in the regulation of the acquisition of the fertile capacity in human sperm. This supports the idea that the opioid system could be used as a therapeutic target in the finding of male contraceptives.

P-121 Assessment of sperm quality after magnetic activated sperm cell separation

Z. Cakar[1], B. Cetinkaya[1], D. Aras[1], B. Koca[1], S. Ozkavukcu[2], A. Can[1], O. Cinar[1]
[1]*Ankara University School of Medicine, Department of Histology and Embryology Laboratories for Reproductive Medicine and Stem Cell Research, Ankara, Turkey*
[2]*Ankara University School of Medicine, Center for IVF, Ankara, Turkey*

Study question: The effectiveness of magnetic activated cell sorting (MACS) in *in vitro fertilization* (IVF) protocols is still controversial. Thus, we examined whether the combination of MACS with other (existing) nontoxic sperm separation techniques increase the chance of finding higher number of competent sperm cells for IVF.
Summary answer: Our results indicated that the spermatozoa obtained from swim up and MACS groups give statistically significant better results compared to other groups, indicating that combined methods may result in better IVF outcomes.
What is known already: Selecting the competent spermatozoa by the current selection techniques, ranging from sperm washing to advanced sperm selection techniques such as the removal of apoptotic spermatozoa or sperm ultra-morphology evaluations, have employed in IVF protocols. MACS was introduced as a novel technique that would remove apoptotic spermatozoa from non-apoptotic ones. However, the potential beneficial effects of MACS in clinical applications are still debatable even in very recently published articles that highlight the importance of further studies.
Study design, size, duration: To examine the sperm quality assessment after combining MACS with swim up (SU) and density gradient (DG) methods, 80 subgroups were created from 10 normozoospermic and 10 oligozoospermic cases. Each sample was further subgrouped as; i) SU, ii) DG, iii) SU + MACS, and iv) DG + MACS.
Participants/materials, setting, methods: Number and morphology of spermatozoa, DNA integrity (with chromomycin-A3), apoptosis (with TUNEL assay), and the distribution and amount of two essential proteins Izumo-1 (fundamental for oocyte fertilization), phospholipase-C-zeta (PLC-zeta, an oocyte activating protein) were evaluated with a confocal microscope and/or flow cytometry. Comparisons were performed with appropriate statistics tests.
Main results and the role of chance: Total and rapid-progressive sperm numbers significantly low in MACS groups. The ratio of spermatozoa having normal morphology was insignificantly higher in SU compared to others. The number of TUNEL positive cells significantly lower in MACS + SU compared to others. No difference was found in among the groups in oligozoospermic cases. DNA integrity was found lower in MACS + SU compared to MACS + DG. The ratio of Izumo-1 sperm in SU group was significantly higher compared to others. Izumo-1 positivity in MACS + SU was similar to that of MACS + DG. Flow cytometry showed that the number of PLC-zeta positive spermatozoa was higher in DG or MACS + DG; however, mean intensity was found higher in SU or MACS + SU, indicating that both SU groups provide isolation of spermatozoa having higher amount of PLC-zeta.
Limitations, reason for caution: Besides ethical concerns, the major limitation of using MACS is the decrease of sperm number, therefore oligozoospermic patients do not seem to be appropriate candidates for MACS applications. It would be ideal to perform IVF cycles following the above cell separation protocols to observe the outcomes of these study groups.
Wider implications of the findings: MACS was presented as one of the pivotal techniques among other advanced sperm selection techniques. Since the combination of MACS with SU gave the higher sperm quality, we suggest using this combination for clinical applications, not the MACS technique alone. To our knowledge, this was the first attempt that MACS was implemented in the oligozoospermic patients, and our findings revealed that MACS does not seem to be appropriate for sperm selection in these cases
Study funding/competing interest(s): Funding by University(ies) – Funding by national/international organization(s). Ankara University BAP. TUBITAK.

P-122 Effect of the supplementation of myo-inositol in the cryopreservation process of human spermatozoa

F. Paternostro[1], E. Capitanio[1], A. Galimberti[1], G. Previtali[1], L. Zanga[1], M. Arnoldi[1], F. Fusi[1]
[1]*Azienda Ospedaliera Papa Giovanni XXIII, USSD Centro PMA, Bergamo, Italy*

Study question: Can the addiction of myo-inositol influence human sperm quality in terms of motility and DNA fragmentation during the cryopreservation process?
Summary answer: Myo-inositol seems to improve semen parameters after thawing only in a group of patients.
What is known already: Cryopreservation of spermatozoa is associated with an oxidative stress induced by reactive oxygen species that cause a reduction in sperm DNA integrity and motility. Myo-inositol is physiologically released in the testis and it directly increases the membrane potential, an index of sperm motility. Recent studies have suggested a possible role of myo-inositol in the chemotaxis and thermo taxis of spermatozoa.
Study design, size, duration: From July to December 2014 a prospective study included semen samples of 90 men undergoing basic semen analysis or ART. Semen analyses were performed according to WHO (2010) criteria.
Participants/materials, setting, methods: Semen samples were cryopreserved using slow freezing. Each sample was divided into two aliquots: one cryopreserved using freezing medium supplemented with 2 mg/mL of myo-inositol, and one using freezing medium without myo-inositol. Motility and DNA fragmentation (SCD test, Halosperm® kit) were assessed both in fresh and thawed spermatozoa.
Main results and the role of chance: After supplementation of myo-inositol a total of 66/90 patients showed an average reduction of 3.7% of DNA fragmentation after thawing, 9/90 patients showed an average increase of 2% and in 15/90 patients were found no variations. Myo-inositol affected also sperm motility: in 45/90 patients we observed an increased motility, but 28/90 patients had a decreased motility.
Limitations, reason for caution: We did not analyse semen samples with a sperm concentration lower than 5 x 10^6/mL.
Wider implications of the findings: Further studies would be necessary to establish which criteria must be investigated to predict the response to myo-inositol addition in terms of motility and DNA fragmentation. Moreover, the supplementation with myo-inositol could be performed on semen samples of patients with asthenozoospermia, high DNA fragmentation index or on testicular sperm to improve fertilization rate and embryo quality.

P-123 Angiotensin II AT2 receptor is expressed in human sperm cells and is involved in sperm motility

M. Gianzo[1], Z. Larreategui[2], I. Urizar[1], I. Muñoa[1], H. Estomba[1], J. Irazusta[1], N. Subirán[1]
[1]*University of Basque Country, Department of Physiology, Leioa, Spain*
[2]*IVI Bilbao Clinic, IVF Laboratoty, Leioa, Spain*

Study question: to investigate the presence of angiotensin receptor AT_2 on human spermatozoa and its implication in sperm motility.
Summary answer: We describe the presence of AT_2 receptor in human sperm cells and its necessary for the maintenance of sperm motility
What is known already: Good motility is a central component for normal male fertility, ART outcomes have demonstrated that the fertilization rates, embryo qualities and pregnancy rates are poor when spermatozoa with low motility have been used for fertilization as compared to those with normal motility. It has been described several components of the rennin-angiotensin system in human sperm cells such as AT_1, ACE, neprilisine and aminopeptidase N. However, the presence and role of the AT_2 is completely unknown.
Study design, size, duration: 1) to investigate the presence of AT_2 receptorin human spermatozoa, 2) to determine its correlation with sperm concentration and motility and 3) and with pathogenic samples. Human samples were

obtained from the Clínica IVI Bilbao, from February 2014 until now. Statistics: Spearman´s rank correlation and Mann-Whitney U-test.
Participants/materials, setting, methods: We used 121 human semen samples. All samples were examined for sperm concentration and motility and classified following WHO guidelines. To confirm the presence of AT_2receptors**,** we performed expression assays for AT_2 receptor by western blot and immunofluorescence. The levels of AT_2 receptor were measured by flow cytometry.
Main results and the role of chance: We demonstrated the existence of angiotensin receptor AT_2 in human sperm by western blot. Immunofluorescence studies showed that AT_2 is mainly located at the equatorial segment of the sperm head. AT_2 receptor levels are associated with sperm motility parameters. Particularly, we found a significant positive correlation between AT_2 receptors and AB motility grade spermatozoa (progressive motility) in freshly and capacitated samples ($p < 0.01$ and $p < 0.01$). Moreover a significant negative correlation with D motility grade spermatozoa in freshly and capacitated samples (inmotile) ($p < 0.05$ and $p < 0.01$). Regarding pathological studies, the levels of AT_2 receptor measured by flow cytometry were lower in spermatozoa of asthenozoospermic men as compared to normozoospermic controls ($p < 0.05$).
Limitations, reason for caution: Duration of the study.
Wider implications of the findings: angiotensin receptor AT_2 is present in human semen and may be involved in the control of sperm motility. These findings suggest the angiotensin receptor AT_2 could be used as a therapeutic target in the finding of male infertility. In-depth understanding of the proteins involved in sperm motility can help elucidates the role of these proteins in male infertility as well as establish biomarkers for male infertility
Study funding/competing interest(s): Funding by University(ies) – Funding by hospital/clinic(s). Department of Physiology, Faculty of Medicine and Dentistry, University of basque Country, Leioa, Spain. IVF Laboratory, Clínica IVI Bilbao, Leio, Spain.
Trial registration number: CEISH/61/2011.
Keywords: rennin-angiotensin system, angiotensin receptor AT_2

P-124 Predictive value of different factors influencing pregnancy rate following intrauterine insemination with homologous semen: results of a prospective observational study of 1041 inseminations

H. Van Kerrebroeck[1], A. thijssen[2], W. Van der Elst[3], G. Mestdagh[4], N. Dhont[4], R. Campo[4], W. Ombelet[4]
[1]Ziekenhuis Oost Limburg, Obstetrics and Gynaecology, Genk, Belgium
[2]Univeristy Hasselt, Physiology, Hasselt, Belgium
[3]Hasselt Univeristy, Centre for Statistics (CENSTAT), Hasselt, Belgium
[4]Ziekenhuis Oost Limburg, Obstetrics and Gynaecology, Genk, Belgium

Study question: This study aimed to examine the extent to which the outcome, i.e. pregnant or not pregnant, of artificial insemination with homologous sperm (AIH) is influenced by certain covariates such as age, smoking/non-smoking, BMI, infertility diagnosis, stimulation method, the insemination procedure itself, sperm quality parameters etc.
Summary answer: Taking all covariates into account, scientific evidence elucidated three predictive factors influencing pregnancy rate: female age, primary or secondary infertility status and the use of natural cycle or ovarian stimulated cycle.
What is known already: Many retrospective studies have examined different prognostic factors influencing pregnancy rates after IUI treatment with homologous semen. Possible effects of covariates such as age, smoking, BMI, ovarian stimulation protocols etc. have been described before. However, in most studies, covariates were studied as independent of each other which may lead to misleading conclusions.
Study design, size, duration: During the period of July 2011 until November 2014, data from 1041 IUI cycles in 454 couples were collected prospectively in a tertiary referral infertility centre. Because outcome results after AIH cannot be analysed independently, the statistical analysis was performed using a Generalized Estimating Equations (GEE) model.
Participants/materials, setting, methods: The examined covariates were female and male age, smoking, BMI, primary/secondary infertility, infertility diagnosis, cycle number, stimulation method, day 0 estradiol/progesterone levels, abstinence period, HCG-insemination interval, the insemination procedure itself, occurrence of blood loss after insemination, sperm quality parameters and inseminating motile count (IMC).
Main results and the role of chance: A clinical pregnancy rate, i.e. presence of fetal heart beat at 6–7 weeks of gestation, of 9.1% per cycle was observed. A univariate statistical analysis of the dataset revealed only one parameter influencing the pregnancy rate per cycle: the ovarian stimulation method. The pregnancy rate per cycle was significantly lower after the use of clomiphene citrate versus natural cycle or gonadotrophin or recombinant-FSH stimulated AIH cycles. A multivariate GEE analysis eventually revealed that the only valuable prognostic covariates included female age, infertility status (i.e. primary or secondary infertility) and ovarian stimulation method. We also observed that a difficult insemination procedure, with or without significant loss of blood, BMI, smoking and the interval between HCG triggering and insemination did not influence the success rate.
Limitations, reason for caution: It is misleading to look at only one covariate at a time since observations are not independent of each other in this series. Furthermore, GEE analysis has a low statistical power to detect statistically significant differences in groups with low success rates, such as observed in an AIH programme.
Wider implications of the findings: According to our results, it seems that female age, infertility status and type of ovarian stimulation are the most important factors influencing the success rate in an AIH programme. Many different prognostic factors described before, such as BMI, smoking, cycle number, easy or difficult insemination procedure etc., did not affect the outcome results in our series. This may be due to the fact that a multivariate GEE statistical analysis was performed.

P-125 Human oocyte calcium analysis (HOCA): a novel test for sperm oocyte-activation potential

M. Ferrer-Buitrago[1], Y. Lu[1], S. Lierman[1], F. Vanden Meerschaut[1], D. Nikiforaki[1], E. Van den Abbeel[1], M. Van der Jeught[1], P. De Sutter[1], B. Heindryckx[1]
[1]Ghent University Hospital, Department for Reproductive Medicine, Ghent, Belgium

Study question: Does human oocyte calcium analysis (HOCA) contribute to reveal sperm-related activation deficiencies in patients with recurrent fertilisation failures?
Summary answer: Mouse oocyte activation test (MOAT) and mouse oocyte calcium analysis (MOCA) are diagnostic assays that allow classifying sperm depending on its activation capacity. We have shown that the mouse model can only reveal severe sperm deficiencies. The use of HOCA detects more precisely sperm activation defects.
What is known already: Oocyte activation deficiency is the main cause for fertilisation failure after ICSI. The sperm-borne factor PLCζ performs a major role in the oocyte activation process. Its function is highly conserved amongst mammals, allowing successful heterologous fertilisation. Although mouse oocytes are used to evaluate the activation potential in human sperm, we have to take into account that human PLCζ (hPLCζ) shows greater potency than mouse (mPLCζ)**.**
Study design, size, duration: Six patients that showed recurrent fertilization failures after ICSI were selected for the study. Activation potential and the calcium patterns were determined by MOAT and MOCA, respectively. Patients showing moderate to normal MOAT activation rate and MOCA score (amplitude x frequency of oscillations, AxF) were further analysed by HOCA.
Participants/materials, setting, methods: *In vitro* matured GV-MII and MI-MII human oocytes were collected and vitrified. After thawing, oocytes were cultured for 2 h and loaded with 7.5 μM Fura-2AM before ICSI. For HOCA, calcium oscillations were recorded by a radiometric method (λ_{exc}340/380 nm) on an inverted epifluorescence microscope every 30 s for 10 h.
Main results and the role of chance: The following data were considered as normal references: (i) MOAT activation rate >80%; (ii) MOCA: product of

frequency (number of peaks/2 h, F) and amplitude of the peaks (fluorescence difference subtracted from baseline, A) ≥9 and (iii) HOCA: Oscillatory activity (number of oocytes peaking, OA) >75%, F = 0.9–1.6 and A = 0.8–1.7.Patients included in the study showed moderate ($n = 2$) to normal activation rates ($n = 4$) after MOAT compared to a positive control (median = 80.4%(66%-97%)). MOCA revealed aberrant patterns in 3 out of 6 patients (median$_{AxF}$ = 9.2 (3.1–46.3)). Interestingly, HOCA revealed a significant reduced activation capacity in all 6 patients. In 4 out of 6 cases no oscillations were observed. The other 2 patients showed normal OA (63%, 80%)and A(0.72, 0.79), however the F was significantly reduced (0.5 and 0.2).

Limitations, reason for caution: The quality of *in vitro* matured human oocytes is impaired compared to *in vivo* matured oocytes. However, the effect of this *in vitro* maturation on the subsequent calcium pattern has already been described in human.

Wider implications of the findings: The present study compares activation capacity of human sperm using homologous and heterologous ICSI. We showed that the diagnostic tests performed using mouse oocytes cannot be directly extrapolated to the human model. This is probably due to the higher activation potential of hPLCζ. In addition, our findings support that the use of HOCA enables the detection of less severe PLCζ deficiencies and provide novel insights for the role of sperm in modulating calcium dynamics.

Study funding/competing interest(s): Funding by University(ies). Funding by hospital/clinic(s) – Ghent University / Ghent University Hospital.

P-126 Use of clomiphene citrate for male infertility caused by idiopathic secondary hypogonadism

N. Vulliemoz[1], M. P. Primi[2], N. Pitteloud[3], L. Vaucher[1]

[1]Centre Hospitalier Universitaire Vaudois, Reproductive Medicine Unit/ Department of Obstetrics and Gynaecology, Lausanne Vaud, Switzerland

[2]Centre Hospitalier Universitaire Vaudois, Andrology and Reproductive Biology Laboratory/Department of Obstetrics and Gynaecology, Lausanne Vaud, Switzerland

[3]Centre Hospitalier Universitaire Vaudois, Department of Endocrinology, Lausanne Vaud, Switzerland

Study question: Idiopathic secondary hypogonadism is a classic cause of male infertility. In those men we evaluated the use of clomiphene citrate (CC) to increase testosterone secretion and improve spermatogenesis.

Summary answer: Clomiphene citrate is an effective and inexpensive treatment to increase testosterone level in idiopathic secondary hypogonadism. It could also potentially improve spermatogenesis in selected patients. The effect of cc on natural pregnancy rates remains to be evaluated.

What is known already: Patients with secondary hypogonadism have inadequate gonadotropin secretion in presence of normal testes. Clomiphene citrate binds to the hypothalamic estrogen receptors resulting in blocking estrogen negative feed-back. This effect induces an increase in FSH and LH secretion, which can improve testosterone secretion by Leydig cells and potentially improve spermatogenesis. Men who meet the following criteria could benefit from the treatment with cc: idiopathic infertility, sperm concentration > 5 million/ml, low or normal FSH/LH levels.

Study design, size, duration: We performed a retrospective review, between January 2010 and January 2013, of 230 men who were referred to our university hospital fertility unit for infertility assessment.

Participants/materials, setting, methods: Secondary hypogonadism was diagnosed in 30 patients. Fourteen met the inclusion criteria of idiopathic secondary hypogonadism with a sperm count over 5 million/ml. They were prescribed cc for 3 months (25 mg/day). Testosterone level was measured at 1 and 3 months, and a semen assessment was performed at 3 months.

Main results and the role of chance: Mean age of the 14 patients who were treated with cc was 38.5 years. After 1 and 3 month, total serum testosterone level increased in all patients from a mean of 7.8 nmol/l (3.8–10.8) to 22.5 nmol/l (15.6–29.1) and 23.2 (14.3–30.1), respectively. Total sperm count doubled in 6/14 patients (baseline sperm concentration 8.8 ± 3.2 million/ml, post treatment sperm concentration 22.2 ± 7.4 million/ml).

Limitations, reason for caution: This is a retrospective review with a small sample size. The potential use and safety of cc in male infertility caused by idiopathic secondary hypogonadism to improve natural pregnancy rates needs to be evaluated in a prospective trial with an adequate sample size.

Wider implications of the findings: Male infertility can be successfully treated with in vitro fertilization and intracytoplasmic sperm injection which is invasive and expensive. It is important to develop new treatments that specifically target the cause of infertility to increase the chance of a natural pregnancy. In selected infertile male patients with secondary hypogondism, cc could represent an alternative to more invasive treatment. Use of cc to increase endogenous testosterone level may have a positive impact on patients' quality of life.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Lausanne University Hospital.

Trial registration number: NA.

P-127 The results of intracytoplasmic sperm injection (ICSI) using testicular spermatozoa among presumed histopathology in testicular biopsy from non-obstructive azoospermia (NOA)

T. Ishikawa[1], S. Mizuta[1], R. Nishiyama[1], K. Kitaya[1], H. Matsubayashi[1]

[1]Reproduction Clinic Osaka, Department of Reproductive Medicine, Osaka, Japan

Study question: What are sperm retrieval rates (SRR) by micro dissection testicular sperm extraction (micro-TESE), fertilization rate, and embryonic development among patients with presumed Sertoli cell only syndrome (SCOS), maturation arrest (MA), and hypospermatogenesis (HS) in testicular biopsy in NOA couples?

Summary answer: The SRR in SCOS and MA was lower than patients with HS. However, good fertilization and embryonic development were achieved without significant differences even in presumed SCOS in those couples whom spermatozoa were obtained.

What is known already: Fertilization and pregnancies can be obtained with spermatozoa recovered from the seminiferous tubules. Sertoli cell only syndrome (SCOS), maturation arrest (MA), and hypospermatogenesis (HS), and, with or without focal spermatogenesis are the commonest histological patterns of patients with non-obstructive azoospermia (NOA). To our knowledge, no study has specifically examined the results of intracytoplasmic sperm injection (ICSI) in SCOS, MA, and HS patients.

Study design, size, duration: We performed a retrospective study based on a reproduction center in Japan and evaluated 221 patients with NOA who underwent micro-TESE between September 2013 and December 2014 in this study.

Participants/materials, setting, methods: We identified patients in whom SCOS, MA, and HS were reported at pathological examination. At the same session of micro-TESE, surgically obtained small tissue specimens were sent to the histopathology laboratory. Two pronuclei (2PN) oocytes, blastocysts development, good-quality blastocysts, biochemical pregnancies and clinical pregnancies rates were examined.

Main results and the role of chance: Spermatozoa were retrieved in 103 of 221 (46.6%) patients with NOA in whom micro-TESE was performed. In 221 patients with histopathology reports, 150 (67.9%), 32 (14.5%), and 39 (17.6%) patients had presumed SCOS, MA, and HS, respectively. SRR in SCOS (44/150 = 29.3%) and MA (20/32 = 62.5%) were lower than patients with HS (39/39 = 100%) patients ($p < 0.001$, respectively). 2PN oocytes, blastocysts development, and good-quality blastocysts rates were 57.2%, 43.1%, and 38.9% in SCOS, 59.2%, 40.8%, and 42.9% in MA, and 62.7%, 44.4%, and 34.5% in HS. Biochemical pregnancy and clinical pregnancy rates were 31.4% (16/51) and 25.5% (13/51) in SCOS, and 30.4% (7/23) and 30.4% (7/23) in MA, and 36.7% (18/49) and 26.5% (13/49) in HS (no significant differences, respectively).

Limitations, reason for caution: The participants are limited to the NOA patients. We excluded obstructive azoospermic (OA) patients, >39 years age of the spouses at the time of ICSI cases in this study, and the patients including with azoospermia factor (AZF) a and AZFb deletion.

Wider implications of the findings: The SRR in patients with SCO was lower than NOA caused by other factors. However, our fertilization and pregnancy rates in patients with SCOS are similar with other histopathological pattern of patients with NOA once successful sperm retrieval is achieved. It is useful to obtain reliable embryonic information from NOA patients and to

encourage micro-TESE for NOA patients even with severe dysregulation of spermatogenesis.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Reproduction Clinic Osaka.
Trial registration number: NA.

POSTER VIEWING

EARLY PREGNANCY

P-128 Epidemiological survey and risk factor analysis of recurrent spontaneous miscarriage in infertile women at large infertility centers

H. Wang[1], Q. Jie[1], S. Wang[2], X. Sun[3], Y. Sun[4], X. Liang[5], F. Liu[6]
[1]*Center of Reproductive Medicine the Third Hospital of Peking University, Reproductive Center, Beijing, China*
[2]*Beijing Obstetrics and Gynecology Hospital, Reproductive Center, Beijing, China*
[3]*Shanghai Ji`ai Diagnosis and Treatment Center for Genetics and Infertility, Reproductive Center, Shanghai, China*
[4]*Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Reproductive Center, Shanghai, China*
[5]*The Sixth Affiliated Hospital Sun Yat-Sen University, Reproductive Center, Guangzhou, China*
[6]*Maternal and Child Health Hospital of Guangdong Province, Reproductive Center, Guangzhou, China*

Study question: What is the prevalence of recurrent spontaneous miscarriage (RSM is defined as ≥ 2 spontaneous miscarriages and ≤ 20 weeks' gestation, following the definition of American Society for Reproductive Medicine in 2008) among infertile women with a history of spontaneous miscarriage at large infertility centers in China?
Summary answer: 200 out of 751 (26.63%) infertile women with a history of spontaneous miscarriage(SM) had actually experienced RSM were recruited from 6 large infertility centers (>150 assisted reproductive technology cycles per month)including 3 from general hospitals and 3 from maternity hospitals.
What is known already: Spontaneous miscarriagerate after assisted reproductive technology (ART) was reported as 12.2% in China. Many more patients with a history of SM were observed in the miscarriage group than in the non-miscarriage group (33.33% vs 7.92%). A small study with 43 patients showed that 25.6% of infertile patients with SM had experienced ≥ 2 times of SM. Thus, an analysis of differences in the various factors in infertile women between RSM group and single SM group may provide information to allow prevention of RSM in infertile women.
Study design, size, duration: This is a multi-center, cross-sectional epidemiological study. Based on an estimated the primary endpoint of 25.6%, 750 patients produced a two-sided 95% confidence interval with a precision equals to 0.033 considering 10% invalid questionnaire. All the patients were recruited from March to November in 2013.
Participants/materials, setting, methods: A total of 757 infertile women with at least one SM history (£ 20 weeks gestation) were recruited. Six of them were excluded due to noncompliance with the inclusion or exclusion criteria. Demographic data, medical history and evaluation of infertility factors of 751patients were analyzed.
Main results and the role of chance: Among 751 patients, there were 200 infertility patients with RSM, accounting for 26.63% (95% CI: 23.50%,29.95%) and 155 (20.64%), 34 (4.53%) and 11 (1.46%) experienced twice, 3 times and at least 4 times SM. In the RSM group, 31.5% (63/200) patients experienced at least one SM between 12–20 weeks. Whereas when all miscarriages were considered together, 15.90% (162/1019) occurred between 12 and 20 weeks. It has been reported from other studies that the rate of SM after 12 weeks in the general pregnant population is 4.4%. Among all the analyzed factors, multivariate logistic regression indicated that age, low educational background, concomitant endocrine disorder, uterine factor and immune factor were associated with RSM independently ($p < 0.05$).
Limitations, reason for caution: This study was a cross-sectional investigation partially based on retrospective medical history collection. There might be bias for either site or patient selection. Furthermore, some independent risk factors were found but the causality could not be defined clearly.
Wider implications of the findings: As more the 25% of infertile women with a history of SM experienced RSM, these women require a good risk assessment of the independent RSM factors, monitoring or prevention treatment if necessary. In clinical practice, more attention is paid to the pregnant women before 12 weeks of gestation, while, this study results shows that women at 12~20 weeks gestation also need close monitoring.

P-129 Expression of GnRHR in Fallopian tube implantation sites from women with ectopic pregnancy

Abstract withdrawn by the author

P-130 Influence of Body mass index (BMI) on risk of early pregnancy loss after high-quality embryo transfer in PCOS patients

X. Wang[1], S. D. Zhang[1], C. L. Zhang[1], Q. L. Wang[2], T. M. Luo[1], G. L. Zhang[1], W. Xia[3]
[1]*The People's Hospital of Henan Province, Reproductive Medicine Institute, Zhengzhou, China*
[2]*Xi 'An Jiaotong University, Epidemiology Teaching and Research Section, Xi'an, China*
[3]*The People's Hospital of Henan Province, Endocrinology Department, Zhengzhou, China*

Study question: Debate exists regarding the effect of BMI and PCOS on the outcome of pregnancies after assisted reproduction technology, therefore, this study accessed the effect of Body mass index (BMI) on early pregnancy loss after high-quality embryo transplantation in PCOS patients.
Summary answer: For PCOS patients conceived after high-quality embryos transplant, raised BMI is significantly associated with higher early pregnancy loss rate, especially biochemical pregnancy loss rate after IVF treatment, and BMI increased significantly along with abnormity of basis sex hormones and insulin resistance, which may lead to early pregnancy loss.
What is known already: Obesity is associated with PCOS and a higher risk of pregnancy complications, and there is evidence that obese women who conceive spontaneously are at an increased risk of miscarriage. Debate exists on whether miscarriage risk would increase for patients with PCOS when embryo quality and BMI were taken into account.
Study design, size, duration: A retrospective analysis was implemented on 453 women who were diagnosed with PCOS and accepted the in vitro fertilization and high quality embryo transplantation (IVF - ET) in reproductive center between January 2011 and September 2013.
Participants/materials, setting, methods: Patients were grouped according to their BMI at the time of accepting ET. The main outcome measure was the early pregnancy loss rate. Confounding variables examined included female age, number of spontaneous abortion, endometrial thickness at transplant day, previous miscarriage, whether cryo-thawed cycles, whether blastocyst, and basic sex hormone. Patients received ICSI, ever had got laparoscopic ovarian drilling, one of couples have chromosome abnormality, or had uterine malformation were excluded.
Main results and the role of chance: Basic LH values of normal BMI group ??(11.45 ± 5.9) was significantly higher than that of high BMI group (8.64 ± 4.34), and index of FBG, FINS, HOMA-IR rose with the increase of BMI, with significant difference between every two groups (<0.05). After transplanted with quality embryo, the obese group has significantly higher early pregnancy loss rate (29.63%) and biochemical pregnancy loss rate (20.37%) than that of normal-weight group, while its implantation rate (42.57%) was significantly lower than that of normal-weight group (57.80%, $P < 0.05$). Logistic regression analysis showed that for patients with PCOS after high quality embryos transplantation, basic androgen level, age, and BMI was related to

early pregnancy loss positively, while endometrial thickness at transplant day negatively correlated with early pregnancy loss.
Limitations, reason for caution: A larger size sample, multi-center study should be carried out to carry out to ensure this conclusion.
Wider implications of the findings: This information should be used in counselling patients on their productive consequences of raised BMI prior to transplant their high-quality embryos. Other clinical variables need more concerns and deep research to avoid EPL. Appropriate measures should be taken to offer effective weight management services for obese women intending to embark on IVF treatment
Study funding/competing interest(s): Funding by hospital/clinic(s) – The People's Hospital of Henan Province.
Trial registration number: NA.
Keywords: PCOS, early pregnancy loss, BMI, insulin resistance

P-131 High and low factor V activity, but not factor V Nara and Hong Kong mutations, might be associated with recurrent miscarriage

M. Izuhara[1], K. Shinozawa[2], T. Kitaori[1], K. Katano[1], Y. Ozaki[1], K. Fukutake[3], M. Sugiura-Ogasawara[1]
[1]*Nagoya City University, Obstetrics and Gynecology, Nagoya, Japan*
[2]*Tokyo Medical University, Molecular Genetics of Coagulation Disorders, Tokyo, Japan*
[3]*Tokyo Medical University, Molecular Genetics of Coagulation Disorders and Laboratory Medicine, Tokyo, Japan*

Study question: Is the factor V (FV) Nara (W1920R) mutation, Hong Kong (R306G) mutation or the plasma levels of FV activity associated with recurrent miscarriage (RM)?
Summary answer: None of the patients and controls had either homozygotes or heterozygotes for the FV Nara or Hong Kong mutations. Mean values of plasma FV activity level were not significantly different. However, the prevalence of patients with low or high FV activity levels was significantly higher than that of controls.
What is known already: FV Leiden (R506Q) mutation, a major cause of activated protein C resistance (APCR) and deep venous thrombosis (DVT) is well-known as a risk factor of RM. The FV Nara mutation, FV Hong Kong mutation and R2 haplotype of FV gene are associated with APCR and DVT.
Study design, size, duration: The frequency of FV Nara and Hong Kong mutation and FV activity were compared between 88 patients with unexplained RM and 95 fertile controls. The frequency of 16 SNPs of R2 haplotype were compared between patients with high and low FV activities.
Participants/materials, setting, methods: We conducted genomic analysis by direct sequencing to determine the presence of the FV Nara, Hong Kong mutation and 16 SNPs reported as FV R2 haplotype. The FV activity levels were determined by a one-stage clotting assay based on the prothrombin time using FV-deficient plasma and factor assay-controlled plasma.
Main results and the role of chance: Both the FV Nara and Hong Kong mutations were not detected in patients and controls. The mean plasma FV activity levels in the patients and controls were 105.0% and 102.5%, with not statistically significant difference. The prevalence of patients with low FV activity levels (<5th percentile) or high FV activity levels (>95th percentile) was significantly higher. In the lower FV activity group homozygous minor types were identified in 13 of 16 SNPs. Two heterozygous and one homozygous states were found at each of Arg 1299 and Gly 2194. Homozygous states of both Ser 1240 (tct) (minor type) and Val 1736 (gtg) (minor type) were found in 4 patients.
Limitations, reason for caution: The sample size was relatively small. The mean age of patients was significantly lower than that of controls. The influence of age on the FV activity level was speculated to be small, because the correlation was not significant in the present study.
Wider implications of the findings: The distribution of FV activity in patients may differ from that in controls. Some of the SNPs including R2 haplotype were seemed to relate to low level of FV activity in some patients with RM. Our results suggested that both low and high level of FV activity might be associated with RM in part of the patients. Further study is needed to examine the association between FV activity and RM.
Study funding/competing interest(s): Funding by national/international organization(s) – The Ministry of Health, Labour and Welfare of Japan.
Trial registration number: NA.
Keywords: recurrent miscarriage, coagulation factor V, FV Nara mutation, FV Hong Kong mutation, FV R2 haplotype

P-132 S protein, factor VIII and D dimer levels comparison in normal pregnancy and under-treatment with low molecular weight heparin

González M. G. Achával[1], M. A. Molina[2], L. Hill[1], A. Del Val[3], S. Ligorria[4], S. R. Ghione[5], J.L. Ordonez[1]
[1]*Origen, Salud Reproductiva, Cordoba, Argentina*
[2]*Hospital Misericordia, Hematologia, Cordoba, Argentina*
[3]*Origen, Salud Reproductiva, Cordoba, Argentina*
[4]*Hospital Misericaordia, Hematologia, Cordoba, Argentina*
[5]*Fundacion Para el Progreso de la Medicina, Hematologia, Cordoba, Argentina*

Study question: To analyze the changes in F VIII, SP (S protein) and DD (D Dimer) levels in pregnant women with documented thrombophilia under LMWH and without thrombophilia and the anticoagulant effect of the LMWH (Low Molecular Weight Heparin)
Summary answer: LMWH treatment shows a stronger effect in the first and the second trimester as much as in SP as in DD, not showing the same behavior on FVIII concentration.
What is known already: Pregnancy represents a physiological prothrombotic state. Factor VIII shows a progressive increase during pregnancy development. S Protein decreases from the first weeks. D Dimer levels increase significantly during the 3 trimesters.
Study design, size, duration: Prostective, case control, diagnostic test. A 162 patients were involved, 66 normal pregnancy patients and 96 with confirmed thrombophilia, between march 2012 and July 2014.
Participants/materials, setting, methods: *66 pregnant without thrombophilia were included:* 25 in first trimester (GIa), 22 second trimester (GIb), 19 third trimester (GIc) 96 pregnant using LMWH: 30 in first trimester (GIIa), 32 second trimester (GIIb) 34 third trimester (GIIc). We measured FVIII with coagulation method, DD with fluoroimmunoassay and SP with coagulometric method
Main results and the role of chance: FVIII GIa 110% (56–154), GIb 137% (80–266), GIc 144% (80–310), *p*: 0.0013; GIIa 118% (58–182), GIIb 137% (70–280), GIIc 201(112–320), *p*: *0.0010.* **SP** GIa 63% (37–94), GIb 53% (38–85), GIc 50% (36–83), *p*: NS. GIIa 80% (30–106), GIIb 63 (32–103), GIIc 45% (28–72), *p*: 0.0010. **DD** GIa: 473 (154–954), GIb 784 (401–1680), GIc 1301 (622–2294) $p < 0.0001$. GIIa 125 (100–621), GIIb 460 (159–1180), GIIc 1115 (311–2270) $p < 0.0001$. **FVIII** GIa (106) vs GIIa (118): *p* NS, GIb (137) vs GIIb (137) pNS, GIc (144) vs GIIc (201) *p*: 0.0167. **SP** GIa (63)vs GIb (80) *p* 0.048. **DD**: GIa (473) vs GIIa (125) $p < 0.0001$, GIb (784) vs GIIb (460) *p* 0.0003.
Limitations, reason for caution: We consider that is important that each center create their own table of values for these parameters.
Wider implications of the findings: LMWH treatment shows a stronger effect in the first and the second trimester as much as in SP as in DD, which is an important parameter to perform a correct treatment and follow up of these patients. It is useful to adequate the dose of heparin in order to prevent obstetrical complications.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Hospital Nuestra Señora de la Misericordia, Origen, Salud Reproductiva, Fundación para el Progreso de la Medicina.
Trial registration number: This is not a RCT study.
Keywords: thrombophilia, pregnancy

P-133 Chorionic villous vascularization related to the uterine pathology in early pregnancy miscarriages

J. H. Kim[1], H. J. Jeong[1], S. R. Kim[2], H. S. Lee[1], M. H. Kim[1], J. W. Kim[1], J. A. Jeong[1]
[1]*Seoul Rachel Fertility Center, Department of Obstetrics and Gynecology, Seoul, South Korea*
[2]*T & C Pathology Clinic, Seoul, South Korea*

Study question: What is the determining factors in the chorionic villous vascularization in early miscarriage specimens?
Summary answer: There were no significant differences in chorionic villous vascularization depeding on either types of miscarriage-embryonic, yolk sac or empty sac miscarriage- or chromosomal status of aborted fetus- euploid or aneupoid. However, uterine pathology was a significant factor in the chorionic villous vascularization.
What is known already: At least half of first trimester miscarriages are due to embryopathogenesis associated with chromosome abnormalities resulting in miscarriages. Absent or decreased chorionic villous vascularization is frequently present in these miscarriage specimens.

Study design, size, duration: For this retrospective study, 134 slides of miscarriage tissue of less than 10 weeks of gestation were collected between July 2013 and October 2014 from a private fertility center.
Participants/materials, setting, methods: Chorionic villous vascularization was determined using a previously published histological classification (Grade 0, unknown; I, normal; IIA, mild hypoplasia; IIB, severe hypoplasia and III, avascular). Uterine pathology was defined as uterine synechia, adenomyosis and myoma with endometrial compression. The vascularization scores of chorionic villi were compared with the ultrasound findings, corresponding chromosome results, and the presence of uterine pathology.
Main results and the role of chance: There were 98 embryonic miscarriages, 18 yolk sac miscarriages and 18 empty sac miscarriages. Chromosome results were obtained in 79 of the 134 miscarriages; 54.4% were noneuploid. Twelve cases (9%) were insufficient villi for evaluation, and 37 (27.6%) were classified as normal, 57 (42.5%) as mild hypoplasia, 25 (18.7%) as severe hypoplasia, and 3 (2.2%) as avascular. Uterine pathology was detected in 25 cases (18.7%). The vascularization score did not differ between embryonic, yolk sac or empty sac miscarriages or euploid or noneuploid miscarriages. It was not related to the gestational age at miscarriage, maternal age, or retention time. However, uterine pathology was a significant factor in the chorionic villous vascularization (p = 0.015 for chi-square test). The rate of preexisting uterine pathology was higher in the avascular villi compared with that in the normal villi (66.7% versus 10.8%, p = 0.054 for Fisher's exact test).
Limitations, reason for caution: The number of samples was limited and the study population was heterogenous.
Wider implications of the findings: Uterine pathologies may impede chorionic villous vascularization. Further study is warranted to determine whether uterine surgery can improve the vascularization.
Study funding/competing interest(s): Funding by hospital/clinic(s) – No funding in this study.
Trial registration number: NA.
Keywords: miscarriage, chorionic villous vascularization, uterine pathology

P-134 Initial serum ß-hCG levels in clinical pregnancies resulting from the transfer of a single vitrified-thawed blastocyst are higher compared to single fresh blastocyst transfers

G. Oron[1], E. Esh-Broder[1], W. Y. Son[1], T. Tulandi[1], H. Holzer[1]
[1]McGill University Health Center, Department of Obstetrics and Gynecology McGill University Montreal QC Canada, Montreal, Canada

Study question: Our objective was to compare serum ß-hCG levels following transfer of a single fresh or a single vitrified-thawed blastocyst and to determine the predictive value of serum ß-hCG levels for pregnancy outcomes.
Summary answer: Our study suggests that initial serum ß-hCG values are higher after the transfer of a single fresh blastocyst compared to a single vitrified-thawed blastocyst transfer resulting in a clinical pregnancy, even after adjusting for confounding variables.
What is known already: Several studies evaluated the predictive levels of serum ß-hCG levels after embryo transfers in an IVF setting. Most of them report serum ß-hCG values after the transfer of single or multiple embryos, and none have compared the predictive value after the transfer of a single fresh versus vitrified blastocyst.
Study design, size, duration: Retrospective analysis of 1144 single blastocyst cycles with a positive ß-hCG results on day 16 after oocyte collection and equivalent calculated day 16 (frozen embryos) between December 2008–2013. Logistic regression determining the association of potential factors and ROC analysis assessing the predictive value of ß-hCG for a clinical intrauterine pregnancy were performed.
Participants/materials, setting, methods: We analyzed covariates including maternal and paternal age, embryo quality, assisted hatching, total dose of FSH, LH, micromanipulation and treatment protocol. Multiple gestations resulting from SET were excluded. Pregnancy outcome included a biochemical pregnancy, ectopic pregnancy, clinical intrauterine pregnancy and live birth.
Main results and the role of chance: There were 801 positive ß-hCG results following the transfer of a single fresh blastocyst and 343 others following the transfer of a single vitrified-thawed blastocyst (650 and 233 clinical intrauterine pregnancies respectively). Mean ß-hCG levels of clinical intrauterine pregnancies were significantly higher following a single vitrified blastocyst than a single fresh blastocyst transfer (383 ± 230 and 334 ± 192; p = 0.01). This difference remained (p = 0.04) after adjusting for the confounding variables. The threshold value predicting a clinical pregnancy for a vitrified blastocyst was 137 IU/L (sensitivity 83%, specificity 68%). For a fresh blastocyst transfer, the predictive threshold value was 111 IU/L (sensitivity 90%, specificity 60%).
Limitations, reason for caution: The limitation of the study is in the retrospective nature of the study. Pregnancy outcome was recorded as part of routine prospective patient follow-up by telephone surveillance and documented in the computerized patient chart. Medical charts were reviewed for patients that delivered at our hospital.
Wider implications of the findings: Transfer of more than one embryo makes it impossible to evaluate the true contribution of the embryo in the very early stages of development. Our study shows that among clinical pregnancies, the initial maternal serum ß-hCG values are significantly higher following the transfer of a single vitrified-thawed blastocyst than a fresh blastocyst. This information might assist clinicians in counseling patients.
Study funding/competing interest(s): Funding by hospital/clinic(s) – None.
Trial registration number: NA.
Keywords: SET, pregnancy, blastocyst, vitrified, ß-hCG

P-135 Endocannabinoids and decidual remodeling: COX-2 oxidative metabolism as a key regulator

M. Almada[1], F. Piscitelli[2], B. M. Fonseca[1], Correia-da-Silva, G.[1], V. Di Marzo[2], N. A. Teixeira[1]
[1]UCIBIO REQUIMTE Faculty of Pharmacy University of Porto, Laboratory of Biochemistry Biological Sciences Department Faculty of Pharmacy University of Porto, Porto, Portugal
[2]Institute of Biomolecular Chemistry Consiglio Nazionale Delle Ricerche Pozzuoli, Endocannabinoid Research Group, Naples, Italy

Study question: We previously described anandamide (AEA)-effect on rat decidual cell apoptosis. Besides its importance in early pregnancy, cyclooxygenase-2 (COX-2) regulates AEA levels. In this study we investigated the role of COX-2 oxidative metabolism in AEA-induced cell death and hypothesized the impact of endocannabinoid disruption on decidual remodeling.
Summary answer: Collectively, our findings suggest that COX-2 has a key role for AEA-induced decidual apoptosis. COX-2 metabolism regulates endocannabinoid levels required for uterine tissue remodeling, and integrates the intracrine uterine stromal crosstalk underlying decidualization.
What is known already: Decidualization is a process crucial for the establishment of pregnancy. COX-2 is restricted to blastocyst surroundings, and disruption of its expression in mice results in decidualization impairment. Endocannabinoids and prostaglandins are lipid mediators involved in endometrial receptivity. Anandamide, the main endocannabinoids, induces apoptosis in rat decidual cell. COX-2 is responsible for the oxidative metabolism of AEA into prostamides. Low levels of AEA allow implantation and alterations of its levels are associated with miscarriages.
Study design, size, duration: Rat decidual tissue from d10 of pregnancy was used to prepare decidual cell cultures. Selective COX-2 inhibitors and a FAAH inhibitor (URB597) were co-incubated with AEA and cell viability assessed after 24 h. The time course of AEA-induction of COX-2 expression (1, 6 and 24 h), in presence and absence of URB597, was analysed.
Participants/materials, setting, methods: To study the effect of AEA or of its oxidative metabolites, cell viability (MTT and LDH release assay) and morphology (Giemsa staining) were analyzed; quantification of prostamides (LC-MS-IT-TOF); caspase -3/-7 and -9 activity, membrane mitochondrial potential alteration ($\Delta\psi m$), generation of ROS (Fluorometry) and Cox-2 expression (Western Blot) were performed.
Main results and the role of chance: The major features of AEA-apoptotic pathway in decidual cells were reversed by selective COX-2 inhibitors (Celecoxib; R-Flurbiprofen). Endogenous levels of prostamide E2 (PME2) in decidual tissue were detected (8.05 pmol/g) and incubation with AEA resulted in a 7-fold increase. PME2 induced cell viability loss in a dose-dependent manner, associated with chromatin condensation, and an increase by 17% of caspase -3/-7 activity. The apoptotic intrinsic pathway was confirmed by a drop in $\Delta\psi m$ by 18%, an increment by 24% of caspase -9 activity, and generation of ROS by 28% in comparison to control. AEA induced a rapid increase of COX-2

activity and expression, sustained in the presence of URB597, a FAAH inhibitor, through a mechanism involving activation of p38 kinase and NF-?B.
Limitations, reason for caution: For ethical reasons, the studies of endometrial tissue remodeling in humans are limited. The rat, like human, exhibits a highly invasive type of placentation, and hence is an acceptable model for studying the mechanisms of decidualization, but caution is required in the translation of results.
Wider implications of the findings: A network of different mediators orchestrates pregnancy, among which endocannabinoids and prostaglandins are prominent. Taking into account that COX-2 spatial-temporal expression indicates that this enzyme is tightly regulated during early pregnancy, we shed light into the role of this enzyme in coordinating the endocannabinoid and eicosanoid systems. COX-2 inhibitors are widely used drugs. Hence, this study is clinically relevant since COX-2 modulation may lead to impairment of decidualization, which predisposes to pregnancy complications, including miscarriage.
Study funding/competing interest(s): Funding by national/international organization(s) – The authors thank Fundação para a Ciência e Tecnologia (FCT) for the grant attributed to Almada M (SFRH/BD/81561/2011) and Fonseca BM (SFRH/BPD/72958/2010).
Trial registration number: NA.
Keywords: Anandamide, COX-2, Decidualization, Apoptosis

P-136 3-fold increased risk of miscarriage in women with a normal BMI undergoing IVF/ICSI if periconceptional TSH level is greater than or equal to 2.5 mU/L

L. Dhaenens[1], S. Somers[1], J. Drubbel[1], J. Van Vlaenderen[1], K. Tilleman[1], P. De Sutter[1]
[1]Ghent University Hospital, Reproductive Medicine, Gent, Belgium

Study question: Is the periconceptional thyroid stimulating hormone (TSH) level in women undergoing in vitro fertilization/ intracytoplasmic sperm injection (IVF/ICSI) correlated with pregnancy outcome in terms of implantation, biochemical pregnancy, clinical pregnancy, miscarriage, live birth and pregnancy complications?
Summary answer: In women with a normal body mass index (BMI) who underwent IVF/ICSI, a periconceptional TSH level of ≥ 2.5 mU/L is correlated with a 3.8-fold increase in risk of miscarriage.
What is known already: Hypothyroidism, and even subclinical hypothyroidism, is associated with a number of adverse reproductive outcomes. The relevance of screening for thyroid function in women undergoing IVF treatment is still controversial, especially since there is no consensus regarding what the treatment threshold should be. Available data is conflicting. To further address this issue, we evaluated the relation between pregnancy outcome and periconceptional TSH levels after IVF/ICSI.
Study design, size, duration: A monocentric retrospective cohort study was performed in patients who underwent a fresh embryo transfer after an IVF/ICSI treatment between January 2007 and September 2011. This study was approved by the local Ethics Committee.
Participants/materials, setting, methods: We included 1128 IVF/ICSI cycles of 626 patients with male subfertility as primary cause of subfertility. Data were analysed in a univariate (Mann-Whitney U-test & Fisher's Exact test) and a multivariate model (multiple logistic regression; adjusting for age ≥ 36, smoking, previous pregnancy/deliveries, > 1 prior miscarriage, number/quality of embryos transferred).
Main results and the role of chance: Outcomes were similar amongst women with TSH < 2.5 mU/L and TSH ≥ 2.5 mU/L. However, women with TSH ≥ 2.5 mU/L had more miscarriages (26.1% of pregnancies established on ultrasound scan versus 13.0%; $p = 0.040$). Interestingly, when considering only women with a normal BMI (18.5–25 kg/m^2) in the multivariate analysis, TSH ≥ 2.5 mU/L was correlated with a more than tri-fold increase in risk of miscarriage ($p = 0.030$, OR = 3.758, 95% CI (1.133–12.468)). In this model adjusting for age ≥ 36, previous pregnancies, previous deliveries, > 1 prior miscarriage, number and quality of embryos transferred, we found other independent risk factors for miscarriage, such as maternal age ≥ 36 ($p = 0.013$, OR = 5.850, 95% CI (1454–23.541)) and having experienced more than one previous miscarriage ($p = 0.028$, OR = 15.448, 95% CI (1.336–178.663)).
Limitations, reason for caution: This study was monocentric and retrospective in design. Only a single measurement of periconceptional TSH was obtained, furthermore free T4, T3 and thyroid antibodies were not available for most cycles.
Wider implications of the findings: Our findings support the recommendation that treatment with levothyroxine should be initiated if serum TSH level are ≥ 2.5 mU/L in order to prevent miscarriages in women with normal BMI undergoing IVF/ICSI. However, prospective studies are needed to examine the effect of substitution therapy on pregnancy outcome in this group of women.
Study funding/competing interest(s): Funding by national/international organization(s) – L. Dhaenens is a holder of a PhD grant of The Agency for Innovation by Science and Technology in Flanders (IWT). The authors declare that they have no conflicts of interest.
Trial registration number: BE670201111456.

P-137 Transgenic overexpression of anti-Müllerian hormone (AMH) causes miscarriage in adult mice

M. W. Pankhurst[1], N. J. Batchelor[1], I.S. McLennan[1]
[1]University of Otago, Department of Anatomy, Dunedin, New Zealand

Study question: Does high AMH expression cause miscarriage?
Summary answer: The post-pubertal overexpression of AMH in female mice causes a large reduction in fertility relative to wild-type females. There is evidence that the effect is caused by miscarriage as foetuses were observed in mid-pregnancy but transgenic dams rarely gave birth.
What is known already: Maternal AMH levels decline as pregnancy progresses which may be necessary for progression of pregnancy. AMH is known to affect processes leading to ovulation but there is also a possibility of actions in other organs as both the pituitary and uterus express AMH receptors. The roles of uterine and pituitary AMH receptors have not been identified.
Study design, size, duration: The study consisted of 12 mice; 6 wild type control mice and 6 transgenic AMH-overexpressing mice (AMH^{Tg}). The study was conducted over a period of 5 months.
Participants/materials, setting, methods: The study utilised a transgenic mouse (AMH^{Tg}) with overexpression of AMH beginning at puberty. Virgin wild-type and AMH^{Tg} female mice underwent 3 matings with wild-type males. Litter size was assessed from matings 1 and 2 and foetuses were examined on the third mating at 10 days post-coitus.
Main results and the role of chance: The majority of wild-type dams gave birth to least one litter in the first two mating periods but only a single litter was observed from five AMH^{Tg} dams. Foetuses were found to be present in AMH^{Tg} dams at 10 days post-coitus but ~40% showed signs of degeneration. Less than 5% of foetuses displayed signs of degeneration in wild-type dams. The mean number of surviving foetuses was significantly different between wild-type (10.3 ± 0.99) and AMH^{Tg} (4.3 ± 0.99) dams ($p = 0.003$).
Limitations, reason for caution: The AMH transgene was produced in the nervous system under control of the neuron-specific enolase promoter leading to high levels of AMH in the brain and blood. Ongoing studies aim to determine whether the miscarriage phenotype arises from excess AMH signalling in the brain, uterus or ovary.
Wider implications of the findings: The majority of research into AMH has focused on its ability to act as a biomarker of ovarian function and its influence on reproductive senescence. This study suggest that AMH may also affect reproductive fitness in young females during the period of peak reproductive fitness. These findings may improve the understanding of clinical conditions such as recurrent miscarriage, for which effective treatments remain elusive.
Study funding/competing interest(s): Funding by national/international organization(s) – Health Research Council of New Zealand.
Trial registration number: NA.
Keywords: anti-mullerian hormone, miscarriage

P-138 Detecting multiple gestations by MALDI ToF Mass spectral profiling of maternal urine: a non-invasive approach for predicting twins and triplets following positive pregnancy test

R. Iles[1], S. A. Butler[1], F. I. Sharara[2]
[1]MAP Diagnostics, Research, London, United Kingdom
[2]Virginia Center for Reproductive Medicine, RE/I, Reston, U.S.A.

Study question: Can the non-invasive analysis of early first trimester urine by MALDI ToF MS distinguish between multiple and singleton pregnancies?
Summary answer: Algorithms exploiting mass/charge variability in the spectra generated from early first trimester urine can accurately detect multiple pregnancies from singleton pregnancies.
What is known already: Detecting a twin or triplet pregnancy is usually established in the 5–6th week of pregnancy following demonstration of multiple embryonic sacs by ultrasound. The analysis of protein markers to indicate pregnancy disorders have been used for decades but proteomic analysis of the serum and urine are relatively new approaches to identifying twins. This study represents the first to correlate the spectral analysis of urine by MALDI ToF MS to identify multiple from singleton pregnancies.
Study design, size, duration: Prospective pilot study examining 117 urine samples from women testing positive for pregnancy and attending ART center in the USA. Urine from 6–10 weeks gestation was analysed by MALDI ToF MS and subsequently correlated with singleton or multiple gestations. Samples were collected and analyzed between March and December 2014.
Participants/materials, setting, methods: Urine samples were obtained from women who conceived spontaneously, after IUI, or after ART, and shipped frozen to the analytical laboratory. Once thawed, samples were subjected to matrix assisted laser desorption ionization (MALDI), time of flight (ToF) mass spectrometry (MS) either as neat urine or diluted 10–1000 in dH_2O.
Main results and the role of chance: Mass spectral data were examined in the region of 6,000–14,000 m/z following MALDI ToF MS of urine from pregnant women. Spectral data was normalized and quantitative characteristics of the profile were compared between outcomes: ongoing singleton pregnancies (N = 111) and ongoing twin or triplet pregnancies (N = 6). Algorithms exploiting the m/z variability were designed to predict outcome with > 98% accuracy. Diagnostic decisions were formulated using a decision tree made up of only three m/z based cut-off criteria.
Limitations, reason for caution: Small number of samples. Not all samples were followed to term.
Wider implications of the findings: Unlike traditional immunoassay based and ultrasound approaches, MALDI ToF MS of very early maternal urine represents an accurate, rapid, and non-invasive method of determining pregnancy outcome and success in women who are trying to conceive. Rapid and non invasive early diagnosis of multiple gestations represents a valuable new tool in the management of women undergoing ART and spontaneous pregnancy.
Study funding/competing interest(s): Funding by hospital/clinic(s). Funding by commercial/corporate company(ies) – Virginia Center for Reproductive Medicine, USA, and MAP Diagnostics, London, UK.

P-139 The effect of medical versus surgical treatment of spontaneous abortion on subsequent in vitro fertilization cycles

R. Tamir Yaniv[1], A. Weisman[2], E. Haikin[1], E. Shalom-Paz[3], A. Shulman[1], A. Wiser[1]
[1]*Meir Medical Center, IVF Unit Department of Obstetrics and Gynecology, Kfar Saba, Israel*
[2]*Wolfson Medical Center, IVF Unit Department of Obstetrics and Gynecology, Holon, Israel*
[3]*Hillel Yaffe Medical Center, IVF Unit Department of Obstetrics and Gynecology, Hadera, Israel*

Study question: To evaluate the effect of dilatation and curettage (D&C) and misoprostol as treatments for spontaneous abortion (SA) on in vitro fertilization (IVF) parameters in the subsequent IVF cycle.
Summary answer: D&C and misoprostol are both effective treatments for IVF patients with SA without an adverse effect on subsequent IVF treatment outcome.
What is known already: Evacuation of the uterus is usually quicker and more effective with surgical rather than medical management. Major complications are rare in each of these methods and the infection rates are similar. No significant differences were found regarding future conception rates and outcomes in the subsequent pregnancy among the general population. To the best of our knowledge, the effect of misoprostol vs. D&C on IVF treatments has not been evaluated previously.
Study design, size, duration: Retrospective, cohort study. Database from 3 academic reproductive centers on 73 women who had SA and treated with either misoprostol or D&C during IVF treatment was collected from 2010–2014. The data contained the patients' baseline demographic and hormonal characteristics. IVF cycle parameters before and after SA were evaluated.
Participants/materials, setting, methods: Women treated for SA after IVF treatment. The SA was treated with either D&C or misoprostol and the patient underwent a subsequent IVF cycle within 12 months of the SA.
Main results and the role of chance: A total of 73 women were included in the study, 32 treated with misoprostol and 41 underwent D&C for uterine evacuation. One patient in the misoprostol group underwent D&C due to incomplete evacuation. There were no significant differences in maternal age, BMI, gravity, parity, duration of infertility and basal FSH between the groups. The maximum hCG level and gestational age at diagnosis were also similar between the two groups. There were no differences in the interval to the subsequent IFV cycle according to the mode of abortion. No significant differences were found in either group regarding the IVF parameters (endometrial thickness, number of eggs retrieved and fertilized, and quality and amount of embryos transferred). The pregnancy and abortion rates were comparable between the groups.
Limitations, reason for caution: The weakness of the current study is its retrospective nature and the small number of patients. However, our results support the safety of larger, prospective studies
Wider implications of the findings: Many infertile patients wish to undergo another treatment as soon as possible after failed pregnancy. Therefore, there is a need to identify treatment for SA that does not affect the ovarian response to IVF and that allows the shortest interval before the next IVF treatment. We found no advantage of D&C vs. misoprostol in all aspects of IVF treatment. These findings allow the physician to individualize treatment according to the specific needs of each patient.

P-140 A non-invasive approach for the early prediction of spontaneous abortion following positive pregnancy test by MALDI ToF Mass spectral profiling of maternal urine in early pregnancy

S. A. Butler[1], R. K. Iles[1], F. I. Sharara[2]
[1]*MAP Diagnostics, R&D, London, United Kingdom*
[2]*Virginia Center for Reproductive Medicine, ART, Reston VA, U.S.A.*

Study question: Can the non-invasive analysis of early first trimester urine by MALDI ToF MS predict ongoing pregnancies in assisted reproduction cycles?
Summary answer: Algorithms exploiting mass/charge variability in the spectra generated from early first trimester urine can accurately predict pregnancy outcomes.
What is known already: Human chorionic gonadotropin has been used as a marker in pregnancy for over one hundred years. However, in the last few decades hCG glycovariation has been detected by more discriminating immunoassays and most recently subtle glycovariations have been observed using mass spectrometry on the urine of woman in early pregnancy. This study represents the first to correlate the spectral analysis of urine by MALDI ToF MS with the ongoing status of pregnancy.
Study design, size, duration: Prospective pilot study examining 121 urine samples from women testing positive for pregnancy and attending ART centre in the USA. Urine from 6–10 weeks gestation was analysed by MALDI ToF MS and subsequently correlated with ongoing singleton pregnancy outcomes. Samples were collected and analyzed between March and December 2014.
Participants/materials, setting, methods: Urine samples were obtained from women who conceived spontaneously, after IUI, or after ART, and shipped frozen to the analytical laboratory. Once thawed, samples were subjected to matrix assisted laser desorption ionization (MALDI), time of flight (ToF) mass spectrometry (MS) as neat urine or diluted 10–1000 fold in dH_2O.
Main results and the role of chance: Mass spectral data were examined in the region of 6,000–14,000 m/z following MALDI ToF MS of urine from pregnant women. Spectral data was normalized and quantitative characteristics of the profile were compared between outcomes: ongoing pregnancy (n = 111), and subsequent spontaneous abortion (n = 10). Algorithms exploiting the m/z

variability were designed to predict outcome with > 99% accuracy and only one false negative. Diagnostic decisions were formulated using a decision tree made up of only five m/z based cut-off criteria.
Limitations, reason for caution: Small number of samples. Not all samples were followed to term.
Wider implications of the findings: Unlike traditional immunoassay based and ultrasound approaches, MALDI ToF MS of very early maternal urine represents an accurate, rapid, and non-invasive method of determining pregnancy outcome and success in women who are trying to conceive. Early diagnosis of the chance of SAB potentially represents a valuable new tool in the management of women with recurrent miscarriage and infertility of unexplained origin.

P-141 Decoy receptor 3 ameliorates recurrent spontaneous abortion by directly counteracting local inflammation and downregulating Th17 cells

Y. L. Liu[1], F. W. Chang[1], G. J. Wu[1], H. K. Sytwu[2]
[1]*Tri-Service General Hospital National Defense Medical Center, Department of Obstetrics and Gynecology, Taipei, Taiwan, R.O.C.*
[2]*National Defense Medical Center, Department and Graduate Institute of Microbiology and Immunology, Taipei, Taiwan, R.O.C.*

Study question: What is the modulatory role of decoy receptor 3 (DcR3) in recurrent spontaneous abortion (RSA)?
Summary answer: The DcR3 is important in counteracting local inflammation and downregulating Th17 cells
What is known already: T cells play a central role in immune system, including immunoregulation and immunostimulation. The peripheral blood and decidua in unexplained recurrent spontaneous abortion patients revealed increased prevalence of T helper 17 (Th17) cells, suggesting an important role of The 17 cells in the pathogenesis of RSA.
Study design, size, duration: Our study is the animal study. We used hydrodynamic-based intravenous (IV) administration of DcR3 plasmid into female CBA/J mated male DBA/2 as the abortion-prone model to elucidate the physiological role of DcR3 on RSA.
Participants/materials, setting, methods: We assessed abortion rate in the abortion-prone model. DcR3 expression was analyzed and its effects on abortion rate were evaluated. Flow cytometry was performed to evaluate the expression levels of T cell subsets.
Main results and the role of chance: DcR3 significantly reduced abortion rate in pregnant female CBA/J mice on d13.5. The expression of IL-17-producing CD4 T cells was lower in the uterus in DcR3-treated mice. Our data suggest that DcR3 has potential as a suppressor of uterus inflammation in the abortion-prone model, which may be attributed to either direct inhibition of uterus inflammation or suppression of abortive Th17 cells.
Limitations, reason for caution: This study is mainly performed in the abortion-prone model. Application of DcR3 in unexplained recurrent spontaneous abortion patients needs further studies.
Wider implications of the findings: This study provides a therapeutic effect of DcR3 in the abortion-prone model, suggesting its potential for treating women RSA.
Study funding/competing interest(s): Funding by hospital/clinic(s) – TSGH-C101-163; CMNDMC10304.
Trial registration number: All animal experiments were approved by the Institutional Animal Care and Use Committees (IACUC) in Taiwan.
Keywords: recurrent spontaneous abortion (RSA), Decoy receptor 3 (DcR3), Th17 cells, Abortion-prone model

P-142 Soluble HLA-G as a non-invasive biomarker from ovulation to early pregnancy in assisted reproduction

G. Filippini-Cattaneo[1], D. Bortolotti[2], S. Spalvieri[1], A. Rotola[2], M. Jemec[3], T. Suter[3], M. Bellavia[3], D. Di Luca[2], R. Rizzo[2]
[1]*ProcreaLab, Human Genetic Laboratory, Lugano, Switzerland*
[2]*University of Ferrara, Department of Medical Sciences, Ferrara, Italy*
[3]*Procrea, Fertility Center, Lugano, Switzerland*

Study question: Human leukocyte antigen (HLA)-G role as biomarker of ovulation induction protocol response and pregnancy course.
Summary answer: sHLA-G plasma levels showed a possible use as a biomarker for women with a higher ovulation induction protocol response and favorable pregnancy course.
What is known already: The artificial induction of ovulation and hyperovulation greatly increased the efficiency of oocyte retrieval in assisted reproduction, but specific follow-up biomarkers are still unknown. HLA-G molecules are expressed by cytotrophoblast cells as membrane bound and soluble isoforms (mHLA-G, sHLA-G), with immune-inhibitory functions as ligand of immune-inhibitory receptors (ILT2, ILT4, KIR2DL4). They were detected in the plasma of pregnant women with increased levels during the first trimester and associated to the clinical outcome.
Study design, size, duration: Eighteen women undergoing in vitro embryo transfer were divided into pregnant (6) and non-pregnant (12), based on β-hCG > 5 mIU/ml and viable intrauterine pregnancy. Plasma samples were taken before ovulation induction, 2 days before and at oocyte collection, at oocyte embryo transfer, after 7 days from transfer and at pregnancy test.
Participants/materials, setting, methods: Plasma samples were analyzed for sHLA-G levels with HLA-G specific enzyme immunosorbent assay with MEM-G9 as capture antibody and anti-beta2microglobulin as detection antibody. The data obtained were compared by T student paired test, Mann Whitney U test and Sperman correlation test (StatView statistical software).
Main results and the role of chance: In pregnant women, there were significant initial higher plasma sHLA-G levels in comparison with non-pregnant women ($p = 0.042$) and a significant increase from the day of oocyte retrieval to that of embryo transfer ($p = 0.04$). These differences were mainly associated with HLA-G5 isoform. In addition, in the viable pregnancy group, plasma sHLA-G was higher at transfer in comparison with non-pregnant women ($p = 0.03$). A trend to correlation was observed between plasma sHLA-G and serum β-hCG (human chorionic gonadotropin) in pregnant women ($r = 0.46$, $p = 0.048$).
Limitations, reason for caution: This study is based on a limited number of subjects. It will be necessary to confirm these data on a larger cohort of subjects.
Wider implications of the findings: These observations are in agreement with the important role of HLA-G molecules during pregnancy. However, this is the first study demonstrating that for a successful pregnancy, a high initial plasma sHLA-G level and a significantly increase from the day of oocyte retrieval to that of embryo transfer are required. We suggest a role as biomarker of ovulation induction protocol response and pregnancy course.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Procrea SA.
Trial registration number: NA.

P-143 Perinatal results after IVF/ICSI. A prospective study

N. Pérez Martinez[1], P. Suarez-Gil[2], S. Garcia[1], D. Llaneza-Suarez[3], Solis J. L. Sanchez[1], P. Llaneza[4]
[1]*Cabueñes Hospital, Obstetrics and Gynecology, Gijon, Spain*
[2]*Cabueñes Hospital, Epidemiologist, Gijon, Spain*
[3]*Cefiva, Embriologist, Oviedo, Spain*
[4]*Central Asturias Hospital, Obstetrics and Gynecology, Oviedo, Spain*

Study question: Increased risk for obstetric and neonatal complications after IVF/ICSI is due to techniques or due to multiple pregnancy and/or advanced maternal age?
Summary answer: Compared to naturally conceived pregnancies, a higher rate of unfavorable obstetrics and neonatal complications after IVF/ICSI was detected in a sample of women with singletons pregnancies, age-matched, and attending to the same tertiary care center
What is known already: After IVF/ICSI techniques an increased risk for a number of obstetric and neonatal complications compared to naturally conceived pregnancies, has been reported. A potential negative impact of micromanipulation techniques, extended culture systems, and medications used in the context of IVF/ICSI has focus on research in this field, but other problems inherent in the infertile couple, pregnancy or delivery management, high rate of multiple pregnancies and advanced maternal age could also explain these worse results.

Study design, size, duration: Prospective, observational, study. Two hundred eighty couples studied between 2012 January and 2014 January.
Participants/materials, setting, methods: One hundred forty couples with single pregnancy conceived via IVF/ICSI were referred to the Department of Obstetrics and Gynecology of Cabueñes Hospital, Gijon, Spain in the early gestational weeks and other 140 couples with single pregnancy naturally conceived age-matched and attending to the same Department were included in the study.
Main results and the role of chance: Maternal parameters as age; BMI; gravity; pregnancy complications such as pregnancy-induced hypertension, preeclampsia, premature rupture of membranes, cervical insufficiency, and premature uterine contractions; and number of hospitalizations; and fetal parameters as gestational age; birth weight; pH of the umbilical artery; APGAR after one minute; APGAR after 1 and 5 minutes; congenital malformation; admission of the newborn to a neonatal intensive care unit; and death of the infant were evaluated. There were no statistical differences between both groups in maternal basal parameters. Women with IVF/ICSI showed statistically significantly more frequent pregnancy complications, such as gestational diabetes ($p < 0.001$), preeclampsia ($p = 0.007$), IGR ($p < 0.001$), premature rupture of membranes and premature birth ($p < 0.001$), cesarean section ($p = 0.028$) and fetal malformations ($p = 0.03$).
Limitations, reason for caution: Increased risk for birth defects, compared to naturally conceived pregnancies (OR: 2.8) must be taken carefully due to the short sample size. Other possible study limitation is that IVF/ICSI procedures were performed in different centers with different controlled ovarian stimulation protocols.
Wider implications of the findings: Increased risk for obstetric and neonatal complications after IVF/ICSI is not related to multiple pregnancy or advanced maternal age.
Study funding/competing interest(s): Funding by hospital/clinic(s) – CABUEÑES HOSPITAL.
Trial registration number: NA.

P-144 The effect of Tokishakuyaku-san on the expression of transcription factors T-bet/GATA-3 in human decidual NK cells in early pregnancy

Z. Y. Huang[1], W. Fan[1], Q. H. Ma[1], S. W. Li[1]
[1]West China Second University Hospital Sichuan University, Department of Obstetrics and Gynecology/Reproductive Medical Centre, Chengdu, China

Study question: To study if the traditional herbal medicine Tokishakuyaku-san has any effect on the expression of transcription factors T-bet/GATA-3 of human decidual NK cells in early pregnancy.
Summary answer: The in vitro experiments found that Tokishakuyaku-san down-regulated the expression of T-bet mRNA and up-regulated the expression of GATA -3 mRNA of human decidual NK cells in early pregnancy.
What is known already: Tokishakuyaku-san has been used empirically in the treatment of immunity-related recurrent miscarriage, but the mechanisms underlying its effectiveness is still largely unknown. Our previous study suggested that Tokishakuyaku-san influenced the expression of transcription factors T-bet/GATA-3 of human peripheral blood mononuclear cells and might play a role in shifting the Th1/Th2 balance toward Th2 polarization. In this study, we examined whether Tokishakuyaku-san modulates the expression of T-bet/GATA-3 in decidual NK cells from early pregnancy.
Study design, size, duration: We enrolled 12 healthy women aged under 35 years who were in 8–9 weeks of pregnancy and chose to terminate the unwanted pregnancy using surgical abortion in our University hospital. The study was approved by the Hospital Ethical Committee, and informed consent was obtained from each patient.
Participants/materials, setting, methods: The decidual NK cells were isolated from decidual tissues obtained from the women included and cultured with various concentrations of Tokishakuyaku-san for 24 h. The cell proliferation was evaluated by CCK-8 assay. The mRNA levels of T-bet and GATA-3 in decidual NK cells were detected by real-time PCR.
Main results and the role of chance: Cell proliferation of decidual NK cells was not changed by treatment with 10 or 100 μg/mL of Tokishakuyaku-san but was significantly inhibited with incubation of Tokishakuyaku-san at the concentration of 1000 μg/mL ($P < 0.05$). The amount of T-bet mRNA was significantly decreased while the GATA-3 mRNA increased after treatment with 10 mg/mL and 100 mg/mL of Tokishakuyaku-san ($P < 0.05$ vs the controls).
Limitations, reason for caution: The limitation is that we investigated the effect of Tokishakuyaku-san on transcription factors T-bet/GATA-3 expression in decidual NK cells only in vitro.
Wider implications of the findings: Considering the ratio of expression of T-bet and GATA-3 reflected changes in the Th1 and Th2-specific cytokines, the down-regulatory effect of Tokishakuyaku-san on T-bet mRNA and stimulatory effect on GATA-3 of decidual NK cells may suggest that Tokishakuyaku-san play a role in shifting the balance of Th1/Th2 toward Th2 polarization at feto-maternal interface, which might have therapeutic potential in alloimmune related miscarriage where Th1 response was pathologically enhanced.
Study funding/competing interest(s): Funding by national/international organization(s) – The National Natural Science Foundation of China (81330018), and Grants of Science & technology department of Sichuan Province (2014KJT062-2014SZ).
Trial registration number: NA.
Keywords: Tokishakuyaku-san, T-bet, GATA-3, decidual NK cell

P-145 Marked improvement in the success rate of medical management of early pregnancy failure (EPF) in clinical practice after dose optimization and clinician education

V. Colleselli[1], C. Brunner[1], T. Bartosik[1], A. Ciresa-Koenig[1], L. Wildt[2], B. Seeber[1]
[1]Medical University of Innsbruck, Gynecologic Endocrinology and Reproductive Medicine, Innsbruck, Austria
[2]Medical University Innsbruck, Obstetrics and Gynecology, Innsbruck, Austria

Study question: Can the success rate of medical management of EPF with Mifepristone and Misoprostol in clinical practice be optimized by formally educating clinicians about the treatment and outcome measures and by adopting a protocol of 200 mg Mifepristone orally followed by a single dose of 800 mcg Misoprostol vaginally after 48 h?
Summary answer: We observed a marked increase in the success rate of treatment (85%), closely approaching that reported under study settings. For these results, we credit the implementation of a novel institutional protocol for medical management of EPF and the formal education of clinical practitioners about the standardized procedure and expected outcomes.
What is known already: EPF is a very common pregnancy complication. Recent studies have supported medical management as a valuable non-invasive alternative to D&C/D&E due to its high success rate, low complication rate, and patient acceptability. However, the variability in medications, dosages, routes of administration and definitions of successful treatment makes it difficult to interpret the published data. Success in clinical practice and in publications from non-research settings is often far below that quoted in the literature.
Study design, size, duration: We retrospectively identified 76 patients with EPF (missed abortion or anembryonic gestation) who were treated according to the adopted protocol over a one year period. Exclusion criteria were complete or incomplete abortion, multiple gestation, gestational age over 13 weeks by ultrasound, and contraindications for Mifepristone or Misoprostol.
Participants/materials, setting, methods: We abstracted data on sonographic results, bleeding, gynecologic, obstetric, and medical history. Unique to our study is the ability to collect data on time to passage of tissue from medication administration, amount of bleeding, and need for analgesics since patients were admitted to an inpatient day-unit for administration of misoprostol.
Main results and the role of chance: We observed a significant increase in the overall success rate of medical management following modification of the institutional protocol and formal clinician education from about 60% to 85% ($p < 0.001$). Clinicians were instructed to diagnose failed treatment by the continued presence of a gestational sac, endometrium thickness > 30 mm, and/or clinical symptoms of persistent heavy bleeding. Also a standardized time to follow up and re-evaluation was defined. Neither gestational age (<9 weeks versus ≥9 weeks) nor diagnosis (missed abortion vs. anembryonic gestation) were predictors of successful treatment. Of successfully treated patients, almost all (96%) passed the pregnancy within 8 hours of receiving vaginal misprostol. Patients reported acceptable pain and bleeding. No serious side effects, such as need for antibiotics or blood transfusion, occurred.
Limitations, reason for caution: The study is limited by its retrospective design. We evaluated data collected in a real life clinical setting influenced by

patients' wishes, treating physicians' decisions and preferences. However, this can also be seen as a strength, reporting results for daily clinical practice, independent of regulated study protocols.

Wider implications of the findings: Our results show that following the revision of the protocol and formal physician education, the subsequent 85% success rate was comparable to that reported in interventional studies. Our results support the use of medical management as a valuable non-invasive alternative to surgery in routine clinical practice. Our findings underscore the importance of formally educating caregivers regarding the expected findings, patterns of bleeding and pain to optimize treatment and to likewise improve patient understanding and expectations.

Study funding/competing interest(s): Funding by University(ies) – Medical University of Innsbruck.

Trial registration number: NA.

[10]*Groene Hart Ziekenhuis, Obstetrics and Gynecology, Gouda, The Netherlands*
[11]*Robinson Research Institute, School of Paediatrics and Reproductive, Adelaide, Australia*

Study question: Does, in women with incomplete evacuation of the uterus after misoprostol treatment for first trimester miscarriage, curettage affects quality of life, compared to expectant management?

Summary answer: In women with an incomplete evacuation of the uterus, curettage and expectant management result in comparable quality of life.

What is known already: Misoprostol treatment for first trimester miscarriage is non-invasive and cost-effective. However, incomplete evacuation of the uterus occurs in about 30% of women treated with misoprostol. Additional curettage is often performed while expectant management is probably equally effective. In order to inform women with an incomplete evacuation of the uterus, we compared quality of life after curettage and expectant management.

Study design, size, duration: Between June 2012 and June 2014, we conducted a multi-center randomized controlled trial (RCT) with a prospective cohort study alongside it. The study was positioned in the consortium form women's health research, and in this study 27 Dutch hospitals participated.

Participants/materials, setting, methods: Women were randomized within 24 hours after sonographic identification of incomplete evacuation of the uterus. Women who refused randomization were asked for follow-up in the cohort. Curettage was performed within three days. Patients answered quality of life related questionnaires HADS, SF-36, RI-10 and EQ5-D at baseline 2, 4 and 12 weeks.

Main results and the role of chance: We randomized 59 women (curettage $n = 30$, expectant management $n = 29$), while 200 women were followed in a prospective cohort study according to the treatment they preferred (curettage $n = 70$, expectant management $n = 130$). Response rate to the questionnaires was 70% in the RCT and 80% in the cohort. The SF-36 showed that for both mental and physical health, women managed expectantly did slightly better but differences were not statistically significant. Similarly, anxiety and depression were slightly more present immediately after treatment in the curettage group (36% vs 30%) to improve to 21% vs 17% after 12 weeks. Both groups improved over time on all dimensions and differences reduced. EQ5D at 12 weeks showed similar scores in both groups. None of the differences were at any moment statistically significant.

Limitations, reason for caution: Randomization was difficult due to preference of treatment. Response-rate to the quality of life related questionnaires at baseline, 2, 4 and 12 weeks was around 75%. Missing data were equally distributed in different treatment groups. In the final analysis, data will be imputed.

Wider implications of the findings: In women with incomplete evacuation of the uterus, expectant management and curettage leads to similar quality of life. It is important to take this into account when counseling women for treatment of a first trimester miscarriage. This might lead to a further implementation of misoprostol treatment for first trimester miscarriages.

P-147 Time to conception (TTC), cumulative conception rate (CCR), and time to live birth (TTLB) in 189 women with recurrent early pregnancy loss (REPL) in an academic RPL program

S.J. Bhatt[1], P.R. Sheth[1], C.E. Boots[2], M.D. Stephenson[1]

[1]*University of Illinois at Chicago, Obstetrics and Gynecology, Chicago, IL, U.S.A.*
[2]*Washington University, Obstetrics and Gynecology, St Louis, MO, U.S.A.*

Study question: What are the TTC, CCR, and TTLB in women with REPL, defined as 2 or more pregnancy losses of less than 10 weeks size?

Summary answer: Mean TTC was 2.3 ± 2.0 menstrual cycles. Mean CCRs were 84% and 96% at 3 and 6 months. Mean TTLB was 46.1 ± 10.4 weeks. Women with REPL appear to be fertile or perhaps 'superfertile', conceiving easily without assisted reproductive technology (ART) and having a high likelihood of a successful pregnancy outcome.

What is known already: In fertile couples, Gnoth (2003) reported a CCR of 88% at 6 months. In recurrent miscarriage, Kaandorp (2014) reported a CCR of 56% at 6 months; median TTC and TTLB was 21 and 102 weeks. In RPL patients with structural chromosomal rearrangements, Desjardins (2012) reported TTC of 1.7 cycles. In women with pregnancy loss, Sapra (2014) reported TTC of 0–3 cycles in 69% and 4–6 cycles in 25%.

Study design, size, duration: This observational cohort study is a secondary analysis of an existing dataset (Boots et al., 2014). All patients were seen in consultation by a single provider (MDS) in an academic RPL Program between July 2004 and June 2012. IRB approval and written consent by all patients were obtained.

Participants/materials, setting, methods: ·Inclusion: REPL patients with subsequent spontaneous pregnancy(ies) following timed intercourse to luteinizing hormone (LH) surge. Pregnancy defined as positive serum human chorionic gonadotropin (hCG) 1–2 days after missed menses. Monitoring: ultrasound q1–2 weeks from 6–10 weeks. TTLB: cumulative TTC x 4 weeks + gestational weeks.

Main results and the role of chance: Cohort: 189 patients with 788 pregnancies prior to RPL consultation consisting of 12% ($n = 94$) livebirths, 41% ($n = 323$) embryonic miscarriages, 36% ($n = 285$) pregnancy losses < 6 weeks, and 11% ($n = 86$) other. Following RPL consultation: The mean maternal age was 35.5 ± 4.0 years at the end of each subsequent pregnancy. There were 263 subsequent spontaneously conceived pregnancies, resulting in 48% ($n = 125$) livebirths, 26% ($n = 68$) embryonic miscarriages, 25% ($n = 66$) pregnancy losses < 6 weeks, and 1% ($n = 4$) other. Mean TTC was 2.3 ± 2 cycles. CCRs were 49%, 84%, and 96% at 1, 3, and 6 months, respectively. Mean TTLB was 46.1 ± 10.4 weeks. 41 patients had prior pregnancies conceived through ART. This subgroup had 52 subsequent spontaneously conceived pregnancies with 37% ($n = 19$) livebirths. Mean TTC was 2.3 ± 1.8 cycles. Mean TTLB was 50.7 ± 17.1 weeks.

Limitations, reason for caution: Whether these encouraging pregnancy outcomes can be replicated outside of an academic, protocol-driven RPL Program needs further study. Direct comparisons of TTC, CCR, and TTLB in spontaneously and ART-conceived pregnancies require identical definitions of 'pregnancy' and 'pregnancy loss', consistently including or excluding pregnancy loss < 6 weeks.
Wider implications of the findings: The diagnosis of recurrent pregnancy loss causes significant distress as couples plan subsequent pregnancies. Based on this study, counseling should include reassurance that the cumulative conception rate is comparable to fertile couples, therefore, assisted reproductive technology is not indicated, unless there is concomitant infertility. In addition, subsequent live births have been shown to be obtainable in a short period of time, following a recurrent pregnancy loss consultation and close monitoring until 10 weeks of gestation.
Study funding/competing interest(s): Funding by University(ies) – University of Illinois at Chicago - no direct financial support.
Trial registration number: NA.

P-148 Our experience in ovarian ectopic pregnancy: ultrasound, clinical and therapeutical correlation

M. Yuri[1], J. Buzzi[2], E. Young[2], M. Diradourian[2], L. Isa[2], B. Garcia[2], A. Kenny[2]
[1]Instituto de Ginecología y Fertilidad de Buenos Aires, Sonography Department, Buenos Aires, Argentina
[2]Instituto de Ginecología y Fertilidad de Buenos Aires, Gynecology and Fertility Department, Buenos Aires, Argentina

Study question: The aim of this study was to evaluate the accuracy of transvaginal ultrasound (TVS) and color Doppler (CD) examination in the diagnosis of Ovarian pregnancy (OP), its surgical treatment and clinical correlation
Summary answer: OP should be suspected in every ectopic pregnancy(EP) if: significant hemoperitoneum and abdominal pain are seen in very early pregnancy. Diagnostic can be reached by combining clinical symptoms, BhCG titters, ultrasound results and confirmed by laparoscopy and/or histology. Early diagnosis allows conservative ovarian treatment, preserving fertility in these women.
What is known already: OP has a reported incidence of 1/6000 to 1/40000 pregnancies. Patients still experience circulatory collapse, with a maternal death rate of 4–10%. Diagnosis has been based on Spielberg's criteria established over 100 years ago: The tubes of the affected side must be intact, the gestational sac must occupy the ovary, the ovary must be joined with the uterus by the utero-ovarian ligament and histology must show ovarian tissue in the chorionic villi.
Study design, size, duration: Descriptive, clinical study, since 1999 to 2014
Participants/materials, setting, methods: TVS were performed in 21534 first trimester pregnancies. 7 OP were detected and prospectively evaluated. Ovarian Ring (OR), presence of free fluid were considered. CD evaluated vascularization in OR and was correlated with B-hCG titters. Amenorrhea, type of pain, vaginal bleeding, surgical treatment, pathologist and follow up were registered.
Main results and the role of chance: The incidence of OP was 0.32‰. Diagnosis was made from 4.5 weeks of amenorrhea. OP was associated to intrauterine device in three cases, to IVF in two, to intrauterine insemination in one, and to benign teratoma in the other. TVS revealed absence of intrauterine sac, presence of OR in ovary. Hemoperitoneum was significant in 6 cases (85.71%) and scarce in 1 (4.28%). The diameters of the OR were between 10 and 33 mm. CD showed in 6 cases trophoblastic flow in OR. B-hCG titters ranged between 800 and 3200 mU/ml. Six patients (85.71%) presented severe abdominal pain and in one was middle (4.28%). Laparoscopy confirmed diagnosis and OR resection was performed. Pathologist reported ovarian tissue in 6 cases. Follow up showed normal evolution.
Limitations, reason for caution: Transvaginal sonography is of diagnostic value in differentiating an ovarian pregnancy from a tubal ectopic pregnancy, but still it is operator dependent and requires considerable experience in this rare condition of ectopic pregnancy.
Wider implications of the findings: The last Spielberg's criteria is not always possible due to conservative treatment of the ovary. Although the histology did not meet the exact definition of OP in all cases, laparoscopic findings and clinical follow-up could not be explained by any other diagnosis.
Study funding/competing interest(s): Funding by hospital/clinic(s) – IFER.
Trial registration number: NA.

P-149 Comprehensive chromosome screening (CCS) improves IVF outcome in recipients suffering from repeated implantation failure (RIF) and recurrent pregnancy loss (RPL)

Gomez J. M. Santana[1], B. Lledó[2], R. Morales[2], J. A. Ortiz[2], J. Guerrero[3], J. Ten[3], J. Llácer[1], R. Bernabeu[1]
[1]Instituto Bernabeu, Reproductive Medicine, Alicante, Spain
[2]Instituto Bernabeu Biotech, Molecular Biology, Alicante, Spain
[3]Instituto Bernabeu, Reproductive Biology, Alicante, Spain

Study question: Is CCS useful to increase egg donation results in RPL and RIF patients?
Summary answer: CCS applied as a therapeutic tool could improve implantation and live birth rates of in-vitro fertilization treatments mainly in RPL and RIF patients.
What is known already: Embryo chromosomal aneuploidy is the most common cause of unsuccessful pregnancy after IVF in RPL and RIF patients. The development of CCS has offered valuable insight into the chromosomal status of human gametes and preimplantation embryos. Applied as a therapeutic tool, it could improve implantation and live birth rates of in-vitro fertilization treatments and provide a means of attenuating pregnancy loss in recurrent pregnancy loss patients and increase implantation rate in recurrent implantation failure patients.
Study design, size, duration: A retrospective study was performed. We included the array-CGH results of 312 embryos (211 RIF and RPL and 101 controls) from 60 RIF and RPL patients and 31 controls performing CCS cycles in 2013 and 2014 at Instituto Bernabeu. Alicante. Spain.
Participants/materials, setting, methods: After discarding known causes, we define RIF if a total of four cleaved good quality embryos transferred failed to implant. RPL was two or more miscarriages. ArrayCGH analysis of the biopsied trophoecthoderm on day5, was performed using Agilent-SurePrintG3-8x60K. The main outcome measures were biochemical pregnancy, implantation rate and ongoing pregnancy.
Main results and the role of chance: Results from D5-CCS were obtained in the 99.5% of the biopsied embryos (310/312). To summarize, the average of biopsed embryo per egg donation cycle was 3.4. The positive beta-HCG was 58.5% and the implantation rate was 43.5%. The miscarriage rate was 10%. The aneuploidy rate in Day 5 embryos from recipients was 30.1% and the majority (70%) showed aneuploidy only in one chromosome. An increase in the implantation rate in RIF and RPL patients to be equal to control patients was reported (41.3% vs 47.1%, $p = 0.578$). Previous results in egg donation RIF and RPL recipients in 50 cycles performed before without CCS showed an implantation rate of 25% ($p < 0.05$).
Limitations, reason for caution: The use of CCS to increase the IVF results mainly in patients suffering from RPL and RIF is a promising tool. The present work shows that euploid embryo selection helps us to improve the results in these patients. Nevertheless, prospective studies are needed to conclude it.
Wider implications of the findings: This investigation reveals a high aneuploidy rate in a population of recipients suffering from RIF and RPL. Application of CCS in these patients is a promising tool. CCS in embryos from an egg donor program could be beneficial as the euploid selection and allowing single-embryo-transfer without decreasing the baby-take-home rate.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Conflicts of interest none declared. This work has been supported by a grant from Rafael Bernabeu Foundation.
Trial registration number: NA.
Keywords: CCS, RIF, RPL

P-150 First genetically confirmed monozygotic dichorionic diamniotic livebirth from day 5 blastocyst single embryo transfer – a new model for twinning and a 10yr retrospective analysis

C. Lynch[1], M. Ragunath[2], D. Maruthini[2], L. Jenner[1], S. Fishel[1]
[1]CARE Fertility, Embryology, Nottingham, United Kingdom
[2]CARE Fertility, Clinician, Nottingham, United Kingdom

Study question: Monozygotic dichorionic (MZ-DC) twinning has historically been believed to occur with splitting of the embryo within 72 h of fertilisation. We have, however, evidenced that it can occur later in development and undertook an investigation of the incidence and possible mechanism.
Summary answer: Monozygotic dichorionic (MZ-DC) twinning is not uncommon after single blastocyst transfer. We theorise the mechanism may involve splitting of the embryo as the inner cell mass hatches, with potential involvement of altered zonal lysis and apoptosis.
What is known already: Approximately 1 in 3 monozygotic twin pregnancies present as dichorionic and diamniotic (DCDA). This has generally believed to have been a result of splitting in the 72 h following fertilisation. However, a literature review of twinning studies in IVF reveals occurrences of MZ-DC twins post single embryo transfer on day 5 without specific investigation into the phenomenon.
Study design, size, duration: We present the first case where monozygosity of a DCDA pregnancy has been confirmed by genetic testing rather than presumed by virtue of single embryo transfer (SET). A retrospective analysis of monozygotic pregnancies from 4780 single embryo transfers 2004–2014 and a literature review was performed.
Participants/materials, setting, methods: A couple underwent PGD treatment with embryo biopsy on day 3 and transfer of a single hatching early blastocyst on day 5. A pregnancy scan at 7 + 6 weeks confirmed DCDA twins and genetic analysis confirmed monozygosity. Clinic data was checked for previous occurrences, as was scientific literature.
Main results and the role of chance: This case report supports a late mechanism for MZ-DC twinning through subdivision of the blastocyst. The retrospective analysis revealed 26 sets of MZ twins, 4 of which were MZ-DC and gender concordant. However zygosity is not genetically confirmed and concurrent natural conception cannot be completely excluded. There are 2 earlier case reports which visualised subdivision of the blastocyst prior to embryo transfer and resulted in MZ-DC pregnancies but zygosity was not genetically confirmed in these cases either. In our case study there were no obvious morphological indications that the blastocyst would subdivide.
Limitations, reason for caution: Only the case study presented has had zygosity genetically confirmed. Discovering the true incidence of MZ-DC twinning is complicated by the number and stage of embryos transferred and the need for genetic confirmation of monozygosity.
Wider implications of the findings: The historical model for twinning is incorrect in supposing that MZ-DC twinning only occurs within 72 h of fertilisation. With increasing moves to single embryo transfer at the blastocyst stage it is incumbent upon us to develop a deeper understanding of the mechanisms behind monozygotic twinning.
Study funding/competing interest(s): Funding by hospital/clinic(s) – CARE Fertility Nottingham.
Trial registration number: NA.

P-151 Accuracy of serum biochemical markers in predicting outcome for women with threatened miscarriage – a systematic review and meta-analysis

R. Pillai[1], N. Potdar[1]
[1]University Hospitals of Leicester, Obstetrics and Gynaecology, Leicester, United Kingdom

Study question: Can serum biochemical markers be used in clinical practice to predict outcome in women with threatened miscarriage?
Summary answer: Various biochemical markers including serum progesterone, beta HCG, PAPP-A, CA 125 and oestradiol have been used to predict outcome of threatened miscarriages. This systematic review and meta-analysis has shown that serum CA 125 and oestradiol have the highest sensitivity and specificity for predicting miscarriage in women with threatened miscarriage
What is known already: Miscarriage is the most common complication in early pregnancy. About 20% of pregnant women present with threatened miscarriage of which about half miscarry. Many biochemical markers have been widely investigated for predicting miscarriage, however, they are not being used in routine practice due to lack of evidence regarding their accuracy.
Study design, size, duration: We conducted a systematic review and meta-analysis of the literature to predict miscarriage in women with threatened miscarriage. Literature search was done using Medline, Embase and the Cochrane Library for relevant citations. Overall, 15 studies were eligible for the systematic review with a sample size of 1147 women.
Participants/materials, setting, methods: Prospective observational studies for women with threatened miscarriage with fetal heart beat visible on ultrasound scan were included in the review. Exclusion criteria were studies including asymptomatic pregnant women, those with pregnancy of unknown location and women with history of infertility, recurrent miscarriage and multiple pregnancies.
Main results and the role of chance: The summary chart of QUADAS (Quality assessment for diagnostic accuracy studies) showed risk of bias in 80% of studies for index test, 35% of studies for reference standard and flow and timing of the studies. Also there were concerns for applicability in 65% of studies for patient selection, 10% of studies for index test and 15 % of studies for reference standard. Amongst the various biochemical markers (serum progesterone, beta HCG, PAPP-A, CA 125 and serum oestradiol), serum CA125 (n = 6 studies) showed the highest sensitivity (CA 125 = 0.92, 95% CI = 0.71, 0.98) and specificity (CA125 = 0.89, 95% CI = 0.75, 0.95) for predicting miscarriage in women with threatened miscarriage.
Limitations, reason for caution: A major drawback is that the threshold level for biochemical marker used has not been specified in majority of the studies, which restricts the applicability. Since the number of studies in the meta-analysis is small, the results need to be interpreted with caution in the absence of high quality studies.
Wider implications of the findings: The biochemical markers of serum progesterone, beta HCG, PAPP-A, CA 125 and oestradiol can be used alone or in combination to predict miscarriage in women with threatened miscarriage. Our study suggests that serum Ca125 should be explored further as a marker to predict miscarriage in a larger cohort of women.
Study funding/competing interest(s): Funding by hospital/clinic(s) – University Hospitals of Leicester.
Trial registration number: NA.

P-152 How low is too low? – Cycle day 28 estradiol levels and pregnancy outcomes

A. P. Melnick[1], N. Pereira[1], E. M. Murphy[1], J. Lekovich[1], Z. Rosenwaks[1], S. D. Spandorfer[1]
[1]Weill Cornell Medical College, Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, New York, U.S.A

Study question: How can a low estradiol level at the time of a first positive pregnancy test after IVF be utilized to predict pregnancy outcomes?
Summary answer: In IVF cycles with a positive hCG, low estradiol levels on cycle day 28 are associated with increased rates of ectopic and biochemical pregnancies and decreased live birth rates. Among pregnancies with low estradiol levels, an hCG <50 mIU/mL is predictive of poorer outcome.
What is known already: The use of luteal estradiol levels to predict pregnancy has been well-studied. Significant differences in estradiol levels 6 days post-LH surge have been found between conception and non-conception cycles. Late luteal phase increases in estradiol have been associated with increased implantation and pregnancy rates, whereas declines are associated with poor cycle outcomes. However, data regarding the value of estradiol level, particularly a low level, in the context of a positive pregnancy test is limited.
Study design, size, duration: This was a retrospective cohort study. 5471 IVF pregnancies achieved at our center between January 2007 and December 2012 were analyzed.
Participants/materials, setting, methods: Cycles resulting in a day 28 hCG >5 mIU/mL were included. Cycles utilizing estradiol for luteal support were excluded. Primary outcome was live birth rate. Secondary outcomes included biochemical, ectopic, and miscarriage rates. Groups were sub-stratified by day 28 hCG. Student's t-test and chi-squared test were used.
Main results and the role of chance: Cycles were stratified by day 28 estradiol level. 1: <50 pg/mL, 2: 51–100 pg/mL, 3: >100 pg/mL. The groups were similar in terms of age, BMI, percentage of blastocyst transfers, and number of embryos transferred. Comparing groups 1 and 3, results were as follows: biochemical 66.5 vs. 7.31% (OR 25.2, 95% CI 20.9-30.4; $p < 0.01$), ectopic 6.2 vs. 0.66% (OR 9.92, 95% CI 6.17-15.9; $p < 0.01$), live birth 15.4 vs. 77.4% (OR 0.05, 95% CI 0.04-0.07; $p < 0.01$). Similar results were observed when

comparing groups 1 and 2 and groups 2 and 3. After sub-stratification of group 1 by hCG level, the odds of biochemical pregnancy was 12.7 times greater when hCG was <50 mIU/mL (95% CI 6.5–24.9; $p < 0.01$) and the odds of a life birth was 0.067 times less (95% CI 0.03–0.1; $p < 0.01$).

Limitations, reason for caution: This was a retrospective study. We did not control for IVF stimulation protocols or peak estrogen levels, although significant differences in peak estradiol levels were only noted between groups 1 and 3 (1633 vs. 1724, $p = 0.02$).

Wider implications of the findings: Low estradiol levels early in IVF pregnancy are associated with poorer pregnancy outcomes. Estradiol can be used alone or in conjunction with hCG levels to predict the odds of a live birth. Clinicians can utilize this data to counsel patients and help them manage expectations about the likelihood of a successful pregnancy.

Study funding/competing interest(s): Funding by University(ies) – Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine – Weill Cornell Medical College.

Trial registration number: NA.

Keywords: IVF, pregnancy outcomes, Day 28 Estradiol

P-153 Embryo selection impact on early pregnancy loss

A. Miskova[1], V. Fodina[1], D. Andzane[2]
[1]*IVF Riga, Reproductology, Riga, Latvia*
[2]*Riga Stradins University, Faculty of Medicine, Riga, Latvia*

Study question: Objective of the study was to compare early pregnancy loss rate between conservative embryo cultivation/selection and time-lapse system based morphokinetic monitoring system groups.

Summary answer: Embryo selection using time-lapse morphokinetic analysis could decrease early pregnancy loss rate and improve success of infertility treatment.

What is known already: One of the noninvasive embryo selection methods is time-lapse based morphokinetic evaluation of the embryonic development. Time-lapse morphokinetic assessment of embryonic development is safe and reliable method improving reproductive outcome and clinical pregnancy rate on more than 10% using Meseguer algorithm of embryo classification. Time-lapse morphokinetic assessment is based on embryo classification according to their implantation rate excluding morphologically normal embryos with discordant cleavage timing.

Study design, size, duration: Embryo development was retrospectively analysed between two study group. In the study 327 patients undergoing infertility treatment were recruited receiving autologous or oocyte donation cycles (poor responders, genetic disorders) between 2013 and 2014. Time-lapse based morphokinetic monitoring system was provided for patient with experience of negative previous treatment outcome.

Participants/materials, setting, methods: Study group included 130 embryo transfers selected using time-lapse morphokinetics analysis. Control group included 388 embryo transfers cultivated/selected conventually using traditional static observations method. Prior to treatment cycle all patients were evaluated and treated for uterine cavity pathology (except uterine septae) by two demential ultrasound or/and hysteroscopy, endocrinopathies, thrombophilias.

Main results and the role of chance: We have found no statistically significant difference in age, endometriosis, polycystic ovary syndrome, poor responders status, previous ART success, oocytes retrieved, oocyte quality, day 5 single embryo transfer (not more than 2 embryos per transfer), biochemical pregnancy rate (50.4% study group vs 51.4% control group) clinical pregnancy rate (49% study group vs 45% control group) or previous ART treatment experience. Embryos cultivated using time lapse morphokinetic analysis were achieved by oocyte fertilisation by olygospermic partner sperm ($p = 0.04$) and PICSI ($p = 0.01$) more often (criterion of time-lapse morphokinetic analysis choice). 27.5% of control group pregnancies were lost before 12 weeks of pregnancy, but time-lapse morphokinetic analysis group early pregnancy loss rate was decreased – 6.1% ($p = 0.01$).

Limitations, reason for caution: The study is a one centre study and is limited due to small patient groups. Patients are not randomly selected due to clinical environment.

Wider implications of the findings: Further multi centre randomised clinical trials are needed to highlight the impact of time-lapse morphokinetic embryo selection on early pregnancy loss in different patients groups undergoing infertility treatment.

Study funding/competing interest(s): Funding by hospital/clinic(s) – IVF Riga.

Trial registration number: NA.

P-154 4G/5G polymorphism of PAI-1 as risk factor fro recurrent miscarriage in Greek population

P. Drakakis[1], A. Vlismas[1], D. Siahami[1], D. Mavrogianni[1], D. Loutradis[1]
[1]*Alexandra Hospital, Division of Human Reproduction Recurrent Miscarriage Unit Molecular Biology of Reproduction Lab 1st Department of Obstetrics and Gynaecology of University of Athens, Athens, Greece*

Study question: The aim of this study was to investigate whether the 4G/5G polymorphism of plasminogen activator inhibitor-1 (PAI-1) is associated with increased risk for recurrent miscarriage in Greek population.

Summary answer: The 4G/4G genotype has been found to be associated with higher rate of recurrent miscarriage.

What is known already: PAI-1 is principal inhibitor of tissue plasminogen activator (t-PA) and major regulator of fibrinolysis. PAI-1 seems to play important role in the initial steps of embryo implantation. 4G variant has been shown to be associated with increased risk of venous thrombosis. Several other reports have linked the 4G allele with complications in pregnancy, although these associations remain controversial. Recent meta-analysis found significant association between 4G/5G polymorphism of PAI-1 and the risk of recurrent miscarriage.

Study design, size, duration: Prospective case – control study of the prevalence of 4G/5G polymorphism of PAI-1 was performed from April 2007 till January 2014. We evaluated 197 patients with recurrent miscarriage and 92 healthy parous women with at least two live births and no history of miscarriages or terminations as control.

Participants/materials, setting, methods: Peripheral blood was collected from 197 patients with recurrent miscarriage defined as above two consecutive pregnancy losses and 92 parous women who attended for the regular smear test the gynaecology outpatient department. Following DNA extraction, real-time PCR was performed for the detection of the polymorphism 4G/5G of PAI-1.

Main results and the role of chance: Both groups had the same demographic characteristics apart from the age, number of miscarriages and parity. The 4G/4G genotype is statistically more frequent in women with recurrent miscarriage compared to control (41.6 vs 20.7%, OR: 2.06, 95% CI: 1.32-3.21, p-value <0.001). Statistical significance was also found for the presence of 4G allele in women with recurrent miscarriages (60.1 vs 39.1%, p-value <0.001). However, the frequency distribution of 4G/5G genotype is similar in both groups (37.1 vs 37%). When we only include patients with history of more than three consecutive recurrent miscarriages the statistical significance for the 4G/4G genotype is maintained (37.6 vs 20.7%, OR: 1.55, 95% CI: 1.06-2.29, p-value = 0.013).

Limitations, reason for caution: In the group of recurrent miscarriages we included women with history of two or more miscarriages, although, in the subgroup analysis where patients with three or more consecutive miscarriages were included, the statistical significance was maintained. We also did not measure the PAI-1 levels in view of performing genotype-phenotype correlations.

Wider implications of the findings: The available data on the association of 4G/5G polymorphism of PAI-1 with increased risk of recurrent miscarriages are still controversial with conflicting findings in the different ethnic populations. This is the first study to associate the 4G/5G polymorphism of PAI-1 with recurrent miscarriages in the Greek population. Our results demonstrate a strong correlation between recurrent miscarriages and 4G/4G genotype. We propose the 4G/5G polymorphism of PAI-1 as important marker of recurrent pregnancy loss.

Study funding/competing interest(s): Funding by University(ies) – 1st Obstetrics and Gynaecology Department of University of Athens.

Trial registration number: NA.

Keywords: recurrent miscarriage, PAI-1 polymorphism, fibrinolysis

P-155 Endocannabinoids impact in trophoblast turnover: 2-arachidonoylglycerol induces reactive oxygen/nitrogen species generation and cell death in primary cultures of cytotrophoblasts

L. Costa[1], M. A. Costa[2], B. M. Fonseca[2], A. Mendes[3], M. J. Pereira[4], N. Teixeira[2], G. Correia-da-Silva[2]
[1]*Universidade de Aveiro Departamento de Biologia & CESAM, and UCIBIO REQUIMTE Laboratório de Bioquímica Departamento de Ciências Biológicas Faculdade de Farmácia Universidade do Porto, Porto, Portugal*

[2]Universidade do Porto, UCIBIO REQUIMTE Laboratório de Bioquímica Departamento de Ciências Biológicas Faculdade de Farmácia Universidade do Porto, Porto, Portugal
[3]Centro Materno-Infantil do Norte-Centro Hospitalar do Porto, Departamento da Mulher e da Criança Serviço de Obstetrícia, Porto, Portugal
[4]Universidade de Aveiro, Departamento de Biologia & CESAM, Aveiro, Portugal

Study question: The placenta development requires a tight regulated proliferation, differentiation and apoptosis of cytotrophoblasts. Is the major endocannabinoid 2-arachidonoylglycerol (2-AG) part of the signaling network involved in cytotrophoblast cell death?
Summary answer: 2-AG induces a decrease in human cytotrophoblast cell viability and a dramatic increase in reactive oxygen/nitrogen species (ROS/RNS) generation. The types of cell death include necrosis for higher concentrations while for lower concentrations other mechanisms, such as apoptosis, may be involved.
What is known already: The endocannabinoid system is implicated in pregnancy events such as implantation and decidualization. Our group has shown the presence of 2-AG metabolic machinery in cytotrophoblast cells and revealed that this endocannabinoid induces apoptosis in the choriocarcinoma cell line- BeWo cells, a cytotrophoblast cell model and in decidual cells.
Study design, size, duration: Human term placenta (n = 5) were used to obtain primary cultures of cytotrophoblasts. After 12 h of adhesion, cells were treated with 2-AG for 24 h at different concentrations (1–50 mM). At the end of incubation time, the impact of 2-AG treatment versus control was assessed by parameters related to cell death.
Participants/materials, setting, methods: Term placentas were collected from normal pregnancies (24–36 years old).To evaluate cell viability, we performed MTT assay and measured LDH released from damaged cells, as a biomarker for cellular cytotoxicity and cytolysis. ROS/RNS generation and mitochondrial membrane potential were evaluated by fluorimetry; morphological changes were observed by Höechst/Giemsa staining.
Main results and the role of chance: Treatment of cell cultures with 2-AG resulted in oxidative stress-related challenges with massive reactive oxygen and nitrogen species generation. In addition, MTT results indicate that 2-AG induced a cytotrophoblast viability loss reflected in the decrease of NAD(P)H-dependent cellular oxidoreductase mitochondrial enzymes activity. These findings were supported by Höechst and Giemsa staining analysis. The highest concentrations caused LDH release suggesting a necrotic process of cell death.
Limitations, reason for caution: Although our data were obtained in human primary cytotrophoblasts, they result from *in vitro* studies. Thus, caution is required in their translation for *in vivo* physiology.
Wider implications of the findings: This study supports the importance of cannabinoid signalling in placenta, more specifically during cytotrophoblast cell turnover. Deregulation of cannabinoid signalling may be implicated in alterations of oxidative state of cytotrophoblasts and may contribute to the pathophysiological mechanisms of some pregnancy complications. Thus, the study of the effects of endocannabinoids on maternal-fetal interface may be relevant for the understanding of the underlying mechanisms in pregnancy pathologies and contribute to future treatments for infertility.
Study funding/competing interest(s): Funding by national/international organization(s) – The authors thank Fundação para a Ciência e Tecnologia for the Post-doctoral grant of Bruno Fonseca (SFRH/BPD/72958/2010).
Trial registration number: NA.
Keywords: 2-arachinoylglycerol, endocannabinoids, placenta, cytotrophoblasts, cell death

P-156 The immunophenotype of women with recurrent pregnancy loss

D. Darmochwal-Kolarz[1]
[1]Medical University of Lublin, Department of Obstetrics and Perinatology, Lublin, Poland

Study question: The purpose of the study was to estimate the alterations in the immunophenotype of women with unexplained pregnancy failures in comparison with healthy women.
Summary answer: The purpose of this study was to estimate selected parameters of the immune system in patients with recurrent pregnancy loss and healthy, fertile women with the history of successful pregnancies. Because it is known that T and NK cells are responsible for the foreign antigen recognition and the adaptive immune response, we studied the populations of T cells and the markers of activation of T lymphocytes. Furthermore, we studied the populations of B cells – especially B-1 cells which are responsible for the production of autoantibodies.
What is known already: Approximately 15–20% of all pregnancies result in miscarriage, usually in the first trimester of pregnancy. The prevalence of recurrent spontaneous abortion (RSA), defined as three or more consecutive losses, is approximately 1–2%. About 40–60% repetitive abortions have no identifiable cause.
Study design, size, duration: The study population included 14 nonpregnant women with the history of recurrent pregnancy miscarriages (defined as 3 or more consecutive, unexplained first trimester spontaneous abortions with the same partner), 25–34 years old (mean – 28.92). A complete medical, surgical, and social history was obtained from all patients evaluated in this study. All couples also had peripheral blood chromosome assessment using standard banding techniques. All patients underwent hysterosalpinography. Luteal phase defects were excluded. The patients with the presence of autoantibodies and infections were excluded.
Participants/materials, setting, methods: The diagnostic thrombosis tests have been performed such as: anticardiolipin antibodies, lupus anticoagulant, activated partial tromboplastin time, prothrombin time, platelet level. In their previous history women did not have neither arterial nor venous thromboembolic events. All patients with a normal profile of the investigations were classified as unexplained repetitive aborters. The control group comprised 18 non-pregnant healthy, fertile women (with the history of successful pregnancies) within the same age range of 26–35 years old (mean – 27.42) were studied. Women with infections (viral and bacterial) or autoimmune diseases were excluded from the control group. The study design was accepted by the local Ethics Committee. Informed consent was obtained from the women before their participation in the study.
Main results and the role of chance: We found that the percentage of T CD 4^+ lymphocytes, $CD3^-16/56^+$ cells, and T CD 8^+11b^- cells was significantly higher in patients with recurrent pregnancy loss in comparison with healthy women. The percentage of B-1 $CD19^+5^+$ lymphocytes was higher than 1.5 % in women with unexplained habitual miscarriages and was also significantly higher in comparison with healthy women. The percentages of B CD 19^+ and T CD 8^+11b^+ lymphocytes were significantly lower in women with pregnancy failures when compared to controls. The ratio of T $CD4^+$: T CD 8^+ was also significantly higher in patients with recurrent pregnancy loss in comparison with healthy women. The percentage of T CD 3^+ lymphocytes and T CD 8^+ cells did not differ in both studied groups. Furthermore, we found higher expression of CD 25 antigen on T CD 3^+ and T CD 4^+ lymphocytes in the study group when compared to controls. The expression of CD 25 antigen and HLA-DR molecule on T CD 8^+ did not differ in the study group when compared to controls. Similarly, the expression of HLA-DR antigen on T CD 3^+ and T CD 4^+ lymphocytes did not differ in the group of women with reproductive failures in comparison with the control group.
Limitations, reason for caution: Chromosomal aberration is the principal cause of fetal loss during the early stage of gestation. The limitations of our study is a lack of chromosomal analysis of the abortion tissue material in previous pregnancies of patients with recurrent pregnancy loss.
Wider implications of the findings: In conclusion, our results suggest that there are alterations in the immunological parameters in women with the history of RSA. These changes can be involved in the etiopathogenesis of recurrent pregnancy loss.
Study funding/competing interest(s): Funding by University(ies) – Medical University of Lublin, Poland.
Trial registration number: There was no trial study.
Keywords: immunology, pregnancy, recurrent pregnancy loss

P-157 Is T cell exhaustion involved in the pathogenesis of idiopathic secondary recurrent miscarriage?

R. J. Kuon[1], J. Schaumann[1], K. Vomstein[1], M. Sadeghi[2], V. Daniel[2], T. Strowitzki[1], B. Toth[1]
[1]University Hospital, Department of Gynecological Endocrinology and Fertility Disorders, Heidelberg, Germany

[2]University Hospital, Department of Transplantation-Immunology, Heidelberg, Germany

Study question: Are immunologic factors involved in the pathogenesis of idiopathic secondary recurrent miscarriages (isRM) of unknown cause?
Summary answer: IsRM patients show immunologic changes that resemble a condition of abnormal T cell function termed T cell exhaustion. Lower levels of $CD3^+$, $CD8^+$ and regulatory T cells but higher proportions of activated $CD3^+$, $CD4^+$ and $CD8^+$ T cells and decreased in-vitro response (proliferation) to various mitogen stimuli are present.
What is known already: Immunologic diagnostic is of growing interest in the context of recurrent miscarriage, especially in patients with isRM. Several studies described immunological parameters that differ in affected patients compared to healthy controls and might be associated with RM. However, results are discussed controversially and limitations of recent studies often are the small size of study populations and inhomogeneous definitions of RM.
Study design, size, duration: N = 276 couples with ≥3 RM were recruited between 10/2011 and 12/2014. A standardized diagnostic procedure including screening for anatomical, endocrinologic, autoimmune, haemostatic, genetic and immunologic disorders was performed. N = 44 patients with ≥3 consecutive RM after a successful pregnancy without abnormalities in the diagnostic were identified. Immunologic diagnostic was compared to n = 31 controls.
Participants/materials, setting, methods: Diagnostic was performed in non-pregnant patients and controls in the mid-luteal phase. Peripheral blood levels of lymphocyte subpopulations, cytokines and neopterin were determined using four-color fluorescence flow cytometry, ELISA, and Luminex technique. In-vitro proliferation was studied using a lymphocyte transformation test with different mitogens and pooled allogeneic stimulator cells.
Main results and the role of chance: IsRM patients showed significantly lower absolute numbers (/mL) of CD45+ (p = 0.032), CD3+ (p = 0.027), CD8+ (p = 0.045) T-lymphocytes, lower proportions of regulatory T cells (CD4 + CD25 + FOXP3 + CD127-; p = 0.028) but higher proportions of activated CD3 + DR+ (p = 0.001), CD4 + DR+ (p < 0.001) and CD8 + DR+ (p = 0.010) lymphocytes and a lower in-vitro stimulation of lymphocytes with phytohaemagglutinin (PHA, p = 0.004), pokeweed mitogen (PWM, p = 0.029) and CD3 mAb (p = 0.048) than healthy controls. Further the analysis of the cytokine assays revealed lower levels of TGF-b2 (pg/ml; p = 0.048) in isRM patients.
Limitations, reason for caution: As screening was performed after isRM it cannot be proven whether the immunologic disorders were cause or consequence of the miscarriages.
Wider implications of the findings: This study increases the understanding of the pathophysiology of RM and assists to establish immunologic diagnostic that helps to identify targets of future immunomodulatory therapies. We suggest T cell exhaustion, induced by a persistent antigen in the maternal circulation, as a potential mechanism involved in isRM. The clearance of the antigen or the repair of the T cell abnormality might be a potential treatment option for isRM.
Study funding/competing interest(s): Funding by University(ies) – Ruprecht-Karls University Heidelberg.
Trial registration number: A trial registration number was not required due to the retrospective study design.

P-158 Effect of thyroid autoantibodies per se on pregnancy outcomes in euthyroid women undergoing IVF/ICSI

H. He[1], S. Jing[1], G. Lin[1], G. X. Lu[1]
[1]Reproductive & Genetics Hospital CITIC-XIANGYA, Assisted reproductive centre, ChangshaHunan, China

Study question: Does thyroid autoantibodies (ATA) per se impair IVF/ICSI outcomes?
Summary answer: Thyroid autoantibodies per se doesn't impair IVF/ICSI outcomes in patients without subclinical hypothyroidism (SCH).
What is known already: The incidence of SCH and the level of ATA was high in infertile women, and they were always co-existed and may have adverse effect on pregnancy outcomes. However, two recent meta-analysis hold opposite opinion about the effect of ATA on pregnancy outcomes in IVF/ICSI patients.
Study design, size, duration: We undertook a systematic review and meta-analysis of the literature published until April 2014. PubMed, Embase, and the Cochrane trial register were searched. The study was conducted according to the MOOSE guidelines.
Participants/materials, setting, methods: We used the software package stata 12.0 for statistical analysis. The risk ratio (RR) with a 95% confidence interval (CI) was calculated using the random/fixed effects model for binary data variables. We displayed the results from the meta-analysis as forest plots.
Main results and the role of chance: Six studies evaluating 2531 women were included in our study, four studies evaluating 1825 women were left after excluding patients with SCH. In euthyroid women not excluding SCH, women with positive ATA was associated with higher risk of miscarriage (pooled RR = 1.638, 95% CI 1.228–2.185, P = 0.001) compared to women with negative ATA, and the pregnancy rate and delivery rate were similar between groups. In euthyroid women excluding SCH, the pregnancy rate was similar in ATA positive women compared to ATA negative women (pooled RR = 0.993, 95% CI 0.853–1.155, P = 0.923). The miscarriage rate was similar in ATA positive women compared to ATA negative women (pooled RR = 1.445, 95% CI 0.970–2.154, P = 0.070). The delivery rate was similar in ATA positive women compared to ATA negative women (pooled RR = 0.935, 95% CI 0.785–1.112, P = 0.446).
Limitations, reason for caution: The study with relatively small number of women included in this review may not have been sufficient to recognise small differences between groups. In addition, unequal TSH level in one of included studies maybe a underlying influencing factor.
Wider implications of the findings: Based on the findings of the current review, it can be concluded that the apparent miscarriage risks resulting from ATA became weaken, even disappeared after excluding the effect of SCH and ATA per se may not impair IVF/ICSI outcomes. However, the results must be interpreted with caution because of limited sample size, bordline P value about miscarriage and methodological weaknesses of the included studies.
Study funding/competing interest(s): Funding by national/international organization(s) – This study was supported by grants from the Major State Basic Research Development Program of China (973 Program; no. 2012CB944902).
Trial registration number: NA.
Keywords: thyroid autoantibodies, subclinical hypothyroidism, miscarriage, ART

P-159

Abstract withdrawn by the author

P-160 Elevated concentrations of circulating serum soluble LH/hCG-Receptor (sLHCGR) and its complex (LH-sLHCGR) are associated with early pregnancy loss (EPL) after blastocyst transfer

R. Fleming[1], C. Fairbairn[2], D. Lucas[2], M. Gaudoin[1], W. Mills[3], A. Chambers[3], S. Banerjee[3]
[1]GCRM Glasgow Centre For Reproductive Medicine, Director, Glasgow, United Kingdom
[2]GCRM Glasgow Centre For Reproductive Medicine, Technology, Glasgow, United Kingdom
[3]Origin Biomarkers, Science, Newhouse, United Kingdom

Study question: Does the circulating complex of sLHCGR/LH-LHCGR remain stable in individuals over time, and does it influence the establishment or course of pregnancy after blastocyst transfer in a programme of IVF?
Summary answer: The sLHCGR concentrations prior to fertility treatment (PT) and on the day of embryo transfer (ET) showed close correlation, suggesting that soluble receptor levels remain stable during the menstrual cycle and fertility treatment.

A significant proportion of women of reproductive age (ca 14%) show elevated concentrations of sLHCGR. These women show positive pregnancy rates which do not differ from women with 'normal' or 'low' concentrations. However, the incidence of EPL in these women was significantly higher than those with 'normal' or 'low' concentrations.
What is known already: The measurement of sLHCGR and its complex has been explored in limited circumstances in IVF so far. However, recently published reports suggest that prenatal testing of sLHCGR and hCG-LHCGR in early human pregnancy (first trimester) significantly contribute to the detection of miscarriage, Down's, preeclamsia.
Study design, size, duration: The study was a prospective exploration of a potential association of extreme concentrations of sLHCGR with pregnancy

outcome after blastocyst transfer in a programme of IVF. Follicular phase serum samples were evaluated in 166 successive blastocyst embryo transfers effected between August 2013 and June 2014.

Participants/materials, setting, methods: All women (n = 166; mean age = 35.5 years) underwent blastocyst transfer effected in a single centre, and 108 of them were frozen embryo transfers mostly during natural cycles. Positive pregnancy test was determined 17 days after ovulation trigger or LH surge by serum bHCG concentrations >5 IU/L. A clinical pregnancy was confirmed by ultrasound identification of a fetal heart at 8 weeks. EPL was confirmed when a positive pregnancy test was followed by a bleed and decline in bHCG prior to the 8-week scan.

The serum sample was collected and stored at -20°C until assay in batches, prior to knowledge of treatment outcome. The assay was a specialist ELISA assays performed in a dedicated laboratory. The sLHCGR and its complex concentrations were expressed as pmol/ml or as multiplicity of median (MoM) values.

Main results and the role of chance: The serum concentrations of the complexes (sLHCGR and its complex) showed good stability over time with pre-treatment and pre-embryo transfer samples showing close correlation (r^2 = 0.99).

The median circulating concentration value was 2.8 pmol/ml (one MoM) showing a non-normal distribution varying from undetectable to an excess of 150 pmol/ml (>53 MoM), and a pragmatic value of ≥28 pmol/ml (≥10 MoM) was used to describe the 'elevated' group (the highest 12% of cases). From the 166 embryo transfers 96 (58%) resulted in a positive pregnancy test. There was no association between sLHCGR concentrations and incidence of positive or negative pregnancy test. Non-continuing pregnancy was confirmed in 34 of the 96 positive tests, and 24% of these cases showed elevated sLHCGR values. In contrast, only 6% of the continuing pregnancies showed elevated values (Fisher's exact test: p = 0.01).

Limitations, reason for caution: A larger series of test evaluations are required to confirm this initial observation, and that series is being undertaken.

Wider implications of the findings: There are numerous reasons for pregnancy failure after embryo transfer, but this first step towards identifying a circulating factor undermining the establishment of clinical pregnancy is a potentially important finding, with implications for recurrent EPL, as high concentrations appear to be patient specific.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Glasgow Centre for Reproductive Biology, UK and Origin Biomarkers, UK.

Trial registration number: NA.

P-161 Genotyping analyses for polymorphisms of PD-1 gene and CTLA4 gene in patients with recurrent pregnancy loss

Y. Hayashi[1], Y. Matsukawa[1], T. Kitaori[1], K. Katano[1], Y. Ozaki[1], M. Sugiura[1]

[1]Nagoya City University Graduate School of Medical Sciences, Obstetrics and Gynecology, Nagoya, Japan

Study question: Are PD-1(programmed Cell Death-1) gene and CTLA4 gene polymorphisms risk factors for recurrent pregnancy loss (RPL) and do the risk alleles have any influence on further miscarriage?

Summary answer: There was a significant difference in frequency of the SNP of the PD-1 gene of the RPL group and the controls group; however the live birth rates of the next pregnancy in patients with and without the risk allele were determined to be 84.6 and 81.7%, showing no significant difference.

What is known already: Because PD-1 controls excessive activity of T cells and causes immune tolerance, disfunction of PD-1 is a cause of autoimmune disease such as systemic lupus erythematosus, and in cases of RPL, decreased regulatory T (Treg) cells have been reported. PD-1 ligand (PD-L1) expresses highly at the placenta and the promoter activity of PD-1 differs between -606G and -606A alleles, the -606G allele being associated with higher promoter activity than the -606A allele.

Study design, size, duration: Genotype analysis was performed on SNPs in PD-1 gene and CTLA4 gene on 264 patients who were diagnosed with unexplained RPL between 2007 and 2012 and on 181 fertile controls. Next, the subsequent live birth rate in the 264 patients was compared with and without the risk allele.

Participants/materials, setting, methods: Genomic DNA was extracted from peripheral blood samples. All genotyping was carried out using TaqMan PCR assays. We calculated the crude OR and 95% confidence intervals (95% CI) in the frequencies of the alleles between patients and controls. Next, we calculated the live birth rates of next pregnancy in patients.

Main results and the role of chance: There was a significant difference in frequency of the SNP of PD-1 gene of the RPL group and the controls group (p = 0.014, OR = 1.21 95% CI; 1.04-1.40), however there was no difference in the SNP of CTLA4 gene. From our cohort study, the live birth rates of patients with the risk allele of PD-1 gene were determined to be 84.6% and those without to be 81.7%, with no significant difference after excluding cases with an abnormal embryonic karyotype. Product of conception (decidua and villus tissue) was tested by immunohistochemistry on cases resulting in miscarriage and having a normal embryo in the next pregnancy and showed little difference in the expression of PD-L1 with or without risk allele of PD-1 gene.

Limitations, reason for caution: Our study includes the patient who had two miscarriages.

Wider implications of the findings: In this study, it was shown that decreased PD-1 activity was related to miscarriage whereas the expression of PD-L1 didn't change. It was shown that genetic polymorphism was related to the immune tolerance which was the cause of the miscarriage. This study gives support to Treg cells playing an important role in the induction of immune tolerance and that steroids could be employed in the treatment of RPL caused by abnormal immune tolerance.

Study funding/competing interest(s): Funding by national/international organization(s) – The Ministry of Health, Labour and Welfare, and the Ministry of Education, Culture, Sports, Science and Technology of Japan/We have no conflict of interest.

Trial registration number: NA.

P-162 The expression of LAMß3 and MFAP5 increases in pregnant women endometrial cells during implantation window

Y. F. Cui[1], S. Y. Zhao[1], C. He[1], M. H. Liu[1], Liu, Y.[1]

[1]Beijing Obstetrics and Gynecology Hospital Capital Medical University, Department of Reproductive Medicine, Beijing, China

Study question: Are the expression of lamininb3 (LAMβ3) and microfibril-associated protein 5 (MFAP5) in endometrial cells during implantation window of pregnant group different from those of non-pregnant group?

Summary answer: LAMβ3 and MFAP5 expressed highly in endometrial cells of pregnant women than those of non-pregnant women during implantation window.

What is known already: LAMβ3 and MFAP5 are important components of extracellular matrix (ECM) and express up-regulated in the LH + 7 samples compared with LH + 2 during the implantation window.

Study design, size, duration: We compared the mRNA expression and protein production of LAMβ3 and MFAP5 in endometrial cells of pregnant women with those of non-pregnant women following IVF. Eighteen endometrial samples cultured in vitro in each group were selected for our detection.

Participants/materials, setting, methods: Thirty-six women were divided into two groups according to their clinical pregnancy outcome: eighteen in pregnant group and eighteen in non-pregnant group. Endometrial samples were collected from them in the 60 day after the dominant follicle disappeared by the transvaginal ultrasound of their natural cycle. The endometrial cells were cultured in vitro. Their morphological characteristics were observed under inverted microscope. The expression of LAMβ3 and MFAP5 were analyzed using quantitative real-time PCR and immunochemical staining.

Main results and the role of chance: The endometrial cells were cultured in 36 endometrium samples, 18 in pregnant group and 18 in non-pregnant group. Their morphological characteristics were similar between the two group. Quantitative real-time PCR showed that the expression level of LAMβ3 and MFAP5 in endometrial cells were significantly higher in pregnant group than that in non-pregnant group (P < 0.05). Immunochemical detection of LAMβ3 and MFAP5 protein showed that they were strongly positive in endometrial glandular epithelial cells and stromal cells in pregnant group while weakly positive in non-pregnant group (P < 0.05).

Limitations, reason for caution: The independent and mutual role of the two genes in endometrial cell signaling needs to investigate further.

Wider implications of the findings: Our study finds that women with a higher expression of LAMβ3 and MFAP5 in endometrial cells during implantation window may have better IVF-ET outcome. LAMβ3 and MFAP5 could be considered as biomarkers of endometrial receptivity.
Study funding/competing interest(s): Funding by national/international organization(s) – This project was funded by National Natural Science Foundation Project (81471520), State Scholarship Fund (2011911033), Beijing Natural Science Foundation Project (5122015), and Beijing Project of Training High-level Medical Technical Personnel in Health System. P-163 Endometrial lgr7 expression and implantation failure: which role for relaxin system?

M. Campitiello[1], F. Caprio[2], D'Eufemia, M.D.[2], D. Mele[2], S. Cesarano[2], N. Colacurci[2]
[1]2nd University of Napoli, Outpatients Fertility Clinic, Napoli, Italy
[2]2nd University of Napoli, Outpatients Fertility Clinic, Naples, Italy

Study question: To compare the endometrial LGR7expression in samples obtained from women with proven fertility to samples obtained from women with history of implantation failure
Summary answer: An analysis of the decreased expression of the endometrial receptor LGR7 in women with implantation failures, both IVF failure and RPL
What is known already: Implantation failure is considered a major cause of infertility not only in women with recurrent pregnancy loss (RPL), but also in otherwise healthy women with unexplained infertility. In a previous study, we have suggested that RLX plays a crucial role in endometrial preparation for implantation. Other studies showed that RLX levels were impaired in women with early pregnancy loss and that granulosa cells.
Study design, size, duration: Three groups of patients referring to the Fertility Clinics of the Second University of Naples were enrolled for this prospective observational study. An endometrial biopsy was planned to be done on every patient in the secretory phases of the menstrual cycle through hysteroscopic examination; determination of LGR7 expression was performed with PCR analysis.
Participants/materials, setting, methods: 69 women with regular ovulatory cycle and normal uterine cavity divided into three groups: 23 patients with recurrent pregnancy loss (Group A), 23 patients with unexplained infertility undergone at least 3 cycles of failed IVF reporting good oocyte and embryo quality (group B), 23 patients with proven fertility (group C).Endometrial biopsy were obtained in the secretory phases (from day +3 to +5); determination of LGR7 expression was performed with PCR analysis immunohistochemistry.
Main results and the role of chance: A significative difference between groups was noticed ($p = 0.02422$). Mean and median values were 1.10 and 1.12 for group A, 0.94 and 0.95 for group B, 1.70 and 1.68 for group C. Multiple comparison test showed a remarkable difference between group B vs C and A vs C. Immunohistochemistry confirmed a lower endometrial expression of LGR7 protein in women with a history of implantation failure.
Limitations, reason for caution: In the control group the time elapsed between the last pregnancy and the sample collection and the possible occurrence of confounding factors were not considered. Moreover, ours was performed in non-conception cycles, and cyclic expression of endometrial factors is unrelated to a subsequently ensuing pregnancy. Chromosomal embryos abnormalities have not been evaluated.
Wider implications of the findings: Our work underscores the important role played in endometrium by RLX – through its receptor LGR7 – in ensuring successful implantation. The decreased expression of the endometrial receptor LGR7 in women with implantation failures, suggests that RLX may play a crucial role during the "window of implantation" – For this reason, our study may open new possibilities for studying and understanding the mechanisms of embryo implantation.
Study funding/competing interest(s): Funding by University(ies) – Second University of Naples.
Trial registration number: Trial registration was not required.

P-164 Relationship between maternal age and numerical abnormalities of fetal chromosomes in spontaneous abortion during the first trimester

T. Wu[1], Y. Zhu[1], B. Yin[1], G. Li[1], H. Liu[1], Y. Zeng[1]
[1]Shenzhen Zhongshan Urology Hospital, Fertility Center, Shenzhen, China

Study question: To investigate whether the relationship between maternal age and numerical abnormalities of chorionic villus chromosomes in spontaneous abortion during the first trimester show a different pattern among different pregnancy ways, different chromosomes and different numbers of abnormal chromosome.
Summary answer: Advanced maternal age is a high risk factor to conceive aneuploidy fetuses in natural conception (NC) and *in vitro* fertilization (IVF), but not in intracytoplasmic sperm injection (ICSI). Abortuses with multiple aneuploidy occur predominantly in advanced maternal age and different biological structure of chromosome shows different susceptibility to aging.
What is known already: Approximately 10–15% of pregnancies end in miscarriage and the major factor contributing to abortion is numerical abnormalities of fetal chromosomes. The prevalence of aneuploidy rises dramatically with increasing maternal age. As the increasing use of assisted reproductive technology (ART), it has generated a concern about its safety. However, it is not clear the plot patterns of maternal age to aneuploidy rate among different pregnancy ways, different chromosomes and different numbers of abnormal chromosome.
Study design, size, duration: Retrospective cohort study. A total of 55 cases of NC, 147 cases of IVF and 85 cases of ICSI suffered from spontaneous abortion during the first trimester were enrolled in this study. The productions of conception were collected as materials.
Participants/materials, setting, methods: Aneuploidy was analysis by multiplex ligation-dependent probe amplification (MLPA) method. According to the maternal age, each group was further divided into 4 subgroups: ≤29, 30 ~ 34, 35 ~ 39 and ≥40. The relationship between maternal age and aneuploidy was compared among different pregnancy ways, different chromosomes and different numbers of abnormal chromosome.
Main results and the role of chance: Maternal age of abortuses with aneuploidy was higher than that without aneuploidy in NC and IVF ($P < 0.05$), but not in ICSI. Abortus' aneuploidy rate was increase with maternal age in NC and IVF but not in ICSI, while statistical difference was observed in IVF ($P = 0.002$). An increase in abnormal rates of chromosomes 15, 20, 21 and 22 was noted with increasing maternal age. Abnormal rates of chromosome 16 were similar in different subgroups. Sex chromosome's abnormal rate of ≥40 years subgroup decreased and without 45, XO in this subgroup. Maternal age of abortuses with multiple aneuploidy was higher than that with single aneuploidy ($P = 0.039$), and the incidence of multiple aneuploidy in ≥40 years subgroup was significantly higher than other three subgroups ($P < 0.05$).
Limitations, reason for caution: It's not valid to detect haploidy and polyploidy by using MLPA methods. This research is just based on analysis of 6 loci per chromosome by adopting 3 different MLPA kits. Therefore, imbalances related to structural rearrangements may be less reliably detected.
Wider implications of the findings: Except advanced maternal age, additional mechanisms may be also involved in causing chromosome abnormality of fetus in ICSI. Abortuses with most of the small chromosomes' aneuploidy occur predominantly in advanced maternal age, whereas abortuses with Turner syndrome are more common in the young gravidas. Effect of maternal age on Trisomy 16 does not exist. It may bring insight into the nature of aneuploidy and exploring the biological mechanisms underlying these pathological processes.
Study funding/competing interest(s): Funding by national/international organization(s) – the Basic Research Program of Shenzhen (no. JCYJ20120829150019349).
Trial registration number: NA.
Keywords: aneuploidy, advanced maternal age (AMA), spontaneous abortion, assisted reproductive technology (ART), chorionic villus

P-165 The prognostic impact of HY restricting HLA class II alleles in secondary recurrent pregnancy loss, a confirmatory study

H. Svarre Nielsen[1], R. N. Steffensen[2], O. B. Christiansen[1], A. M. Kolte[1]
[1]Copenhagen University Hospital Rigshospitalet, Recurrent Pregnancy Loss Unit Fertility Clinic Section 4071, Copenhagen, Denmark
[2]Aalborg University Hospital, Clinical Immunology, Aalborg, Denmark

Study question: Is maternal carriage of HLA class II alleles known to present male specific (HY) antigens associated with a poor prognosis for live birth in secondary recurrent pregnancy loss (SRPL) after the birth of a boy?
Summary answer: Maternal carriage of the HY restricting HLA class II alleles HLA-DRB1*15; -DRB1*07 and DQB1*05:01/02 are associated with a lower chance of cumulative live birth in SRPL after a first-born boy, in a dose-response related manner.
What is known already: SRPL is defined as three or more pregnancy losses after the birth of a child. We have shown that maternal carriage of HLA class II alleles HLA-DRB1*15 and HLA-DQB1*0501/02 is associated with a decreased chance of live birth in the first pregnancy after referral among women with SRPL after a boy. These HLA alleles are known to restrict CD4+ cell immunity against male-specific HY antigens. In 2013, HLA-DRB1*07 was reported also to present HY-antigens.
Study design, size, duration: A prospective cohort study was carried out on women with SRPL after the birth of a boy ($N = 151$) or a girl ($N = 135$) referred between 2005 and 2013, follow-up ranged from 2 to 9 years. HLA-DRB1*15; -DRB1*07; -DRB3*0301; -DQB1*05:01/02 were considered putatively important, in concordance with published studies.
Participants/materials, setting, methods: HLA class II typing was performed by PCR-SSO on DNA from peripheral blood drawn at first consultation at the Danish RPL Unit at Rigshospitalet.

We dichotomized cumulative outcome as 'live birth' or 'no live birth' for c^2 testing with risk estimates.
Main results and the role of chance: Of the 286 women, 151 had a first-born boy, and 135 had a first-born girl. 126 women carried one HY-restricting HLA allele and 60 carried two. Cumulative live birth rate for all patients was 63%, and there was no significant difference according to the sex of the first-born child (OR for live birth: boy vs. girl. 0.87; 95% CI 0.52; 1.42). Live birth rate for women with first-born boys decreased with increasing number of HY-restricting alleles (N (%): 40 (76%); 38 (57%); 15 (48%), OR: 0 (reference) vs. 1: 0.43 (0.19; 0.94); 0 vs 2: 0.31 (0.12; 0.78). We did not show this for women with first-born girls: Live birth rates: 34 (73%), 37 (63%), 17 (59%); OR 0.64 (0.28; 1.47), 0.52 (0.20; 1.44), respectively.
Limitations, reason for caution: A longer follow-up period would add to the merits of the study.
Wider implications of the findings: We found that maternal carriage of HY-restricting HLA class II alleles HLA-DRB1*15; -DQB1*05:01/02 and –DRB1*07 decreased the chance of live birth among women with SRPL after a boy in a dose-response related manner. This extends our previous findings to cumulative outcome and adds –DRB1*07 as prognostically negative. Our findings support the hypothesis that an aberrant immune response to the semi-allogenic fetus by the mother's immune system plays an important role in SRPL after a boy.
Study funding/competing interest(s): Funding by University(ies) – Funding by hospital/clinic(s) – Funding by national/international organization(s) – University Hospital Copenhagen, Rigshospitalet; University of Copenhagen, Den Obelske Familiefond; Maersk Foundation.

P-166 Crucial role of hypoxia inducible factor 2alpha in the pregnant uterus

L. Matsumoto[1], Y. Hirota[1], T. Saito-Fujita[1], H. Haraguchi[1], M. Egashira[1], M. Matsuo[1], T. Hiraoka[1], T. Tanaka[1], N. Takeda[2], T. Fujii[1], Y. Osuga[1]
[1]*The University of Tokyo, Obstetrics and Gynecology, Tokyo, Japan*
[2]*The University of Tokyo, Cardiovascular Medicine, Tokyo, Japan*

Study question: It has been shown that hypoxia inducible factor 2α(Hif2α), one of major transcriptional factors induced by low oxygen tension, is strongly induced in the mouse decidua during early pregnancy. Does it play an important role in early pregnancy? And if so, what is its role?
Summary answer: Our findings suggest that uterine Hif2α plays a critical role in early pregnancy by optimizing progesterone-dependent decidualization and supporting progesterone-independent fetal and placental growth.
What is known already: Although Hif2α is predominantly expressed in the decidualizing stroma in mice, its functions in the pregnant uterus remain unclear.
Study design, size, duration: A mouse model with the deletion of uterine Hif2α was used in this study.
Participants/materials, setting, methods: Uterus-specific Hif2α null ($Hif2a^{loxP/loxP}Pgr^{cre/+}$; Hif2α cKO) and control ($Hif2\alpha^{loxP/loxP}$) mice were generated by crossing Hif2α-floxed mice with Pgr-cre mice. Embryo implantation, decidualization, placental and fetal growth, and litter size in these mice were evaluated after mating with wild-type fertile male mice.
Main results and the role of chance: Although the control mice demonstrated normal litter size, Hif2α cKO females showed infertility. In addition, Hif2α cKO mice showed early pregnancy loss with compromised decidualization. Moreover, the administration of progesterone improved decidualization in the Hif2α-deleted uterus, and however, it could not recover early pregnancy loss in Hif2α cKO females.
Limitations, reason for caution: We performed all the analyses using a mouse model. Further investigations using human cells are needed to confirm the similar cellular effects of Hif2α in the human endometrium.
Wider implications of the findings: These findings provide for molecular evidence for the essentiality of Hif2α in the pregnant uterus.
Study funding/competing interest(s): Funding by national/international organization(s) – This work was supported by the Grant-in-Aid for Scientific Research from Japan Society for the Promotion of Science.

P-167 Pregnancy of unknown location (PUL): prevalence and clinical outcome

A. Malik[1], K. Jayaprakasan[1], D. P. Hay[1], J. Dasgupta[1]
[1]*Royal Derby Hospital, Obstetric and Gynaecology, Derby, United Kingdom*

Study question: To examine the prevalence and clinical outcome of pregnancy of unknown location
Summary answer: One in ten women attending for early pregnancy scans had PUL. While >90% of them had conservative management, 3.6% needed laparoscopy and 1.8% of them had methotrxate.
What is known already: With the development of sensitive urine pregnancy tests and modern high-resolution ultrasound, an increasing number of women are being diagnosed with ectopic pregnancies and PULs. A vast majority of these women are offered medical and expectant management, however some may still require significant surgical intervention for diagnosis and treatment. The data on the clinical outcomes in these women vary widely among various studies, and is dependent upon many factors.
Study design, size, duration: A single centred, retrospective analysis of 1443 consecutive women who had early pregnancy ultrasound scans over a period of four months. Cases with PULs were identified and their management was reviewed.
Participants/materials, setting, methods: All women with a positive pregnancy test and no evidence of an intrauterine or extrauterine pregnancy on ultrasound were included as PUL. The data was collected from 112 cases of PULs.
Main results and the role of chance: The overall prevalence of PUL in our population is 10.7% (154/1443) with 87.5% (1262/1443) intrauterine pregnancies and 1.8% (28/1443) ectopic pregnancies. Of the 112 PUL cases followed up for a mean of 7 days (range: 2–49 days), 69 (61.6%) cases were identified as failing PULs, 32 (28.6%) were intrauterine pregnancies and 2 (1.8%) were ectopic pregnancies. 9 (8%) were diagnosed to have persistent PULs, of which 3 treated with surgical evacuation of uterus, 4 with laparaoscopic management and 2 with Methotrexate. There were no serious adverse event with regards to significant bleeding requiring transfusion.
Limitations, reason for caution: A significant proportion of women had incomplete follow up and was therefore excluded from the data analysis.
Wider implications of the findings: Utilisation of high-resolution ultrasound and serial serum surveillance with hCG estimations will enable the early pregnancy units to manage PULs efficiently and safely in most cases.
Study funding/competing interest(s): Funding by hospital/clinic(s) – None declared.
Trial registration number: NA.

P-168 Peri-conceptional Progesterone treatment in women with unexplained recurrent miscarriage, A randomized double-blind controlled trial

A. Ismail[1], A. Nasr[1], A. Amin[1], H. Al-Inany[2]
[1]Assuit University, Obstetrics & Gynecology, Assuit, Egypt
[2]Cairo University, Obstetrics & Gynecology, Cairo, Egypt

Study question: Is peri-conception progesterone effective in preventing miscarriage in patients with history of recurrent unexplained miscarriages.
Summary answer: Peri-conceptional progesterone in women with unexplained recurrent miscarriage is not only effective in reducing miscarriages but also preterm birth and lowering pregnancy complications with no observed maternal or peri-natal complications.
What is known already: Progesterone is necessary for successful implantation and the maintenance of pregnancy. This benefit of progesterone could be explained by its immmunomodulatory actions in inducing a pregnancy-protective shift from pro-inflammatoryTh-1 cytokine responses to a more favorable anti-inflammatory Th-2 cytokine response and or postulated that decidualization of endometrial stromal Cells serve as sensors of embryo quality upon implantation.
Study design, size, duration: Two hundred and eighty patients of recurrent unexplained miscarriages were randomised using sealed envelopes.
Participants/materials, setting, methods: The study group ($n = 140$) received progesterone (400 mg pessaries, twice daily), started soon as possible at luteal phase and continued after a positive pregnancy test till 28 weeks of gestation, compared to the control group ($n = 140$) who received placebo of the same time and duration. Main outcome measures were miscarriage rate and the rate of continuation of pregnancy beyond 20 weeks of gestation.
Main results and the role of chance: There was improvement in the clinical pregnancy rate with reduction of miscarriage among the study group compared to control group. The rate of miscarriages among the progesterone group is significantly lower than the placebo one (12.1 vs. 22.8%, $p < 0.02$). The rate of preterm delivery is lower (15.7 vs. 26.4%, $p < 0.001$) and the patients completing 36 weeks gestation is significantly higher, (71.4 vs. 32.1%, $p < 0.0001$). There were no observed maternal, fetal or neonatal complications observed.
Limitations, reason for caution: First it did not study the long term effects of the progesterone on the infantile, childhood and adulthood of the offspring; second it needs large population of study with more focusing on the probable mechanisms of progesterone in prevention of the miscarriages.
Wider implications of the findings: This is the first study which use of the vaginal rout progesterone in the peri conception period in recurrent unexplained miscarriages with higher patients acceptability and minimal adverse effects on the mother and the fetus with potential beneficial effect in reducing the miscarriage rate.
Study funding/competing interest(s): Funding by University(ies) – Assuit University.
Trial registration number: ClinicalTrials.gov Identifier: NCT01670929.
Keywords: progesterone, periconception, miscarriage, randomised controlled trial

P-169 Increased expression of Plasminogen-Activator-Inhibitor Type 1 (PAI-1) in the sera of patients with recurrent miscarriages (RM) and anti-trophoblast antibodies (ATAB)

von V. Schönfeldt[1], N. Rogenhofer[1], K. Friese[1], U. Jeschke[1], C. J. Thaler[1]
[1]Klinik und Poliklinik für Frauenheilkunde und Geburtshilfe der Ludwig Maximillians Universität, Hormon- & Kinderwunschzentrum, München, Germany

Study question: To study potential mechanisms how ATAB may interfere with early gestation, we compared the expression of pro-inflammatory cytokines and acute-phase-proteins in the sera of ATAB- positive and -negative RM patients and healthy controls.
Summary answer: ATAB-positive sera of women suffering from recurrent miscarriages display significantly increased expression of Plasminogen-Activator-Inhibitor Type 1 (PAI-1) compared to sera of ATAB-negative RM patients and healthy controls.
What is known already: Reproductive failure including RM has been suggested to correlate with antibodies that cross react with HLA-negative syncytiotrophoblasts. We found that 17% of women with 2 or more miscarriages and 34% of women with 3 or more miscarriages express anti-trophoblast antibodies (ATAB) [1]. The mechanism, how ATAB interfere with early gestation remains currently unknown. Successful early pregnancies require an intricate balance of regulatory cytokines and acute-phase-proteins possibly disrupted in ATAB-positive RM patients.
Study design, size, duration: Sera of patients with a history of idiopathic RM were screened for ATAB. The presence of ATAB was detected as described earlier [1]. Sera of each 18 RM patients with ATAB and of 18 RM patients without ATAB were pooled and termed ATAB-positive or ATAB-negative. Pooled sera of 10 healthy control individuals with at least one pregnancy carried to term and without miscarriages served as controls. All pools were investigated with respect to their cytokine expression level.
Participants/materials, setting, methods: The expression levels of 36 different cytokines, chemokines and akute-phase proteins were investigated with a human cytokine array (Panel A, R&D Systems) in all 3 sera pools. Detected semi quantitative differences were further analysed with an enzyme-linked immunosorbent assay (ELISA).
Main results and the role of chance: ATAB-positive sera of RM patients show increased expression of Plasminogen-Activator-Inhibitor Type 1 (PAI-1) compared to sera of ATAB-negative RM patients and healthy controls in the human cytokine array. ELISA results confirmed a significant higher expression level of PAI-1 in ATAB-positive sera of RM patients compared to ATAB-negative sera and controls ($p = 0.027$).
Limitations, reason for caution: The identification of PAI-1 as differentially expressed in ATAB-positive RM patients compared to healthy controls is a first hint at how ATAB may interfere with early gestation. Further investigations are required to sufficiently elucidate the pathomechanism of RM in patients with ATAB.
Wider implications of the findings: PAI-1 is the main inhibitor of tissue plasminogen activator and urokinase, which both convert plasminogen to plasmin, thus promoting fibrinolysis. Increased activity of PAI-1 and consecutive hypofibrinolysis may result in elevated intervillous fibrin deposition leading to lower placental perfusion in RSA patients with ATAB.
Study funding/competing interest(s): Funding by University(ies) – Klinik und Poliklinik für Frauenheilkunde und Geburtshilfe, Klinikum der Ludwig-Maximilians-Universität, Campus Großhadern, Munich, Germany.
Trial registration number: NA.
Keywords: recurrent miscarriage, anti-trophoblast antibodies, early gestation, PAI-1

P-170 Patient-centered care for couples faced with early pregnancy complications: a systematic review of the literature

M. van den Berg[1], E. A. F. Dancet[1], F. van der Veen[1], M. Goddijn[1], F. Mol[2]
[1]Academic Medical Centre, Centre for Reproductive Medicine, Amsterdam, The Netherlands
[2]Academic Medical Centre, Obstetrics and Gynaecology, Amsterdam, The Netherlands

Study question: What is the perspective of couples faced with early pregnancy complications, defined as miscarriage, recurrent miscarriage or ectopic pregnancy, on current healthcare and is there a need for improvement in patient-centered care?
Summary answer: Patient-centered care for (recurrent) miscarriage should be improved, regarding seven of the eight dimensions of patient-centeredness. Twenty-four specific care aspects were reported by couples to be important. For each of these care aspects healthcare performance was experienced as problematic. Data on patients' perspective on ectopic pregnancy care was not available.
What is known already: Early pregnancy complications affect the physical and emotional wellbeing of intended parents. Research in the field of (recurrent) miscarriage and ectopic pregnancy has so far mainly focused on improving accuracy of diagnostic tests and safety and effectiveness of therapeutic management. An overview of care aspects regarding values, preferences and needs important to couples and an identification of which of these care aspects performs well or poorly in current healthcare is missing.
Study design, size, duration: This systematic literature review followed a predefined protocol replicated by two reviewers. In December 2014, five electronic databases were searched for empirical studies on couples' perspective on care

for early pregnancy complications. Both quantitative and qualitative data was eligible, which implied performing a meta-synthesis rather than a meta-analysis.
Participants/materials, setting, methods: Data was extracted on couples' value clarification and service quality assessment and dichotomized in important/non-important and problematic/non-problematic, respectively. The eight dimensions of patient-centered care (**www.Pickerinstitute.org**) served to organize the reported care aspects varying from strengths to maintain to high priority targets for improving patient-centered care.
Main results and the role of chance: The search yielded 3,630 publications, of which 21 were eligible. Couples' perspective of care was examined by interviews and/or questionnaires. All 21 studies focused on (recurrent) miscarriage care and none on ectopic pregnancy. Twenty-four care aspects were important to couples according to at least one study and for all care aspects healthcare performance was reported problematic by at least one study. The 24 care aspects covered all but one (i.e. emotional support) of the eight dimensions of patient-centered care. For 16 care aspects, all studies agreed on the importance to couples and on the reported problematic performance. The most frequently reported care aspect that required high priority improvement was 'treating individual human beings experiencing a significant live event rather than a common condition' (n = 12 studies).
Limitations, reason for caution: The methodology of the included studies was often insufficiently reported and their quality varied. All but one study only included the female partner of the couple confronted with (recurrent) miscarriage and therefore data on males' perspective is limited.
Wider implications of the findings: The quality of healthcare depends on its safety, effectiveness, timeliness, efficiency, equity and patient-centeredness. Our systematic literature review identified care aspects likely to require improvement of current early pregnancy care. Further research is required to develop and test improvement strategies.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Not applicable.
Trial registration number: NA.

POSTER VIEWING

EMBRYOLOGY

P-171 Late (blastocyst) morphokinetic parameters are better predictors of live birth compared to early (cleavage) ones: retrospective study of 212 single blastocyst transfers following mild IVF

D. Bodri[1], T. Sugimoto[1], Y. Yao Serna[1], M. Kondo[1], M. Kawachiya[1], T. Matsumoto[1]
[1]*Kobe Motomachi Yume Clinic, Assisted Reproduction Unit, Kobe, Japan*

Study question: Which morphokinetic markers are predictive of live birth in a cohort of unselected infertile patients undergoing single blastocyst transfer following mild ovarian stimulation?
Summary answer: The late morphokinetic parameter observed at expanded blastocyst stage (tEB2: time until reaching 160 mm of expansion) was highly predictive of live birth following single blastocyst transfer. Among previously described early (cleavage-stage) morphokinetic parameters only cc2a (t3-t2) was found to be associated with clinical outcome albeit at a lower statistical significance.
What is known already: Published reports (Campbell, 2013) are still scarce on the predictive value of late (blastocyst-stage) morphokinetic parameters. Most TLM (time-lapse monitoring) studies involved cleavage-stage embryos and the prediction models developed so far only included early morphokinetic parameters (Meseguer 2011, Rubio 2014). Our series is unique because it has involved single blastocyst transfers exclusively. Therefore all resulting implantations could be taken into account without relying on known implantation data (KID) only or excluding any transferred embryos.
Study design, size, duration: A 2-year, retrospective study performed between October 2012 and September 2014 in a single private infertility centre. Pregnancies were followed-up until live birth or at least until 20 weeks of gestation. Embryos were cultured with a TLM incubator (EmbryoScope, Unisense Fertilitech, Aarhus, Denmark).
Participants/materials, setting, methods: Early (PNf, t2-t9), late (start of blastulation, time until reaching expanded blastocyst size of 130 (tEB1) and 160 um (tEB2), respectively) and interval (cc2 a-b, s2 and s3) morphokinetic parameters were scored according to recently published consensus criteria. Data were analysed by choosing quartiles with the highest implantation rates.
Main results and the role of chance: 212 consecutive single blastocyst transfers from 144 infertile patients (median age 38.1 ± 4.1 years, range: 28-47) undergoing natural cycle IVF or minimal ovarian stimulation. The overall live birth rate of the cohort was 34% (72/212). Compared to non-implanted ones, blastocysts that resulted in live birth needed on average -4.7 and -5.7 h less to reach the previously defined stages of expansion (tEB1 and 2). Implantation rates for tEB2 were significantly different (43 and 23%, p = 0.0025) for the lower and higher two quartiles, respectively. For cc2a the difference was statistically less significant (44 and 27%, p = 0.027).
Limitations, reason for caution: Our unselected patient cohort was biased towards advanced-aged, poor-prognosis patients who undergone mild IVF treatment coupled with single blastocyst transfer exclusively. This might limit generalizibility to other less infertile populations or to centres which use different treatment protocols.
Wider implications of the findings: Late morphokinetic parameters (especially those that incorporate a defined size of blastocyst expansion) might prove to be superior too early ones in predicting clinical outcome. Our findings are in line with the previously published studies of Campbell et al which have suggested that late morphokinetic markers (tSB and tB) could predict both euploidy status and clinical outcome.

P-172 The spatiotemporal dynamics of centrosomes and the genome during first cleavage in human tripronuclear zygotes in vitro

Y. Kai[1], A. Kurimasa[2], K. Iwata[1], K. Yumoto[1], Y. Iba[1], Y. Mio[1]
[1]*Mio Fertility Clinic, Fertility Research Centre, Yonago, Japan*
[2]*Tottori University, Institute of Regenerative Medicine and Biofunction Graduate School of Medical Science, Yonago, Japan*

Study question: Most tripronuclear (3PN) zygotes obtained through assisted reproductive technology (ART) present an abnormal cleavage pattern, such as multipolar mitosis. To reveal the underlying mechanism of this abnormality, we analyzed the behavior of centrosomes and genome segregation during the first cleavage of human 3PN zygotes using live-imaging techniques.
Summary answer: We established three-dimensional (3D) centrosome-tracking datasets during the first cleavage using human 3PN zygotes. Not every centrosome participated in genome segregation during this process in those zygotes retaining four centrosomes. In 3PN zygotes retaining two centrosomes, each centrosome moved in a different direction during genome segregation.
What is known already: Some 3PN zygotes derived from conventional *in vitro* fertilization (c-IVF) divide into three cells via a tripolar spindle (Plachot and Crozet, 1992; Balakier, 1993). We previously demonstrated that 3PN zygotes derived from intra-cytoplasmic sperm injection (ICSI) had two centrosomes, whereas of those derived from c-IVF, almost all had four centrosomes and they showed a Y-shaped metaphase plate and tripolar spindle in syngamy.
Study design, size, duration: Donated 3PN zygotes derived from c-IVF and ICSI were used in this study (n = 5). We visualized the centrosomes and histone H2B of these zygotes, then performed live imaging from zygote stage to first cleavage. The obtained datasets were used to analyze the dynamics of centrosomes and histone H2B.
Participants/materials, setting, methods: We constructed a plasmid to express histone H2B using commercially available plasmids from Evrogen. We also modified pCAG-PACT-mKO1, gifted by Dr. Matsuzaki (RIKEN CDB), and synthesized mRNA using an mMESSAGE mMACHINE Kit (Ambion). Images were obtained using CV1000 (Yokogawa) and tracking datasets were generated using R program and ImageJ.

Main results and the role of chance: In this study, centrosomes appeared just before the pronucleus disappeared, and assembled around the genome at syngamy. All 3PN zygotes derived from c-IVF ($n = 3$) demonstrated tripolar division after first cleavage, and commonly showed four centrosomes with a genome divided into 3–4 components after syngamy. The four centrosomes moved in different directions following genome segregation during the first cleavage, with most centrosome leading the genome components during the cleavage, while some were detached from genome segregation. The centrosomes and genome were not always distributed to all blastomeres after the cleavage. As a result, one embryo had a blastomere containing no centrosome and no genome. The 3PN zygotes derived from ICSI ($n = 2$) showed even cleavage with bidirectional genome segregation by two centrosomes.
Limitations, reason for caution: Our sample size was only small in this study, and further similar studied are needed to confirm these results. The limitation in study design size lies in the time required to obtain sufficient fluorescent signals to analyze, due to temporal differences between mRNA injection and translation.
Wider implications of the findings: In this study, we successfully tracked the spatiotemporal dynamics of centrosomes and genome segregation during first cleavage in human zygotes. Our techniques proved very useful in establishing characteristic morphological patterns in abnormal zygotes such as polyspermy. In future studies, we will investigate the mechanism by which four centrosomes participate in the division of a triploid genome during the first cleavage.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Mio fertility clinic.
Trial registration number: NA.

P-173 An automated time-lapse embryo selection algorithm is correlated with embryo implantation potential; clinical validation of Eeva

B. Aparicio-Ruiz[1], S. Pérez-Albalá[1], N. Basile[2], L. Romany[1], P. Gámiz[1], M. Meseguer[1]
[1]*Instituto Valenciano de Infertilidad (IVI), In vitro fertilization Laboratory, Valencia, Spain*
[2]*Instituto Valenciano de Infertilidad (IVI), In vitro fertilization Laboratory, Madrid, Spain*

Study question: Is there a correlation between the three EEVA (early embryo viability assessment) predictive categories: High, Medium, Low and implantation rates?
Summary answer: Yes, the three EEVA predictive categories are correlated with implantation rates
What is known already: A preliminary analysis of a published morphokinetic algorithm (Wong2010) was designed for blastocyst prediction. The algorithm was used for embryo selection by an automated time-lapse technology based on the combination of two parameters:P2 = t3-t2 (time to 3 cell-time to 2 cell) and P3 = t4-t3 (time to 4 cell-time to 3 cell) to predict blastocyst formation rate. The algorithm classifies embryos as having High, Medium or Low probabilities of becoming a blastocyst. Our objective is to correlate these categories with implantation.
Study design, size, duration: Retrospective, cohort study. This study includes 2198 embryos from our oocyte donation program undergoing ICSI from October 2013 to November 2014 of which 774 were transferred.
Participants/materials, setting, methods: University-affiliated infertility clinic. Patients were cultured in a standard incubator using a non-invasive test that combines time-lapse image analysis with an automatic cell-tracking software, EEVA (Early Embryo Viability Assessment).
Main results and the role of chance: We observed a direct relationship between morphokinetic categories and implantation potential. Results were only referred to those embryos with known implantation ($n = 518$) (number of gestational sacs matched with number of embryos transferred).

When categorizing according to EEVA: 146(28%) embryos were labelled as High, 123 (24%) were labelled as Medium and 155 (30%) as Low. The rest of embryos ($n = 94$ (18%)) were not suitable for grading by the software. Implantation rates of all embryos despite day of transfer were HIGH 50% (CI 95% 41.79–58.21); MEDIUM 39.84% (CI 95% 31.06–48.61) and LOW 33.55% (CI 95% 26.03–41.06), being statistically significant ($p = 0.036$).

A further analysis depending on the day of embryo transfer was performed: **Transfer Day3** implantation rates were: HIGH 45.13% ($n = 113$); MEDIUM 32.95% ($n = 88$) and LOW 27.50% ($n = 120$) ($p = 0.040$). **Transfer Day5** implantation rates were: HIGH 67.74% ($n = 31$); MEDIUM 57.14% ($n = 28$) and LOW 53.13% ($n = 32$).
Limitations, reason for caution: The retrospective nature of this study may be a reason for caution; however it is representing a consistent amount of embryos analysed by EEVA test and the starting point of future prospective studies to demonstrate the clinical usefulness of this test in our clinic.
Wider implications of the findings: Our study has demonstrated that embryo selection in the automated time-lapse supported by the use of a two variable morphokinetic model is related with reproductive outcome. The observed relationship with the implantation potential reflects a direct link between the parameters provided by the automatic system and embryo quality. A larger sample size will be mandatory to demonstrate a significant relationship and prospective randomized studies to exhibit the potential improvement that this clinical tool may offer.
Study funding/competing interest(s): Funding by hospital/clinic(s) – none.
Trial registration number: NA.
Keywords: Morphokinetic parameters, time-lapse, embryo, implantation

P-174 Analysis of clinical outcome achieved with 126 poor quality blastocysts obtained on day-7 of culture in 944 Preimplantation Genetic Screening cycles

A. Ruberti[1], A. Biricik[2], E. Greco[1], E. Cursio[1], A. M. Lobascio[1], A. Nuccitelli[2], A. Colasante[1], R. P. Cotarelo[1], A. Caragia[1], K. Litwicka[1], M. G. Minasi[1], F. Fiorentino[2]
[1]*Reproductive Medicine, European Hospital, Rome, Italy*
[2]*Molecular Genetics Laboratory, Genoma Group, Rome, Italy*

Study question: The aim of this study was to evaluate the development and implantation potential of poor quality blastocysts obtained on day-7 of culture in Preimplantation Genetic Screening (PGS) cycles performed with trophoectoderm biopsy and array comparative genomic hybridization (aCGH).
Summary answer: The blastocysts obtained on day-7 are often discarded, due to their poor morphological quality. Our study demonstrates that these blastocycts have the same probability of being euploid, as those showing morphologically higher quality and they lead to a good implantation rate; therefore they should be considered for cryopreservation and transfer.
What is known already: Historically, the more widespread employed selection strategy to identify embryos with higher implantation potential, has been based on morphological criteria. However, several studies highlighted a weak correlation between this conventional method of embryo evaluation and their ploidy status. Recently, other embryo selection strategies, both invasive and non-invasive, are under evaluation. To date, the most efficient way to identify euploid blastocysts seems to be the trophectorderm biobsy followed by the genetic test.
Study design, size, duration: From January 2012 to December 2014, 944 PGS cycles with trophoectoderm biopsy and aCGH were performed. The development of 126 poor quality blastocysts, obtained on day-7 of culture, was analyzed. Mean female age was 37.2 ± 4.46 years old.
Participants/materials, setting, methods: Blastocysts were biopsied on day-5, day-6 or day-7 and immediately vitrified, waiting for the genetic results. Sometimes, the blastocysts obtained on day-5 were transferred on day-6 of the fresh cycle. The euploid balstocysts formed on day-6 or day-7 were transferred after thawing in a subsequent natural cycle.
Main results and the role of chance: A total of 7384 oocytes were injected and 5820 (78.8%) of them fertilized; 5742 (98.7%) embryos formed on day-3 and other 210 embryos, previously frozen without genetic analysis, were thawed and cultured until the blastocyst stage, in order to perform a trophectoderm biopsy. A total of 3076 (56.2%) blastocysts were obtained (1914 on day-5, 1036 on day-6 and 126 on day-7); 2983 of them were biopsied (1871 on day-5, 996 on day-6 and 116 on day-7). After the genetic analysis, 977 blastocysts (32.8%) resulted euploid. Of the 116 blastocysts analyzed on day-7, 32 (27.6%) were euploid even if 53.1% ($N = 17$) of them showed a poor morphological grade. Seventeen day-7 blastocysts were transferred and 8 (47.1%) of them implanted.
Limitations, reason for caution: More data, including take home baby rate and perinatal outcomes on babies born, are necessary. There is still a considerable disagreement if morphological evaluation of the embryos can be representative of their ploidy status.

Wider implications of the findings: The findings of this study show that also the poor quality and slower blastocysts, that would have been discarded before reaching the full blastocyst stage, can be euploid and implant, improving cumulative pregnancy rate. Even if blastocyst morphology, developmental rate and ploidy status seem to show a weak association, there is still a lack of knowledge regarding their viability and PGS remain the safer technique to minimize the risk of transferring chromosomally abnormal embryos.
Study funding/competing interest(s): Funding by hospital/clinic(s) – No specific funding was obtained for this study. None of the authors have any competing interests to declare.
Trial registration number: NA.

P-175 Effect of embryo culture media on percentage of males at birth

J. Zhu[1], X. Zhuang[1], P. Liu[1]
[1]*Peking University Third Hospital, Obstetrics and Gynecology, Beijing, China*

Study question: Does culture medium influence the percentage of males at birth?
Summary answer: G5™, Global, G5™ PLUS, and Quinn's Advantage Media are associated with different percentages of males at birth within the ICSI cycle group; the percentage of males of G5™ is significantly higher than Global, G5™ PLUS, and Quinn's Advantage Media.
What is known already: Male and female embryos have different physiologies during pre-implantation development. Manipulating the energy substrate and adding growth factors have a differential impact on the development of male and female embryos.
Study design, size, duration: This was a retrospective analysis of the percentage of males at birth, and included 4,411 singletons born from fresh embryo transfer cycles between January 2011 and August 2013.
Participants/materials, setting, methods: Only singleton gestations were included. Participants were excluded if pre-implantation genetic diagnosis, donor oocytes, and donor sperm were used. The database between January 2011 and August 2013 was searched with unique medical record number, all patients were present in the database with only one cycle. Demographics, cycle characteristics, and the percentage of males in the four culture media groups were compared with analysis of variance or c^2 tests. Multivariable logistic regression was performed to determine the association between the sex at birth and culture media after adjusting for other confounding factors, including parental age, parental BMI, type of infertility, parity, number of embryos transferred, number of early gestational sacs, cycles with testicular sperm aspiration (TESA)/percutaneous epididymal sperm aspiration (PESA)/testicular sperm extraction (TESE), number of oocytes retrieved, cycles with blastocyst transfers, and gestational age within ICSI group.
Main results and the role of chance: Within the IVF group, the percentage of males at birth for G5™, Global, Quinn's, and G5™ PLUS media were comparable ($p > 0.05$); however, within the ICSI group, there was a lower percentage of males in the Global (47.16 vs. 56.05%; $p = 0.003$), G5™ PLUS (47.69 vs. 56.05%; $p = 0.005$), and Quinn's media (44.97 vs. 56.05%; $p = 0.009$) compared with the G5™ media. The percentage of males at birth in the Global, G5™ PLUS, and Quinn's media were comparable ($p > 0.05$). Multivariable logistic regression indicated that culture media (G5™ vs. Global, G5™ PLUS, and Quinn's) were significantly associated with the sex at birth ($p = 0.008$) after adjusting for parental age, parental BMI, type of infertility, parity, number of embryos transferred, number of early gestational sacs, cycles with TESA/PESA/TESE, number of oocytes retrieved, cycles with blastocyst transfers, and gestational age.
Limitations, reason for caution: This study was not a RCT and that allocation of treatment cycles over the four media was not completely at random. Cigarette smoking was not included in the current study because this confounding factor was not registered in our database. Moreover, intra-variability of sperm selection between the five embryologists may directly affect the percentage of males;
Wider implications of the findings: Our study suggests that human embryogenesis responds differently to G5™, Global, G5™ PLUS, and Quinn's Advantage Medium. This finding can be generalized to other commercial culture media.
Study funding/competing interest(s): Funding by national/international organization(s) – National Natural Science Foundation of China.
Trial registration number: NA.

P-176 Comparison of dynamic culture and dynamic culture with specialized surfaces culture method in poor responders

Y. S. Hur[1], E. K. Ryu[1], S. J. Park[1], S. H. Yoon[2], C. Y. Hur[1], W. D. Lee[3], J. H. Lim[3]
[1]*Maria Fertility Hospital, 2nd Research Center, Seoul, South Korea*
[2]*Maria Fertility Hospital, Maria Research Center, Seoul, South Korea*
[3]*Maria Fertility Hospital, 1st Research Center, Seoul, South Korea*

Study question: In poor responders, conventional static culture (SC) method was used as a control group. We compared dynamic culture (DC) group that using micro-vibrator and dynamic culture with co-culture (DCC) group that using cumulus cell as a specialized surfaces. Embryonic development rates and pregnancy rates were compared among the groups.
Summary answer: The total pregnancy rates were significantly increased when the DC was applied to the embryonic culture in poor responders. There were no differences in the total pregnancy rates between DC group and DCC group. The blastocyst development rates were improved when DCC was applied to surplus embryos in poor responders.
What is known already: Advanced culture platforms that are classified as new static culture platforms, dynamic culture platforms, specialized surfaces have been developed in the current ART fields. The beneficial effects of micro-vibration have been reported already in human IVF. Furthermore, new trends have been attempted to try combining each culture platforms. We are looking forward to find out the effects of combination of dynamic culture and specialized surfaces.
Study design, size, duration: We conducted a review between January 2011 and November 2014. Cycles of conventional SC group, DC group and DCC group were 857, 804 and 484 cycles respectively. Number of surplus embryos of SC group, DC group and DCC group were 592, 623, and 373 respectively.
Participants/materials, setting, methods: The zygotes were cultured in a 50? Micro-droplet for 48 h, and the embryos were subsequently selected for transfer. Some surplus embryos were cultured for blastocyst development. A micro-vibrator was set at a frequency of 42 Hz, 5 s/30 min duration for embryo development. Autologous cumulus cell was used for co-culture.
Main results and the role of chance: There were no differences in the average age, number of oocytes, fertilization rate, zygote number, embryo transfer number among the groups. The total pregnancy rates were significantly higher in the DC group (175/804 = 21.8%) and DCC group (105/484 = 21.7%) than in the SC group (142/857 = 16.6%). There were no differences in the total pregnancy rates between DC group and DCC group. And, there were no differences in the blastocyst development rates between the SC group (158/592 = 26.7%) and the DC group (189/623 = 30.3%). However, the blastocyst development rate in the DCC group (141/373 = 37.8%) was higher than in the SC group and DC group.
Limitations, reason for caution: Poor responders exhibit advanced age, previous ovarian surgery or pelvic adhesions, all of which can contribute to a reduced oocytes and embryo quality in comparison with normal responders. Induction protocols for various poor responders are routinely utilized to maximize the numbers of eggs in this hospital.
Wider implications of the findings: The embryonic development rate was improved in DC method in poor responders. Especially, the blastocyst development rates were significantly increased when DCC was applied to surplus embryos in poor responders. And, the cumulative pregnancy rate in the DCC group is expected to be higher than in the SC group and the DC group because of significantly higher blastocyst development rates. Further investigations are necessary to determine the effects of combination of the culture platforms.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Maria Fertility Hospital.

P-177 Pregnancy outcome of frozen warmed blastocysts developed from multinucleated cleavage stage embryos

L. Arizzi[1], A. Kopakaki[2], L. Kelly[2], L. Pastorelli[2], R. Sciorio[2], K. J. Thong[2], S. Pickering[2]
[1]*Newcastle Fertility Centre, Biomedicine, Newcastle Upon Tyne, United Kingdom*
[2]*Royal Infirmary of Edinburgh, EFREC – ACU, Edinburgh, United Kingdom*

Study question: This study aimed to ascertain whether frozen-warmed blastocysts arising from embryos identified as having one or more multinucleate

blastomeres (MNB) during development, were capable of giving rise to a clinical pregnancy and live birth following frozen transfer.
Summary answer: Good quality blastocysts which had developed from embryos with MNB at cleavage stages, had a high rate of survival following vitrification and warming and also gave rise to a high proportion of clinical pregnancies as well as live births following frozen embryo transfer.
What is known already: Embryos with MNB are frequently observed during preimplantation development. Such embryos have previously been associated with a low pregnancy and implantation rate, compromised embryo development and potential increased chromosomal abnormalities during *in vitro* studies. MNB embryos are therefore often regarded as abnormal and excluded from clinical use. However, some retain the capability of developing into good quality blastocysts and occasionally give rise to a live birth, following transfer in a fresh cycle.
Study design, size, duration: Retrospective study carried out over a four year period. All embryos which developed into good quality blastocysts were vitrified and stored. In subsequent frozen embryo transfer cycles pregnancy and implantation rate was compared for blastocysts in which MNB had been identified and a control group with no evidence of MNB.
Participants/materials, setting, methods: All embryos which were not replaced or frozen on day 3 were cultured to the blastocyst stage of development using Vitrolife sequential medium in a low oxygen atmosphere. Good quality blastocysts were frozen using a vitrification protocol (Irvine). Blastocysts were warmed and replaced in a frozen embryo transfer cycle.
Main results and the role of chance: 141 blastocysts arising from MNB embryos were vitrified and stored. So far, 17 MNB blastocysts have been thawed. Fifteen have been replaced in a single embryo transfer (SET) resulting in an implantation rate (IPR) of 73% (11/15 foetal sacs) and a clinical pregnancy rate (CPR) of 53% (8/15 foetal hearts). Five gave rise to a healthy live birth with 3 pregnancies ongoing. This compares with a control group of 127 thawed and transferred non-MNB blastocysts, with IPR and CPR of 49% (62/127) and 39% (50/127) respectively following SET. In addition, in two separate double embryo transfers, an MNB blastocyst was transferred with an accompanying non-MNB blastocyst, resulting in two twin clinical pregnancies and two live births of healthy dizygotic twins in each case.
Limitations, reason for caution: Under normal circumstances, blastocysts arising from embryos without MNB are used first for fresh and frozen embryo transfer procedures. Therefore, due to practical constraints, the number of embryos in the MNB study group is limited and a larger cohort study is required to obtain robust long term outcome data.
Wider implications of the findings: Although the number of transfers in the study group is small, the data presented provides evidence that embryos with multinucleated blastomeres, which then develop into good quality blastocysts, are capable of implanting at a rate comparable with the control group and can give rise to a normal live birth. This suggests that such embryos should be assessed in relation to their developmental capacity rather than their cleavage stage morphology and should not be routinely discarded.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Funding by Edinburgh Reproductive Endocrine Centre.

P-178 Effect of storage duration of cryopreserved blastocysts on pregnancy and neonatal outcome: a retrospective single-center cohort study of 6,117 blastocysts vitrified by open vitrification system

S. Ueno[1], K. Uchiyama[1], T. Okimura[1], A. Yabuuchi[1], T. Okuno[1], T. Kobayashi[1], K. Kato[1]
[1]Kato Ladies Clinic, Tokyo, Japan

Study question: Does the storage duration of blastocysts vitrified by open vitirification system influence the pregnancy and neonatal outcomes?
Summary answer: The storage duration of blastocysts vitrified by open vitirification system caused no negative influence on pregnancy and neonatal outcomes.
What is known already: It has been known that storage duration of embryos cryopreserved by slow freezing and closed vitrification system had no negative impact on survival, implantation and live birth rates, neonatal outcomes and congenital malformations in babies born. However, a large cohort study on the effect of storage duration in the case of embryos vitrified by open vitrification system has not been evaluated.
Study design, size, duration: A retrospective cohort study of 6,117 autologous single vitrified-warmed blastocyst transfer (SVBT) cycles was conducted in single center from 2007 to 2012. This cohort fulfilled the following criteria: egg retrieval age 35–39 years, SVBT of day 5 blastocyst and follow-up data on pregnancy and neonatal outcome was available.
Participants/materials, setting, methods: The oocytes were retrieved by minimum stimulation or natural cycles. Blastocysts were vitrified by cryotop methods. Main outcome measures were clinical pregnancy (CPR: confirmation of gestational sac) and live birth rate (LBR) per SVBT. Secondary outcome was neonatal outcome including congenital malformation rate and gestational age.
Main results and the role of chance: Of 6,117 SVBT cycles, cryo-storage duration was classified into four groups: A: 0–3 months ($n = 4761$), B: 4–12 months ($n = 683$), C: 1–3 years ($n = 596$), and D: 4–8 years ($n = 77$). The survival rates after warming were comparable among groups. No significant differences was observed in CPR and LBR (CPR: A: 57.2%, B: 54.1%, C: 52.9% and D: 53.9% and LBR: A: 44.2%, B: 41.4%, C: 41.5% and D: 48.7%). Birth weight, gestational age and congenital malformation rates were similar in all groups.
Limitations, reason for caution: This study was limited by SVBT in minimal stimulation and natural cycle IVF. This cohort included multiparous patients (A: 14.3%, B: 18.0, C: 77.8%, D: 97.4%) and the patients who received multiple cycles. The long-term follow-up studies would be necessary.
Wider implications of the findings: Our results showed blastocyst cryo-storage duration didn't influence pregnancy and neonatal outcomes even in the case of open vitrification system. Therefore, the open vitrification system is usefully applicable as a cryopreservation devices for infertile couple in ART and long-term storage is also possible with no negative impact on IVF outcomes.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Kato Ladies Clinic.
Trial registration number: NA.

P-179 Retrospective validation of EEVA (Early Embryo Viability Assessment) at large scale. Correlation between eeva categories and blastocyst formation rate

N. Basile[1], I. Cabañes[1], M. Caiazzo[1], B. Aparicio-Ruiz[2], S. Perez-Albana[2], M. Meseguer[2]
[1]IVI Madrid, IVF Laboratory, Madrid, Spain
[2]IVI Valencia, IVF Laboratory, Valencia, Spain

Study question: Is there a correlation between the three EEVA predictive categories: High, Medium, Low and the blastocyst formation/quality rate?
Summary answer: Yes, the three EEVA predictive categories are correlated with the formation of blastocysts and with the formation of good quality blastocysts.
What is known already: The EEVA test utilizes an algorithm based on early kinetic markers defined as P2 = t3-t2 (time to 3 cell – time to 2 cell) and P3 = t4-t3 (time to 4 cell – time to 3 cell). Taking in consideration these variables, the model classifies embryos as High, Medium or Low according to their probability of becoming a blastocyst. A few groups have tested this algorithm; however a large scale validation is necessary.
Study design, size, duration: Retrospective study of 432 patients and 2198 embryos analysed between February and November of 2014.
Participants/materials, setting, methods: University-affiliated infertility clinic. Patients were cultured in a standard incubator using a non-invasive test that combines time-lapse image analysis with cell-tracking software, EEVA (Early Embryo Viability Assessment).
Main results and the role of chance: A total of 432 patients generated 2198 embryos. Out of those, 59.5% (1307/2198) developed to the blastocyst stage; however when categorizing by EEVA, the blastocyst formation rate for the three categories was: High = 80.4% (201/250); Medium = 61.1% (323/529) and Low = 52.0% (509/961); $p < 0.0001$. The rest of the embryos ($n = 458$) were not suitable for grading by the software. In addition, development to 'good quality' blastocysts (defined by inner cell mass and trophectoderm morphology) was also analysed with decreasing percentages as we moved on between categories. More specifically: High = 44.7% (90/201); Medium = 37.4% (121/323) and

Low = 32.6 % (166/509), $p = 0.014$. These results validate the ability of this objective and automated tool for blastocyst prediction and embryo selection.
Limitations, reason for caution: The retrospective nature of this study may be a reason for caution; however it represents a consistent amount of embryos being analysed by the EEVA test and the starting point of future prospective studies to demonstrate the clinical usefulness of this test in our clinic. This study is underway.
Wider implications of the findings: Blastocyst transfer has proven to improve implantation rates. This strategy may not apply when few or poor embryos are present on day 3. An automatic cell tracking system with early prediction of blastocyst formation represents an attractive alternative in these situations. The EEVA test improves embryo selection while minimizing handling and monitoring by the embryologist. To the best of our knowledge this is the largest independent data set used to retrospectively validate the EEVA test.
Study funding/competing interest(s): Funding by hospital/clinic(s) – IVI.
Trial registration number: NA.

P-180 Contamination risks in human oocyte and embryos cryopreservation: open vs closed vitrifying systems

M. Mari[1], I. Molina[1], J. Martinez[1], J. Peman[2], A. Pellicer[1], E. Novella-Maestre[3], A. Pellicer[1]
[1]*Hospital La Fe, Unidad de Reproducción, Valencia, Spain*
[2]*Hospital La Fe, Microbiologia, Valencia, Spain*
[3]*Hospital La Fe, Unidad de Genetica, Valencia, Spain*

Study question: To study the risk of contamination in open (cryotop) and closed (cryotip) vitrifying devices for oocyte and embryo cryopreservation by evaluating the presence of contaminants (bacteria and fungi) in the same medium in which they were thawed and evaluate the sterility conditions of NL2 in oocytes and embryos banks.
Summary answer: No contaminants were found in the oocytes thawing media (open device) or in embryos (closed device). No fungi were found in NL2. However, saprophytic and pathogenic bacteria were found in all NL2 containers of the oocytes and embryos bank. Periodic chemically sterilization in NL2 containers is recommended.
What is known already: The risk of disease transmission in humans during assisted reproductive technology (ART) procedures has been described. Most micro-organisms can survive storage at LN2 temperatures. The cryoprotectants used in embryo and oocyte cryopreservation also protect bacteria and viruses. During assisted reproductive procedures, cryostorage is the only situation where large quantities of biological materials of patients are kept together in a common liquid medium. Although the temperature of liquid nitrogen is -196ºC, it may transmit infective agents from one sample to the other if they are not sealed properly.
Study design, size, duration: Retrospective study of vitrifying device safety and NL2 sterility performed from January to November 2014. Every month, a sample of open and one of closed device was evaluated. The NL2 supplied by the company, that of the storage container and also the NL2 of the containers of the oocyte-embryo bank were also evaluated.
Participants/materials, setting, methods: From each of the eight bank containers, 96 thawing media of oocytes vitrified in cryotop and 96 of embryos vitrified in cryotip were evaluated for the presence of contaminants (bacteria and fungi). Both types of devices were stored in the lower canister position. The NL2 was analyzed 3 times a year. Vitek2 automated system (BioMerieux) and the corresponding susceptibility to antibiotics were used for the bacteria identification. Fungus detection was performed by evaluating the colonies morphology developed and their microscopic characteristics.
Main results and the role of chance: No bacteria or fungi were observed in any of the devitrifying media regardless of the type of device used (open or closed), nor in the NL2 supplied by the company. No fungi were observed in any of the NL2 samples tested. However, saprophytic bacteria such as: *Stenotrophomonas maltophilia, Enterobacter* spp; *Bacillus* spp were found in all NL2 containers of the oocyte-embryo bank. Mostly environmental bacteria were identified in all samples of LN2. However, in the containers bottom some agents such as: *Alcaligenes faecalis ssp faecalis-Sphingomonas paucimobilis*, *Sphingomonas paucimobilis*, *Acinetobacter baumannii* and *Chrysenomonas luteola* were isolated. *Sphingomonas paucimobilis* was resistant to 6 antimicrobial compounds and are capable of causing nosocomial infections in humans. Cryopreservation devices cryotop and cryotip were safe for oocyte and embryo banking.
Limitations, reason for caution: The fact that micro-organisms survive in LN2 is important for the potential of disease transmission to recipients by embryo transfer and for testing of samples for health certification of embryos for international movement.
Wider implications of the findings: Storage containers should be emptied and cleaned periodically due to the risk of lost straws or small particles of contaminated material that falls to the bottom of a large container. The air in the room could be also the cause of bacterial contaminations. The operators can lead to contamination by contact or peeling during processing of samples or the handling of cryogenic tanks. Periodic chemically sterilization in NL2 containers is recommended for oocyte and embryo banking.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Hospital Universitario y Politécnico La Fe, Valencia, Spain.
Trial registration number: NA.
Keywords: oocyte and embryos vitrification, open vs closed vitrifying systems, NL2 contamination risk

P-181 Distribution of mitochondria in fresh and frozen-thawed/devitrified human oocytes at different stages of maturation

M. Stimpfel[1], E. Bokal-Vrtacnik[1], B. Pozlep[1], I. Virant-Klun[1]
[1]*University Medical Centre Ljubljana, Department of Obstetrics and Gynaecology, Ljubljana, Slovenia*

Study question: The aim of this study was to elucidate what is the distribution of mitochondria in human mature MII (unfertilized) oocytes and immature germinal vesicle (GV) oocytes and if the cryopreservation procedure (vitrification or slow freezing) affects it.
Summary answer: In GV oocytes the pattern of mitochondrial distribution was appearing as aggregated clusters and was similar in all cells, while in MII oocytes differed and varied from aggregated clusters to smooth pattern. There was no difference in distribution of mitochondria between fresh, devitrified and frozen-thawed oocytes.
What is known already: The proper function and distribution of mitochondria in the oocyte is essential for subsequent embryo development since the early embryo is dependent only on mitochondria stored in the mature oocyte and zygote. From the literature is it known that in GV oocytes mitochondria are distributed in homogeneous clusters around the oocyte, while in MII oocytes mitochondria are more concentrated around the polar body and appear as clusters in the perinuclear ring.
Study design, size, duration: Altogether 127 oocytes were included into our study: 29 fresh oocytes (22 MII and 7 GV oocytes), 37 oocytes after vitrification/devitrification (24 MII and 13 GV), and 61 oocytes after freeze-thawing (43 MII and 18 GV oocytes) to evaluate the mitochondrial distribution and differences between the groups.
Participants/materials, setting, methods: The fresh, devitrified or frozen-thawed oocytes were stained by Mitotracker to analyze the mitochondrial distribution and by Hoechst 33258 to identify the position of genetic material and then observed under the fluorescent microscope.
Main results and the role of chance: In GV oocytes the pattern of mitochondrial distribution appeared as aggregated clusters around the oocyte and it was similar in all cells, irrespective to fresh, frozen-thawed and devitrified oocytes. Otherwise, 3 different patterns of mitochondrial distribution were observed in MII oocytes: (1) smooth pattern around the polar body with aggregated clusters in the perinuclear ring (54.5% of fresh oocytes, 54.5% of devitrified oocytes and 52.9% of frozen-thawed oocytes), (2) smooth pattern throughout the whole cell (36.4% of fresh oocytes, 27.3% of devitrified oocytes and 32.4% of frozen-thawed oocytes) and (3) aggregated clusters as in GV oocytes (9.1% of fresh oocytes, 18.2% of devitrified oocytes and 14.7% of frozen-thawed oocytes). There was no significant differences in these patterns between fresh, devitrified and frozen-thawed oocytes.
Limitations, reason for caution: It would be necessary to analyze a higher number of oocytes to be more relevant in a conclusion about no significant differences in the mitochondrial distribution between fresh, devitrified and frozen-thawed oocytes.
Wider implications of the findings: The data from literature show that mitochondria in MII oocytes are more concentrated around the polar body (smooth pattern) and appear as clusters in the perinuclear ring. Our results suggest two

additional patterns of mitochondrial distribution in MII oocytes. These two patterns might appear because the oocytes were not normal and for this reason did not fertilize. Maybe this staining could explain why the oocytes did not fertilize.
Study funding/competing interest(s): Funding by hospital/clinic(s) – No funding sources and no competing interest to declare.
Trial registration number: NA.
Keywords: oocytes, mitocondrial distribution, cryopreservation, vitrification

P-182 A new strategy to diagnose embryo viability combining protearray and time-lapse technologies

M. Meseguer[1], F. Dominguez[2], A. Tejera[1], A. Quiñonero[3], B. Aparicio-Ruiz[1], C. Simon[4]
[1]IVI Valencia, IVF Laboratory, Valencia, Spain
[2]Fundación IVI-INCLIVA, Miguel Servet Principal Investigator, Valencia, Spain
[3]Fundación IVI-INCLIVA, Miguel Servet Lab Technician, Valencia, Spain
[4]IVI Valencia, Reproductive Medicine, Valencia, Spain

Study question: Can we develop an embryo viability diagnostic tool using a combination of biochemical fingerprint and a time-lapse morphokinetic analysis?
Summary answer: Our results suggest for the first time the utility of a combined biochemical/morphokinetic diagnostic tool to select embryos for transfer according to their implantation potential.
What is known already: Time-lapse technology and morphokinetics has been validated as a clinical tool to improve embryo selection (Rubio et al 2014). Biochemical fingerprinting by proteomics is currently available for embryo spent culture media analysis and experimental data suggest its potential as method to study embryo viability (Dominguez et al. 2014). Both technologies has not been combined yet.
Study design, size, duration: Retrospective cohort study on 21 recipients during 2014 undergoing ICSI with donor oocytes and embryo transfer on blastocyst stage. We selected 28 transferred embryos for a detailed analysis of spent culture media and morphokinetic parameters, 16 implanted embryos after single embryo transfer and 12 non-implanted.
Participants/materials, setting, methods: We analyzed six proteins in the embryo spent media: SCF, TNFR1, IFNa2, IL-6, CXCL11, GM-CSF by Luminex technology and combined with exact timings (hours) of [cell cycle duration (cc2), blastomere synchrony (s2) and exact timing of 5 blastomere cleavage (t5)] analyzed by a time-lapse incubator.
Main results and the role of chance: Logistic regression analysis by forward step likelihood selection method revealed that the presence/absence of IL-6 and the duration of the second cell cycle (cc2) were the most relevant embryo features to be used for embryo selection. We combined these two parameters to obtain a hierarchical model, this establish four categories (A/B/C/D) based on the presence of IL-6 and cc2 range between 5 and 12 h. A direct relationship was observed between morphology categories and implantation rates, those with IL-6 presence and cc2 (5-12) implanted significantly more ($p = 0.036$). Table. Results were only referred to those embryos with known implantation (KID embryos).
Limitations, reason for caution: The retrospective nature of this study may be a reason for caution. Clinical validation is mandatory to confirm the effectiveness of this study.
Wider implications of the findings: Blastocyst transfer has proven to improve implantation rates. This strategy may be applied in combination with time-lapse and proteome analysis to improve embryo selection while minimizing handling and monitoring by the embryologist. To the best of our knowledge this is the first evidence provided of the clinical combination of both technologies.
Study funding/competing interest(s): Funding by hospital/clinic(s) – IVI Valencia.

P-183 Value of transferring embryos formed by non-pronuclear oocytes at the time of fertilization assessment

M. Li[1], P. Liu[1], J. Qiao[1]
[1]Peking University Third Hospital, Reproductive Medical Center, Beijing, China

Study question: Is there value in transferring embryos formed by non-pronuclear (0PN) oocytes at the time of the fertilization assessment?
Summary answer: There is value in transferring 0PN embryos when there is a lack of normal 2PN embryos for transfer in fresh cycles. Supernumerary 0PN embryos after transfer in fresh cycles are worth freezing for a subsequent frozen-thawed embryo transfer cycle.
What is known already: There are few reports which describe the transfer of embryos formed by 0PN oocytes; the available data are limited and a systematic study is lacking.
Study design, size, duration: The current study was a retrospective analysis of 0PN embryo transfers in fresh and frozen-thawed cycles. In fresh cycles, transfer of cleavage-stage 0PN embryos occurred in 159 cycles (research group [FC-G]). To determine whether or not the outcomes of transfer in FC-G was related to the origin of the embryos from 0PN oocytes, a matched group (FM-G [159 cycles]) were set in the study. In frozen-thawed cycles, 39 cleavage-stage and 82 blastocyst-stage 0PN embryo transfers were chosen as the research groups (cleavage-stage embryos [TC-G]; blastocyst-stage embryos [TB-G]). To study the effect of 0PN transfer In frozen-thawed cycles, 39 cleavage-stage (cTC-G) and 82 blastocyst-stage transfers (cTB-G) were set for comparison groups. These transfer cycles were performed during the same period at the Reproductive Medical Center of Peking University Third Hospital.
Participants/materials, setting, methods: In the fresh cycles, the recruitment criteria for FM-G were as follows: 1. matched the female ages, number of oocytes retrieved, and fertilization technologies (IVF or ICSI) one-to-one with FC-G; and 2. Transfer of only 2PN cleavage-stage embryos. In frozen-thawed cycles, the recruitment criteria for cTC-G and cTB-G were as follows: 1. matching the female ages and fertilization technologies (IVF or ICSI) one-to-one with TC-G and TB-G, separately. 2. Transfer of only 2PN (cleavage-stage in cTC-G and blastocyst-stage in cTB-G) embryos was performed during the same period for the TC-G and TB-G.
Main results and the role of chance: In fresh cycles, the characteristics of patients in the FC-G were comparable with the patients in the FM-G. Implantation rate (IR) in the FC-G was lower than the FM-G (8.04% [16/198] vs. 19.50% [55/282]; $P = 0.000$). In frozen-thawed cycles, the IR in the TC-G was lower than the cTC-G (15.38% [12/78] vs. 28.24% [25/85]; $P < 0.05$), and the IR in the TB-G was comparable to the cTB-G (39.56% [36/91] vs. 48.18% [53/110]; $P > 0.05$). The low IR of 0PN embryos was related to embryos originating from 0PN oocytes. Blastocyst cultures can be a way to select better the normal 0PN embryos for transfer and achieved a satisfactory IR.
Limitations, reason for caution: Further study is warranted regarding time-lapse technology of 0PN oocytes. The security of 0PN transfer remains to be confirmed in a large patient sample with long-term follow-up.
Wider implications of the findings: There is a value to transferring 0PN embryos in fresh or frozen-thawed cycles that result in pregnancy and live births. The transfer of 0PN embryos is safe based on the current results, and blastocyst cultures give rise to normal 0PN embryos for transfer and a satisfactory outcome.
Study funding/competing interest(s): Funding by national/international organization(s) – This study was funded by the National Natural Science Foundation of China for Young Scholars (grant nos. 81200437 and 81300483). The authors have no conflicts of interest to declare.
Trial registration number: The study was approved by the Ethics Committee of Peking University Third Hospital (reference no. 20080612) and all patients signed written informed consent.
Keywords: 0PN, embryo transfer, implantation rate

P-184 Blastomere nuclearity: the influence of blastomeres with no apparent nuclei on blastocyst formation and quality

A. S. Setti[1], D. P. A. F. Braga[1], R. C. S. Figueira[2], A. Iaconelli[3], R. S. Rodrigues[4], E. Borges Jr. [3]
[1]Fertility – Centro de Fertilização Assistida and Instituto Sapientiae – Centro de Estudos e Pesquisa em Reprodução Assistida, Scientific department, Sao Paulo, SP, Brazil
[2]Fertility – Centro de Fertilização Assistida, IVF laboratory, Sao Paulo, SP, Brazil
[3]Fertility – Centro de Fertilização Assistida and Instituto Sapientiae – Centro de Estudos e Pesquisa em Reprodução Assistida, Clinical department, Sao Paulo, SP, Brazil
[4]Fertility – Centro de Fertilização Assistida, Clinical department, Sao Paulo, SP, Brazil

Study question: Are embryos presenting at least one blastomere with no apparent nucleus on the second or third day of development more likely to fail to develop into blastocysts?
Summary answer: The presence of at least one blastomere with no apparent nucleus on day 2 or day 3 reduces blastocyst formation in 22 and 24% respectively. The presence of at least one blastomere with no apparent nucleus on day 2 or day 3 reduces blastocyst hatching in 27 and 32% respectively.
What is known already: Embryos are generally selected for transfer based on their morphological appearance. In day 2 and day 3 transfers, embryos are scored according to parameters such as number of blastomeres, blastomere symmetry and fragmentation rate. Additionally, the detection of multinucleation in blastomeres is an important criterion in embryo selection. Multinucleated embryos are related to increased aneuploidy rate and lower blastocyst formation, implantation and live birth rates. However, information regarding blastomeres with no apparent nuclei is scarce.
Study design, size, duration: A total of 17,340 zygotes obtained from 2,835 intracytoplasmic sperm injection (ICSI) cycles, performed in unselected patients attending a private assisted fertilization center between January 2010 and December 2013, were prospectively analyzed.
Participants/materials, setting, methods: Embryos were morphologically evaluated on days 2, 3 and 5 of development. The presence of blastomeres with no apparent nuclei on day 2 and 3 was recorded and then associated with blastocyst formation, quality and hatching status using logistic regression.
Main results and the role of chance: A total of 1985 embryos on day 2 and 2249 embryos on day 3 showed at least one blastomere with no apparent nucleus (11.4 and 14.0%, respectively). The presence of at least one blastomere with no apparent nucleus on day 2 or day 3 of development were determinant to the decreased odds of blastocyst formation (OR: 0.76, CI: 0.69–0.84 and OR: 0.78, CI: 0.69–0.87, respectively). The presence of blastomere with no apparent nucleus did not influence trophectoderm and inner cell mass quality. The presence of at least one blastomere with no apparent nucleus on day 2 or day 3 of development were determinant to the decreased odds of blastocyst hatching (OR: 0.73, CI: 0.59–0.89 and OR: 0.68, CI: 0.54–0.86, respectively).
Limitations, reason for caution: Since nuclear formation is a dynamic process, it may be mistaken to evaluate the nuclear status relying on observations performed within a short time interval. Nevertheless, the evaluation of nuclear status using simple light microscopy has proven to be predictive of embryo developmental capacity.
Wider implications of the findings: One of the most important steps in assisted reproduction is embryo selection for transfer. Although the combination of embryo developmental rate and morphology is noninvasive and easy to perform, the usefulness in predicting pregnancy is questionable. The search continues for additional morphological markers of embryo quality. Careful nuclear observation, taking into account not only the presence of blastomere multinucleation but also the absence of nucleus, should be part of the strategies used for embryo selection.

[4]*Fertility – Centro de Fertilização Assistida, IVF laboratory, Sao Paulo, SP, Brazil*
[5]*ThoMSon Mass Spectrometry Laboratory, Chemistry institute, Campinas, SP, Brazil*

Study question: Is mass spectrometry (MS) fingerprinting able to predict cleavage or blastocyst stage embryo implantation?
Summary answer: Mass spectrometry fingerprinting combined with multivariate statistical model is a valuable tool for selecting the embryo with the highest implantation potential on the third or fifth day of development.
What is known already: The success of assisted reproductive technologies depends on the ability to select the most viable embryo in a cohort, which remains a challenge. Recently, new approaches have been reported, such as genomic, proteomic and metabolome profiling. Metabolomics is an emerging technology that provides the overall metabolic footprint of the surrounding medium rather than measures specific nutrients and metabolites. Recently MS fingerprinting has been shown to provide a reliable approach to evaluate culture media profile.
Study design, size, duration: Culture media samples harvested from 1,322 embryos obtained from 678 patients undergoing ICSI cycles, were split into those collected and transferred on respectively: (i) day-3 and day-3 (n = 395); (ii) day-5 and day-5 (n = 488); and (iii) day 3 and day 5 (n = 439).
Participants/materials, setting, methods: Samples were classified according to the cycle's implantation rate (100, 66.7, 50, 33.3, and 0%) and were individually diluted and analysed. Mass spectra were analysed by a multivariate statistical-model. The likelihood ratios were calculated for assessing the value of performing a diagnostic test by measuring sensitivity, specificity and predictive values.
Main results and the role of chance: More than 1350 ions per sample were observed within the range of 100–1000 m/z. Regarding the calibration set (0 and 100% samples), MS was capable of predicting the embryo implantation with: (i) 100% sensitivity and 90% specificity for samples collected on day 3 and embryo transfer performed on day 3, (ii) 98% sensitivity and 61% specificity for samples collected on day 3 and embryo transfer performed on day 5, and (iii) 100% sensitivity and 79% specificity for samples collected on day 5 and embryo transfer performed on day 5. For the other implantation groups (the validation set), the MS was capable of predicting the embryo implantation with a sensibility ranging from 87 to 100% and a specificity ranging from 41.6 to 100%.
Limitations, reason for caution: The model was able to predict with high reliability embryo implantation potential, but not in a definitive way, which is plausible since implantation requires a cross talk with a receptive endometrium.
Wider implications of the findings: The MS fingerprinting represents an independent but complementary tool to morphological parameters. In fact, MS fingerprinting combined with multivariate statistical model is a valuable tool for selecting the embryo with the highest viability, when used as an adjunct to morphological criteria. Therefore, it should be included in the laboratory routine for facilitating the selection of the most competent embryo for transfer.

P-186 Spiral wave: a novel phenomenon during fertilization observed by high-resolution time-lapse cinematography

K. Iwata[1], K. Yumoto[1], C. Mizoguchi[1], S. Furuyama[1], Y. Matoba[1], Y. Iba[1], Y. Mio[1]
[1]*Mio Fertility Clinic, Reproductive Centre, Yonago, Japan*

Study question: Using high-resolution time-lapse cinematography (hR-TLC) we observed a novel phenomenon in the ooplasm during the fertilization process. As a preliminary study, we investigated the relationship between this phenomenon, which we termed the 'spiral wave', and further embryonic development.
Summary answer: In both c-IVF and ICSI zygotes the spiral wave was initiated at sperm entry and continued until the cytoplasmic flare appeared. Since the spiral wave significantly delays flare initiation, it may have a negative impact on the fertilization process.
What is known already: In previous hR-TLC studies, we confirmed that after sperm-oocyte fusion, the 2nd polar body was extruded within 3 h, followed by the appearance of the fertilization cone within 30 min. After the disappearance of the fertilization cone, the cytoplasmic flare appeared at the sperm entry point, followed by pronuclear formation. We observed that cytoplasmic granules

moved around within the cytoplasm (the spiral wave), before the appearance of the cytoplasmic flare.
Study design, size, duration: We retrospectively analyzed hR-TLC images obtained from 199 oocytes from 189 patients who consented to our study. In some images we observed a 'spiral wave' in the cytoplasm during the fertilization process. We then investigated further embryonic development in zygotes with and without the spiral wave.
Participants/materials, setting, methods: A total of 199 oocytes were candidates for c-IVF ($n = 96$) and ICSI ($n = 103$). The hR-TLC was commenced 1.5 h after insemination in c-IVF oocytes and immediately after sperm injection in ICSI oocytes. Digital images were acquired for 2 days at 2-min intervals with an exposure time of 1/20 s.
Main results and the role of chance: Of 199 oocytes, 153 (60 in c-IVF, 93 in ICSI) fertilized normally and 16 (12 in c-IVF, 4 in ICSI) fertilized abnormally. The spiral wave was observed in 52 normally fertilized zygotes (14 in c-IVF, 38 in ICSI), and 6 abnormally fertilized zygotes (2 in c-IVF, 4 in ICSI), but not in unfertilized oocytes. The spiral wave was initiated at sperm entry and continued until the cytoplasmic flare appeared. The flare appeared from 4.8 ± 1.1 h in zygotes with the spiral wave (SW+) and 4.1 ± 1.3 h in zygotes without the spiral wave (SW-). The time required for flare appearance in SW+ zygotes was significantly less than in SW- zygotes ($P = 0.014$). Further embryonic development after flare appearance was similar in both groups.
Limitations, reason for caution: We could only observe whether the spiral wave occurred in the cross-sectional direction because hR-TLC images were 2-D. We speculated that the spiral wave might be caused by alteration of the cytoplasmic microtubules. We plan to analyze these cytoplasmic events using molecular biological methods.
Wider implications of the findings: The spiral wave was only observed in fertilized oocytes, irrespective of whether fertilization occurred normally and was closely associated with a delay in the appearance of the cytoplasmic flare. This study suggests that the spiral wave is related to an aberrant fertilization process, particularly the delayed formation of the sperm aster and may have negative impacts on zygote development.

P-187 Blastocyst morphology does not significantly increase the selection between euploid blastocysts in frozen embryo transfer cycles: evidences from a prospective non-selection study

A. Capalbo[1], D. Cimadomo[1], C. Patassini[2], C. Poggiana[2], E. Scepi[1], M. Stoppa[1], L. Dovere[1], L. Dusi[1], F. M. Ubaldi[1], L. Rienzi[1]
[1]Genera c/o Clinica Valle Giulia, Reproductive Medicine, Rome, Italy
[2]GENETYX, Molecular genetics laboratory, Marostica, Italy

Study question: Does blastocyst morphological evaluation correlate with reproductive competence of euploid embryos during frozen transfer cycles?
Summary answer: Even if extremely poor quality blastocysts implanted at a significantly lower rate, morphological grade and timing of development to the blastocyst stage are not good indicators to improve the selection among euploid embryos.
What is known already: No studies have prospectively attempted to correlate conventional parameters of blastocyst evaluation with euploid embryo viability in frozen embryo transfer (FET) cycles. It is still unknown whether euploid blastocysts with a different morphology and developmental rate implant at a different rate. This knowledge may be useful to further enhance embryo selection during PGS cycles. In this study, the relationship between conventional parameters of blastocyst evaluation and implantation potential of euploid blastocysts is investigated.
Study design, size, duration: This is a prospective non-selection study performed between December-2013 and October-2014 including 335 single FET of euploid blastocysts. Whenever more than one euploid blastocyst was obtained within a PGS cycle, the selection of the embryo to be transferred was subjected to randomization to rule out patient's specific confounding factors.
Participants/materials, setting, methods: PGS was performed in infertile patients of advanced female age (>35 years). Trophectoderm (TE) biopsy was performed on fully expanded or hatching blastocyst. Prior to biopsy, morphology was assessed and categorized (excellent/good/average/poor quality). The developmental rate was defined according to the day of biopsy post-fertilization (day 5/ 6/ 7).
Main results and the role of chance: Mean female age was 38.2 ± 3.4. 335 SET of euploid blastocysts (200 excellent, 54 good, 51 average and 30 poor; 143 day 5, 175 day 6, and 17 day 7) were performed in 300 patients resulting in 144 ongoing pregnancies (43%, 95% CI = 37.6–48.5), 19 biochemical (10.1%; 95% CI = 6.5–16.1) and 16 miscarriages (10%; 95% CI = 5.8–15.7). Logistic regression showed that only blastocysts morphology was weakly related to implantation. In particular, only poor quality blastocysts showed a significantly lower implantation rate compared to excellent, good and average quality ones (10 vs 47%, 37 and 55%, respectively, OR = 0.15, 95% CI = 0.04-0.53, $p < 0.01$). TE morphology was a stronger predictor compared to ICM (OR = 0.39, 95% CI = 0.02–0.21 and OR = 0.1, 95% CI = -0.1 to 0.1, respectively). Timing of development to blastocyst was not associated with implantation (day 5 = 51.7%, day 6 = 37.1%, day 7 = 29.4%) when adjusting for morphology ($p = 0.07$). Morphology were not associated to biochemical and miscarriages.
Limitations, reason for caution: Even if based on prospective design and a high sample size, this study is still not powered to exclude possible associations between blastocyst morphology and biochemical pregnancies, miscarriages and neonatal outcomes.
Wider implications of the findings: These data suggest that, provided that the expanded stage is reached, all poor morphology and slower growing embryos have to be biopsied and similarly considered for FET cycles avoiding the potential for exclusion of low quality but viable embryos from PGS cycles or, in general, from IVF procedures. Future research to identify additional biomarkers of reproductive potential to be used in parallel with aneuploidy screening is needed to further enhance selection among euploid blastocysts.
Study funding/competing interest(s): Funding by hospital/clinic(s) – GENERA, Reproductive Medicine Centers, Rome, Italy.
Trial registration number: ISRCTN81216689.

P-188 Oxygen level during human IVF embryo culture does not affect birth weight

A. P. A. Van Montfoort[1,5], E. G. J. M. Arts[1], L. Wijnandts[2], A. Sluijmer[3], M. J. Pelinck[4], J. Land[1], J. Van Echten-Arends[1]
[1]University Medical Center Groningen, Department of Obstetrics and Gynaecology, Groningen, The Netherlands
[2]Medical Center Leeuwarden, Department of Obstetrics and Gynaecology, Leeuwarden, The Netherlands
[3]Wilhelmina Hospital Assen, Department of Obstetrics and Gynaecology, Assen, The Netherlands
[4]Scheper Hospital Emmen, Department of Obstetrics and Gynaecology, Emmen, The Netherlands
[5]Maastricht University Medical Center, Department Of Obstetrics and Gynaecology, Maastricht, The Netherlands

Study question: Does oxygen level during human IVF embryo culture affect birth weight of the resulting children?
Summary answer: Our findings indicate that oxygen level during human IVF embryo culture does not affect birth weight.
What is known already: In animal studies, and also some human studies, embryo culture or more specifically the medium in which embryos are cultured during an IVF treatment affects birth weight, probably through epigenetic programming of the embryo. Little is known on the effect of oxygen level during culture on birth weight. Most IVF laboratories use either 20% (atmospheric) oxygen level or 5% (physiological situation).
Study design, size, duration: From January 2012 to December 2013, all oocytes and embryos from the same cycle were fertilized and cultured under 5 or 20% oxygen. Cycles were randomly allocated to one incubator with 5% ($n = 363$) or three with 20% oxygen ($n = 1043$). Clinical and other laboratory procedures were similar in both groups.
Participants/materials, setting, methods: Data between the oxygen groups were compared for the first cycle of a patient only ($n = 612$) and for all cycles ($n = 1406$). Neonatal data were collected from delivery reports from the hospitals or midwife practices.

Main results and the role of chance: In the 5% oxygen group there were significantly more embryos of good morphology ($P < 0.05$). This did not result in a higher ongoing pregnancy rate, but more embryos could be cryopreserved ($P < 0.01$). After a follow-up period in which (part of) these cryopreserved embryos were transferred, the cumulative ongoing pregnancy rate was higher in the 5% compared to the 20% group (5% difference for first cycles, $P < 0.05$). This did however not result in significantly more live births. In 95 live born singletons, birth weight, birth weight corrected for gestational age and gender (Z-score) and gestational age were similar in both groups, also when analysed separately for fresh or cryopreserved embryo transfers. In the analysis including all cycles, similar pregnancy and birth weight results ($n = 222$) were found.
Limitations, reason for caution: This is a retrospective exploratory study, not powered for a predefined birth weight difference. Significantly more cryopreserved embryos are still stored in the 5% oxygen group. Their future transfer may further improve live birth rates, which may result in a significantly better outcome when compared with the 20% oxygen group.
Wider implications of the findings: Based on our findings, the oxygen level during culture does not seem to affect birth weight. Nevertheless, culture under 5% oxygen is preferred as this might improve IVF success rates, especially when used in an IVF program with embryo cryopreservation.

P-189 Morphokinetics of embryos developed from oocytes matured in vitro and in vivo in IVM cycles

M. Dal Canto[1], P. V. Novara[1], G. Coticchio[1], M. Mignini Renzini[1], M. Merola[1], M. Lain[1], M. Sottocornola[1], R. Fadini[1]
[1]*Biogenesi Reproductive Medicine Centre, Istituti Clinici Zucchi, Monza, Italy*

Study question: Does oocyte in vitro maturation (IVM) influence embryo development as assessed by morphokinetics?
Summary answer: Oocyte IVM does not affect embryo development in terms of morphokinetic parameters monitored by time lapse microscopy (TLM).
What is known already: The introduction of TLM in human IVF offers novel opportunities to assess embryo development. In fact temporal parameters, such as specific cleavage times and intervals, are able the predict blastocyst development and quality, as well as embryo implantation. Hence, we pursued the goal of comparing the morphokinetic behaviour of embryos developed from oocytes matured in vitro and in vivo in IVM cycles, to the aim of assessing possible effects of IVM on embryo development.
Study design, size, duration: The morphokinetics of embryos developed from oocytes matured in vitro (CC, $n = 35$) or in vivo (EC-MII, $n = 102$) was compared following culture and image acquisition at short intervals (20 min) by adopting the Embryoscope equipment.
Participants/materials, setting, methods: Oocytes were obtained from patients undergoing FSH/hCG-primed IVM cycles. Mature oocytes were microinjected after 6 h of culture, while immature oocytes were matured in vitro for 30-32 h prior to ICSI. Embryo morphokinetics was comparatively analysed in terms of cleavage times (T2–T5 and T8) and intervals (cc2, cc3, s2, s3).
Main results and the role of chance: The morphokinetic behaviour of EC-MII and CC embryos was entirely comparable, as suggested by the absence of statistical differences in the averages of all cleavage times and intervals. In particular, the T2–T5 and T8 times (hours) were 27.0 ± 3.7, 36.6 ± 4.8, 38.6 ± 5.5, 48.5 ± 6.4 and 54.6 ± 6.0 in the EC-MII group and 26.8 ± 4.6, 35.9 ± 3.5, 38.1 ± 4.8, 48.0 ± 5.5 and 54.7 ± 7.6 in the CC group. P was 0.378, 0.449, 0.644, 0.539 and 0.973, respectively. cc2, cc3, s2, s3 intervals were also very similar, with P of 0.891, 0.585, 0.112 and 0.638, respectively.
Limitations, reason for caution: The study is based on small numbers. It should be extended to larger populations and additional morphokinetic parameters.
Wider implications of the findings: This is the first observation describing thoroughly the development of embryos derived from in vitro matured oocytes. The fact that their morphokinetics is entirely comparable to that of embryos developed from oocytes matured in vivo does not support the hypothesis that IVM affects early embryo development.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Biogenesi, Reproductive Medicine Centre.

P-190 Comparison of clinical results and morphokinetics analysis between fresh and vitrified oocytes by intracytoplasmic sperm injection with testicular sperm

H. Hattori[1], Y. Nakajo[1], N. Aono[2], Y. Nakamura[1], Y. Sato[1], C. Shitara[1], M. Takahashi[1], N. Matsukawa[1], S. Shibasaki[1], T. Hashimoto[2], M. Doshida[1], M. Toya[1], T. Okuda[2], T. Takeuchi[2], K. Kyono[1]
[1]*Kyono ART Clinic, Obstetrics and Gynecology, Sendai, Japan*
[2]*Kyono ART Clinic Takanawa, Obstetrics and Gynecology, Tokyo, Japan*

Study question: The aim of this study was to assess the clinical efficacy of vitrified oocytes and fresh testicular sperm in TESE-ICSI for azoospermic patients. How does oocyte vitrification affect embryonic development?
Summary answer: There were no significant differences in clinical results or cell kinetics between fresh and vitrified oocytes with TESE-ICSI.
What is known already: Vitrification has been reported to be a simple, cost effective, efficient method for cryopreservation of mammalian and human oocytes.

Many studies have shown more positive results with oocyte vitrification than with slow freezing procedures.
Study design, size, duration: Retrospective study. The subjects were 138 couples with 149 oocyte-retrieval cycles for TESE-ICSI from June, 2006 to September, 2014. These were divided into 2 groups: Group I (vitrified oocytes + fresh testicular sperm) in 61 cycles, and Group II (fresh oocytes + fresh testicular sperm) in 88 cycles.
Participants/materials, setting, methods: We assessed the embryo development and clinical results in the two groups including cases of obstructive azoospermia (OA), non-obstructive azoospermia (NOA) and Klinefelter's syndrome (KS). In some cases, inseminated oocytes were individually cultured in a time-lapse system (Primo Vision), and analyzed the time points of each morphokinetic event were analyzed.
Main results and the role of chance: The survival rate of oocytes after warming was 87.4% (464/531). There were no significant differences in FR (57.5%:438/703 vs. 62.3%:438/703), good quality embryo rate (37.2%:94/253 vs. 45.2%:178/394), blastocyst formation rate (48.2%:96/199 vs. 56.4%:193/342), pregnancy rate per embryo transfer (34.7%32/96 vs. 47.9%:86/181) or miscarriage rate (22.5%:7/32 vs. 26.1%:23/86) between group I and group II under OA, NOA and KS. Furthermore, cell kinetics did not difference, while there were high standard deviations (S.D.) in the times of embryonic cell divisions, and intervals in vitrified oocytes.
Limitations, reason for caution: None.
Wider implications of the findings: Vitrification of oocytes before TESE allows the use of best condition sperm without freezing for ICSI. There were no significant differences of embryo development or clinical results between fresh and vitrified oocytes with TESE-ICSI. However, the time range of embryo divisions varied in vitrified oocytes. This seems to be an effect of vitrification. The use of vitrified unfertilized oocytes should surely be recommended for wide medical treatment.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Kyono ART Clinic – Kyono ART clinic Takanawa.
Trial registration number: NA.

P-191 The development of embryos from translocation carriers presenting for pre-implantation genetic diagnosis and single blastocyst transfer

T. Truninger[1], M. Weybury[1], M. Amin[1], D. Mehmet[1], H. Barblett[1]
[1]*Hollywood Fertility Centre, Embryology, Perth, Western Australia, Australia*

Study question: Do translocations affect the development of embryos and the proportion of top quality blastocysts suitable for trophectoderm biopsy, comparative genomic hybridisation (CGH) and single blastocyst transfer?
Summary answer: In couples where the maternal age is <38 and at least one partner is carrying a translocation there is a significant reduction in formation

and top quality blastocyst development compared to the general patient population in the same age group presenting for IVF over a 12-month period.
What is known already: Translocations and advanced maternal age have been linked with higher yields of chromosomal abnormalities. Comparative Genome Hybridisation (CGH) enables the identification of the whole genome, offering greater detection of chromosomal rearrangements. Blastocyst formation and overall morphology has been associated with higher implantation rates, further to this single blastocyst transfer have been shown to produce better rates of ongoing pregnancies.
Study design, size, duration: In a retrospective cohort study over a 12-month period the blastocyst development and quality parameters from embryos (n = 136) of translocation carriers presenting for IVF treatment and CGH were compared with embryos (n = 2402) from the general patient population.
Participants/materials, setting, methods: Embryos were assessed on days 3, 5 and 6 of development. Cell division of inner cell mass (ICM) and trophectoderm (TE) was used to distinguish top quality blastocysts. Cleavage stage transfer, oocyte donor and patients aged ≥38 were excluded.
Main results and the role of chance: Blastocyst formation rate assessed as the identification of a blastocoel was significantly lower in the translocation carrier patient group than the general patient population group (62.5 vs. 72.3%, $p < 0.01$). Top quality blastocysts suitable for either vitrification or transfer were also significantly reduced in translocation patients (31.6 vs. 49.5%, $p < 0.05$). Average age between patient groups did not differ ($p > 0.5$), although translocation patients were found to have more oocytes collected per cycle (16 ± 3.6 vs. 11 ± 6.3, $p < 0.05$) and a higher proportion of oocytes fertilised normally (12 ± 2.6 vs. 8 ± 4.9, $p = < 0.05$).
Limitations, reason for caution: Poor sperm parameters may influence embryo development and blastocyst quality and this was not addressed in the current study. Further analysis of an increased sample size would allow for improved matching of controls between the two patient populations.
Wider implications of the findings: Translocations in patients presenting for ART can be associated with greater incidence of cellular arrest and poor development of blastocysts prior to embryo transfer. The first waves of embryonic genome activation are driven by parental factors. If a parent were to carry a chromosomal anomaly, this could lead to alteration in transcription activation, protein synthesis and cytokinesis, all of which influence embryo development.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Hollywood Fertility Centre.
Trial registration number: NA.

P-192 "Ruffling" phenomenon prior to the first cleavage observed by high-resolution time-lapse cinematography and its impacts on human embryonic development in vitro

K. Yumoto[1], K. Iwata[1], C. Mizoguchi[1], Y. Matoba[1], S. Furuyama[1], Y. Iba[1], Y. Mio[1]
[1]Mio Fertility Clinic, Reproductive Centre, Yonago, Japan

Study question: Does the 'ruffling' phenomenon that occurs prior to the first cleavage in human zygotes and that we found by high-resolution time-lapse cinematography (hR-TLC) play a negative role in developing good-quality embryos using assisted reproduction technology (ART) programs?
Summary answer: Although the etiology of embryonic ruffling remains unknown, this phenomenon is closely related to an increased incidence of multinucleated blastomere (MNB) formation and reduced developmental velocity during the zygote stage, which is, in turn, associated with an increased rate of poor-quality embryos.
What is known already: In previous hR-TLC studies, we clarified the time course of development during ART from fertilization to hatched blastocyst stage, including several specific physiological events. The first cleavage started within 2.4 ± 0.6 h after the male and female pronucleus (PN) disappeared (syngamy). During this period, the ooplasm showed no movement in most zygotes; however, some zygotes showed a 'ruffling' phenomenon caused by cytoplasmic fluctuations between syngamy and commencement of the first cleavage.
Study design, size, duration: Since 2003, donated oocytes (n = 210) have been used for hR-TLC observation. Of those, normally fertilized zygotes were categorized into two groups: without ruffling [ruffling (-)] and with ruffling [ruffling (+)]. We compared the incidence of MNB, developmental velocity, and the quality of embryos between these groups.
Participants/materials, setting, methods: Of the 210 oocytes available, 101 were candidates for c-IVF and 109 for ICSI. We started hR-TLC 1 h after insemination in c-IVF oocytes, and immediately after the ICSI procedure. Digital-images were acquired for 2 days. Good-quality embryos subsequently developed to the 4-cell stage were cryopreserved for future clinical use.
Main results and the role of chance: There was no significant difference in the incidence of ruffling between c-IVF and ICSI zygotes (32.2 vs. 27.3%, respectively). The ruffling (+) group showed significantly higher numbers of MNBs, compared to the ruffling (-) group (72.1 vs. 20.2%, respectively). The time required from second polar body extrusion to syngamy in the ruffling (-) zygotes was significantly lower than that for the ruffling (+) zygotes (20.1 ± 3.0 vs. 22.4 ± 3.7 h, respectively). However, there was no difference in the time required from syngamy to the commencement of first cleavage between groups. Of the ruffling (-) zygotes, 74.7% (74/99) developed into good-quality embryos, whereas only 32.6% (14/43) of ruffling (+) zygotes developed into good-quality embryos; this difference was significant.
Limitations, reason for caution: Our findings suggested that the ruffling phenomenon might be involved in the consequence of cytoskeletal instability. However, further studies, including molecular biological analyses, are needed to further characterize this phenomenon.
Wider implications of the findings: Our study demonstrated for the first time that ruffling prior to the first cleavage is closely associated with embryonic development, and therefore, might serve as a useful observational parameter for predicting embryo quality before first cleavage. However, because ruffling was also significantly related to high incidences of MNB and poor-quality embryos, this phenomenon could reflect alterations in cytoskeletal stability that may directly influence further cytokinesis including chromosome segregation, cytoplasmic fragmentation, and further development.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Mio Fertility Clinic.
Trial registration number: NA.
Keywords: hR-TLC, ruffling, syngamy, multinucleated blastomere, embryonic development

P-193 Evaluation of embryo development cultured individually or in group : a prospective single center study of 200 ICSI cycles

T. Okimura[1], K. Uchiyama[1], A. Yabuuchi[2], T. Okuno[3], T. Kobayashi[3], K. Kato[3]
[1]Kato Ladies Clinic, Embriology Laboratory, Tokyo, Japan
[2]Kato Ladies Clinic, Research Laboratory, Tokyo, Japan
[3]Kato Ladies Clinic, Medical Office, Tokyo, Japan

Study question: Does the culture of embryos individually or in groups effect upon blastocyst formation and quality when the embryos inseminated exclusively by ICSI are analysed?
Summary answer: Although there were no significant differences on blastocyst formation rate between individual and group culture, morphologically good quality blastocyst rate was significantly higher in group culture group.
What is known already: Previous studies have shown that group culture of zygotes is superior in terms of blastocyst formation, implantation and live birth as compared with individual culture in human. These zygotes in the previous studies included different insemination background; ICSI or conventional IVF and the study to compare these two culture methods in the case of zygotes produced exclusively by ICSI has not been assessed.
Study design, size, duration: A single-center cohort study of 200 cycles to compare the IVF outcome between group and individual culture was conducted in single center. Patients aged 30–46 years whose cycles obtained 3 matured oocytes and 3 regularly fertilized embryos by ICSI were enrolled from February 2014 through October 2014.
Participants/materials, setting, methods: IVF cycles were performed by minimum stimulation protocol. These cycles were randomly divided to two groups (100 cycles each); embryos cultured in groups of 3 embryos (group culture) or embryos cultured singly (individual culture) in 20ul droplet(s) of media. The development to blastocyst stage and blastocyst quality were evaluated.
Main results and the role of chance: The rates of blastocyst formation with expansion grades of 3 or greater (Gardner criteria) were 39.7% (119/300) in group culture and 39.33% (118/300)in individual culture group and no significant difference was observed in blastocyst formation rate. The rates of morphologically good quality blastocyst with ICM and TE grades of 3BB or greater were 47.9% (57/119) in group culture and 29.7% (35/118) in individual culture

group. Morphologically good quality blastocyst rate was significantly higher in group culture group ($p < 0.05$).
Limitations, reason for caution: This study was limited in minimal stimulation IVF. Therefore, the developmental outcome in the case of culturing more than 3 embryos was not assessed. The follow-up studies on pregnancy and neonatal outcome are needed.
Wider implications of the findings: Our results showed that group culture was superior in the term of morphologically good quality blastocyst rate suggesting the beneficial effect of group culture on increasing the proportion of blastocyst used for transfer or cryopreservation. There would be a possibility that group culture will become the recommended embryo culture system in the near future.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Kato ladies clinic.

P-194 Role of Sirt3 on mitochondria biogenesis and developmental competence of human in-vitro matured oocytes

Y. Yu[1], H. C. Zhao[1], R. Li[1], J. Qiao[1]
[1]Peking University Third Hospital, Reproductive Medical Center, Beijing, China

Study question: Does Sirt3 dysfucntion result in poor development outcome of human in-vitro matured (IVM) oocytes?
Summary answer: Inefficiency Sirt3 expression induced mitochondria dysfunction, and therefore failure to wipe off reactive oxygen species that declined the developmental competence of human IVM oocytes.
What is known already: Cytoplasm immaturation in IVM oocytes impaired IVM oocytes developmental competence. Mitochondria dysfunction resulted in the accumulation of free radicals that leads to DNA mutations, protein damage, telomere shortening and apoptosis. SIRT3 has emerged as a mitochondrial fidelity protein that directs energy generation and regulates ROS scavenging proteins. We investigated the potential role of Sirt3 gene in development process of human IVM oocytes by regulating mitochondrial biogenesis.
Study design, size, duration: Total 39 in vivo matured (IVO) oocytes and 242 IVM oocytes were collected from patients in ART cycles to detect Sirt1-7 expression, mitochondria biogenesis identification, produce fertilized embryos and function detection by siRNA injection. Blastocysts from IVO, IVM, mRNA- and siRNA-injection groups were used for ES cells derivation.
Participants/materials, setting, methods: Gene expression was performed by single cell RT-PCR methods. The karyotyping were detected by aCGH and cytogenetic method. The function of genes was identified using siRNA and in vitro transcripted mRNA injection methods. Embryos were graded as published criterions. Markers of ES cells were identified using immunofluorescence methods.
Main results and the role of chance: Retrospective analysis results reveled the higher abortion rate and increased ratio of poor quality embryos in patients with IVM cycles, which resulted in the poor ART outcome. Declined Sirt3 expression and mitochondria biogenesis were identified in IVM oocytes and the subsequent fertilized embryos compared with IVO counterparts. IVM oocytes developmental competence was further decreased when Sirt3 expression was inhibited using Sirt3 siRNA injection, but can be improved after injected with in-vitro transcribed Sirt3 mRNA. Comparable derivation efficiency of embryonic stem cells can be obtained using the blastocysts from IVM with Sirt3 mRNA injection, which suggested potential improvement of IVM oocytes during post-implantation.
Limitations, reason for caution: Additional studies with a larger number of oocytes are required to confirm the present results owing to the limited oocytes in the present study. Moreover specific Sirt3 activator should be studied and could be a source to improve ART outcome of patients in IVM cycles.
Wider implications of the findings: To our knowledge, this is the first study investigating the role of Sirt3 gene on mitochondria biogenesis and developmental competence of human in-vitro matured oocytes. Together with prior animal studies, the data support the positive role of Sirt3 on promoting mitochondria biogenesis. The present study promotes an important step towards establishing the human oocyte maturation mechanism, with a view to facilitating their application in the clinic.

[2]Obstetrics and Gynecology, Oita University Faculty of Medicine, Oita, Japan
[3]Department of Obstetrics and Gynecology, Faculty of Medicine Fukuoka University, Fukuoka, Japan
[4]Doctor, St. Luke Clinic, Oita, Japan

Study question: Time-lapse imaging enables consecutive observation of human embryos non-invasively. The SECM (scanning electrochemical microscopy) system enables measurements of intracellular respiration activity of embryos. We assessed the potential of pronuclear stage embryos to develop into highly-reliable stage embryos using the time-lapse and SECM methods in the field of ART.
Summary answer: Continuous monitoring of embryo morphology may provide data with a predictive value for the subsequent embryo developmental viability using morphological evaluation and time-lapse imaging, along with respiration rates. We are now able to evaluate embryos in their earliest stage: pronuclear stage.
What is known already: Time-lapse imaging presents an opportunity for optimizing embryo selection based on morphological grading, as well as providing novel morphological parameters, which may further improve accurate selection of viable embryos. The first kinetic behavior is able to be observed in pronuclear stage embryos. Combining embryo respiration activity measurement with morphological evaluation can provide new information regarding the quality of human embryos and improve selection of superior embryos.
Study design, size, duration: A prospective study was conducted from January to August 2014. A total of 152 embryos from 48 couples undergoing ICSI cycle were included in the blastocyst development analysis based on ethical considerations.
Participants/materials, setting, methods: Participants were patients of St. Luke Clinic. The study analyzed, observation points during time-lapse monitoring, the time at nuclei appearance, and at nuclei disappearance. In addition, the locations of two pronuclei at appearance, and the oxygen consumption rates were also examined.
Main results and the role of chance: The time of each embryo appearance and disappearance of the nuclei envelope was calculated after extrusion of the second polar body. The embryos in which nuclei appeared after 6 h, developed high quality blastocysts: 3BB on day 5. Moreover, the embryos in which the nuclei envelope disappeared earlier than 18h, developed high quality blastocysts. The rate of blastocyst formation was significantly higher in embryos in which there was distance between the two pronuclei in the cytoplasm at appearance, than in embryos with close pronuclei in the cytoplasm. Oxygen consumption rate showed that when embryo respiration activity at Day 1 was low, embryos developed to significantly high quality blastocysts.
Limitations, reason for caution: The limited number of embryos whose oxygen consumption rate could be measured, limited the information used to predict high quality blastocysts. A larger sample size may also demonstrate other statistically significant development parameters.
Wider implications of the findings: Morphological evaluation has been the only method to evaluate embryo quality for the last 36 years. Continuous monitoring of embryo morphology may provide data with a predictive value for the subsequent embryo developmental viability using morphological evaluation and time-lapse imaging, along with respiration rates. We are now able to evaluate embryos in their earliest stage: pronuclear stage. These will contribute to growth in the field of ART, especially regarding e-SET.
Study funding/competing interest(s): Funding by hospital/clinic(s) – St. Luke Clinic.
Trial registration number: NA.
Keywords: ART, embryo selection, oxygen consumption rate, time-lapse imaging, pronuclear stage embryo

P-196 Systematic assessment of nucleation error phenotypes by Time-lapse analysis of human embryos and their impact on embryo quality and implantation potential

S. Sayed[1], J. W. Hausken[1], A. Schwennicke[1], S. N. Eikeland[1]
[1]*Klinikk Hausken, IVF, Haugesund, Norway*

Study question: To assess the significance of nucleation error phenotypes (NEP) after the first embryo cleavage by Time-lapse imaging and to subsequently assess their impact on top quality embryo (TQE) formation and known implantation potential (KID) in a human IVF clinical setting.
Summary answer: Nucleation assessment of 1540 human embryos revealed that multinucleated 2-cell stage embryos had significantly lower TQE and KID than those that displayed no nucleation error. Binucleated and micronucleated 2-cell stage embryos were significantly more likely to develop into TQE than multinucleated embryos.
What is known already: With the advent of Time-lapse imaging, additional deselection parameters like blastomere nucleation error have been used as indicator of embryo viability. Nucleation status assessed by the presence and proportion of visible nuclei in blastomeres has been indicative of the implantation potential of the embryo. Nucleation error phenotypes include binucleation (presence of two nuclei per blastomere), multinucleation (more than 2 nuclei), and micronucleation (one or two larger nuclei surrounded by one or more smaller nuclei).
Study design, size, duration: 1540 transferred embryos cultured in EmbryoScope™ incubator between 2011 and 2014 were retrospectively analyzed. Only IVF cycles with exact traceability of transferred embryos (KID) were included. To assess formation of TQE, 1192 zygotes incubated for minimum of 42 h were retrospectively analyzed between April and December 2014.
Participants/materials, setting, methods: Nucleation status was assessed for 1540 transferred embryos and the different NEPs were annotated along with embryo development from 2 cell stage to determine KID. 1192 fertilized embryos which cleaved were subsequently annotated for their nucleation status and proportion of error to determine ability to form TQE.
Main results and the role of chance: Of 1540 embryos, KID was significantly higher in embryos that displayed no NEP compared with embryos exhibiting NEP at any stage (22.3 vs.10.5%) ($p < .00001$). There was no significant difference in KID between types of NEPs at 2-cell stage.

Of 1192 zygotes, 39.8% embryos were morphological TQE at 42 h (Istanbul consensus 2011). Of these TQE, 16.5% displayed NEP at the 2-cell stage. Those with NEP had significantly lower likelihood of developing into TQE compared with those with no NEP (29.7 vs. 44.8%) ($p = .00001$). Binucleated and micronucleated embryos at 2-cell stage were significantly more likely to develop into TQE compared with multinucleated embryos (36.0 vs. 19.2%) ($p < .01$). None of the 46 embryos that were multinucleated at 3, 4 or 5 cell stage developed into TQE.
Limitations, reason for caution: This retrospective study analyzed only the fate of transferred embryos. Therefore, information regarding the nucleation status of other embryos of poor or mediocre quality is unavailable. Information regarding to the final outcome of IVF treatment i.e., live births have not been included and a long-term assessment is therefore recommended.
Wider implications of the findings: Time-lapse imaging of embryos reveal the importance of dynamic evaluation of NEPs in predicting embryo viability as well as implantation potential. Nuclear formation is a transient process and hence single static observation will not accurately predict outcome. With the advent of Time-lapse imaging, a morphological assessment of the embryo aided by deselection parameters including cleavage anomalies and NEPs along with morphokinetics will enhance selection of top-quality embryo and should augment success rates in IVF.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Klinikk Hausken, Haugesund, Norway.
Trial registration number: NA.

P-197 A clinically useful simplified blastocyst grading system

A. Richardson[1], S. Brearley[2], L. Zujovic[2], T. Davey[2], S. Ahitan[2], S. Chamberlain[2], J. Hopkisson[1], B. Campbell[1], N. Raine-Fenning[1]
[1]*University of Nottingham, Obstetrics and Gynaecology, Nottingham, United Kingdom*
[2]*Nurture Fertility, The East Midlands Fertility Clinic, Nottingham, United Kingdom*

Study question: We have devised a simplified blastocyst grading system: A: fully expanded, clear inner cell mass (ICM), cohesive trophectoderm, B: partially expanded, clear ICM, cohesive trophectoderm, C: small ICM ± irregular trophectoderm ± excluded/degenerate cells, Is it clinically useful? Can it predict IVF outcome? Is it accurate, precise and reproducible?
Summary answer: Our simplified blastocyst grading system can be used to effectively predict IVF outcome in terms of implantation, clinical pregnancy and live birth. The inter- and intra-observer variability associated with it is minimal demonstrating it is both accurate and precise. It is therefore clinically very useful.
What is known already: Embryo grading based on qualitative criteria is subjective and inevitably results in inter- and intra-observer variability. The more permutations there are in any grading system, the greater the variability. Minimising variability in embryo scoring is important because the grade of the embryo has certain connotations. The only practical way to minimize variability is to simplify the grading system. In addition to being accurate and reproducible however, a grading system must also confer prognostic information.
Study design, size, duration: A retrospective cohort of day 5 sETs between 15/06/09 and 29/06/12 was undertaken. Implantation, clinical pregnancy and live birth rates were correlated to embryo quality according to the simplified blastocyst grading system. Embryologists used the grading system to grade and determine the fate of blastocyst images on two occasions.
Participants/materials, setting, methods: 545 embryo transfers were included. Categorical data were analysed using Chi-square. Bonferroni corrections were applied for multiple comparisons. A p-value of <0.05 was considered statistically significant. Five embryologists assessed 80 still images using the simplified grading system. The Fleiss-Kappa statistic was used to describe inter- and intra-observer variability.
Main results and the role of chance: Implantation, clinical pregnancy and live birth decreased with deteriorating embryo quality according to the simplified grading system. There was a highly significant ($p < 0.01$) difference between the groups in all parameters, largely due to the highly significant ($p < 0.01$) difference in all outcomes between grade A and B blastocysts and the significant ($p < 0.05$) difference in clinical pregnancies and live births between grade B and C blastocysts. For implantation the difference between grade C blastocysts and cavitating embryos was also significant ($p < 0.05$). There was no significant difference in outcome amongst the poorer quality embryos. Inter-observer agreement was substantial for grade allocation ($K = 0.63$) and clinical decision-making ($K = 0.66$). Intra-observer agreement ranged from substantial ($K = 0.71$) to almost perfect ($K = 0.88$) for grade allocation and was almost perfect for fate determination ($K \geq 0.84$).
Limitations, reason for caution: Only a limited number of cavitating ($n = 38$) and compacting ($n = 15$) embryos were available for determination of prognostic potential. Still images were used for the assessment of variability providing an artificial environment for the grading of embryos. The simplified grading system needs to be externally validated prior to widespread implementation.
Wider implications of the findings: This study demonstrates the prognostic potential and inter- and intra-observer variability of our simplified blastocyst grading system. The grading system is able to effectively predict IVF outcome. Slight variation exists both between and within embryologists but overall the levels of agreement are similar to, if not better than, those associated with more complex grading systems. This, combined with the fact it is quick and easy to use, make it clinically very useful.
Study funding/competing interest(s): Funding by University(ies) – Funding by hospital/clinic(s), University of Nottingham, Nurture Fertility.

P-198 Variations in outdoors pollutants do not affect significantly embryo viability and pregnancy outcome

M. Aguirre-Arias[1], M. Meseguer[2], C. Troncoso[3], D. Machuca[4], S. Varela[3], M. Calonge[5]
[1]*IVI Santiago de Chile SA, IVF Laboratory, Santiago RM, Chile*
[2]*IVI – Valencia, IVF Laboratory, Valencia, Spain*
[3]*IVI – Santiago, Medical Staff – Director, Santiago RM, Chile*
[4]*IVI Santiago de Chile SA, IVF Laboratory, Santiago RM, Chile*
[5]*IVI – Santiago, IVF Laboratory, Santiago RM, Chile*

Study question: Even though IVF laboratories are equipped with High Efficiency Particulate Air (HEPA) filters, ambient air of in vitro fertilization laboratories could carry small quantities of pollutants. In this regard, the arising question is: Can increased outdoor pollutants circulating affect IVF outcomes?
Summary answer: Episodes of high environmental pollution in Santiago the Chile are not closely related with abnormal fertilization and embryos degeneration, but reduced implantation rate.
What is known already: To obtain optimal results at IVF laboratories, it is important to maintain stable air parameters as pollutants may produce IVF outcome failure. Therefore, our laboratory is equipped with HEPA filters, positive pressure, and all personnel accomplishes with security and hygiene rules to work inside. Despite of these cautions, small quantities of air pollutants can still damage embryo viability especially when Santiago de Chile, the sixth most polluted city in the world, exhibits episodic high contamination levels.
Study design, size, duration: Retrospective cohort study approached with ovum recipients, who asked for an assisted reproduction treatment at IVI – Santiago de Chile during the years 2010–2013. From a total number of 636 cases registered during this term, 562 were taking into consideration for the study.
Participants/materials, setting, methods: High contamination period (HCP) was estimated as the term in which the daily registration of both pollutants NO_2 and CO exceeded steadily the annual average plus one standard deviation. Homogeneity analysis was approached through Student's t-test. The parameters evaluated were: degeneration on day 1, viability on day 2, and embryo quality on day 3. The statistic contrast was performed with chi-squared test and Fisher exact test.
Main results and the role of chance: HCPs were steadily present during autumn and winter from 2010 to 2013. During these periods, embryos degeneration and abnormal fertilization on day 1 exhibit higher but not statistically significant values (**4.5 ± 1.4 vs. 7.5 ± 1.0%**, and **26.0 ± 4.0 vs 37.5 ± 4.8%** respectively) In a similar way, viability on day 3 was slightly affected in HCPs (**18.2 ± 6.2 vs. 15.0 ± 2.1%**); however, embryo quality on this day exhibited similar for cycles accomplished during high and low contamination periods. Pregnancy rate was a little diminished (**53.0 ± 1.5 vs. 47.0 ± 1.8%**); meanwhile implantation rate was significantly reduced (**46.3 ± 0.2 vs 35 ± 0.6%, *p* = 0.0091**) in cycles that took place in HCP but in both All the patients surveyed in this study exhibited similar baseline characteristics as featured from our oocyte donation program.
Limitations, reason for caution: This study does take into account only the daily local registration of NO2, and CO; however, neither these pollutants nor others were measured inside our IVF laboratory facilities. The retrospective design and the potential bias from unknown clinical factors may condition the outcome results presented in this abstract.
Wider implications of the findings: The results of this study reinforce the well known fact of an optimal air quality to obtain the best outcomes in an IVF laboratory. Also, they suggest that outdoors pollution still conditions embryo quality despite controlled laboratory conditions as the low contamination periods may ensure the highest rate of implantation. However, further studies should be designed taking in consideration indoor/outdoor relationship measurements of pollutants.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Clínica IVI – Santiago.
Trial registration number: 0000.
Keywords: IVF, air pollution, pregnancy, implantation rate

P-199 Comparable timings of early developmental events in embryos from fresh and vitrified oocytes

M. Martínez[1], A. Obradors[1], J. Santaló[2], V. Vernaeve[1], R. Vassena[1]
[1]Clínica EUGIN, Barcelona, Spain
[2]Universidad Autónoma de Barcelona, Departamento de Biología Celular Fisiología e Immunología, Barcelona, Spain

Study question: Are there differences in early developmental events and early cleavage times between embryos developing from freshly collected oocytes versus those developing from vitrified/warmed oocytes?
Summary answer: There are not significant differences for the median developmental and cleavage times: second polar body extrusion (2nPB), appearance of the two pronuclei (2PN), two pronuclei breakdown (BPN), and cleavage times t2, t3, t4, t5, t6, t7 and t8 between embryos developing from fresh oocytes and embryos developing from vitrified/warmed oocytes.
What is known already: Oocyte vitrification causes a temporary disassembly of the metaphase plate and spindle, which needs recovering after warming. As a result, it is possible that early post fertilization events such as the 2nPB might be altered in timing, with unknown effect on preimplantation development speed, BPN, and cleavage times (t2-t8). Although pregnancy rates are similar when fresh oocytes or vitrified oocytes are used, not much is known about their developmental kinetics.
Study design, size, duration: This is a prospective cohort study carried out in a large private fertility center between February and October 2014; 203 embryos were included. Inclusion criteria were embryos from fresh or vitrified oocytes from women aged 23–29 years, and normozoospermia according to WHO 2010 criteria.
Participants/materials, setting, methods: Fresh or vitrified/warmed oocytes fertilized with either partner or donor sperm. Developmental and cleavage times were collected with Primovision® Analyzer. Statistical analysis was performed by generating Kaplan-Meier curves of each time-lapse marker, and using a Log-rank test to identify differences between the two study groups (fresh vs vitrified/warmed).
Main results and the role of chance: Median developmental times (point at which 50% of the embryos have achieved each developmental stage) did not differ among embryos in the study groups (Log-rank test): **2nPB** = 3:30 vs 3:36 (*p* = 0.72); **2PN** = 7:43 vs 7:48 (*p* = 0.44); **PNB (** = 23:48 vs 23:46 (*p* = 0.64); **t2** = 22:43 vs 27:28 (*p* = 0.40); **t3** = 37:12 vs 39:27 (*p* = 0.25); **t4** = 39:10 vs 40:47 (*p* = 0.39); **t5** = 50:41 vs 50:27 (*p* = 0.79);**t6** = 51:41 vs 51:23 (*p* = 0.54); **t7** = 51:22 vs 53:22 (*p* = 0.14); **t8** = 53:9 vs 50:27 (*p* = 0.33), for fresh and vitrified/warmed oocytes, respectively. Because of the characteristics of oocyte donors, and the inclusion criteria for sperm, the two groups of embryos analyzed were comparable at baseline.
Limitations, reason for caution: Survival times do not follow a normal distribution therefore median times were analyzed. Caution may be exerted when comparing results with other studies where mean times are provided. The study population was selected to include only normospermic samples; results are not generalizable to all patients performing an oocyte donation cycle.
Wider implications of the findings: We conclude that the times of early cleavages and events of embryonic development are not different between embryos originating from fresh and vitrified/warmed oocytes; oocytes vitrification does not affect the preimplantation kinetics of the resulting embryos.
Study funding/competing interest(s): Funding by hospital/clinic(s).
Trial registration number: NA.

P-200 Cumulus cell transcription analysis of in-vitro and in-vivo matured human cumulus cell-oocyte complexes

R. Fadini[1], M. Dal Canto[1], M. Mignini Renzini[1], M. C. Guglielmo[1], D. Turchi[1], F. Brambillasca[1], G. M. Yerushalmi[2], A. Hourvitz[2], G. Coticchio[1]
[1]Biogenesi Reproductive Medicine Centre, Isitutti Clinici Zucchi, Monza, Italy
[2]IVF Unit and Reproduction Lab, Department of Obstetrics and Gynecology Sheba Medical Center Tel Hashomer, Tel-Aviv, Israel

Study question: Does the transcriptional profile of selected genes expressed by cumulus cells (CC) vary in in-vivo and in-vitro matured cumulus cell-oocyte complexes (COC)?
Summary answer: In CC, the expression of genes crucially involved in oocyte maturation signalling or cumulus expansion is influenced by in vitro maturation conditions.
What is known already: Many studies suggest that in CC the expression profiles of specific mRNA reflect the functional status of the oocyte and therefore could be adopted as non-invasive biomarkers of oocyte quality. This concept could be extended to COC that are retrieved at the immature germinal vesicle (GV) stage and are matured in vitro in oocyte in vitro maturation (IVM) cycles. However, current evidence on CC gene expression after IVM is very scarce.
Study design, size, duration: The expression profiles of specific genes involved in oocyte maturation were compared between CC obtained from COC matured in vivo or in vitro. In-vivo matured COC were obtained from fully stimulated cycles, while immature COC were retrieved from IVM cycles and cultured for 30 h to achieve oocyte maturation.
Participants/materials, setting, methods: CC were separated from their companion oocytes and RNA was isolated and prepared for expression analysis. RNA was used to produce cDNA libraries whose elements were sequenced, mapped and identified. Relative abundance of transcripts of genes of interest was validated by quantitative RT-PCR and comparatively analyzed.

Main results and the role of chance: Several difference were found in CC gene expression after maturation in vivo or in vitro. The major findings can be summarized as follows: (a) the *FSHR* mRNA was non-detectable in both in-vivo and in-vitro matured sample, while the *LHR* mRNA was four-fold more expressed in in-vitro matured COC; (b) the amphiregulin mRNA was three-fold more represented in in-vivo matured samples, while the mRNA of its cognate receptor (*EGFR*) was only moderately more expressed (1.5 folds) in in-vitro matured COC; (c) transcripts of genes involved in cumulus expansion, such as *PTGS2* and *HAS2,* were much more represented (respectively, three- and ten-folds) under in vivo maturation conditions; (d) the *GJA* gene, encoding for connexin-43, was ten-fold more expressed in IVM COC.
Limitations, reason for caution: Although informative and based on a well-established methodology, the study should be extended to transcripts of other genes known to have a function in oocyte maturation or to reflect oocyte quality.
Wider implications of the findings: The present data indicate that in vitro maturation conditions influence the expression of several genes involved in oocyte maturation signalling networks and cumulus expansion. Interestingly, as shown by collective knowledge on human IVM, such changes do not necessarily preclude the oocyte ability to mature and often give rise to embryos able to establish a viable pregnancy. Therefore, the functional significance of modifications of gene expression during IVM remains to be established.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Biogenesi, Reproductive Medicine Centre – Monza, Italy.

P-201 Ultrastructural comparison of *in-vitro* and *in-vivo* matured human oocytes

G. Coticchio[1], M. Dal Canto[1], R. Fadini[1], M. Mignini Renzini[1], S. Miglietta[2], M. G. Palmerini[3], G. Macchiarelli[3], S. A. Nottola[2]
[1]Biogenesi Reproductive Medicine Centre, Istituti Clinici Zucchi, Monza, Italy
[2]University "La Sapienza", Department of Anatomy Histology Forensic Medicine and Orthopaedics, Rome, Italy
[3]University of L'Aquila, Department of Life Health and Environmental Sciences, L'Aquila, Italy

Study question: Is the ultrastructure of the cytoplasm of human *in-vitro* and *in-vivo* matured oocytes comparable?
Summary answer: Overall, the ultrastructure of human *in-vitro* matured oocytes is comparable to that of *in-vivo* matured controls, although following *in vitro* maturation (IVM) mitochondria-smooth endoplasmic reticulum (M-SER) complexes are partly replaced by mitochondria-vesicles (M-V) aggregates.
What is known already: Immature oocytes retrieved from antral follicles of patients undergoing IVM treatment can achieve meiotic maturation *in vitro*, fertilize and develop into embryos able to implant and give rise to viable pregnancies. However, nothing is known on the ultrastructure of IVM oocytes.
Study design, size, duration: The ultrastructure of *in-vitro* matured oocytes ($n = 7$) was compared with that of *in-vivo* matured oocytes ($n = 10$) by light and transmission electron microscopy (LM, TEM). The study was carried out over a period of 18 months.
Participants/materials, setting, methods: Immature cumulus cell-enclosed oocytes, retrieved from mid-sized antral follicles of women requiring IVM treatment, were matured *in vitro* for 30 h. Mature oocytes were obtained from age-matched women undergoing full ovarian stimulation. *In-vitro* and *in-vivo* matured oocytes were fixed and analysed by LM and TEM.
Main results and the role of chance: *In-vitro* matured oocytes showed general features comparable to *in-vivo* matured controls. All oocytes had normal ooplasm showing uniform distribution of organelles. M-SER aggregates and M-V complexes were commonly found in *in-vivo* matured oocytes. Large M-V complexes partially replaced M-SER aggregates in IVM oocytes. Mitochondria appeared morphologically unaffected by IVM. Cortical granules appeared typically stratified in a single, mostly continuous row just beneath the ooplasm in all oocytes. Microvilli were well preserved after IVM. Vacuoles were only occasionally found in all oocytes and, if present, they were frequently associated with lysosomes. The morphological features of the MII spindle and the first polar body of in-vitro matured oocytes were comparable to those shown by control oocytes.
Limitations, reason for caution: Although informative and based on a well-established methodology, the study should be extended to larger number of oocytes and different maturation conditions.
Wider implications of the findings: Ultrastructural analysis offers an objective approach for the comparison of organelle structure and distribution in in-vitro and *in-vivo* matured oocytes. The present data confirm that following IVM the overall oocyte cytoplasmic architecture is well preserved, although subtle differences in comparison to *in vivo*-matured controls encourage a further refinement of IVM protocols.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Biogenesi, Reproductive Medicine Centre, Monza, Italy.

P-202 Spindle morphology in human oocytes changes with ageing and causes effect upon developmental competence

R. Matsunaga[1], M. Kamihata[1], T. Tanaka[1], N. Yamanaka[1], S. Watanabe[1], H. Miyamura[2], A. Kuwahata[1], M. Ochi[1], T. Fujii[2], T. Horiuchi[3]
[1]Ochi Yume Clinic Nagoya, IVF Laboratory, Nagoya, Japan
[2]Department of Obstetrics and Gynecology, Fujita Health University, University, Toyoake, Japan
[3]Graduate School of Comprehensive Scientific Research Prefectural, University of Hiroshima, University, Shobara, Japan

Study question: We analyzed the relationship between biological aging and spindle configuration in human oocytes visualized with a Polscope and evaluated developmental competence. However, in the old group, the blastocyst formation rate of oocytes with a smaller area and grater retardance were higher.
Summary answer: The length and area of oocyte spindles became greater, and spindle density (retardance) became lower, with age. Development to the blastocyst stage was generally reduced with age.
What is known already: Existing reports suggest that human oocytes, with or without birefringent spindles, as imaged with a Polscope, are associated with oocyte quality. However, the relationship between oocyte spindle morphology and patient age and embryo development remains unknown.
Study design, size, duration: This study performed from August 2013 to September 2014. We analyzed 710 matured oocytes from 241 patients following letrozole stimulation.
Participants/materials, setting, methods: Oocyte spindle morphology was analyzed before ICSI using a Polscope. Oocytes were divided into three groups according to patient age: under 36 years (young), between 36 and 41 years (middle), and over 41 years (old). Spindle morphology, fertilization rate, and blastocyst formation rate was compared across the three groups.
Main results and the role of chance: Oocyte spindle area became greater with age (young vs. middle vs. old: 93.8 ± 18.7 nm^2, 101.9 ± 22.6 nm^2, 110.8 ± 26.3 nm^2). Retardance of the old group was lower than either the young or middle group (1.8 ± 0.4 nm, 2.0 ± 0.5 nm, 1.9 ± 0.4 nm). There was no significant difference in fertilization rate among the three groups. Blastocyst formation rate in the oldest group was lower than either the young or middle group (33.6%, 66.7%, 66.3%). However, in the old group, the blastocyst formation rate of oocytes with a smaller area and grater retardance were higher.
Limitations, reason for caution: It is important to examine further whether spindle morphology in human oocytes influences pregnancy and live birth rates.
Wider implications of the findings: This study demonstrates that spindle morphology in human oocytes changes with patient age and influences the developmental competence of embryos. The evaluation of spindle morphology will enable us to select good quality oocytes with high developmental competence.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Ochi Yume Clinic, Nagoya.

P-203 Positive clinical outcomes when hyaluronan solution replaces polyvinylpyrrolidone in ICSI protocols; a comparative multicentre study

E. Andaloro[1], S. Baohm[1]
[1]City Fertility Centre, Laboratory, Melbourne, Australia

Study question: Does the replacement of non-biodegradable polyvinylpyrrolidone (PVP) with a commercially available product containing natural hyaluronan (SpermSlow™) lead to superior IVF outcomes?

Summary answer: SpermSlow™ represents a superior alternative to PVP in terms of fertilisation, clinical pregnancy rates and ongoing pregnancy rates.
What is known already: When used as an adjunct during ICSI, PVP can lead to sperm DNA damage and can result in deleterious effects on embryo development (Barak et al., 2001). Hyaluronan (HA) receptors located on the Zona Pellucida are responsible for binding sperm which are mature and have good DNA integrity. Utilising SpermSlow™, which is a viscous HA solution, allows for sperm selection and has the benefits of PVP whilst eliminating the potential deleterious effects.
Study design, size, duration: In this comparative multicentre study, 3023 oocytes injected with HA were retrospectively analysed against 2624 PVP injected oocytes over a 6-month period. Clinical outcomes were measured from 545 transfer cycles. Fisher's exact test was performed using GraphPad™ software where $P < 0.05$ was considered significant.
Participants/materials, setting, methods: Sperm was prepared to a final motile concentration of 1×10^6/mL and added to PVP (Cook®) with ICSI performed in Cleavage Media (Cook®). For the HA group, PVP was replaced with SpermSlow™ (Origio®) and a 10 min incubation included to permit adequate sperm-HA substrate binding.
Main results and the role of chance: Oocytes injected with sperm selected in SpermSlow™ had a significantly higher fertilisation rate when compared to PVP usage (67.8% vs. 64.2%, $p = 0.0048$). An average of 1.3 embryos was transferred in each group. SpermSlow™ resulted in a clinical pregnancy rate of 30.2% ($n = 81$), significantly higher ($p = 0.0077$) than the PVP rate of 20.2% ($n = 56$). SpermSlow™ also had a significantly lower miscarriage rate (20.6% vs. 39.1%, $p = 0.0070$). No statistical difference was observed in biochemical pregnancy rate (38.1% SpermSlow™ vs. 33.2% PVP). There was no difference in the average maternal age, which was 36.3 for SpermSlow™ patients and 36.2 for PVP patients.
Limitations, reason for caution: An inherent property of SpermSlow™ is that it relies on forward progressing sperm and is therefore not suitable for testicular biopsy or severe asthenozoospermic samples.
Wider implications of the findings: SpermSlow™ is a user friendly product that can be easily integrated into ICSI protocols. With a natural HA active ingredient, clinics now have the option of eliminating potentially toxic PVP, selecting mature sperm with high DNA integrity and therefore generating a superior clinical pregnancy rate. Furthermore, a lower miscarriage rate was observed, potentially attributed to better DNA sperm selection at ICSI.
Study funding/competing interest(s): Funding by hospital/clinic(s) – City Fertility Centre.
Trial registration number: NA.

P-204 A randomized controlled study comparing two slow-freezing methods for cryopreservation of human cleavage stage embryos

Y. Ye[1], L. Fang[1]
[1]*Women's Hospital School of Medicine, Zhejiang University, Reproductive Endocrinology, Hangzhou, China*

Study question: To compare two slow-freezing methods for cryopreservation of human cleavage stage embryos.
Summary answer: Embryo slow freezing using Vitrolife® method is superior to the Irvine® method in terms of embryo survival rate, intact embryo rate and clinical pregnancy rate.
What is known already: Slow-freezing protocols have been intensively used for cryopreservation of human embryos. However, over the past few years, vitrification has been shown to be superior to slow freezing by increasing embryo survival rate.
Study design, size, duration: From March to August, 2014, cleavage embryos were randomly cryopreserved with Irvine® or Vitrolife® slow-freezing method. Until November 2014, totally 1581 embryos from 635 cycles were thawed.
Participants/materials, setting, methods: Patient age, oocyte number of Irvine® and Vitrolife® group are 30.49 ± 4.33 and 30.58 ± 4.36; 17.81 ± 7.96 and 17.00 ± 7.05, respectively. Setting: University affiliated IVF center. The embryo survival rate, fully intact embryo rate, clinical pregnancy rate, and implantation rate were compared between the two groups.
Main results and the role of chance: Post warming embryo survival rate was significantly higher in Vitrolife® method compared to Irvine® method (94.3% vs. 84.0%, $p < 0.001$). Fully intact embryo rate was also significantly increased in Vitrolife® method (80.7% vs. 56.5%, $p < 0.001$). Of the 320 thaw cycles using Irvine® method, 9 cycles were cancelled because there were no viable embryos suitable for transfer while none of 315 cycle was cancelled in Vitrolife® method. Significant higher clinical pregnancy rate was observed using Vitrolife® compared to Irvine® method (54.0% vs. 46.0%, $p = 0.046$). Implantation rate was 33.5% and 30.1% for Vitrolife® and Irvine®, respectively.
Limitations, reason for caution: The study was performed at an IVF centre, comparing two commercial slow-freezing reagents.
Wider implications of the findings: For cleavage stage embryos, improved slow-freezing methods can produce comparable results to vitrification.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Women's Hospital, Zhejiang University School of Medicine.
Trial registration number: NA.
Keywords: cleavage embryo, slow-freezing, clinical outcomes

P-205 Comparison of embryo ranking at fixed standard time-points with a decision support tool based on time-lapse data correlated with known implantation

M. Montag[1], B. M. Petersen[2]
[1]*ilabcomm GmbH, CEO, Sankt Augustin, Germany*
[2]*Vitrolife A/S, Data Analysis, Aarhus, Denmark*

Study question: This study evaluates how embryologists rank embryos based on static morphological information of embryo development at the ESHRE/ASRM consensus fixed time-points in comparison with a decision support tool (KIDScore) that calculated an implantation potential score for the same embryos using time-lapse information.
Summary answer: Embryo ranking based on strict morphological appearance differ between embryologists. The embryologist's ranking is also different from that of the decision support tool, which makes use of morphokinetic data. The latter could give an immediate benefit to embryologists independent of their working experiences to avoid selecting embryos with a very low chance of implantation, in addition to implementing a more standardized method for embryo ranking.
What is known already: Standard observation of embryo development at fixed time-points could miss irregular cell divisions, inadequate cell cycle length and abnormal developmental pace – events all associated with low implantation rates. A decision support tool based on time-lapse characteristics of thousands of embryos with known implantation has been developed. This determines the relative implantation potential of embryos with a score from 0 (lowest) to 5 (highest). This decision support tool may be useful to support embryologists who apply time-lapse technology in their embryo evaluation.
Study design, size, duration: Embryologists were asked to rank eight embryos based on images taken at seven focal planes at recommended ESHRE/ALPHA consensus fixed time-points (17, 26, 44, 66 h of development). Ranking by embryologists was compared to that calculated by the time-lapse decision support tool (KIDScore Basic D3).
Participants/materials, setting, methods: 80 embryologists (working experience 1–28 years, median 7.0; 44 with and 36 without time-lapse experience) participated. For each embryo the ranking by embryologists was compared to the rank given by KIDScore. Statistics were calculated using Graph Pad Prism (unpaired *t*-test with Welchs correction and linear regression analysis).
Main results and the role of chance: Out of eight embryos, four were ranked by KIDScore with score 1, two with score 3, one with score 4 and one with score 5 (highest implantation potential). From the participants 41.3% gave the top rank to a KIDScore 3 embryo, 27.5% to a score 1, 22.5% to a score 5 and 8.7% to another score 1 embryo. The statistical analysis showed a significant difference in the selection of the score 5 and 1 embryo between time-lapse and non time-lapse users ($P = 0.038$ and 0.005, respectively). Neither the general working experience as embryologist nor the experience in time-lapse did correlate with the decision to select the best embryo (KIDScore 5). In contrast, the score 1 embryo was more likely deselected with increasing time-lapse experience ($P = 0.0006$).
Limitations, reason for caution: This study was limited to eight embryos where still pictures at the different time-points and seven focal planes for each embryo were shown. Embryologists were not able to move embryos as in

normal routine practice. Using a time-lapse based decision tool requires correct and consistent annotation.
Wider implications of the findings: Our findings show, that embryo evaluation at fixed time-points is highly biased by the morphology that is present at the time of observation. Given the different level of experience of the embryologists who participated in this study and the observed differences in ranking of embryos, time-lapse based decision support tools including additional observations from continuous monitoring may help to improve standardization in clinical embryology.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – This study was conducted at workshops which were organized by FertiliTech (now part of Vitrolife).
Trial registration number: NA.
Keywords: time-lapse imaging, embryo score, morphokinetics, morphology, standardization

P-206 The assessment of the influence of iron, cadmium and lead concentrations on time-lapse parameters in ICSI procedure

S. Bakalczuk[1], A. Wdowiak[2], I. Bojar[3], G. Bakalczuk[4], A. Mroczkowski[1]
[1]Non-Public Health Care Unit "Ovum Reproduction and Andrology", Lublin Poland, Lublin, Poland
[2]Medical University of Lublin, Diagnostic Techniques Unit, Faculty of Health Sciences, Lublin, Poland
[3]Institute of Rural Health, Department for Health Problems of Ageing, Lublin, Poland
[4]Medical University of Lublin, Department of Obstetrics Gynaecology and Obstetric-Gynaecological Nursing, Faculty of Health Sciences, Lublin, Poland

Study question: This research aims to evaluate to what extent the concentrations of iron, cadmium and lead affect the dynamics of embryo development.
Summary answer: It has been shown that the concentrations of cadmium and lead in the follicular fluid affect the dynamics of embryo development from the last observation of both pronuclei (tC) to the four-cell stage embryo (t4). The concentration of iron does not have an impact on the dynamics of embryo development.
What is known already: Heavy metals have a strong capacity to induce oxidative stress in body cells by disintegration of the lipid membrane, and spermatozoa are quite sensitive to oxidative stress. This may be caused by the weakening of cellular-based defensive mechanisms. The oxidant-antioxidant imbalance has an adverse effect on all stages of reproduction. The egg cell is probably damaged by the toxic microenvironment during primordial stage of follicle development and at the time of oocyte maturation.
Study design, size, duration: The growth of all the embryos from each patient was monitored continuously by obtaining images at 10 min intervals. The Pb, Cd, Fe measurements were performed by the electrothermal-atomic absorption spectrometry method.
Participants/materials, setting, methods: The present study was conducted in 2013 and 2014 in the 'Ovum Reproduction and Andrology' Non-Public Health Care Unit in Lublin (Poland), and involved 219 women aged 25–35 years undergoing fresh IVF. The study has been approved by the ethics committee of the Institute of Rural Health in Lublin.
Main results and the role of chance: We have shown that there is a positive correlation between the concentration of lead and the following times: tC(r = ,321,p = ,000), t1(r = 0,311, p = 0,000), t2(r = 0,359, p = 0,000), t3(r = 0,305, p = 0,000), t4(r = 0,235, p = 0,000), as well as between cadmium and times: tC(r = 0,388, p = 0,000), t1(r = 0,357, p = 0,000), t2(r = 0,395, p = 0,000), t3(r = 0,282, p = 0,000), t4(r = 0,296, p = 0,000). Considering other correlations, no statistically significant correlations have been found between iron, cadmium and lead.
Limitations, reason for caution: None
Wider implications of the findings: Overexposition of an organism to cadmium and lead adversely affects the dynamics of embryo development up to the four-cell embryo stage. Exposition to iron does not affect the dynamics of embryo development.
Study funding/competing interest(s): Funding by national/international organization(s) and International Scientific Association for the Support and Development of Medical Technologies.
Trial registration number: Local institutional registration
Keywords: iron, cadmium, lead, time lapse

P-207 Binding of FGF2 to FGFR2 in an autocrine manner in trophectoderm cells is indispensable for expanded blastocyst formation through activation of the PKC-p38 signalling pathway

J. Yang[1], X. H. Lin[1], Y. H. Ye[1], D. Zhang[1], L. Jin[1], Y. Yu[1], X. L. Hu[1], H. F. Huang[1], J. Z. Sheng[1]
[1]Zhejiang University, School of Medicine, Hangzhou, China

Study question: Fibroblast growth factors (FGF1, FGF2 and FGF4) and fibroblast growth factor receptors (FGFR1, FGFR2, FGFR3 and FGFR4) have been reported to be expressed in preimplantation embryos and be required for their development. However, the functions of these molecules in trophectoderm cells (TEs) that lead to the formation of the blastocyst as well as the underlying mechanism have not been elucidated.
Summary answer: The present study has demonstrated for the first time that endogenous FGF2 secreted by TEs can regulate protein expression and distribution in TEs via the FGFR2-mediated activation of PKC and p38, which are important for the development of expanded blastocysts.
What is known already: Fibroblast growth factors (FGF1, FGF2 and FGF4) and fibroblast growth factor receptors (FGFR1, FGFR2, FGFR3 and FGFR4) have been reported to be expressed in preimplantation embryos and be required for their development.
Study design, size, duration: Total number of subjects were involved. About one thousand of embryos were involved. It took 1 year for this experiment.
Participants/materials, setting, methods: We collected ICR mice 4–8 cells embryos to study the formation of expanded Blastocysts. SiRNA, immunoflurence technology, kinase inhibitors co-culture and Real-time PCR was used.
Main results and the role of chance: Endogenous FGF2 secreted by TEs can regulate protein expression and distribution in TEs via the FGFR2-mediated activation of PKC and p38, which are important for the development of expanded blastocysts.
Limitations, reason for caution: It is difficult to obtain a certain amount of embryos to test from protein quantitative level.
Wider implications of the findings: This finding provides the first explanation for the long-observed phenomenon that only high concentrations of exogenous FGFs have effects on embryonic development, but *in vivo* the amount of endogenous FGFs are trace. Besides, the present results suggest that FGF2/FGFR2 may act in an autocrine fashion and activate the downstream PKC/p38 pathway in TEs during expanded blastocyst formation.
Study funding/competing interest(s): Funding by University(ies) – (1) International Peace Maternity and Child Health Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai 200030, China. (2) The Key Laboratory of Reproductive Genetics, Ministry of Education (Zhejiang University), Hangzhou, Zhejiang 310006, China.
Trial registration number: No clinical.

P-208 Outgrowth embryo-derived extracellular vesicles improve the developmental competence of mouse pre- and peri-implantation embryos

J. Kim[1], Y. Choi[1], L. Kim[1], J. Jun[2,3]
[1]Department of Senior Healthcare, BK21 Plus Program Graduated School, Eulji University, Gyeonggi do, South Korea
[2]Department of Senior Healthcare, BK21 Plus Program Graduated School, Eulji Medi-Bio Research Institute (EMBRI), Eulji University, Gyeonggi do, South Korea
[3]Department of Biomedical Laboratory Science, BK21 Plus Program Graduated School, Eulji Medi-Bio Research Institute (EMBRI), Eulji University, Gyeonggi do, South Korea

Study question: Does outgrowth embryos secrete extracellular vesicles and Does it improve the pre- and peri-implantation embryonic development?
Summary answer: Outgrowth embryos secrete extracellular vesicles and it improves mouse embryonic development on blastulation rate, blastocyst cell number and outgrowth rate as well as mean of outgrowth areas and morphological scores.
What is known already: A large variety of extracellular vesicles produced within the mammalian embryos and secreted into the surrounding environment of uterus have been called exosomes, shedding vesicles, and extracellular vesicles (EVs). Embryos alter the microenvironment through secretions of those

vesicles and it has physiological roles during embryonic development and gene expressions.
Study design, size, duration: Two-cell embryos were collected from super-ovulated ICR mice (day-2) and cultured in basal medium, Quinn's advantage blastocyst medium (QABM), up to blastocyst (day-5). In vitro cultured blastocysts were transferred to be outgrowth on fibronectin-coated dish without serum supplementation for 3 days (day-8). Then, EVs were prepared from conditioned media of outgrowth embryos (EVs-QABM) on day-8. Two-cell embryos were cultured in basal medium without or with outgrowth embryo derived-EVs. Pre-implantation embryonic development was assessed by rates of morula, blastocyst and hatching and TUNEL assay and peri-implantation embryonic development was assessed by outgrowth rates, spreading area and morphological scoring.
Participants/materials, setting, methods: Conditioned media of outgrowth embryos was examined by using TEM to observe the morphology and size of EVs. Mouse 2-cell embryos were treated with 0–50% of EVs-QABM and 10% serum protein substitute (SPS) for the positive control (PC). Blastocysts were (i) stained for cell number, (ii) for TUNEL assay, (iii) analyzed quantitatively the expression of survival-related genes and (iv) transferred to wells coated with fibronectin for peri-implantation outgrowth. Outgrowth embryos were (iv) measured trophoblastic spreading area and ranked against the morphological scoring of trophoblast cells and inner cell mass (ICM).
Main results and the role of chance: The EVs had conventional membrane structures and the sizes were 50–200 nm. Significant differences in pre-implantation embryonic development, as well as the cell number of blastocyst (0% vs. 12.5%, $p < 0.05$), apoptotic index (0% vs. 12.5%, PC% vs. 12.5%, $p < 0.01$) and rates of morula (0% vs. 25%, $p < 0.01$) and blastocyst (0% vs. 12.5%, 0% vs. 25%, $p < 0.01$), were found when the embryos were treated with EVs-QABM. And survival-related genes such as Bcl-2, Survivn and LIF were up-regulated in 12.5% and 25% of EVs-QABM treated group ($p < 0.01$) compared to negative control while pro-apoptosis gene, Bax, was down-regulated in EVs-QABM group ($p < 0.05$). Also EVs-QABM affected the peri-implantation embryonic development by improving outgrowth rates (0% vs. 12.5%, $p < 0.01$), trophoblastic spreading area (0% vs. 12.5%, PC vs. 12.5%, $p < 0.01$) and morphological scoring of trophoblastic outgrowth (0% vs. 12.5%, PC vs. 12.5%, $p < 0.01$) and ICM (0% vs. 12.5%, $p < 0.01$).
Limitations, reason for caution: Findings in the mouse embryos were assessed only in vitro, not in vivo. Due to the nature of this work, this study was not fully transferable to humans.
Wider implications of the findings: Our study showed the extraction of EVs from outgrowth embryos was successful, and our study is reassuring in what kind of factors exists in EVs-QAMB and investigating the biological mechanisms of EVs.
Study funding/competing interest(s): Funding by national/international organization(s) – This work was supported by a grant of the Korea Healthcare Technology R&D Project, Ministry of Health and Welfare (A120043).
Trial registration number: EUIACUC 13-18.
Keywords: pre-implantation embryo, peri-implantation embryo, extracellular vesicles, outgrowth embryo, developmental competence

P-209 A historical cohort study to investigate the relation between blastomere survival and mitosis resumption in frozen-thawed embryo's and ongoing pregnancy

J. D. N. Diaz de Pool[1], G. S. K Pilgram[1], L. A. J. Van Der Westerlaken[1]
[1]*LUMC, Gynaecology, Leiden, The Netherlands*

Study question: What is the association between frozen-thawed embryo morphological characteristics (FEMC: blastomere survival and mitosis resumption) and ongoing pregnancy (OP), when adjusted for potential confounders belonging to embryo morphological characteristics before cryopreservation, maternal characteristics and cycle influences. In addition we investigated whether FEMC are also predictors of OP.
Summary answer: Mitosis resumption is positively associated with OP. After adjustment of mitosis resumption for embryo morphologic characteristics before cryopreservation, the association with OP no longer existed. Therefore mitosis resumption is not an independent predictor of OP. Adjusting for the other confounders did not alter the association between FEMC and OP.
What is known already: Frozen-thawed embryo transfers (FETs) have a reduced pregnancy rate compared to fresh embryo transfers. Next to FEMC, embryo characteristics before cryopreservation (number of blastomeres and embryo quality), maternal characteristics (age, cause of infertility and pregnancy history) and cycle influences (type of stimulation, number of attempts, number of oocytes and embryo availability) influence the chance on OP. Adjusting for these confounders to assess whether FEMC are true predictors of OP has not been performed before.
Study design, size, duration: In this historical cohort study, 1242 first unique single FETs in our database between 2001 and 2012, consisting of 1242 patients who underwent in vitro fertilization treatment, were analyzed. This approach was used to prevent overestimation of the results by individuals appearing more than once in the dataset.
Participants/materials, setting, methods: Patients at Leiden University Medical Center, whose embryos were cryopreserved 72 h after oocyte retrieval and cultured overnight prior to FET were included. To assess the association between FEMC with OP an association model was built. FEMC were also evaluated as OP predictors using univariable and multivariable logistic regression analysis.
Main results and the role of chance: There was a significant ($P < 0.001$) positive association (OR 2.15, 95% CI 1.5–2.97) of mitosis resumption and OP in the univariable logistic regression analysis. Blastomere survival was not associated ($P = 0.26$) with OP. After adjustment of mitosis resumption for number of blastomeres after overnight culture, the association ($P = 0.86$) with OP no longer existed. This study shows that the number of blastomeres after overnight culture is the only embryo characteristic that serves as an independent predictor of OP. As a result of mitosis resumption, which results in an increased number of blastomeres, the latter becomes an independent predictor.
Limitations, reason for caution: In contrast to other studies we were unable to identify a significant association between blastomere survival and OP. In our database blastomere survival was divided into 4 groups: 0%, >0%–<50%, >50%–<100% and 100%. Splitting those groups in subgroups might give more accurate results. We adapted our database for future studies.
Wider implications of the findings: Our findings may contribute to cost-effectiveness studies to increase the efficiency of FETs. E.g., cancelation of transfers with <8 blastomeres, would almost halve ($N = 615$) the number of transfers while losing 25% ($N = 44$) OPs. A cut off point for the number of blastomeres at time of FET might be determined. Thawing another embryo if available may reduce the time to pregnancy in such cases.
Study funding/competing interest(s): Funding by University(ies) – Leiden University Medical Center.
Trial registration number: No Trial registration number.
Keywords: cryopreservation, blastomere survival, mitosis resumption

P-210 Intracytoplasmic sperm injection (ICSI) outcome versus intracytoplasmic morphologically selected sperm injection (IMSI) outcome according to male age: a retrospective trial

M. A. Tufekci[1], M. M. Basar[1] H. Yelke[1], S. Kahraman[1]
[1]*Memorial Hospital Sisli, IVF Center Laboratory, Istanbul, Turkey*

Study question: Is there any difference between IMSI and ICSI in terms of IVF outcomes in selected infertile patient population in according to male ages?
Summary answer: A trend towards improvement in IVF outcomes was detected in all male age subgroups when IMSI was applied. The subgroup analyses according to male age did not show a statistical difference between ICSI and IMSI. Our results show that the IMSI technique slightly but not significantly improves IVF outcomes in a selected infertile population
What is known already: It was known that selection of vacuole-free spermatozoa by IMSI under high magnification (X6400) may have a positive impact on IVF outcome in severe male infertility factor or repeated pregnancy failure cases. In some studies reported that there is no significant clinical improvements with IMSI in an unselected patient population (with various aetiologies of infertility and with and without previous ICSI failures).
Study design, size, duration: Retrospectively 4022 cycles (1399 ICSI and 2623 IMSI) were included from July 2011 to July 2014. The study was approved by the local Institute Review Board.
Participants/materials, setting, methods: Patients with any of leucospermia, orchiopexy/undescended testis, genetically problems and chemotherapy/radiotherapy and for women age >40, BMI >30, genetically problems and chemotherapy/radiotherapy were excluded from the study. Patients separated four group as <30, 30–35, 36–39 and >40-years old according to male ages.

Main results and the role of chance: ICSI vs IMSI groups were comparable when considering (+) βhcG (ICSI: 49.7%; IMSI: 56.2%, $p < 0.0001$), clinical pregnancy rate (ICSI: 45.5%; IMSI: 51.1%, $p < 0.0001$), ongoing pregnancy rate (ICSI: 38.5%; IMSI: 45.0%, $p < 0.0001$) and miscarriage rate (ICSI: 13.3; IMSI: 12.0%, $p = 0.82$) in overall. However, in the subgroup analyses there were an increase in the mean of (+)βhcG, clinical pregnancy rate, ongoing pregnancy rate, but slightly decrease in miscarriages in IMSI groups compared to ICSI groups, but not statistically significant. A trend towards improvement in IVF outcomes was detected in all male age subgroups when IMSI was applied.
Limitations, reason for caution: Retrospective study. Take home baby rate should be giving.
Wider implications of the findings: Our results show that a nonsignificant trend towards higher pregnancy and lower misscarriages rates in the IMSI group than in the ICSI group in according to male age. IMSI seems to be an expensive and time-consuming procedure, depending on the degree of sperm morphology impairment and the number of oocytes to be injected, so it is should be better to apply only selected patients.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Memorial Sisli Hospital IVF Clinics.
Trial registration number: NA.
Keywords: ICSI, IMSI, ART, male Age

P-211 Differences in morphokinetic parameters and clinical outcomes between IMSI and ICSI-derived embryos by time-lapse imaging

H. J. Kim[1], H. J. Yoon[1], J. M. Jang[1], H. J. Yoon[1], W. D. Lee[2], S. H. Yoon[3], K. H. Kim[3], Y. J. Kang[3], J. H. Lim[3]
[1]Maria Fertility Clinic, Research, Seoul, South Korea
[2]Maria Fertility Clinic, Ob/Gyn, Seoul, South Korea
[3]Maria Research Center, Maria Medical Foundation, Seoul, South Korea

Study question: The aim of this study was to evaluate the efficiency of the intracytoplasmic morphologically selected sperm injection (IMSI) technique compared with conventional ICSI.
Summary answer: No correlation has been found between morphokinetic variables. However, Compared to conventional ICSI, this study found that IMSI increased the IVF-ET success rates in patients with oligoasthenoteratozoospermia (OAT).
What is known already: Many studies have reported that the presence of large nuclear vacuoles in the spermatozoa is associated with reduced fertilization, pregnancy rates, and with an increased risk of miscarriage. IMSI treatment results in higher success rates compared to conventional ICSI treatment. However, it is unknown whether this difference is linked to embryo morphokinetic.
Study design, size, duration: Retrospective analysis of fertilized embryos ($n = 506$, IMSI: 236 vs. ICSI: 270) were cultured in time-lapse incubator from June 2013 to August 2014. This study was performed in 101 cycles that had undergone ICSI treatment in the previous cycle for OAT infertility.
Participants/materials, setting, methods: The motile spermatozoa were analyzed under high magnification (6,600x) microscopy incorporating with modulation contrast illumination. Conventional ICSI was performed under an optical magnification of approximately 200 or 400×. All embryos were cultured after IMSI/ICSI assessed a time-lapse incubator (EmbryoScope, Unisense Fertilitech, Denmark) and annotated for pattern time of cleavage.
Main results and the role of chance: No significant differences were observed between groups for age, fertilization rate, good quality embryo rate and number of embryos transferred. There was not and significant differences were shown in embryo morphokinetics. The mean time-points for IMSI and conventional ICSI respectively were; (tPB2) 3.1 vs. 3.2, (tPNf) 24.1 vs. 24.6, (t2) 27.5 vs. 27.2, (t3) 36.8 vs. 36.5, (t4) 39.9 vs. 39.5, (t5) 49.9 vs. 49.2, (cc2) 8.4 vs. 9.0, (s2) 2.7 vs. 2.6. The pregnancy and implantation rates with IMSI were significantly higher than those of the ICSI cycles (36.5% vs. 15.6% and 16.3% vs. 7.8%, respectively; $p < 0.05$). The miscarriage rate among pregnant patients (12.8% vs. 28.1%) showed statistically significant difference between groups ($p < 0.05$).
Limitations, reason for caution: This retrospective study was conducted in a limited cohort of patients. Data set size is a limiting factor, making reliable statistical analyses difficult.
Wider implications of the findings: IMSI performed at high magnification such as 6,600x has the advantage of enabling the sorting of sperm with vacuoles in their heads or other defects that cannot be observed during conventional ICSI. The overall embryological parameters remain similar regardless of the between the two groups. However, clinical IMSI is an effective technique for IVF-ET with positive clinical outcomes such as better pregnancy and implantation rates than conventional ICSI.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Maria Fertility Hospital.
Trial registration number: We don't need to Trial registration number.
Keywords: IMSI, morphokinetic, time-lapse

P-212 The impact of embryo fragmentation and morphokinetic events within the first 48 h of culture on the rate of blastocyst formation

K. Nakayama[1], N. Fukunaga[1], H. Kitasaka[1], T. Yoshimura[2], F. Tamura[1], M. Katou[2], Y. Konuma[2], M. Kanayama[1], Y. Hattori[2], M. Kondou[1], Y. Wakahara[1], K. Kinoshita[3], Y. Yakushi[3], Y. Hashiba[3], Y. Asada[1]
[1]Asada Ladies Clinic Medical Corporation, Asada Ladies Nagoya Clinic, Nagoya, Japan
[2]Asada Ladies Clinic Medical Corporation, Asada Ladies Kachigawa Clinic, Kasugai, Japan
[3]Asada Ladies Clinic Medical Corporation, Asada Ladies Kachigawa Clinic, Ksugai, Japan

Study question: Does the degree of embryo fragmentation affect the rate of blastocyst formation?
Summary answer: The degree of fragmentation affects the rate of blastocyst formation. Fragmentation in the 4 cell stage embryo was the most important predictor of blastocyst formation.
What is known already: Findings of previous studies suggest that dynamic markers of viability improve blastocyst formation rates more than morphological grading. The results of studies on the affect of fragmentation on blastocycst formation are somewhat ambigious, as several reports have stated that fragments are resorbed into the blastomere.
Study design, size, duration: During the 1st quarter of 2013, 262 embryos were obtained by IVF from 41 cycles and cultured to day 7 without medium change in a Time-lapse Imaging system (EmbryoScope, Vitrolife).
Participants/materials, setting, methods: Outcomes were assessed by multiple logistic regression analyses with repeated measures. Logistic regression models were built to predict blastocyst formation as determined by fragmentation degree and time-lapse derived morphokinetic parameters. Independent predictors included degree of fragmentation at 2- and 4-cell stage, and multiple embryo events within the first 48 h of development. Statistically significant effects were determined at a $P < 0.05$ level.
Main results and the role of chance: The time-lapse variables as potential predictors of blastocyst development were degree of fragmentation at 4 cell-stage (OR; 2.928 95% CI; 01.794–4.781), duration of 3-cell stage (OR; 1.092 95% CI; 1.008–1.183) and time point of division to 2-cell (OR; 1.234 95% CI; 1.102–1.383).
Limitations, reason for caution: The study was a retrospective study.
Wider implications of the findings: These results suggest that the degree of fragmentation at the 4 cell stage is a relevant predictor of blastocyst formation and should be routinely measured.
Study funding/competing interest(s): Funding by hospital/clinic(s), None.

P-213 Gender Specific Selection of Individual spermatozoa by ICSI

Q. V. Neri[1], S. Cheung[1], Z. Rosenwaks[1], G. D. Palermo[1]
[1]Weill Medical College, Reproductive Medicine, New York, U.S.A.

Study question: Attempts to select spermatozoa of a specific chromosomal character for use in IUI and/or IVF may fail to produce the desired gender due to disparity in motility and fertilizing capacity. We questioned whether it is possible to pick up individual spermatozoa during ICSI to maintain the gender-specific specimen selection.
Summary answer: Gradient self-selection of spermatozoa is capable of providing X-bearing spermatozoon at 85.2% Y-bearing at 79.6%. Individual selection of spermatozoa post-enrichment maintained the gender proportion, as confirmed by in situ hybridization, and provides improved chances of generating the conceptus of the wished sex.

What is known already: Several techniques have been proposed to successfully select X- or Y-bearing spermatozoa. These include centrifugation methods and layering techniques, as well as the use of electrophoretic devices. The most effective method to date uses flow cytometry, capable of achieving selection of 90% for X- and 80% for Y-bearing spermatozoa. This method, however, is expensive and requires exposure of spermatozoa to a fluorescent dye.
Study design, size, duration: In a 19-month period, we processed ejaculates by gradient self-selection (GSS) and gradient self-selection plus (GSS+) prior to cytogenetic analysis. Single spermatozoa were aspirated by microtool from the selected and unselected aliquots and dispensed on a glass slide for cytogenetics.
Participants/materials, setting, methods: From six formulations of gradients, GSS and GSS+ carried out at 4°C were the most successful. GSS+, however, yielded lower spermatozoon concentrations. For consistency, we assessed chromosomes X, Y, 15, 16, 17 and 18 on at least 1000 cells and on individually isolated sperm cells.
Main results and the role of chance: In 15 samples with a concentration of $47.9 \pm 15 \times 10^6$/ml, 49.4 ± 5% motility and normal morphology, GSS method yielded 78.9% for X- and 75.0% for Y-bearing spermatozoa. When GSS+ was used, 85.2% X- and 79.6% Y-bearing fraction were obtained, albeit at concentrations under 1×10^6. For the single cell experiment, an ejaculate was processed for routine semen analysis and yielded 53.8% X- and 46.2% Y-bearing spermatozoa. After retrieving 10 individual spermatozoa from this original specimen, 6(60.0%) were found to be female and 4(40.0%) to be male. An aliquot of the specimen was subjected to GSS, obtaining 78.9% X- and 75.0% Y-bearing spermatozoa at 5- and 10×10^6 concentration, respectively. Finally, we individually retrieved 10 spermatozoa from each gender-specific fraction, resulting in 7(70.0%) for X- and 7(70.0%) for Y-cells.
Limitations, reason for caution: These observations aim at limiting interference of cell motility, natural competition, and functional cell integrity in a spermatozoa population purposely skewed in favor of the desired gender. Individual sperm selection may or may not maintain the gender-enriched proportion, unless gender-specific morphometric characteristics are integrated during selection of the cell.
Wider implications of the findings: Multi-gradient methods of spermatozoa self-selection offer the ability to offset the proportion of spermatozoa of the desired gender in an economical and safe manner. Individual retrieval of spermatozoa during an ICSI procedure is able to maintain the same proportion of gender-specific cells achieved by GSS. Single sperm sex selection may be enhanced by the identification of eventual morphometric characteristics distinctive of a sex-specific spermatozoon.

P-214 EGF-like growth factors improve in vitro maturation and embryo development by enhanced normal distribution of cortical granules and global DNA methylation

K. M. Juhn[1], J. Yoon[1], B. I. Shim[1], H. R. Kang[1], S. H. Yoon[1], Y. Ko[2], J. H. Lim[3]
[1]*Maria Research Center, Seoul, South Korea*
[2]*Korea University, Division of Biotechnology, Seoul, South Korea*
[3]*Maria Fertility Hospital, Seoul, South Korea*

Study question: The objectives of this study were (1) to examine whether epidermal growth factor (EGF)-like growth factors should be influence maturation rates and developmental competences and (2) to investigate the effects of EGF-like growth factor on distribution of cortical granules (CGs) and the DNA methylation changes at metaphase II stage.
Summary answer: (1) The maturation rate of mouse germinal vesicle (GV) oocytes was increased by EGF-like growth factors (amphiregulin: AR and epiregulin: EPI). (2) AR or EPI treatment increased the proportion of oocytes with normal CGs distribution and the global DNA methylation.
What is known already: It was reported that AR and EPI affect both in vitro maturation (IVM) of mouse immature oocytes and embryo development. However, little is known about how the AR and EPI relate to oocyte maturation and developmental competence. It has been demonstrated that distribution of CGs has been used as a criterion for the assessment of cytoplasmic maturation. Recently, a reduction in global DNA methylation of MII oocytes result in compromised in vitro developmental potential in mouse embryos (Liang et al., 2014).
Study design, size, duration: In this prospective experimental study, GV oocytes were randomly divided into three groups; IVM medium only (Control), IVM medium with AR, and IVM medium with EPI.
Participants/materials, setting, methods: (1) GV oocytes were matured in maturation medium with/without AR or EPI. Maturation, fertilization rate and embryo development were monitored. (2) CGs distribution in MII oocytes after IVM was stained with Lens culinaris agglutinin probe. The level of DNA methylation was examined by immunofluorescence staining using an anti-5-methylcytosine antibody.
Main results and the role of chance: (1) A total of 776 immature oocytes were cultured in vitro (control: 268; AR: 253; EPI: 255). The maturation rates were statistically higher in AR and EPI-treated groups than in control group (63.2%, 61.6% and 46.6%, respectively) ($P < 0.05$). There were no statistically differences in fertilization rates among groups. Only EPI groups (87.0%) were increased the blastocyst rates rather than control group (77.2%, $P < 0.05$). (2) The percentage of matured MII oocytes with normal distribution of CGs (appear as small granules linearly arranged under the oolemma) was high in the AR and EPI groups (78.8% and 75.5%, $P < 0.05$) as compare to the control group (61.8%). The density of global DNA methylation was significantly increased in AR and EPI-treated group ($p < 0.001$).
Limitations, reason for caution: The effect of AR and EPI can be tested reliably with mouse oocytes, yet the findings should be extended to the human oocytes with caution.
Wider implications of the findings: Our data suggested that AR and EPI are involved in oocyte maturation process. This finding may be applied to human IVM protocol, which is still a low-success rate in the clinical practice. The addition of AR and EPI to human IVM media may improve the outcome of human IVM cycles.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Maria Fertility Hospital.
Trial registration number: NA.

P-215 Effects of sperm insemination on final meiotic maturation of mouse oocytes arrested at metaphase I after *in vitro* maturation

J. Yoon[1], K. M. Juhn[1], B. I. Shim[1], H. R. Kang[1], S. H. Yoon[1], Y. Ko[2], J. H. Lim[3]
[1]*Maria Research Center, Seoul, South Korea*
[2]*Korea University, Division of Biotechnology, Seoul, South Korea*
[3]*Maria Fertility Hospital, Seoul, South Korea*

Study question: The aims of this study were (1) to investigate whether fertilization could induce the resumption of meiosis in mouse oocytes that are arrested metaphase I (MI) after *in vitro* maturation (IVM) and (2) to investigate the effect of calcium oscillation by fertilization on MI to MII transition.
Summary answer: (1) Higher proportions of arrested MI oocytes progressed MII by fertilization. Although the fertilization rates were similar, the blastocyst rates and live birth were significantly higher in MII oocytes than in MI oocytes. (2) Fertilization may induce MI oocyte maturation by calcium oscillation.
What is known already: During IVM, some oocytes arrested spontaneously at MI that unable to achieve MII even after prolonged culture. There were some reports that these arrested MI oocytes have similar sperm-induced calcium oscillation pattern with MII oocytes. Moreover, insemination of immature oocytes enhanced maturation rates in vitro. However, it is unknown whether (1) fertilization could induce the resumption of meiosis in arrested MI oocytes and these oocytes can lead to live birth (2) calcium oscillation may have influence on overcome the MI arrest.
Study design, size, duration: (1) MII (MII group) and arrested MI (MI group) mouse oocytes after IVM were fertilized with spermatozoa, and then assessed their maturity and developmental potency. (2) Arrested MI oocytes after IVM were treated with calcium chelator to investigate the effect of calcium oscillation driven by fertilization on MI to MII transition.
Participants/materials, setting, methods: (1) The embryonic development was monitored and cell numbers were counted. Blastocysts from each group were transferred into 2.5 dpc pseudo-pregnancy ICR mice using non-surgical embryo-transfer device. (2) Arrested MI oocytes were treated with calcium chelator and fertilized with sperm, then evaluated their maturity by monitoring of first polar body.

Main results and the role of chance: (1) As insemination time increased, the oocytes reached to MII stage in MI group also increased (5.5% at 2 h, 72.9% at 3 h, and 94.8% at 4 h, respectively). However, the spontaneous maturation rate of oocytes at the MI stage cultured for up to 4 h without sperm was 0.7%. There was no difference in fertilization rate between two groups. However, the blastocyst rates and the total cell numbers in MII group were significantly higher than those in MI group ($P < 0.05$). Ninety-six blastocysts of each group were transferred in 12 recipients. No pregnancy was obtained from MI group. However, 10 pregnancies were achieved (10/12, 83.3%) in MII group and the rate of live pups per transferred embryos was 32.3% (31/96). (2) The proportion of MI maturing to MII oocytes after fertilization was significantly higher in non-treated group (93.2%) compared with the 1 μM (3.0%) or 10 μM (1.2%) calcium chelator treated groups ($P < 0.01$).
Limitations, reason for caution: According to the previous report, arrested human MI oocyte was fertilized and developed to a healthy neonate who had a normal karyotype. However, in this study, no pregnancy was obtained from arrested mouse MI oocytes. Further investigations are needed to confirm this difference.
Wider implications of the findings: Although the oocytes in the MI group was fertilized and developed to the blastocyst normally, no pregnancy was obtained from MI group. It suggested that their developmental competence was lower than the MII group. Higher proportions of arrested MI oocytes progressed MII by fertilization. MI to MII transition was blocked by calcium chelator treatments before fertilization. This result indicated that MI oocytes maturing to MII after fertilization were related to the intracellular calcium oscillation driven by fertilization.

P-216 Sperm telomere length is positively associated with the quality of early embryonic development

Q. Yang[1], F. Zhao[1], N. Zhang[1], R. Bai[1], Y. Sun[1]
[1]*The First Affiliated Hospital of Zhengzhou University, Reproductive Center, Zhengzhou, China*

Study question: What is the relationship between telomere length in sperm and early embryonic development in *in vitro* fertilization (IVF)?
Summary answer: We provide the first report that sperm telomere length (STL) is positively associated with embryo quality in IVF. This suggests that STL plays an essential role in early embryonic development and that selecting sperm with longer telomeres might help us obtain good-quality embryos in assisted reproductive technology (ART).
What is known already: Previous studies have shown that sperm telomere STL differs among human males. However, little is known about whether STL is related to embryo quality and whether it is relevant in clinical pregnancy for IVF in ART.
Study design, size, duration: Patients undergoing IVF treatment from August 2013 to August 2014, we analyzed the associations between STL, fertilization laboratory parameters and clinical pregnancy using Pearson's correlation, partial Pearson's correlation or multiple linear regression, as appropriate.
Participants/materials, setting, methods: We used quantitative PCR technique to detect the mean STL in 418 couples undergoing IVF treatment.
Main results and the role of chance: The mean STL was positively correlated with age of patient and total sperm count/ejaculate Analysis of the age-adjusted mean STL in relation to the male patient's paternal and maternal ages at the time of conception showed a significant positive relationship between STL and both paternal and maternal age. But, the relative contribution of paternal age at conception to the patient's STL was great than that of maternal age analyzed by multivariable linear regression. In addition, significant correlations were found between STL and good quality embryo and transplantable embryorates, but clinical pregnancy rate was not affected.
Limitations, reason for caution: This is the first study report that that STL is positively associated with embryo quality in IVF. Additional studies are needed to confirm these observations, and the methods selecting sperm with longer telomere effectively need to be exploited in the future.
Wider implications of the findings: Sperm telomere length may be as a indicator of early embryonic development.
Study funding/competing interest(s): Funding by national/international organization(s) – National Natural Science Foundation of China, and the National Science Foundation for Young Scientists of China.

P-217 Morphokinetic differences between bovine blastocysts cultured in media supplemented with human serum albumin or recombinant human albumin

M. Murakami[1], D. K. Gardner[2], T. Kuramoto[3]
[1]*Kuramoto Women's Clinic, Research Laboratory, Fukuoka, Japan*
[2]*The University of Melbourne, School of BioSciences, Melbourne, Australia*
[3]*Kuramoto Women's Clinic, Clinical Department, Fukuoka, Japan*

Study question: A bovine model was used to compare the morphokinetics between matured oocytes fertilised/cultured in conventional commercial media supplemented with human serum albumin (HSA) or recombinant human albumin (rHA).
Summary answer: The HSA group took longer to reach the 9-cell stage from insemination, but reached the compact morula stage from the 9-cell stage and the start of blastulation from the compact morula stage faster than the rHA group. The blastocyst yield and time from insemination to blastocysts were similar between groups.
What is known already: HSA, a common protein source in ART, can contribute to biological variation and disease transmission. Using rHA can reduce these risks, but the extant literature is limited. We previously reported that replacement of HSA supplemented during culture with lower amounts of rHA produced good-quality bovine blastocysts (ESHRE 2014). On the other hand, studies have shown that the presence of whole serum during culture causes altered morphokinetics of mammalian embryos (e.g., impaired compaction and premature blastulation).
Study design, size, duration: Bovine oocytes were collected from abattoir ovaries and matured in defined media. Matured oocytes were randomly divided into 2 groups and fertilised/cultured in media containing HSA or rHA. Morphokinetics were evaluated from the start of insemination to the blastocyst stage (day 8) by time-lapse microscopy (Vitrolife) ($n = 416$, 13 trials).
Participants/materials, setting, methods: Oocytes underwent conventional IVF (with sperm from a bull) in G-IVF medium containing 10 μg/mL HSA or 1 μg/mL rHA, and were cultured in G1/G2 media containing 5 μg/mL HSA or 0.5 μg/mL rHA. Morphokinetics of good-quality blastocysts (expanded [diameter >160 mm], <50% fragmentation at the morula stage) were analysed.
Main results and the role of chance: Good-quality blastocyst rates were similar for the HSA (31/208, 14.9 ± 3.2%) and rHA (40/208, 19.2 ± 2.5%) groups. The HSA group took longer ($P < 0.01$) to reach the 9-cell stage from insemination than the rHA group (98.9 ± 1.2 h vs. 92.9 ± 1.3 h). Conversely, the HSA group showed shorter ($P < 0.0001$) times from the 9-cell stage to compact morula (26.5 ± 0.9 h vs. 32.2 ± 0.8 h) and from the compact morula to the start of blastulation (20.6 ± 1.0 h vs. 29.2 ± 0.9 h). Typically, the compact morula was tighter in the rHA group. Overall, the times to reach full blastocysts (blastocoel completely filling the embryo) from insemination were similar for the HSA (160.2 ± 1.9 h) and rHA (164.0 ± 1.9 h) groups, which were slightly shorter than the estimated time for in vivo-derived bovine blastocysts (7–8 days).
Limitations, reason for caution: HSA supplementation during culture may retard the precompaction development of bovine embryos, affect compaction, and trigger premature blastulation. However, to confirm this possibility, further studies, including comparisons of morphokinetics and gene expression between the in vivo-derived embryos and in vitro-produced embryos in the presence of HSA or rHA, are warranted.
Wider implications of the findings: To our knowledge, this is the first study to illustrate clear differences in morphokinetics between mammalian blastocysts cultured in conventional (HSA) and defined (rHA) media. Based on our results, we are currently investigating the yield, morphokinetics, and pregnancy rate after ET of human blastocysts cultured with HSA or rHA in clinical settings. These investigations will aid in the development of standardised and defined ART systems to eliminate the variation and risks associated with blood-derived products.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Kuramoto Women's Clinic.

P-218 Day 3 embryos release intact mitochondrial DNA into the surrounding culture medium

E. R. Hammond[1], M. D. VerMilyea[2], L. Chamley[1], L. M. Cree[1]
[1]*University of Auckland, Department of Obstetrics and Gynaecology, Auckland, New Zealand*
[2]*Fertility Associates, Auckland, Auckland, New Zealand*

Study question: Do day 3 embryos release intact mitochondrial DNA (mtDNA) into the surrounding culture medium?
Summary answer: 60 percent of day 3 embryos release detectable levels of intact mtDNA into the surrounding culture medium.
What is known already: Recent evidence suggests that human embryos release mtDNA into the surrounding culture medium, and that this process may be modulated by embryo quality. Previous studies have confirmed the presence of short mtDNA fragments in the embryo culture medium, but no study has assessed whether the mtDNA released by day 3 embryos is intact or is largely fragmented or deleted.
Study design, size, duration: 48 individually cultured embryos from 12 patients were analysed for the presence of intact mtDNA in day 3 culture medium droplets (20 ml), along with controls. Embryos were cultured to day 5 using a sequential culture medium protocol and day 3 medium was analysed for the presence of intact mtDNA.
Participants/materials, setting, methods: To confirm the presence of the entire mtDNA genome, a long range PCR protocol was developed for the detection of low template mtDNA, and targeted to a 15 kb fragment encompassing the entire mitochondrial genome and a 2 kb fragment encompassing the ND2 and COX1 gene in purified embryo culture medium.
Main results and the role of chance: The 2 kb mtDNA fragment was detected in 85% of day 3 embryo culture medium samples. The entire mtDNA genome was detected in 60% of day 3 embryo culture medium samples, and was absent in culture medium control droplets, suggesting that the mtDNA was released from the embryo rather than originating from contamination during the culture period. mtDNA deletions were detected in only 2% of embryo culture medium samples, suggesting that the embryo may not preferentially release damaged mtDNA. The high percentage of intact mtDNA detected in culture medium samples suggests that the release of the entire mitochondrial genome may be a normal phenomenon occurring in day 3 embryos.
Limitations, reason for caution: Data is from a preliminary study that is limited by a small sample size.
Wider implications of the findings: Results presented in this study support previous reports that day 3 embryos release mtDNA into the surrounding culture medium. For the first time, the current study shows that embryos release the entire mitochondrial genome into the surrounding culture medium. It is possible that the presence of intact mtDNA in the embryo culture medium may relate to embryo quality on day 3 or be predictive of blastocyst quality, where this should be elucidated in a larger cohort.
Study funding/competing interest(s): Funding by national/international organization(s) – Auckland Medical Research foundation.
Trial registration number: NA.

P-219 Peroxiredoxin 4, a new oxidative stress marker in follicular fluid may predict IVF outcomes

Y. Qian[1], L. B. Cai[1], C. Y. Jiang[1], Y. G. Cui[1], J. Y. Liu[1], Y. Meng[1]
[1]*The First Affiliated Hospital of Nanjing Medical University, The State Key Laboratory of Reproductive Medicine, Nanjing, China*

Study question: For better predicting *in vitro* fertilization (IVF) outcomes, it is necessary to identify some non-invasive and sensitive markers.
Summary answer: Our results provide evidence that the upregulated expression of antioxidants in IVF patients follicular fluid (FF), such as peroxiredoxin4 (Prdx4), tend to increase the potential pregnancy via oocyte quality mechanism.
What is known already: Studies indicated that oxidative stress status in patients was closely associated with IVF outcomes, while the results are still controversial. Prdx4 as one member in Prdx family, can catalyze the reduction of reactive oxygen species. While little data on the relationship of Prdx4 and female reproduction were demonstrated.
Study design, size, duration: Our study is a prospective clinical study. All participants were recruited in the center of clinical reproductive medicine from September 2013 to December 2014. Infertile women with either tubal factor or male factor (n = 85) and polycystic ovary syndrome (PCOS) patients (n = 85) undergoing controlled ovarian hyperstimulation and IVF were recruited in our study.
Participants/materials, setting, methods: FF samples from patients were collected on the day of oocyte collection and then centrifuged and frozen up for analysis. Prdx4 concentration in FF was measured in each participant. Furthermore, the correlation between Prdx4 level and IVF outcomes, such as clinical pregnancy rate and oocyte quality was analyzed.
Main results and the role of chance: In both control and PCOS groups, pregnant women had higher levels of Prdx4 in FF than non-pregnant women. Prdx4 was also positively correlated with oocyte fertilization rates (r = 0.326; p = 0.013) and good quality embryo rates (r = 0.334; p = 0.011).
Limitations, reason for caution: A larger study should be conducted in order to investigate whether follicular fluid Prdx4 levels are correlated with good quality embryo rates and pregnancy outcomes. Moreover, the role of Prdx4 on oocyte and embryo quality should be studied to determine whether low Prdx4 concentration in FF is only a consequence or also a cause of follicular dysfunction.
Wider implications of the findings: Prdx4 evaluation in individual FF samples might represent an innovative biomarker of embryo quality to use as a supplemental tool to predict oocyte and embryo quality during IVF.
Study funding/competing interest(s): Funding by University(ies), Funding by national/international organization(s) – The present work was supported by grants from China 973 Program (2012CB944703, 2012CB944702), the National Science Foundation of China (81200439) and the Graduate Students Scientific Research Innovation Plan of Jiangsu Higher Education Institutions.
Trial registration number: Not an RCT.

P-220 Cumulative live birth rate in conditions where according to the restrictive law only up to 3 oocytes could be inseminated per cycle

P. Stanic[1], V. Hlavati[1], N. Gelo[1], G. Kirinec[1], D. Pavicic-Baldani[1], M. Sprem-Goldstajn[1], B. Radakovic[1], M. Kasum[1], M. Strelec[1], V. Simunic[1], H. Vrcic[1]
[1]*University Hospital Centre Zagreb, Department of Gynecology and Obstetrics, Zagreb, Croatia*

Study question: The purpose of this study was to examine the cumulative live birth rates of infertile couples, where according to the restrictive legal conditions only a limited number of oocytes (up to 3) could be inseminated per cycle.
Summary answer: Our results indicate that acceptable cumulative live birth rates of infertile couples can be obtained in conditions where according to the restrictive law only a limited number of oocytes could be inseminated per cycle.
What is known already: Cryopreservation allows expanding the options available to infertile couples. Oocyte cryopreservation has become increasingly available as an option for fertility preservation. During the last few years oocyte cryopreservation has become more successful contributing to the cumulative live birth rates. The transfer of cryopreserved embryos and oocytes increases the cumulative success rates after a single IVF stimulation.
Study design, size, duration: This retrospective cohort study included 148 stimulated cycles performed between May 2010 and December 2011. The subsequent 82 cycles with warmed oocytes and 20 frozen embryo transfers were done till March 2014.
Participants/materials, setting, methods: Metaphase II oocytes and embryos were vitrified according to Cryotop protocol. If pregnancy was not obtained during stimulated cycle a subsequent ICSI cycle was done with warmed oocytes. Also, if embryo transfer was not performed during stimulated cycle a frozen embryo transfer was done in subsequent natural cycle.
Main results and the role of chance: The mean numbers of aspirated oocytes and embryos transferred per patient during stimulated cycles were 9.12 ± 3.06 and 2.11 ± 0.62, respectively. In the fresh cycles, the clinical pregnancy and live birth rates obtained were 32.5% and 23.6%, respectively. The mean numbers of warmed oocytes and embryos transferred per patient were 3.04 ± 1.14 and 1.68 ± 0.71, respectively. The clinical pregnancy and live birth rates per embryo transfer obtained with vitrified oocytes were 16% and 10%, respectively. The mean number of frozen embryos transferred was 1.75 ± 0.55. The clinical pregnancy and live birth rates obtained with frozen embryo transfer were 60% and 50%, respectively. The cumulative pregnancy rate and live birth rate observed per started stimulated cycle was 42.5% and 31%, respectively.

Limitations, reason for caution: Results are specific and limited due to our restrictive law in that period - maximum of 3 oocytes per infertile couple were fertilized. Also, if embryo transfer was not performed during stimulated cycle in cases of ovarian hyperstimulation syndrome, endometrial polyp or hydrosalpinx a frozen embryo transfer was done in subsequent natural cycle.
Wider implications of the findings: Our results indicate that contribution of oocyte vitrification procedure followed by ICSI to cumulative live birth rate is inferior to fresh insemination procedure and frozen embryo transfer. Cumulative live birth rates from oocyte collections may provide the most relevant index of success.
Study funding/competing interest(s): Funding by hospital/clinic(s) – University Hospital Centre Zagreb, Croatia.
Trial registration number: NA.

P-221 Comparison of the clinical outcomes following the transfer of blastocysts vitrified at day 5 and day 6

J. M. Jang[1], I. H. Bae[1], H. J. Yoon[1], H. J. Kim[1], W. D. Lee[2], S. H. Yoon[3], J. H. Lim[3]
[1]*Maria Fertility Hospital, Clinical Research, Seoul, South Korea*
[2]*Maria Fertility Hospital, Clinical Hospital, Seoul, South Korea*
[3]*Fertility Research Center, Maria Medical Foundation, Seoul, South Korea*

Study question: The aim of the present study was to compare the clinical outcomes following the transfer according to the day (day 5 versus day 6) of vitrification.
Summary answer: In both blastocysts transfer of vitrified at day 5 and day 6 groups, the implantation and ongoing pregnancy rates were not statistically significant differences. The surplus day 6 blastocysts available for vitrification compromise to enhance the chance of pregnancy per oocytes retrieval and improve the cumulative pregnancy rate.
What is known already: The day 5 blastocysts include early blastocysts tends to result in higher pregnancy rates than day 6 blastocysts in the fresh cycle. However, in the thawed cycle, the blastocysts vitrified on day 5 and day 6 had the same morphological quality at the time of freezing showed no difference in clinical and ongoing pregnancy rates. The vitrification of the delayed blastocysts on day 6 reduces the embryo wastage and increases the cumulative pregnancy rate.
Study design, size, duration: The study was retrospectively 541 cycles (day 5 group: 334 and day 6 group: 207) analyzed from blastocyst transfers between January 2009 and April 2012. A total of 1292 embryos were vitrified-thawed and 1076 embryos were transferred.
Participants/materials, setting, methods: The surplus day 5 and 6 embryos were vitrified by EM-grid following artificial shrinkage. The equilibrium (EG20) and vitrification (EFS40) solutions were prepared, and embryo thawing was performed by a two-step dilution method. The thawed embryos were cultured overnight and survived embryos were transferred into the patient's uterine cavity.
Main results and the role of chance: The implantation and clinical pregnancy rates per transfer did not differ in the day 5 group (29.6% and 35.0%, retrospectively) compared with the day 6 group (24.2% and 28.0%). The corresponding ongoing pregnancy rate was 53.0% (62/117) in the day 5 group, and 51.7% (30/58) in the day 6 group, retrospectively ($p = 0.874$). The percentage of multiple pregnancy rate was not different between the two groups (33.9% versus 20%, $p = 0.171$). The number of transferred embryos in the vitrified blastocysts in the day 5 and the day 6 was 1.97 and 2.01 and the average of female age was 32.72 and 32.97, retrospectively, there were no significant differences.
Limitations, reason for caution: This is a relatively small study and the results are required large study population. The study of comparison was limited by the differences sample size in two groups.
Wider implications of the findings: The results showed the vitrified blastocysts on day 5 and day 6 lead to similar clinical outcomes when replaced in thawed embryo transfer cycles. The delayed day 6 blastocyst development does not influence the implantation and ongoing rates of vitrified-thawed transfer. Consequently, the vitrified-thawed day 6 blastocysts would be transferred in subsequent cycles to contribute to increasing cumulative pregnancy rates.

P-222 Comparative time lapse imaging of embryos obtained after oocyte in vitro maturation (IVM) in two different IVM media

I. Segers[1], L. Guzman[2], G. Cauffman[1], H. Van de Velde[1], J. Smitz[2], M. De Vos[1], G. Verheyen[1]
[1]*UZ Brussel, CRG, Jette Brussels, Belgium*
[2]*Vrije Universiteit Brussel, EMGE-FOBI, Jette Brussels, Belgium*

Study question: Are there any differences in efficiency of oocyte maturation between two IVM media and is the timing of embryo cleavage divisions after oocyte IVM altered when comparing two different IVM media with standard ICSI (control).
Summary answer: Overall, both IVM media were comparable in terms of oocyte maturation rate, fertilization rate and embryo utilization rate. Top quality embryos were obtained in both media. Embryo kinetics after IVM in two different media were similar, but cleavage after the 4-cell stage was delayed when compared with standard ICSI.
What is known already: Non-hCG triggered oocyte IVM is particularly useful in women diagnosed with PCO(S) in order to avoid the risk of OHSS. Recently high maturation rates after oocyte IVM (69.7%; Junk et al., 2012) were reported using blastocyst medium for IVM with subsequently good embryo development. The availability of time lapse (TL) monitoring offers new insights in embryological development, although the predictive power of implantation potential by using TL monitoring is still under debate.
Study design, size, duration: Between January and April 2013, 27 PCO(S) patients were recruited for 29 IVM cycles. 473 sibling COCs were incubated in one of two IVM media. Retrospective TL analysis (Embryoscope; Fertilitech) was performed on 45 'Medicult-IVM' and 38 'BlastoCook-IVM' embryos and compared with 54 standard ICSI embryos.
Participants/materials, setting, methods: IVM media were: 'Medicult-IVM' containing Medicult IVM system (Origio) plus HSA, FSH, hCG and 'BlastoCook-IVM' containing Blastocyst medium (Cook) plus protein supplement, FSH, hCG. After 28 h, mature oocytes were inseminated and cultured 3 days in Quinn's Advantage Cleavage medium (Sage) in the Embryoscope. Statistics were performed using Wilcoxon and ANOVA + Tukey.
Main results and the role of chance: In 'Medicult-IVM' and BlastoCook-IVM' maturation rates were 37.3% and 35.2% (NS), fertilisation rates 57.4% and 59.7% (NS), utilisation rates of day 3 embryos 50.0% and 48.7% (NS) and top quality rates 18.1% vs. 34.9% ($p = 0.06$; Wilcoxon signed rank test). Normally fertilised embryos were analysed for cleavage timings. No differences were recorded after IVM in the two IVM media. Compared to control embryos, extrusion of the second polar body was slower in embryos generated with 'Medicult-IVM' (4.2 h vs. 3.4 h in control, $p = 0.03$), division to 5-cell was slower in embryos generated with 'BlastoCook-IVM' (53.1 h vs. 47.3 h; $p = 0.005$) and division to 6-cell appeared slower in embryos from both IVM media (53.1 h in 'Medicult-IVM' and 54.4 h in 'BlastoCook-IVM vs. 48.8 h in control $p = 0.001$; ANOVA + Tukey).
Limitations, reason for caution: The number of embryos for TL analysis in this study is too limited to analyse pregnancy rates. The optimal control group for TL would be embryos generated in standard ICSI cycles of PCO(S) women, as they show a delay in timing of embryonic development compared to non-PCO(S) women.
Wider implications of the findings: Although the use of blastocyst medium for IVM has been reported to generate high rates of mature oocytes, this value was not confirmed by our data. Not the same blastocyst medium has been used in our study and patient serum was averted due to its undefined nature. Oocyte IVM delays embryonic cleavage divisions and possibly contributes to the currently lower live birth rates obtained after IVM compared to standard ICSI.

P-223 Blastocyst versus day 2–3 transfer in ICSI cycles for male factor infertility: a multicenter randomized controlled trial

S. H. Gaafar[1], I. El Fourtia[2], S. El tawil[2], D. El Guiziry[3], H. El Maghraby[1]
[1]*Alexandria University, Obstetrics and Gynecology, Alexandria, Egypt*
[2]*Misrata National Center for Infertility, Obstetrics and Gynecology, Misrata, Libya*
[3]*Alexandria University, Clinical pathology, Alexandria, Egypt*

Study question: What is the effect of extended embryo culture till day 5 in cases suffering from male factor infertility on clinical pregnancy rate?
Summary answer: Blastocyst transfer in cases suffering from male factor infertility resulted in significant increase in clinical pregnancy rate and insignificant decrease in abortion rate.
What is known already: A recent meta-analysis concluded that implantation and pregnancy rates are improved and abortion rates are decreased following blastocyst transfer as compared to cleavage stage embryos. However, in male factor infertility the evidence is still insufficient to recommend blastocyst transfer in these cases.
Study design, size, duration: Single blinded prospective multicenteric randomized controlled trial. 326 participates were randomized for day 2/3 or day 5 transfer. Randomization was done by computer permuted blocks size of 4, allocation by closed envelops, parallel technique. The study was conducted between June 2013 and March 2014.
Participants/materials, setting, methods: 400 couples suffering of male factor agreed to participate in the study of which 326 were eligible. Long agonist protocol was used and ICSI was done. 126 cases had day 2/3 transfer and 126 had blastocyst transfer. Primary outcome was clinical pregnancy rate. Secondary outcome was abortion rate.
Main results and the role of chance: There were insignificant difference between both groups regarding the number of retrieved oocytes, fertilization and cleavage rates and day 2 class A embryos. There was significant increase in the clinical pregnancy rates in the blastocyst group as compared to the cleavage stage group (60% vs. 35%) $p < 0.01$. The abortion rate was insignificant lower in the blastocyst group as compared to day 2/3 group (16% vs. 27%) $p = 0.237$
Limitations, reason for caution: The study only included fresh transfers and adding the data of cryopreserved embryos may affect the cumulative pregnancy rates in both groups. In addition the study was not extended to detect live birth rates as literature proved improvement in live birth rate after blastocyst transfer.
Wider implications of the findings: Infertility etiology as male factor is an important variable that should be considered when deciding the timing of transfer. Individualized policy for embryo transfer regarding timing, number of embryos and fresh or frozen cycles is mandatory to improve implantation and pregnancy rates. Blastocyst transfer should be the first choice in fresh cycles and further studies are needed to compare cumulative pregnancy rates as in cleavage stage embryos usually there are more embryos available for cryopreservation.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Alexandria ICSI – IVF Center, Egypt, Misrata National Center for Infertility, Libya.
Trial registration number: PACTR201308000581376.

P-224 Ultrastructural assessment of human metaphase II oocytes after cryopreservation with media containing different macromolecular supplements

L. De Santis[1], G. Macchiarelli[2], E. Gismano[1], B. Iussig[1], E. Rabellotti[1], I. Cino[1], G. Intra[1], M. Candiani[3], S. A. Nottola[4]
[1]*San Raffaele Scientific Institute, Department of Ob/Gyn, IVF Unit, Milan, Italy*
[2]*University of L'Aquila, Department of Life Health and Environmental Sciences, L'Aquila, Italy*
[3]*San Raffaele Scientific Institute, Department of Ob/Gyn, Milan, Italy*
[4]*Department of Anatomy Histology Forensic Medicine and Orthopaedics, "La Sapienza" University, Rome, Italy*

Study question: To verify whether type and concentration of protein supplement included in freezing solutions affect the ultrastructure of human metaphase II (MII) oocytes cryopreserved by slow cooling and therefore optimize cryopreservation conditions.
Summary answer: This study confirms: (1) slow freezing ensures good preservation of the oocyte; (2) premature cortical granules (CG) exocytosis and vacuolization are both markers of cryodamage; (3) prolonged culture before cryopreservation may cause enlargement of mitochondria-vesicle (MV) complexes. Furthermore serum supplementation induces good preservation of the ooplasm avoiding extensive vacuolization.
What is known already: Cryoprotective agents (CPAs) are essential components in freezing solutions, but may also disrupt the meiotic spindle and organelles. Together with conventional CPAs, protein supplement is known to preserve cell structure. CG exocytosis requires a healthy plasma membrane and cytoskeleton. This process may be affected by cryopreservation as a result of shrinkage during CPA addition leading to subjacent localization of cortical granules and resulting in release of their contents because of plasma membrane fusion after rewarming.
Study design, size, duration: Forty supernumerary MII oocytes were donated by consenting patients (aged 28–36) enrolled in an IVF program. Thirty-four oocytes were cryopreserved using slow freezing with 0.2M sucrose, 1.5M 1–2 propanediol (PROH) and either serum or Plasma Protein Solution (PPS) in the freezing mixture. Six oocytes were used as fresh controls.
Participants/materials, setting, methods: Oocytes were cryopreserved with 20% ($n = 12$) and 10% ($n = 10$) serum or 10% PPS ($n = 12$). Samples were fixed by 2 h after thawing and prepared for light and transmission electron microscopy (LM and TEM) for ultrastructural analysis of CG, mitochondria-smooth endoplasmic reticulum aggregates (M-SER) and vacuolization.
Main results and the role of chance: By LM, both control and cryopreserved oocytes appeared rounded and with uniform distribution of organelles. By TEM, M-SER and small (MV) complexes were the most numerous structures found in all oocytes. Only in a few cryopreserved oocytes, irrespective of macromolecular supplement, numerous large MV complexes were found, probably due prolonged culture (3–4 h) before cryopreservation. Amount and density of CG appeared abnormally reduced in all samples. Different degrees of vacuolization were present in the ooplasm of cryopreserved, but not fresh oocytes. Extensive vacuolization was present only in a minority of oocytes cryopreserved with serum (16.6% of the oocytes supplemented with 20% serum and 20% of the oocytes supplemented with 10% serum), whereas a higher number (66.6%) of oocytes supplemented with 10% PPS were largely vacuolized.
Limitations, reason for caution: Although the interest raised by the investigation of which macromolecular supplement gives best results in terms of ultrastructural preservation of oocyte quality and integrity, this study should be extended in order to verify this finding in clinical routine.
Wider implications of the findings: This approach can be considered of interest for different cryopreservation methods extensively adopted in assisted reproductive treatments. In fact, the matter of protein supplement in different formulations and concentrations is still debated both for culture media supplementation and vitrification solutions.
Study funding/competing interest(s): Funding by hospital/clinic(s) – San Raffaele Scientific Institute, Milan, Italy.
Trial registration number: NA.

P-225 Day 3 low quality embryos can develop to blastocysts and produce pregnancies: A retrospective study

E. López Bejarano[1], M. Hebles Dúvison[1], M. Dorado Silva[1], M. Gallardo Molina[1], B. Migueles Pastor[1], L. Aguilera Dúvison[1], M. González Martínez[1], F. Sánchez Martín[1], P. Sánchez Martín[1]
[1]*Ginemed, Embryology, Seville, Spain*

Study question: Can day three embryos of low quality, which would usually be discarded, develop into blastocysts and produce a pregnancy?
Summary answer: The culture of these low quality embryos to blastocyst stage allows us to recover and freeze some embryos that would have otherwise been discarded. When transferred in a posterior frozen cycle, these embryos can produce a pregnancy.
What is known already: There is not a consensus to decide the fate of the poor quality supernumerary embryos on day 3. Vitrification of these embryos is highly inefficient due to their low implantation rates. However, by discarding the embryos we risk losing embryos that might implant. Their culture to blastocyst stage is an additional opportunity to assess whether it is worth it to cryopreserve them.

Study design, size, duration: This retrospective study includes 743 IVF cycles performed between January 2013 and September 2014.
Participants/materials, setting, methods: 743 patients were recruited, with ages between 22 and 45. They had fresh embryo transfers in day 3 and low quality supernumerary embryos that were not selected for transfer nor vitrification. Those embryos remained in culture up to day 5–6, and were re-assessed and cryopreserved if they had developed into blastocysts.
Main results and the role of chance: Of 1574 supernumerary embryos of low quality in day 3 that were left in culture until day 5–6, 80 (5.1%) developed into blastocysts (Grade 3CC or superior). 11 couples underwent a transfer of the study embryos, obtaining 6 pregnancies (54.5%), 5 of them being confirmed as clinical pregnancy rates (45.4%), resulting in 3 deliveries (27.3%).
Limitations, reason for caution: This study included patients of different characteristics, so we cannot determine if this policy is useful for all kind of couples.
Wider implications of the findings: Extended culture to day 5–6 of low quality supernumerary embryos on day 3 is an efficient strategy to cryopreserve embryos with low implantation potential on day 3. This strategy allows re-assessing embryos in their blastocyst stage, which is more indicative of their potential to produce a pregnancy. It its time and resource saving and provides a second opportunity to embryos that would otherwise be discarded.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Ginemed Clinic.
Trial registration number: NA.

P-226 Global single step medium for uninterrupted culture to blastocyst in the EmbryoScope: examination of clinical outcome and live birth data from blastocyst transfer cycles

N. Desai[1], Goldberg Jeffrey[1], Austin Cynthia[1], Falcone Tommaso[1]
[1]Cleveland Clinic, Department of Ob/Gyn, Beachwood, OH, U.S.A.

Study question: Is medium refreshment beneficial in maximizing blastocyst formation, clinical pregnancy and live birth rate when culturing to day 5 in a single step medium?
Summary answer: Global single step medium could be successfully used for continuous uninterrupted culture to blastocyst in the EmbryoScope. Blastocyst formation, overall embryo utilization, implantation rate, on-going pregnancy and live birth rates were not enhanced by medium refreshment on day 3. Mean birth weight was however higher with uninterruped culture.
What is known already: Sequential two-step culture media for blastocyst formation present embryos with different nutrients pre and post genomic activation. In contrast, single step media allow the embryo to select the nutrients it needs at the appropriate time. With the introduction of time-lapse imaging systems, transition to a single step media that allows uninterrupted culture to blastocyst is highly desirable. However, depletion of nutrients or build-up of deleterious embryonic metabolites in microdrop culture may negatively influence outcomes.
Study design, size, duration: Data from three consecutive years was retrospectively analyzed for patients having a blastocyst stage transfer. The study group included patients <40 with ≥6 zygotes cultured in the Embryoscope time-lapse incubator. Blastocyst development, implantation, pregnancy and neonatal outcomes were contrasted after continuous culture with or without medium refreshment.
Participants/materials, setting, methods: Zygotes were cultured (25 µl) in GB medium supplemented with 10% SPS (Synthetic Protein Substitute) in the EmbryoScope at 37°C, 6% CO_2, 6% O_2. Group A embryos (medium refreshed on day 3) were contrasted to Group B embryos (uninterrupted culture). Blastocysts were transferred on day 5 and surplus embryos frozen.
Main results and the role of chance: With exception of mean birth weight, blastocyst development and clinical outcome parameters did not differ between treatments. Embryonic metabolite accumulation in microdrops did not appear to be deleterious. Overall embryo utilization i.e. percentage of blastocysts available for either transfer or freezing was not enhanced by day 3 medium exchange.

	Medium refresh	Uninterrupted culture
Transfer Cycles	59	220
Patient Age	33.9 ± 3.4	3.4 ± 3.3
Mature Oocytes	12.7 ± 4.0	12.0 ± 4.0
Fertilization rate	66%	61%
Total Zygotes	718	2332
Embryos transferred	1.9 ± 0.5	1.9 ± 0.4
Positive hCG	80% (47/59)	86% (176/220)
Clinical Pregnancy	69% (41/59)	74% (163/220)
Implantation Rate	53%	59%
Blastulation Rate	64%	65%
Blastocysts Frozen	74%	70%
Embryo Utilization	65%	63%
Ongoing pregnancies	–	97
Pregnancy losses (to date)	1/41 (2.4%)	7/163 (4.3%)
Delivered pregnancies	40	59
Singleton	21	37
Twins/Triplet	19/0	21 /1
Birth weight (grams)	2531.0 ± 1.3	2748.8 ± 1.5*

*p-value <0.05 considered to be significant.

Limitations, reason for caution: This was a retrospective analysis. Although no differences were observed to the point of establishing a clinical pregnancy, detailed comparison of neonatal data is still pending as not all pregnancies have delivered. Confounding factors such as patient age, diagnosis and cycle characteristics were not controlled for.
Wider implications of the findings: With new time-lapse culture systems, it is highly desirable to perform 'hands- off' uninterrupted culture of zygotes to the blastocyst stage. These preliminary data indicate that nutrient depletion and metabolic waste buildup in microdrops is not a significant problem when using one-step Global medium. Moreover, the environmental conditions for blastocyst culture provided with this medium and the EmbryoScope incubation chamber translated in to high implantation, pregnancy and live birth rates with day 5 embryo transfers.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Cleveland Clinic.
Trial registration number: NA.

P-227 Morphokinetic range reduces from embryos that implant, to embryos that blastulate but cannot implant, to embryos that cannot blastulate: Evidence in favour of time-lapse

T. Wilkinson[1], C. F. L. Hickman[1], O. Oliana[1], D. Gwinnett[1], S. Best[2], A. Carby[3], G. Trew[4], S. Lavery[4]
[1]Boston Place Clinic, Embryology, London, United Kingdom
[2]Affiliated to Boston Place Clinic, Embryology, London, United Kingdom
[3]Boston Place Clinic, Clinical, London, United Kingdom
[4]IVF Hammersmith, Clinical, London, United Kingdom

Study question: Can we narrow down the choice of embryos for transfer through determining minimum and maximum time-points of embryonic developmental stages in cleaving, blastulating and implanting embryos?
Summary answer: There is a narrower time-range at all developmental stages for embryos that go on to form an on-going clinical pregnancy compared to those that do not. These maximum and minimum values can be used to de-select non-viable embryos from treatment to assist in counselling patients on their chances of pregnancy.
What is known already: The efficacy of time-lapse technology is dependent on understanding the relationship between morphokinetics and implantation. Originally, models were designed around blastulation rather than implantation and consequently some models are not accurate predictors of implantation. Models have also been demonstrated to require local validations to identify optimal morphokinetic limits for each clinic. Consequently, there has been considerable debate as to the clinical use of time-lapse technology over conventional static observations in predicting embryo viability.
Study design, size, duration: Data were collected from 3201 cleaved 2PN embryos with known implantation data (KID) cultured in Embryoscope incubators from September 2013 to November 2014 and annotated using the Academic Reproductive Partnership annotation protocols from insemination to transfer, vitrification or discard.
Participants/materials, setting, methods: Embryos were divided into three categories: cleaved but not blastulated (C, n = 2027); blastulated but not implanted(B, n = 1111); implanted(I, n = 63). Minimum, maximum, ranges for morphokinetic parameters for each category (C, B, I) were compared using relevant statistical tests. t2 embryos were categorised between <22, 22–25, 25–28, 28–32 and ≥32 h post insemination (hpi).
Main results and the role of chance: With all morphokinetic parameters, the range was largest for cleaved, followed by blastulated and smallest for

implanted embryos(paired *t*-test, $p < 0.001$). For C,B and I, range increased as the embryo progressed in development from tPB2-tsB (correlation, $p < 0.001$), demonstrating that absolute time points become more variable at later stages of development. No embryos implanted outside the I ranges[(minimum-maximum): tPNf(19.21–28.61), t2(21.72–31.78), t3(28.65–44.56), t4(30.15–44.56), t5(33.99–63.87), t6(37.49–63.87), t7(37.82–64.84), t8(40.83–78.29), tSC(52.04–98.31), tM(70.88–108.22), tSB(81.02–114.03), tB(88.69–126.33), tEB(96.39–135.51), tHB(96.89–119.38), relative cc2(1.00–6.67), cc2(1.00–6.67), s2(0.00–4.80)]. The range in morphokinetics for implanting embryos as a proportion of the range by blastulating embryos were: tPB2(63%), tPNa(43%); tPNf(28%); t2(30%); t3(35%); t4(26%); t5(51%); t6(35%); t7(35%); t8(49%); tsC(50%); tM(41%); tSB(41%); tB(48%); tEB(47%); tHB(29%); cc2(77%); s2(19%); relative cc2(5%). Therefore, de-selection of a considerable proportion of blastocysts is possible and is most effective at earlier stages of embryo development(tPNf-t4) compared to later stages (t8-teB). In 1583 embryos, frequencies of embryos cleaving <22, 22–25, 25–28, 28–32 and ≥32 hpi were 3%, 21%, 27%, 25%, 24% and KID ratios were 3%, 14%, 9%, 4%, 0% ($p < 0.001$). Therefore, despite 24% of embryos dividing post 32 hpi, none implanted.

Limitations, reason for caution: Data were collected from one laboratory using a specific culture system and protocols. Since multiple environmental factors affect embryo development, these data should not be assumed to be applicable to all IVF laboratories. It is therefore important that each IVF clinic validates their own embryo selection models.

Wider implications of the findings: Ability to predict implantation potential will not only aid embryo selection (with possible increases in success rates), but also aid management of patients' expectations of pregnancy prior to transfer. A considerable proportion of blastocysts cannot lead to implantation, some of which can be predicted and deselected using time-lapse technology.

Study funding/competing interest(s): Funding by hospital/clinic(s) – IVF Hammersmith, Boston Place Clinic.

Trial registration number: NA.

P-228 The benefit of prolonged culture with primary aseptic vitrification embryo transfer (aVET) in cases of slow blastulating embryos

P. Vanderzwalmen[1], B. Wirleitner[1], A. Stecher[1], M. Schuff[1], N. H. Zech[1]
[1]*IVF-Centers Prof. Zech, Bregenz, Austria*

Study question: Aim of this study was to evaluate whether IVF/ IMSI success rates of slow blastulating embryo (SBEs) can be improved with prolonged embryo culture and aVET. We compared clinical outcome of fresh day 5 embryo transfer (ET) of SBEs, with aVET of SBEs after prolonged culture.

Summary answer: We observed very low pregnancy- (PR) and birth rates (BR) after fresh ET of SBEs on day 5. Vitrification of SBEs and prolonged culture, either before or after cryopreservation remarkably improved clinical outcomes. Better synchronization between embryo development and endometrium are suggested to be mainly responsible for this finding.

What is known already: IVF-embryos should present as fully expanded or hatching blastocysts on day 5 (Istanbul Consensus, 2011). These embryos show the highest chance to establish a pregnancy. However, in some cases often related with patient's age and medical histories, it is observed that a embryos undergo a slower development with delayed blastulation (SBE). It is well recognized, that such embryos, when transferred on day 5 show strongly reduced implantation rates.

Study design, size, duration: A retrospective study during 2007–2013 was conducted comparing clinical outcome after fresh day 5 ET of SBEs, and after aVET following prolonged embryo culture in 2 protocols: (i) SBEs vitrified day 5 and warmed 24 h before aVET, (ii) SBEs vitrified day 6 and warmed 3 h prior to aVET.

Participants/materials, setting, methods: Outcomes of 488 fresh day 5 ETs with SBEs were included. Data were compared with clinical outcomes of (i) 82 aVETs with SBEs vitrified day 5 and warmed 24 h before ET and (ii) 58 aVETs with SBEs vitrified day 6. All aVETs were transferred in a day 5 receptive endometrium.

Main results and the role of chance: PR after day 5 fresh single embryo transfer (SET) with top early blastocysts (mean female age 37.5 years) was 36.4%, with non-top early blastocysts (mean age 37.1 years) PR was 13.7%. BR was 26.1% and 6.5%, respectively. In 181 SETs and 95 DETs with morulae or compacting embryos on day 5, PR was 4.4% and 7.4%, BR 3.9% and 3.2%, respectively. In aVET cycles (mean age 38.2 years) of (i) SBEs vitrified day 5 and warmed 24hrs prior to ET, PR rate was 35.4%, BR 18.3%; after aVET of (ii) embryos vitrified day 6, PR and BR with top-grading blastocysts derived from SBEs was 57.1% and 42.9% respectively. Non-top grading blastocysts vitrified on day 6 showed PR of 26.7% and BR 18.3%.

Limitations, reason for caution: Although results are promising and no increase in the rate of congenital malformations was observed in our data set, further studies need to verify that there is no health risk for the offspring derived from SBEs.

Wider implications of the findings: This study demonstrates that prolonged embryo culture and aVET into a day 5 receptive endometrium can improve clinical outcome of SBEs. This strategy could be an important improvement for patients with recurrent slow embryo development in IVF-culture. We show that prolonged culture and a primary aVET should be proposed over a fresh day 5 ET with SBEs. We hypothesize that a better synchronization between embryo development and endometrium might be responsible for this finding.

Study funding/competing interest(s): Funding by hospital/clinic(s) – This study was not externally funded.

Trial registration number: All research was conducted in accordance with the Helsinki Declaration.

Keywords: implantation rate, slow embryo development, blastocyst, birth outcome

P-229 Clinical outcome of multinucleated embryos: is it worthwhile vitrifying them?

L. Van Landuyt[1], Santos-S. Ribeiro[1], A. De Vos[1], I. Mateizel[1], Van de H. Velde[1], G. Verheyen[1]
[1]*UZ Brussel, CRG, Jette Brussels, Belgium*

Study question: What is the clinical outcome in single embryo transfers (SET) of vitrified-warmed day 3 embryos and day 5/6 blastocysts that showed multinucleation in the early-cleavage stage. Is it worthwhile to vitrify multinucleated embryos?

Summary answer: Multinucleated embryos may have a good implantation potential, especially when cultured up to day 5. For embryos cultured up to day 3, a higher implantation rate was found when the multinucleation was seen on day 1, instead of day 2 or day 3.

What is known already: Since multinucleated embryos are associated with an increased risk for aneuploidy and lower implantation rates, they are preferentially not selected for fresh embryo transfer. However, some multinucleated embryos are cryopreserved when they develop into morphologically good quality embryos. Therefore it is important to assess the outcome of warming cycles in which multinucleated embryos have been transferred.

Study design, size, duration: Retrospective analysis of 189 SET warming cycles performed between 2010 and 2012, in which day 3 ($n = 99$) or day 5/6 ($n = 90$) embryos showing multinucleation on day 1 ($n = 38$), 2 ($n = 104$) or 3 ($n = 47$) of development were warmed. The main outcome parameters were clinical pregnancy rate (CPR) and implantation rate (IR, with FHB).

Participants/materials, setting, methods: Multinucleation was typed as either K2 (2 nuclei in ≤ 50% of blastomeres, $n = 70$), K3 (>2 nuclei in ≤50% of blastomeres, $n = 97$) or K4 (≥2 nuclei in >50% of blastomeres, $n = 22$). The outcome was compared according to the type and day (1, 2 or 3) of multinucleation.

Main results and the role of chance: No significant differences in CPR and in IR were observed between multinucleation type K2 (24.3% and 18.6%), K3 (24.7% and 18.6%) and K4 (36.4% and 31.8%). CPR and IR were similar for multinucleation detected on day 1 (36.8% and 31.6%), day 2 (22.1% and 16.4%) and day 3 (25.5% and 19.2%). CPR and IR were significantly higher after day 5/6 vitrification (38.9% and 30.0%) compared to day 3 (14.1% and 11.1%, $p < 0.01$). Also a subgroup analysis according to the day of vitrification was performed. While day 3 embryos had a significantly higher CPR for multinucleation on day 1 (35.7%) compared to day 2 and day 3 (10.5%, $p = 0.018$ and 10.7%, $p = 0.049$, respectively), this difference was not observed for embryos vitrified on day 5.

Limitations, reason for caution: The results are based on a retrospective analysis with a relatively small sample size.

Wider implications of the findings: Our current findings indicate that transfer of multinucleated embryos may result in good IR. However, it seems preferable to culture multinucleated embryos up to day 5/6 and selectively vitrify

those that develop into blastocysts. When cryopreservation is performed on day 3, selection criteria should take into account which day multinucleation was detected, since day 1 multinucleated embryos show the highest implantation potential. Furthermore, multinucleated embryos may be used as second choice embryos in fresh transfers.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Universitair ziekenhuis Brussel.

Trial registration number: NA, no RCT.

Study question: Is there a marker of embryo morphokinetics that improves the prognostic capability of morphological embryo categories in embryo implantation?

Summary answer: Pronuclear fading was the only morphokinetic parameter found to improve the prognostic capability of morphological embryo categories in embryo implantation.

What is known already: To date, most studies of morphokinetics and embryo implantation have proposed contradictory prognostic models, based solely on morphokinetic criteria. At present, there is no consensus as to which is the best morphokinetic parameter for predicting embryo implantation. One strategy for improving the performance of morphokinetic parameters is to incorporate in predictive models the conventional static morphological parameters used before the onset of time-lapse technology.

Study design, size, duration: A multicentre prospective study was conducted from January to November 2014. Fourteen centres participated in this study, which included 347 ICSI cycles with day-3 transfers, resulting in 85 implanted embryos, 206 non-implanted embryos and 118 embryos in which the implantation result was unknown.

Participants/materials, setting, methods: The embryos were analysed with a time-lapse system (Primo Vision, Vitrolife, Sweden). All the embryos were classified into four categories (A, B, C, D), following the Spanish Association of Reproduction Biology Studies recommendations (ASEBIR categories), according to which category A gave the best and category D the worst prognosis for a combination of various morphological parameters. Confounding factors such as diagnosis, patient age, years of sterility, origin of oocytes, stimulation and lab protocols were controlled.

Main results and the role of chance: In the univariate analysis, ASEBIR categories, pronuclear fading, CC1, t5-t4 and years of sterility were found to be related with embryo implantation. Logistic regression showed that ASEBIR categories and pronuclear fading were significant predictors of implantation. The implantation rate and pronuclear fading in the ASEBIR categories were statistically different (Implantation rate: A = 48.2%; B = 26.5%; C = 20.4%; D = 6.0%; Pronuclear fading: A = 22.8 ± 2.8; B = 24.0 ± 5.1; C = 24.3 ± 6.3; D = 25.8 ± 5.0). The Nagerlkerke-corrected R^2 value showed that the model with both variables produced a better model of implantation (0.227) than when pronuclear fading (0.071) or ASEBIR categories (0.172) were analysed independently. The area under the curve obtained for embryo implantation was similar for pronuclear fading (0.619 [0.555–0.683]) and for ASEBIR categories (0.701 [0.642–0.760]).

Limitations, reason for caution: This model was developed using embryos obtained by ICSI alone, and so requires further validation for embryos obtained by IVF. The sample size must be increased in order to improve the prognostic value of the model obtained.

Wider implications of the findings: The inclusion of kinetic parameters within morphological embryo categories improves embryo selection criteria and can predict implantation. The study findings support the utility of time lapse and kinetic markers to assess embryo competence. In contrast to retrospective single-centre studies, in our multicentre study, the implanted and non-implanted embryos differ mainly in the existence of an early morphokinetic marker. Later morphokinetic markers could be affected by individual laboratory conditions (workflow, number of incubator, air quality, etc.) and thus have poorer prognostic value for embryo implantation between laboratory.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Funding by Hospital Universitario Virgen de las Nieves (Granada) and Centro MasVida Reproducción (Sevilla). Internal funding.

Trial registration number: NA.

Keywords: time-lapse, implantation, morphokinetic.

P-231 Modified, successful method of cryoprotectant dilution after oocyte slow-freezing

K. Papis[1], P. Lewandowski[2], E. Stachowiak[2], J. K. Wolski[3], K. Koziol[2]

[1]Fertility Clinic "nOvum" and Institute of Genetics and Animal Breeding Polish Academy of Sciences, Department of Experimental Embryology, Warszawa and Jastrzebiec, Poland
[2]Fertility Clinic "nOvum", Warszawa, Poland
[3]Fertility Clinic "nOvum" and Maria Sklodowska-Curie Memorial Cancer Centre, Urology-Oncology Department, Warszawa, Poland

Study question: Does it exist any difference in survival rate of slow-frozen oocytes depending on cryoprotectant dilution approach, reflecting on clinical effects?

Summary answer: Different from traditional, sucrose mediated propanediol (PrOH) dilution leads to significantly higher survival rate of slow-frozen oocytes and may have positive effect on implantation and pregnancy rates.

What is known already: Slow-frozen human oocytes usually survive thawing with lower success rate than their vitrified-warmed counterparts. However, very recently it was shown that an improvement of survival and activation rates of slow-frozen oocytes may be achieved using an alternative, warming-like thawing system (Parmegiani et al., *Reprod Biomed Online* 2014;28:614–623).

Study design, size, duration: Retrospective analysis of thawing effects of 291 slow-frozen oocytes, obtained in 56 thawing cycles, performed in two consecutive periods: March 2007 – February 2012 and March 2012 – June 2014. Oocyte survival rate in both periods was compared, following with analysis of clinical data after fertilization and embryo transfer.

Participants/materials, setting, methods: Oocytes were subjected to thawing and traditional, 4 step propanediol dilution method or to modified, sucrose mediated 3 step dilution. Two concentrations of sucrose solution (0.5 and 0.1M) were applied for this purpose. After 1 and 2 min of treatment, respectively, oocytes were moved to IVF medium and fertilized.

Main results and the role of chance: Twenty two and 34 thawing cycles were performed in the first and second period, respectively. Survival rate of oocytes subjected to the traditional dilution was 65.1% whereas 92.9% of oocytes survived thawing procedure if followed with the modified dilution method ($P \leq 0.0001$, the two-sided P value, Fisher's exact test). Clinical pregnancy (CPR) and implantation rates (IR) tended to be higher after transfer of embryos developed in the modified dilution group (33.3% and 27.8% vs. 23.5% and 14.8%, respectively). After transfer of embryos developed from oocytes subjected to the second, modified dilution method 8 births resulting in 9 healthy and one preterm baby have occurred by now. Two twin pregnancies are still ongoing.

Limitations, reason for caution: Study presented here bases on retrospective data, collected during 2 subsequent periods. Number of thawing cycles and number of oocytes thawed were rather limited. It was feasible to confirm

statistical difference in survival rate of oocytes between analyzed groups, but differences in CPR and IR did not reach statistical significance.
Wider implications of the findings: The high oocyte survival, CPR and IR obtained using modified, sucrose mediated dilution method, resembling data obtained using vitrified/warmed oocytes, suggest a new, simple way to obtain a satisfactory yield from slow-frozen oocytes. Healthy babies born after this modification ensure safety of the method employed. Taken together, if confirmed in following studies, presented data provide optimistic view on fate of oocytes cryopreserved already by means of slow-freezing method.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Private Fertility Clinic 'nOvum'.
Trial registration number: Retrospective study.

P-232 Does endometriosis affect oocyte and embryo quality: perspectives from in vitro fertilisation cycles

S. Lane[1], M. Hamdan[2], D. Yell[2], N. Razali[3], Y. Cheong[4]
[1]*University of Southampton, Centre of Biological Sciences, Southampton, United Kingdom*
[2]*Complete Fertility Centre Princess Anne Hospital University of Malaya, Human Development and Health, Southampton, United Kingdom*
[3]*University of Malaya, Obstetrics and Gynaecology, Kuala Lumpur, Malaysia*
[4]*Complete Fertility Centre Princess Anne Hospital, Human Development and Health, Southampton, United Kingdom*

Study question: Does endometriosis affect oocyte and embryo quality?
Summary answer: In women undergoing IVF, the presence of endometriosis does not affect oocyte quality and its development potential.
What is known already: Endometriosis is known to be detrimental to fertility. This may be related to factors associated with the endometrium and also oocyte/embryo quality. Whilst many studies have explored the endometrium related pathophysiology of endometriosis, very few studies examined the latter. Animal studies suggest that oocyte and embryo development is poorer when exposed to follicular and peritoneal fluid of women with endometriosis. Recent evidence suggests that women with endometriosis have a higher chance of aneuploidy not dissimilar to those with advance maternal age.
Study design, size, duration: We performed a retrospective evaluation of women with endometriosis undergoing IVF in our centre. We reviewed treatment cycle and embryology records via IDEAS™ database from January 2011 to December 2014. Comparative analysis was performed between groups and was expressed as means ± SD or percentages as required.
Participants/materials, setting, methods: Women who were <40-years old who underwent IVF treatment using their own gametes were included. The study group consisted of women who had endometriosis (EN) diagnosed by laparoscopy and the control groups were those with tubal factor (TF) and unexplained (UN) subfertility. We excluded couples with co-existing male factor subfertility who required ICSI. There is no restriction on the stimulation protocols and stimulation drugs used.
Main results and the role of chance: We reviewed 474 IVF cycles, out of which EN; 45, TF; 81 and UN; 130 cycles were analysed. Baseline characteristics were comparable including age (EN; 34 ± 4, TF; 33 ± 4 and UN; 34 ± 3), stimulation protocol and type of FSH between groups. The total number of oocytes collected (EN; 9.2 ± 5, TF; 10.4 ± 7 and UN; 9.6 ± 5), number of normally fertilised oocytes (EN; 6.0 ± 4, TF; 6.5 ± 4 and UN; 6.4 ± 4), and total number of embryos transferred per patient were comparable. With regards to embryology data, cleavage rates were the same for both comparisons. The proportion of good quality embryos per cycle were the same (OR 0.75 95% CI [0.56–0.99]. The number of embryos arresting at D3 and rate of blastocyst per retrieved oocytes were similar in all groups.
Limitations, reason for caution: This study was limited by the small number of patients and a larger cohort of patients is required to give more definitive conclusions. Additionally, women with endometriosis were pooled and not stratified according to disease severity, which may give different outcome to oocyte quality.
Wider implications of the findings: Our results showed oocyte quality and its development were similar in the presence of endometriosis when compared to other indications.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s) – Ministry of Education, Malaysia, Complete Fertility Centre.
Trial registration number: NA.

P-233 Day 3 transfer using the automated time-lapse enabled EevaTM Test results in similar clinical pregnancy and implantation rates to blastocyst transfer: a longitudinal cohort study

M. Gaudoin[1], C. Adam[1], N. Gibson[1], C. Blaney[1], C. Noble[1], P. Mitchell[1], R. Fleming[1]
[1]*GCRM Glasgow Centre For Reproductive Medicine, IVF Unit, Glasgow, United Kingdom*

Study question: The Eeva Test predicts the likelihood that an embryo will form a blastocyst based on automated time-lapse analysis of early cell division timings. Can cleavage stage transfer, following the use of the Eeva Test to improve embryo selection, achieve comparable clinical outcomes of blastocyst stage transfer?
Summary answer: Day-3 transfers using the Eeva Test combined with morphology to select embryos resulted in equivalent implantation rates compared to concurrent blastocyst transfers. The results were consistent in both younger and older cohorts, even though patients using the Eeva Test had fewer eggs and embryos for selection.
What is known already: Blastocyst culture enables embryo self-selection and improves pregnancy and implantation rates. However, this requires optimal culturing conditions and is associated with adverse epigenetic effects. The Eeva Test, using automated time-lapse analysis and a generalizable prediction model, provides predictive information about embryo developmental potential on day-3 to improve the success of cleavage stage transfer. This is the first longitudinal cohort study directly comparing clinical outcomes between cleavage stage transfer using the Eeva Test and blastocyst transfer.
Study design, size, duration: Prospective longitudinal cohort study (September 2012–August 2014) comparing clinical pregnancy and implantation rates between a group of patients who had cleavage stage transfer using the Eeva Test ($N = 341$) and a concurrent parallel group of patients who had blastocyst stage transfer without using the Eeva Test ($N = 203$).
Participants/materials, setting, methods: Women <43 years old with two or more embryos on Day-3 elected for Day-3 transfer with Eeva Test or blastocyst transfer. Clinical pregnancy and implantation rates were compared, and *p*-values were calculated using Fisher's exact test. Logistic regression further assessed the impact of transfer-day on clinical pregnancy.
Main results and the role of chance: In women <37 years old, the Eeva Test and Blastocyst Group ($N = 176$ and 144) showed no statistical differences in CPR (46% vs. 48%, $P = 0.74$) and IR (35% vs. 41%, $P = 0.17$), even though Eeva patients had fewer eggs and embryos. Similar results were found in women 37–42 years old (Eeva Test vs. Blastocyst Group: $N = 165$ vs. 59; CPR: 44% vs. 25%, $P = 0.51$); IR: 18% vs. 20%, $P = 0.88$). Logistic regression revealed that transfer-day did not predict outcome, suggesting that Day-3 embryos selected using the Eeva Test together with morphology had the implantation potential of blastocysts.
Limitations, reason for caution: Patients elected to use the Eeva Test or to have blastocyst transfer; therefore, they were not randomized into the two groups. Nevertheless, the study included a broad population of patients (<43 years old), and the Eeva Test group constituted a poorer prognosis than the control group.
Wider implications of the findings: Our study indicated that cleavage stage transfer, using the Eeva Test to improve embryo selection, can achieve comparable clinical outcomes to blastocyst stage transfer. This provides a viable option for programs with limited resources to perform blastocyst culture to improve their success. For patients with higher risk of cycle cancellation, using the Eeva Test may result in better outcome. Improved implantation for day 3 ET will encourage single embryo transfer practice and reduce potential risks associated with multiple pregnancies and extended culture.
Study funding/competing interest(s): Funding by hospital/clinic(s) – No external funding.
Trial registration number: NA.
Keywords: automated time-lapse, Eeva test, embryo selection, cleavage stage transfer, blastocyst transfer

P-234 Embryo ornithine release: a predicative marker for implantation failure?

A. Benhaim[1], A. Ancelle[1], M. H. Read[2], V. Roques[3], C. Denoual[4], C. Devienne[4], M. A. Clarotti[5]
[1]*University of Caen Basse Normandie CHU Côte de Nacre, EA 2608-USC INRA Unity of Biology of Reproduction, Caen Cedex, France*

[2]CHU Côte de Nacre, Unity of Biochemistry, Caen Cedex, France
[3]CHU Côte de Nacre, Unity of Biology of Reproduction, Caen Cedex, France
[4]CHU Côte de Nacre, Unity of Gynecology-obstetric, Caen Cedex, France
[5]CHU Côte de Nacre, Unity of Biology of reproduction, Caen Cedex, France

Study question: The selection of embryos with higher implantation potential has been one of the major challenges in assisted reproductive technology (ART). This selection currently based on morphological criteria has been correlated with implantation potential but its accuracy has proved limited. Actually, too many embryo are transferred without capacity of implantation. Thus, rather find a 'successful' marker, we propose to search for a 'failure' biomarker which can be used to eliminate embryo unable to implant.
Summary answer: The non-invasive determination of ornithine in embryo culture may constitute an attractive marker of implantation failure, morphology independent.
What is known already: Metabolomic profiling of culture medium from growing embryos attracted much research. Amino acid turnover were associated with blastocyst development and with clinical pregnancy (Houghton et al., 2002; Brison et al., 2004). But, despite number of metabolomics studies, any biological marker for successful of implantation has emerged. Moreover, a number studies were focused on the 20 amino acids that are constituents of proteins but the profile of non-protein amino acids were not investigated in human.
Study design, size, duration: We performed a retrospective study.
Participants/materials, setting, methods: We analyzed by *liquid chromatography-tandem mass spectrometry* (LC/MS/MS), the ratio consumption/production of a physiological mixture of 10 amino acids constituents of proteins and a non-protein amino acids, ornithine, by growing embryo in culture at days 2 and 3 following the in vitro fertilization. The validation step of the method was performed on 240 single embryo culture medium from 40 patients and a fast and reliable protocol of amino-acid analysis in the culture media was established.
Main results and the role of chance: (1) The analysis on day 2 of the amino acids profile was more discriminative than on day 3 of culture. (2) Amino acids constituents of proteins flux patterns could discriminate morphologically healthy embryos from morphologically unhealthy embryos but were not useful to predict the successful of implantation. But, we also observed amino acid flux patterns distinct between embryos with similar morphological appearance. (3) In a second time, we have analysis media samples from 20 transferred embryo (20 patients). All the embryos displaying an excess of ornithine production towards consumption (ratio >1,2) failed to implant subsequently and so, independently of their morphology in culture.
Limitations, reason for caution: At the time, these potential markers were identified based on metabolomics studies, which needed to be assessed prospectively on large samples.
Wider implications of the findings: Ornithine is a central part of the urea cycle, which allows for the disposal of excess nitrogen and so could be a marker of a poor embryo cell detoxification. Adequate cell detoxification may be of prime importance in the ability of embryo to survive. The non-invasive determination of ornithine in embryo culture may constitute an attractive marker of implantation failure, morphology independent and that due to its swiftness, could be easily used in ART laboratories.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s) – EA2608-USC INRA. University of Caen Basse-Normandie, FRANCE, Hospital, CHU Côte de Nacre, CAEN, France.
Trial registration number: No concerned.

P-235 Details to consider when setting-up dishes and heated stages in the IVF lab: how to minimize the impact of temperature fluctuations outside the incubator

E. Mestres[1], I. Vanrell[1], Costa-N. Borges[1], G. Calderon[1]
[1]Embryotools, QC/QA, Barcelona, Spain

Study question: How can different set-up of dishes and working conditions affect the temperature in medium droplets when dishes are taken out of the incubator?
Summary answer: In this study we show how several factors related to the setup of culture dishes and the temperature set-point of heated stages directly affect heat transfer in culture medium droplets. All details must be well controlled to minimize the impact of temperature fluctuations outside of the incubator.
What is known already: It is widely known that microtubule spindle is a thermo sensible-structure. Changes in temperature may irreversibly affect spindle integrity, resulting in chromosomal abnormalities in oocytes and embryos. Although during embryo manipulation in routine IVF tasks temperature fluctuations are inevitable, the optimization of the right setup in culture dishes and heated stages may reduce this impact.
Study design, size, duration: Experiments were run at Embryotools between September and December 2014. Set-up was prepared according to the following variables: type of oil (light vs. heavy density), medium droplets distribution (peripheral vs. central), type of culture dish (35 mm, 60 mm, GPS) and temperature set-point (37ºC vs. 40ºC) of heated surfaces.
Participants/materials, setting, methods: Temperature set-point of a heated laminar hood was monitored with external probes (±0.07ºC iButtons, Thermodata). Dishes were taken out of the incubator and placed on the heated surface. A digital fine gauge thermocouple probe (±0.01ºC, TC, Okolab) was used to measure temperature inside culture medium droplets every 30 seconds.
Main results and the role of chance: Different set-up and conditions resulted in greatly varying temperature fluctuations. Whilst some combinations (e.g. central droplets covered with heavy oil in 60 mm or GPS dishes and 40ºC heated stage) succeeded in holding temperature above 36ºC for more than 13 min, others reached excessively warm (>38ºC) or cold (<35ºC) temperatures in few minutes. Overall, heavy oil resulted more competent to slowdown cooling than light oil. Moreover, peripheral droplet distribution proved to cause a faster temperature drop than central distribution. A 40ºC heated surface set-point extended temperature holding times, but resulted in over-heating of culture medium in dishes prepared with light oil. GPS dishes were the most stable on keeping temperature outside the incubator, regardless of the oil type used or temperature set-point of the heated stage.
Limitations, reason for caution: In this study observations are limited to few combinations of culture dishes setup and heated stages set-points. Further studies should be performed to assess temperature recovery when dishes are put back inside the incubator using the same variables, along with the impact of these settings on other parameters like pH.
Wider implications of the findings: This study confirms the impact of several settings (including: type of oil and plastic dish, medium droplets distribution and temperature set-point of heated stages), on temperature fluctuation of medium droplets when dishes are taken out of the incubator. Depending on the settings and disposables used, temperature may behave differently and irreversibly compromise embryo development and quality. Simple details controlled in the lab can minimize stress on embryos and gametes, avoiding unnecessary risks during embryo manipulation.
Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Embryotools, LifeGlobal.
Trial registration number: NA.
Keywords: culture dish, set-up, quality control, temperature

P-236 Time-lapse evaluation of pronuclear morphology in euploid and aneuplid embryos

V. Casciani[1], E. Iovine[1], P. R. Cotarelo[1], F. Scarselli[1], T. Riccio[1], A. Colasante[1], A. Ruberti[1], M. G. Minasi[1], E. Greco[1]
[1]European Hospital, Centre for Reproductive Medicine, Rome, Italy

Study question: We hypothesize that during zygote development, morphological and morphokinetcs parameters could be informative of normal/abnormal chromosomal status. An observational study is currently ongoing in our fertility centre, aiming to evaluate embryos at the pronuclear (2PN) stage and to relate pronuclei (PN) appearance to the ploidy status of the embryos.
Summary answer: Preliminary results indicate that PN relative position evaluated at different time-points (T1,T2,T3) could help identify embryos with higher probability of being euploid; PN juxtapposition at T3 (before fading) is significantly more frequent in euploid then aneuploid embryos. A similar relation, although not signficant, is observed at T2 (14h post-ICSI).
What is known already: Morphokinetics studies have focused on the timing of embryo divisions/morulation/blastulation in relation to morphology, ploidy and clinical outcomes. Information lacks on zygote development. Several studies have evaluated PN at a single time point (17–18 h post-ICSI). However, modern time-lapse incubation allows PN recording from appearance to fading. Pronuclei position is distinguished in "distant" (PN not in contact), "near"

(in contact by one single point) or "juxtapposed" (strictly in contact with a plate of adherence between them).

Study design, size, duration: We randomly selected 18 couples (female age 38 ± 5.2 SD) who underwent ICSI and preimplantation genetic screening in May/2013–March/2014. Morphokinetics was retrospectively recorded: time of II-polar body (IIPB) extrusion, PN appearance/fading, PN position at three time-points: T1 = T0 + 6h, T2 = T0 + 12h, T3 = T0 + 18h (T0 being the time of IIPB extrusion, coinciding with end of meiosis).

Participants/materials, setting, methods: Ninety-three embryos were cultured in time-lapse incubators with sequential media. Blastocysts were biopsied from day-5 to day-7 and their ploidy status evaluated by array-CGH; 38/93(=41%) resulted euploid. Pronuclei relative position was categorized as "distant", "near" or "juxtapposed" (based on previous literature). Morphokinetic parameters were compared between aneuploid and euploid embryos.

Main results and the role of chance: No difference was found between aneuploid and euploid embryos in IIPB extrusion (3.6 ± 0.2 and 3.5 ± 0.2 SE), 2PN appearance (10.5 ± 0.3 and 10.6 ± 0.4), fading (24.0 ± 0.4 and 23.6 ± 0.5), duration of 1-cell stage (26.8 ± 0.5 and 26.5 ± 0.5). At T1 (n = 58 records) most embryos had "distant" (39.5% aneuploid, 35% euploid; NS) or "near" (39.5% aneuploid, 45% euploid; NS) PN; only few showed "juxtapposed" PN (21.1% aneuploid, 20.0% euploid; NS). At T2 (n = 37), 71% aneuploid and 89% euploid embryos (NS) had "jusxtapposed" PN; 3.6% aneuploid and 11.1% euploid embryos (NS) had "distant" PN; 25% aneuploid and none euploid embryos had "near" PN (NS). At T3 (n = 41) all euploid embryos (100%) had "juxtapposed" PN versus 66.7% of the aneuploid embryos (OR = 0.14, 95%CI, p = 0.05); 10% aneuploid and non-euploid embryos had "near" PN (NS).

Limitations, reason for caution: Our study is still ongoing and the sample size needs to be enlarged. The time-lapse system does not allow to manipulate the embryos and to rotate them in case the pronuclei appear overlapping. In this case the evaluation of the PN position cannot be accurate and the record is discarded.

Wider implications of the findings: Besides PN relative position other parameters are important for PN evaluation such as nucleolar precursor bodies (NPB) number and position within the PN (data not shown, still in progress). We believe that a more extensive evaluation of zygote and PN appearance and development will help, together with morphokinetics data on cleavage embryos and blastocysts, identifing embryos with higher probability of being aneuploid/euploid. The importance of this evaluation method relies in its non-invasiveness.

Study funding/competing interest(s): Funding by hospital/clinic(s) – No conflicts of interests have to be declared. No external funding was obtained for the present study.

Trial registration number: NA.

Keywords: time-lapse, pronuclei, zygote

P-237 The occurrence of smooth endoplasmic reticulum clusters in metaphase II oocytes and the outcome of ICSI and IVF cycles

E. Oudshoorn-Roessen[1], G. S. K. Pilgram[1], J. D. N. Diaz de Pool[1], L. A. J. van der Westerlaken[1]

[1]*Leiden University Medical Center, IVF laboratory, Leiden, The Netherlands*

Study question: Is there a difference in fertilization rate (FR), ongoing pregnancy rate (OPR) and life birth rate between ICSI and IVF cycles with and without smooth endoplasmic reticulum clusters (SERC+/SERC-)?

Summary answer: The FR of SERC+ IVF cycles is decreased compared to the FR of SERC+ ICSI cycles and unaffected cycles, which seems partially due to an increased incidence of total fertilization failure (TFF). The OPR and life birth rate of affected ICSI and IVF cycles are not different from SERC- cycles.

What is known already: Due to several alarming reports on increased risks for abnormal neonatal outcome in ICSI cycles containing oocytes with the dysmorphism SERC, it was recommended in 2011 to discard SERC+ oocytes. Recently, authors showed that healthy babies are born from both SERC- and SERC+ oocytes in SERC+ cycles. This dysmorphism occurs in metaphase II oocytes and disappears in case of fertilization. Therefore, embryos from SERC+ oocytes cannot be recognized in IVF cycles and may be transferred.

Study design, size, duration: Observational study between October 2012 and November 2014 of 56 SERC+ ICSI and IVF cycles, containing a total number of 701 oocytes of which 139 are SERC+. TFF, FR, OPR and life birth rate per embryo transfer in SERC+ and SERC- cycles are analyzed and compared.

Participants/materials, setting, methods: ICSI, IVF and mixed cycles from 51 infertile couples treated in the Leiden University Medical Center with at least one oocyte containing SERC observed either after denudation in ICSI cycles or in unfertilized oocytes after PN score in IVF cycles.

Main results and the role of chance: In SERC+ IVF-cycles, the frequency of SERC+ oocytes is lower than in SERC+ ICSI cycles (16,9% vs. 22,8%), which may be explained by the time of observation and disappearance of SERC in fertilized oocytes. Although the FR of SERC- oocytes is slightly higher than that of SERC+ oocytes, the overall FR of affected ICSI cycles is not significantly different from normal ICSI cycles. However, in SERC + IVF cycles the FR is significantly reduced (37,1% vs. 61%). This may be explained by the high incidence of TFF in these cycles (31,8% vs. 5,4%). All three pregnancies from SERC+ oocytes in ICSI cycles resulted in miscarriages. The OPR and life birth rate of both ICSI and IVF SERC+ cycles are not significantly different from SERC- cycles.

Limitations, reason for caution: The frequency of SERC+ cycles may be an underestimation, particularly in IVF cycles, because SERC may be overseen in oocytes during assessment of fertilization. Relatively few embryos from affected oocytes have been selected for transfer, which may explain the lack of life births from SERC+ oocytes in our dataset.

Wider implications of the findings: Our study confirms that life births can occur from SERC+ ICSI and IVF cycles. In case of TFF in a SERC+ IVF cycle, it may be useful to proceed with an ICSI cycle, even if SERC+ oocytes are observed, to increase the FR. Future studies are needed to evaluate whether the high TFF rate in SERC+ IVF cycles is related to the occurrence of SERC.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Leiden University Medical Center.

P-238 Adding morphokinetics to morphology, is there an added benefit in live births?

S. N. Eikeland[1], S. Sayed[1], A. Schwennicke[1], J. Hausken[1]

[1]*Klinikk Hausken, Haugesund, Haugesund, Norway*

Study question: If embryos are morphologically top quality (TQE), does applying further morphokinetic criteria result in higher birth rates?

Summary answer: TQEs that fulfilled the morphokinetic criteria had a significantly higher live birth rate than TQEs that did not pass the criteria.

What is known already: It is known that morphokinetic information from time-lapse (TL) incubation of embryos can be used to distinguish between the implantation potential of embryos, which has traditionally been done by standard morphological assessment under the microscope. However, there are few studies examining the possibility of added benefit from TL if an embryo is TQE.

Study design, size, duration: This was a retrospective, cohort study of 211 single embryo transfers of TQE on day 2 performed at the clinic between June 2012 until December 2014. Only embryos that had been cultured in the TL EmbryoScope™ incubator from fertilization check until embryo transfer were included in the study.

Participants/materials, setting, methods: 211 embryos that had four even blastomeres, <20% fragmentation and no multinucleation at 44 h, making them TQE were included in this study. 126 passed the additional morphokinetic criteria of no nucleation error at any given time, no cleavage anomalies, and matching the in-house timeline, while 85 embryos did not.

Main results and the role of chance: Of the 211 embryos transferred in the study, 63 resulted in a live birth (29.9%). Of the 126 embryos that fulfilled the additional morphokinetic criteria, 48 resulted in a live birth (38.1%), which was a significantly higher live birth rate compared with the 15 out of 85 embryos (17.6%) that did not pass the additional criteria (p = 0.001). This equates to a relative risk of live birth increase of 116% when applying information obtained from TL in addition to the standard assessment of TQE.

Limitations, reason for caution: Embryos were transferred in a clinical setting, so the distribution sub-characteristics of TQEs in the study may not reflect the overall distributions. This is particularly true for TQEs with observed

nucleation error or cleavage anomaly as such embryos were not preferentially transferred.
Wider implications of the findings: To the best of our knowledge, this is the first study to show that applying morphokinetic criteria in addition to traditional morphological grading results in improved birth rates. It also suggests that using a morphokinetic timeline created specifically for the clinic in question used in combination with morphokinetic deselection criteria further improves rates compared to using just deselection criteria.

P-239 Morphokinetic characteristics of embryos time-lapse-imaged up to the 8-cell stage after polar body diagnosis are not affected by ploidy

J. E. Dietrich[1], J. Weigert[1], T. Strowitzki[1], B. Toth[1]
[1]*Heidelberg University Women's Hospital, Department of Gynecologic Endocrinology and Fertility Disorders, Heidelberg, Germany*

Study question: Can morphokinetic parameters be used to distinguish between euploid and aneuploid embryos that were time-lapse-imaged up to the 8-cell stage after polar body diagnosis (PBD)?
Summary answer: Morphokinetic parameters analyzed in this study cannot be used to distinguish between euploid and aneuploid embryos up to the 8-cell stage.
What is known already: It was previously shown that after 8-cell the time from insemination to the initiation of compaction (tSC), start of blastulation (tSB) and full blastocyst (tB) differ significantly among euploid and aneuploid embryos (eE and aE). Aneuploid embryos showed a delayed tSC, tSB and tB. However, until the 8-cell stage no morphokinetic differences were identified. (Campbell et al., RBM Online, 2013, 26, 477–485).
Study design, size, duration: This retrospective study analyzed 139 embryos (n = 38 cycles, n = 30 patients) undergoing ICSI and PBD in our clinic between 09/2013 and 12/2014). All women had a normal karyogram except for one (mosaic 47XXX/46XX). ICSI was performed on n = 263 oocytes with n = 176 being fertilized and n = 139 included for analysis.
Participants/materials, setting, methods: PBD was performed using FISH against chromosomes 13,16,18,21,22 (n = 57 ooyctes) or 13,16,18,21,22,X (n = 82 oocytes). Time-lapse imaging was performed up to day 3. Data in hours are presented as median (quartiles 25 and 75) and were analyzed by pairwise exclusion using Shapiro-Wilks- and Mann-Whitney-Test (SPSS Version 22). Significance level is $p = 0.05$.
Main results and the role of chance: To identify morphokinetic differences among eE and aE we compared several parameters. Both pronuclei had faded at tPNf(eE) = 24.65 (23.19–27.00) and tPNf(aE) = 24.83 (22.55–28.58) ($p = 0.58$). The time from insemination to completion of division to 2–8 cells (tn) did not differ between euploid and aneuploid embryos. When comparing developmental periods neither the duration of cell cycles (CC) 2 ($p = 0.56$) or 3 ($p = 0.81$), nor the relative proportion of CC2 in relation to the combined durations of CC2 and CC3 differed between euploid and aneuploid embryos ($p = 0.42$). The synchrony of the n^{th} cell cycle (sn) was s2(eE) = 0.67 (0.29–1.08) and s2(aE) = 0.50 (0.17–1.37) ($p = 0.68$), s3(eE) = 4.83 (2.16–12.57) and s3(aE) = 3.83 (2.33–9.10) ($p = 0.89$).
Limitations, reason for caution: Ploidy was assessed by PBD through FISH on just a limited number of chromosomes. In addition, sample size is small.
Wider implications of the findings: Our results are in agreement with previous findings by Campbell et al. (2013) and Kramer et al. (2014) and implicate that morphokinetic parameters up to the 8-cell stage cannot be used to identify aneuploid embryos. Therefore testing for ploidy should be performed by other means, i.e. FISH, ArrayCGH or NGS.
Study funding/competing interest(s): Funding by University(ies), Funding by hospital/clinic(s) – This study was performed at the Heidelberg University Hospital (Germany) and received no funding. The authors declare no competing interests.
Trial registration number: A trial registration number was not required due to the retrospective study design.
Keywords: embryology, PGS, time-lapse, morphokinetics

P-240 Development of new procedure to reduce the amount of recipient cytoplasm (mitochondria) at the M-II karyoplast transfer for the treatment of mitochondrial diseases

I. Tanaka[1], A. Tanaka[1], M. Nagayoshi[1], Y. Takemoto[1], H. Kusunoki[2], S. Watanabe[3]
[1]*Saint Mother Obstetrics and Gynecology Clinic and Institute for ART, Fukuoka, Kitakyusyu, Japan*
[2]*Faunal Diversity Sciences Graduate School of Agriculture, Kobe University, Hyogo, Kobe, Japan*
[3]*Department of Anatomical Science, Hirosaki University, Graduate school of Medicine, Aomori, Hirosaki, Japan*

Study question: Is it possible to decrease the amount of transferred cytoplasma to almost zero to avoid the inheritance of mutated mitochondrial DNA (MT-DNA)?
Summary answer: This newly developed procedure has the potential to become crucial in the treatment of cytoplasmic transfer for mitochondrial diseases.
What is known already: The Mitochondrial diseases caused by mitochondrial DNA mutation are inherited through the maternal cytoplasm. The radical treatment for this is the exchange of patient's cytoplasm for a healthy one (from a donor), even a small amount of transferred patient's cytoplasma may possibly cause mitochondrial disease.
Study design, size, duration: We performed a retrospective study to investigate by how much we could decrease the amount of transferred recipient MT-DNA in 25 donor oocytes. This study was conducted between December 2010 and January 2014.
Participants/materials, setting, methods: The first karyoplast was aspirated using a φ10–12 mm glass pipette. Then the first karyoplast was aspirated into a φ5–6 mm pipette and the M-II chromosome was isolated from the remaining cytoplasm by shaking the pipette. By repeating this procedure mostly M-II chromosome could be isolated (second karyoplast).
Main results and the role of chance: 1. The membrane of the second karyoplast was easily broken and this M-II chromosome was injected directly into the enucleated donor oocyte using a Piezo manipulator (PRIME TECH LTD.: PMM-4G). After 2 h incubation in the medium ICSI was performed. 2. MT-DNA in the first karyoplast and second karyoplast were 7.05 ± 2.31 and 0.76 ± 0.85 in comparison with the set point of 100 in the whole M-II cytoplasm measured quantitative by real time PCR. (211/50). 3. The percentage of successful first and second karyoplast was 100% (25/25), 92.0% (23/25). 4. Fertilization, cleavage and blastocyst rates after ICSI were 65.2% (15/23). 73.3% (11/15) and 27.3% (3/11) respectively.
Limitations, reason for caution: The final amount of cytoplasm in the second karyoplast could not be reduced to zero. It might produce mitochondrial disease through bottle neck phenomenon though this might hardly occur.
Wider implications of the findings: The amount of recipient transferred MT-DNA was reported as 0.5 ~ 0.6% measured by amplification refractory mutation system-quantitative polymerase chain reaction, then it could not be detected at all in a year. It is not clear whether recipient MT-DNA was absorbed or discharged. There is a possibility that the MT-DNA might be detected using more accurate devices. There is clear evidence that the percentage of transferred recipient MT-DNA decreased to almost zero in a year.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Saint Mother Obstetrics and Gynecology Clinic and Institute for ART.
Trial registration number: NA.

P-241 Invention of a novel micromanipulator for ICSI, Venus (Vortex-like-movement-Evoked Nicking Upon Stick-site), which enables surer puncture of oocyte membrane with less stress

M. Jinno[1], F. Inoue[2], A. Watanabe[1], N. Hatakeyama[1], R. Hiura[1], T. Gouda[1]
[1]*Women's Clinic Jinno, Reproductive Medicine, Tokyo, Japan*
[2]*Kitazato Corporation, Reproductive Medicine, Fuji City, Japan*

Study question: We invented a novel micromanipulator for smoother and less-stressful puncture of oocyte, Venus (Vortex-like-movement-Evoked Nicking Upon Stick-site, PAT.P), which rotates an injection pipette while sticking like a gimlet. We prospectively examined whether Venus improves intracytoplasmic sperm injection (ICSI) outcomes.

Summary answer: Venus provides smoother and surer puncture of oocyte membrane by gimlet-like movement of the injection pipette, consequently improving embryonic growth by reduction of oocyte stress.
What is known already: Non-stress and sure puncture of oocyte membrane is essential for ICSI to achieve successful pregnancies. Conventional procedures of simple stick, Piezo, and aspiration, however, often encounter penetration difficulty, impact-damage, and injection problem due to a stuck pipette, respectively. For surer puncture of oocyte with less stress, therefore, we have invented a novel micromanipulator, Venus, which enables an injection pipette to rotate while sticking like a gimlet.
Study design, size, duration: Prospective randomized studies: a pilot study compares two ICSI ways using Venus (SV and DV, as described below) versus a conventional way (C) and a confirmation study (midway analysis at present) compares SV versus C. Both studies include 51 and 48 oocytes in 3 and 6 ICSI cases, respectively.
Participants/materials, setting, methods: Injection pipette was stuck without penetration, making a dead-end tunnel, and then penetrated through the side-wall of tunnel using Venus (Side-wall Venus, SV) or not (conventional way, C). Alternatively, pipette was penetrated by single stick using Venus (Direct Venus, DV). Stick numbers, survival rate and embryo growth were compared.
Main results and the role of chance: Pilot study: The numbers of sticks until penetration were 3.4 ± 0.5 with C (n = 18), and significantly decreased to 2.5 ± 0.3 with SV ($p < 0.05$, n = 18) and further to 1.4 ± 0.3 with DV ($p < 0.001$, n = 17).With C, SV and DV, oocyte survival rate were 100, 94 and 47% ($p < 0.01$) and development rates to superior blastocysts from surviving oocytes (%SB) were 11, 20 and 0%, respectively. Midway evaluation: With C and SV (n = 24 and 24), oocyte survival were 100 and 100%, and %SB were 24 and 48% (p = 0.1). Superior blastocysts developed significantly more frequently with SV than C (Odds ratio: 4.4, 95% C.I.: 1.01–19.2, logistic). In additional 21 patients with SV alone, 33% resulted in pregnancies.
Limitations, reason for caution: A prospective confirmation study requires 150 oocytes in each group of SV and C to obtain definite conclusions by power analysis. Present pilot and midway analyses showed important beneficial effects of Venus on ICSI outcomes but definite conclusions await further accumulation of data.
Wider implications of the findings: Present study showed beneficial effects of Venus on oocytes derived from 39 years old or younger women. Because weaker oocytes are more vulnerable to ICSI stress, Venus may contribute to aged women and poor responders much more by reduction of puncture stress.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Women's Clinic Jinno.
Trial registration number: UMIN000014600.

P-242 Prediction of embryonic development and clinical outcome following ICSI according to the stages of nuclear maturation division

M. Nagayoshi[1], A. Tanaka[1], I. Tanaka[1], Y. Takemoto[1]
[1]Saint Mother Obstetrics and Gynecology Clinic and Institute for ART, Fukuoka, Kitakyusyu, Japan

Study question: Is it possible to predict embryonic development and clinical outcome according to the stages of nuclear maturation division?
Summary answer: Identification of chromosomal stages has a high potential to predict the embryonic development and clinical outcome by adjusting the preincubation time. Longer pre-incubation (5–6 h) might be beneficial for prometaphase II oocytes to advance to Metaphase II oocytes. Irregularly arranged chromosomes might be a sign of nuclear degradation.
What is known already: Pre-ovulatory oocytes collected after controlled ovarian stimulation are considered mature with the extrusion of the first polar body at ICSI. However, embryonic development varies following ICSI for morphologically mature oocytes.
Study design, size, duration: We performed this retrospective study to investigate the relationship between the clinical outcome and various nucleus stages of M-II oocytes in 53 patients under 38 years of age on 211 cycle
Participants/materials, setting, methods: M-II chromosomes identified using an inverted microscope equipped with Normarski optics. M-II oocytes were divided into four groups, Group A: oocytes that had the M-II chromosomes arranged in two lines, Group B: oocytes at prometaphase II not yet arranged in two lines and Group C: oocytes with irregularly arranged chromosomes.
Main results and the role of chance: 1. The 211 freshly ovulated M-II oocytes were examined. The proportion of grouped oocytes according to the stages of M-II chromosomes were 78.1% (165/211) in group A, 7.1% (15/211) in group B and 14.7% (31/211) in group C. 2. The fertilization, cleavage, blastocyst stage rates and pregnancy, miscarriage and birth rates in four groups are listed in table.

Table 1: Clinical outcome following ICSI according to the stages of nuclear maturation division.

	Fertilization rates (%)	Cleavage rates (%)	Blastocyst rates (%)	Pregnancy rates (%)	Miscarriage rates (%)
A	79.4(131/165)	80.2(105/131)	58.0(76/131)	44.7(34/76)	11.8(4/34)
B	73.3(11/15)	63.6(7/11)	36.3(4/11)	25.0(1/4)	100(1/1)
C	54.8(17/31)	70.5(12/17)	17.6(3/17)	0(0/3)	0

Limitations, reason for caution: Normal embryonic development needs maturation of both of nucleus and cytoplasm. This study investigated whether it is possible to predict embryonic development from the point of view of nuclear condition. However, when maturity of nucleus and cytoplasm do not match this prediction method is not applicable.
Wider implications of the findings: It is very important to collect information to improve the embryonic development just after the oocyte collection.
It is beneficial for embryonic development if oocyte maturity can be adjusted to optimal condition by observing the nuclear maturation division.
Study funding/competing interest(s): Funding by hospital/clinic(s) – Saint Mother Obstetrics and Gynecology Clinic and Institute for ART.
Trial registration number: NA.
Keywords: ICSI, M-II oocyte, nuclear maturation

P-243 Aggregates of smooth endoplasmic reticulum (SERa) in human oocytes: impact on in vitro fertilization (IVF)

L. Restelli[1], S. Delle Noci[1], S. Ferrari[1], V. Bolis[1], G. Candotti[1], I. La Vecchia[1], A. Paffoni[1], E. Somigliana[1]
[1]Fondazione Ca' Granda Ospedale Maggiore Policlinico, Infertility Unit, Milan, Italy

Study question: To determine if patients undergoing IVF and whose oocytes present SERa, a particular morphological feature, have a higher change of negative outcome compared to patients without SERa oocytes.
Summary answer: The present study indicates that, when SERa+ oocytes are excluded from an ICSI programme, women with SERa oocytes (cases) have an higher chance of negative outcome compared to controls. The negative outcome is defined as the absence of suitable oocytes or viable embryos or during the IVF cycle
What is known already: Two reports in literature have associated the use of SERa oocytes IVF to malformation or genetic abnormalities in the newborns. In 2011, based on these data, the Alpha Scientists and ESHRE issued guidelines that, as a precaution, advised against the use of those gametes in IVF. Our unit does not use SERa oocytes and aimed to gather more information on the impact of this limitation on IVF outcome.
Study design, size, duration: A retrospective cross-sectional case-control study. Our hypothesis was that a negative outcome occurs in 30% of cases and 15% of controls. 120 patients is the minimum sample needed, as revealed by a power study (a = 0,05; b = 0,2). The study period ranged from July 2012 till December 2013.
Participants/materials, setting, methods: Cases were IVF patients showing ≥1 SERa+ oocytes at the time of ICSI. Controls were subsequent patients showing no SERa+ oocytes and matched for age, clinical indication to IVF and body mass index (BMI). The ICSI cycle was performed in a standard way, excluding SERa oocytes from insemination.
Main results and the role of chance: The percentage of women experiencing a negative result in their IVF cycle was significantly higher in cases (18%) compared to controls (8%) (p = 0.02) with an Odds Ratio = 2.6 [95%CI = 1.2–5.7]. The Odds Ratio adjusted for age, BMI, basal FSH, duration of infertility, number of retrieved oocytes and used oocytes was 2.6 [95%CI = 1.1–6.5]. Factors that mostly influenced this result were the number of suitable oocytes and basal FSH. A survival function (Kaplan-Meyer method) from pick-up to embryo transfer highlighted that the only significant difference between cases

and controls was the percentage of suitable oocytes: 61% vs. 73% in cases and in controls, respectively ($p = 0.001$). Clinical pregnancy and delivery rates were not statistically different between the two groups (34% vs. 37% and 25% vs. 30%, respectively)

Limitations, reason for caution: The present study has been designed to elucidate an embryological outcome so we cannot draw conclusions about chances of pregnancy or delivery.

Wider implications of the findings: Our results cannot be compared with others in the literature because, differently from other papers, we did not use SERa + oocytes in IVF. Although we have no information regarding the fate of inseminated SERa + oocytes, we can give important data for prognosis of patients showing this particular morphological feature.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Fondazione IRCCS Ca' Granda.

Trial registration number: NA.

P-244 Predicted blastocyst development based on the cellular features of day 2 embryos by time-lapse observations

J. Otsuki[1], H. Ogata[1], T. Iwasaki[1], Y. Katada[1], H. Sato[1], Y. Tsutsumi[1], K. Hatano[1], S. Kokeguchi[1], M. Shiotani[1]

[1]*Hanabusa Women's Clinic, Reproductive Medicine, Kobe Hyogo, Japan*

Study question: Is it possible to reliably predict blastocyst development on day 2 after fertilization in order to reduce the occurrence of monozygotic twinning and to reduce the duration of *in-vitro* embryo culture?

Summary answer: It is possible to predict the likelihood of blastocyst development based on the following criteria. The size of cellular fragmentation is less than 26 mm in diameter, 2PN zygotes undergo normal twofold cell division, cell vacuoles are not larger than 10mm in diameter and reverse cleavage is not observed.

What is known already: It has been reported that blastocyst culture causes a higher rate of monozygotic twinning and a delay in embryo development compared to *in-vivo* embryo growth. The presence of cellular vacuoles (larger than 10 mm) and reverse cleavage are known to diminish blastocyst development.

Study design, size, duration: A retrospective study of 351 2PN zygotes, that were observed by a time-lapse system until day 5 of development conducted at the Hanabusa Women's Clinic from January 2014 to December 2014.

Participants/materials, setting, methods: The size of fragmentation and the presence of vacuoles at the time of the first cleavage were recorded. The rates of blastocyst development and high-grade blastocyst formation (>3AA) were analysed in embryos, with or without normal twofold cell division, and the detection of vacuoles and reverse cleavage.

Main results and the role of chance: The cutoff size of fragments that distinguished normal from abnormal cleaved cells was defined as <26 mm. Based on this criterion, the rate of blastocyst formation from 2PN zygotes with normal twofold cell division without large vacuoles was 97.2% (104/107) and was significantly higher than those with reversed cleavage (50.8% (33/65), $p < 0.001$), erratic cell division into 3–4 cells (56.7% (56/99), $p < 0.001$), or 5 and more cells (13.5%(10/74), $p < 0.001$). The rate of high-grade blastocyst formation (>3AA) from 2PN zygotes with normal twofold cell division without large vacuoles was 42.1% (45/107) and was also significantly higher than those with reversed cleavage (4.6% (3/65), $p < 0.001$), erratic cell division into 3–4 cells (6.1% (6/99), $p < 0.001$), or 5 and more cells (0% (0/74), $p < 0.001$).

Limitations, reason for caution: It is not known whether chromosomes are present in the larger fragments and abnormally cleaved blastomeres. Further studies are required to determine pregnancy rates and take-home baby rates based on the criteria used in the present work.

Wider implications of the findings: As this method can predict blastocyst development with high accuracy from day 2 embryos, blastocyst culture may no longer be necessary for choosing viable embryos. This new method simplifies the procedure for selecting the best embryos, without labor-intensive protocols, such as measuring the time of cleavage and the duration of each cell stage.

Study funding/competing interest(s): Funding by hospital/clinic(s) – Hanabusa Women's Clinic.

Trial registration number: NA.

P-245 Should we worry about the clock? Relationship between time for ICSI and reproductive outcomes in cycles with fresh and vitrified oocytes

P. Barcena[1], M. Rodríguez[1], D. García[2], A. Obradors[1], V. Vernaeve[1], R. Vassena[1]

[1]*Clínica EUGIN, Barcelona, Spain*

[2]*Fundació Privada EUGIN, Barcelona, Spain*

Study question: What are the best time interval to perform ICSI with respect to the times of ovum pick-up (OPU), cumulus cells removal (denudation), and vitrification/warming of oocytes in order to maximize fertilization rate, embryo quality, and biochemical, clinical, and ongoing pregnancy rate (PR) in fresh and vitrified cycles?

Summary answer: There are no significant differences in fertilization rate (FR), embryo quality (EQ), and pregnancy rate (PR) of ICSI cycles within a wide range of times employed between OPU and ICSI, including partial time analysis for denudation and recovery from vitrification/warming.

What is known already: During IVF, the oocyte can be subjected to denudation, vitrification/warming, and ICSI. Insufficient interaction with cumulus cells, oocyte ageing outside of the follicle, and improper recovery after warming can all impact the resulting embryo developmental competence; therefore, strictly controlled times between procedures are often implemented. However, most protocols are never tested against reproductive results, and little information is available on the ideal times to be followed to achieve the highest PR.

Study design, size, duration: Data from 3,986 ICSI cycles performed at a fertility center between December 2012 and May 2014 were included (3,178 with fresh and 808 with vitrified/warmed oocytes). Exact times between OPU, denudation, vitrification, warming, and ICSI were recorded automatically by a radiofrequency based system. OPU was performed strictly 36h after trigger.

Participants/materials, setting, methods: ICSI was performed using donor oocytes and either patient's or donor sperm. Univariate differences between manipulation times and PR were tested by Student's t-test; adjusted effect of time was analyzed by logistic regression; linear trend was tested by linear-by-linear test. Effect of time on FR/EQ was modeled by probit/ordinal regression.

Main results and the role of chance: Total OPU-ICSI times ranged from 1 h 25 m to 17 h 13 m (average 4 h 58 m ± 1 h fresh; 9 h 18 m ± 2 h vitrified oocytes). We found no effect of total OPU-ICSI time on FR ($p_{fresh} = 0.39$; $p_{vitrified} = 0.86$;) or EQ ($p_{fresh} = 0.08$; $p_{vitrified} = 0.22$). There was no difference in average total OPU-ICSI times between positive and negative pregnancies (biochemical, clinical, and ongoing) in either vitrified ($p = 0.52$, $p = 0.12$, $p = 0.12$) or fresh ($p = 0.74$, $p = 0.81$, $p = 0.99$) cycles. No effect of adjusted total OPU-ICSI time on PR for either vitrified ($p = 0.59$, $p = 0.20$, $p = 0.13$) or fresh ($p = 0.79$, $p = 0.73$, $p = 0.99$) oocytes was found. Further analysis for linear trend using total OPU-ICSI time categorized in deciles showed that PR do not increase or decrease across deciles. No effect on PR was found for denudation to vitrification, warming to ICSI, and denudation to ICSI times.

Limitations, reason for caution: This is a study with automatically collected times from a high number of ICSI cases; however, its retrospective nature cannot exclude the influence of unaccounted for variables on the results. All women included in the study were ≤35 years old, so findings should not be automatically extended to older women.

Wider implications of the findings: Our results indicate that the effective window of time for insemination by ICSI is wider than previously thought, as total time from OPU to ICSI can be as long as 17 h without developmental competence loss in the resulting embryos. Within appropriate times, the management of cycles in embryology laboratories could be adjusted to accommodate caseloads and workflow without loss of oocyte viability or cycle efficiency.

Study funding/competing interest(s): Funding by hospital/clinic(s).

Study question: The expression of *Slpi* and its role in preimplantation embryos.
Summary answer: *Slpi* expresses in preimplantation stage embryos and important in implantation competence
What is known already: SLPI is known a uterine implantation factor and expressed in reproductive tracts
Study design, size, duration: 2-cell stage mouse embryo in vitro culture for 72 h (more than 80 embryos per group), recombinant SLPI, ODN, embryo transfer
Participants/materials, setting, methods: CD1 female mice were superovulated with gonadotropins and collected the embryos after hCG 48 h. 2-cell embryos were cultured with or without recombinant SLPI and the expression of Slpi were analyzed with qRT-PCR. The embryos were transferred to the pseudopregnant female. Slpi mRNA specific ODNs were used to knockdown.
Main results and the role of chance: Slpi mRNA was detected in all cleavage stages except morula stage. However, SLPI was localized in all examined stage at the cytoplasm or membrane in a stage-dependent manners. Treatment of SLPI protein speeded up cleavage without the changes of total cell numbers or inner cell numbers of blastocyst. Silencing of *Slpi* expression delayed the embryo development after 8-cell stage without changes in the total cell number or inner cell numbers of blastocyst. The decreased developmental speed and implantation rate by *Slpi* silencing were recovered by the treatment of SLPI protein. The implantation rates were increased significantly by SLPI-treatment in both in vitro developed and *Slpi* silenced embryos.
Limitations, reason for caution: No
Wider implications of the findings: SLPI may regulate the cleavage speed and implantation competence of early-stage embryos.

P-247 Ongoing pregnancy in vitrified blastocyst transfer is not influenced by the extent of the zona pellucida dissection after thawing, but mainly by the blastocyst re-expansion

L. Corti[1], P. Rubino[1], L. Pagliardini[1], A. M. Sanchez[1], G. Intra[1], L. De Santis[1], P. Vigan[2], E. Papaleo[1]
[1]*IRCCS San Raffaele Scientific Institute, Obstetrics and Gynecology Unit, Milan, Italy*
[2]*IRCCS San Raffaele Scientific Institute, Division of Genetics and Cellular Biology, Milan, Italy*

Study question: Has the extent of laser-dissection of the zona pellucida (ZP) after thawing (from <25% to 25–50%) an influence on ongoing pregnancy rates in frozen-thawed single blastocyst transfer cycles?
Summary answer: The dimension of the ZP laser-dissection after thawing (from <25% to 25–50%) has no influence on ongoing pregnancy rates in frozen-thawed blastocyst transfer cycles.

Pre-freeze blastocoele expansion and inner cell mass (ICM) grade and post-thaw blastocoele re-expansion to the original degree are the most significant predictors.
What is known already: The freeze–thaw process might exacerbate the hardening of the ZP, which could impair successful embryonic hatching and implantation. Although still debated, some randomized studies have shown that laser-assisted hatching (AH) may improve the implantation rates in these cases. Historically, concerns have been raised on the length of the AH, because a small sized AH may trap the blastocyst in a typical figure-eight shape. Wider dissection of the zona might overcome this phenomenon.
Study design, size, duration: This was a retrospective study of $n = 258$ patients (258 blastocysts) who underwent a frozen-thawed single blastocyst transfer at our Center between January 2013 and September 2014.
Participants/materials, setting, methods: Blastocoele expansion, ICM and trophectoderm (TE) grade both pre-freezing and post-thawing were recorded. All blastocysts were artificial laser-collapsed before vitrification. After thawing and before the embryo-transfer, the zona was dissected from <25% to 25–50%, depending on the space between the TE and the ZP.
Main results and the role of chance: Multivariate logistic regression revealed no difference in ongoing pregnancy rate between the two groups characterized by different laser-dissection extent (< 25% and 25–50%) after correction for female age, Istanbul Consensus blastocyst morphological parameters and time from thawing (adjusted OR = 1.74, 95% CI: 0.76–4.00, $p = 0.19$). Hatching of blastocyst did not result to be more frequent after a wider dissection (adjusted OR = 0.98, 95% CI: 0.51–1.89, $p = 0.96$). Best pre-freeze predicting factors for ongoing pregnancy were blastocoele expansion (grade 2 vs. 3 adjusted OR = 0.37, 95% CI: 0.14–0.99, $p = 0.047$) and ICM grade (grade C vs. A adjusted OR = 0.27, 95% CI: 0.08–0.88, $p = 0.031$). Among post-thawing morphological parameters, only re-expansion could significantly predict ongoing pregnancy (grade 2 vs. 3 adjusted OR = 0.29, 95% CI: 0.09–0.91, $p = 0.034$).
Limitations, reason for caution: This was a retrospective study; a prospective randomized study that analyzes the influence of the extent of laser-dissection after blastocyst thawing on the ongoing pregnancy rate would be more reliable.
Wider implications of the findings: Blastocysts with higher pre-freeze grades of blastocoele expansion and ICM should be given priority when thawing. Blastocyst re-expansion after thawing should be the most important parameter to be taken into consideration to predict a pregnancy.

P-248 The impact of treatment and patient-related factors on timing of embryo development in a cohort of good prognosis patients

K. Kirkegaard[1], L. Sundvall[2], J. J. Hindkjaer[2], H. J. Ingerslev[2]
[1]*Aarhus University Hospital, Department of Clinical Biochemistry, Aarhus, Denmark*
[2]*Aarhus University Hospital, Fertility Clinic/Center for Preimplantation Genetic Diagnosis, Aarhus, Denmark*

Study question: How much do confounding factors contribute to the variation observed for the morphokinetic parameters proposed as viability markers?
Summary answer: The treatment and patient-related factors explain only a small part of the variation observed for morphokinetic parameters, in particular at the cleavage stage. Variation in timing of embryo development is likely to be related genuine biological differences between embryos.
What is known already: Time-lapse monitoring has been shown to improve clinical outcome. At present, data do not allow for distinguishing between improved culture conditions and selection using time-lapse parameters. Furthermore, several studies report that culture conditions, patients and treatment influence timing of the morphokinetic parameters, which have promoted the perception that each clinic must develop individual models. Whether this is necessary will, however, depend on the individual contribution of the proposed factors, which remains to be investigated.
Study design, size, duration: Infertile patients were prospectively recruited at the Fertility Clinic, Aarhus University Hospital from February 2011 to May 2013. Patients aged <38 years without endometriosis were eligible if ≥8 oocytes were retrieved. Patients were included once. All embryos were monitored for 6 days in a time-lapse incubator (EmbryoScope).
Participants/materials, setting, methods: 1931 embryos (2 PN) from 239 patients were included. The influence of fertilisation method, BMI, maternal age, FSH dose, cause of infertility and number of oocytes retrieved on timing of t2–t5, development of a blastocoel (tEB), and full blastocoel (tFB) was tested in linear regression models for clustered data.
Main results and the role of chance: BMI and number of oocytes retrieved and cause for infertility showed no correlation to timing of t2, t3, t4, t5, tEB, and tFB. Fertilization method affected only t2 significantly. Age and FSH dose significantly affected tEB, and tFB in an unadjusted model, where as only FSH dose showed a significant correlation in an adjusted model. In contrast to the other parameters evaluated, total FHS dose showed a significant correlation to whether t5 and duration of the 2-cell stage (cc2) were in-or outside the time-intervals proposed as optimal in a published hierarchical model (t5 45–55; cc2 9–12 h). The analysis was largely unchanged whether all embryos or only good quality blastocysts were included.
Limitations, reason for caution: Culture media and oxygen concentration were constant during the study period, and the possible effect of these was therefore not analysed.

Wider implications of the findings: Although we can not exclude that is relevant to adjust proposed model to different clinical settings with regard to potential confounders such as fertilisation method, BMI, maternal age, FSH dose, cause of infertility and number of oocytes retrieved, our analysis suggest that the contribution of these external factors to variation in timing of embryo development is less than genuine biological differences between embryos. The impact of FSH dose might reflect the importance of ovarian reserve/quality.

Study funding/competing interest(s): Funding by commercial/corporate company(ies) – Research at the Fertility Clinic was funded by an unrestricted grant from Ferring and MSD. The authors declare no competing interest.

Trial registration number: NCT01953146 and NCT01139268.

P-249 Predictive value of soluble human leukocytic antigen-G levels in embryo culture medium for embryo selection in patients undergoing intracytoplasmic sperm injection

D. M. El-Kaffash[1], S. H. Sallam[2], D. N. Younan[1], A. A. Ismail[3], Abdel-A. F. Rahman[2], H. N. Sallam[3]

[1]Alexandria University, Faculty of Medicine, Department of Clinical Pathology, Alexandria, Egypt

[2]Alexandria Fertility Center, Assisted Reproduction Unit, Alexandria, Egypt

[3]Alexandria University, Faculty of Medicine, Department of Obstetrics and Gynaecology, Alexandria, Egypt

Study question: Is the measurement of soluble human leukocytic antigen-G (sHLA-G) in the spent culture medium a good predictor of the clinical pregnancy rate (CPR) in infertile patients treated with intracytoplasmic sperm injection (ICSI)?

Summary answer: The measurement of sHLA-G in the culture medium (CM) at 72 h post-insemination is a fair predictor of the CPR in women undergoing ICSI. Its predictive value is lower than the embryo score (ES). However, the combination of both predictors gives a higher predictive value compared to each predictor alone.

What is known already: Researchers have suggested that there is an association between implantation potential and embryonic secretion of sHLA-G. Studies have shown that pregnancy rates were higher when sHLA-G was detected in the spent culture media of day 3 embryos. However, the results were not definitive as pregnancies were also established from the sHLA-G negative embryos. More research is needed in this area to clarify the role of sHLA-G in embryo selection.

Study design, size, duration: A retrospective study of the sHLA-G concentration in the spent CM and the morphology score of embryos (ES) of ICSI-treated women between 1st January and 31st March 2014. Assuming an a value of 0.25 and a 70% probability of detecting a true difference, the minimum sample size was 22.

Participants/materials, setting, methods: The CM of 80 separately cultured embryos from 25 patients undergoing ICSI in our Assisted Conception Center were analyzed for their concentration of sHLA-G at 72 h post insemination using a double monoclonal sandwich enzyme immunoassay assay. The results were compared to the morphological evaluation of the embryos (ES).

Main results and the role of chance: The CPR was 28% (7/25). The mean (±SD) concentration of sHLA-G in the CM of pregnant women was 4.77 (±2.34) U/ml compared to 3.50 (±1.99) U/ml in non-pregnant women ($P = 0.057$). The mean ES in pregnant women was 9.18 (±1.07) compared to 6.24 (±1.41) in non-pregnant women ($P < 0.001$). Receiver operating characteristic (ROC) curves showed that the ES had a higher predictive value for clinical pregnancy (AUC = 0.925; $P = 0.001$) compared to the sHLA-G concentration (AUC = 0.794; $P = 0.025$). The cut-off values were of 5.21 and 3.35 U/ml for both predictors, respectively. The combination of both predictors gave a higher predictive value (AUC = 0.968; $P < 0.001$) compared to each predictor alone.

Limitations, reason for caution: In order to evaluate the clinical usefulness of these findings, a prospective randomized trial (RCT) is needed, where only embryos with a sHLA-G concentration >3.35 U/ml in the culture medium at 72 h post-insemination and an ES >5.21 will be transferred and compared to the classical morphological evaluation method.

Wider implications of the findings: It is concluded that the measurement of sHLA-G in the embryo CM is a fair predictor of clinical pregnancy in women undergoing ICSI. Its combination with embryo scoring gives a higher predictive value compared to each predictor alone. If these results are confirmed by a prospective RCT, this combined method can be used for the selection of embryos to maximize the chances of clinical pregnancy and diminish the incidence of multiple pregnancies.

P-250 Is a morphokinetic based selection model for fresh blastocysts transferrable to vitrified blastocysts?

L. Best[1], A. Campbell[2], S. Montgomery[1], R. Smith[3], S. Duffy[1], D. Hulme[2], D. Sivanantham[4], L. Jenner[2], L. Nice[4], K. Berrisford[2], S. Fishel[2]

[1]CARE Fertility, Embryology, Manchester, United Kingdom

[2]CARE Fertility, Embryology, Nottingham, United Kingdom

[3]CARE Fertility, Embryology, Sheffield, United Kingdom

[4]CARE Fertility, Embryology, Northampton, United Kingdom

Study question: Is a novel morphokinetic blastocyst selection model, which ranks fresh embryos according to implantation potential, also valid for vitrified blastocysts?

Summary answer: The selection model – developed and validated in-house to rank embryos according to implantation potential - was effective when applied to vitrified/ warmed blastocysts.

What is known already: Selection models based on the comparison of morphokinetic variables have been used to develop clinical evidence-based embryo selection algorithms. To date these have been used for selection of blastocysts for transfer in fresh cycles only.

Study design, size, duration: An in-house morphokinetic ranking was retrospectively applied to 181 blastocysts warmed and transferred between August 2011 and November 2014 with known implantation data (KID±). KID + rates (KID + /KID + plus KID – ×100%) were compared in relation to clinical pregnancy and live birth.

Participants/materials, setting, methods: Morphokinetic variables were recorded using EmbryoScope™ (Vitrolife, Sweden) in a private IVF setting. A novel morphokinetic embryo selection model was developed in house and tested retrospectively on blastocysts cultured between June 2011 and March 2014. The KID ratio of fresh blastocysts transferred and frozen blastocysts subsequently transferred were analysed.

Main results and the role of chance: For high, medium and low implantation potential warmed blastocysts, defined by the in-house model, KID + rate was 43.3%, 34.2% and 8.3% ($n = 90, 79, 12$). The live birth KID for high, medium and low implantation potential warmed blastocysts, was 33.3%, 27.9% and 0% ($n = 63, 61, 10$). There were no live births from the low potential warmed blastocysts transferred. Although no statistical significance between these KID ratios was seen, they relate well to the KID + rate of previously presented fresh blastocyst transfers in which high, medium and low implantation potential KID + rate was 57.1%, 34.6% and 0% ($n = 273, 153, 8$)

Limitations, reason for caution: The sample size of this preliminary study is small and more data will be included in the study, including more live birth data as it is available. This model may not be transferrable between different settings and confounders of morphokinetic models may exist.

Wider implications of the findings: Validation of morphokinetic models prior to use and consideration of potential confounding factors, such as effect of endometrial preparation and luteal support during frozen embryo replacement cycles. This work supports the use of a morphokinetic blastocyst implantation ranking, assigned at time of vitrification, used prospectively to select blastocysts for warming and transfer.

P-251 An increased trend in pregnancy rate following day 5 transfer of single embryos selected using Eeva Test compared with embryos selected using morphology alone

H. Newby[1], R. Wheeler[1], L. Asgari[1], K. Schnauffer[1], C. Kingsland[1], S. Troup[1]
[1]*Liverpool Women's Hospital, Hewitt Fertility Centre, Liverpool, United Kingdom*

Study question: This study aimed to investigate the clinical outcomes of day 5 single embryo transfer (SET) patients whose embryos were selected using the Eeva Test, compared to control day 5 SET patients whose embryos were selected using morphology alone.
Summary answer: Day 5 SET pregnancy rates may be improved when the embryos were selected using the Eeva Test combined with morphology, compared to Day 5 SET patients where the embryo selection was using morphology alone.
What is known already: The Eeva Test combines time-lapse monitoring with automated cell-tracking software providing quantitative information regarding embryo developmental potential. Although the Eeva Test has proven to be a useful aid to embryo selection, most studies to date have evaluated broad patient populations that include day-3 and day-5 transfers. Here, we assess to what extent the Eeva Test impacts embryo selection and clinical outcomes for a population of good prognostic patients who qualify for day 5 SET.
Study design, size, duration: Retrospective, observational cohort study. A total of 501 day 5 patients who underwent elective SET at first treatment cycle were included in this study, with 114 patients using the Eeva Test (Eeva Test group) and morphology for embryo selection and 387 patients using morphology alone (Control group).
Participants/materials, setting, methods: Day 5 SET patients were identified using standard criteria. Eeva Test was an elective option offered to aid embryo selection. All day 5 SET patients during the study period were included. Implantation and clinical pregnancy was defined by presence of a fetal heartbeat.
Main results and the role of chance: There were 114 Day 5 SET patients in the Eeva Test group and 387 patients in the Control group. Whilst there was no significant difference between the number of eggs collected or fertilized for Eeva vs. Control group, patients in the Eeva Test group were significantly older (33.2 ± 3.8 vs. 32.3 ± 4.2, $p = 0.03$). The total number of eggs collected and fertilized for the Eeva test group were 12.4 ± 5.3 and 7.7 ± 4.0 respectively, whereas the control group was 13.4 ± 5.3 and 7.8 ± 5.3. The clinical pregnancy rate indicated a trend towards being increased in those patients whose embryos had been selected through the Eeva Test and morphology against those which had used morphology alone (49% vs. 39%, $p = 0.06$).
Limitations, reason for caution: As this was not a randomized controlled trial, the study groups did not have equivalent patient characteristics. However, control patients were better prognosis than Eeva Test patients due to reduced age, suggesting that patient characteristics did not account for the trend toward improved outcomes in the Eeva Test group.
Wider implications of the findings: Patients whose embryos were selected for SET using the Eeva Test and morphology showed an increased trend in clinical pregnancy compared with control SET patients. Although definitive studies such as randomized controlled trials are necessary, our data indicate that incorporating early cell division timing parameters (Eeva Test) for day 5 blastocyst selection may improve the success of day 5 SET, thus clinics can apply day 5 SET more broadly and further reduce multiple pregnancies.

P-252 Comparative analysis of twin blastocysts derived from human embryo splitting at cleavage stage

L. Noli[1], Y. Dajani[1], A. Capalbo[2], N. Fogarty[3], K. Niakan[3], Y. Khalaf[1], D. Ilic[1]
[1]*Assisted Conception Unit, Guy's Hospital, London, United Kingdom*
[2]*GENERA, GENETYX Molecular Genetics Laboratory, Rome, Italy*
[3]*NIMR, Stem Cell Biology and Developmental Genetics, London, United Kingdom*

Study question: Embryo splitting has a potential to reduce number of the embryos needed for research. Our aim was to investigate embryo splitting technique and comparing, at a morphokinetic and molecular level monozygotic twin blastocysts derived from split embryos with normal non-manipulated blastocysts.
Summary answer: The blastocysts derived from split embryos are in general smaller and often have poorly developed or indistinguishable inner cell mass (ICM), containing cells with a dual expression of trophectoderm (TE) and ICM markers.
What is known already: Very limited number of studies investigated splitting of human embryos. Single blastomeres from four cell-stage embryos could develop into blastocysts. The more advanced cleavage stage at which the embryos were split, a higher number of viable twin embryos were able to develop into the blastocyst.
Study design, size, duration: Cleavage stage embryos, donated for research and undergoing splitting, were grouped into two groups based on number of blastomeres that survived thawing. Group 1 consists of embryo with 2–5 ($n = 30$) and the Group 2 of embryos with 6–10 blastomeres ($n = 30$). Non-manipulated matching cleavage stage embryos were used as a control.
Participants/materials, setting, methods: Research embryos were biopsied and half of the blastomeres were transferred into an empty recipient zona pellucida. Resulting twin embryos were cultured in EmbryoScope® for morphokinetic studies. Further, we investigated the expression of early lineage-specific gene markers in the blastocysts derived from split embryos using immunostaining.
Main results and the role of chance: Blastocysts developed from split embryos were smaller than the control non-manipulated blastocysts. In majority of split embryos, ICM was poorly developed or indistinguishable, containing cells with a dual expression of TE and ICM markers. Regardless, splitting human pre-implantation embryos from the Group 2 (6–10 cells) resulted, in general, in more viable and better quality of blastocysts compared to embryos from the Group 1 (2–5 cells). Furthermore, the average time of cell division differs between these two groups. Detailed morphokinetics and immunostaining data will be presented.
Limitations, reason for caution: Original cleavage stage embryos have been donated by different IVF clinics across the UK and their culture condition may differ. After splitting, all twin embryos were cultured only under one condition, which may or may not be different from original.
Wider implications of the findings: The data suggest that although blastocysts can be derived from split embryos, they are inferior in comparison with normal non-manipulated blastocysts and their suitability as a research tool may be questionable.
Study funding/competing interest(s): Funding by hospital/clinic(s). Funding by national/international organization(s) – The work has been funded by Studentship from Saudi Arabia government and by the incentive funds from the Assisted Conception Unit at Guy's Hospital.
Trial registration number: The work has been done under Human Fertilisation and Embryology Authority research licence number R0075.
