

## Annex 8: Evidence tables

---

### PART A: Ovarian response testing

#### 1. Pre-stimulation management

---

**KEY QUESTION: IS THE ASSESSMENT OF THE PREDICTED RESPONSE TO OVARIAN STIMULATION SUFFICIENTLY RELIABLE?**

P	I	C	O
Women undergoing IVF/ICSI	AFC AMH Basal FSH Inhibin B Basal oestradiol Age BMI	Compare against  - other tests - age alone	Test Accuracy for predicting Poor response Hyper-response ROC curves Cut-offs False positive/false negative results

### 1.1 ANTRAL FOLLICLE COUNT (AFC)

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Diagnostic test evaluated Reference standard test Include: Time interval and treatment	Prevalence	Accuracy (Se, Sp, PPV, NPV, LR+, LR-)	Reproducibility	Authors conclusion	Comments
Broer, S. L., Dolleman, M., van Disseldorp, J., Broeze, K. A., Opmeer, B. C., Bossuyt, P. M., Eijkemans, M. J., Mol, B. W. and Broekmans, F. J. Fertil Steril. 2013; 100 (2): 420-9.e7. (23721718)	SR	1023 patients (32 studies)	Ovarian response testing in combination with patient characteristics for prediction of excessive response		The ROC analysis showed high accuracy for AMH (AUC 0.81, 95% CI 0.76– 0.87) and for AFC (AUC 0.79, 95% CI 0.74–0.84), but only a moderate accuracy for FSH (AUC 0.66, 95% CI 0.60–0.73). a model incl. age, AFC, and AMH (AUC 0.85) had a significantly higher predictive accuracy than a model based on age alone (AUC 0.61; P<.001).		Both AFC and AMH clearly add value to female age alone in the prediction of excessive response. AMH and AFC in concert have high predictive accuracy, even without adding female age. The results also indicate that the performance of the ORTs may vary across patient subgroups, as determined by female age especially.	
Broer, S. L., van Disseldorp, J., Broeze, K. A., Dolleman, M., Opmeer, B. C., Bossuyt, P., Eijkemans, M. J., Mol, B. W. and Broekmans, F. J. Hum Reprod Update. 2013; 19 (1): 26-36. (23188168)	SR	5705 patients (28 studies)	Ovarian response testing in combination with patient characteristics for prediction of poor response and nonpregnancy		high accuracy for AMH (AUC 0.78: 95% CI 0.72– 0.84) and for AFC (AUC 0.76: 95% CI 0.70–0.82) in predicting poor response, but only a moderate accuracy for FSH (AUC 0.68: 95% CI 0.61–0.74; Table III). In predicting pregnancy after IVF, all three ORT had only a very small or no predictive effect (Table II). The AUC were 0.53, 0.50 and 0.55 for FSH, AFC and AMH, respectively (Table III).		Both AFC and AMH clearly add value to female age in the prediction of poor ovarian response in IVF. Comparably good predictions can be made with either AMH or AFC alone, without using female age. Age was the strongest single predictor of pregnancy after IVF, with moderate accuracy (AUC 0.57).	

Arce, Jc, Marca, A, Mirner, Klein B, Nyboe, Andersen A and Fleming, R. Fertil steril. 2013; 99 (6): 1644-53. (23394782)	RCT CS	Secondary analysis of the Megaset trial 749 women treated with 150 IU FSH + GnRH antagonist fixed scheme control	AMH and AFC were measured with the DSL kit and ultrasound respectively		AFC auc for poor and hyper response were 0.741 and 0.636 resp.		AMH was superior to AFC in predicting extremes of ovarian response	Secondary analysis of RCT, cohort in this sense.
Kwee, J., Elting, M. E., Schats, R., McDonnell, J. and Lambalk, C. B. Reprod Biol Endocrinol. 2007; 5 9. (17362511)	RCT CS	110 women performing an IVF cycle	AFC, ovarian volume, EFORT, Clomiphene challenge test were measured by ultrasound. AFC was considered the total number of 2-10 mm Poor was < 6 and hyper > 20 oocytes		AFC ROCAuc for POR prediction was 0.83. at the best cut-off (<6) the sensitivity 41% was the specificity was 95% and the PPV 75%. For hyper response the ROCAuc was 0.92. The best cut-off 14 was associated to sensitivity, specificity and PPV as follows: 82,89 and 58%		AFC performs well as a test for ovarian response being superior or at least similar to complex expensive and time consuming endocrine tests, probably most applicable in general practise	Secondary analysis of RCT, cohort in this sense.
Lan, V. T., Linh, N. K., Tuong, H. M., Wong, P. C. and Howles, C. M. Reprod Biomed Online. 2013; 27 (4): 390-9. (23953069)	RCT CS	N=348 aged <40 years body mass index <28 kg/m <sup>2</sup> , early follicular phase (day 2-4) basal FSH serum concentrations <12 IU/l,	AFC and AMH measured. Methodology for both two measurements was not specified. Poor was < 3 and hyper > 20 oocytes		Area under the curve (AUC) values and 95% confidence intervals (CI) for AFC for predicting hyporesponse to ovarian stimulation was 0.80 (0.73-0.89) ( P < 0.0001). For the prediction of hyperresponse (>20 oocytes retrieved), AUC values and 95% CI were statistically significant for AFC (0.81, 0.74-0.88) Cut off values were 6 and 125 respectively		With subtle differences, both AMH and AFC appear to have the ability to predict poor ovarian response and guide the starting dose of rFSH	Secondary analysis of RCT, cohort in this sense.

Oehninger, S, Nelson, Sm, Verweij, P and Stegmann, Bj. Reproductive Biology and Endocrinology. 2015; 13 (1): (26520396)	RCT CS	infertile women aged 35–42 years (n = 694). Pursue trial. Infertile women aged 35–42 years with a body weight of $\geq 50$ kg and body mass index (BMI) $\geq 18$ and $\leq 32$ kg/m <sup>2</sup>	AFC and other biomarkers were measured before corifollitropin administration Low response defined as $< 6$ oocytes, High response as $> 18$ oocytes. AMH was measured with Gen II. Not specified the AMH methodology		Prediction of low: ROCauc 0.88. Prediction of high: ROCauc 0.88 They developed a combined model including age, AFC, AMH, FSH and cycle length	in women aged 35 to 42 years undergoing ovarian stimulation with corifollitropin alfa in a GnRH antagonist protocol, AMH, AFC and age at the start of stimulation were prognostic for both high and low ovarian response, in addition to FSH for high ovarian response and menstrual cycle length for low ovarian response.	Secondary analysis of RCT, cohort in this sense.
Bancsi, L. F., Broekmans, F. J., Eijkemans, M. J., de Jong, F. H., Habbema, J. D. and te Velde, E. R. Fertil Steril. 2002; 77 (2): 328-36. (11821092)	CS	120 women (112 conventional IVF, 18 ICSI Incl.: [1] a regular spontaneous menstrual cycle; [2] presence of both ovaries; [3] no evidence of endocrine disorders Accepted to 45 years  Subdivided also to in further analysis on: poor (26) and normal responders (n=84) and on: age $<41$ , and/or FSH $<15$ (n=92) age $>41$ , and/or FSH $>15$ (n=28)  Setting: One center,	The number of antral follicles and the total ovarian volume by ultrasound, basal levels of FSH, E2, and inhibin B on cycle day 3.  The poor response was defined as: [1] collection of fewer than four oocytes at retrieval or [2] cycle cancellation because of impaired follicular reaction ( $< 3$ follicles) in response to exogenous gonadotropins. High response was defined as the collection of $> 20$ oocytes at retrieval		The antral follicle count appeared to have the best discriminative potential for poor response, expressed by the largest ROC AUC of 0.87, FSH 0.04, Inhibin B 0.77	1.The number of antral follicles is the best basal marker of ovarian reserve in terms of predicting poor response in IVF. 2.Addition of basal FSH and inhibin B levels to a logistic model with the antral follicle count significantly improved the prediction of poor response;	Addition of FSH to AFC improves prediction of poor response
Bancsi, L. F., Broekmans, F. J., Looman, C. W., Habbema, J. D. and te Velde, E. R. Fertil Steril. 2004; 81 (1): 35-41. (14711542)	CS	130 women All patients met the following criteria: [1] regular spontaneous menstrual cycle (25–35 days); [2] presence of both ovaries; [3] no evidence of endocrine disorders (normal levels of TSH, T, androstenedione (A), and PRL)	Poor response: $< 4$ oocytes at retrieval		1st cycle AFC: ROC-AUC: 0.87  Mean AFC: ROC-AUC: 0.87	ultrasound-based antral follicle counts seem to be a reliable tool for the assessment of ovarian reserve and studies on the prediction of poor ovarian response to exogenous gonadotropins	

Elgindy, E. A., El-Haieg, D. O. and El-Sebaey, A. Fertil Steril. 2008; 89 (6): 1670-6. (17658520)	CS	33 women, Age <38y D3 FSH <10IU/L BMI: 18-29 kg/m2	AMH, FSH and LH, AFC, mean ovarian volume	9/33 poor responders	ROC-AUC 0.94 (95% CI 0.85-1.018) for poor response			
Jayaprakasan, K., Al-Hasie, H., Jayaprakasan, R., Campbell, B., Hopkisson, J., Johnson, I. and Raine-Fenning, N. Fertil Steril. 2009; 92 (6): 1862-9. (18973895)	CS	141 patients entering IVF programme, under 43 years with FSH < 12 IU/L	Ultrasound measurement. No definition of AFC Poor response was defined as < 4 oocytes		41 patients were PORs AFC had a ROCAUC 0.88. At the best cut-off (AFC=11) the sensitivity, specificity and positive likelihood ratio were 83%,83% and 4.9 respectively		AFC had a very good performance in predicting POR	
Jayaprakasan, K., Campbell, B., Hopkisson, J., Johnson, I. and Raine-Fenning, N. Fertil Steril. 2010; 93 (3): 855-64. (19046583)	CS	Prospective study on 150 patients in an IVF clinic	Hormonal and endocrine markers were measured		AFC AUC 0.935 for prediction of poor response		AMH and AFC were the most useful predictors of retrieved oocytes	
Khairy, M., Clough, A., El-Toukhy, T., Coomarasamy, A. and Khalaf, Y. Reprod Biomed Online. 2008; 17 (4): 508-14. (18854104)	CS	148 women entering IVF	Ultrasound measurement of follicles Between 2 and 10 mm POR defined as < 4 oocytes		23 women had POR The AFC prediction of POR: ROCAUC 0.79 The best cut-off was < 11, with a Likelihood ratio of 5.4 (post-test probability of POR 50%)		AFC had a good performance in predicting POR. No relevant contribution of adding other variables	
Mutlu, M. F., Erdem, M., Erdem, A., Yildiz, S., Mutlu, I., Arisoy, O. and Oktem, M. J Assist Reprod Genet. 2013; 30 (5): 657-65. (23508679)	CS	192 patients entering IVF cycle Prospective study	AMH and AFC predictive value on ovarian response after stimulation in IVF programs and live birth rates compared with age and basal FSH		Age was related to ovarian response. The ROCAUC prediction of poor response was 0.76 (0.68-0.84). OR was 1.21 (1.12-1.3) Sensitivity 30.6%, specificity 96.5% AMH and AFC were superior to AFC		AFC is better than AMH in predicting ovarian response; they although show both limitations in predicting live births; age is the best predictor for live birth rates (OR 0.92 (0-86-0.99)	

Penarrubia, J., Peralta, S., Fabregues, F., Carmona, F., Casamitjana, R. and Balasch, J. <i>Fertil Steril.</i> 2010; 94 (7): 2590-5. (20400077)	CS	104 women in the IVF programme (25-41 yrs.) healthy and regular cycles	Ultrasound biomarkers measurement (AFC 2-10mm) + some hormonal markers (Inhibin B, FSH and oestradiol). Poor response defined as < 4 oocytes or cancellation for low follicular growth		AFC predicted POR (ROC auc 0.9). Sensitivity 80.7% Specificity 83.3%		AFC and inhibin b have the same, good, performance of predicting ovarian response																																														
Soldevila, P. N., Carreras, O., Tur, R., Coroleu, B. and Barri, P. N. <i>Gynecol Endocrinol.</i> 2007; 23 (4): 206-12. (17505940)	CS	327 patients entering IVF program Prospective study	Predictive value of AFC on ovarian response to stimulation and pregnancy, and its comparison with other predictive parameters of ovarian reserve such as basal FSH and age		AUC of AFC: 0.73 (95% CI 0.67-0.77) for prediction of poor response.		AFC correlates negatively and statistically significantly with age, basal FSH and LH.																																														
Tolikas, A., Tsakos, E., Gerou, S., Prapas, Y. and Loufopoulos, A. <i>Hum Fertil (Camb).</i> 2011; 14 (4): 246-53. (22088130)	CS	Prospective study on 90 women	AMH, FSH and AFC were measured. AMH was measured by DSL assay. No specification for AFC. Poor was for <4 oocytes. High response was for > 12 oocytes		AFC predicted POR better than AMH (ROC auc 0.8 vs 0.7) A cut-off value of AFC=4.50 gives 72.4% sensitivity, 80.3% specificity, 63.6% PPV (positive predictive value) and 86% NPV (negative predictive value) for prognosis of poor response		AFC was a good predictor of ovarian response																																														
Tsakos, E., Tolikas, A., Daniilidis, A. and Asimakopoulos, B. <i>Arch Gynecol Obstet.</i> 2014; 290 (6): 1249-53. (25001569)	CS	Prospective study on 105 women. 25-45 years of age, regular cycles. Entering IVF	Markers were measured		<p><b>Table 3</b> ROC analysis for the evaluation of prognostic value of baseline FSH, baseline AMH and AFC on the number of retrieved oocytes</p> <table border="1"> <thead> <tr> <th></th> <th>Area under the curve (AUC)</th> <th>Significance (p)</th> <th>Asymptotic 95 % CI Lower bound</th> <th>Upper bound</th> </tr> </thead> <tbody> <tr> <td colspan="5"><b>Poor responders</b></td> </tr> <tr> <td>AFC</td> <td>0.858</td> <td>&lt;0.001</td> <td>0.785</td> <td>0.930</td> </tr> <tr> <td>Baseline FSH</td> <td>0.671</td> <td>0.004</td> <td>0.563</td> <td>0.780</td> </tr> <tr> <td>Baseline AMH</td> <td>0.634</td> <td>0.026</td> <td>0.523</td> <td>0.745</td> </tr> <tr> <td colspan="5"><b>High responders</b></td> </tr> <tr> <td>AFC</td> <td>0.862</td> <td>0.001</td> <td>0.772</td> <td>0.952</td> </tr> <tr> <td>Baseline FSH</td> <td>0.724</td> <td>0.036</td> <td>0.565</td> <td>0.882</td> </tr> <tr> <td>Baseline AMH</td> <td>0.664</td> <td>0.125</td> <td>0.465</td> <td>0.863</td> </tr> </tbody> </table>		Area under the curve (AUC)	Significance (p)	Asymptotic 95 % CI Lower bound	Upper bound	<b>Poor responders</b>					AFC	0.858	<0.001	0.785	0.930	Baseline FSH	0.671	0.004	0.563	0.780	Baseline AMH	0.634	0.026	0.523	0.745	<b>High responders</b>					AFC	0.862	0.001	0.772	0.952	Baseline FSH	0.724	0.036	0.565	0.882	Baseline AMH	0.664	0.125	0.465	0.863		AFC has better diagnostic performance than AMH and age in predicting the extremes of ovarian response	
	Area under the curve (AUC)	Significance (p)	Asymptotic 95 % CI Lower bound	Upper bound

## 1.2 ANTI-MÜLLERIAN HORMONE (AMH)

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Diagnostic test evaluated Reference standard test Include: Time interval and treatment	Prevalence	Accuracy (Se, Sp, PPV, NPV, LR+, LR-)	Reproducibility	Authors conclusion	Comments
Broer, S. L., Dolleman, M., van Disseldorp, J., Broeze, K. A., Opmeer, B. C., Bossuyt, P. M., Eijkemans, M. J., Mol, B. W. and Broekmans, F. J. Fertil Steril. 2013; 100 (2): 420-9.e7. (23721718)	SR	N 4786 patients (32 studies) Model building (all ORT 1023 patients)  Study characteristics and assays differed per study but corrected for in random intercept logistic regression models.	IPD meta-analyses Ovarian response testing in combination with patient characteristics for prediction of excessive response  Excessive response > 15 oocytes	Normal responders N= 3892  Excessive responders N= 894	AMH OR 1.61 (1.48-1.76), p value < 0.001 The ROC analysis showed high accuracy for AMH (AUC 0.81, 95% CI 0.76–0.87) A model incl. age, AFC, and AMH (AUC 0.85) had a significantly higher predictive accuracy than a model based on age alone (AUC 0.61; P<.001).		Both AFC and AMH clearly add value to female age alone in the prediction of excessive response. AMH and AFC in concert have high predictive accuracy, even without adding female age.  The results also indicate that the performance of the ORTs may vary across patient subgroups, as determined by female age especially.	
Broer, S. L., van Disseldorp, J., Broeze, K. A., Dolleman, M., Opmeer, B. C., Bossuyt, P., Eijkemans, M. J., Mol, B. W. and Broekmans, F. J. Hum Reprod Update. 2013; 19 (1): 26-36. (23188168)	SR	5705 patients (28 studies) 4170 patients for poor response analysis Model building (all ORT 617 patients)  Study characteristics and assays differed per study but corrected for in random intercept logistic regression models.	IPD meta-analysis Ovarian response testing in combination with patient characteristics for prediction of poor response and nonpregnancy  Poor response ≤ 4 oocytes	Poor response N= 893 (21%)  Normal response N = 3277 (79%)	AMH OR 0.50 (0.41-0.60), p value < 0.001  The ROC analyses showed high accuracy for AMH (AUC 0.78: 95% CI 0.72–0.84)  A model including age, AFC and AMH had a significantly higher predictive accuracy than a model based on age alone (AUC 0.80 vs 0.61; P < 0.001). This model is not better than single use of AMH or AFC.		Both AFC and AMH clearly add value to female age in the prediction of poor ovarian response in IVF. Comparably good predictions can be made with either AMH or AFC alone, without using female age.	

Andersen, An, Witjes, H, Gordon, K and Mannaerts, B. Human reproduction (Oxford, England). 2011; 26 (12): 3413-23. (21954280)	RCT CS	442 patients Age 18-39 years BMI $\leq$ 32 kg/m <sup>2</sup> Regular cycle 24-35 days No endocrine abnormalities FSH levels $\leq$ 12 IU/L rFSH 200 IU/day GnRH antagonist Randomized for pre-treatment with OC or no pre-treatment AMH assay DSL	RCT for OC or no OC pre-treatment. For this question cohort study AMH, AFC, FSH in the prediction or ovarian response  Poor response < 6 oocytes Excessive response > 18 oocytes	Incidence low and excessive response not stated	Low response Total group: AUC 0.84 OC group: 0.84 Non-OC group: 0.88  High response Total group: 0.77 OC group: 0.74 Non-OC group: 0.82		AMH appeared to be an important predictor for the number of oocytes retrieved.	Secondary analysis of RCT, cohort in this sense.
Arce, Jc, Marca, A, Mirner, Klein B, Nyboe, Andersen A and Fleming, R. Fertil steril. 2013; 99 (6): 1644-53. (23394782)	RCT CS	749 women, (n=375 recombinant FSH, n=374 hp-HMG) aged 21 to 34 years, serum follicle-stimulating hormone (FSH) level 1–12 IU/L and antral follicle count (AFC) >10. mild male factor or unexplained fertility	Relation: AMH at start of stimulation and ovarian response and treatment outcome.	IVF population	AMH accounted for 85%, FSH for 14%, and inhibin B and AFC for <1% each of the explained variation in oocyte yield. Multiple regression model revealed that AMH (P<.001) and FSH (P<.001) were statistically significant predictors of the number of oocytes retrieved, but AFC (P=.125) and inhibin B (P=.706) were not		AMH is the best predictor for identifying patients with poor and high ovarian response	Secondary analysis of RCT, cohort in this sense.
Lan, V. T., Linh, N. K., Tuong, H. M., Wong, P. C. and Howles, C. M. Reprod Biomed Online. 2013; 27 (4): 390-9. (23953069)	RCT CS	382 patients Age < 40 years BMI < 28 kg/m <sup>2</sup> FSH $\leq$ 12 IU/L GnRH agonist protocol rFSH individualized dosage between 150 – 375 IU/day.  AMH assay?	RCT comparing dose algorithms with AMH or AFC. Cohort for prediction of ovarian response  Poor response < 3 oocytes Excessive response > 20 oocytes	Incidence total group not stated	Poor response AMH: AUC 0.88 (0.81-0.95),  Excessive response AMH AUC 0.76 (0.69-0.83)		AMH is a good predictor of poor ovarian response.	Secondary analysis of RCT, cohort in this sense.

Oehninger, S, Nelson, Sm, Verweij, P and Stegmann, Bj. Reproductive Biology and Endocrinology. 2015; 13 (1): (26520396)	RCT	686 patients, Age 35-42 yrs. BMI $\geq 18$ and $\leq 32$ kg/m <sup>2</sup> PCOS excluded GnRH antagonist 150 ugr corifollitropin alfa or rFSH 300 IU/day AMH assay gen II	RCT comparing corifollitropin alfa vs rFSH, cohort study for predicting ovarian response with AMH, AFC and FSH. Poor response < 6 oocytes Excessive response > 18 oocytes	Low response N = 159 (23.2%) Excessive response N = 97 (14.1%)	Low response OR 0.19 (0.12-0.28), P < 0.0001 AMH AUC 0.871 High AMH OR 1.93 (1.58-2.36) P < 0.0001 AMH AUC 0.864		In older women AMH is a significant predictor of ovarian response	
Elgindy, E. A., El-Haieg, D. O. and El-Sebaey, A. Fertil Steril. 2008; 89 (6): 1670-6. (17658520)	CS	33 women, Age <38y D3 FSH <10IU/L BMI: 18-29 kg/m <sup>2</sup>	AMH, FSH and LH, AFC, mean ovarian volume	9/33 poor responders	ROC-AUC 0.9 (95% CI 0.8-1.006) for poor response			
Heidar, Z., Bakhtiyari, M., Mirzamoradi, M., Zadehmodarres, S., Sarfjoo, F. S. and Mansournia, M. A. J Endocrinol Invest. 2015; 38 (9): 1007-15. (25981081)	CS	188 women No endocrine disease No PCOS GnRH agonist uFSH AMH assay GEN II	Prospective cohort study of AMH in ovarian response Poor ovarian response $\leq 3$ oocytes Excessive ovarian response $\geq 12$ oocytes	No ovarian response N 15 (7.8%) Poor response N = 22 (11.4%) Excessive response N = 53 (28.2%)	Poor response AMH OR 0.36 (0.19-0.68) AUC 0.76 (0.66-0.86) Sensitivity 0.72 (0.63-0.81) Specificity 0.81 (0.60-0.93) Excessive response AMH OR 1.71 (1.09-2.7) AUC 0.69 (0.60-0.77) Sensitivity 0.57 (0.43-0.69) Specificity 0.73 (0.63-0.81)		AMH levels showed to be a good test to discriminate between different ovarian responses.	
Jayaprakasan, K., Campbell, B., Hopkisson, J., Johnson, I. and Raine-Fenning, N. Fertil Steril. 2010; 93 (3): 855-64. (19046583)	CS	Prospective study on 150 patients in an IVF clinic Age: <41y First cycle IVF	FSH, LH, E2, inhibin B, AMH Poor response <4 oocytes AMH assay: MIS/AMH ELISA		ROC-AUC 0.91 for prediction of poor response		AFC and AMH are the most significant predictors of the number of oocytes retrieved and of poor ovarian response.	

Li, R, Gong, F, Zhu, Y, Fang, W, Yang, J, Liu, J, Hu, L, Yang, D, Liang, X and Qiao, J. Reproductive biomedicine online. 2016; 33 (4): 506-512. (27502068)	CS	615 patients Normal ovulatory cycles No PCOS  GnRH agonist rFSH (+rLH)  AMH assay gen II	Prospective cohort study for AMH as ovarian response predictor.  Poor ovarian response ≤ 5 oocytes  Excessive ovarian response > 15 oocytes		Poor response OR 0.61 AUC-ROC 0.70 (0.60-0.80). cut-off value 1.1 ng/ml sensitivity: 52.27%, specificity: 87.23%  Excessive response: OR 1.65 AUC-ROC curve is 0.76 (0.72-0.80) Cut off 2.6 ng/ml with sensitivity: 81.28%, specificity: 59.51%.		serum AMH concentration was positively correlated with the number of oocytes and AMH concentration could predict the ovarian response.	
Mutlu, M. F., Erdem, M., Erdem, A., Yildiz, S., Mutlu, I., Arisoy, O. and Oktem, M. J Assist Reprod Genet. 2013; 30 (5): 657-65. (23508679)	CS	192 patients entering IVF cycle Prospective study Age: 18-44y No endocrine disorders	AMH and AFC predictive value on ovarian response after stimulation in IVF programs and live birth rates compared with age and basal FSH		AMH AUC-ROC: 0.86 (95% CI 0.80-0.92) for discriminating between poor and normal response		ROC analysis revealed that AFC was the most accurate of all tests in predicting poor response to ovarian stimulation; AUC for AMH was lower than AFC but better than basal FSH and age.	
Tolikas, A., Tsakos, E., Gerou, S., Prapas, Y. and Loufopoulos, A. Hum Fertil (Camb). 2011; 14 (4): 246-53. (22088130)	CS	Prospective study on 90 women. Age: 25-45y no serious endocrinology disorders BMI: 19-30	AMH, FSH and AFC were measured. AMH was measured by DSL assay. No specification for AFC. Poor was for <4 oocytes. High response was for > 12 oocytes		Baseline AMH ROC: 0.7 (95% CI 0.58-0.82) D5 AMH: AUC 0.682 (95% CI 0.57-0.80) For prediction of poor response		baseline serum AMH level is a good predictor of poor ovarian response but mid-stimulation (day 5) AMH serum levels do not offer better prediction of response in stimulated IVF and ICSI cycles.	
Tsakos, E., Tolikas, A., Daniilidis, A. and Asimakopoulos, B. Arch Gynecol Obstet. 2014; 290 (6): 1249-53. (25001569)	CS	105 women Age 25-45 yrs. No endocrine disorders BMI 19-30 kg/m2  r/uFSH individualized dose GnRH antagonist AMH assay DSL	Prospective cohort study predictive value of AMH in ovarian response  Poor response < 4 oocytes Excessive response > 12 oocytes	Poor response N = 35  Excessive response N = 8	Poor <4oocytes AMH AUC 0.634 (0.523-0.745), P 0.026  High response > 12 oocytes AMH AUC 0.664 (0.465-0.863), p 0.125		AFC, baseline AMH and baseline FSH are good predictors for the outcome of ovarian stimulation in GnRH-antagonist cycles	

### 1.3 BASAL FOLLICLE STIMULATING HORMONE (FSH)

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Diagnostic test evaluated Reference standard test Include: Time interval and treatment	Prevalence	Accuracy (Se, Sp, PPV, NPV, LR+, LR-)	Reproducibility	Authors conclusion	Comments
Broer, S. L., Dolleman, M., van Disseldorp, J., Broeze, K. A., Opmeer, B. C., Bossuyt, P. M., Eijkemans, M. J., Mol, B. W. and Broekmans, F. J. Fertil Steril. 2013; 100 (2): 420-9.e7. (23721718)	SR	4786 patients (32 studies)	Ovarian response testing in combination with patient characteristics for prediction of excessive response		ROC-AUC of 0.64 (95% CI 0.61-0.67) for the prediction of an excessive response			
Broer, S. L., van Disseldorp, J., Broeze, K. A., Dolleman, M., Opmeer, B. C., Bossuyt, P., Eijkemans, M. J., Mol, B. W. and Broekmans, F. J. Hum Reprod Update. 2013; 19 (1): 26-36. (23188168)	SR	5705 patients (28 studies)	Ovarian response testing in combination with patient characteristics for prediction of poor response and nonpregnancy		ROC-AUC of 0.66 (95% CI 0.62-0.69) for the prediction of a poor response			

Arce, Jc, Marca, A, Mirner, Klein B, Nyboe, Andersen A and Fleming, R. Fertility and sterility. 2013; 99 (6): 1644-53. (23394782)	RCT CS	749 women, ivf population, (n=375 recombinant FSH, n=374 hp HMG) aged 21 to 34 years, serum follicle-stimulating hormone (FSH) level 1–12 IU/L and antral follicle count (AFC) >10. mild male factor or unexplained fertility	Relation: AMH at start of stimulation and ovarian response and treatment outcome.		FSH accounted for 14% of the explained variation in oocyte yield. Multiple regression model revealed that AMH (P<.001) and FSH (P<.001) were statistically significant predictors of the number of oocytes retrieved ROC-AUC of 0.73 for the prediction of poor response and an ROC-AUC of 0.71 for high response after hp-hMG stimulation, and an ROC-AUC of 0.72 for poor response and an ROC-AUC of 0.73 for high response after rFSH stimulation		AMH is the best predictor for identifying patients with poor and high ovarian response AMH+ FSH for prediction both low and high response AUC for values were not significantly higher in comparison to those obtained for AMH only.	Secondary analysis of RCT, cohort in this sense.
Kwee, J., Elting, M. E., Schats, R., McDonnell, J. and Lambalk, C. B. Reprod Biol Endocrinol. 2007; 5 9 (17362511)	RCT CS	110 patients: 56 CCCT, 54 EFFORT before first IVF aged 18–39 years Incl.: idiopathic for >3 years and/or due to a male factor and/or cervical hostility Excl.: severe male factor and PCOS	AFC, basal ovarian volume (BOV), the exogenous FSH ovarian reserve test (EFORT) and the clomiphene citrate challenge test (CCCT), in prediction poor and hyperresponders		1. Univariate logistic regression bFSH ROC-AUC = 0.83 2. Multiple logistic regression analysis did not produce a better model in terms of improving the prediction of poor response.		FSH were similar as AFC in the prediction of poor response.	Secondary analysis of RCT, cohort in this sense.
Oehninger, S, Nelson, Sm, Verweij, P and Stegmann, Bj. Reproductive Biology and Endocrinology. 2015; 13 (1): (26520396)	RCT CS	infertile women aged 35–42 years (n = 694). Pursue trial. Infertile women aged 35–42 years with a body weight of ≥50 kg and body mass index (BMI) ≥18 and ≤32 kg/m <sup>2</sup>	AFC, AMH, age and basal FSH were measured before corifollitropin administration Low response defined as < 6 oocytes, High response as >18 oocytes.		Prediction of high response: ROCauc 0.88.  They developed a combined model including age, AFC, AMH, FSH and cycle length		in women aged 35 to 42 years undergoing ovarian stimulation with corifollitropin alfa in a GnRH antagonist protocol, AMH, AFC and age at the start of stimulation were prognostic for both high and low ovarian response, in addition to FSH for high ovarian response and menstrual cycle length for low ovarian response.	Secondary analysis of RCT, cohort in this sense.

<p>Bancsi, L. F., Broekmans, F. J., Eijkemans, M. J., de Jong, F. H., Habbema, J. D. and te Velde, E. R. Fertil Steril. 2002; 77 (2): 328-36. (11821092)</p>	CS	<p>120 women (112 conventional IVF, 18 ICSI Incl:[1] a regular spontaneous menstrual cycle ; [2] presence of both ovaries; [3] no evidence of endocrine disorders Accepted to 45 years</p> <p>Subdivided also to in further analysis on: poor (26) and normal responders ( n=84) and on: age&lt;41, and/orFSH&lt;15 (n=92) age&gt;41, and/orFSH&gt;15 (n=28)</p> <p>Setting: One center,</p>	<p>The number of antral follicles and the total ovarian volume by ultrasound, basal levels of FSH, E2, and inhibin B on cycle day 3.</p> <p>The poor response was defined as: [1] collection of fewer than four oocytes at retrieval or [2] cycle cancellation because of impaired follicular reaction (&lt; 3 follicles) in response to exogenous gonadotropins. High response was defined as the collection of &gt;20 oocytes at retrieval</p>		<p>The antral follicle count appeared to have the best discriminative potential for poor response, expressed by the largest ROC AUC of 0.87, FSH 0.04, Inhibin B 0.77</p>		<p>1.The number of antral follicles is the best basal marker of ovarian reserve in terms of predicting poor response in IVF. 2.Addition of basal FSH and inhibin B levels to a logistic model with the antral follicle count significantly improved the prediction of poor response;</p>	<p>Addition of FSH to AFC improves prediction of poor response</p>

Khairy, M., Clough, A., El-Toukhy, T., Coomarasamy, A. and Khalaf, Y. <i>Reprod Biomed Online</i> . 2008; 17 (4): 508-14. (18854104)	CS	148 women entering IVF POR defined as < 4 oocytes	Performance of different variables in the prediction of poor ovarian response: Age BMI AFC FSH Oestradiol		23 women had POR The AFC prediction of POR: ROCauc 0.69		AFC had a good performance in predicting POR. No relevant contribution of adding other variables	
Mutlu, M. F., Erdem, M., Erdem, A., Yildiz, S., Mutlu, I., Arisoy, O. and Oktem, M. <i>J Assist Reprod Genet</i> . 2013; 30 (5): 657-65. (23508679)	CS	192 women normoresponders 143- poor responders 49 Inclusion: : age between 18 and 44 years, regular menstrual cycles (21–35 days), no endocrine disorders	Basal levels of AMH, FSH and antral follicle prior to IVF treatment. The predictive value of these parameters in terms of 1. retrieved oocyte number 2. live birth rates		ROC-AUC of 0.75 (95% CI 0.66-0.85) for prediction of poor and normal ovarian response		1. AFC is better than AMH and these two are better than FSH in predicting poor response 2. The only significant predictor of the probability of achieving a live birth was age.	
Penarrubia, J., Peralta, S., Fabregues, F., Carmona, F., Casamitjana, R. and Balasch, J. <i>Fertil Steril</i> . 2010; 94 (7): 2590-5. (20400077)	CS	98 women, IVF population 72 normal responders and 26 poor responders. age range: 25 to 41 years, undergoing their first ART cycle and fulfilling our inclusion criteria. All patients were infertile but otherwise healthy women, had both ovaries with no previous ovarian surgery	D-5Inhibin B, AFC		ROC-AUC of 0.62 (95% CI 0.51-0.71) for prediction of ovarian response		1. Basal FSH and day-5 inhibin B have similar predictive properties for ovarian response in assisted reproduction cycles	
Soldevila, P. N., Carreras, O., Tur, R., Coroleu, B. and Barri, P. N. <i>Gynecol Endocrinol</i> . 2007; 23 (4): 206-12. (17505940)	CS	327 women; first IVF cycle, one center 107 low response, 206 normal response. Incl. crit.: first IVF cycle Excl. crit.: Exclusion criteria incorrect viewing of the ovaries and the presence of organic ovarian pathology.	AFC, basal FSH, age, BMI, E2, LH		1. Predictive value for poor response OR 95% CI FSH 0.93 (0.87-0.98)  2. Predictive value of follicle-stimulating hormone (FSH) for poor response  ROC-AUC: 0.629 (95% CI 0.57-0.68) for prediction of poor response		1. The AFC has predictive value for ovarian response in an IVF cycle, with a cut-off value of 7 follicles above which there are more chances of normal response. Its predictive value is higher than that of basal FSH  2.. The number of antral follicles is shown as an independent marker of poor response, with an importance comparable with basal FSH and age.	

Tolikas, A., Tsakos, E., Gerou, S., Prapas, Y. and Loufopoulos, A. Hum Fertil (Camb). 2011; 14 (4): 246-53. (22088130)	CS	Prospective study on 90 women. Poor was for <4 oocytes. High response was for > 12 oocytes	AMH, FSH and AFC were measured. AMH was measured by DSI assay.		Prediction of poor response: ROC auc: 0.65		AFC the best predictor of ovarian response, followed by AMH	
Tsakos, E., Tolikas, A., Daniilidis, A. and Asimakopoulos, B. Arch Gynecol Obstet. 2014; 290 (6): 1249-53. (25001569)	CS	Prospective study on 105 women. 25-45 years of age, regular cycles. Entering IVF	Markers were measured		Prediction of poor ovarian response: ROCauc: 0.67 Prediction of high ovarian response: ROCauc: 0.72		AFC has better diagnostic performance than AMH and age in predicting the extremes of ovarian response	

## 1.4 INHIBIN B

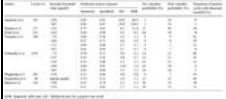

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Diagnostic test evaluated Reference standard test Include: Time interval and treatment	Prevalence	Accuracy (Se, Sp, PPV, NPV, LR+, LR-)	Reproducibility	Authors conclusion	Comments
Broekmans, F. J., Kwee, J., Hendriks, D. J., Mol, B. W. and Lambalk, C. B. Hum Reprod Update. 2006; 12 (6): 685-718. (16891297)	SR	(9 studies)  Variation among the definitions of poor response and study quality and design characteristics is clearly present but logistic regression analysis revealed that none of the items significantly impacted the predictive performance of the test	Inhibin B for poor response prediction and/or non-pregnancy prediction		Spearman correlation coefficient for poor response: -0.93, for non-pregnancy prediction: -0.94		With the use of basal inhibin B in regularly cycling women, the accuracy in the prediction of poor response and non-pregnancy is only modest at a very low threshold level. At best the test may be used as screening test for counselling purposes or to direct further diagnostic steps	The inhibin B is not good marker as the other specified in prediction of poor response.
Arce, Jc, Marca, A, Mirner, Klein B, Nyboe, Andersen A and Fleming, R. Fertility and sterility. 2013; 99 (6): 1644-53. (CN-00872359)	RCT	749 women, aged 21 to 34 years, unexplained infertility or mild male factor infertility and with serum FSH level 1–12 IU/L and AFC >10, BMI of 18 to 25 kg/m <sup>2</sup> , and regular menstrual cycles of 24 to 35 days.	AMH, FSH, Inhibin B  Inhibin B-ELISA (2.6 ng/ml sensitivity)		ROC-AUC of 0.62 for the prediction of poor response and an ROC-AUC of 0.60 for high response after hp-hMG stimulation, and an ROC-AUC of 0.64 for poor response and an ROC-AUC of 0.53 for high response after rFSH stimulation		The inhibin B has the lower AUC in predicting both low and excessive ovarian response in comparison to other tests (FSH, age, AFC)	Secondary analysis of RCT, cohort in this sense.
Kwee, J., Elting, M. E., Schats, R., McDonnell, J. and Lambalk, C. B. Reprod Biol Endocrinol. 2007; 5 9. (17362511)	RCT	110 patients: 56 CCCT, 54 EFFORT before first IVF aged 18–39 years Incl.: idiopathic for >3 years and/or due to a male factor and/or cervical hostility Excl.: severe male factor and PCOS	AFC, basal ovarian volume (BOV), the exogenous FSH ovarian reserve test (EFORT) and the clomiphene citrate challenge test (CCCT), in prediction poor and hyperresponders		ROC-AUC of 0.86 for the increment of inhibin B in the EFORT for the prediction of poor response and an ROC-AUC of 0.93 for the increment of inhibin B in the EFORT for the prediction of hyper response		AFC performs well as a test for ovarian response being superior or at least similar to complex expensive and time consuming endocrine tests	Secondary analysis of RCT, cohort in this sense.

Fawzy, M, Lambert, A, Harrison, Rf, Knight, Pg, Groome, N, Hennelly, B and Robertson, Wr. Human reproduction (Oxford, England). 2002; 17 (6): 1535-43. (12042274)	CT	54 women <39 years	inhibin B, Inhibin A, E2 assessment after 4 days treatment of gonadotropins		ROC-AUC of 0.96 (95% CI 0.86-0.99) for D5 inhibin B for predicting poor response (<8 mature oocytes)		women with inhibin B < 400 pg/ ml in d-5 have a poor response to ovarian stimulation and are less likely to conceive compare to women with inh B > 400 pg/ ml Day 5 inhibin B was the best predictor of pregnancy (no live births and four cycles cancelled, low inhibin group;	
Hendriks, D. J., Broekmans, F. J., Bancsi, L. F., de Jong, F. H., Looman, C. W. and Te Velde, E. R. Hum Reprod. 2005; 20 (1): 163-9. (15471926)	CS	63 patients	CCCT test (repeated) in comparison to basal FSH, AFC, inhibin B  Poor response (<4 oocytes or cancellation due to impaired (<3 follicles) or absent follicular growth) was used as primary outcome measure	IVF population first cycle long rFSH	For basal and rep CCCT (ROCAUC): FSH cd10 = 0.79, inhibin B cd10 = 0.79, mean FSH cd10 = 0.82 and mean inhibin B cd10 = 0.88). This compared well with the performance of the basal markers (FSH 0.82, inhibin B 0.72 and AFC 0.83). In a multivariate analysis		CCCT (single or repeated) has a rather good ability to predict poor response in IVF. However, it appears that the predictive accuracy and clinical value of the CCCT is not clearly better than that of basal FSH in combination with an AFC.	
Penarrubia, J., Peralta, S., Fabregues, F., Carmona, F., Casamitjana, R. and Balasch, J. Fertil Steril. 2010; 94 (7): 2590-5. (20400077)	CS	98 women: 72 normal responders and 26 poor responders. age range: 25 to 41 years) undergoing their first ART cycle and fulfilling our inclusion criteria. All patients were infertile but otherwise healthy women, had both ovaries with no previous ovarian surgery,	D-5 Inhibin B, AFC  Inhibin B measurements were performed by an enzymatically amplified two-site-step sandwich immunoassay (enzyme-linked immunosorbent assay) in microtiter plates (Diagnostic Systems Laboratories Inc., Webster, TX). The assay sensitivity was 15 pg/mL, and the intra-assay coefficient of variation was 5.5%. The inter-assay coefficient of variation at low (36 pg/mL) and high (246 pg/mL) concentrations was 12% and 7%, respectively.		For prediction of poor response ROC curves (AUCROC) were 0.91 (0.83–0.96) for inh B Odds ratio (95% CI) 1.00 (0.95–1.05) sensitivity, specificity, and diagnostic accuracy of 92.31%, 80.56%, and 91%,		1. Basal AFC and day-5 inhibin B have similar predictive properties for ovarian response in assisted reproduction cycles 2. day-5 inhibin B is a superior predictor of live birth.	

<p>van Rooij, I. A., Broekmans, F. J., te Velde, E. R., Fauser, B. C., Bancsi, L. F., de Jong, F. H. and Themmen, A. P. Hum Reprod. 2002; 17 (12): 3065-71. ## 1.6 AGE

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Diagnostic test evaluated Reference standard test Include: Time interval and treatment	Prevalence	Accuracy (Se, Sp, PPV, NPV, LR+, LR-)	Reprod ucibility	Authors conclusion	Comments
Broer, S. L., et al. Fertil Steril. 2013; 100 (2): 420-9.e7. (23721718)	SR	57 studies included for a total of 4786 women. IPD metanalysis	Comparison of markers for prediction of excessive response		The multivariable analyses demonstrated that a model including age, AFC, and AMH (AUC 0.85) had a significantly higher predictive accuracy than a model based on age alone (AUC .61; P <.001). Interestingly, a single AMH or AFC test had a comparable accuracy (AUC 0.81 and 0.79, respectively).		In conclusion, this IPD meta-analysis shows that AFC and AMH add predictive accuracy to age in the prediction of an excessive response. A model combining these ORTs provides good predictive accuracy, without the necessity of including female age	
Broer, S. L., et al. . Hum Reprod Update. 2013; 19 (1): 26-36. (23188168).	SR	5705 patients from 28 studies (IPD metanalysis)	Comparison of markers for prediction of poor response		The multivariable analyses for poor response prediction showed that a model with age, AFC and AMH had a significantly higher predictive accuracy than a model based on age alone (AUC 0.80 versus 0.61; P≤0.001). The predictive value of the multivariable model, including age and the two ORTs, AMH and AFC, was not significantly better than that of a single ORT		The study demonstrates that the ORTs, AFC and AMH are highly capable of forecasting a poor responder to ovarian hyperstimulation for IVF, even without using female age	
Kwee, J., Elting, M. E., Schatz, R., McDonnell, J. and Lambalk, C. B. Reprod Biol Endocrinol. 2007; 5 9 (17362511)	RCT CS	110 patients: 56 CCCT, 54 EFFORT before first IVF aged 18–39 years Incl.: idiopathic for >3 years and/or due to a male factor and/or cervical hostility Excl.: severe male factor and PCOS	Age, AFC, basal ovarian volume (BOV), the exogenous FSH ovarian reserve test (EFORT) and the clomiphene citrate challenge test (CCCT), in prediction poor and hyperresponders		1. Univariate logistic regression age ROC-AUC = 0.63 for prediction of poor response  Univariate logistic regression age ROC-AUC = 0.71 for prediction of high response		AFC is able to accurately predict the number of follicles obtained during maximal ovarian stimulation.	Secondary analysis of RCT, cohort in this sense.

Oehninger, S, Nelson, Sm, Verweij, P and Stegmann, Bj. Reproductive Biology and Endocrinology. 2015; 13 (1): (26520396)	RCT CS	infertile women aged 35–42 years (n = 694). Pursue trial. Infertile women aged 35–42 years with a body weight of $\geq 50$ kg and body mass index (BMI) $\geq 18$ and $\leq 32$ kg/m <sup>2</sup>	AFC, AMH, age and basal FSH were measured before corifollitropin administration  Low response defined as $< 6$ oocytes, High response as $>18$ oocytes.		Prediction of low response: ROCAuc 0.61.  Prediction of high response: ROCAuc 0.61  They developed a combined model including age, AFC, AMH, FSH and cycle length		in women aged 35 to 42 years undergoing ovarian stimulation with corifollitropin alfa in a GnRH antagonist protocol, AMH, AFC and age at the start of stimulation were prognostic for both high and low ovarian response, in addition to FSH for high ovarian response and menstrual cycle length for low ovarian response.	Secondary analysis of RCT, cohort in this sense.
Bancsi, L. F., Broekmans, F. J., Eijkemans, M. J., de Jong, F. H., Habbema, J. D. and te Velde, E. R. Fertil Steril. 2002; 77 (2): 328-36. (11821092)	CS	120 women entering IVF program	Measurement of the number of antral follicles and the total ovarian volume by ultrasound, and of basal levels of FSH, E2, and inhibin B on cycle day 3		Age did not increase the performance of the predictive model based on antral follicles, inhibin b and serum FSH ROC-AUC of 0.61 for prediction of poor response		the antral follicle count provides better prognostic information on the occurrence of poor response during hormone stimulation for IVF than does the patient's chronological age	
Jayaprakasan, K., Al-Hasie, H., Jayaprakasan, R., Campbell, B., Hopkisson, J., Johnson, I. and Raine-Fenning, N. Fertil Steril. 2009; 92 (6): 1862-9. (18973895)	CS	141 women, IVF population first cycle, two groups poor responders n=41, normal responders n=100 Incl.: age $< 43$ , FSH $<12$ Excl.: history of ovarian surgery or were found to have an ovarian cyst or follicle measuring 20 mm or more in diameter setting: one centre	Ovarian vascularity indices (VI, FI, and VFI), ovarian volume (OV), antral follicle count (AFC) and age		prediction of poor ovarian response: ROCAuc: 0.74		AFC and basal FSH were the only significant predictors of poor ovarian response on multiple regression analysis	
Khairy, M., Clough, A., El-Toukhy, T., Coomarasamy, A. and Khalaf, Y. Reprod Biomed Online. 2008; 17 (4): 508-14. (18854104)	CS	148 patients entering IVF program Prospective study	Performance of different variables in the prediction of poor ovarian response: Age BMI AFC FSH Oestradiol		the accuracy of age was moderate (LR = 5.43) ROC-AUC of 0.71 for prediction of poor ovarian response		AFC had a good performance in predicting POR. No relevant contribution of adding other variables	dAFC showed to be the single most important predictor of ovarian response amongst the tested variables in this study (age, BMI, basal FSH and oestradiol concentrations)

Mutlu, M. F., Erdem, M., Erdem, A., Yildiz, S., Mutlu, I., Arisoy, O. and Oktem, M. J Assist Reprod Genet. 2013; 30 (5): 657-65. (23508679)	CS	192 patients entering IVF cycle Prospective study	AMH and AFC predictive value on ovarian response after stimulation in IVF programs and live birth rates compared with age and basal FSH		Age was related to ovarian response. The ROCauc prediction of poor response was 0.76 (0.68-0.84). OR was 1.21 (1.12-1.3) Sensitivity 30.6%, specificity 96.5% AMH and AFC were superior to AFC	AFC is better than AMH in predicting ovarian response; they although show both limitations in predicting live births; age is the best predictor for live birth rates (OR 0.92 (0-86-0.99))	
Penarrubia, J., Peralta, S., Fabregues, F., Carmona, F., Casamitjana, R. and Balasch, J. Fertil Steril. 2010; 94 (7): 2590-5. (20400077)	CS	98 women, IVF population 72 normal responders and 26 poor responders. age range: 25 to 41 years, undergoing their first ART cycle and fulfilling our inclusion criteria. All patients were infertile but otherwise healthy women, had both ovaries with no previous ovarian surgery	D-5Inhibin B, AFC, age		ROC-AUC of 0.55 for prediction of ovarian response	1. Basal FSH and day-5 inhibin B have similar predictive properties for ovarian response in assisted reproduction cycles	

## 1.7 BODY MASS INDEX (BMI)

## 1.3 PROGESTERONE

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Diagnostic test evaluated Reference standard test Include: Time interval and treatment	Prevalence	Accuracy (Se, Sp, PPV, NPV, LR+, LR-)	Reproducibility	Authors conclusion
Hamdine, O., Macklon, N. S., Eijkemans, M. J., Laven, J. S., Cohlen, B. J., Verhoeff, A., van Dop, P. A., Bernardus, R. E., Lambalk, C. B., Oosterhuis, G. J., Holleboom, C. A., van den Dool-Maasland, G. C., Verburg, H. J., van der Heijden, P. F., Blankhart, A., Fauser, B. C. and Broekmans, F. J. Fertil Steril. 2014; 102 (2): 448-454.e1. (24929258)	SR/MA	1052 patients	Progesterone levels at initiation of stimulation (CD2)	6.7% (recalculated properly: 7% 95%CI 4-11)	Sensitivity:0.08 (95%CI: 0.06-0.09) Specificity:0.99 (95%CI: 0.97-1) PPV:0.90 (95%CI:0.83 – 0.97) NPV:0.72(95%CI: 0.70 – 0.75) calculated	RD -0.15 (95%CI: -0.23 to -0.07) This is what is published and is a fixed model although I2=64.8 The application of a random model gives: -RD: 0.165 95%CI -0.297 to -0.033 Or RR: 0.456 95%CI: 0.243 - 0.856, fixed model, I2 = 7.8)	Early elevated P levels are associated with a lower OPR in ovarian stimulation using GnRH antagonists. The incidence of such a condition, however, is 7%. Problems in the meta-analysis: In two of the studies included, an intervention is applied in patients with high P: Kolibianakis: delay of initiation of stimulation by 1-2 days (P cut-off 1.6) Blockeel: administration of GnRH antagonist for three days prior to initiation of stimulation (P cut-off 1.6) Thus, the association observed is valid only when these interventions are applied.  In the non-interventional study by Hamdine et al (2014), included patients had GnRH antagonist started either on CD 2 or on CD 6 (P cut-off 1.5). Thus, again extrapolation of the association between baseline P and the probability of pregnancy is restricted to such a setting

<p>Faulisi, S., Reschini, M., Borroni, R., Paffoni, A., Busnelli, A. and Somigliana, E. Gynecol Obstet Invest. 2017; 82 (2): 175-180. (27522226)</p>	CS	312 (143 excluded)	<p>Progesterone levels at initiation of stimulation (CD3) Cut-off 1.6 ng/ml</p>	0.2% (0 - 1.2)	<p>Sensitivity:0.003 Specificity:1 PPV:1 NPV:0.18 LR+/- LR-:0.997 Accuracy:0.19  calculated</p>	<p>Does not offer a result on the cut-off level for which the study was performed. It can be calculated though from the publication, by also including the "excluded patients" RD: -0.185 (95%CI: -0.786 to + 0.416)  RR:1.346 (95%CI: 0.121 - 14.960)</p>	<p>Routine day 3 serum progesterone assessment in IVF cycles with the use of GnRH antagonists is not justified. Further evidence is warranted prior to claiming its systematic use.</p>
<p>Panaino, T. R., Silva, J. B., Lima, M. A., Lira, P., Areas, P. C., Mancebo, A. C., Souza, M. M., Antunes, R. A., Souza, M. D. JBRA Assisted Reproduction 2017;21(1):11-14 (28333025)</p>	CS	418 patients 468 ETs	<p>Progesterone levels at initiation of stimulation (CD2) Cut-off 1.5 ng/ml</p>	3.7% (2.3-5.8)	<p>Sensitivity:0.045 Specificity:0.98 PPV:0.76 NPV:0.38 LR+:1.95 LR-:0.98 Accuracy:0.39  calculated</p>	<p>RD: -16.3 95% CI:-37.0 to +4.3  RR:0.59 95%CI:0.25 -1.40</p>	<p>The impact of serum progesterone in the beginning of stimulation and pregnancy outcomes is a matter of concern. Basal elevated levels could help identify patients that will repeat it on hCG day, being probably a marker to help a freeze-all strategy to these cycles.  More cycles than patients were analysed without proper adjustment  Statistical analysis regarding CP is flawed</p>

### 3. Pre-treatment therapies

---

#### KEY QUESTION: DOES HORMONE PRE-TREATMENT IMPROVE EFFICACY AND SAFETY OF OVARIAN STIMULATION?

P	I	C	O
Women undergoing IVF/ICSI	<ul style="list-style-type: none"> <li>- oestradiol</li> <li>- progesterone</li> <li>- contraceptive (estradiol + progesterone) (COC) (incl dual suppression)</li> <li>- GnRH antagonist</li> </ul>	<ul style="list-style-type: none"> <li>- No pre-treatment</li> </ul>	<p><u>Efficacy:</u></p> <ul style="list-style-type: none"> <li>- cumulative LBR/cycle</li> <li>- Cumulative ongoing pregnancy rate /started cycle (fresh + frozen)</li> <li>- Clinical pregnancy rate/started cycle</li> <li>- Nr of Oocytes/ nr of MII oocyte recovery rate (yield)</li> <li>- number of embryo's (fresh+frozen)</li> </ul> <p><u>Safety</u></p> <ul style="list-style-type: none"> <li>- incidence of different grades of OHSS</li> <li>- grade of OHSS</li> <li>- incidence of cycle cancellation for hyper-response (predefined)</li> <li>- Bleeding</li> <li>- Infection</li> <li>- Torsion</li> <li>- Long-term effect on maternal/child health</li> <li>- other adverse events (treatment related)</li> </ul> <p><u>Patient-related outcomes</u></p> <ul style="list-style-type: none"> <li>- Compliance</li> <li>- Drop-out rates</li> <li>- Patient burden</li> <li>- QoL</li> <li>- Patient preferences</li> </ul>

## 3.1 OESTROGEN PRE-TREATMENT

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Farquhar C, Rombauts L, Kremer JA, Lethaby A, Ayeleke RO. Cochrane Database Syst Rev. 2017; 5:CD006109. (28540977)	SR	4 RCTs 17B estradiol 4mg: Cédrin- Durnerin 2007; Cédrin- Durnerin 2012; Fanchin 2003	oestradiol pre-treatment vs no pre-treatment in GnRH antagonist protocols	1/ live birth or ongoing pregnancy 2/ clinical pregnancy rate 3/ number of oocytes 4/ OHSS	1/ live birth or ongoing pregnancy OR 0.79 (0.53 to 1.17); 2 RCTs; 502 women; moderate quality 2/ clinical PR OR 0.91 [0.66, 1.24]; 4RCT; 688 women; very low Q 3/number of oocytes mean diff 2.23 (0.71- 3.75) p<0.004; 2 RCT; 139 women (Cedrin 2007;Cedrin 2012; normoresponders) 4/ ND	When oestrogen in antagonist cycles was compared with no pre- treatment in either antagonist or agonist cycles, there was no clear evidence of a difference between the groups in rates of live births or ongoing pregnancies or OHSS.	GRADE evidence profile
Shahrokh Tehrani Nejad, E., Bakhtiari Ghaleh, F., Eslami, B., Haghollahi, F., Bagheri, M. and Masoumi, M. Int J Reprod Biomed (Yazd). 2018 (30288488)	RCT	N=210 included but 176 analyzed 18-35 yrs. AMH1-6 <2 IVF attempts  OCP (N=53) vs E2 (N=63) vs no prett (N=70) → lost of follow up +++ (different proportion in each group) → unrealistic hypothesis for the calculation of number of patient	OCP start at day 20 for 1à days (6d window before OS)  E2 = 4mg/d start day 20 for 10 days (6d window before OS)  Exclusion if no menstrual bleeding during the 6d before OS  Control start D2 rFSH 150  GnRH antagonist protocol for LH suppression in the 3 groups	1/clinical pregnancy 2/mature oocytes	No statistical diff for clinical PR (42.9% (27/63) vs. 34.3% (24/70))  or number of mature oocytes retrieved (10.71±3.73 vs. 10.40±4.38)  no case of OHSS in either group	results of the present study failed to show the statistically significant differences in pregnancy rate in IVF patients who received cycle scheduling with OCP, E2 valerate with a comparison to control group in a randomized clinical trial after 6 days of pretreatment discontinuation in GnRH antagonist cycles	poor quality RCT but more recent one

## 3.2 PROGESTOGEN PRE-TREATMENT

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Farquhar C, Rombauts L, Kremer JA, Lethaby A, Ayeleke RO. Cochrane Database Syst Rev. 2017; 5:CD006109. (28540977)	SR	7 RCTs  Norethisterone 10mg: Cédric-Durnerin 2007; Ditkoff 1996; Engmann 1999; Hugues 1994  MPA 10mg: Aston 1995  Ethinodiol acetate 4mg: Salat-Baroux 1988  Progesterone inj 100mg: Shaker 1995	Comparisons - progestogen prett vs no prett in agonist protocols - progestogen prett vs no prett in antagonist protocols - progestogen+Gn vs Gn (no agonist or antagonist): data exclude	1/ live birth or ongoing pregnancy 2/ clinical pregnancy rate 3/ number of oocytes 4/ cyst formation	<b>P vs no P in agonist</b> 1/ live birth/ongoing pregnancy OR 1.35 (0.69 to 2.65); 2 RCTs; 222 women; low quality evidence; 2/ clinical pregnancy OR 1.99 (1.20 to 3.28); 3 RCTs (1 with HCG+); 374 women 3/ number of oocyte MD -0.52 NS; 2 RCTs; 222 women; 4/ cyst OR 0.16 (0.08 to 0.32) p ; 3 RCT; 374 women; moderate quality evidence  <b>P vs no P in antagonist</b> 1/ live birth/ongoing pregnancy OR 0.67 (0.18 to 2.54); 1 RCT; 47 women; low quality evidence; 2/clinical pregnancy OR 0.52 (0.16 to 1.71); 1 RCT; 47 women 3/number of oocyte MD 2.7 NS; 1 RCT; 47 women 4/ND	There was insufficient evidence to determine any differences in rates of live birth/ongoing pregnancy or number of oocyte.  There was evidence of more clinical pregnancies in the group pretreated with a progestogen in agonist protocol. In agonist protocol, fewer women had ovarian cyst formation in the group pretreated with a progestogen compared with those who had no pretreatment	GRADE evidence profile

## 3.3 COMBINED ORAL CONTRACEPTIVE PILL PRE-TREATMENT

## 4A.1 GNRH ANTAGONIST VERSUS GNRH AGONIST

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Lambalk CB, Banga FR, Huirne JA, Toftager M, Pinborg A, Homburg R, van der Veen F, van Wely M. Hum Reprod Update. 2017;23(5):560-579. (28903472)	SR	PCOS women: Nine trials including 1294 couples from a PCOS population (for the primary outcome OPR)	GnRH antagonist vs GnRH agonist protocols in women with high ovarian response	LBR OPR CPR OHSS Number of oocytes	ANTAGONIST vs AGONIST <b>-Ongoing pregnancy</b> (RR 0.97, 95% CI 0.84–1.11), I <sup>2</sup> =0% 9 trials (1294 women)  <b>- Live birth</b> RR 0.90 (CI 0.69–1.19) 3 trials, 363 patients  <b>-clinical pregnancy</b> (RR 1.01, 95% CI 0.86–1.19) 10 trials, 1086 patients  <b>-OHSS</b> (RR 0.53, 95% CI 0.30–0.95) 9 trials (1294 women)  <b>-Number of oocytes</b> RR 0.40 (0.97-1.77)  In PCOS patients, the number needed to prevent one case of OHSS was 14 (95% CI 7 – 50) treatments with antagonist.	In couples with PCOS, we found no evidence for a difference in ongoing pregnancy or clinical pregnancy rate, but again there was a significantly lower OHSS rate in the antagonist group. In PCOS patients, the number needed to prevent one case of OHSS was 14 (95% CI 7 – 50) treatments with antagonist.  In women with PCOS and application of the GnRH antagonist as the first choice seems justified.	GRADE evidence profile Meta-analysis per patient type 1.1.2 PCOS patients 1.1.3 poor responders

Shin, J. J., Park, K. E., Choi, Y. M., Kim, H. O., Choi, D. H., Lee, W. S. and Cho, J. H. Clin Exp Reprod Med. 2018; 45 (3): 135-142 (3020274)	RCT	36, randomized across three arms, pilot study. 14 early antagonist 11 conventional antagonist 11 agonist  All three arms OC pretreatment/ All three arms start dosage 150 IU but not fixed by protocol.  PCOS acc to Rotterdam	early antagonist start day 1 conventional antagonist start day 5 agonist long suppression start under OC.  1 cycle comparison.	Oocyte number Clinical Pregnancy per ET OHSS rate mod/sev OHSS rate mod/sev in cases with E2 level> 2000 Pg/ml	Oocyte number 16/12/19, NS Clinical Pregnancy per ET 50/11/22%, NS  OHSS rate mod/sev 7.7/18.2/27.3%  OHSS rate mod/sev in cases with E2 level> 2000 Pg/ml 12.5/40/50%	We found no difference in the number of total oocytes and mature oocytes retrieved, the clinical pregnancy rate, or the incidence of moderate-to-severe OHSS among the three different protocols.	Starting dosage high 150 and over. Power calculated on oocyte number difference: 80 cases. Power not achieved.  Biological rationale not clear
Trenkic, M., Popovic, J., Kopitovic, V., Bjelica, A., Zivadinovic, R. and Pop-Trajkovic, S. Ginekol Pol. 2016; 87 (4): 265-70. (27321097)	RCT	PCOS patients  2013-2014  Inclusion criteria: PCOS Rotterdam criteria 18-39 years BMI 18-30kg/m2  Exclusion criteria: Uterine cavity abnormalities Thyroid dysfunction Abnormal prolactin levels Ovarian cyst Severe male factor infertility requiring ICSI	Group 1: Long GnRH agonist N=45  Group 2: Flexible GnRH antagonist N=45	CPR OHSS N MIIs N oocytes	Group 1 vs 2 <b>CPR</b> 44.4%(20) 46.7%(21) p=0.832  <b>OHSS</b> 15.56%(7) 6.70%(3) p= 0.241  <b>N MIIs</b> 9.90± 6.08 7.29±4.95 p=0.035  <b>Number of oocytes</b> 13.71± 6.69 10.11± 6.46 p=0.005	The GnRH antagonist protocol in PCOS patients has a pregnancy rate comparable to that of the GnRH agonist protocol. Since this protocol has a lower rate of complications and is more convenient for patients, we believe that the GnRH antagonist protocol should be used as the first-line treatment for PCOS patients in an IVF program.	RCT quality: LOW Randomization mode YES Allocation concealment NO Blinding –NO Incomplete outcome reporting: UNCLEAR Free of other bias: NO  No sample size calculation Unclear number of embryos transferred in 2 groups

## 4A.2 MILD STIMULATION

### 4A.2.1 CLOMIPHENE CITRATE (CC)

## 4A.2.3 REDUCED DOSE PROTOCOL

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Oudshoorn, S. C., van Tilborg, T. C., Eijkemans, M. J. C., Oosterhuis, G. J. E., Friederich, J., van Hooff, M. H. A., van Santbrink, E. J. P., Brinkhuis, E. A., Smeenk, J. M. J., Kwee, J., de Koning, C. H., Groen, H., Lambalk, C. B., Mol, B. W. J., Broekmans, F. J. M. and Torrance, H. L. 32(12):2506-2514 (29121269)	RCT	521 expected high responders  AFC > 15	255 women to 100IU daily FSH 266 women to 150IU daily FSH	PRIMARY was ongoing pregnancy achieved within 18 months after randomization and resulting in a live birth.  SECONDARY occurrence of OHSS and cost-effectiveness  OTHER Biochemical pregnancy Clinical pregnancy Ongoing pregnancy Cycle cancellation rate Live birth (fresh only)c CLBR 1st cycle Live birth (fresh and cryo) Time to ongoing pregnancy leading to live birth (days)	100IU vs 150IU  Ongoing pregnancy within 18 months of FU resulting in live birth 169 (66.3%) 185 (69.5%) RR 0.953 [0.85–1.07]  Clinical pregnancy 180 (70.6%) 207 (77.8%) RR 0.907 [0.82–1.00] NS  Ongoing pregnancy 173 (67.8%)e 189 (71.1%) RR 0.955 [0.85–1.07] NS  Live birth (fresh only)c 65 (25.7%) 67 (25.2%) NS  CLBR 1st cycle Live birth (fresh and cryo) 91 (36.0%) 104 (39.1%) NS  Number of OHSS events 24/456 (5.2%) 56/474 (11.8%) p=0.001 Mild 18/456 (3.9%) 40/474 (8.4%) p=0.008 Moderate 0/456 11/474 (2.3%) p=0.001 Severe 6/456 (1.3%) 5/474 (1.1%) p=0.712	In women with a predicted hyper response scheduled for IVF/ICSI, a reduced FSH dose does not affect live birth rates but reduce the incidence of mild and moderate OHSS, but had no impact on severe OHSS.  Future studies should therefore also include the effect of prevention measures such as cancellation for hyper response, GnRH-agonist triggering and a freeze-all policy. However, as cycle cancellation occurred twice as often in the first cycle in the reduced dose group, a definite claim advocating FSH dose reduction in predicted hyper responders cannot be made until results from future studies comparing various safety management approaches have become available.	RCT quality: MODERATE/HIGH Randomization mode OK Allocation concealment OK Blinding –none Incomplete outcome reporting: No (number of oocytes were reported per oocyte retrieval) Free of other bias: NO  Mixing agonist and antagonist protocols Allowing dose adjustments in 2nd cycle Cycle cancellation in high response should be considered with caution given that this is likely to have happened mostly in Agonist cycles since there is no possibility to trigger with GnRH agonist Freeze all policy was not adopted and this is current clinical practice.

## 4B.2.3 REDUCED DOSE PROTOCOL

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Sterrenburg, M. D., Veltman-Verhulst, S. M., Eijkemans, M. J., Hughes, E. G., Macklon, N. S., Broekmans, F. J., Fauser, B. C., Hum Reprod Update 2011; 17(2): 184-96 (20843965)	SR	5 RCT, 960 women	COMPARISON A 100 vs 200 IU/day rFSH	Number of oocytes retrieved CPR OHSS	Number of oocytes retrieved MD -3.5 (95% CI -4.86, - 2.27), p<0.05 CPR: OR 0.95 (95% CI 0.69- 1.30), NS OHSS OR 0.58 (95% CI 0.18- 1.90), NS	This meta-analysis suggests that the optimal daily recFSH stimulation dose is 150 IU/day in presumed normal responders younger than 39 years undergoing IVF. Compared with higher doses, this dose is associated with a slightly lower oocyte yield, but similar pregnancy and embryo cryopreservation rates. Furthermore, the wide spread adherence to this optimal dose will allow for a considerable reduction in IVF costs and complications	QUALITY: MODERATE -Reporting on trials quality (randomization mode, blinding, allocation concealment) -No reporting on other sources of bias -Proper search strategy live Meta-analysis clearly concluding in favor of a dose of 150IUrFSH despite the difference in the number of oocytes retrieved in favor of higher doses. Although it is clear that higher doses do not increase live birth rates in the fresh IVF cycle, we cannot exclude a beneficial effect of higher doses and higher oocyte yield on cumulative live births

Baart EB, Martini E, Eijkemans MJ, Van Opstal D, Beckers NG, Verhoeff A, Macklon NS, Fauser BC. Hum Reprod. 2007;22(4):980-8. (17204525)	RCT	111 patients 44 conventional arm 67 mild arm groups comparable women below 38 years of age, with a regular indication for IVF and with a partner with a sperm count .5 million progressively motile sperm per ml (prior to capacitation)	Conventional stimulation: Long GnRH agonist with fixed daily dose of 225 IU r FSH  Mild stimulation: fixed dose of 150 IU rFSH starting on cycle Day 5. GnRH antagonist co-treatment at 0.25 mg per day s.c. was initiated on the day the leading follicle reached a diameter of 14 mm  December 2002 to August 2005.	Primary outcome(s) 1. number of oocytes obtained 2. proportion of chromosomally abnormal embryos per patient. This was expressed as the ratio of abnormal embryos on the number of embryos diagnosed per patient.	CONVENTIONAL vs MILD Oocytes retrieved (n) 12.1+5.7 vs 8.3+4.7 p=0.01 Diff (5%CI) 3.7 (1.6–5.9)	Mild ovarian stimulation results in fewer oocytes and a decreased proportion of aneuploid and mosaic embryos. However, based on the current findings, we would like to propose that future ovarian stimulation strategies should not focus on obtaining as many oocytes as possible. Instead, strategies should aim at less interference with ovarian physiology, thus minimizing embryo aneuploidy rate and facilitating selection of the best quality embryo for transfer.	QUALITY: MODERATE Randomization mode – Adequate Bias LOW Allocation concealment+adequate Bias LOW Blinding NO Bias HIGH Incomplete outcome data – NO Bias HIGH Selective reporting- NO Bias LOW Other bias: LOW  PGS study with biopsy of 9 Chromosomes and FISH. Currently outdated technique
Blockeel, C., Sterrenburg, M. D., Broekmans, F. J., Eijkemans, M. J., Smits, J., Devroey, P. and Fauser, B. C. J Clin Endocrinol Metab. 2011; 96 (4): 1122-8. (21307142)	RCT	Inclusion: regular indication and first treatment cycle of IVF; 18 and 36 yr.; BMI 18 - 29 kg/m <sup>2</sup> ; regular cycle (25–35); FSH (< 12 U/liter); no major uterine or ovarian abnormalities; no endocrine/metabolic abnormalities; no PCOS; no severe endometrioses (≥ grade 3).	GROUP 1 FSH fixed 150 IU/d [D2 - hCG] + ganirelix 0.25 mg [D6] N= 36  GROUP 2 rFSH fixed 150 IU/d [D5 - hCG] + ganirelix 0.25 mg [D6] n=40  2008 - 2009	OPR Positive hCG Total gonadotropin dose Stimulation days	Group 1 vs Group2 OPR 28% vs 25% p=0.78  Positive hCG 36% vs 25% p=0.29  Total gonadotropin dose 1364 ( 226) vs 1177(295) p <0.01  Stimulation days 9.1(1.5) vs 7.8 (2.0) p <0.01	This study shows that the administration of recFSH starting on d 2 or d 5 of the cycle in a GnRH antagonist protocol for IVF/intracytoplasmic sperm injection patients yields a comparable endocrine profile and follicular development. Future studies should focus on the design of more patient-tailored ovarian stimulation protocols. Whether there is a difference in embryo quality, pregnancy rate, and live birth rate remains to be determined in a larger trial.	QUALITY: LOW Randomization mode –NO Bias HIGH Allocation concealment- NO Bias HIGH Blinding NO Bias HIGH Incomplete outcome data –adequate Bias LOW Selective reporting- NO Bias LOW Other bias: YES  Small study. Clinical data based on a small number of events. Severely underpowered to drive conclusions

<p>Hohmann, Fp, Macklon, Ns and Fauser, Bc. The Journal of clinical endocrinology and metabolism. 2003; 88 (1): 166-73. (12519847)</p>	<p>RCT</p>	<p>169 patients randomized Inclusion criteria: 20 - 38 yr; BMI 19- 29; regular cycles (25 - 35); no relavant disease; no severe endometriosis; no ovarian abnormalities; ≤ 3 IVF cycles; no previous POR; no previous OHSS. Exclusion: NA</p>	<p>GROUP 1: Long agonist protocol 150rFSH  GROUP 2: Flexible antagonist protocol 150rFSH D2 start  GROUP 3: Flexible antagonist protocol 150rFSH D5 start</p>	<p>OPR Positive hCG N oocytes</p>	<p>Group 1 vs 2 vs 3  OPR 8 (18%) vs 8 (17%) vs 8 (16%) p=0.98  Positive hCG 10 (22%) vs 10 (20%) vs 10 (20%) p=0.96  N oocytes 9 (1-25) vs 8 (2-31) vs 7 (1-27) p=0.57</p>	<p>Application of the described mild OS protocol resulted in pregnancy rates per started IVF cycle similar to those observed after profound stimulation with GnRH agonist cotreatment despite shorter stimulation and a 27% reduction in exogenous FSH. A higher cancellation rate before oocyte retrieval was compensated by improved embryo quality concomitant with a higher chance of undergoing embryo transfer. A relatively low number of oocytes retrieved after mild ovarian stimulation distinctly differs from the pathological reduction in the number of oocytes retrieved after profound ovarian stimulation (poor response) associated with poor IVF outcome. The relatively small number of oocytes obtained after mild ovarian stimulation may represent the best of the cohort in a given cycle</p>	<p>QUALITY: LOW Randomization mode – Adequate Bias LOW Allocation concealment- NO Bias HIGH Blinding NO Bias HIGH Incomplete outcome data – adequate Bias LOW Selective reporting- NO Bias LOW Other bias: UNCLEAR</p>

#### 4C.2.3 REDUCED DOSE PROTOCOL

No relevant studies were identified

## 4C.3 HIGHER GONADOTROPIN DOSE

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion
Lensen, Sarah F, Wilkinson, Jack, Mol, Ben Willem J, La, Marca Antonio, Torrance, Helen and Broekmans, Frank J. Cochrane Database of Systematic Reviews. 2017; (6): (29388198)	SR	5 RCTs in predicted low responders.  Overall pooling of studies not possible due to variation of gonadotrophin dose in study and control arms.	2 studies comparing 300/ 450 IU daily versus 150 IU daily (Klinkert 2005, van Tilborg 2017). 2 studies comparing 400/ 450 IU daily versus 300 IU daily (Harrison 2001, Batsu 2016). 1 study comparing 600 IU daily versus 450 IU daily (Lefebvre 2015).	Live birth/ ongoing pregnancy rate. Clinical pregnancy Number of oocytes Cycle cancellation for poor response	Live birth or ongoing pregnancy 300/450 IU vs 150 IU: OR (95% CI) 0.71[0.32-1.58] 400/450 IU vs 300 IU: OR (95% CI) 0.77[0.19-3.19] 600 IU vs 450 IU: OR (95% CI) 1.33 [0.71-2.52]  Clinical pregnancy 300/450 IU vs 150 IU: OR(95%CI) 0.50[0.25-1.00] 400/450 IU vs 300 IU: OR(95%CI) 0.84[0.26-2.69] 600 IU vs 450 IU: OR(95%CI) 1.14[0.66-1.99]  Number of oocytes 300/450 IU vs 150 IU: MD(95%CI) 0.69 (0.50 to 0.88). 400/450 IU vs 300 IU: MD(95%CI) -0.03; (-0.30 to 0.88). 600 IU vs 450 IU: MD(95%CI) 0.08; (-0.04 to 0.20).  Cycle cancellations for poor response 300/450 IU vs 150 IU OR (95% CI) 0.23[0.11-0.47] 400/450 IU vs 300 IU OR (95% CI) 1.47[0.62-3.49] 600 IU vs 450 IU: OR (95% CI) 0.86[0.50-1.50]	Due to differences in dose comparisons, caution is warranted in interpreting the findings of five small trials assessing predicted low responders. The effect estimates were very imprecise, and increased FSH dosing may or may not have an impact on rates of live birth/ ongoing pregnancy, OHSS and clinical pregnancy.

## 4C.4 MODIFIED NATURAL CYCLE

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Morgia, F., Sbracia, M., Schimberni, M., Giallonardo, A., Piscitelli, C., Giannini, P. and Aragona, C. Morgia Fertil Steril. 2004; 81 (6): 1542-7. (15193474)	RCT	125 women (215 cycles)  Definition: <43 years and had undergone a previous IVF cycle at our IVF clinic that resulted in a poor response, that is, three or fewer follicles recruited or cycle cancelled because of no follicle activation.  Comparable groups	Group A MNC 55 patients 114 cycles  Group B microdose GnRH analog flare 70 women 101 cycles  January 2000 and July 2002	PR Cycles with oocytes Cycles with ET	Pregnancy/cycle (%) 6.1 vs 6.9 NS Pregnancy/transfer (%) 14.9 vs 10.1 NS  Results also presented for 3 age categories <36, 36-39, >39 but groups are very small	In our study, the use of IVF with a natural-cycle protocol was a valuable alternative to COH in poor responders. In these patients, natural-cycle IVF is at least as effective as COH, especially in younger patients, with a better implantation rate. This alternative should be proposed to poor responders, because the natural cycle is cheaper than hyperstimulation and permits a more "friendly" approach to IVF with results comparable to those with COH, at least in these patients.	RCT quality: LOW/MODERATE Randomization mode OK Allocation concealment OK Blinding – NO(low) Incomplete outcome reporting: Unclear Free of other bias: NO  LOW/MODERATE No sample size calculation Results also presented for 3 age categories <36, 36-39, >39 but groups are very small

## 6.1.4 RECOMBINANT (rFSH) VS RECOMBINANT FSH + RECOMBINANT LH (rFSH+rLH)

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Mochtar MH, Danhof NA, Ayeleke RO, Van der Veen F, van Wely M. Cochrane Database Syst Rev. 2017;5:CD005070. (28537052)	SR	36 RCTs - 8125 women	rLH combined with rFSH for ovarian stimulation compared to rFSH alone	Live birth rates OHSS Ongoing pregnancy rate Miscarriage rate Cancellation rate	LB: OR 1.32, 95% CI 0.85 - 2.06; n = 499; Agonist: 1.73 [ 0.95 - 3.16] Antagonist 0.94 [ 0.48 - 1.85]  OHSS: OR 0.38, 95% CI 0.14 to 1.01; n = 2178 Agonist: 0.16 [ 0.03, 0.88] (favour rFSH) Antagonist 0.80 [ 0.21, 3.00]  OPR: OR 1.20, 95% CI 1.01 to 1.42; participants = 3129; Agonist: 1.27 [ 1.02, 1.57] Antagonist 1.08 [ 0.82, 1.43]  CP: OR 1.177 (1.034 - 1.340) Agonist: 1.215 (1.052 - 1.403) Antagonist: 1.029 (0.764 - 1.386)  Cancellation due to imminent OHSS 0.821 (0.342 - 1.969) Agonist: 0.687(0.146 - 3.218) Antagonist 1.069 (0.541 - 2.113)	We found no clear evidence of a difference between rLH combined with rFSH and rFSH alone in rates of live birth or OHSS. We found moderate quality evidence that the use of rLH combined with rFSH may lead to more ongoing pregnancies than rFSH alone. There was no clear evidence of a difference between the groups in rates of cancellation due to low response or imminent OHSS, the evidence is insufficient to encourage or discourage stimulation regimens that include rLH combined with rFSH in IVF/ICSI cycles.	GRADE evidence profile quality of the evidence ranged from very low to moderate.  A higher probability of OPR was observed in the agonist treated patients which was not accompanied by a significant difference in LB. In antagonist cycles no differences were observed  in the review a fixed model was used despite significant heterogeneity (60.1 p=0.014)

<p>Humaidan, P., Chin, W., Rogoff, D., D'Hooghe, T., Longobardi, S., Hubbard, J. and Schertz, J. Hum Reprod. 2017; 32 (3): 544-555. (28137754)</p>	<p>RCT</p>	<p>939 women were randomized (1:1) to receive either r-hFSH/r-hLH or r-hFSH</p> <p>≥18–&lt;41 years old, BMI between 18 and 31 kg/m<sup>2</sup> diagnosis of POR (Bologna criteria)</p> <p>Baseline characteristics and demographics were similar for women in the two treatment groups</p>	<p>r-hFSH/r-hLH vs. r-hFSH</p> <p>r-hFSH 300 IU plus r-hLH 150 IU (follitropin alfa/ lutropin alfa; Pergoveris®) or r-hFSH 300 IU monotherapy (follitropin alfa; GONAL-f®), with the dose fixed for the first 4 days of OS.</p> <p>long GnRH agonist protocol</p> <p>January 2014 and February 2015.</p>	<p>The primary efficacy endpoint</p> <p>COCs retrieved</p> <p>Secondary endpoints</p> <p>biochemical pregnancy</p> <p>clinical pregnancy</p> <p>ongoing pregnancy</p> <p>live birth rate</p> <p>cycle cancellation rate;</p> <p>number of metaphase II (MII) oocytes in ICSI patients.</p>	<p>Rfsh+LH vs. rFSH</p> <p>COCs</p> <p>3.6 (2.82) 3.3 (2.71)</p> <p>Cancelled cycles</p> <p>OR:1.12 (0.68, 1.85)</p> <p>Ongoing pregnancy</p> <p>OR:0.90 (0.60, 1.35)</p> <p>Live birth</p> <p>OR:0.91 (0.60, 1.38)</p> <p>MI I oocytes in ICSI</p> <p>-0.24 (-0.64 to +0.15)</p>	<p>The study did not meet its primary endpoint of superiority of r-hFSH/r-hLH to r-hFSH in terms of number of oocytes retrieved following OS. Furthermore, the live birth rates per cycle were similar in both groups, but considerably higher than previously reported in retrospective studies that included Bologna POR patients, suggesting that recombinant gonadotropin stimulation protocols represent an effective treatment strategy in this challenging patient category.</p>	
--	------------	---	--	--	---	---	--

<p>Lahoud, R, Ryan, J, Illingworth, P, Quinn, F and Costello, M. European journal of obstetrics gynecology and reproductive biology. 2017; 210 300-305. (28107729)</p>	<p>RCT</p>	<p>238 patients Inclusion criteria: Infertility, IVF/ICSI using long pituitary down regulation, no more than 3 previous stimulated IVF/ICSI treatment cycles, age 18 to 42, not an oocyte donor, not already taken part in the study, no current endocrine disorder A prospective RCT was performed from 2007 to 2009 at IVF Australia, a multi-center IVF organization based in Sydney, Australia.  2007 to 2009 mid-luteal long down-regulation protocol</p>	<p>Serum LH measurements were taken on day 0 and day 6 of FSH administration. A LH ratio was calculated by dividing the LH concentration on the day 6 of FSH injections by the LH concentration on LH day 0. LH ratio .LH day 6/ LH day 0 Where the ratio was less than or equal to 0.5 (LH ratio <math>\leq 0.5</math>), the patient was randomised to one of two study groups  Group 1: routine protocol of GnRH agonist and rFSH + rLH supplementation 75IU subcutaneously daily starting on days 7 or 8 of FSH injections and continuing daily until the day of rhCG trigger  Group 2: no rLH supplementation. Where the LH ratio was greater than 0.5 (LH ratio <math>&gt; 0.5</math>), the participant was not randomized but acted as a third study group.</p>	<p>The primary outcomes were live birth rate per embryo transfer and clinical pregnancy rate per embryo transfer.  Secondary outcomes miscarriage rate, total amount of FSH days of FSH stimulation, peak estradiol level, progesterone concentration on day of HCG trigger, COCs retrieved, top grade embryos the number embryos for cryopreservation.</p>	<p>rLH+rFSH vs rFSH Number of oocytes retrieved 12 (6.3) vs. 11.6 (5.6)  Clinical pregnancy rate/transfer RR 0.84, 95%CI 0.5–1.48,  Live Birth rate/cycle started RR 0.78 95%CI 0.4–1.53,</p>	<p>In conclusion the addition of rLH in patients with a relative reduction in serum LH concentration during COH for IVF/ICSI did not improve live birth or clinical pregnancy rates. However the results were not conclusive and further large well-designed RCTs are required to confirm these findings.</p>

## 6.2 HIGHLY PURIFIED FSH (HP-FSH) VS HUMAN MENOPAUSAL GONADOTROPIN (HMG)

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Duijkers, I. J., Vemer, H. M., Hollanders, J. M., Willemsen, W. N., Bastiaans, L. A., Hamilton, C. J., Thomas, C. M. and Borm, G. F. Hum Reprod. 1993; 8 (9): 1387-91. (8253923)	RCT	20 patients 10: Org 31338 (containing 75 IU FSH and 25 IU LH per ampoule)  10: Metrodin (purified FSH)  age between 20 and 40 years, a normal endocrine serum profile, no hormonal medication during the 3 months prior to the study, no endometriosis observed on laparoscopy, both ovaries present, normal semen analysis or >50% of the oocytes fertilized in a previous IVF treatment. Unclear whether patient characteristics were similar between groups compared	Org 31338 (FSH/LH 3:!) vs Metrodin	retrieved oocytes pregnancy	Org 31338 vs Metrodin  retrieved oocytes: 13 (4-23) vs. 8 (4-11)  1 pregnancy in the Org 31338 group  2 pregnancies in the Metrodin group (1 miscarriage)	No significant differences were found in hormonal values. In women with normal endocrine profiles, lowering of the LH activity in gonadotrophic preparations during gonadotrophin-releasing hormone agonist treatment results in adequate ovarian stimulation. However, a preparation with some LH needed a shorter stimulation than a purified FSH preparation. Whether the other beneficial effects of Org 31338 also occur in a larger population needs further investigation.	Transferred from p-FSH search, Metrodin is hp- FSH

Parsanezhad, Me, Jahromi, Bn, Rezaee, S, Kooshesh, L and Alaei, S. Iranian journal of medical sciences. 2017; 42 (1): 57-65. (CN-01338801)	RCT	<p>January 2014 to May 2014.</p> <p>160 patients</p> <p>Inclusion criteria</p> <p>Patients with unexplained or male factor infertility were included in the study if they met the following criteria:</p> <ol style="list-style-type: none"> <li>1) age 20 -38 years;</li> <li>2) BMI 19 - 29 kg/m<sup>2</sup>;</li> <li>3) history of regular menstrual cycles, ranging from 25–35 days; 4) no relevant systemic disease, severe endometriosis, or uterine or ovarian abnormalities;</li> <li>5) no more than 3 previous IVF cycles;</li> <li>6) no previous IVF cycle with a poor response or the ovarian hyperstimulation syndrome.</li> </ol> <p>Exclusion criteria</p> <p>Additionally, patients with FSH &gt;10 IU/mL, with &lt;5 follicles in AFC, and AMH&lt;1 ng/ mL were excluded from the study.</p> <p>age, BMI, duration of infertility, and EMT at baseline were similar in all the groups.</p>	<p>40 patients hMG</p> <p>40 patients FSH-HP</p> <p>40 patients rFSH</p> <p>40 patients who received hFSH for the first 6 days, followed by rFSH</p> <p>Long agonist</p>	<p>The primary end points were oocyte and embryo quality and pregnancy outcomes.</p> <p>The secondary endpoints were the total number of collected oocytes</p>	<p>LBR</p> <p>hMG 27.5%</p> <p>FSH-HP 22.5%</p> <p>rFSH 40%</p> <p>no significant differences</p> <p>CP</p> <p>hMG 45%</p> <p>FSH-HP 37.5%</p> <p>rFSH 50%</p> <p>no significant differences</p> <p>COCs retrieved</p> <p>hMG 9.5±4.83</p> <p>FSH-HP 8.2±4.7</p> <p>rFSH 11.2±6.7</p> <p>no significant differences</p>	<p>Our data revealed no statistically significant differences in the mean oocyte number, embryo quality, clinical pregnancy rate, or live birth rate between the hMG, hFSH, rFSH, and sequential hFSH/rFSH protocols. ## 8.1 METFORMIN

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Tso, L. O., Costello, M. F., Albuquerque, L. E., Andriolo, R. B. and Macedo, C. R. Cochrane Database Syst Rev. 2014; (11): Cd006105. (25406011)	SR	Nine randomised controlled trials involving a total of 816 women with PCOS who were randomised to receive metformin (411) versus placebo or no treatment (405).	Metformin commencement varied from the start of ovarian stimulation with FSH or 16 weeks before (earliest) to the first day (latest) of GnRH-agonist administration in the studies reporting metformin use before FSH treatment and continued at least until the day of the hCG trigger.  Metformin dose varied from 500 mg twice daily, 500 mg three times daily, 850 mg twice daily, 850 mg thrice daily, 1 gm twice daily, 500 mg twice daily gradually increased to 2 gm daily.	Number of oocytes retrieved Clinical pregnancy rate Live birth rate OHSS	No of oocytes retrieved (MD-0.76; 95% CI -2.02 to 0.50, eight RCTs, 635 women, I <sup>2</sup> = 36%).  Clinical pregnancy rates (OR 1.52; 95%CI 1.07 to 2.15, 8 studies, 775 women, I <sup>2</sup> = 18%, moderate quality evidence).  live birth rates (OR 1.39; 95% CI 0.81 to 2.40, five RCTs, 551 women, I <sup>2</sup> =52%, low quality evidence).  The incidence of OHSS (OR 0.29; 95% CI 0.18 to 0.49, eight RCTs, 798 women, I <sup>2</sup> =11%, moderate quality evidence). GnRH agonist protocol: reduction in OHSS GnRH antagonist protocol: no reduction, 1 RCT	No conclusive evidence that metformin before or during ART cycles improves live birth rates in women with PCOS. However, use of metformin increased clinical pregnancy rates and decreased the risk of OHSS.  The overall quality of the evidence was moderate for the outcomes of clinical pregnancy, OHSS and low for other outcomes. The main limitations in the evidence were imprecision and inconsistency.	GRADE evidence profile In the subgroup analysis OHSS was lower when used with the agonist regimen but no significant difference when used with the antagonist regimen.

<p>Jacob, S. L., Brewer, C., Tang, T., Picton, H. M., Barth, J. H. and Balen, A. H. Hum Reprod. 2016; 31 (12): 2756-2764. (27816925)</p>	<p>RCT</p>	<p>153 patients were randomised, 77 received metformin and 76 placebo. All patients met the Rotterdam criteria for PCOS and were treated with a standard GnRH antagonist IVF/ICSI treatment cycle.</p>	<p>The study medication was started prior to stimulation and continued to oocyte retrieval.</p>	<p>Number of oocytes retrieved Clinical pregnancy rate Live birth rate OHSS</p>	<p>No of oocytes retrieved (placebo = 15, metformin = 14, 95% CI -2.37-4.37, P = 0.66).  Clinical pregnancy rate (placebo = 48.7%, meformin = 28.6%, 95% CI 0.04-0.35, P = 0.02)  live birth rate (placebo = 51.6%, metformin = 27.6%, 95% CI 0.05-0.40, P = 0.02).  incidence of OHSS between the metformin and placebo groups (OR 1.376, 95% CI 0.542-3.491).</p>	<p>The first adequately powered RCT to assess the impact of metformin on OHSS in a high-risk group (women with PCOS) undergoing a GnRH antagonist cycle. It does not support the empirical prescribing of metformin as an adjunct to a GnRH antagonist treatment.</p>	
<p>Abdalmageed, O. S., Farghaly, T. A., Abdelaleem, A. A., Abdelmagied, A. E., Ali, M. K. and Abbas, A. M. Reprod Sci. 2018; 1933719118765985. (29576001)</p>	<p>RCT</p>	<p>Women with PCOS who were less than 39 years, overweight, and obese with body mass index (BMI) &gt;24 kg/m<sup>2</sup>, having their first IVF. 102 women in total, 51 each in the study and placebo groups.</p>	<p>Eligible women were allocated to either group I (metformin group) received 2 tablets of metformin 500 mg or group II (placebo group) received 2 placebo tablets. Metformin or placebo were commenced from the start of controlled ovarian stimulation and continued until a negative pregnancy test or 12 weeks of pregnancy.</p>	<p>Number of oocytes retrieved Mature oocytes Clinical pregnancy rate Miscarriage rate Live birth rate</p>	<p><b>Metformin vs placebo:</b> No of oocytes retrieved: (9.06+4.23 vs 16.86+8.3, P &lt; .01).  CPR 33% vs 27.5% .p = 0.52),  LBR (25.5% vs 17.6%, P = 34).</p>	<p>Short-term administration of metformin to overweight or obese women with PCOS undergoing IVF decreased number of the retrieved oocytes but did not improve the LBR.</p>	<p>Authors state primary outcome is number of oocytes. However, sample size calculation was based on CPR increase 30% to 70% with metformin.</p>

## 8.2 GROWTH HORMONE (GH)

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Duffy, J. M., Ahmad, G., Mohiyiddeen, L., Nardo, L. G. and Watson, A. Cochrane Database Syst Rev. 2010; (1): Cd000099. (20091500)	SR	Routine use of growth hormone as an adjuvant in IVF protocols – 2 trials.  Non-routine use of growth hormone as an adjuvant in IVF protocols in women considered poor responders – 8 trials.	There was no consistency as to the dose or timing of growth hormone administration.  The dose of growth hormone ranged from 8IU to 24IU.	Live birth rate per woman randomised Pregnancy rate per woman randomised Adverse events	Use of adjuvant growth hormone in women who are not poor responders live birth rate (OR 1.32; 95% CI 0.40 – 4.43)  pregnancy rate (OR 1.78; 95% CI 0.49 – 6.50)  adverse events with use of growth hormone (OR 0.62, 95% CI 0.18 to 2.15)	Results of the meta-analysis demonstrated no difference in outcome measures and adverse events in the routine use of adjuvant growth hormone in in-vitro fertilisation protocols. The result needs to be interpreted with caution, the included trials were few and small sample size.	GRADE evidence profile For GH in non-poor responder GRADE Evidence profile for GH in poor responders from Li 2017 (as is more recent to this review)
Li, X. L., Wang, L., Lv, F., Huang, X. M., Wang, L. P., Pan, Y. and Zhang, X. M. Medicine (Baltimore). 2017; 96(12): e6443. (28328856)	SR	11 RCTs including women with POR undergoing IVF were included.		Number of oocytes retrieved Mature oocytes retrieved Clinical pregnancy rate Live birth rate	Number of oocytes (SMD 1.09, 95% CI 0.54–1.64).  Number of MII oocytes (SMD 1.48, 0.84–2.13),  Clinical pregnancy rate (RR 1.65, 95% CI 1.23–2.22).  Live birth rate (RR1.73, 1.25–2.40).	The GH addition can significantly improve the clinical pregnancy rate and live birth rate.	GRADE evidence profile Poor responder Follicular – luteal administration

<p>Choe, S. A., Kim, M. J., Lee, H. J., Kim, J., Chang, E. M., Kim, J. W., Park, H. M., Lyu, S. W., Lee, W. S., Yoon, T. K. and Kim, Y. S. Arch Gynecol Obstet. 2018; 297 (3): 791-796. (29264647)</p>	<p>RCT</p>	<p>RCT of sustained-release human GH in Bologna criteria poor responders undergoing IVF, GH treatment group (N = 62) and controls (N = 65).</p>	<p>The treatment group received a sustained-release GH three times before and during OS (mid-luteal, late luteal, and menstrual cycle day 2).</p>	<p>Number of mature oocytes Clinical/ ongoing pregnancy rate Miscarriage rate</p>	<p>Mature oocytes (67.5 vs. 52.3%, P = 0.030) were higher in the GH group than in controls.  CPR 9.7% vs 16.9%, p = 0.348,  OPR 8.1% vs 9.2%, p = 1.000.</p>	<p>Supplementation of sustained-release GH before and during OS improved ovarian response, with an increase in mature oocytes in poor responders. Further studies are needed to ensure this benefit in general infertility patients.</p>	<p>Primary outcomes of interest were the number of (mature) oocytes and serum level of estradiol on hCG triggering day. Secondary outcomes included serum level of IGF-1 and IGFBP-3, number of follicles with diameter <math>\geq</math> 14 mm, level of progesterone on hCG triggering day, fertilization/implantation rate, proportion of metaphase II (MII) oocytes, proportion of good quality embryos, clinical/ongoing pregnancy rate, and spontaneous abortion rate.</p>
<p>Owen, E. J., West, C., Mason, B. A. and Jacobs, H. S.. Hum Reprod. 1991; 6 (4): 524-8. (1918302)</p>	<p>RCT</p>	<p>Participation patients had to be &lt;38 years, having undergone one or more IVF cycles in which the response was considered suboptimal, defined as a response in which fewer than six oocytes were collected and than four embryos developed.  Twenty-five patients were recruited into this study of cotreatment with biosynthetic natural sequence human GH (n=13) compared with placebo (n=12).</p>	<p>GH (24 units per injection given 1M). The drug was given on alternate days for a maximum period of 2 weeks until the administration hCG.</p>	<p>Number of oocytes retrieved</p>	<p>No significant difference in the number of oocytes retrieved between the GH and placebo groups (6 (0-8) vs 3.5 (2-6).</p>	<p>There may be a place for GH treatment in selected IVF cycles after pituitary suppression.</p>	

## 8.3 TESTOSTERONE

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Nagels, H. E., Rishworth, J. R., Siristatidis, C. S., Kroon, B. Cochrane Database Syst Rev 2015; 11: Cd009749 (26608695)	SR	Effect of transdermal testosterone preceding ovarian stimulation in women with poor ovarian response undergoing IVF.  Four trials (Massin 2006; Fabregues 2009; Kim 2010; Kim 2011) were included (203 women in the testosterone group, 142 in the control group).	One study compared transdermal testosterone with placebo gel (Massin 2006). Three studies compared transdermal testosterone with no treatment (Fábregues 2009; Kim 2010; Kim 2011).  The dose and length of pre-treatment varied: 2.5 mg/ day for 5 days (Fábregues 2009); 10 mg/ day for 15 to 20 days (Massin 2006); 12.5 mg/ day for 14, 21 or 28 days (Kim 2010) and 12.5 mg/ day for 21 days (Kim 2011)..	Ongoing pregnancy/ live birth rate Clinical pregnancy rate Adverse effects	Testosterone compared with controls higher live birth rates (OR 2.60, 95% CI 1.30 to 5.20; 4 RCTs, N = 345, moderate evidence).  removal of studies at high risk of performance bias in a sensitivity analysis, the remaining study showed no evidence of a difference between the groups (OR 2.00, 95% CI 0.17 to 23.49; one RCT, N = 53)	In women identified as poor responders, testosterone may be associated with improved live birth rates. The overall quality of the evidence is moderate. There is insufficient evidence to draw any conclusions about the safety of testosterone. Definitive conclusions regarding the clinical role of testosterone awaits evidence from further well-designed studies.	

<p>Gonzalez-Comadran, M., Duran, M., Sola, I., Fabregues, F., Carreras, R. and Checa, M. A. <i>Reprod Biomed Online</i>. 2012; 25 (5): 450-9. (22999555)</p>	SR	<p>Effect of transdermal testosterone preceding ovarian stimulation in women with poor ovarian response undergoing IVF.</p> <p>Three trials (Massin 2006; Fabregues 2009; Kim 2011) were included (113 women in the testosterone group, 112 in the control group).</p> <p>Type of intervention evaluated was administration of transdermal testosterone preceding gonadotrophin treatment compared with standard gonadotrophin ovarian stimulation protocols without administration of transdermal testosterone during the period of follicular stimulation.</p>	<p>Pretreatment with transdermal testosterone gel was applied in two studies (Massin et al., 2006; Kim et al., 2011), in a dose of 10 and 12.5 mg/day, respectively, for 15 to 21 days during pituitary desensitization.</p> <p>Testosterone patches of 2.5 mg daily for 5 days during pituitary desensitization (Fabregues 2009).</p>	<p>Number of oocytes retrieved Clinical pregnancy rate Live birth rate</p>	<p>number of oocytes retrieved (RR 1.28, 95% CI 0.77 to 1.78).  clinical pregnancy rate (RR 2.07, 95% CI 1.13 to 3.78).  live birth rate (RR 1.91, 95% CI 1.01 to 3.63).</p>	<p>Transdermal testosterone significantly increases live birth.</p> <p>The present data should be interpreted with caution because of the small number of trials and clinical heterogeneity. The identification of poor responders that could especially benefit from testosterone treatment should be addressed in further studies.</p>	<p>GRADE evidence profile Study included for outcome on number of oocytes as this outcome was not analysed in SR Nagels.</p>
<p>Bosdou, J. K., Venetis, C. A., Dafopoulos, K., Zepiridis, L., Chatzimeletiou, K., Anifandis, G., Mitsoli, A., Makedos, A., Messinis, I. E., Tarlatzis, B. C. and Kolibianakis, E. ## 8.4 DEHYDROEPIANDROSTERONE (DHEA)

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Nagels, H. E., Rishworth, J. R., Siristatidis, C. S., Kroon, B. Cochrane Database Syst Rev 2015; 11: Cd009749 (26608695)	SR	Of the 12 included studies, majority (10) of the studies were in women identified as poor responders. Two studies included women with normal ovarian reserve (Yeung et al., 2013; Tartagni et al., 2016).	6 studies compared DHEA with placebo (Divita 2003; Evans 2013; Tartagni 2015a; Tartagni 2015b; Yeung 2013a; Yeung 2014), and six studies (Artini 2012; Jindal 2014; Kara 2014; Moawad 2012; Wiser 2010; Zhang 2014) compared DHEA with no treatment.  Studies varied in the dose and duration of the intervention, but most studies used 75 mg of DHEA daily before and during stimulation,  The long GnRH agonist protocol was most commonly used in majority of the studies.	Ongoing pregnancy/ live birth rate Clinical pregnancy rate Adverse effects	live birth or ongoing pregnancy (OR 1.88, 95% CI 1.30 to 2.71; 8 RCTs, N = 878, moderate quality evidence).  However, in a sensitivity analysis removing trials at high risk of performance bias, the effect size was reduced and no longer reached significance (OR 1.50, 95% CI 0.88 to 2.56; 5 RCTs, N = 306).	In women identified as poor responders undergoing ART, pre-treatment with DHEA may be associated with improved live birth rates. The overall quality of the evidence is moderate. There is insufficient evidence to draw any conclusions about safety. Definitive conclusions regarding the clinical role of DHEA awaits evidence from further well-designed studies	Studies involving poor responders and normal responders were pooled together in the meta-analysis.
Kotb, M. M., Hassan, A. M. and AwadAllah, A. M. Eur J Obstet Gynecol Reprod Biol. 2016; 200 11-5. (26963897)	RCT	140 women undergoing IVF/ICSI with POR according to the Bologna criteria were randomly divided into 2 equal groups.	The study group received DHEA 75 mg daily for 12 weeks before the IVF/ICSI cycles and the control group did not receive DHEA.	Number of oocytes retrieved Mature oocytes Clinical pregnancy rate Ongoing pregnancy rate	<b>DHEA vs control</b> Number of oocytes retrieved (6.9±3 vs 5.8±3.1; p=0.03).  Clinical pregnancy rate (32.8% vs 15.7%; p=0.029).  Ongoing pregnancy (28.5% vs 12.8%; p=0.036).	DHEA increases the number of oocytes, fertilization rate, and clinical pregnancy rate in women with POR according to the Bologna criteria. DHEA was well tolerated by the patients and was associated with less COH days and gonadotropins doses.	Number of oocytes and clinical outcomes inconsistent with what would be expected for Bologna criteria poor responders.

<p>Narkwichean, A., Maalouf, W., Baumgarten, M., Polanski, L., Raine-Fenning, N., Campbell, B. and Jayaprakasan, K. Eur J Obstet Gynecol Reprod Biol. 2017; 218 39-48. (28934714)</p>	<p>RCT</p>	<p>60 women with POR based on antral follicle count or anti- Mullerian hormone thresholds undergoing IVF/ ICSI were randomised to receive DHEA or placebo.</p> <p>Following exclusion of 8 women, 25 women received DHEA and 27 women received placebo.</p> <p>AFC less than 10 and/or AMH less than 5 pmol/L.</p>	<p>The study group received 75 mg DHEA and the control group received placebo capsule. Both groups were advised to take intervention for at least 12 weeks before the egg collection procedure (prior to and during controlled ovarian stimulation).</p>	<p>Number of oocytes retrieved Clinical pregnancy rate Live birth rate</p>	<p><b>DHEA vs control</b> number of oocytes retrieved (median 4, 0-18 vs 4, 0-15, p=0.54)  clinical pregnancy rate (30% vs 36%, P=0.63)  live birth rate (26% vs 32%, P=0.63)</p>	<p>Pre-treatment DHEA supplementation, albeit statistical power in this study is low, did not improve the response to controlled ovarian hyperstimulation or oocyte quality or live birth rates during IVF treatment with long protocol in women predicted to have POR.</p>	
<p>Yeung, T., Chai, J., Li, R., Lee, V., Ho, P. C. and Ng, E. Bjog. 2016; 123 (7): 1097-105. (26663817)</p>	<p>RCT</p>	<p>72 subfertile women with AFC of 5–15 undergoing IVF (anticipated normal responders), 36 in the DHEA and 36 in the placebo group.</p> <p>Both groups (study and control) were comparable.</p>	<p>Twelve weeks before scheduled IVF women in study group received 75 mg of DHEA daily and women in control group received placebo.</p>	<p>Number of oocytes retrieved</p>	<p><b>DHEA vs control</b> number of oocytes retrieved (6 (4-9) vs 7 (3-10), NS)</p>	<p>No significant differences in AFC, ovarian response to a standard low dose of gonadotrophin stimulation and number of oocytes obtained were detected in anticipated normal responders receiving 12 weeks of DHEA prior to IVF treatment relative to placebo.</p>	

## 8.5 ASPIRIN

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Siristatidis, C. S., Basios, G., Pergialiotis, V. and Vogiatzi, P. Cochrane Database Syst Rev. 2016; 11 Cd004832. (27807847)	SR	ONLY ANALYSIS FOR LIVE BIRTH AND ONGOING PREGNANCY RATES INCLUDED FROM THIS SR (ANALYSES EXCLUDED ARE - CLINICAL PREGNANCY RATE WHICH POOLED STUDIES THAT STARTED ASPIRIN AT THE TIME OF EMBRYO TRANSFER AND MISCARRIAGE RATE WHICH INCLUDED STUDY THAT HAD CO-INTERVENTIONS COMMENCED BEFORE THE MISCARRIAGE OUTCOME – URMAN 2000)  Patient characteristics varied between the included studies. Likely to be comparable between study and control groups as all studies included in the meta- analysis are RCTs	Aspirin was commenced before stimulation or during stimulation and continued until hCG administration, fetal heart noted on ultrasound or until delivery.  Dose of aspirin was 100 mg/ day in all studies pooled in the meta-analysis for outcome of live birth and ongoing pregnancy.	Live birth rate per woman or couple Ongoing pregnancy rate per woman or couple Safety – vaginal bleeding	<b>Aspirin vs placebo</b> live birth rate; pooled risk ratio (RR) 0.91, 95% CI 0.72 to 1.15.  ongoing pregnancy rate; pooled risk ratio (RR) 0.94, 95% CI 0.69 to 1.27.  adverse events (vaginal bleeding) (RR) 1.01, 95% CI 0.14 to 7.13.	Currently there is no evidence in favour of routine use of aspirin to improve pregnancy rates for a general IVF population.	GRADE evidence profile.
Dirckx, K., Cabri, P., Merien, A., Galajdova, L., Gerris, J., Dhont, M. and De Sutter, P. Hum Reprod. 2009; 24 (4): 856-60. (19131401)	RCT	97 women received aspirin and 96 women received placebo.		Number of oocytes Clinical pregnancy rate/cycle Live birth rate/cycle	<b>Aspirin vs placebo</b> number of oocytes retrieved (12.6±7.6 vs 12.9±7.9; p=0.788).  Clinical pregnancy rate (OR 1.033; 95% CI 0.565–1.890).		This study is included in the live birth rate meta-analysis in Siristatidis (2016). Hence evidence not formulated separately in detail.

Lambers, M. J., Hoozemans, D. A., Schats, R., Homburg, R., Lambalk, C. B. and Hompes, P. G. Fertil Steril. 2009; 92 (3): 923-9. (18973893)	RCT	169 patients, 84 assigned to aspirin treatment and 85 to placebo treatment.			<b>Aspirin vs placebo</b> number of oocytes retrieved (13.7 vs 13.5; NS).  clinical pregnancy rate (41.8% vs 36.9%, p=0.525).		This study is included in the ongoing pregnancy rate meta-analysis in Siristatidis (2016). Hence evidence not formulated separately in detail.
Lok, I. H., Yip, S. K., Cheung, L. P., Yin Leung, P. H. and Haines, C. J. Fertil Steril. 2004; 81 (3): 556-61. (15037402)	RCT	Patients included were poor responders defined as previous IVF cycles cancelled because of recruitment of fewer than three mature follicles ( $\geq 17$ mm) or patients with repeated high basal levels of FSH ( $>10$ IU/L). Patients older than 40 years of age were excluded. Patients with polycystic ovarian syndrome or those with an ovarian cyst or endometrioma at baseline were also excluded. Heavy smokers, patients with cardiovascular disorders, and those taking medications that could affect the circulation were also excluded.	Patients were randomly allocated to receive either low-dose aspirin (80 mg daily) or placebo beginning at the time of commencement of GnRH agonist in the preceding cycle and continuing until the day of hCG administration or cancellation  Total of 60 women (30 in each group) completed treatment and were analysed. 62 women were randomised initially but 1 were also excluded. Heavy smokers, patients with cardiovascular disorders, and those taking medications that could affect the circulation were also excluded.	1. Cycle cancellation rate 2. Number of oocytes retrieved 3. Clinical pregnancy	<b>Aspirin vs placebo</b> cycle cancellation rate (26.7% vs 33.3%)  median number of oocytes retrieved (3; IQR 2 – 7.25 vs 4; IQR 2 – 7.25)  clinical pregnancy rate (1 in vs 2)	Supplementation with low dose aspirin failed to improve ovarian response in poor responders.	Evidence formulated as this study was not included in the outcomes of the included SR detailed in this evidence table.
Moini, A., Zafarani, F., Haddadian, S., Ahmadi, J., Honar, H. and Riazi, K. Saudi Med J. 2007; 28 (5): 732-6. (17457441)	RCT	145 women undergoing IVF (72 in the study and 73 in the control group) were randomised and analysed.  Mean age was similar in both groups.	Aspirin (100 mg) or placebo was started on the 21st day of the preceding menstrual cycle and continued until a negative pregnancy test or 12 weeks of pregnancy.	Number of oocytes retrieved Pregnancy rate OHSS  STUDY DID NOT PROVIDE DEFINITION/ CRITERIA FOR OHSS.	<b>Aspirin vs placebo</b> number of oocytes retrieved (6.9 $\pm$ 5.6 vs 8.6 $\pm$ 6.8).  clinical pregnancy rate (45.5% vs. 33.3%)  OHSS rate (5.6%) vs. (23.3%).	The addition of aspirin did not improve pregnancy and implantation rates in unselected women undergoing IVF cycles.	Evidence formulated as this study was not included in the outcomes of the SR Siristatidis (2016) that are detailed in this evidence table.  Note: No actual numbers were provided for outcome clinical pregnancy, results only given as %

Pakkila, M., Rasanen, J., Heinonen, S., Tinkanen, H., Tuomivaara, L., Makikallio, K., Hippelainen, M., Tapanainen, J. S. and Martikainen, H. Hum Reprod. 2005; 20 (8): 2211-4. (15817582)	RCT	374 women who were to undergo IVF/ICSI were randomized to receive 100mg of aspirin (n = 186) or placebo (n = 188) daily.		Number of oocytes Clinical pregnancy rate	<b>Aspirin vs placebo</b> number of oocytes retrieved (12.0±7.0 vs 12.7±7.2; NS).  clinical pregnancy/ embryo transferred (25.3% vs 27.4%).		This study is included in the live birth rate meta-analysis in Siristatidis (2016). Hence evidence not formulated separately in detail.
Rubinstein, M., Marazzi, A. and Polak de Fried, E. Fertil Steril. 1999; 71 (5): 825-9. (10231040)	RCT	298 patients were randomly divided into treatment and control groups.  The treatment group (149 patients; mean [± SD] age, 35.9 ± 4.2 years) received a daily oral dose of 100 mg aspirin, and the control group (149 patients; mean age, 35.4 ± 3.9 years) received placebo. No significant difference in age between the two groups.	Both groups started aspirin or placebo cotreatment on the 21st day of their preceding menstrual cycle. Pregnant patients continued the medication, which included aspirin or placebo cotreatment, through 12 weeks' gestation.	Number of oocytes retrieved Cycle cancellation rate Clinical pregnancy rate Safety	<b>Aspirin vs control</b> Mean (± SD) number of oocytes retrieved 16.2 ± 6.7, vs 8.6 ± 4.6 (P<05).  cancellation rate (4% vs 9%; P<05).  Clinical pregnancy rate was 45% vs 28% (P<05).  No side effects were observed in patients treated with aspirin, and bleeding was similar for both groups.	Low-dose aspirin treatment significantly improves ovarian responsiveness, implantation and pregnancy rates in IVF patients.	Evidence formulated as this study was not included in the outcomes of the SR Siristatidis (2016) that are detailed in this evidence table.  Note: No actual numbers were provided for outcome clinical pregnancy, results only given as %

## 8.6 INDOMETACIN

No relevant studies were identified

## 8.7 SILDENAFIL

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Ataalla, Wm, Elhamid, Ta and Elhalwagy, Ae. Middle east fertility society journal. 2017; 21 (3): 175-179. (CN-01308022)	RCT	Sixty patients were classified as low responders undergoing IVF, 30 in the study and 30 in the placebo group. Low responders were defined as those who had <3 dominant follicles on the day of hCG administration or <3 retrieved oocytes or those who had previous cycle cancelation due to poor follicular development.  There were no significant differences in the patient characteristics in the two groups.	Supplementation with sildenafil (50 mg daily) or Placebo.	Number of oocytes retrieved	The difference between the number of oocytes retrieved was not statistically significant in the two groups.  MEAN OR MEDIAN NUMBER OF OOCYTES NOT STATED IN THE PAPER.	Adjuvant sildenafil does not enhance ovarian responsiveness in cases of previous low ovarian response to controlled ovarian hyperstimulation.	Pseudorandomisation.

## PART C: Monitoring

### 11. Hormonal assessment during ovarian stimulation

**KEY QUESTION: IS THE ADDITION OF HORMONAL ASSESSMENT (OESTRADIOL/PROGESTERONE/LH) TO ULTRASOUND MONITORING IMPROVING EFFICACY AND SAFETY?**

P	I	C	O
Women undergoing IVF/ICSI	Ultrasound + E2 Ultrasound + progesterone Ultrasound + LH Ultrasound + E2 AND/OR LH AND/OR progesterone	Ultrasound only Blind IVF	<u>Efficacy:</u> <ul style="list-style-type: none"> <li>- cumulative LBR/cycle</li> <li>- Cumulative ongoing pregnancy rate /started cycle (fresh + frozen)</li> <li>- Clinical pregnancy rate/started cycle</li> <li>- Nr of Oocytes/ nr of MII oocyte recovery rate (yield)</li> <li>- number of embryo's (fresh+frozen)</li> </ul> <u>Safety</u> <ul style="list-style-type: none"> <li>- incidence of different grades of OHSS</li> <li>- grade of OHSS</li> <li>- incidence of cycle cancellation for hyper-response (predefined)</li> <li>- Bleeding</li> <li>- Infection</li> <li>- Torsion</li> <li>- Long-term effect on maternal/child health</li> <li>- other adverse events (treatment related)</li> </ul> <u>Patient-related outcomes</u> <ul style="list-style-type: none"> <li>- Compliance</li> <li>- Drop-out rates</li> <li>- Patient burden</li> <li>- QoL</li> <li>- Patient preferences</li> </ul>

## 11.1 ULTRASOUND AND OESTRADIOL MEASUREMENTS

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Kwan I, Bhattacharya S, Kang A, Woolner A 2014 Cochrane Library	SR Cochrane	six trials including 781 women	In 4 out of the six studies The comparison was between USS and USS+E2 In the remaining studies the comparison was between USS and USS+E2+P(Wiser) and between USS and USS+E2+P+LH (Golan)	Clinical pregnancy, OHSS, COCs, cancellation	Clinical pregnancy per woman: OR 1.05 (0.79 to 1.54) 617 (4 studies) COCs per woman: +0.32 higher in the USS only group (-0.6 to +1.24), N=595(5 studies) Cycle cancellation rate per woman: OR 0.57 (0.07 to 4.39) N=115, (2 studies) OHSS rate (mild, moderate or severe) per woman: OR 1.03 (0.48 to 2.20) N=781, (6 studies) <b>RECALCULATED OUTCOMES</b> without Wiser (2012) and Golan (1994): OR for clinical pregnancy: 1.02 (0.71-1.45) OR for OHSS: 0.94(0.39-2.26) OR for cancellation(1 study) 0.5 (0.04 – 5.89) WMD for COCs: 0.03(-0.99 to 1.04)	This review update found no evidence from RCTs to suggest that combined monitoring by TVUS and serum estradiol is more efficacious than monitoring by TVUS alone with regard to clinical pregnancy rates and the incidence of OHSS. The number of oocytes retrieved appeared similar for both monitoring protocols. The data suggest that both these monitoring methods are safe and reliable. However, these results should be interpreted with caution because the overall quality of the evidence was low. Results were compromised by imprecision and poor reporting of study methodology. A combined monitoring protocol including both TVUS and serum estradiol may need to be retained as precautionary good clinical practice and as a confirmatory test in a subset of women to identify those at high risk of OHSS. An economic evaluation of the costs involved with the two methods and the views of the women undergoing cycle monitoring would be welcome.	Quality of the evidence (GRADE) Low for all evaluated outcomes The objective is relevant and clear: "To assess the effect of monitoring controlled ovarian hyperstimulation (COH) in IVF and ICSI cycles in subfertile couples with TVUS only versus TVUS plus serum estradiol concentration, with respect to rates of live birth, pregnancy and OHSS." However, the studies by Wiser and Golan assess besides E2 progesterone (Wiser, Golan) and LH(Golan).

## 11.2 ULTRASOUND AND PROGESTERONE MEASUREMENTS OR ULTRASOUND AND LH MEASUREMENTS

No relevant studies were identified

## 11.3 ULTRASOUND AND COMBINATION OF HORMONAL MEASUREMENTS

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Golan, A., Herman, A., Soffer, Y., Bukovsky, I. and Ron-El, R.. Hum Reprod. 1994; 9 (9): 1631-3. (7836512)	RCT	114 comparable groups	Monitoring by USS alone vs. USS+E2+P+LH (The concentrations of serum oestradiol were determined in Group B as well, and only became known to the clinicians after oocyte retrieval)	Outcome measures not defined Outcome measures used: duration of stimulation, FSH required, E2 patterns, COCs, pregnancy rate, OHSS	<b>Hormonal panel +USS vs USS</b> Pregnancy rate: 22% vs 25% Difference 1.8% 95%CI:-17.2 to +13.8  severe OHSS: 1.7% vs 1.7% difference: 0 (95%CI of the difference: -7.6 to+7.6)	We conclude that 'ultrasound-only' monitoring of ovulation induction in IVF cycles treated by GnRHa-HMG in the long protocol is as effective and safe as the conventional ultrasound and hormone determination, but far simpler, swifter and more cost-effective.	
Wiser, A., Gonen, O., Ghetler, Y., Shavit, T., Berkovitz, A. and Shulman, A. Gynecol Endocrinol. 2012; 28 (6): 429-31. (22456062)	RCT	65 patients  Inclusion criteria were patients before first IVF treatment (to avoid bias from determining doses according to the previous treatment) and women younger than 40 years of age.  Groups were comparable at baseline	Study group: USS only for follicle size and endometrial thickness without blood tests. In this group, only one blood test was taken before hCG injection, to ensure safe estradiol level regarding OHSS risk. N=34  The control group: USS+ serum estradiol + P at each visit. N=31	CPR OHSS	<b>USS alone vs USS+E2</b> clinical pregnancy rate (57.5%) vs (40.0%), P = 0.25.  No cases of OHSS were found in either group.		

## 12. Endometrial thickness

---

### KEY QUESTION: DOES MONITORING OF ENDOMETRIAL THICKNESS AFFECT THE EFFICACY AND SAFETY?

P	I	C	O
Women undergoing IVF/ICSI	Ultrasound of the endometrium On day of triggering Any day of stimulation phase	- No monitoring	<u>Efficacy:</u> - cumulative LBR/cycle - Cumulative ongoing pregnancy rate /started cycle (fresh + frozen) - Clinical pregnancy rate/started cycle - Nr of Oocytes/ nr of MII oocyte recovery rate (yield) - number of embryo's (fresh+frozen) <u>Safety</u> - incidence of different grades of OHSS - grade of OHSS - incidence of cycle cancellation for hyper-response (predefined) - Bleeding - Infection - Torsion - Long-term effect on maternal/child health - other adverse events (treatment related) <u>Patient-related outcomes</u> - Compliance - Drop-out rates - Patient burden - QoL - Patient preferences

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Diagnostic test evaluated Reference standard test Include: Time interval and treatment	Prevalence	Accuracy (Se, Sp, PPV, NPV, LR+, LR-)	Reproducibility	Authors conclusion	Comments
Kasius A, Smit JG, Torrance HL, Eijkemans MJ, Mol BW, Opmeer BC, Broekmans FJ. Hum Reprod Update. 2014 Jul-Aug;20(4):530-41. (24664156)	SR	22 studies 10 724 Exclusion criteria: - donor oocyte cycles; - intra uterine pathology [e.g. uterine polyps, submucosal or intramural myoma's and adhesions (Asherman syndrome)].	EMT had to be measured by TVU on the day of ovulation triggering as the maximal echogenic distance between the junction of the endometrium and myometrium in the mid-sagittal plane.	A thin endometrium ( $\leq 7$ mm) was observed in 2.4% (260/10724)	STROBE checklist sROC ORs with 95% CIs were calculated using a Mantel–Haenszel random effect model Meta-regression Analyses for the different cut-off values show that sensitivity increases from near zero at a cut-off of $\leq 7$ mm [0.05 (95% CI 0.03–0.09)] to a sensitivity of 0.21 (95%CI 0.18–0.26) at a cut-off of $\leq 9$ mm. The specificity decreases at the same rate from close to 1 at $\leq 7$ mm [0.98 (95%CI 0.97–0.99)] to a minimum level of 0.85 at $\leq 9$ mm [0.81–0.87]	Positive and negative predictive values for the outcome of pregnancy 77 and 48%, respectively The predictive accuracy of EMT for non-pregnancy was low, AUC=0.56	Current data indicate that EMT has a limited capacity to identify women who have a low chance to conceive after IVF. The frequently reported cut-off of 7 mm is related to a lower chance of pregnancy but occurs infrequently. The use of EMT as a tool to decide on cycle cancellation, freezing of all embryos or refraining from further IVF treatment seems not to be justified based on the current meta-analysis. Further research is needed to investigate the real independent significance of EMT in IVF.	This lack of consensus can possibly be explained by the fact that no exact definition of thin endometrium as assessed by ultrasound exists. EMT cannot be used to predict IVF outcome in terms of the occurrence of pregnancy (pregnant versus not pregnant), it does seem to be a factor for the assessment of the probability of conceiving after IVF. For clinical pregnancy rates, the probability of pregnancy was significantly lower in the group with thin EMT [EMT $\leq 7$ mm: OR 0.42 (95% CI 0.27–0.67) P=0.0003]

---	-----------	--	--	--	--	---	---	--

<p>Griesinger, G., Trevisan, S., Cometti, B. Hum Reprod Open 2018(1):hox031-hox031</p>	<p>CS</p>	<p>n = 1401 aged between 18 and 42 years, BMI &lt;30 kg/m<sup>2</sup>, &lt;3 prior ART cycles ≥ 3 oocytes after COH with GnRH-agonist or GnRH antagonist.</p> <p>EMT ≤ 8 mm n=117 (8.35%) EMT 8-15 mm n=1200 (85.65%) EMT &gt;15 mm n=84 (6%)</p>	<p>EMT was assessed on day of embryo transfer</p>	<p>EMT ≤ 8 mm n=117 (8.35%) On-going PR in patients with EMT ≤ 8 mm was 29.1% (95% CI: 21.60–37.8%).</p>	<p>univariate analysis: ongoing PR correlate to EMT. cut-off of ≥ 9 mm EMT, the chance of pregnancy was higher as compared to patients with an EMT of 3–8 mm (OR = 1.69, 95% CI: 1.23–2.35, P = 0.001; sensitivity 88.89%, specificity 72.64% and likelihood ratio 1.08).</p> <p>In multivariate regression analysis, after controlling for trial, female age and oocyte numbers, EMT was a statistically significant predictor of live birth (OR = 1.05, 95% CI: 1.00–1.10; P = 0.0351).</p> <p>poor performance of the EMT to predict ongoing PR (AUC: 0.53; 95% CI: 0.50–0.56).</p>	<p>An increase of the on-going PR with increasing EMT was observed (Mantel–Haenszel chi-square P = 0.042). Spearman's and Pearson's correlation coefficients indicated a positive, yet weak linear trend (r = 0.0537 and r = 0.0543, respectively).</p>	<p>The independent contribution of EMT to live birth likelihood is small and may result from (undetermined) confounding. EMT can be ignored during cycle monitoring, only the extremes of EMT deserve further diagnostic work-up. Oocyte number is significantly related to EMT, e.g. the more oocytes collected, the higher the EMT. EMT assessed on day of embryo transfer, a cut-off of 9 mm could predict ongoing pregnancy, but the predictive performance was poor overall and also highly similar to the poor test characteristics reported by Kasius et al. (2014). Interventions to correct thin EMT have little rational basis and should be abandoned until contrary evidence arises.</p>	<p>The predictive capacity of EMT was tested for each millimeter cut off. The on-going PR was compared below and above each millimeter threshold to determine the optimal cut-off of EMT.</p> <p>At present it appears as if for the clinical utility of endometrial pattern assessment, no clear message can be derived from conflicting study results.</p>
--	-----------	---	---	--	--	---	--	--

<p>Holden, E. C. Dodge, L. E. Sneeringer, R. Moragianni, V. A. Penzias, A. S. Hacker, M. R. Hum Fertil (Camb) 2017; 1-6. (28627314)</p>	<p>CS</p>	<p>6331 women undergoing their first, fresh autologous IVF cycle  347 (5.5%) EMT≤7mm 2943 (46.5%) EMT &gt;7/&lt;11mm 3041 (48.0%) EMT ≥11mm.  The three groups were similar with regards to age, BMI, gravidity and the median number of embryos transferred and embryos frozen (all p&gt;0.07).</p>	<p>EMT was measured by professional sonographers for all patients on the day of ovulation trigger using TV ultrasound.  The lining was measured in the sagittal plane at the point of the largest anterior to posterior thickness.</p>	<p>347 (5.5%) EMT≤7mm  151 (2.4%) cycles were cancelled on or after the day of trigger. Among women with EMT ≤7mm, 32 cycles (9.2%) were cancelled, which was significantly more than among the &gt;7 to&lt;11mm group (3.1%) and the ≥11 group (1.0%; p&lt;0.001).</p>	<p>SAS 9.3  risk ratio (RR) and 95% confidence interval (CI)  Poisson regression with robust variance estimates  post hoc analysis</p>	<p>Likelihood of a live birth was significantly lower for the ≤7mm group (adjusted RR: 0.64; 95% CI: 0.45–0.90).  For each additional millimetre of EMT, a statistically significant increased risk of positive b-hCG (adjusted RR: 1.14; 95% CI: 1.09–1.18) and live birth (RR: 1.08; 95% CI: 1.05–1.11).</p>	<p>Women in the ≥11mm group had a significantly higher likelihood of delivering a live infant (32.2%) compared with women in the &gt;7 to&lt;11mm group (27.1%), which yielded a statistically significant age-adjusted RR of 1.23 (95% CI: 1.11–1.37).  In conclusion, thicker endometrial linings were associated with increased pregnancy and live birth rates.</p>	<p>Interesting  The thinnest EMT at which pregnancy occurred was 3.7mm, and this pregnancy resulted in a live birth. The thickest EMT at which pregnancy occurred was 27mm, and this pregnancy also resulted in a live birth.  There does not appear to be an upper limit at which pregnancy is guaranteed or a lower limit of endometrial thickness at which pregnancy cannot be achieved. This suggests that there are likely to be other uterine and endometrial factors that influence the likelihood of live birth.</p>

# 13. Criteria for triggering

---

**KEY QUESTION: IS THE OUTCOME OF OVARIAN STIMULATION DEPENDENT ON THE CRITERIA FOR TRIGGERING?**

P	I	C	O
Women undergoing IVF/ICSI	Follicle size + Number Oestradiol Oestradiol/Follicle Ratio	Ultrasound only Blind IVF	<u>Efficacy:</u> <ul style="list-style-type: none"> <li>- cumulative LBR/cycle</li> <li>- Cumulative ongoing pregnancy rate /started cycle (fresh + frozen)</li> <li>- Clinical pregnancy rate/started cycle</li> <li>- Nr of Oocytes/ nr of MII oocyte recovery rate (yield)</li> <li>- number of embryo's (fresh+frozen)</li> </ul> <u>Safety</u> <ul style="list-style-type: none"> <li>- incidence of different grades of OHSS</li> <li>- grade of OHSS</li> <li>- incidence of cycle cancellation for hyper-response (predefined)</li> <li>- Bleeding</li> <li>- Infection</li> <li>- Torsion</li> <li>- Long-term effect on maternal/child health</li> <li>- other adverse events (treatment related)</li> </ul> <u>Patient-related outcomes</u> <ul style="list-style-type: none"> <li>- Compliance</li> <li>- Drop-out rates</li> <li>- Patient burden</li> <li>- QoL</li> <li>- Patient preferences</li> </ul>

## 13.1 FOLLICLE SIZE

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Chen Y, Zhang Y, Hu M, Liu X, Qi H. Gynecol Endocrinol. 2014 Jun;30(6):431-7 (24731070)	SR	N=1295	5 of 6 RCTs: Control group intervention: hCG administration by the criterion "number and size of follicles growing in response to ovarian stimulation for IVF assessed by transvaginal sonography" <u>Timing of hCG administration in early hCG group</u> At least three follicles reached a diameter of $\geq 17$ mm The leading follicle reached a diameter of 18 mm ( $\pm 1$ mm) Three or more follicles of $\geq 16$ mm At least three follicles reached a diameter of $\geq 17$ mm The largest follicle reached 18 mm, at least two other follicles reached a diameter of $\geq 14$ mm The leading two follicle reached a diameter of $\geq 17$ mm Three largest follicles reached a diameter of $\geq 17$ mm and estradiol consistent with the number of follicles Study group interventions: As control group +24h As control group +48h As control group +24h or +48h  1 of 6 RCTs: hCG administration when the leading follicle was 18 mm vs. 22mm	Estradiol levels on day of hCG (pg/ml) Progesterone levels on day of hCG (ng/ml) Oocyte numbers Fertilization rate oPR (per cycle) LBR (per cycle) Miscarriage rate	Oocyte numbers increased in late hCG groups (MD= +1.2, P<0.00001) [comment: homogenous effect in 2 GnRH agonist and 2 GnRH antagonist studies]  No homogenous and/or statistically significant effects on OPR (per cycle) more women reached an ongoing pregnancy (38% (37/97)) compared with the 18-mm group (24% (22/93)) (RR 1.6, 95% CI: 1.03–2.5)  LBR (per cycle) 22 mm (35% (34/97)) compared to 18 mm (23% (21/93)) (RR 1.6 (0.98–2.47))	The prolongation of follicular phase by delaying hCG administration could increase estradiol, progesterone levels and oocyte retrieval, which will not influence ongoing pregnancy rate per oocyte pick-up, miscarriage rate and live birth rate.	Non-randomized study included (Dimitry et al. 1991)  All studies, but one, measure effect of delay of hCG administration instead of effect of giving hCG at different follicular size criteria  Studies heterogenous in methodology (most importantly triggering criteria in the control group, quality, protocols and time intervals)  Studies significantly heterogenous for most outcomes except estradiol and progesterone levels and oocyte numbers  Fertilization rate: authors conclude that a significant difference exists in favor of late group, but the combined effect is 0.7% and 99.7% of weight comes for one study with implausible SDs and fertilization rate is only a surrogate outcome

No relevant studies were identified

### 13.3 OESTRADIOL/FOLLICLE RATIO

No relevant studies were identified

# 14. Criteria for cycle cancellation

**KEY QUESTION: WHICH CRITERIA FOR CYCLE CANCELLATION ARE MEANINGFULL REGARDING PREDICTED LOW/HIGH OOCYTE YIELD?**

P	I	C	O
Women undergoing IVF/ICSI with predicted <b>LOW</b> ovarian response	Cancellation criterium: Number of follicles		<u>Efficacy:</u> <ul style="list-style-type: none"> <li>- cumulative LBR/cycle</li> <li>- Cumulative ongoing pregnancy rate /started cycle (fresh + frozen)</li> <li>- Clinical pregnancy rate/started cycle</li> <li>- Nr of Oocytes/ nr of MII oocyte recovery rate (yield)</li> <li>- number of embryo's (fresh+frozen)</li> </ul> <u>Safety</u> <ul style="list-style-type: none"> <li>- incidence of different grades of OHSS</li> <li>- grade of OHSS</li> <li>- incidence of cycle cancellation for hyper-response (predefined)</li> </ul>
Women undergoing IVF/ICSI with predicted <b>HIGH</b> ovarian response	Cancellation criterium: Number of follicles		<ul style="list-style-type: none"> <li>- Bleeding</li> <li>- Infection</li> <li>- Torsion</li> <li>- Long-term effect on maternal/child health</li> <li>- other adverse events (treatment related)</li> </ul> <u>Patient-related outcomes</u> <ul style="list-style-type: none"> <li>- Compliance</li> <li>- Drop-out rates</li> <li>- Patient burden</li> <li>- QoL</li> <li>- Patient preferences</li> </ul>

## LOW OOCYTE YIELD

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Diagnostic test evaluated Reference standard test Include: Time interval and treatment	Prevalence	Accuracy (Se, Sp, PPV, NPV, LR+, LR-)	Reproducibility	Authors conclusion	Comments
Oudendijk JF, Yarde F, Eijkemans MJ, Broekmans FJ, Broer SL. Hum Reprod Update. 2012 Jan-Feb;18(1):1-11 (21987525)	SR	14.338 patients, with poor response (different definition) from $\leq 3$ follicles (oocytes) to $< \leq 5$ oocytes  No information regarding type of stimulation in the study but included studies use both ago and antagonist cycles	Pregnancy rate (%) in poor responders vs normal responders  Female age and pregnancy rate (%) per started cycle  Number of oocytes retrieved and pregnancy rate per first cycle started  Poor responder and pregnancy rate in subsequent cycles.		CPR 1 oocyte 0–7% 2 oocytes 4.3-11.5% 3 oocytes 8.7-15.6% 4 oocytes 11.5–18.6%		Poor responders are not a homogeneous group of women with regards to pregnancy prospects.  Female age and number of oocytes retrieved in particular will modulate the chances for pregnancy in current and subsequent cycles.  Applying these criteria will allow the identification of couples with a reasonable	The decision should be individually making taking into account history of the couple, burden of therapy, quality of life, preferences. The pregnancy could occur even with one follicle/oocyte retrieved
Jayaprakasan, K., Chan, Y., Islam, R., Haoula, Z., Hopkisson, J., Coomarasamy, A. and Raine-Fenning, N. Fertil Steril. 2012; 98 (3): 657-63. (22749225)	CS	1012 women  Subjects were excluded if they were found to have an ovarian cyst or follicle measuring 20 mm or more in diameter on their pretreatment ultrasound scan  long GnRH agonist protocol hCG trigger 10000uhCG or 6000rhCG	Live birth rate, poor ovarian response, and ovarian hyperstimulation syndrome (OHSS) in relation to different AFC  At AFC quartiles of 3–10, 11–15, 16–22, and $>23$ , the mean live birth rates were 23%, 34%, 39%, and 44%, respectively.  No live birth was observed in women with AFC $<4$ .		AFC was the best predictor of poor ovarian response (odds ratio [95% CI]: 0.86 [0.82–0.90])		AFC is a significant predictor of ovarian response and live birth after IVF/ICSI treatment. There are limitations with the use of AFC cutoff levels, particularly if they are used to deny couples ART: the live birth rate was still 5% at an AFC cutoff of four and only fell to zero for women with three or fewer follicles,	The decision making is always difficult although in this study no LBR was reported when AFC was $<4$ The limitations was the small number of women with such low no AFC Additionally I agree AFC predicts quantitative aspects of ovarian reserve ( e.g. response to gonadotropins) than the qualitative as LBR .The pregnancy and LBR could be when one follicle is present

<p>Nicopoulos, J. D. and Abdalla, H.. Fertil Steril. 2011; 95 (1): 68-71. (20646690)</p>	<p>CS</p>	<p>1350 women ICSI  Long GnRH agonist/GnRH antagonist protocol hCG trigger  39.6 + 3.9 one or two follicles&gt;12 mm</p>	<p>Live birth rate, clinical pregnancy rate, and biochemical pregnancy rate  BPR of 13.1%, CPR of 8.1%, OPR- 6.8%,</p>		<p>One follicle: BPR-8.5%, CPR 5.4%, OPR- 4.5%  Two follicles: BPR-14.9%, CPR 9.2%, OPR-7.6%</p>		<p>1.for poor responders, proceeding to VEC may represent their best chance of successful outcome.  2.Conversion to IUI offers the poorest outcome,  3.Abandoning and a further attempt does not improve outcome</p>	<p>The presence of one or two follicles in poor responders still could lead to obtain pregnancy. Thus the strategy should be discussed with couples as the IVF even with one or two follicles could be the best choice.</p>
<p>Sunkara, S. K., Rittenberg, V., Raine-Fenning, N., Bhattacharya, S., Zamora, J. and Coomarasamy, A.. Hum Reprod. 2011; 26 (7): 1768-74. (21558332)</p>	<p>CS</p>	<p>400 135 IVF cycles no of eggs in respect to LBR (not directly related to cycle cancellation)  cycles involving gamete or zygote intra-fallopian transfer (GIFT, ZIFT), egg donation, egg sharing, embryo donation or where the source of embryos was not specified, preimplantation genetic diagnosis, surrogacy, oocyte cryopreservation, frozen embryo replacement, and cycles where no eggs were retrieved or all embryos were frozen were excluded from the analysis  no info on LH suppression regimes</p>	<p>LBR in relation to age category</p>		<p>the predicted LBR for women with 15 eggs retrieved in age groups 18–34, 35–37, 38–39 and 40 years and over was 40, 36, 27 and 16%,</p>		<p>There was a strong association between the number of eggs and LBR; LBR rose with an increasing number of eggs up to 15, plateaued between 15 and 20 eggs and steadily declined beyond 20 eggs</p>	<p>No data regarding cancellation both with small and excessive no of eggs. If we look on the results: in women &gt;40 years with only one egg the predicted LBR is 2 % thus decision regarding cancellation even with one follicle should be discussed with patients</p>

<p>Steward, R. G., Lan, L., Shah, A. A., Yeh, J. S., Price, T. M., Goldfarb, J. M. and Muasher, S. J. Fertil Steril. 2014; 101 (4): 967-73. ## 15.3 GNRH AGONIST TRIGGER VERSUS HCG

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Griesinger, G., Diedrich, K., Devroey, P. and Kolibianakis, E. M. Hum Reprod Update. 2006; 12 (2): 159-68. (16254001)	SR	3 RCT's n=275 (139 GnRH agonist, 136 HCG) Two of the studies (Humaidan et al., 2005; Kolibianakis et al., 2005) were prematurely stopped due to significant differences between study groups in clinical pregnancy rates	triggering of final oocyte maturation with GnRH agonist; control group randomized to receive HCG for final oocyte maturation Luteal phase support: any means of luteal phase support other than HCG.	-clinical pregnancy per randomized patient; -number of oocytes retrieved; -proportion of metaphase II -fertilization rate; -embryo quality score; -first trimester abortion rate; -(OHSS) incidence	-Clinical pregnancy rate: Combined point estimate calculation was performed on the number of patients randomized 0.21, 95% CI = 0.05–0.84, P = 0.03, in favour of HCG  -Number of oocytes –0.94, –0.33–0.14, P = 0.43.  -Proportion of metaphase II oocytes –0.03, –0.58–0.52, P = 0.90  -OHSS incidence No cases of OHSS occurred in two of the trials (Humaidan et al., 2005; Kolibianakis et al., 2005), irrespective of the type of drug employed for triggering final oocyte maturation. In the third trial, (Fauser et al., 2002) OHSS incidence was not reported. Thus, no estimate on OHSS incidence can be inferred from the literature	GnRH agonist administration in GnRH antagonist protocols to triggering final oocyte maturation yields a number of oocytes capable of undergoing fertilization and subsequent embryonic cleavage, which is comparable to that achieved with HCG. However, GnRH agonist usage for this purpose as assessed by the available studies is associated with decreased pregnancy likelihood.	

<p>Youssef, M. A., Van der Veen, F., Al-Inany, H. G., Mochtar, M. H., Griesinger, G., Nagi Moheesen, M., Aboulfoutouh, I. and van Wely, M. Cochrane Database Syst Rev. 2014; (10): Cd008046. (25358904)</p>	SR	<p>17 RCTs (n = 1847 Subfertile women undergoing IVF/ICSI treatment cycles. At high or low risk to develop OHSS), of which 13 studies assessed fresh autologous cycles and four studies assessed donor-recipient cycles.</p> <p>High risk for OHSS was defined as studies including women with PCOS or women with high numbers of ovarian follicles (<math>\geq 14</math> follicles) <math>\geq 11</math> mm in diameter.</p>	<p>GnRH agonists in comparison with HCG for final oocyte maturation triggering in GnRH antagonist-controlled hyperstimulation cycles, IVF or ICSI followed by embryo transfer (ET) with or without luteal phase support, (Type of luteal phase support (</p> <ul style="list-style-type: none"> <li>• Luteal phase support with LH activity (single or two doses of HCG, reLH and repeated GnRH doses)</li> <li>• Luteal phase support without LH activity (progesterone only or progesterone plus oestradiol.)</li> </ul> <p>in autologous or donor cycle</p>	<ul style="list-style-type: none"> <li>• Live birth rate (LBR) per woman randomised:</li> <li>• Incidence of OHSS per woman randomised (mild, moderate or severe)</li> </ul> <p>Secondary outcomes</p> <ul style="list-style-type: none"> <li>• Ongoing pregnancy rate (OPR) per woman randomised:</li> <li>• Clinical pregnancy rate (CPR) per woman randomised</li> </ul>	<p>LBR (OR 0.47, 95% CI 0.31-0.70; 5 RCTs, 532 women (MQ) studies with LPS with LH activity: OR 0.63, 95% CI 0.40-0.98; 3 RCTs, 382 women; studies with LPS without LH activity: OR 0.13, 95% CI 0.04-0.39; 2 RCTs, 150 women,</p> <p>OHSS (OR 0.15, 95% CI 0.05-0.47; 8 RCTs, 989 women (MQ)</p> <p>No evidence was found of a difference between GnRH<sub>a</sub> and HCG groups among women who had LPS with LH activity (OR 0.47, 95%CI 0.11-2.09; 5 RCTs), but the OHSS rate was lower in the GnRH<sub>a</sub> group among women who had LPS without LH activity (OR 0.04, 95% CI 0.01-0.34)</p> <p>Ongoing PR (OR 0.70, 95% CI 0.54-0.91; 11 RCTs, 1198 women (MQ)</p> <p>No evidence was found of differences between groups among women who had LPS with LH activity (OR 0.89, 95% CI 0.65-1.21; 5 RCTs), but the ongoing PR in the HCG group was higher among women who had LPS without LH activity (OR 0.36, 95% CI 0.21-0.62; 5 RCTs, 370 women)</p> <p>Clinical pregnancy rate per woman randomised (OR 0.81, 95% CI 0.61-1.04; 11 RCTs, 1198 women)</p>	<p>Final oocyte maturation triggering with GnRH<sub>a</sub> instead of HCG in fresh autologous GnRH antagonist IVF/ICSI treatment cycles prevents OHSS to the detriment of the live birth rate. In donor-recipient cycles, use of GnRH agonists instead of HCG resulted in a lower incidence of OHSS, with no evidence of a difference in live birth rate. Evidence suggests that GnRH agonist as a final oocyte maturation trigger in fresh autologous cycles is associated with a lower live birth rate, a lower ongoing pregnancy rate (pregnancy beyond 12 weeks and a higher rate of early miscarriage (less than 12 weeks). GnRH agonist as an oocyte maturation trigger could be useful for women who choose to avoid fresh transfers (for whatever reason), women who donate oocytes to recipients or women who wish to freeze their eggs for later use in the context of fertility preservation.</p>	GRADE evidence profile

## 16.2 DYDROGESTERONE

## PROGESTERONE VERSUS DYDROGESTERONE

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Barbosa, M. W. P., Valadares, N. P. B., Barbosa, A. C. P., Amaral, A. S., Iglesias, J. R., Nastri, C. O., Martins, W. P. and Nakagawa, H. M. JBRA Assist Reprod. 2018; 22 (2): 148-156. (29488367)	SR	Systematic review 9 RCTs; including 4,061 women	Studies included to the sr were ones comparing oral dydrogesterone to vaginal progesterone capsules.	LBR, OPR, CPR, miscarriage rate	<b>Oral dydrogesterone vs vaginal progesterone</b> live birth/ongoing pregnancy (RR=1.08, 95%CI=0.92-1.26, I2=29%, 8 RCTs, 3,386 women)  clinical pregnancy rates (RR 1.10, 95% CI 0.95 to 1.27; I2=43%; 9 RCTs; 4,061 women).	Good quality evidence from RCTs suggest that oral dydrogesterone provides at least similar reproductive outcomes than vaginal progesterone capsules when used for LPS in women undergoing embryo transfers. Dydrogesterone is a reasonable option and the choice of either of the medications should be based on cost and side effects.	Include.
Griesinger, G., Blockeel, C., G, T. Sukhikh, Patki, A., Dhorepatil, B., Yang, D. Z., Chen, Z. J., Kahler, E., Pexman-Fieth, C. and Tournaye, H. Hum Reprod. 2018; (30304457)	RCT	1034 women undergoing IVF were randomized to 1:1 receive oral dydrogesterone 30mg or 8% MVPgel 90mg daily. The groups were compararale.	Receive oral dydrogesterone (n = 520) MVP gel (n = 514)  on the day of oocyte retrieval, and luteal phase support continued until 12 weeks of gestation	Presence of fetal heartbeats at 12 weeks of gestation, as determined by transvaginal ultrasound.	Dydrogesterone vs progesterone CPR (12 weeks) 38.7% (191/494) and 35.0% (171/489) (adjusted difference, 3.7%; 95% CI: -2.3 to 9.7  Live birth rates in the FAS of 34.4% (170/494) and 32.5% (159/489) (adjusted difference 1.9%; 95% CI: -4.0 to 7.8).	Non-inferiority of oral dydrogesterone was demonstrated. This study demonstrates that oral dydrogesterone is a viable alternative to MVP gel, due to its comparable efficacy and tolerability profiles.	P vs dydro

## DYDROGESTERONE VERSUS PLACEBO

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
Kupferminc, M. J., Lessing, J. B., Amit, A., Yovel, I., David, M. P. and Peyser, M. R. Hum Reprod. 1990; 5 (3): 271-3. (2351709)	RCT	Prospective randomized study to test a need for LPS. 156 patients. Stimulated with HMG and triggered with 10 000 IU HCG. ET on day 2 and the patients were randomized to begin LPS.	Group 1 received (N=54) Dydrogesterone 10 mg 1x3 Group 2 received (n=51) placebo tabl 3x daily Group 3 received (n=51) 2500 IU hCG on d 3, 6 and 10 following et.	PR,	<b>Dydrogesterone vs placebo</b> clinical pregnancy rate (29.6% (16/54) vs. 27.4% (14/51))	The data indicate that supplementation of the luteal phase may not improve the success rates of IVF-ET cycles.	

## 16.3 OESTRADIOL SUPPLEMENTATION

Reference	Study type	PATIENTS No. Of patients Patient characteristics + group comparability	Interventions (+comparison) Include: Study duration / follow-up	Outcome measures Include: Harms / adverse events	Effect size	Authors conclusion	Comments
van der Linden, M., Buckingham, K., Farquhar, C., Kremer, J. A. and Metwally, M. Cochrane Database Syst Rev. 2015; (7): Cd009154. (26148507)	SR	Progesterone vs P+E2 16 RCTs, 2577 women.	Compared E2 + P(n=728) to P only (n=923) for LPS Oral E2 received 533 women from 2 to 6 mg daily. Compared to only P 733. Transdermal E2 received 111 women compared to 108 receiving only P. Vaginal E2 received 84 and were compared to 82 with only P.	Clinical pregnancy rate. Ongoing pregnancy over 12 weeks and LBR.	No differences were found between groups live birth/ongoing pregnancy (OR 1,12 95% CI 0,91 to 1,38) 9 RCTS 1651 women I2=0, low qual evidence)  OHSS (OR 0,56 95% CI 0,2 to 1.63, two RCTs, 461 women, low quality evidence.)	Addition of estrogen does not improve probability of pregnancy in IVF.	GRADE evidence profile Progesterone vs progesterone+estradiol
Gizzo, S., Andrisani, A., Esposito, F., Noventa, M., Di Gangi, S., Angioni, S., Litta, P., Gangemi, M. and Nardelli, G. B. Gynecol Endocrinol. 2014; 30 (12): 902-8. (25268567)	RCT	Dosage of P and addition of E2  best LPS (drugs association, daily dose and administration way) 360 women divided into subgroups by stimulation protocol 180 treated by long-GnRH agonist 90 by short-GnRH agonist 90 by shortGnRH antagonist protocol	From different stimulations subgroups were formed to receive low-dose P (200mg vaginal capsule twice daily) , 60+30+30 patients High dose P (200mg vaginal capsule three times daily plus 100mg intramuscular daily High dose P + E2 (200mg vaginal capsule three times daily plus 100mg intramuscular daily) in association with valerate E2 (2mg vaginal tablet twice daily). LPS began day after OR. Low dose P was the control.	CPR and ongoing PR Detect differences between the different LPS schemes (considering all stimulation protocols) in term of odds ratio (OR) to achieve clinical and ongoing pregnancy in cases of E2max at ovulation induction <5nmol/l, endometrial thickness at pick-up<10mm and woman age<35 years.	<b>P+E2 vs P</b> Clinical pregnancy rate - long GnRH agonist protocol 43.3% vs. 35% - GnRH antagonist protocol 60% vs. 36.6% - Short GnRH agonist protocol 43.3% vs 40%	High dose P increased the possibility of clinical and ongoing pregnancy rate. Addition of E2 does not have an effect on pregnancy rate. in short-GnRH-ag protocols the addition of E2 to high-dose PG does not increase the clinical pregnancy rate.	

Ismail Madkour, W. A., Noah, B., Abdel Hamid, A. M., Zaheer, H., Al-Bahr, A., Shaeer, M. and Moawad, A. Hum Fertil (Camb). 2016; 19 (2): 142-9. (27434094)	RCT	220 patients undergoing antagonist intracytoplasmic sperm injection (ICSI) cycles protocol. Randomized in 2 groups	<p>Group 1: vaginal progesterone alone (90mg once daily) starting on the day of oocyte retrieval for up to 12 weeks if pregnancy occurred. N = 110</p> <p>Group 2 vaginal progesterone (90mg once daily) with oral e2 4 mg daily until week 7 starting on the day of oocyte retrieval for up to 12 weeks if pregnancy occurred. N = 110</p>	Primary outcomes were pregnancy and ongoing pregnancy rates per embryo transfer. Secondary outcomes were implantation and early pregnancy loss rates	<p><b>Group 1 vs 2</b> PR (39.09%) vs (43.63%) (p value%0.3)</p> <p>ongoing pregnancy rate (32.7% vs 36.3%, p value%0.1).</p>	the addition of 4mg estrogen daily to progesterone for luteal support in antagonist ICSI cycles is not beneficial for pregnancy outcome.	P vs P+E2
Kutlusoy, F., Guler, I., Erdem, M., Erdem, A., Bozkurt, N., Biberoglu, E. H. and Biberoglu, K. O. Gynecol Endocrinol. 2014; 30 (5): 363-6. (24517720)	RCT	Effect of addition of E2 to progestin (P) for LPS on pregnancy outcome in IVF for poor responders. Total of 95 patients.	<p>Group 1 (n=33) received only intravaginal progesterone gel (Crinone 8% gel).</p> <p>Group 2 (n=27) received intravaginal progesterone plus oral 2 mg estradiol hemihydrate</p> <p>Group 3 (n=35) received intravaginal progesterone plus oral 6mg estradiol hemihydrate,</p>	CPR and PR	<p>PR: Group 1: 18.2%, Group 2, 44.4% Group 3: 34.3% p&lt;0.05</p> <p>CPR: Group 1: 12.1%, Group2: 37.0%, Group 3: 25.7% p&lt;0.05</p> <p>LB: Group1: 12.1%, Group2: 37.0% Group3: 22.9% p&lt;0.05</p> <p>Sample size is quite small.</p>	Poor responders given 2mg/day Estradiol Hemihydrate in addition to progesterone for LPS significantly improved IVF outcome. The main restrictions of this study are the number of cases being rather small in the groups and the COH protocol applied being heterogeneous	P vs P+E2

<p>Tonguc, E., Var, T., Ozyer, S., Cital, A. and Dogan, M. Eur J Obstet Gynecol Reprod Biol. 2011; 154 (2): 172-6.
